For the last several years, the author has experimented with interdisciplinary curriculum design in college algebra classes at the University of Minnesota. The outcome is a model for interdisciplinary algebra curriculum design that encompasses five components: (a) an introduction covering content from a partner discipline, (b) an essay written by a specialist in a partner discipline, (c) explicit learning goals for algebra and for content in the partner discipline, (d) discussion and homework questions, and (e) a bibliography of readings in the partner discipline. The five-part model responds to the needs of both instructors and students by conveying disciplinary expectations explicitly and efficiently. This curriculum is assigned as homework without direct lectures, and so can supplement any College Algebra class without displacing large amounts of existing course content.

The introduction presents content from the partner discipline to support both mathematics instructors and their students in integrating the discipline with mathematics. The central essay may be written in any genre. The one discussed in this presentation is a short story that was written to accompany the financial mathematics section of the algebra course. The story poses dilemmas about indebtedness from a financial and a psychological viewpoint. In general, posing interdisciplinary dilemmas through a wide variety of writing genres—fiction, memoir, poetry, expository writing—signals to students their responsibility work outside of the expectations of a single discipline as they develop their integrative solutions to the dilemmas. The introduction and the learning goals section help both instructors and students access information from another discipline. They both inform the instructor and limit the range of new information discussed in class. Discussion and homework sections include scaffolding questions in both disciplines, and interdisciplinary assignments. The bibliography is a support for instructors who wish to conduct further reading in the partner discipline.

Theoretical Foundations for Interdisciplinary Algebra Curriculum Design

This model is based on research in interdisciplinary curriculum design, in the pedagogy of mathematical modeling, and on principles of universal instructional design. Interdisciplinary learning involves creating an explanation or tool that could not be produced through the perspective of a single discipline (Boix Mansilla & Duraisingh, 2007; Klein, 1990; Newell, 2009). Interdisciplinarity may require choices among incompatible worldviews as well as a synthesis of them. Because interdisciplinary assignments require creative integration of ideas, they cannot be judged according to a fixed content. Evaluation may focus on students' analysis of multiple aspects of a problem, moving towards an integrated, generalized understanding (Biggs & Collis, 1982; Invantiskaya, Clark, Montgomery, & Primeau, 2002) or their rigorous grounding in disciplinary content and methods, whether they produce an integrated understanding of the scenario, and the level of student reflection on purposes and limitations of their work (Boix Mansilla & Duraisingh, 2007).

Two of these aspects of interdisciplinary learning—a process orientation to learning and critical reflection—are also important in the pedagogy of mathematics modeling. Through "Model Eliciting Activities," students learn about the broad context of a realistic scenario, then they develop mathematical problem-solving tools, and finally, they reflect on their method, improve and generalize it (Lesh, Cramer, Doerr, Post, & Zawojewski, 2003; Maaß, 2006). This project's goals rely heavily on the correspondences between interdisciplinary education and mathematical modeling: students create integrative tools and critically reflect on their solutions in order to identify weaknesses and to create a more generalized solution or perspective. The design model aims to develop strong novice-level interdisciplinary analytical skills.

Universal instructional design (UID) developed within the field of disability studies to encourage communities and institutions to develop infrastructure and information systems that are accessible to people with disabilities. UID broadened to include the development of curriculum and pedagogies that improve access for people who experience barriers to educational opportunities (McGuire, 2011). The difficulties of implementing authentic interdisciplinary curriculum in a mathematics class suggest that the concept of UID should be broadened again to include the instructor as well. Interdisciplinary instruction can pose an educational barrier for an instructor just as a weakly designed class poses an educational barrier for a student. The mathematics instructor needs to have access to information in partner disciplines that is substantial, reliable, and easily understood. The proposed model reduces knowledge barriers for faculty by making the content and their own responsibilities for knowledge limited and explicit, particularly through the learning goals and the introduction, as recommended by UID.

Indebted: Exploring the Emotional Side of Financial Mathematics

For the last several years, the author has used a short story in class that addresses family financial decision-making written by Gary Peter titled *Indebted*. Peter wrote the short story to accompany the material on financial mathematics that is covered in the algebra class, with the goal of complicating the typical word problems of the textbook. A typical word problem asks:

> A couple wishes to save money for their daughter's college education. They save $500 per quarter in an annuity that pays 3.5% interest for 18 years. How much money have they saved after 18 years?

The story *Indebted* provides an example of a more realistic scenario. The narrator in the story is a young man visiting his grandfather, who suffers from Alzheimer's disease and who lives in a nursing home. The grandfather is distressed because his life's savings are expended on his health care, instead of contributing to his grandson's education as he had hoped. Finally, the young man uses a finely crafted writing pen—a graduation gift from his grandfather—to sign his college loan papers. The story hints at mathematical questions that might arise through the young man's considerations: the question of whether working and saving money is a better option in view of rapidly rising college tuition; and the per capita value of the national debt.

The introduction to the story frames these dilemmas in terms of content covered in many introductory psychology textbooks, Erik Erikson's model of life stage development. This disciplinary context was chosen because it presents a challenge—we may learn more about interdisciplinary teaching and learning by integrating topics that are usually very distinct. In addition, Erickson's theory of identity crises that emerge at distinct points in the life span meshes well with Peter's story of intergenerational relationships. Students complete this module with writing short stories or essays that describe the emotional dimension of financial decision making integrated with calculations of the financial outcomes of these decisions.

Uniting the research on interdisciplinary learning and on mathematical modeling suggests two major themes for assessing students' interdisciplinary algebra solutions: integration of disciplinary content and critical reflection. In the *Indebted* module, for example, students showed knowledge of financial mathematics by describing life trajectories accompanied by calculations of the results of financial decisions. They demonstrated integration of psychological ideas by analyzing these decisions in terms of Erikson's model of life stage development. Students demonstrated critical reflection when they considered the possibility of different outcomes or different interpretations than the ones that they elaborated in their writing.

In a recent small class of algebra students, a preliminary analysis of student writing suggests that students tended to perform disciplinary integration more easily than critical reflection. Students were able to construct stories and essays that posed humanistic dilemmas that effect financial decision-making and most were able to use financial mathematics equations to describe the financial outcomes of these scenarios. Students usually presented a single calculation or a comparison of calculations within their stories. While all students were able to integrate ideas from algebra and psychology, relatively few students reflected on interpretations or scenarios that opposed their interpretation. It is possible that the integration of two disciplines was in itself cognitively and creatively challenging, and that students would have required a more directive assignment to reach the level of critical reflection on their work.

Conclusion

This presentation outlines an approach to interdisciplinary curriculum design that may enable mathematics instructors to supplement a standard college algebra class with novice-level, but authentic interdisciplinary activities. While team-taught classes and linking classes into learning communities are superior ways of promoting interdisciplinary thinking, their expense and complexity preclude the involvement of many students. If future versions of this project prove successful, the curriculum design model will support a single instructor delivery format that increases the number of students who can experience the challenges of interdisciplinary learning.

EPISTEMIC NETWORK ANALYSIS FOR EXPLORING CONNECTEDNESS IN TEACHER KNOWLEDGE

James Patrick Burke
UMass Dartmouth
james.burke@umassd.edu

Chandra Hawley Orrill
UMass Dartmouth
corrill@umassd.edu

David Williamson Shaffer
University of Wisconsin
dws@education.wisc.edu

While researchers agree that teacher knowledge matters, the nature of the relationship between teacher knowledge and practice remains elusive. To better understand what knowledge matters, researchers have tried to characterize the special knowledge teachers need (e.g., Ball, Thames, & Phelps, 2008). These efforts have made strides in identifying subconstructs of teacher knowledge. Baumert and colleagues (2010) have linked specialized teacher knowledge to student growth (Hill, Rowan, & Ball, 2005). To better understand how to support students' learning, we need to better understand how teacher understanding matters. To this end, we are considering how teacher knowledge is organized rather than simply discussing quantity of knowledge. This builds from prior research on expertise (e.g., Bransford, Brown, & Cocking, 2000) and knowledge in pieces (diSessa, 2006). This poster will present findings of an approach for looking at teacher's coherence, rather than amount, of knowledge.

To examine coherence of knowledge, we rely on Epistemic Network Analysis (ENA; Shaffer et al., 2009). This mixed methods approach is based on social network analysis. It allows us to identify and code for the key understandings a teacher needs to teach a particular topic. Then, through statistical analysis, patterns in the co-occurrences of those understandings emerge, thus highlighting the aspects of teachers' knowledge that are invoked for particular problem situations.

For this pilot effort, we drew data from clinical interviews of three teachers focused on aspects of proportional reasoning that intersect with fraction knowledge (e.g., if there is a ratio of 2:5, is there 2/5 of something in that situation?). Our analysis indicated that ENA was able to differentiate between the teachers in terms of the connections between their understandings. The poster will feature visual mappings of the teachers' understandings from the clinical interviews.

THE IMPACT OF DATA-DRIVEN DECISION MAKING ON MATHEMATICS INSTRUCTION: OPPORTUNITIES FOR PROFESSIONAL LEARNING

Ann R. Edwards
University of Maryland
aedwards@umd.edu

In many districts, the use of student data to inform decision-making is a key practice at virtually all levels. These efforts are premised on the notion that armed with the right data soundly analyzed stakeholders can make well-informed policy and instructional decisions that improve student performance. This study takes up this notion, examining how stakeholders in a large, diverse district in the mid-Atlantic region—including teachers, school leadership and district personnel—use data to make decisions that impact middle school mathematics instruction and to address pressures to improve middle school mathematics achievement. The study also examines how teachers' data use supports or constrains their professional learning.

A growing body of literature has identified factors that shape data-driven educational decision making, such as the questions asked, forms of data, technologies for presenting and analyzing data, and school and district conditions (e.g., Coburn & Talbert, 2006; Ikemoto & Marsh, 2007). This literature, however, has paid little attention to how data collection, analysis and interpretation shape planning, teaching and assessment in subject matter specific ways. In addition, research has not examined how data use can provide teachers with opportunities for professional learning. If the aim of data use is improving student outcomes, then it is reasonable to examine how teachers may be developing understandings and practices specific to mathematics through data use that improve mathematics learning.

Primary data include interviews with stakeholders in mathematics in four middle schools and the district office and video recordings of department and school meetings involving mathematics instruction relevant data. The selected schools contrast along several dimensions, including demographics, adequate yearly progress, and openness to examine data use. Analysis utilizes a grounded theory approach to identify themes within and across the cases and discourse analytic methods to examine opportunities for learning about mathematics teaching and learning in data meetings through teachers' problematizing of their practice (Horn & Little, 2010).

The poster reports on opportunities for teacher learning in "data chats," a type of district mandated teacher meeting typically involving student assessment data (e.g., formative, unit summative and state standardized tests). One case highlights how organizational structures and norms support meaningful use of data for collaboratively reflecting on student learning and instructional practices. Another case illustrates how, when a school is under severe pressure to raise student outcomes, mandated collection and reporting procedures can undermine the professional development goals of data chats, resulting instead in a focus on identifying and labeling students. These and other cases suggest the potential of data use for mathematics teacher learning and the conditions under which learning is cultivated or stymied.

LEARNING TO TEACH MATH WITH TECHNOLOGY: COLLABORATION BETWEEN MIDDLE SCHOOL MATHEMATICS TEACHERS AND LIBRARIANS

Ann R. Edwards
University of Maryland, College Park
aedwards@umd.edu

Mega Subramaniam
University of Maryland, College Park
mmsubram@umd.edu

Rebecca Oxley
University of Maryland, College Park
roxley47@umd.edu

Minjung Ryu
University of Maryland, College Park
mryu@umd.edu

This study examines the conditions that shape how mathematics teachers and school librarians collaborate in the use of technologies to support student mathematics engagement and learning in four low performing, diverse middle schools and how those collaborations may promote teachers' technological pedagogical content knowledge (TPACK). Research on technology use in mathematics instruction suggests many barriers to technology integration, including lack of access to technologies, inadequate professional development, inexperience with technology, and skepticism about relevance to mathematics (e.g., Guerrero, Walker, & Dugdale, 2004; Wallace, 2004). Furthermore, recent conceptualizations of teacher knowledge, particularly TPACK (Mishra & Koehler, 2006), underscore the complexity of the knowledge needed for thoughtful pedagogy with technology and the challenges of supporting technology integration.

Little research, however, has attended to resources that may already be available in schools, particularly school librarians. Research on librarians suggests that they may be key change agents in technology integration because they are leaders of school media programs, well-versed in newer technologies (e.g., social media, Web 2.0) as well as more traditional technologies, and positioned to spread innovations via their collaborations with teachers (Subramaniam et al., 2012). Also, since research suggests that teachers adopt technology more effectively from collaborating with colleagues, librarians are well suited to be partners in taking up pedagogical innovations. However, the potential of librarians to facilitate the technology integration in math instruction and support TPACK development has not been explored.

We conducted semi-structured interviews with mathematics teachers, librarians, school and district leadership. Utilizing a grounded theory approach, our analysis reveals that while librarians seek deeper collaborations with mathematics teachers, their ability to work with them is limited to isolated events. Math teachers seek guidance and expertise about effectively integrating technologies but not at the perceived expense of instructional time or test preparation. We find several factors influence the nature of collaboration and opportunities for TPACK development, including: institutional structures (e.g., administrative support, scheduling); access to technologies; professional roles; testing pressure; and beliefs and knowledge about mathematics teaching and learning. This work informs professional development for technology integration in mathematics instruction, particularly regarding collaborative teaching between teachers and librarians, as well as school leadership's understanding of how their decisions affect opportunities for professional learning.

PROBLEM SOLVING ABILITIES AND PERCEPTIONS IN ALTERNATIVE CERTIFICATION MATHEMATICS TEACHERS

Brian R. Evans
Pace University
bevans@pace.edu

The purpose of this study was to understand alternative certification middle and high school teachers' mathematical problem solving abilities and perceptions. Participants were given a problem solving examination and required to reflect upon their students' and their own problem solving. Findings revealed there was a significant improvement in problem solving abilities for the teachers over the course of the semester. Teachers perceived their students' problem solving abilities as generally weak, but found they also shared some of the same weaknesses in problem solving as did their students.

Keywords: Problem Solving; Teacher Knowledge

Problem solving continues to be of high importance in mathematics education (NCTM, 2000). The objective of this study is to understand the problem solving abilities and perceptions of their own and their students' abilities among New York City Teaching Fellows (NYCTF).

Research Questions

1. What differences were there in problem solving abilities between the beginning and end of the semester in a mathematics content course for NYCTF teachers?
2. What were teacher perceptions of their students' problem solving abilities? Further, what differences in perceptions of student problem solving abilities existed between the beginning and end of the semester in a mathematics content course for NYCTF teachers?
3. What were teacher perceptions of their own problem solving abilities? Further, what differences in perceptions of their own problem solving abilities existed between the beginning and end of the semester in a mathematics content course for NYCTF teachers?

The sample in this study consisted of 34 new teachers in the NYCTF program. Teachers were given a problem solving examination at the beginning and end of the semester, and there was a statistically significant difference found between the pre- and post-tests. Additionally, teachers were required to reflect upon both their students' and their own problem solving at the beginning and end of the semester. It was found that teachers perceived their students' problem solving abilities as generally weak, but found they also shared some of the same weaknesses in problem solving as did their students.

Strong problem solving abilities and skills are essential not just in mathematics, but in other subject areas and life in general. It is important that teacher educators be aware of their pre- and in-service teachers' problem solving perceptions both for the students and the pre- and in-service teachers themselves.

DEVELOPING TEACHERS' ALGEBRAIC REASONING SKILLS WITH SPREADSHEET TECHNOLOGY IN AN ONLINE EDUCATIONAL ENVIRONMENT

Henry Gillow-Wiles
Oregon State University
gillowwh@onid.orst.edu

Margaret L. Niess
Oregon State University
niessm@onid.orst.edu

Keywords: Teacher Education–Inservice/Professional Development; Technology

Framework

Online, technology focused educational experiences provide access to continuing professional education for an extended teacher population, some of whom have no other means of continuing their professional education (Shea & Bidjerano, 2009; Stein, Wanstreet, Glazer, Engle, Harris, Johnston, Simons, & Trinko, 2007). To explore the impact of situating a continuing education program focusing on integrating technology (spreadsheets) into teaching mathematics (algebraic reasoning) in an online context, two research questions guided this study: Is an asynchronous, text-based online continuing professional education learning experience able to support teachers in learning: (1) about algebraic reasoning with spreadsheets as the learning tool, and (2) about teaching algebraic reasoning with spreadsheets as the learning tool?

Study and Results

Using a cadre of 10 teachers participating in a mathematics education course as part of a three-year online MS program focusing on mathematics, science and technology as study participants, course artifacts consisting of prompted reflective essays focusing on using dynamic spreadsheets as a teaching and learning tool and their knowledge of using dynamic spreadsheets as a teaching and learning tool were collected. In addition to these essays, learning products illustrating their spreadsheet Technological Pedagogical Content Knowledge (TPACK) about algebraic reasoning were collected. The analysis of these data sources revealed two primary themes: (1) through their activities in the course, the participants developed their understanding of how to use spreadsheets as tools to develop their own algebraic reasoning skills, and (2) through their activities in the course, the participants developed their understanding of how to facilitate students using spreadsheets in developing algebraic reasoning skills.

A sampling of evidence is provided by comments from two participants. K wrote, "The primary idea this topic emphasized is the universal nature of the average function versus a user created form of the same function." Her understanding of the importance of generalization indicated her developing knowledge of using spreadsheets as tools for developing algebraic reasoning skills. M wrote, "The students can conceptualize the numbers that are input aren't definite, rather can be changed by the user to observe different situations." This comment illustrated his understanding of how students are able to use spreadsheets in algebraic reasoning, through the manipulation of variables and values, to investigate mathematical concepts.

Discussion and Implications

The results of this study demonstrated the capabilities for online continuing education programs to deliver educational experiences that are effective in supporting teachers in developing critical mathematics TPACK with spreadsheets skills. This effectiveness reinforces situating meaningful learning for educators in an online context where deep thinking and higher-order learning are the desired outcomes. The importance of developing algebraic reasoning skills and an understanding of teaching and learning with spreadsheets suggests a need for further research in how best to situate these learning experiences in an online context.

ANALYSIS OF RESEARCH CONTRIBUTIONS AND FRAMEWORKS FOR MATHEMATICS PROFESSIONAL DEVELOPMENT ONLINE

Veronica Hoyos
Universidad Pedagogica Nacional, Mexico
vhoyosa@upn.mx

Synthesis of Main Descriptive Aspects

In this work we review different scenarios of instruction issued from important research related to teacher professional development. Specifically, we have proposed to account for the work of the professional development of teachers of mathematics through the use of digital platforms and where the aspect of technology integration in classrooms played a primary role in the design of the scenarios of instruction.

In two of the scenarios of instruction reviewed, the use of mathematics technology (Zbiek & Hollebrands, 2008) served as a catalyst to trigger the reflection of teachers on teaching some school mathematics topics (see Sánchez 2010), or on teacher planning or preparing lessons dealing with innovative topics of mathematics education (see Borba et al., 2005–2009). In another study, (Silverman 2011–2012) teachers gained knowledge of mathematical content for teaching. Finally, in the fourth of the works reviewed (Hoyos et al., 2009–2011), teachers made moderate progress in the incorporation of digital technologies into their classrooms, showing different ways of integrating technology into their teaching. These contributions are summarized in the Table 1.

Table 1: Characteristics and Contributions of the Scenarios of Instruction Reviewed

Characteristics / Teams	Online Communication modality	Internet interface used	Type of interaction	Theoretical frame	Main Contribution
GPIMEM (Brazil)	synchronous	Chat room	Between participants and the tutor	Humans-with-media and Lévy contribution on production of knowledge	Defining characteristics of interaction in online modality
Silverman et al. (USA)	asynchronous	forum	Between participants and the tutor	Sociocultural and discursive approach to development of knowledge	Clarification of interaction role in online learning
CICATA (Mexico)	asynchronous	forum	Between teams of participants	Documentary approach	Promotion of reflection in online modality
MAyTE (Mexico)	asynchronous	forum	Between participants and content	PURIA model and development of craft knowledge	Achievements on the incorporation of mathematics technology in teaching practice

Note: More information and bibliographical references will be given during the conference.

KNOWLEDGE AND PERSONAL EFFICACY FOR TEACHING AND THE SOURCES OF TEACHING SELF-EFFICACY FOR MULTIPLICATIVE REASONING

Erik Jacobson
University of Georgia
ejacobsn@uga.edu

Teachers' dispositions toward the work of teaching and the content they teach influence how their knowledge is used in practice. This poster session reports quantitative validation work on a new measure of mathematics teacher disposition that was built from Bandura's (1986, 1997) social-cognitive theory and Shulman's (1986) pioneering work on teacher knowledge.

Bandura (1986) theorized self-efficacy as the major source of motivation for human endeavor and identified two dimensions: personal efficacy and outcome expectancy. I focus on personal efficacy beliefs (confidence in one's own ability to do a task) because these beliefs are less stable and may respond to professional development efforts. Shulman (1986) differentiated *subject matter knowledge* from *pedagogical content knowledge*: the knowledge of a subject that is closely tied to the demands of teaching that subject. I evaluated a new model of teaching self-efficacy with two factors: personal efficacy (PE) and (pedagogical content) knowledge efficacy (KE). These factors represent teachers' confidence in their ability to teach and their confidence in their content knowledge for teaching, respectively.

The new measure was adapted from one designed for pre-service science teachers (Roberts & Henson, 2000) by focusing on inservice teachers' multiplicative reasoning (fractions, ratios, and proportions). This content is a major goal of elementary curriculum and a foundation for secondary curriculum, yet is difficult for K–12 teachers and their students. To support the validity argument, I developed measures for the four sources of self-efficacy postulated by theory (Bandura, 1997) that were specific to inservice teaching and multiplicative reasoning by adapting items for the sources of (general) teaching self-efficacy previously piloted by Morris (2010).

Results using a preliminary sample of 266 K–12 mathematics teachers in Texas indicate high reliability for both 7-item subscales ($\alpha_{PE} = .83$, $\alpha_{KE} = .88$). A χ^2 difference test showed that the two-factor confirmatory factor analysis (CFA) model was superior to the undifferentiated single-factor CFA model ($\chi^2 = 146.93$, df = 1, p <.000). All factor loadings in the two-factor model were significant and had R^2 values greater than .28. In multiple regression analyses, the four source measures explained the majority of the variance of the new self-efficacy measures ($R^2_{PE} = 0.67$, $R^2_{KE} = 0.57$). Moreover, a structural equation model with direct paths from the sources to the correlated self-efficacy measures exhibited reasonably good fit ($\chi^2 = 2575.06$, $df = 265$, RMSEA = 0.068, CFI = 0.91, SRMR = 0.056).

The self-efficacy measure will be used as tool to better understand how teachers navigate the professional learning continuum, for example, by assessing dispositional differences among teachers at different grade levels and with different preparation and training experiences.

MIDDLE SCHOOL MATHEMATICS TEACHERS' JUSTIFICATIONS ABOUT FRACTIONS

Yi-Yin Ko
Tufts University
Winnie.Ko@tufts.edu

Caroline J. Hagen
Tufts University
Caroline.Hagen@tufts.edu

Keywords: Teacher Knowledge; Middle School Education; Reasoning and Proof; Teacher Education–Inservice/Professional Development

Current reforms suggest that the teaching and learning of proof should be integrated into all mathematical domains, not only geometry (National Council of Teachers of Mathematics [NCTM], 2009). In order to implement these reform recommendations regarding proof successfully, mathematics teachers should possess adequate understanding of proof itself. The wealth of studies investigating pre-service and in-service mathematics teachers' conceptions of proof suggests that many teachers view example-based justifications as sufficient mathematical proofs (e.g., Knuth, 2002; Morris, 2002). To date, not enough is known about what middle school (grades 5–9) teachers' justifications look like and how teachers' educational background affects their competencies in constructing justifications about fractions—a topic that is both central to and pervasive in middle school mathematics. To address this research gap, this study investigates what types of justifications about fractions middle school mathematics teachers construct and how their justifications relate to their educational background.

This study involved 56 in-service middle school mathematics teachers from nine public school districts in the northeastern United States. The participanting teachers had varied educational backgrounds in matheamtics (n = 13), mathematics education (n = 8), science (n = 8), and other subjects (n = 27). The primary source of data for this analysis was teachers' written justifications for two problems about fractions. Their justifications about fractions were categorized according to Harel and Sowder's (2007) and Simon and Blume's (1996) taxonomies of proof. The results suggest that many teachers tend to construct symbolic justifications with logical errors. The results also suggest that many teachers experience difficulty generating a correct proof, regardless of whether or not their educational background is in mathematics.

HOW AND WHY DO MATH TEACHERS BECOME INTERESTED IN EQUITY?

Kari Kokka
Harvard Graduate School of Education
kari_kokka@mail.harvard.edu

In this poster, I compare and contrast preservice teachers' beliefs about equity in mathematics education with those of teacher participants of an annual conference about mathematics education and social justice (Creating Balance in an Unjust World www.creatingbalanceconference.org). I aim to better understand the development of interest in equity among math teachers and how it may shape their pedagogical practices. How and why do math educators become interested in issues of equity relating to math instruction and how does it affect their pedagogical approaches? Might teachers' 2,000-hour "apprenticeship of observation" (Lortie, 1975) as students impact their beliefs about teaching mathematics, particularly related to issues of equity? Scholars have investigated various pedagogical approaches that result in more equitable outcomes, such as complex instruction (Boaler, 2002), culturally relevant pedagogy (Ladson Billings, 1997), and comparison of algebraic problem solving methods (Star & Rittle-Johnson, 2009). However, despite preservice teachers' exposure to research, some may not implement these pedagogical practices. Some teachers may be interested in equity and believe that they are implementing such practices, while in reality they are not (Cohen, 1990). Others may not be interested in equity, or more plausibly must focus on a myriad of other more urgent concerns as a preservice teacher, such as classroom management, daily planning, and grading. In this poster I present findings of preservice teachers' weekly journal entries to explore their thoughts regarding equity in mathematics instruction. In comparison I present interview results and attendees' written evaluations of the Creating Balance in an Unjust World conference, in an attempt to understand how and why they became interested in equity in mathematics education. Preliminary results suggest great variation in preservice teachers' interest in equity. Some teachers enter the teacher preparation program with an interest and commitment to equity in math achievement. Some have other interests (not related to equity) and reasons for pursuing mathematics teaching as a career, yet others grow to value equitable pedagogical approaches in the math classroom. Conference attendees demonstrate strong commitment to equity in math education often related to a broader and more general commitment to social justice. Results suggest that prior education and personal experience play an influential role in math educators' interest in equity. Results also raise questions about the ability of a one-semester preservice methods to impact teacher beliefs regarding equity in mathematics achievement. Further research, using qualitative methods such as interviews and participant observation, may help shed light on the reasons and experiences behind math teachers' interest in pursuing equity.

CO-EVOLVING LEADERSHIP AMONG MIDDLE GRADES MATHEMATICS TEACHERS IN AN AUTONOMOUS PROFESSIONAL DEVELOPMENT GROUP

Della R. Leavitt
Rutgers University
Della.Leavitt@rutgers.edu

Robert Babst
Sayreville Middle School
Robert.Babst@sayrevillek12.net

Keywords: Teacher Education–Inservice/Professional Development; Middle School Education; Instructional Activities and Practices; Equity and Diversity

Kazemi and Hubbard's (2008)'s concept of *co-evolution* offers understandings of teachers' *transformations of participation*. Here, an autonomous Professional Learning Community (PLC) shifted teacher learning with respect to noticing (Sherin, Jacobs, & Philipp, 2011). Autonomous teacher-led groups contrast with mandated PLC's because teachers take control of purposes and directions (Cochran-Smith & Lytle, 2009). This study relates to PMENA 2012 themes in three ways: (1) conceptualization of students' transitions between middle and high school mathematics, (2) intra-group professional learning with colleagues, and (3) innovative use of research for equitable grading. The study responded to the following research questions:

1. What is the nature of the issues teachers deem important and choose to explore?
2. How do teacher/participants set norms for structure, topics and leaders for each session?
3. What demonstrates changing leadership development among the teacher/participants?

Fourteen mid-career middle grades mathematics teachers from two partner districts of the NSF-sponsored New Jersey Partnership for Excellence in Middle School Mathematics (NJPEMSM) were invited to participate. Seven teachers volunteered.

Teachers designed a structure for the 90 minute sessions, divided into three parts: (1) recap, (2) "cool" mathematics class activities, and (3) selected topics led by rotating leaders from the group. The data consist of 10 hours each of video and audio recordings analyzed using NViVO software beginning with an interaction framework (Eskelson, 2012). Initially, teachers expressed: (a) great value in increased communications with fellow participants; (b) reluctance to share this work with oppositional colleagues—later, several presented their activities at a department meeting; (c) increased confidence to lead discussions with peers; (d) new acceptance of one teacher's introduction of an unconventional, equitable approach to grading; and (e) agreement about the overall worth of these sessions, with intentions to meet in the 2012–2013 school year.

Acknowledgments

We appreciate the endorsements and support of New Jersey partner districts' mathematics supervisors, Robert Preston and Jean Ferrara, as well as Dr. Amy Cohen, PI of NJPEMSM.

Keywords: Mathematical Knowledge for Teaching; Modeling; Teacher Knowledge

The goal of the current research project is to explore the nature of state-licensed mathematics specialists' and teachers' noticing of student use of representations of mathematical problems.

Imagine mathematical knowledge taking the form a network, the individual nodes representing five representations of a mathematical problem or concept. Following the Lesh Translation Model, these five nodes are real life contexts, manipulative representations, pictures, symbols, and also verbal representations of a problem (Cramer, 2003). Each of these nodes is populated by various manifestations, each separate and distinct from others. Building connections between each of these nodes and sub-nodes creates a complex web of conceptual links between representations of a mathematical context. Strategic competence, defined as the "ability to formulate, represent, and solve mathematical problems" (NRC, 2001, p. 116), is the direct result of a strong, interconnected understanding of a problem context. In the network model, a teacher who "notices" is willing to extend a tenuous link between one representation and another in order to follow student thinking. This conception of noticing, the act of making observations of a classroom and managing choices based on those observations (Mason, 2011), provides a lens to examine the dialogue that occurs during the lesson study debrief.

Four classroom teachers collaboratively planned a lesson introducing subtraction of integers to a class of seventh grade middle schoolers. The students' use of the provided manipulatives exposed their difficulties formulating and representing the mathematical contexts of the given tasks. The lesson debrief revealed that the mathematics specialists and the teachers who created the lesson differed widely in their understanding of manipulatives as representations of mathematical contexts. The specialists, on the whole, showed a qualitatively different type of noticing of students' attempts to link representational nodes than did the lesson study participants. Specialists were more likely to show awareness of links between different representations of the problem. While this is a small case study, the conceptual framework and the important differences between teachers' and specialists' acts of noticing indicate that further study of the role of mathematics specialists in teacher development may be revelatory.

EXPLORING THE USE OF URBAN STUDENT MATH LEARNING VIDEO TO CHALLENGE INSTITUTIONALIZED EDUCATION STEREOTYPES

Joyce Leslie
Rutgers University
joyce.leslie@gmail.com

Hanna Misir
Rutgers University
hmisir84@gmail.com

Deidre Richardson
Rutgers University

Keywords: Affect, Emotions, Beliefs, and Attitudes; Assessment and Evaluation; Teacher Beliefs; Teacher Education–Inservice/Professional Development

This research examines how video can be used to help professionals transition their own perceptions about the potential of students and the power of student explorations in mathematics. It is known that student behaviors and attitudes in school often affect the education they receive. It is also known that decisions about how to design the curriculum and manage classes can be based on the socio-economic level of a community, the behavior profiles of a school, and stereotypes about student behaviors (Anyon, 1980; Jussim, Robustelli, & Cain, 2009). The question guiding our research is: How can innovative video technology be used to parse out a student's learning behavior from other behavioral attributes to help educators see their students in a new light?

This poster presentation reports on our analysis of videos from the Video Mosaic Collaborative (VMC) that feature urban students engaged in mathematics learning. Our work is part of an initiative at Rutgers University where a team of education researchers and librarians are creating a digital video repository to house 25 years of research on children's mathematics learning. The VMC (www.videomosaic.org) gives the educational community access to students' math learning in classrooms and informal settings, in urban and suburban communities (Agnew, Mills, & Maher, 2010). This project also introduces a new tool, the Analytic, which supports creation of video narratives that concatenate multiple video clips with descriptive text to reveal specific aspects of the full video. Video data is rich and supports development of a variety of analytics, each having a unique lens on the original video. The tool is designed to maintain the relationship between each video clip, the source video in the library, source video transcripts and other metadata pertaining to the original learning context (Agnew, Mills, & Maher, 2010).

Our preliminary work focused on three different groups of urban students with the goal of revealing the intellectual power in students at risk of being judged incapable by their non-math behavior. We used a descriptive model for video data analysis (Davis, Maher, & Martino, 1992) to extract the math learning clips from full videos that contained both learning and distracting behavior. Our poster presentation details the results of our video analyses and showcases our goals of repurposing video for (1) professional development for educational leaders in low SES urban districts, and (2) promoting a transition among teachers and students to embrace a model of high cognitive demand in math classes with low SES, urban (or rural) students.

CHINESE MATHEMATICS TEACHING REFORM IN FOUR-YEARS TIME: THE DJP MODEL

Lianfang Lu
University of Arkansas–Little Rock
lxlu@ualr.edu

Thomas E. Ricks
Louisiana State University
tomricks@lsu.edu

Keywords: Teacher Education–Inservice/Professional Development

Like the United States, China struggles with the professional development of its mathematics teaching corps. We describe how middle school mathematics teachers from a poor rural area of southwest China successfully reformed their practice in only four years time by utilizing a systemic collaborative reflection model called DJP—D (导) refers to guided self-learning, J (讲) to sharing solutions, and P (评) to reflective evaluation. Data in our study include 13 video-taped consecutive classroom teaching observations, semi-structured teacher interviews, and surveys of all 152 students' perceptions of mathematics and the respective pedagogy in their classes. Our findings indicate that since the enactment of the DJP model, the school (historically ranked last on achievement tests), now ranks in the top level on academic testing in its district. Students developed supportive learning communities and their interests in learning mathematics improved significantly during this time frame.

We specifically focus our discussion on strategies and issues related to the learning tasks, the structure of instruction, the grouping of students, and the assessment approach in the DJP model. Teachers purposefully chose learning tasks to engage students in higher-level mathematics thinking (Stein et al., 2000). Similar problems were posed, analyzed and synthesized to find common mathematical structures underlying various situations (Cullen, 2002). The students worked on the problems collaboratively and shared their solutions with the larger class. The DJP model of teaching allows students more opportunity to teach each other, and replaces more traditional Chinese lecture formats. The teacher and the class reflected together on core mathematics content knowledge and related reasoning strategies that facilitated successful solution generation, and together evaluated the performance of each student-group. Small groups were the basic units accountable for learning; ongoing multifaceted assessments focused on the student-groups rather than on specific individuals. Friendly competition between groups and rewards for achievement and progress aided student learning. We also discuss some issues that arose for the teachers during DJP implementation, including development of dynamic discourse and underlying cultural and social assumptions that might support the DJP model as a reform approach in other schools, especially the United States. Our poster describes the DJP model for a North American audience, and provides structured suggestions for how this Chinese professional development can be adapted for American mathematics classes. Such recommendations are significant and timely as the United States seek to improve its mathematics education.

SUPPORTING TEACHERS IN TECHNOLOGY INTEGRATION IN KENYAN SECONDARY SCHOOLS

Marguerite Miheso-O'Connor
Kenyatta University
khakasaconnor@gmail.com

Joanna O. Masingila
Syracuse University
jomasing@syr.edu

Teaching is a complex practice that requires teachers to drawn upon their content knowledge, pedagogical approaches and strategies, and knowledge about learners in order to support learning. Integrating technology into the teaching and learning practice of a classroom is a strategy that many teachers are drawing upon. When integrated effectively, technology can support student learning and lead to deeper conceptual understanding and procedural fluency (Bransford, Brown, & Cocking, 2000). However, there are factors that serve as barriers to teachers integrating ICT into their classroom practice and some may seem difficult to overcome, especially in developing countries (Ogwu & Ogwu, 2010). It is therefore important for teacher educators and other educational policymakers to understand what factors assist in effective ICT integration and what factors may inhibit this integration.

Researchers have identified a number of common factors that promote effective ICT integration (e.g., McMillan Culp et al., 1999). While most of this research has been carried out in developed countries, Light has applied a framework of common factors to classroom integration of ICT in developing countries (Light, 2010). These researchers have used what they describe as the seven of the "most commonly cited factors" (Light, 2010, p. 41). In an international study examining 174 case studies of innovation pedagogical practices using technology in 28 countries, Kozma (2003) identified seven "meaningful patterns of classroom practice" (p. 6).

In this study, we are using a case study approach to examine how eight secondary mathematics and science teachers moved from no experience in technology use to integrating technology into the teaching and learning practice of their classroom, and to examine what factors assist and what factors inhibit this integration. We are analyzing these teachers' classroom practices in light of research literature in this area, while being open to other factors and patterns emerging within the context in which we are investigating. We are collecting data through questionnaires, individual interviews, and classroom observations.

The research study participants are teachers at two national high schools in Kenya, one boys' school and one girls' school. The participants were involved in a HP Catalyst Initiative project and were each given a HP tablet and participated in several professional development workshops to be exploring ways to integrate technology into their classroom practice. Our poster will present several case studies as examples of what we found through our investigation.

ELEMENTARY TEACHERS' IMPLEMENTATION OF COMPLEX INSTRUCTION

Gemma Mojica
University of North Carolina–Chapel Hill
gmojica@email.unc.edu

Bryan Fede
University of North Carolina–Chapel Hill
fede@live.unc.edu

Marta Civil
University of North Carolina–Chapel Hill
civil@email.unc.edu

As one component of a larger research project, we examined how eight elementary mathematics teachers in an English/Spanish dual language program learned to implement Complex Instruction (CI) (Cohen & Lotan, 1997), an approach to group work with a special emphasis on equity issues (e.g., status). Over a seven-month period, we investigated the dilemmas that these teachers faced as they learned to implement CI. The following data was collected and analyzed using qualitative methods: video recordings of teacher meetings, audio recordings of teacher interviews, and researchers field notes of classroom observations.

One unanticipated finding that surfaced early on was the tension between teachers' willingness to implement components of CI and their orientation towards their district's chosen curriculum. The school had previously used a reform-based curriculum, which had recently been replaced by a nonreform-based curriculum. However, the enacted curriculum is what is implemented in the classroom (Clandinin & Connelly, 1992) and may differ from the intended curriculum. According to Remillard and Bryans (2004), teachers' orientation toward curriculum influences their implementation. They identify three categories of teachers' implementation. *Intermittent and narrow use* teachers use the curriculum minimally, relying on their own routines or other materials. Teachers in the *adopting and adapting* category use the curriculum as a guide for instruction, such as in sequencing topics. Finally, *thorough piloting* involves teachers who use curriculum as their primary guide for instructional activities.

We found that teachers' orientation to the curriculum influenced their implementation of CI. Use by one of the eight teachers was categorized as intermittent and narrow use. This teacher began to implement CI at the onset of the study and began to use CI effectively almost immediately. Often, this teacher relied on the reform-based curriculum that had been replaced. She felt that she had the freedom to do so. Use by four of the teachers was categorized by adopting and adapting. These teachers only began to implement CI when explicitly asked to do so. They did not consistently use CI effectively and did not always recognize possible causes, such as implementing inappropriate group tasks. However, once these teachers found success in implementing parts of CI, they were willing to continue to keep trying to incorporate CI in their instruction. Use by the other three teachers could be categorized as thorough piloting. These teachers were the most hesitant to attempt to implement CI in their classrooms. They often described a desire to use CI, but they felt constrained by many elements of the newly adopted curriculum, such as insufficient time to engage students in CI tasks due to the number of topics that needed to be covered. They also felt pressure to adhere closely to the curriculum, even though they felt it was ineffective in engaging children in significant, meaningful mathematics.

TRANSITIONING FROM RATIONALIZATION TO CRITICAL REFLECTION THROUGH REFLECTIVE TEACHING CYCLES

Eileen Murray
Harvard Graduate School of Education
drmurraye@gmail.com

Practice-based professional development provides teachers with learning experiences that are connected to and contextualized in professional practice. Therefore, this type of professional development can also be customized to meet teachers at their point of need in part by the use of *professional learning tasks* (Smith, 2001), which takes teachers' prior knowledge and experiences into consideration. The type of professional learning task I used in this study was the *reflective teaching cycle* (Smith, 2001). The reflective teaching cycle consists of three phases: (a) planning, (b) teaching, and (c) reflecting. The purpose of this study was to examine how a series of cycles influenced two middle school mathematics teachers' selection and implementation of tasks that had the potential to facilitate higher-order thinking. I used a series of seven cycles to engage two seventh-grade mathematics teachers in conversations about mathematics, pedagogy, and higher-order thinking in order to provide students with mathematics lessons that could promote the use of higher-order thinking. During planning and reflection meetings, I recorded the conversations and used thematic analysis to identify, analyze, and report themes within the data.

In this poster, I present results from the study, which illustrate how the cycles helped one teacher transition from *rationalizing* to *critically reflecting* on her practice. Teachers rationalize when they do not, or cannot, view a problem in other ways and possibly see it as "residing within the students rather than in the practice setting itself" (Loughran, 2002, p. 35). Critical reflection involves teachers considering the best way of understanding, changing, or implementing their practice, where 'best' implies "considering implications of practice and weighing them against relevant goals, values, and ethics" (Jay & Johnson, 2002, p. 79). In this study, one teacher transitioned from rationalizing the reasons why she was unable to facilitate higher-order thinking in her classroom to critically reflecting on her practice to understand how it was inhibiting her ability to facilitate higher-order thinking.

The reflective teaching cycles allowed the teacher to make this transition through collaboration and the focus on mathematics and pedagogy. In particular, the teacher was able to hear what her colleague was doing, which helped her consider the implications of her practice and how she could change it. Also, as the facilitator, I was able to ask her questions about specific events in her classroom, which prompted her to think about her practice rather than the students. This research could help teacher educators and professional developers determine the most effective characteristics of the reflective teaching cycle and the types of facilitation that would be most successful at promoting critical reflection.

TEACHER MODELS OF STUDENT THINKING

Kathryn Underwood
Arizona State University
kathryn.underwood@asu.edu

Marilyn Carlson
Arizona State University
marilyn.carlson@asu.edu

Keywords: Mathematical Knowledge for Teaching; Curriculum; Instructional Activities and Practices

The purpose of this poster is to describe a study, which explores how precalculus teachers using a research-based curriculum develop models of students' mathematical thinking. The study builds on a framework developed by Silverman and Thompson (2008), which describes how teachers develop Mathematical Knowledge for Teaching (MKT). Teachers develop MKT through developing deep connected mathematical understandings which Silverman and Thompson call Key Developmental Understandings (KDU's) (Simon, 2006), and through attending to student thinking in ways that allow them to understand both how students think and how students might interpret new information. The teachers' new MKT is developed through reflection, which occurs when they are faced with perturbations to their current way of thinking. (Dewey, 1910).

In this study we explore teachers' current models of student thinking about key precalculus ideas including functions and rate of change, and try different approaches to challenge teachers to reflect on student thinking in ways that will support the teachers in developing more complete and useful models of student thinking. In interviews, teachers are asked to review student work and video clips of their own classroom interaction with students, and then to interpret how the students might be thinking. Initially, it appeared that teachers and researchers had different interpretations of what is meant by attending to student thinking. Questions were developed that we hoped would help support teachers in knowing what it might mean to attend to student thinking, and suggest a different possibility for considering student thinking. Teachers were asked several different types of questions. They were given different possibilities, based on research, for how students might be thinking, and asked to evaluate each possibility. They were asked to compare student mathematical thinking to their own mathematical thinking, and to consider how these ways of thinking might influence how students interpreted classroom activities. They were asked what meaning they hoped students would make of the mathematics and what meaning they thought students were making of the mathematics. Finally, they were asked how they might in a specific situation have explored further what a student was thinking.

We will report progress in understanding teachers' models of student thinking and how these models might develop, and in understanding how to promote teacher reflection on student thinking and mathematics.

RECIPROCAL FUNDS OF KNOWLEDGE IN PRE-K MATHEMATICS

Anita A. Wager
University of Wisconsin–Madison
awager@wisc.edu

Families' observations of children's counting and number expertise typically occurs in everyday contexts whereas teachers see this expertise in the context of school. The differences in these everyday and school based contexts has been shown to leave children with the view that there are two kinds of mathematics—one for school and one for everything else (Presmeg, 2007). We hypothesize that if this dissonance begins early, it will become entrenched early. Thus, for mathematics pedagogy to be effective, teachers need to transition from a learned focus on what and how mathematics is traditionally taught in school to connecting to the mathematical practices children engage in outside school (Wager, 2012). Further, there must be a shared understanding between teachers and families of both mathematics contexts. Identifying ways for families and teachers to inform each other and bridge that divide is at the heart of the concept we call "reciprocal funds of knowledge."

Drawing on scholarship in funds of knowledge, early childhood, and early mathematics, a two-year professional development program was designed in an effort to support pre-K teachers as they worked with children and families to build the bridge between home and school mathematics. As part of the professional development teachers engaged in multiple practices with families including: (a) home visits, (b) two-way reflective conferences, (c) creating and sharing artifacts/learning stories, and (d) developing family math activities. Each activity contributed to a rich understanding of what children know, how they know it, where they learned it, and perhaps most importantly—what teachers can do with that knowledge in order to support children's learning. This study was designed to respond to the following questions:

1. How does reciprocal engagement with families contribute to teachers' understanding of a child's numeracy skills?
2. What various resources do families provide to support children's numeracy development?
3. In what ways do teachers modify their instruction based on learning about family knowledge, resources, and practices?

Through their engagement with families, teachers learned the types of numeracy activities families engaged in with their children, the wide range of resources provided by families, and the different competencies children demonstrated depending on the context in which they counted. By accessing the knowledge and resources that reside in children's homes teachers planned for instruction that better supported children's mathematical understanding. Without drawing on this knowledge from home, we are only accessing part of children's understanding. Further, by engaging in the practices supported by this professional development, connections between families and schools are improved.

We use ethnography of argumentation to analyze part of a lesson from an algebra course for elementary teachers preparing to be mathematics specialists (Krummheuer, 1995, 2009). During this part of the lesson, the instructor and teachers discussed the behavior of the quantity *r/s* as *s* increases. As they did so, they established two qualitatively different argumentations. Following Krummheuer (1995, 2009), we use the notion of framing to explain the qualitatively different backings, and hence arguments, participants established that supported the claims that they made. Like Stephan and Rasmussen (2002), we highlight the types of argumentative supports that the classroom participants offer that advance the argument at hand. Whereas Stephan and Rasmussen illustrate how the absence of these supports points to collective shifts in the classroom participants' understandings, we focus our discussion on the important role that these argumentative supports play in promoting individual learning opportunities.

Participants established an *inductive backing* to support the ensuing warrants in the form of backings that collectively served a generalizing role. One of the teachers initiated this process by introducing arbitrary examples for the quantity, *r/s* as *s* increases, using a partitive division frame to support her claim. The instructor took a lead role in facilitating this part of the discussion by representing the teacher's examples and, in collaboration with the teachers, generated additional examples. The instructor and the teachers established this framing by collectively generating examples situated within the context of sharing donuts. As they engaged in this discussion, teachers had opportunities to reason quite sensibly about the behavior of the quantity, *r/s*.

We also provide an example of *authoritative backings*, argumentative supports that are irrefutable. This type of backing was socially constituted when the instructor, along with one of the teachers, referred to a meaningful context (steepness of a hill) that provided argumentative support for another argument. This teacher gave a different explanation for the behavior of *r/s* as *s* increases. The structure of the argument was different from the previous one. First, participants established an inductive warrant. The instructor provided a backing (and challenge) that unequivocally validated the teachers' argumentative supports. In this case, the backing and, more generally, the argument are indisputable because the backing was couched exclusively in a contextual situation. In fact the framing and the backing seemed to be one and the same.

In sum, teachers had opportunities to make connections about *r/s* albeit the connections they made were constrained and/or enabled by the backings they and the instructor established.

TWO MODELS OF PROFESSIONAL DEVELOPMENT USING EDUCATIVE CURRICULUM MATERIALS

Fay Zenigami
University of Hawaiʻi at Mānoa

University of Hawaiʻi at Mānoa
hslovin@hawaii.edu

This poster shares two models of professional development in which teachers wrote curriculum materials to promote their own learning and change their instruction. In one project, teachers from a K–5 school wrote materials for lessons they deemed critical for students' success in mathematics. In the other project, middle and high school teachers from six schools prepared materials for topics in algebra that students find difficult to learn. These materials are referred to as educative curriculum materials (ECM) (Davis & Krajcik, 2005).

Keywords: Teacher Education–Inservice/Professional Development

Hill, Rowan, and Ball (2005) note that teachers' mathematical knowledge affects the effectiveness of their teaching. Moreover, how they hold that knowledge affects their ability to use it in teaching. Thus, our research goals were to characterize and articulate the nature of content knowledge for teaching and to understand how teachers developed this knowledge.

Both professional development models focused on content knowledge for teaching through teachers' creation of curricular materials, including pedagogical suggestions, to appropriately prepare themselves for successful implementation of their own goals and ideas. Pedagogical content knowledge is developed through planning, classroom instruction, and reflective collaboration (Van Driel & Berry, 2012). The professional development provided for teacher learning that involves developing and integrating one's knowledge base about content, teaching, and learning. To be reflective practitioners, teachers must participate in discourse on teaching and apply that knowledge to make instructional decisions. ECM set up these opportunities.

Preparing ECM that contain accurate mathematics, coherently portray the trajectory of the content, include appropriate technology, and effectively use technology is a difficult mission. We provided guidelines for teachers to use in writing their ECM in an effort to assist them in developing a clear purpose for their teaching and to provide multiple opportunities for students to explain their ideas. These included: (1) learning how to anticipate and interpret students' thinking and responses; (2) broadening their repertoire of instructional strategies and developing their knowledge base; (3) connecting topics during the year; (4) making pedagogical judgments visible; and () attending to ideas underlying the tasks rather than merely guiding actions.

By participating in the construction of ECM, teachers deepened their mathematical content knowledge, developed and included processes such as problem solving, reasoning, and communication into their instructional materials and instruction, made their teaching public, and reflected on their knowledge of mathematics and their teaching of mathematics.

PROSPECTIVE TEACHERS' TRANSITION FROM THINKING ARITHMETICALLY TO THINKING ALGEBRAICALLY ABOUT EVEN AND ODD NUMBERS

Kadian M. Callahan
Kennesaw State University
kmcallahan@kennesaw.edu

Amy F. Hillen
Kennesaw State University
ahillen@kennesaw.edu

We present findings from a study of prospective middle school teachers' reasoning as they transitioned from thinking arithmetically to thinking algebraically about even and odd numbers. Teachers were asked to make sense of and use two representations of even and odd numbers to model them and to make connections between the representations. Analysis of a whole-class discussion indicates that although teachers easily represented even and odd numbers using an algebraic generalization, they grappled to make sense of a given geometric model. As teachers worked to make sense of the geometric model, they transitioned back and forth among three ways of interpreting the model (two of which were incorrect; one of which was correct).

Purpose of the Study

Standards for K–12 mathematics emphasize the use of multiple representations (e.g., written words, diagrams, symbolic expressions, physical models, graphs) for making sense of and communicating mathematical ideas (Common Core State Standards Initiative [CCSSI], 2010; National Council of Teachers of Mathematics [NCTM], 2000). Scholars argue that examining different representations can make mathematics more meaningful by illuminating different aspects of a mathematical idea or relationship (Cuoco, 2001; NCTM, 2000). Representations may be particularly important in the middle grades as students make the transition from thinking *arithmetically*—for example, working with specific even and odd numbers—to thinking *algebraically*—for example, making sense of even and odd numbers as sets of numbers that can be generalized (CCSSI, 2010; NCTM, 2000). The difficulties that many students have in making this transition are well documented (e.g., Chazan, & Yerushalmy, 2003; Smith, 2003), and scholars suggest that considering both visual and numerical modes of generalizing may facilitate this transition by helping students understand the nature of variable and familiarizing them with the structure of algebraic expressions (Lannin, 2003; Rivera & Becker, 2009; Thornton, 2001).

Considering different mathematical representations has also proven to be beneficial for teachers. Research shows that making sense of and using different representations can strengthen teachers' content knowledge by requiring them to make connections among representations and can strengthen teachers' pedagogical content knowledge by providing them greater access to student thinking as students interpret different representations (Herbel-Eisenmann & Phillips, 2005; Izsák & Sherin, 2003). Thus, one way to strengthen teachers' ability to support middle school students' transition from arithmetic thinking to algebraic thinking is to provide them with opportunities to reason about and use different representations to make sense of mathematical ideas. In particular, the mathematics content courses taken during their teacher preparation programs might be a promising context for such learning experiences.

This research report presents findings from a study that investigated the ways in which a class of prospective middle school teachers (PMSTs) reasoned about different representations of even and odd numbers during their work on a number theory unit in a mathematics content course for PMSTs. The context of even and odd numbers was chosen for two reasons: (a) it is central to the number theory ideas that are studied in the middle grades (CCSSI, 2010; Lappan, Fey, Fitzgerald, Friel, & Phillips, 2006); and (b) it is accessible, yet still presents some challenge, for teachers (Smith, 2011).

Theoretical Perspective

Much of the mathematics education literature in recent years conceptualizes the learning of mathematics as a collective act. The view that learning is a social endeavor is rooted in theories of cognitive development based on foundational ideas by Jean Piaget and Lev Vygotsky. Piaget argued that social interactions are central to knowledge development because they influence individuals' attempts to resolve conflicts between their perspective and the perspectives of others (Brown & Palincsar, 1989; Rogoff, 1998). Vygotsky also emphasized social interaction as an essential element of cognitive development. He asserted that there is fluidity between self and others, and cognitive exchanges at this boundary mitigate the process through which knowledge development occurs. Sociocultural theories of mathematics learning integrate the perspectives of both Piaget and Vygotsky and maintain that one cannot examine individual students' reasoning and cognitive development without considering how it is influenced by the social context or examine the social context without considering how individual students' reasoning influences that context (Cobb, 2001; Cobb & Yackel, 1996).

Particularly relevant to the present study is the notion that representation can be conceptualized as a collective act occurring within a specific social and mathematical context. Collective representation involves "negotiating individually constructed representations in the shared space of a group or classroom as well as the teacher's role in facilitating these interactions" (Stylianou, 2010, p. 327). This study investigated the extent to which considering different representations of even and odd numbers was helpful in PMSTs' collective transition from thinking arithmetically to thinking algebraically.

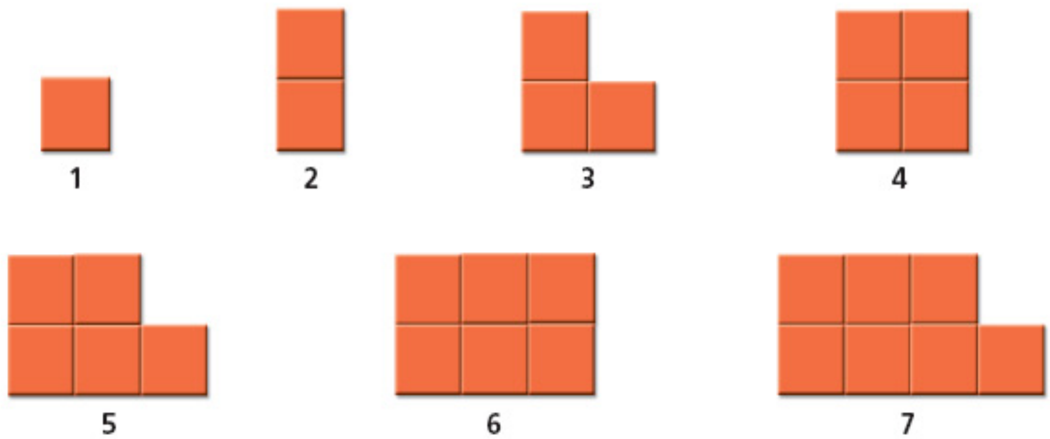
Methods

The study was conducted during Spring 2011 at a four-year, public university in the southeastern United States. The 22 participants (14 female; 8 male) were PMSTs enrolled in a required 16-week mathematics content course for prospective middle and secondary school teachers. (Since secondary school teachers at this university are certified to teach both middle and secondary school, all participants were considered prospective middle school teachers.)

The course met once a week for two hours and thirty minutes and focused on three content strands central to the middle grades: (a) number and operations; (b) algebra and functions; and (c) geometry and measurement (CCSSI, 2010; NCTM, 2000). Throughout the course PMSTs were asked to reason about and make connections between and among representations of mathematical ideas across these three content strands. The instructor (and first author) also immersed PMSTs in the processes of mathematical inquiry (CCSSI, 2010; NCTM, 2000) and modeled a type of teaching whose goal was learning with understanding (Carpenter & Lehrer, 1999). PMSTs were encouraged and expected to regularly engage in discussions with their peers as they shared their thinking about problems and solution strategies, reasoned about and made connections between mathematical ideas, made and evaluated conjectures, and developed and revised mathematical arguments.

Data collection occurred during a five-week unit on number theory that included considering numeric, algebraic, and geometric representations of even and odd numbers and exploring how to add and multiply even and odd numbers using these different representations. The primary data source was transcripts of video of the whole-class discussions that the second author filmed. Secondary data sources included: (a) the second author's field notes; (b) written work produced by PMSTs during each class; and (c) audio recordings of weekly meetings between the first and second authors in which they reflected on each class meeting, identified and discussed any ideas that the PMSTs seemed to be struggling with, and discussed the instructor's plans for the next class meeting.

The study reported herein focuses on the first idea that PMSTs grappled with during the data collection, which occurred during the second class meeting of the unit (the fifth class meeting of the semester): explaining how the different components ('2', 'n', and '+1') of the algebraic generalizations of even and odd numbers ('2n' and '2n+1', respectively) were represented geometrically in "Tilo's model" (shown in Figure 1). In particular, PMSTs had difficulty making connections between: (a) the '2' in the algebraic generalizations of both even numbers and odd numbers and the maximum number of tiles in each column of Tilo’s model; (b) the ‘n’ in the algebraic generalizations of both even and odd numbers and the total number of ‘complete’ columns (i.e., columns that contain two tiles); and (c) the ‘+1’ in the algebraic generalization of odd numbers and the one extra tile that makes an ‘incomplete’ column. (Although 2n-1 is also a valid generalization of the set of odd numbers, the instructor chose to focus on the 2n+1 generalization in order to be consistent with the source of Tilo’s model, the *Connected Mathematics Project* curriculum.)



(Lappan, Fey, Fitzgerald, Friel, & Phillips, 2006, p. 25)

Figure 1: Tilo’s model

The transcript of the class meeting that is the focus of this study was analyzed to identify the ways in which PMSTs used the different representations of even and odd numbers to reason about the meaning of the components of the algebraic generalizations of even and odd numbers. Three milestones in PMSTs’ thinking about the variable ‘n’ (shown in Figure 2) emerged from the data: (a) claiming that ‘n’ represented *one tile*; (b) claiming that ‘n’ represented *one complete column*; and (c) claiming that ‘n’ represented the *total number of complete columns*.

Thinking Arithmetically		***Thinking Algebraically***
Milestone a ‘n’ represents one tile (incorrect)	Milestone b ‘n’ represents one complete column (incorrect)	Milestone c ‘n’ represents the total number of complete columns (correct)

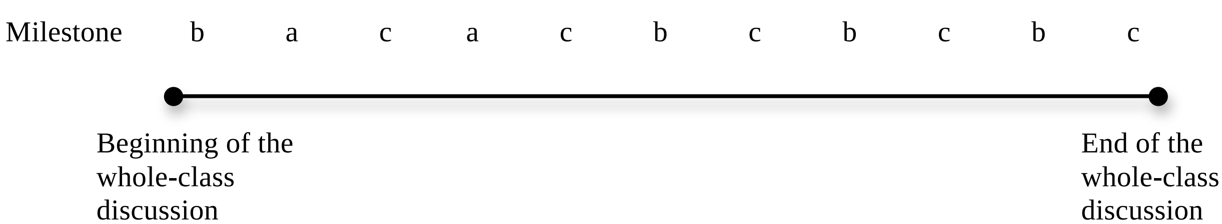
Figure 2: Milestones in PMSTs’ transition from arithmetic to algebraic thinking

Conceptualizing ‘n’ as representing *one tile* (Milestone a) would result in a different algebraic expression for each natural number (e.g., 2=(2n), 3=(3n), 4=(4n), 5=(5n), 6=(6n), where n=1 tile) and reflects arithmetic thinking since it treats each number *individually* rather than as belonging to a *set* of numbers with shared characteristics. Conceptualizing ‘n’ as representing *one complete column* (Milestone b) also results in a different algebraic expression for each natural number (e.g., 2=2(n), 3=2(n)+1, 4=2(2n), 5=2(2n)+1, 6=2(3n) where n=1 complete column); however, it recognizes that even numbers have the characteristic of being able to put the tiles into groups of two with no tiles left over, and that odd numbers have the characteristic of being able to be put the tiles into groups of two with one tile left over. Thus, Milestone b is considered to be a more algebraic way of thinking because it suggests that there are some shared characteristics among numbers within the same *set*. However, this way of thinking is not completely algebraic because it does not allow for a single algebraic generalization to represent even numbers and another algebraic expression to represent odd numbers. Conceptualizing ‘n’ as representing *the total number of complete columns* (Milestone c) reflects algebraic thinking by recognizing the shared characteristic among even numbers as being able to put the tiles into groups of two with no tiles left over, the shared characteristic among odd numbers as being able to put the tiles into groups of two with one tile left over, and results in one algebraic expression for the *set* of even numbers (2n) and another algebraic expression for the *set* of odd numbers (2n+1).

After identifying and coming to agreement on the extent to which the three milestones reflected arithmetic and algebraic thinking, the authors reanalyzed the transcripts to trace PMSTs’ ideas as they moved back and forth between the three milestones in their transition from thinking *arithmetically* about *individual* even and odd numbers to thinking *algebraically* about *generalizations* of the *set* of even numbers and the *set* of odd numbers.

Results

The transition from thinking arithmetically about *individual* even and odd numbers to thinking algebraically as *sets* of numbers that can be generalized was challenging for this group of PMSTs and did not occur in one direction (from thinking arithmetically to thinking algebraically). Instead, in their efforts to make connections between the geometric and algebraic representations, PMSTs’ understanding of the meaning of the variable ‘n’ in the algebraic generalizations of even and odd numbers (‘2n’ and ‘2n+1’, respectively) shifted back and forth between the three milestones: (a) ‘n’ representing *one tile*; (b) ‘n’ representing *one complete column*; and (c) ‘n’ representing the *total number of complete columns*. As shown in Figure 3, all three milestones were considered at least twice during the whole-class discussion. That Milestone a was abandoned fairly early in the discussion suggests that PMSTs realized that putting tiles into groups of two to make complete columns helped to make some distinction between the *set* of even and the *set* of odd numbers. However, the movement back and forth between Milestones b and c indicates that PMSTs were not convinced that grouping the complete columns together would allow them to clearly distinguish the *set* of even numbers from the *set* of odd numbers and connect to the algebraic generalizations they had identified. Thus, although the discussion ended on the (correct) Milestone c, PMSTs’ understanding of ‘n’ as representing the *total number of complete columns* may have remained fragile. Field notes from the subsequent class, in which PMSTs began operating on even and odd numbers, also reflected this instability.



Milestone a: ‘n’ representing *one tile*
Milestone b: ‘n’ representing *one complete column*
Milestone c: ‘n’ representing the *total number of complete columns*

Figure 3: PMSTs’ transition among the three milestones

The excerpts that follow are illustrative of the struggle that PMSTs had as they collectively made sense of the different representations and transitioned from thinking arithmetically to thinking algebraically about even and odd numbers. In the first section, PMSTs work to make sense of the variable ‘n’ in the algebraic generalizations and to find commonality within the *set* of even numbers and within the *set* of odd numbers – thus making the transition toward thinking more algebraically, and moving away from Milestone a. In the second section, PMSTs focus on making explicit connections between the features of Tilo’s model and the specific components of the algebraic generalizations and move back and forth between Milestones b and c. All names used in the excerpts that follow are pseudonyms.

Finding Commonality Within the Sets of Even and Odd Numbers

Prior to introducing Tilo’s model, the instructor asked PMSTs to describe the set of even numbers. PMSTs easily identified commonalities across all numbers in this set. For example, they described even numbers as being *divisible by 2, having no remainder after dividing by 2, being a multiple of 2, being an integer, and including 0*. Despite these ways of describing the set of even numbers, PMSTs struggled to make sense of Tilo’s model (shown in Figure 1) when the instructor introduced it. In particular, PMSTs struggled to make connections between individual representations of even and odd numbers in Tilo’s model and the algebraic generalizations of even and odd numbers that they identified (Even=2n and Odd=2n+1, where n is a whole number). The source of difficulty was in making sense of the meaning of the variable ‘n’ in both the algebraic and geometric representations of even and odd numbers. This difficulty is illustrated in the following excerpt where the PMSTs grapple with whether ‘n’ represents *one tile*, *one complete column*, or *the total number of complete columns* in Tilo’s model:

Uberto: Every, every n is a column.
Olive: Yeah, every n is a column.
Uberto: [Tilo’s] saying there [are] no sets- there’s no columns and then there’s one extra.
Kaila: Every two n would have to be a column.
Uberto: Yeah. Every two n is a column.
Instructor: Every two n is a column, ok. Help me see where that is here. How do you see that?
Uberto: Actually isn’t it just the n? It is just the n because, look at two. If you plug it [into] the two n equation, you have one [complete] column, and therefore two tiles.

In this excerpt, Uberto and Olive initially state that every ‘n’ is a column – suggesting that ‘n’ represents each column. This understanding of the variable is not consistent with the algebraic generalizations of the sets of even or odd numbers. Instead, even and odd numbers were being represented differently and treated *individually* rather than as belonging to a *set* of numbers with common attributes (e.g., 2=2(n), 3=2(n)+1, 4=2(2n), 5=2(2n)+1, 6=2(3n) where n=1 column). Kaila argues that every ‘2n’ would be a column – suggesting that ‘n’ represents an individual tile. Again, this understanding of the variable would result in different expressions for even and odd numbers (e.g., 2=(2n), 3=(3n), 4=(4n), 5=(5n), 6=(6n), where n=1 tile). While both of these ways of making sense of even numbers suggest that the PMSTs were thinking more arithmetically than algebraically, there seems to be a qualitative difference in Uberto and Olive’s thinking as compared to Kaila’s thinking. Whereas the expressions aligned with Kaila’s thinking showed no commonality within the sets of even or odd numbers, expressions for Uberto and Olive’s thinking suggested that the components of the algebraic expressions for even and odd numbers (i.e., ‘2’, ‘n’, ‘+1’) needed to be considered. This became more evident after Uberto responded to Kaila’s idea about the meaning of ‘n’ by drawing the PMSTs’ attention to the number of tiles in a column compared to the total number of columns. As such, Uberto was extending the PMSTs’ reasoning beyond thinking about individual even and odd numbers to beginning to find commonality within these two sets of numbers.

Explicitly Connecting the Geometric and Algebraic Models

As the PMSTs continued to reason collectively about the meaning of the variable ‘n’ in the algebraic generalizations of even and odd numbers, they frequently used the geometric representations to make further distinctions between the components of the algebraic expression. This movement back and forth between representations is reflected in Bobbie's comment:

> How about we just define n and say for two, you have two tiles on top of each other and that's a column, that's one [complete] column. So if you define n as the [total] number of [complete] columns, if you put [it] in the formula, two n, two times one, it'd give you two. So we have seven, right, to get eight, you would add another tile on top of the one that's out we would end up with one, two, three, four columns, n representing the number of [complete] columns, you do two times four, it would give you eight. So we should just have- n should just represent the [total] number of [complete] columns, and it'll give you the number of- um even number.

In this excerpt, Bobbie was thinking algebraically and making an argument for why 'n' represents the *total number of complete columns* rather than representing *one complete column*. By comparing specific even and odd numbers in the geometric representation to the algebraic generalization of even and odd numbers, she was able to determine that the '2' represents the number of tiles in a column, and that the 'n' represents the total number of complete columns. Furthermore, Bobbie identified a difference between columns that are complete (by explicitly stating, "you have two tiles on top of each other and that's a column, that's one [complete] column") and those that are not complete for an odd number (by stating, "you would have to add another tile on top of the one that's out.") As such, Bobbie's way of thinking was consistent with the algebraic generalizations of even numbers and odd numbers and allowed for even numbers to be expressed as '2n' and odd numbers to be expressed as '2n+1'. Isabel clarified the meaning of the components even further by noting:

> I think what [Bobbie and others] are trying to say is that two is a constant; there are two tiles in a column, so that doesn't change. So that the only number that changes is n, and it says how many [total complete columns]. So if you have like eleven [complete columns], it'd be two times eleven which would put you at twenty-two tiles.

Despite PMSTs' transition toward thinking about even and odd numbers algebraically (the discussion ended with Milestone c), as the class continued to make connections between the different representations, the meaning of the variable 'n' in the algebraic generalization was often revisited. The pattern of Milestones c, b, c, b, c, b, c (shown in Figure 3)—shifting back and forth between Milestones b and c—suggests that PMSTs' understanding of the meaning of 'n' in the algebraic expressions for even and odd numbers remained unstable.

Discussion

This study examined PMSTs' reasoning as they transitioned from thinking arithmetically to thinking algebraically about even and odd numbers while making connections between algebraic and geometric representations of even and odd numbers. Flexibility in connecting multiple representations is a critical aspect of mathematical understanding (e.g., Lesh, Post, & Behr, 1987; NCTM, 2000), and the results of this study suggest that this is challenging for teachers. The geometric model (Tilo's model) seemed to be a catalyst for helping the PMSTs in this study reason about the different components of the algebraic generalizations of even and odd numbers (i.e., the '2', the 'n', and the '+1') as they transitioned from thinking about *individual* even and odd numbers to thinking about the *set* of even and the *set* of odd numbers. Furthermore, although PMSTs easily generated algebraic representations of even and odd numbers—that included the variable 'n'—they had difficulty making sense of what 'n' represents when asked to *connect* the algebraic representations to the geometric one. Thus, the introduction of the geometric model revealed PMSTs' conceptions in ways that working exclusively with the algebraic model may not have.

The results of this study also suggest that the transition from thinking about *individual* numbers to thinking about *sets* of numbers is not uni-directional, but rather involves several conceptual milestones—some of which are incorrect—that teachers move back and forth between as they made sense of generalizations of even and odd numbers. It is also important to note that teachers reverted back to the incorrect conceptual milestones throughout the whole-class discussion – suggesting that their misconceptions were rather stable. Thus, the results of this study indicate that mathematics teacher educators face a serious challenge: how to support prospective or practicing middle school teachers in making sense of and connecting multiple representations of mathematical ideas. Future work will investigate how PMSTs used these different representations to add and multiply even and odd numbers and how the mathematics teacher educator who was the instructor of this course supported them in making sense of the representations.

In this paper, we describe the initial stage of reliability and validity testing for the Mathematics Education of English Learners Scale (MEELS), which is designed to measure preservice teachers' beliefs about the mathematics education of English learners. To address the content validity, we consulted with experts within the field of mathematics education to assess the relevance and representation of specific items. We used Principal Component Factor Analysis to determine construct validity. Finally, we tested reliability of the factors using Cronbach's coefficient alpha. After sharing the findings from these analyses, we describe the next stages in the development of MEELS.

Keywords: Beliefs; Measurement; Equity and Diversity; Teacher Education–Preservice

The growing population of English Learners (ELs) in schools across the country has made it necessary to prepare all teachers, including mathematics teachers, to work with EL students in their classrooms (Costa, McPhail, Smith, & Brisk, 2005; Lucas & Grinberg, 2008). Given that beliefs are "lenses that affect one's view of some aspect of the world or as dispositions toward action" (Philip, 2007, p. 259), it is important for educators to know what preservice teachers (PSTs) believe about the mathematics education of ELs, especially when they assume a deficit perspective. As a first step in challenging these beliefs, the goal of our study is to develop a valid and reliable instrument, called the Mathematics Education of English Learners Scale (MEELS), which will measure the beliefs that PSTs have about issues related to the teaching and learning of mathematics to ELs. In this paper, we will describe the first stage analysis for validity and reliability that was conducted after 334 PSTs responded to MEELS.

Literature Review

A review of the literature revealed that there are a number of surveys in the areas of PSTs' or teachers' beliefs about diversity and multiculturalism, language attitudes, and inclusion of ELs. One such survey is the Cultural Diversity Awareness Inventory (CDAI; Henry, 1986), which consisted of 28 statements. The CDAI was developed to measure general cultural awareness that educators had about young children from culturally diverse backgrounds. The inventory was based on the understanding of "culture" that included five areas: (1) values and beliefs, (2) communication, (3) social relationships, (4) food and diet, and (5) dress. Despite the lack of information regarding the validity and reliability of the CDAI, it has been used by other researchers (e.g., Davis & Turner, 1993; Larke, 1990) to assess the cultural sensitivity of elementary PSTs.

Pohan and Aguilar (2001) designed two measures to elicit the personal and professional beliefs that educators had about diversity. In their survey, they extend traditional definitions of diversity of race and/or ethnicity to include other marginalized groups based on social class, gender, religion and sexual orientation. The researchers conjectured that there were some beliefs in the personal and professional spheres that could be in conflict. For example, an educator might believe that bilingualism was good in the current diverse society; however, they may not approve of public money being spent in maintaining bilingual programs. The reliability and validity of both scales were extensively tested with samples that included PSTs, graduate students, and practicing educators from rural and urban schools.

Byrnes and Kiger (1994) designed the Language Attitudes to Teaching Scale (LATS) that contained 13 items about the beliefs that teachers had about EL students. A factor analysis yielded 3 factors tied to the politics of language, intolerance of EL students and language support. The researchers carried out face and construct validity, and the subscale reliabilities, using Cronbach's alpha, ranged from 0.60 to 0.72.

Discussion about best practices for EL students in the content area have consistently advocated for inclusion of these students in mainstream classes along with the use of Sheltered Instruction practices (Echevarria, Vogt, & Short, 2008). This aspect has motivated researchers to examine the beliefs that teachers have towards the inclusion of ELs in their content classes. For example, Reeves (2006) investigated the beliefs that secondary teachers had about having EL students in their classroom through a self-designed survey. Walker, Shafer, and Iliams (2004) used a survey to assess mainstream teachers attitudes towards EL students and how these attitudes varied across schools where there were few ELs, a rapidly growing EL population, and ones where ELs were predominant. In both studies, only the face validity of the instrument was discussed.

All of the surveys reviewed, only a sample of which were discussed in this section, measured teachers' and/or PSTs' beliefs about cultural diversity, their attitudes towards linguistic diversity, and inclusion of EL students in their classroom. The instruments were broad in scope and encompassed teachers and PSTs in all subject areas. Reliability and validity were done only in two instruments (Byrnes & Kiger, 1994; Pohan & Aguilar, 2001). In all other cases, researchers developed surveys to examine the impact of an intervention, but validity and reliability of the instruments were either not discussed or the researchers only used participants' feedback to determine the clarity of the questions (face validity). Absent from these descriptions were other forms of validity like content, construct and criterion, and measures of reliability such as internal consistency reliability and test-retest reliability. Thus we need an instrument that will capture the different dimensions of the construct, have items that are consistent on each dimension, and that remains stable over time.

Beyond the dearth of statistically demonstrated valid and reliable surveys, we also did not find a survey that measured discipline specific beliefs with respect to the mathematics education of ELs. According to Cooney Shealy, and Arvold (1998) and Philip (2007), beliefs are tied to the context and this could be very different for different situations. In mathematics, as compared to other subjects, it is possible that the PSTs may assume that language plays a minimal role in the teaching and learning of mathematics, despite evidence to the contrary (e.g., Moschkovich, 2010). Teachers who assume that language plays a minimal role in the teaching and learning of mathematics then may be less likely to adjust their teaching in order to accommodate ELs. In fact misconceptions about language lead to a high proportion of ELs being labeled with a learning disability when they can converse in English, but struggle with the content, which involves academic English (Gandára & Contreras, 2009). With these considerations, the goal of our study was to design a valid and reliable measure that examined the beliefs that PSTs had about the mathematics education of ELs.

Theoretical Perspective

The overall framing of MEELS and the items in particular were guided by non-deficit views about ELs and their communities (Civil, 2007; Moschkovich, 2010). According to Moschkovich, "deficit models stem from assumptions about learners and their communities based on race, ethnicity, SES (socio-economic status), and other characteristics assumed to be related in simple, and typically negative ways to cognition and learning in general" (p. 11). Non-deficit models, on the other hand, assume that the EL students are part of different Discourse communities and have valuable resources that are assets which teachers can use to develop the students' knowledge (Civil, 2007; Moschkovich, 2010). For example, mathematical algorithms that students may have studied in other countries could be welcomed by the teacher, viewed as a resource, and shared with other students in the class. Further, the communities and parents of the ELs are also seen to have valuable knowledge that could be utilized in the classroom (Civil, 2007). Thus in framing and later scoring the items we assumed, for example, that bilingualism was an asset rather than a hindrance to EL students and that parents from all communities fundamentally cared about the intellectual development of their children, even if this was not visible to the teacher or did not adhere to a preconception of what that caring should look like (e.g., attending parent-teacher conference, volunteering in the classroom, etc.). Overall, the items for MEELS were drawn from recommendations from research, interactions with other mathematics educators, and other diversity surveys [refer to

McLeman & Fernandes (under review) for a review of the literature that guided the item development of MEELS].

Methods

Sample

MEELS was administered to 334 PSTs, about 75% of whom were located at one university in the southeast of the United States. Of the 330 responses we analyzed (4 were determined to be outliers), about 86.1% were female and about 84.8% self-reported their race as "White, not of Hispanic origin." Furthermore, a little more than 70% of the participants wanted to teach grades K–5, while about the same percentage of participants had no prior teaching experience. Close to 72% had been exposed to issues involving ELs in prior coursework and about 77% had been involved in some type of field experience during their teacher preparation program. Finally, about 92% of the participants self-reported that they were not fluent in a language other than English, though about 85% did report that they had some experience in learning a second language.

Instrument

The first iteration of MEELS consisted of two sections: the first was comprised of 8 demographic items while the second had 26 items related to the teaching and learning of mathematics to ELs. Each item was measured on a 5-point Likert-type scale: Strongly Disagree (1), Disagree (2), Undecided (3), Agree (4), and Strongly Agree (5). At the end of the survey, participants were asked to answer three open-ended questions to ascertain the readability and clarity of the instrument. Content validity was determined by sending an initial set of items to 10 mathematics education experts in the area of ELs. Based on their feedback, we modified some of the items before the first pilot of MEELS. For example, the language in several items was modified and additional items were included.

MEELS was administered online through SurveyShare (http://www.surveyshare.com) and thereafter the data were downloaded to SPSS 17 for analysis. Using our theoretical perspective as a basis, we reverse scored certain items that would reflect deficit beliefs based on our reading of the literature. For example, the item "Some EL's home culture negatively impacts their math learning" was reverse coded with a PST strongly agreeing scoring a 1 and strongly disagreeing scoring a 5. Since beliefs can only be inferred, it was conjectured that a PST who believed that an EL's home culture could negatively impact their mathematical learning would be less open to seeing certain ELs' home culture as resource in the classroom. In total, 14 of the 26 items on the survey were reverse coded; these are shown with an r in Table 1. Note that there are 23 items in Table 1 as three items were dropped in later analysis. One of the dropped items was reverse coded.

Statistical Analyses

Our main goal was to establish construct validity of MEELS through factor analysis and examine reliability of the resulting subscales associated with the factors (also referred to as internal consistency). We first scanned the data for outliers using Mahalanobis distance. Next, we examined the coefficient matrix, which summarizes the interrelations between the set of items. We performed Bartlett's test of sphericity to ensure that the correlation matrix was not an identity matrix, which would indicate that there was no relationship between the items. We examined the Kaiser-Meyer-Olkin (KMO) statistic that indicates if the sample size was adequate relative to the 26 items in the instrument. In addition to the overall KMO, we also examined the anti-image correlation matrix for a Measure of Sampling Adequacy (MSA) for the individual items. Pett, Lackey, and Sullivan (2003) recommended that the individual MSA (numbers along the diagonal of the anti-image correlation matrix) should be greater than 0.60 to ensure the presence of underlying factors.

After this preliminary analysis, we proceeded to identify clusters of inter-correlated items, usually referred to as factors, which would indicate the various dimensions related to our construct of the mathematics education of ELs. It is important to note that in developing the items we had some conjectures based on the literature about what these dimensions might be. We used exploratory factor analysis as opposed to confirmatory factor analysis because we were uncertain about the dimensions, and in the process also wanted to ensure construct validity. There are different factor extraction methods in SPSS 17, though Principal Component Analysis (PCA) and Principal Axis Factoring (PAF) are most widely used (Pett, Lackey, & Sullivan, 2003). In trying to determine the best method for our purposes, we relied on the advice of Pett, Lackey, and Sullivan to start with a preliminary solution using PCA, refine the solution by examining the items that load on the various factors (where *load* refers to the correlation between an item and factor), and then develop a preliminary solution. This solution is then compared to the PAF solution on the same matrix and the final solution is "one that is the best fit and that makes the most intuitive sense" (Pett, Lackey, & Sullivan, 2003, p. 115). Once we obtained our factors we worked out the internal consistency of the items that made up a particular factor using Cronbach's coefficient alphas.

Results

The Mahalanobis distance for multivariate data ($p < .001$) (Stevens, 1992; Tabachnick & Fidell, 1996) revealed four outliers that were dropped from the subsequent analysis. Thus the total number of responses examined was 330. Bartlett's test of sphericity was significant (chi-square = 1951.35, df = 253, $p < 0.001$) indicating that there were relationships between the items. The Kaiser-Meyer-Olkin of 0.854 was greater than 0.7 suggesting a sufficient sample size (Kaiser, 1974). The diagonal of the anti-image correlation matrix yielded the Measures of Sampling Adequacy (MSA) which ranged from 0.54 to 0.91, with most values greater than 0.7 and the off-diagonal absolute values were small, thus suggesting that the matrix was factorable (Pett, Lackey, & Sullivan, 2003).

Factor Analysis

Initial PCA suggested 7 factors that satisfied Kaiser's rule (Kaiser, 1974) with eigenvalues greater than 1. Note that our goal in factor analysis was to reduce the number of variables (items in the instrument) into a smaller number of factors that would account for as much of the variation between the individual variables. Towards this end, we chose factors with the largest eigenvalues that would explain more of the variance than an individual item. In exploratory factor analysis, once the initial solution is obtained, variables generally tend to load highly on a factor and have small loadings on others. By rotating the factor axes, the loading of a variable is increased on one of the extracted factors and is minimized on the other factors (also called a simple structure). Thus rotation increases the interpretability of the factor as a group of items load highly on it. In trying to determine the number of factors to retain after rotation, Pett, Lackey, and Sullivan (2003) suggested retaining the fewest number of factors that explained at least 50% of the variance and that the factors make intuitive sense in the given context. With this in mind, we sought to have at least 3 items load on a factor with a loading greater than 0.3, all the factors account for at least 50% of the variance, and that the resulting item-factor correlation matrix achieve simple structure. A closer examination of the rotated matrix with loadings that were more than 0.30, suggested factor 6 comprised of items 18, 23, and 33, and items 23 and 29 loaded on factor 7. Items 33 and 29 loaded only on factors 6 and 7, respectively, while items 18 and 23 also loaded on factors 4 and 5. Since items 29 and 33 only loaded on 6 and 7, we decided to rerun the analysis without these items. A subsequent PCA with Varimax rotation yielded 6 factors with eigenvalues more than 1 and several items that loaded on multiple factors. To make it easier for interpretation, we decided to look at items that loaded 0.40 or more on a factor. Still there were 5 items that loaded on multiple factors and after dropping these items one at a time in further analyses, a decision was made to eliminate item 26. A rerun of the PCA with Varimax rotation, in this case, extracted 5 factors with eigenvalues more than 1. The factors accounted for about 52% of the variance in these items. Table 1 displays the 23 items with loadings greater than 0.4 that loaded on 5 factors in an almost simple structure (three items loaded on multiple factors). After we obtained this initial solution, we followed Pett, Lackey, and Sullivan's (2003) suggestion and ran the PAF with Varimax rotation (with items 26, 29, and 33 dropped). This yielded 4 items that did not load (>0.40) on any of the 5 factors; one of the factors had only 2 items, and another factor that was difficult to interpret. Thus we retained the 5 factor solution obtained with PCA and Varimax rotation as it was the one that most aligned with our extraction criteria (modifying the loadings from >0.30 to >0.40). For the three items that loaded on multiple factors, we decided to associate them with the factor for which a higher loading was demonstrated. Note that a consideration of loadings more than 0.45 would have yielded a simple structure for the item-factor loading matrix shown in Table 1. Note that since we approximated simple structure with the simpler orthogonal rotation (Varimax), we avoided using oblique rotation in the above analysis.

Table 1: Factor Loadings

	Items	**T**	**LSC**	**F**	**LM**	**C**
17	Open to teaching ELs math.	0.52				
22	Open to integrating EL's background in math.	0.62				
27	Adjust the language on math problems.	0.65				
28	Focus on the language skills.	0.67				
30	Accept EL's non-verbal communication.	0.70				
31	Accept alternative math algorithms.	0.55				
36	Open to using alternative math assessments.	0.57		(0.41)		
11	*Fluency* in more than one language.		0.65			
12r	English as only language of instruction		0.75			
13r	More important for beginning ELs to learn English.		0.45			
14	Open to use of native language.	(0.44)	0.56			
15r	Native language use hampers learning English.		0.50			
16	State math tests in different languages.		0.50			
18r	Rich math discussions.			0.61		
32r	Teach ELs and non-ELs in the same way.			0.62		
34r	Accommodations are unfair.			0.53		
35r	Same standards for ELs and non-ELs.			0.79		
19r	Math ideal for transition of beginning ELs.				0.71	
20r	Conversational language.			(0.40)	0.64	
21r	Math is not language intensive.				0.77	
23r	EL's home culture.					0.57
24r	Parents.					0.72
25r	Some ethnicities better at math.					0.71

T=Teaching, LSC=Language in school context, F=Fairness, LM=Language and Mathematics, C=Culture.

Based on the items that loaded on the 5 factors, and paying particular attention to the items that displayed higher loadings, we labeled the factors—Beliefs about teaching (T; 7 items), Beliefs about language in the school context (LSC; 6 items), Beliefs about fairness (F; 4 items), Beliefs about the interconnection of language and mathematics (LM; 3 items) and Beliefs about culture (C; 3 items). The alpha coefficients are given in Table 2.

Table 2: Cronbach's Coefficient Alphas

	Alpha
Teaching	.79
Language in School Context	.73
Fairness	.66
Language and Mathematics	.59
Culture	.48

Discussion

The development of a survey and establishing validity and reliability is an evolving process. In this first iteration, we determined content and construct validity along with internal consistency reliability. For the content validity we consulted with experts within the field of mathematics education to assess the relevance and representation of the items we included in our instrument. We used Principal Component Factor Analysis (PCA) along with Varimax rotation to determine the construct validity of the underlying factors that impact PSTs' beliefs about the mathematics education of ELs. To determine reliability of the factor subscales, we used Cronbach's coefficient alpha. These analyses point to the next steps in the refinement of MEELS.

Next Steps

Cronbach's coefficient alphas for the two subscales LM and C are lower than 0.6, which is poor (Burns & Burns, 2008) and will need to be addressed in the next phase of refinement and testing of MEELS. The presence of only 3 items in each of these subscales could be a possible reason for the low alphas. Thus one course of action would be to increase the number of items in this category. However the inclusion of additional items will need to take into the consideration the connection that issues of culture and education have to outside influences such as political ideology. Furthermore, how a participant interprets particular words in the items is of importance to consider. Therefore, we intend to interview a group of PSTs to ascertain their interpretations of particular items. By doing so, we will be able to refine the wording of certain items that were dropped and/or add additional items. In either case, the goal will be to load the items on to the specific factors we have (and not to generate new factors).

The interviews with the PSTs will also help us reframe items 36, 14 and 20 that loaded on multiple factors. In each case, deleting the item from the factor to which it was assigned (based on the higher load) would reduce the alpha. Therefore, a decision was made to retain each item and refine the wording so that it was more likely to load on the assigned factor. Further, by removing item 20 the LM factor would consist of only two items and not meet our criteria for retaining factors. Given the goal of MEELS is to examine PSTs' beliefs about the mathematics education of ELs, having a subscale related to the beliefs about the interconnection of language and mathematics is important.

In the next iteration of MEELS, once the items are refined, we intend to also carry out Confirmatory Factor Analysis (CFA) and test-retest reliability. Confirmatory Factor Analysis (CFA) allows us to test the five factors that we have. The test-retest reliability ensures that the instrument has temporal stability. Specifically we will administer MEELS to a group of PSTs at differing points in the semester (but no longer than a few weeks of each other) to determine if there is a high correlation between their scores at each point. The purpose of administering MEELS at multiple points within a short period of time is to speak to stability in the given constructs.

Finally, our long-term goal is to establish predictive validity of the MEELS. This would require tracking the PSTs into their teaching careers to establish a relationship between the PSTs performance on the MEELS and their teaching of ELs in their mathematics classes. The latter would require the development of observational instruments that could measure the performance of the teacher in implementing best practices for teaching ELs. Currently, we are not aware of such an instrument.

Implications

The Mathematics Education of English Learners Scale (MEELS) is a powerful and necessary instrument for teacher preparation programs. At the end of our validation and reliability process, we will have developed a measure that can be used to ascertain the beliefs of PSTs regarding the mathematics education of ELs on a large scale, an undertaking that we have not come across in our review of the literature. Additionally, among other things, MEELS can be shared with individuals in the field so that the effectiveness of particular interventions with ELs can be measured.

While still in the early stages of reliability and validity testing for our instrument, we have generated some important implications for the field of mathematics education, in general, and teacher education, specifically. Though the content validity of MEELS was determined and only a few (about 4%) participants reported any vague or confusing questions, our initial analysis revealed that not all of the items we developed mapped onto our initial dimensions. In other words, some of the items in MEELS did not describe the beliefs with which the wording appeared. Thus the use of surveys that are not shown to be statistically validated and reliable may be problematic, as they may not always be measuring what they appear to be on the surface.

The goal of this study is to develop the professional noticing abilities of preservice elementary teachers in the context of the Stages of Early Arithmetic Learning. In their mathematics methods course, the preservice elementary teachers participated in a researcher-developed multi-session module that progressively nests the three interrelated components of professional noticing—attending, interpreting, and deciding. A pre- and post-assessment was administered to measure their change in the three components of professional noticing. The preservice elementary teachers demonstrated significant growth in all three components.

Introduction and Literature

This study examines the extent to which an innovative learning experience focused on the professional noticing of children's early numeracy develops Preservice Elementary Teachers' (PSETs) capacity to attend to, interpret, and make effective instructional decisions related to the mathematical thinking of children. The study relies upon a module, *Noticing Numeracy Now (N^3)*, developed by the researchers and based on literature in the areas of professional noticing (Jacobs, Lamb, & Philipp, 2010) and the Stages of Early Arithmetic Learning (SEAL) (Steffe, von Glasersfeld, Richards, & Cobb, 1983; Steffe, Cobb, & von Glasersfeld, 1988; Steffe, 1992). Specifically, we intend to investigate the following research question: To what extent can teacher educators facilitate the development of PSETs' capacity to professionally notice children's mathematical thinking?

Professional Noticing

Professional noticing is an ability to recognize and act on key indicators significant to one's profession. The literature exploring the impact of professional noticing in mathematics teaching grew significantly in recent years. Sherin and van Es (2009) examined teacher video clubs as a tool for analyzing the club participants' classrooms and found that using focused noticing as a lens for learning about teaching was productive beyond the video club, impacting the teachers' instructional practices. Star and Strickland (2008) demonstrated improvements in preservice teachers' ability to attend to the salient features of a secondary mathematics classroom. Numerous professional development modules incorporated the use of video to focus observers' attention on children's mathematical thinking (Carpenter, Fennema, Franke, Levi, & Empson, 1999; Schifter, Bastable, & Russell, 2000; Seago, Mumme, & Branca, 2004). Sherin, Jacobs, and Philipp's recently edited volume (2011) contributed to the compounding evidence of both the need and the value of professional noticing to effective mathematics teaching.

Recent evidence shows that teachers' attention to children's mathematical thinking can positively affect student learning (Carpenter et al, 1999; Kersting et al, 2010); however, such attention is just one component skill of *professional noticing* of children's mathematical thinking as defined by Jacobs, Lamb, and Philipp (2010). They conceptualized professional noticing as "a set of three interrelated skills: *attending* to children's strategies, *interpreting* children's understandings, and *deciding* how to respond on the basis of children's understandings" (p. 172). Their research examined the professional noticing of preservice teachers as well as three groups of in-service teachers all having 12–14 years of teaching experience but varying degrees of professional development. The results indicate that teaching experience alone does not develop all three components of professional noticing. Teachers with 12–14 years experience, but no sustained professional development, aligned more closely with preservice teachers on this construct, especially on the deciding component. Star and Strickland (2008) further contend that developing the skill of professional noticing must be an early focus of teacher preparation programs given the importance of skillful, nuanced observation in learning to teach.

Practice-based Teacher Preparation

Preparing for the profession of teaching requires opportunities to practice one's teaching. Current trends in teacher preparation focus on practice-based teacher preparation but with varying degrees of guidance on the particulars of what should be practiced and where practice should take place. Grossman, Compton, Igra, Ronfeldt, Shahan, and Williamson (2009) found that teacher preparation practices focused heavily on the preactive aspects of teaching, such as lesson and unit planning, and less on interactive or reflective aspects. The interactive and reflective aspects include the nearly invisible decisions based on professional noticing that must be made 'in the moment' of teaching. We expect novice teachers to observe the professional noticing in real-time classrooms, but without explicit guidance, novice teachers may not observe it. Videos of teaching/learning exchanges are representations of practice, one of three pedagogies of practice proposed by Grossman and her colleagues. Such representations can potentially provide powerful settings for learning the practice of teaching and in doing so can provide a scaffold for subsequent practice in actual classroom-based contexts.

Stages of Early Arithmetic Learning

There is consensus that the term "numeracy" is grounded in an understanding of fundamental and foundational aspects of number and operations (Mulligan, Bobis, & Francis, 1999; National Council of Teachers of Mathematics, 2006) and is a significant content strand for PSET exploration. Steffe and his colleagues have provided a useful model for structuring the mathematics of the N^3 module. Born of longitudinal teaching experiments, the Stages of Early Arithmetic Learning (SEAL) hypothesize a progression for the development of quantitative understanding (Steffe, von Glasersfeld, Richards, & Cobb, 1983; Steffe, Cobb, & von Glasersfeld, 1988; Steffe, 1992; Wright, Martland, & Stafford, 2006). This progression includes the following levels: Emergent, Perceptual, Figurative, Initial Number Sequence, Intermediate Number Sequence, and Facile. Given the supporting methodology, SEAL is exemplary of "learning trajectories built upon natural developmental progressions identified in empirically based models of children's thinking and learning" (Clements, 2007, p. 45).

Methodology

Participants

The participants in this study were preservice elementary teachers (PSETs) enrolled in one of three participating universities; two are regional universities and one is a "Research Very High" university (Carnegie Foundation for the Advancement of Teaching). All universities are public institutions and the participants (n = 94) represent a cross-section of the general population of a state in the east-central United States. Participants were enrolled in elementary mathematics methods courses at their respective universities and the module was a component of this course.

Module Description

The module consists of multiple in-class sessions during which the three components of professional noticing are developed in the context of the Stages of Early Arithmetic Learning. The three components of professional noticing, attending, interpreting, and deciding, are nested through the module (Boerst, Sleep, Ball, & Bass, 2011). The first two sessions focus on the development of attending only. Subsequent sessions further develop attending while progressively layering in interpreting and deciding. Integrated with the nested development of professional noticing, the Stages of Early Arithmetic Learning gradually unfold through video clip representations of practice. The researchers of the N^3 project intentionally chose video around early number sense for two reasons: (1) video is a representation of practice that provides opportunities to explicitly attend to and discuss salient features of children's mathematical thinking that can go unnoticed by novices in a real-time classroom setting, and (2) early number sense is an area of mathematics with which PSETs are generally comfortable so the mathematics itself would not be a barrier to the examination of children's mathematical thinking.

The video clips are diagnostic interviews with children conducted by teacher educators or a former PSET. A significant number of video clips are from one author's dissertation research of quantitative mental imagery (Thomas, 2010). PSETs are asked to respond to the videos in various ways, including writing about what they attend to in the video and engaging in discussion with a partner, with a small group, and in whole class discussions led by the instructor. At the beginning of the module, the discussion prompts are more general, such as asking them to observe the physical actions and verbal exchanges taking place. As the module continues, the PSETs learn to focus on the salient features of students' mathematical actions and words. In addition to these salient features, PSETs' attention is drawn to teacher moves and the mathematics of the tasks. As the sessions progress, PSETs learn to interpret the salient features in terms of SEAL and finally they learn to make decisions about next steps, either diagnostic or instructional. Between the sessions, the PSETs have homework including articles to read and videos to watch. The culminating experience is an assignment that requires the PSETs to conduct at least one diagnostic interview with a child. The interview assignment varies across the universities. Some are assigned immediately following the module, and others are assigned much later in the semester, dependent upon each university's field placement schedules.

Professional Noticing Measures

A pre- and post-assessment designed to measure a PSET's ability to apply professional noticing to a video clip representation of practice was developed. The pre-assessment was administered within a week of the start of the semester at all participating institutions. The professional noticing measure consists of a brief video clip (25 seconds) in which the interviewer poses a partially screened task that goes beyond finger range. The task is a comparison task, where the difference between two sets is unknown (Carpenter et al, 1999). After viewing the video twice, PSETs were asked to respond to three prompts, each related to one of the three aspects of professional noticing—attending, interpreting, and deciding. The three prompts, drawn from the work of Jacobs, Lamb, and Philipp (2010) are: (1) Please describe in detail what *you think* this child did in response to this problem, (2) Please explain what you learned about this child's understanding of mathematics, and (3) Pretend that you are the teacher of this child. What problems or questions might you pose next? Provide a rationale for your answer. In subsequent semesters, the italicized words were removed from the prompt to emphasize addressing the factual evidence of the video clip, not assumptions. The post-assessment task and protocol for delivery was identical to the pre-assessment. Administration of the post-assessment occurred within the last two weeks of the semester.

Construction of Noticing Benchmarks

The research team reviewed the professional noticing video segment and identified key response features for the attending prompt. We examined PSET attending responses from a single institution to identify emerging themes (Glaser & Strauss, 1967). Themes that emerged from this analysis included:

- Identifying key, salient activity (i.e., " . . . the child counted the bears, and then counted up to the amount of shells on his fingers")
- Identifying additional activity (i.e., " . . . he then looked to see how many fingers he had up")
- Operational presumptions (i.e., ". . . he subtracted 11-7")

- Purporting evidence that did not occur in the segment (i.e., " . . . the child counted back from 11 to 7")
- Cognitive interpretations (i.e., ". . . the child lacks a sense of cardinality")

We created the themes based on the emerging patterns in order to co-construct a set of initial common benchmarks. The identification of emergent themes played a significant role during this initial drafting process as the characteristics of PSET attending responses coupled with researcher-identified key features suggested four distinct response types (elaborate, salient, limited, subordinate), ranging from a score of 4 to a score of 1. We scored our calibration data using these initial benchmarks. We replicated this process for the construction of the interpreting benchmarks and the deciding benchmarks. It is important to note that the coupling of emergent themes with researcher-identified key features resulted in three response categories, for the interpreting and deciding benchmarks, one fewer than the four natural levels that resulted for the attending benchmarks.

Scoring and Statistical Tests

Once the scoring benchmarks for each of the professional noticing questions were established, the research team scored all data. Each researcher scored one set (grouped by university) of data and a second researcher scored it again. Scores were compared and any discrepancies were discussed between the two researchers for a consensus. A third researcher was used in any case where a consensus was not reached.

An example of a time when a third researcher was needed consisted of a response in the attending question of the survey that stated the following: "I've learned that children, especially at younger ages, use their fingers a lot to help them count. It takes children a while to think mathematically in their head and not rely on objects to count." The first researcher felt this response deemed level 2 because the PSET recognized the progression of children's thinking from more concrete to more mental, however the second researcher felt it was too generic for this question and it should score a level 0 score. The second researcher felt if the response was specifically directed toward the student in the video, instead of children in general, then they would have agreed with the first researcher's score. When the third researcher scored this question, they also felt it was too generic and a score of 0 was given for this response.

Only participants with six scores consisting of the pre-assessment and post-assessment scores for each of the three components of professional noticing at the conclusion of the scoring process remained in the data set. Any participant who did not have six was removed, resulting in $n = 94$. *T*-test analyses were conducted to determine if significant changes occurred between the pre-assessment and post-assessment scores. This information was determined for the entire group as well as between the individual universities.

Results and Discussion

A one-way ANOVA was conducted to determine if there were overall statistically significant differences between the pre- and post- total scores for the professional noticing measure. Additionally, pre- and post-scores on each of the three individual professional noticing questions were tested for significance using a one-way ANOVA. The descriptive statistics, stratified by university as well as totals, are reported in Table 1 below. Also, Table 2 below shows the average gain in score from pre- to post-assessment, stratified by university as well as total participants.

Table 1: Descriptive Statistics of Professional Noticing Measures by University

			Attending		Interpreting		Deciding	
		N	*M*	*SD*	*M*	*SD*	*M*	*SD*
University A	Pre-Test	37	2.14	.79	1.59	.797	1.54	.61
	Post-Test	37	2.43	.87	2.05	.84	2.22	.79
University B	Pre-Test	23	2.39	.99	1.82	.89	2.04	.56
	Post-Test	23	3.09	1.04	2.43	.73	2.70	.56
University C	Pre-Test	34	2.38	1.10	1.76	.78	1.97	.67
	Post-Test	34	3.00	1.10	2.15	.89	2.47	.75
All Participants	Pre-Test	94	2.29	.96	1.71	.81	1.82	.66
	Post-Test	94	2.80	1.03	2.18	.84	2.43	.74

Table 2: Average Gains of Professional Noticing Measures by University

	Average Change			
	Attending	*Interpreting*	*Deciding*	*Total*
University A	.29	.46	.68	1.43
University B	.70	.61	.66	1.97
University C	.62	.39	.50	1.51
All Participants	.51	.47	.61	1.59

The means show growth on all three professional noticing measures between the pre-assessment and post-assessment measures at all universities. The increase was found to be significant ($F = 63.169$, $p < .001$) following tests to determine whether there is a statistically significant difference between the total pre- and post- scores of professional noticing. Interaction between the total scores and each university was not found to be significant ($F = .493$, $p = .612$). This is a positive result in that each university in the study is showing gains consistent with other universities.

A one-way ANOVA was conducted for each of the three questions to determine whether statistically significant gains were found for each component of professional noticing (attending, interpreting, deciding). The results of the ANOVA are found in Table 3 below. The smaller *F*-value found for the attending component can be attributed to the larger scale for that question (4-point scale) when compared to the interpreting and deciding questions (3-point scale).

Table 3: Results of ANOVA Comparing Pre- and Post-Assessments of All Universities

	Scale	*N*	*F*	*p*
Attending	1-4	94	61.43	< .001
Interpreting	1-3	94	1075.92	< .001
Deciding	1-3	94	1014.84	< .001

The interpreting component demonstrated the smallest change in growth overall ($\Delta = .47$), while the deciding component found the largest change in growth ($\Delta = .61$). Although significance was found between the pre- and post-scores for interpreting, this was the most difficult benchmark to construct due to the diversity of the responses, so the researchers are optimistic that a suitable benchmark has been created to adequately measure the PSETs interpreting skills. PSETs reported that the five-session module was repetitive in instruction for attending and interpreting and did not include enough instruction on the deciding component. They believed they needed further instructions on how to determine the next steps in mathematical questioning and instructional tasks to advance students into a higher SEAL stage. The five-session module was reduced to a four-session module (to reduce length and repetitiveness) and a stronger emphasis on instructional deciding was included. Future analyses with the new module and further refinement of the scoring benchmarks could provide more accurate assessments for growth in the three areas of professional noticing.

A statistically significant difference was not found for the attending component ($F = .519$, $p = .597$) and the deciding component ($F = 2.187$, $p = .118$) when comparing the three components of professional noticing within the three universities in the study. However, a statistically significant difference was found ($p < .05$) between the universities for the interpreting component ($F = 3.962$, $p = .022$). This lack of a statistically significant difference between the universities in attending and deciding is a positive result because it informs the researchers that the PSETs in the study are equally distributed in those components. In order to examine the statistically significant difference in the interpreting component, a Tukey's post-hoc analysis was conducted. This test suggested that University A's scores were the cause of the significance when compared within the overall data. This seems realistic considering University A's scores in the interpreting component were lower than University B and C. However, an independent means t-test was conducted for each of the professional noticing components in efforts to further investigate the scores from the individual universities.

The data was stratified by university and University A had statistically significant differences at $p < .05$ between pre- and post-assessments for interpreting ($t = -2.217$, $p = .033$) and at $p < .01$ for deciding ($t = –4.104$, $p = .000$). Attending was not statistically significant ($t = –1.571$, $p = .125$). University B had statistically significant differences at $p < .05$ for attending ($t = –2.729$, $p = .012$) and interpreting ($t = –2.440$, $p = .023$), and at $p < .01$ for deciding ($t = –4.035$, $p = .001$). University 2 had similar results with statistical significance at $p < .05$ for attending ($t = –2.670$, $p = .012$) and interpreting ($t = -2.196$, $p = .035$), and significance at $p < .01$ for deciding ($t = –3.253$, $p = .003$). Despite the fact that University A was statistically significantly lower overall than Universities B and C in interpreting based on the ANOVA test, the *t*-tests still reveal significance between pre- and post-assessments in interpreting for University A. The lack of significance in the attending component for University A is not surprising either, considering the PSETs from University A demonstrated the smallest amount of growth when compared to Universities B and C.

It should be noted that in cases where students scored high on the pre-assessment, they would not be expected to show growth. For example, in the attending component, 37% of students (12 of 37) from University A scored at least a 3 on the pre-assessment indicating they attended to the most salient features of the video assessment. University B and C had similar results with 39% (9 of 23) and 38% (13 of 34), respectively on the pre-assessment. In the interpreting component, 19% (7 of 37) from University A, 30% (7 of 23) from University B, and 21% (7 of 34) from University C all scored the highest possible score on the pre-assessment. The results in the deciding component were similar with 5% (2 of 37) from University A, 17% (4 of 23) from University B, and 21% (7 of 34) from University C all scoring perfect scores in the pre-assessment for instructional deciding, thus not allowing those students to show growth in that component. The researchers see the limited upper range as an opportunity to further refine the scoring benchmarks to include additional range, allowing for the sector of PSETs who scored perfect pre-assessment scores to show growth.

Final Remarks

In summary, preliminary findings at three sites suggest the efficacy of a researcher-developed module aimed at promoting professional noticing capacities among PSETs in the area of early number and operation. The development of such capacities among aspiring teachers at multiple sites bodes well for scaled establishment of responsive teaching practices within teacher preparation programs. Towards this end, subsequent module implementation and measurement will occur in teacher preparation programs at two additional institutions (for a total of five implementation sites); moreover, two different institutions have been identified to serve as non-implementing comparison sites.

Research has repeatedly documented that teachers are underprepared to teach mathematics effectively in diverse classrooms. We believe critical aspect of learning to be an effective mathematics teacher for diverse learners is developing knowledge, dispositions, and practices that support capitalizing on children's cultural, linguistic, and community-based knowledge and experiences in mathematics instruction. This study examined beginning perceptions, beliefs, and dispositions of prospective teachers (PSTs) toward students' family, community, and culture. Results indicate that PSTs hold a range of beliefs based on how they see the resources and supports available to students in the home and community, how they compare and contrast themselves with their students and the students with each other, and how they see the nature of the relationships that can and should be formed by teachers with students and families.

Keywords: Equity and Diversity; Teacher Beliefs; Teacher Education–Preservice

Research has repeatedly documented that teachers are underprepared to teach mathematics effectively in diverse classrooms (Kitchen, 2005; Sleeter, 2001). While there is significant research related to preparing teachers to work in diverse classrooms, little of it addresses the specific challenges and resources of learning to teach *mathematics* to diverse learners (for exceptions see Aguirre, 2009; Foote, 2009; Kitchen, 2005; Moschkovich & Nelson-Barber, 2009). One component of learning to be an effective mathematics teacher for diverse learners is developing *knowledge*, *dispositions*, and *practices* that support capitalizing on children's cultural, linguistic, and community-based knowledge and experiences. Also relevant are dispositions and practices that support eliciting and incorporating this knowledge into mathematics instruction (e.g., Civil, 2007; Ladson-Billings, 1994; Leonard, 2008). Research documents that historically underrepresented groups benefit from instruction that draws upon their diverse cultural, linguistic, home, and community-based knowledge (Ladson-Billings, 1994; Lipka et al., 2005; Silver & Stein, 1996). This research has argued that teachers need to understand how children's *funds of knowledge*—the knowledge, skills, and experiences found in children's homes and communities—can support children's mathematical learning (Civil, 2002; González, Andrade, Civil, & Moll, 2001). And yet there exists a gap in lived experiences between the largely White middle-class teachers and their ever more diverse students (Howard, 1999; Wiggins & Follo, 1999) that may influence their ability to do just that.

This study is part of a larger research project entitled Teachers Empowered to Advance CHange in Mathematics (TEACH MATH). The overall goal of this project is to transform preK–8 mathematics teacher preparation so that new generations of teachers will be equipped with powerful tools and strategies to increase mathematics learning and achievement in our nation's increasingly diverse public schools. In this paper we examine the beliefs, perceptions, and dispositions that prospective teachers (PSTs) bring to the mathematics methods class. In preparing PSTs, it is important for mathematics teacher educators (MTEs) to understand the range of PSTs' beliefs, perceptions, and dispositions so that MTEs can support PSTs in valuing what students bring to school rather than looking at homes and communities from a deficit perspective. Insights from this paper may serve to shape how MTEs interact with PSTs around issues of supporting the development of effective mathematics instruction (Ball & Tyson, 2011).

In previous work (Turner et al., 2012) we presented a hypothetical trajectory for PST learning. Drawing on Mason (2008), one phase of this trajectory includes a focus on initial practices of *attention* and *awareness. Attention* refers to *what* teachers attend to, including what they notice (as well as what they fail to notice), and the depth and detail of their attention. Mason argued that a key role of teacher educators is to direct PSTs' attention to relevant practices, theories, and ideas that can guide their decisions and actions when teaching. One particular form of attending to specifics Mason refers to as *discerning details.* In cases we will discuss in this paper, PSTs are discerning details when they attend to the specifics of children's home and community contexts.

Awareness refers to understandings, insights, knowledge, and beliefs about teaching and learning mathematics. While attention refers to *what* teachers notice, awareness refers to *how* teachers interpret what they notice (Mason, 2008). Mason described the role of the teacher educator as one of educating awareness, both so teachers are more cognizant of their own knowledge and beliefs and to help teachers develop core types of awareness that support effective mathematics teaching. What PSTs attend to and how they interpret or assign meaning is influenced by the beliefs and dispositions they bring to observing and working with students.

We are attempting to support PSTs in developing a positive stance toward students and their families and communities. We hope that in accessing PSTs' notions, we can confront deficit thinking in the mathematics methods classroom so that PSTs are indeed better prepared to teach the diverse students they will meet. We nonetheless have seen (Turner et al., 2012) that PSTs' awareness is often inconsistent with a positive stance. Mason (2008) referred to such inconsistencies as *fragmented awareness*. As the findings from Turner and colleagues demonstrated, fragmented awareness was often evident in PSTs' comments about the role that families and communities play in supporting children's mathematics learning. Although PSTs spoke about families as capable of encouraging children's learning and supporting the development of mathematics skills (i.e., families as resources), at the same time, they framed certain characteristics of some families and communities as deterministic and detrimental to children's learning, particularly a lack of English proficiency and a low socioeconomic status (i.e., deficit-based view of families/communities). In this paper, we examine more specifically both early positive and deficit notions of children's families and communities. One research question for the larger project is: What is the nature of PSTs knowledge and beliefs related to integrating children's mathematical thinking and children's cultural, linguistic and community-based funds of knowledge in mathematics instruction? In this study we are focusing on PSTs' initial self-positioning by asking: What is the nature of PSTs' knowledge and beliefs with regard to children's family, culture, and community?

Methods

This study draws on interview data from 17 participants interviewed either at the beginning or the end of the semester (or in some cases at both junctures) [9 pre and post; 4 each pre or post] while they were enrolled in an elementary or middle school mathematics methods course. Participants were selected from a group of approximately 200 elementary and middle school PSTs enrolled in mathematics methods courses at six university sites that represent a diverse range of teaching contexts (i.e., urban; a mixture of urban, suburban, and rural; suburban; and borderlands). These PSTs participated both in pre- and post-course surveys. The surveys included 18 Likert-type items, six short answer responses, and between two and four instructional scenarios (pre-survey only). Follow-up interviews to the survey were conducted with 17 PSTs at three of the universities (one on the east coast, one in the western region, and one in a borderlands region in the southwest). During the interview PSTs were asked to clarify and expand on their answers to a number of the survey items. The interviews were audio-recorded and transcribed for analysis. These interviews serve as the data source for this paper.

Three pairs of researchers worked on the initial coding of data, using a set of codes that emerged from the research question. These codes included such things as PSTs themselves as teachers, students as learners, and the role of language and culture in the learning of mathematics. HyperResearcher, a coding software, was used in the coding process. Each interview was coded twice by pairs of researchers. These pairs then met to discuss discrepancies in coding until there was agreement on the coding of each interview passage. We define a passage to be a number of lines of interview text that addressed one of the ideas we were examining. Codes were then collapsed and refined, and the data were reorganized by these new categories. Different pairs of researchers began work on subsections of the data. One of these subsections included data that had been coded in the first round with codes that pertained to family, culture, and community both generally and as they pertained to the teaching and learning of mathematics. This subsection of data is the one that was analyzed for this study. These data were then coded using an open-coding scheme (Bogdan & Biklen, 2006). After an initial pass through this subset of data, codes were collapsed under three themes - all from a perspective of learning mathematics. Coding of passages with more than one of the three themes was allowed.

Results

The three themes that emerged from the data were: resources and influences of home and community, sameness versus difference, and relationships between teacher and student/parent. In the sections that follow, we discuss the results in relation to each of these themes in detail.

Resources and Influences

There were 90 passages that were coded with the resources and influences code, making this theme the most prominent of the four themes with slightly more passages being coded with this theme than with the other three combined. This theme encompassed responses that pertained to how students' backgrounds, families, and communities serve as resources or influence the teaching and learning of mathematics. The discussion of resources and influences was not always positively oriented and this collection of passages also included instances discussing a lack of resources or negative influences on students. There were two orientations that we noticed in examining these passages. In one orientation, PSTs positioned mathematics as a school activity, and in the other they discussed how teachers need to understand, value, access, and search for ways to build on the knowledge that children bring to school from their homes and communities.

Mathematics as a school activity. Within this orientation toward school mathematics, PSTs (a) indicated reasons why children may not be receiving support at home, (b) characterized the resources available in the home and/or community as those that can or should be mustered in the service of supporting the teaching of mathematics in school, or (c) discussed ways in which the school needs to take responsibility for supporting children who they characterize as not receiving support at home. About half of the passages expressed an orientation toward mathematics as a school activity.

In discussing reasons why they believe children may not be being supported at home, PSTs often in some way indicted the home environment. PSTs indicated that there may be no one at home who can help the student. Sometimes a deeper understanding of the situation was evident as some PSTs also said that this could be due to parents working multiple jobs. "If the parents are working two jobs and aren't home when the students come home [they won't be able to] reinforce that the students should really spend time doing [homework] and learning from school."

PSTs put significant emphasis on the importance of the home in mathematics learning and often explicitly named practices that SHOULD be going on in the home in order to support the learning of school mathematics, saying such things as, "Being successful in [math] depends even further on what's going on at home." "If they're not getting anything [i.e., help with homework] at home and they're just getting it at school it's going to be harder for them." PSTs also suggested that parents should take responsibility for relating activities that occur in the home or community to mathematics. "They could go to the grocery store and have their child work on math. They could have their kid sit next to them while they're doing their bills."

In discussing the importance of home support for school learning, PSTs mentioned that some homes have fewer material resources for parents to draw on, and therefore may be less able to help. "In a very poor community, then you might not have all of the availability that others from say a better socio-economic class would really have." In the following passage, the PST did not talk about deficits in the home, but rather mentioned that the help and support at home might be inconsistent with school mathematics teaching and thus contribute to underperformance.

If the student doesn't understand math most of the time they go to their parents for help. And if their

> parents are teaching them a different way than what the teachers are teaching . . . the teachers need to understand that.

One final focus within this orientation was raised only a few times and so represents the view of a minority of participants. In these passages, PSTs mentioned what schools should do in order to support students whose families are not able to provide support at home. Within these passages, although there is an inherent belief that the home is not providing support, the focus is shifted from merely recounting these failings to elaborating on what the school should do to make up for this perceived lack of support. For example, one PST said,

> Some children don't have the time they need at home with their parents to help them and what not, so in the classroom you may need to give the student more time or give them work. . . . I guess it's more taking into consideration the individual child's home environment, how to mesh what you do in the classroom with what goes on at home.

Teachers need to build on knowledge students bring from home. The second orientation within the category of resources and influences focused on the need for teachers to understand, value, access, and search for ways to build on the knowledge that children bring to school from their homes and communities. About half of the passages were coded as reflecting this more positive orientation toward families. Within these passages PSTs indicated understanding that all children have experiences at home that may be leveraged in the mathematics classroom if the teacher accesses them. PSTs said such things as, "the ideas for what your context of your problem would be based on family issues or community issues," and "I think [mathematics] is going to be more meaningful if they investigate things that are happening in their lives or their community." PSTs also indicated that it is the responsibility of the teacher to access these practices. One PST noted,

> I think teachers, let's say after they do the family conferences, could find something that all students have in common, or that the families have in common, and implement that into the curriculum. And I think they should let students kind of draw on that to solve mathematics.

PSTs mentioned specific activities that might serve this purpose. "They cook with their grandmother, and they calculate measurements and then things like that they can use that to do math problems in the classroom."

In addition, this code was used to capture the few times in which PSTs discussed how school mathematics could influence what was happening at home, suggesting that the link between home and school is bi-directional, with home practices being available for use in school and school mathematics practices being available for use at home. One PST suggested that while studying measurement, families could support children in applying measurement concepts and skills at home by engaging in a "home improvement project."

Sameness and Difference

A second theme that emerged from participants' responses is one of sameness and difference. Within this theme participants compared and/or contrasted such things as culture, race and ethnicity, home and family life and resources, communities, and mathematical skills, abilities, and performance. The comparisons/contrasts made by the PSTs were of two orientations: (a) those that made comparisons among various groups of students and their families, and (b) those that made comparisons between PSTs and the students and families about whom they were speaking. There were 50 passages that were coded with the sameness/difference code.

Comparisons among students and families. Within this orientation, PSTs compared students and/or their families and family-community circumstances in one or more of the following ways: (a) differences in support or differences in circumstances that students have at home, or (b) differences in the knowledge bases that students brought to the classroom.

In some cases the differences in home circumstances were looked on positively by the PSTs. For example, one PST noted, "It doesn't really matter whether or not the parents are educated or not, and know the information themselves. . . . They can help the student find the information they need with the resources in the community." In other cases, PSTs focused on situations where family resources were limited or family circumstances did not support family involvement in schooling. In these cases some of the PSTs saw these situations as negatively impacting success in mathematics as with the PST who said, "If they're not getting anything at home and they're just getting it at school it's going to be harder for them." Other PSTs, on the other hand, saw them as instances in which the school needed to be more involved. "I think that, where students may not get it at home, it is important for teachers to bring it in."

In most instances PSTs saw the different knowledge that students brought to the classroom as something that teachers could learn about, and should be aware of. In addition, some explicitly discussed how they might build on this knowledge in instruction. In a couple of instances PSTs discussed differences in computational or problem solving strategies that parents might employ when helping children compared to what they might be learning in school. In discussing how she would react to a student who brought to the classroom a division algorithm learned at home, one PST said she would put the example on the board and ask, "Has anybody else seen this before? And go from there. That could be your starting point."

Comparisons between PSTs and students. PSTs at times made some type of comparison between themselves and their circumstances and the circumstances of the students they worked with. One major focus was the significance of help and support for the learning of mathematics. PSTs presented the view that their families had helped them with homework and emphasized how important it was for families to be supportive in this way in order for children to be successful with mathematics learning. A small number of PSTs shared that for different reasons they had not had help with mathematics at home, suggesting by contrast that if students don't have help at home it isn't necessarily something that interferes with academic success.

Other PSTs discussed their own experiences interacting with parents or university teachers around non-school type mathematics. They suggested that these informal encounters with mathematics were likely to be available to all students. "Doing fractions and I would think a lot about cooking because I like to bake with my mom and so I can draw on my baking experience to help me with math because then I can visualize what's a fourth or what's four ounces."

Relationships

A third theme that emerged from participants' responses was how they have, intend to, and/or need to build knowledge about and/or relationships with students, their families, communities, and culture. There were 25 passages that were coded with the relationships code. There were three major orientations from which PSTs discussed these relationships: (a) specific ways in which teachers could be involved with parents or make connections to the family or community of the students, (b) relationships with students and their families/communities in terms of a general orientation that they had toward parents, and (c) challenges involved in getting to know the communities to which students belonged as well as difficulties incorporating community knowledge into mathematics teaching.

How teachers can connect with families. The most prevalent views on relationships with families and communities fell into this category, with some PSTs having more than one idea as to how to forge these connections. One idea presented by several PSTs related to drawing on home/community knowledge in instruction. Another idea discussed by others was communicating with parents in specific ways. Some of these included home visits, student interviews, email or phone communication with parents, questionnaires sent home, and family conferences where families are invited to share information with the teacher. (This stands in contrast to parent-teacher conferences where the parents come to learn from the teacher how their child is performing in the school setting.) One PST suggested that school-based events were sometimes difficult especially for parents from non-dominant groups, and mentioned that she would like to organize a fun family activity: "I would see myself planning, like, a family picnic and having all the students come with whoever they want, their parents, brothers and sisters."

A general orientation toward parents. PSTs also discussed in general terms their orientations toward families and their expectations or plans for connecting with them. These included such ideas as "keep[ing] in contact,"; "talk[ing] to parents as much as possible;" and "know[ing] our students." Some PSTs understood that there were things that they could learn from parents. One said, "I think as much communication as possible [is important], and also as much listening. Parents are going to have ideas; they're going to know their kid way better than you are." Some of these passages, however, indicated a deficit orientation toward families or a lack of faith that all families are prepared to support student success. One PST, for example, said, "[Parents] play a big role. It just depends on whether it is a positive one, or a negative one."

Challenges in developing relationships with parents. A few PSTs discussed challenges they might face or difficulties they might confront in interacting with or drawing on community resources. The lack of familiarity with and understanding of students' home and community contexts due to having grown up in a different environment or being new to the school community was one challenge that was articulated.

Discussion and Implications

PSTs bring beliefs and dispositions to the methods class that inform (a) what they attend to, and (b) the awareness they bring to the interpretation of that attending. In the above results we see PSTs struggling with multiple perspectives on students' family, culture, and community. While we see considerable positive thinking about the resources families and communities offer children, we also see considerable deficit thinking from PSTs. These negative views can be hidden and subtle—but it's important for MTEs to recognize that, as our data indicate, many PSTs hold these negative views. We see that these views are based on how PSTs are attending to and interpreting evidence they gather from working with and talking to children and cooperating teachers.

Some of the deficit thinking may be due to the fact that PSTs have a limited perspective on the role of parents. Some of it is because PSTs hold a deterministic view of parents and families, thinking that a non-English home language or a lower socio-economic status means that children necessarily lack resources in their homes and communities. MTEs need to support PSTs in broadening their perspectives to see that parents can educate their children in other ways than helping with homework. For example, instead of "feeling sorry" for the child who helps her mother pay bills because her mother doesn't read English, we can support the PST to consider that this child has an opportunity to apply mathematics in a real-world context.

At the same time, we are encouraged by the number of PSTs who saw families and communities as full of resources that the teacher could draw on in the classroom. This indicates that at least some PSTs have adopted a cultural affirmation approach to difference (Brenner, 1998). Not only did some PSTs recognize the resources present in children's lives, they also articulated how they could bring this knowledge into the classroom. These are instances in which PSTs are discerning details about children's lives outside of school when the attend to the specifics of those children's experiences (Mason, 2008).

A prevalent idea held by PSTs is that responsibility for success in mathematics rests in the home as opposed to the notion that the responsibility rests in the school. PSTs need support in seeing that they can be active agents of change, supporting students' academic growth and taking responsibility for their learning, instead of assigning that responsibility to parents. PSTs can be supported to see that drawing on resources children bring to school will assist them in this effort. Drawing on those resources involves becoming a culture broker (Gay, 2010). This involves getting to know students and their circumstances, competencies, experiences, and interests. It also involves making connections with parents and families to tap into the vast and useful knowledge they have of their child. From the Relationships findings, it seems clear that many PSTs are not only attending to the need to establish these kinds of connections, but also considering practices that might help them in meeting this need. However, the tendency of PSTs to think in terms of Sameness and Difference tends to construct children and their families in ways that limit the kinds of connections and relationships PSTs can build. Here, again, we see the fragile and often conflicting ways in which PSTs are making sense of the roles of teachers, children, families, and schools in teaching and learning mathematics.

The results of this study can shape how MTEs approach PSTs and the views they bring to the methods classroom. It is important to be aware of the views that PSTs bring to their mathematics teacher preparation and to be aware that in the early stages of this preparation, the awareness of many is fragmented (Mason, 2008) and includes deficit thinking. An encouraging note is that many PSTs do bring positive views of families and communities that provide a balance for the negative views and moreover can serve as an entry point to challenging those negative views.

A GENERAL THEORY OF INSTRUCTION TO ASSIST THE PROFESSIONAL DEVELOPMENT OF BEGINNING MATHEMATICS TEACHERS

Denise B. Forrest
Coastal Carolina University
dforrest@coastal.edu

Austin M. Hitt
Coastal Carolina University
amhitt@coastal.edu

In this paper we discuss how a general theory of instruction called Concept-Focused Instruction (CFI) can assist in the professional development of prospective teachers. CFI provides prospective teachers with a foundation and logical decision-making process for selecting, designing, and teaching mathematics. First, we provide a theoretical and practical context for having a theory of instruction. This leads into a description of the theory. The background and three core principles are provided, in particular in the context of the university methods course. The paper concludes with an overview of the findings and areas for future development.

Keywords: Teacher Education–Preservice; Teacher Beliefs; Teacher Knowledge

Introduction

Researchers in mathematics education have shown considerable interest in the professional development of prospective mathematics teachers. Ball and her colleagues (Ball, Lubiennski, & Mewborn, 2001) have contributed for over a decade to this knowledge base by contemplating the specific knowledge, skills, and dispositions that prospective mathematics teachers need to learn while they are in their university program. For example, prospective mathematics teachers need to learn how to elicit student talk; how to lead a discussion by eliciting and asking good questions; how to interpret students' thinking so they can learn to develop and support student learning. In a more general sense, Darling-Hammond and her colleagues have suggested the importance of framing the university experience more towards the sensitive nature of learning and the effects of teaching. In particular, Darling-Hammond (1998) states there is a need to prepare prospective mathematics teachers "with greater understanding of complex situations rather than seeking to control them with simplistic formulas or cookie-cutter routines" (p. 10).

According to Sowder (2007), "successful professional development programs remains the greatest challenge we educators face… our goal should be to prepare them [prospective teachers] for future learning, in part because at the university we can focus only on learning-for-practice (and not enough of that), and we know they have much more to learn *in* practice while teaching" (p. 213). Prospective teachers need opportunities to understand and use effectively and creatively fundamental mathematical content and concepts; teach content through the perspectives and methods of inquiry and problem solving; integrate education theory with actual teaching practice; and integrate mathematics teaching experiences with research on how people learn mathematics.

Hiebert, Morris, Berk, and Jansen (2007) address this challenge, of preparing the beginning teacher, by proposing a framework composed of four competencies: (a) setting learning goals for students, (b) assessing whether the goals are being achieved during the lesson, (c) specifying hypotheses for why the lesson did or did not work well, and (d) using the hypotheses to revise the lesson. They claim that teaching prospective teachers the knowledge, skills, and dispositions in each of these areas will allow the future teachers to have a deliberate, systematic path to analyzing cause-effect relationships between teaching and learning; and therefore, becoming an effective teacher over time.

The mathematics methods course typically lays the foundation for developing the knowledge, skills, and dispositions for mathematics teaching. The challenge there, as established by mathematics educators, is the prospective teachers often interpret the university-based course as disconnected to what actually happens in classroom experiences in schools. Frequently the preservice teachers expect they will learn *how* to teach mathematics but instead feel like they are presented with a menagerie of instructional theories (Mewborn, 1999, 2000). In addition, the seemingly discrete instructional techniques and approaches presented in the methods class create the impression that the mathematics methods course is theoretical and impractical. This perception is then reinforced during field experiences where classroom management issues and the cooperating teachers' views seem incompatible with information presented by the mathematics methods instructor Ebby (2000). Over three years ago, this disconnect between the methods course and the student teaching classroom experience, caused us to consider an alternative approach for the mathematics methods university course. Our alternative, related to what Heibert and colleagues describe above, was to frame the course using a theory of instruction.

According to Jerome Bruner (1966), a theory of instruction "sets forth rules concerning the most effective way of achieving knowledge or skill…a theory of instruction, in short, is concerned with how what one wishes to teach can best be learned, with improving rather than describing learning" (p. 40). Further, Jerome Bruner says a viable theory of instruction (1) identifies the experiences that are compatible with the way students learn, (2) explains the structure of the knowledge within a discipline, (3) identifies the most effective instructional sequences, and (4) addresses appropriate pacing and motivational strategies. Others have described a similar set of principles, each focusing on the application of knowledge and guidance on how to help students learn (Reigeluth, 1999). In summary, instructional theories are created as a set of principles and guidelines. They are not rigid sets of rules that must be followed at all cost but are guidelines that help the practitioner.

One could argue that every teacher employs a theory of instruction when they select, design, and teach mathematical content, albeit typically an implicit theory of instruction. If prospective teachers could begin their professional development with an explicit theory of instruction that meets the above criteria as defined by Bruner, the new teacher could leave the university experience with a means to logically select, design, and teach mathematics. As Bruner (1966) states, the viable theory of instruction must identify with the experiences that are compatible with the way students learn mathematics, explains the structure of mathematical knowledge, identifies an effective instructional sequence, and addresses appropriate pacing and motivational strategies. If prospective teachers experience this during their professional development at the university, would they be more likely to connect their university coursework experiences with the public classroom?

In this paper, we wish to share the evolution of a general theory of instruction that was developed for prospective mathematics teachers. The theory of instruction, called Concept-Focused Instruction (CFI), has been used the last three years in the university mathematics methods course. Each year, the theory and how it is being implemented in the methods course has been refined. Preliminary findings indicate the prospective teachers from 2011-2012 demonstrate (1) an improved understanding of mathematical concepts, (2) lesson plans and teaching practices that are learner-centered, and (3) more in-depth reflections and conversations about student learning and understanding in the classroom.

In the next section of this paper, the theory of instruction is shared by first describing the process that led the authors of this paper to consider this alternative approach for teaching the methods course. Concept-Focused Instruction (CFI) is then defined, including an overview of the progress that led up to the current version. Afterwards, a brief overview of the research findings showing how CFI has had a positive impact with the training of prospective mathematics teachers is described. The paper ends with a discussion of current thoughts, challenges and questions.

Concept-Focused Instruction

Background and Context

Over four years ago the authors of this paper began a conversation about the relationship between the methods course experiences and the student teaching, or internship, experience. This conversation was consistent with the established research by Mewborn (1999), that is, the prospective teachers did not employ much of the knowledge and skills learned in the course. The prospective teachers seemed to view the knowledge they gained in professional education classes as rules or prescriptions to apply to classrooms, and because these rules were not consistent with what they experienced, they saw it as a disconnect between the university coursework and classroom experience. The views of the cooperating teacher became the student teachers' dominant practice.

This encouraged us to look at the traditional teacher-training model, in particular for the mathematics methods course. The course typically addresses the instructional blocks framed in one of these three elements (Figure 1).

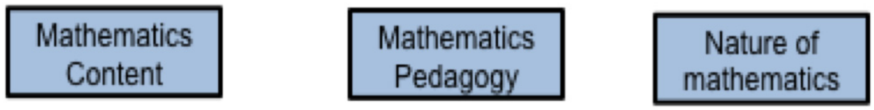

Figure 1: The traditional mathematics methods course elements

What we found is that the prospective teachers seemed to interpret these elements as separate and distinct. Mathematics content was what was learned in their mathematics coursework. The nature of mathematics was considered a philosophical idea that did not relate to what they were there to learn, and pedagogy was the sole purpose of the methods course. Because mathematics educators have established that the teacher's mathematical knowledge for teaching is directly related to how a teacher teaches and how well students learn (Hill, Rowan, & Ball, 2005) as well as their beliefs about the nature of mathematics (Borko & Putman, 1996; Philipp, 2007), our initial attempt was to find ways to connect the course elements.

Even when we purposefully tried to connect these elements, our preservice teachers did not connect the blocks. At the conclusion, preservice teachers still interpreted the set of information as discrete elements and believed the sole purpose of this course was to teach them *how* to teach mathematics. Then during the student teaching experience, when the prospective teacher would try to apply the knowledge learned in the methods course, the issue of classroom management would become prevalent. This resulted in their not thinking at all about the methods course material. Instead the teachers found themselves in a figurative sea of educational ideas, lesson plans and activities which in turn made the task of planning and implementing unfamiliar, yet recommended practices, daunting. They resorted to the educational practices of the cooperating teacher, which were often incompatible with the methods course knowledge, skills, and dispositions. In our conversations, the preservice teachers would recall the knowledge discussed in the methods about teaching and student learning, but did not have the mindset to access and apply this information in their practice. This finding led us to reconsider again the methods course elements and towards the idea of finding a clear and decisive format that prospective teachers could make sense of and use to make effective instructional decisions that focused on student learning. In other words, we aimed to identify an alternative approach for teaching prospective teachers about the nature of mathematics, mathematics content, and pedagogy so they would begin to (1) see the connections between mathematics and mathematical knowledge, (2) understand how students learn mathematics, and (3) teach for conceptual understanding.

Reframing the Methods Course Elements

Instead of looking at the three blocks of information as separate, we began to focus our attention on finding a common idea across the blocks. The common idea was conceptual understanding. For the nature of mathematics, in the methods course, the aim was to develop a view of mathematics being a dynamic, conceptualizing process. In terms of mathematical content, the emphasis was on conceptually understanding the mathematics the prospective teachers may teach. Finally, in the pedagogy block, a key element was how to teach and assess conceptual understanding. It was hypothesized that focusing on conceptual understanding would allow us to naturally address the nature of mathematics, pedagogy, and content topics.

To place an emphasis on conceptual understanding, we first had to clarify this idea for a prospective teacher. We established all mathematical concepts have three attributes: a macroscopic, model, and symbolic attribute (Hitt, 2005; Hitt & Townsend, 2007). The macroscopic attribute defines the context for the mathematical concept, in other words, a situation that enables individuals to visualize an application of the concept. The model attribute is the tangible representation of the macroscopic attribute. Finally, the symbolic attribute embodies the definitions and formulas associated with the concept. Figure 2 below shows this relationship.

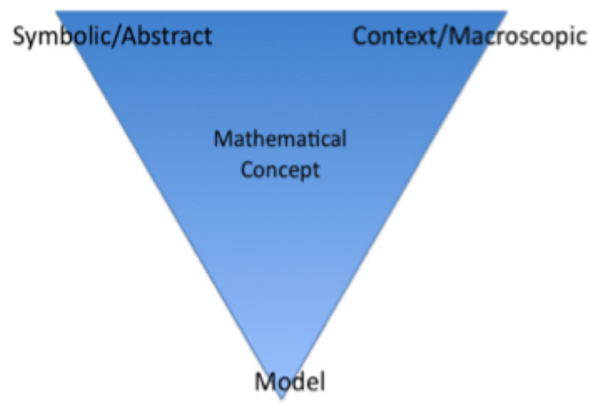

Figure 2: Attributes of mathematical concepts

For example, when thinking about adding fractions, it connects two concepts: fractions and addition. The macroscopic attribute could be a word problem that applies these concepts (Bob and Sue ordered 2 identical-sized pizzas, one cheese and one pepperoni. Bob ate ¾ of a pizza and Sue ate 1/8 of a pizza. How much pizza did they eat together?). The model would be a drawing of the pizzas, and the symbolic would include the vocabulary and algorithms for adding and finding common denominators. See Figure 3.

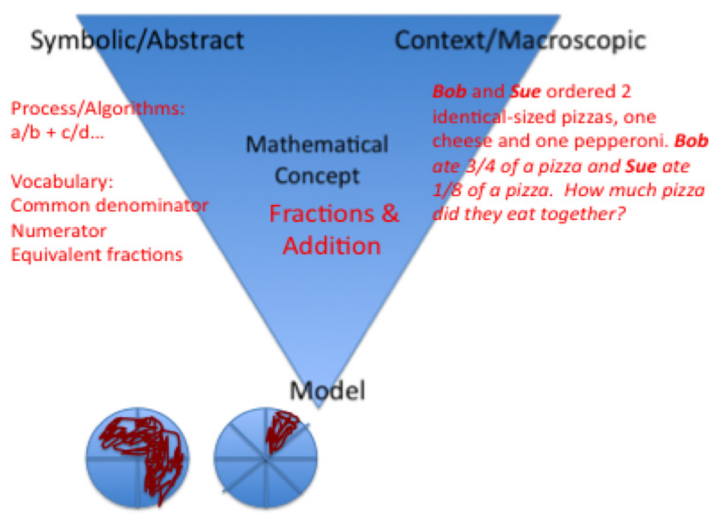

Figure 3: Three attributes describing the concepts Fractions and Addition

The methods course shifted from addressing the nature of mathematics, pedagogy, and content to a focus on identifying and analyzing macroscopic, model, and symbolic attributes of mathematical concepts first as a learner, then as a teacher. Within 2 years, we could establish Concept-Focused Instruction (CFI) as a theory of instruction. Readers may wish to refer to earlier publications that explain and justify CFI as a theory of instruction (Forrest & Hitt, 2010). In this paper, the focus will be on explaining how the theory of instruction has provided a systematic and deliberate framework for training prospective teachers, and specifically how it has been a better format for the university mathematics methods course.

Concept-Focused Instruction (CFI) Principles

Concept-Focused Instruction (CFI) is based on three core principles. The core principles are (1) mathematics is a conceptualizing process; (2) when individuals can explicitly reflect on the three attributes of mathematical concepts (macroscopic, model and symbolic) and can relate them to one another, they achieve conceptual understanding; and (3) in order to teach conceptually, teachers need to provide instruction that addresses the three attributes of mathematical concepts beginning with the macroscopic and model relationship (macroscopic, model and symbolic). These three related core principles frame the methods course design and delivery. Our hypothesis is that CFI enables prospective teachers to make better sense of teaching and learning mathematics as well as apply fundamental perspectives and methods that support education theory and the research on how people learn mathematics. It is not a novel idea to train prospective teachers by focusing on mathematics and developing understanding. Sowder (2007) describes successful implementations of such programs, for example, Cognitively Guided Instruction (CGI). CFI extends this line of work.

The focus of the next section is on the core principles of Concept-Focused Instruction (CFI). Each principle clarifies further the notion of conceptual understanding. Each principle can be interpreted as a basic hierarchical process building up and clarifying further the thoughts around conceptual understanding.

Core principle #1. Mathematics is a conceptualizing process. It has been shown by researchers who have studied mathematics teachers' epistemological beliefs that teachers who view mathematics as a dynamic conceptualizing process will be more inclined to use approaches for teaching mathematics. Additionally, students who understand mathematics as a conceptualizing process will likely have a more accurate perspective on what it means to understand and learn mathematics.

In the methods course, prospective teachers begin as mathematicians analyzing and solving a collection of mathematical tasks. The outcome is that the prospective teachers experience mathematics as a conceptualizing process. Discussion focuses on the process and thinking they used to solved the tasks. The instructor role models the tenets of Concept-Focused Instruction (CFI), highlighting each attribute of the concept to allow the prospective teachers to derive at Core Principle #2.

Core principle #2. When individuals can explicitly reflect on the three attributes of mathematical concepts (macroscopic, model and symbolic) and can relate them to one another, they achieve conceptual understanding. This principle helps us address two key ideas for teaching and learning mathematics. First, it provides a fairly simple explanation for mathematical understanding. The prospective teachers analyze a variety of mathematical topics in terms of the macroscopic, model, and symbolic attributes. That is they make and/or find possible macroscopic observations that allow a mental picture of the concept to be formed, create models that represent the phenomena, and then state the symbolic terms and formulas that are applicable. As a result, not only do the prospective teachers develop a better understanding of the mathematical content they are expected to teach. Through this process they begin to conceptualize and integrate complex mathematical ideas into their thinking. They also start to realize and discuss reasons why individuals may have a superficial and restricted understanding of mathematical content. Finally, they realize how critical the model attribute is when discussing mathematics. This sets up the third principle, which focuses on teaching mathematics.

Core principle #3. In order to effectively teach mathematical concepts, teachers need to provide instruction that addresses the macroscopic, model and symbolic attributes of concepts beginning with the macroscopic and model relationship. Specifically teachers provide a macroscopic experience that allows an opportunity to visualize the mathematics being taught. The students then create models to represent the macroscopic experience, and the teacher is then instructed to use the students' models to diagnose whether the students have a working model. Once a working model has been established, students are prepared to learn the symbolic attributes.

During the phase of instruction where the teacher is diagnosing the student models, the prospective teachers are trained to ask critical questions such as "How does your model explain this situation?" "Show me where your model addresses this particular idea?" etc. In addition, prospective teachers are instructed that once students have generated models, and while instruction is focused on students learning the mathematics, the instruction will be highlighting either the macroscopic attribute of the mathematics, that is the visual, or instruction will be highlighting the symbolic attribute. Highlighting refers to what is being made loud and clear during the instruction.

Looking back again at our diagram of the three attributes of a concept (the figure is repeated below for convenience), one can see how the model attribute becomes the pivotal attribute. Once students produce a model of the macroscopic experience, depending on whether this model is a workable model, the prospective teacher thinks about emphasizing either the macroscopic-model relationship or the model-symbolic relationship. This allows the prospective teacher to focus his/her instruction on a specific outcome.

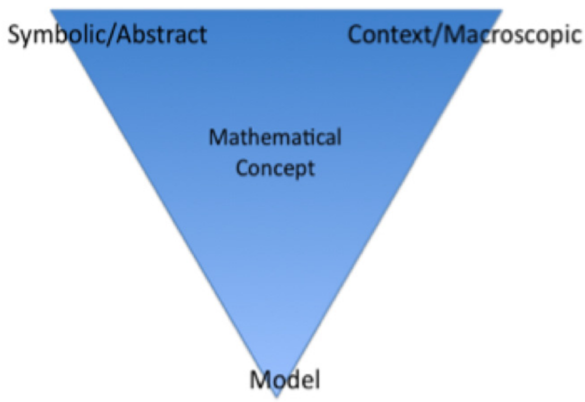

Figure 4: Attributes of mathematical concepts

In summary, using the three core principles of Concept-Focused Instruction (CFI) to frame the university methods course has resulted in our prospective teachers having better understanding and practice in the teaching and learning of mathematics. Without explicitly teaching the knowledge, skills, and dispositions related to the nature of mathematics, mathematics pedagogy and mathematical content, our preservice teachers have naturally acquired these skills in a manner that makes sense to them. They now comprehend how the nature of mathematics, pedagogy, and content are related when it comes to teaching students mathematics.

Concept-Focused Instruction is beginning to show promise as a means for developing prospective mathematics teachers, but it is still a work in progress. Each year, empirical evidence is gathered to create a case documenting each of the prospective teachers experience in the university mathematics methods course through the internship. Each case includes documentation showing the prospective teachers' mathematical content knowledge, beliefs about teaching and learning, the prospective teachers' views of mathematics and mathematical knowledge, and use of inquiry and mathematical processes in planning and delivery. In addition, documents ranging from lesson plans, supervised observations and evaluations are part of each prospective teacher's case.

Conclusion

Concept-Focused Instruction (CFI) is a theory of instruction that has been successfully used to develop prospective teachers' understanding of mathematics, as well as their knowledge, skill, and dispositions for teaching and learning mathematics. However, the authors are just beginning to establish a comprehensive research design to test the specific impact of CFI on preservice teachers. For example, the authors have identified one issue that they feel warrants further investigation. It is unclear ***how*** Concept-Focused Instruction (CFI) shapes prospective teachers' perspectives on mathematics or their ability to teach lessons effectively. In order to determine when and how preservice teachers integrate the CFI core principles into their thinking, it is critical to collect and analyze more qualitative data from artifacts such as journal reflections, class assignments and digitally recorded teaching presentations.

In closing, we want to summarize (1) the purpose of integrating Concept-Focused Instruction (CFI) into mathematics methods instruction, and (2) clarify how CFI fits within the current practices in the field of preservice mathematics teacher education. First, a theory of instruction, specifically CFI, can help prospective teachers simplify and visualize the connections between how mathematics is done, the way that students intuitively learn mathematics and effective approaches for teaching mathematics. When prospective teachers are just beginning their professional development, they tend to see these ideas as separate because as a student of mathematics, they have no explicit experiences with connecting these elements. We have found that once the above connections make sense to the prospective teacher, they are better able to understand and discuss many of the current ideas found in the mathematics education literature. In addition, we have realized until the connections make sense to the preservice teacher, the preservice teacher will fail to integrate the more constructivist ideas in their instruction.

Second, Concept-Focused Instruction (CFI) is not a replacement for instructional approaches discussed in methods courses, such as problem-based or inquiry-based instruction. CFI merely provides a foundation for prospective teachers to build upon. Once this foundation is established, the instructional approaches discussed in the method course make more sense to them. Concept-Focused Instruction merely provides preservice teachers with a basic understanding of how to think about mathematics learning and teaching, which then assists them in understanding and then designing and implementing learner-centered instruction.

This study developed twelve instructional modules based on the National Assessment of Educational Progress for mathematics content and methods courses for preservice elementary and middle school teachers and examined their impact on PSTs' mathematical content knowledge and self-efficacy beliefs about teaching mathematics. The modules help preservice teachers: (1) improve their mathematical content knowledge, (2) learn how to use effective methods to teach mathematics; and (3) become aware of uses of NAEP. Mathematical content knowledge was measured by instruments from the Learning Mathematics for Teaching project and mathematics teaching efficacy beliefs were measured by the Mathematics Teaching Efficacy Beliefs Instrument or the Yackel Beliefs Survey. Modules were found to increase PSTs' mathematical content knowledge for teaching and improve their teaching efficacy beliefs.

Keywords: Teacher Education–Preservice; Teacher Knowledge; Teacher Beliefs

National reports (Project Kaleidoscope, 2006; National Academies, 2003, 2008; Ball, Ferrini-Mundy, Kilpatrick, Milgram, Schmid, & Schaar, 2005) pointed out the urgent need to improve the quality of science, technology, engineering, and mathematics (STEM) education programs. The National Academies (2006, cited in PKAL, 2006) advised increasing "America's talent pool by vastly improving K–12 science and mathematics education" (p. 4-2). Such progress rests on improved mathematical education of teachers. Morris (2006) stated, "Preservice teachers rarely exit their mathematics teacher education program as experts" (p. 471). The question therefore becomes, how do mathematics teacher educators help PSTs better develop their expertise, especially during their early careers? It is difficult to address the learning needs of preservice teachers (PSTs) due to the large number of concepts, skills, and strategies that must be acquired at a high level of competence to teach successfully. This fact must be kept closely in view by faculty of mathematics content and methods (MC&M) courses for teachers. We must carefully examine the goals of these courses and ask: (1) *Are we giving students enough experiences in the areas we expect them to master?* (2) *Do they have sufficient opportunities to consider problems from both students' and teachers' viewpoints?* and (3) *Do they have sufficient opportunities to examine both student work and student achievement data?*

It is insufficient to discuss problem solving, development of student conceptions, and assessment of mathematical learning, in abstraction. Preservice teacher education must have a strong student focus and be rooted in authentic classroom data. Novices need specific experiences in how to analyze student work, assess student understanding, and in scoring student work with various rubrics. Previous researchers (Morris, 2006; Osana, Lacroix, Tucker, & Desrosiers, 2006) reported the benefits of asking PSTs to analyze mathematics teaching episodes from real practice. Morris (2006) described a study where PSTs' abilities to analyze videotaped teaching episodes differed markedly on the basis of whether they were told beforehand that a lesson was unsuccessful or whether they had to make this determination independently. Morris's study suggests that what PSTs *focus on and attend to*, in analyzing teaching and student performance, is linked to what experiences and guidance they receive from teacher educators.

Current efforts to improve mathematics teaching recognize the importance of helping teachers (a) gain depth in their mathematical content knowledge, (b) master specialized content-related strategies needed to help children learn mathematics, and (c) learn pedagogical and assessment practices to improve the quality of teaching and student learning (Hill, Rowan, & Ball, 2005; Ball & Hill, 2004; Ball & Bass, 2000). We believe that the analysis of sound mathematical tasks, discussion of explanations for mathematics procedures and concepts, careful analysis of student work, and discussion of assessment practices should be a focus of preservice mathematics content and methods courses and that these experiences should occur across the teacher education program. The North Carolina NAEP project found preservice teachers to be especially receptive to NAEP-related instruction that was clearly linked to examples of student work, analysis of that work, and examination of student performance data.

Purpose

The goal of the *North Carolina NAEP: Improving Mathematics Content and Methods Courses* project was to modify materials from *Learning from NAEP: Professional Development for Teachers* (Brown & Clark, 2006) for use in preservice mathematics content and methods courses, to expand the materials to include more recent NAEP assessment results, and to include, and focus on, more mathematics content. While NAEP produces a vast amount of data concerning students' learning and achievement, this wealth of data is not always used effectively within preservice teacher education courses to help PSTs become aware of what these data show. The project addressed three research questions, two of which are addressed in this paper:

1. How can mathematics content and methods (MC&M) courses for preservice undergraduates and graduate students be improved through the integration of NAEP?
2. How can NAEP-related materials be used in MC&M courses to help beginning teachers see the connections among the following areas: (a) teachers' content knowledge, (b) student understanding, (c) classroom assessment practices, (d) analysis of student performance data, and (e) use of NAEP data to address issues of equity?

The results described here explain the ways in which the modules appeared to influence preservice teachers' mathematical content knowledge and how they seemed to influence their mathematics teaching efficacy beliefs. Goals and outcomes of the project include:

1. The improvement of MC&M courses for elementary and middle school PSTs to produce teachers knowledgeable about mathematics content and pedagogy and knowledgeable about difficulties students have in learning mathematics topics.
2. The improvement of MC&M courses to produce teachers able to use NAEP and other assessment data to consider issues of equity and to modify teaching to address them.
3. Improving teachers' knowledge of various assessment strategies including designing and using problem solving rubrics.
4. The development of (a) multimedia materials that illustrate critical mathematics concepts, NAEP-related problems, examples of student errors, statistics concerning student achievement on NAEP problems, and activity sheets providing guidance for group analysis of this information within MC&M courses; and (b) a project website.
5. Enhancing instruction and communication between institutions within the North Carolina Community College system and the University of North Carolina system.

The project team involved mathematicians and mathematics educators from the following universities and community colleges: Appalachian State University, the University of North Carolina Charlotte, the University of North Carolina Wilmington, Forsyth Technical Community College, Mayland Community College, and Wilkes Community College. *The UNC Teacher Preparation Program Effectiveness Report*

(Henry, Thompson, Bastian, Fortner, Kershaw, Marcus, & Zulli, 2011) concluded that the following programs were outperforming their reference group comparisons in these areas:

> Appalachian State University – Elementary Program: *elementary mathematics*
> University of North Carolina Wilmington – Middle School and Secondary Mathematics Programs: *middle school and secondary mathematics*
> University of North Carolina Charlotte– Middle School Programs: *middle school mathematics* (Henry et al., 2011, p. 11)

Thus, we were able to integrate, within the project modules, instructional practices that have been deemed effective in improving teacher preparation at the participating institutions.

The project team included two practicing teachers, one from the elementary level (Ms. Anderson) and one from middle school (Mr. Schmal). These teachers helped the team link the NAEP assessment results to the realities of daily classroom practice through their contributions to the writing teams and through their commentaries concerning how NAEP data mirror the types of student work and difficulties that they observe in their classrooms. Twelve modules were produced, four for each of these levels: elementary, middle school, and community college. The community college modules are directed at undergraduate mathematics courses frequented by preservice teachers. The modules employ a variety of instructional approaches including: using active learning strategies; conducting analyses of NAEP results; conducting analyses of student work; developing understanding of the mathematics contained in NAEP problems; and developing awareness of NAEP rubrics and procedures for assessing student work. The elementary modules address the areas of: *fraction number sense, addition and subtraction, early algebra,* and *geometry*. The middle school modules include the topics: *proportional reasoning, geometric and spatial reasoning, linear growth and rates of change,* and *data analysis*. The community college modules cover the topics of*: algebra, probability, proportional reasoning,* and *spatial reasoning*. The study results suggest that seeing their college mathematics and mathematics education instructors model more inquiry-based pedagogical strategies positively influences and broadens PSTs' vision of effective mathematics instruction.

The modules are flexible allowing for inclusion within different course structures and time allotments. Each module contains:

1. Purpose
   a. Specification of the mathematical concept(s) addressed
   b. Specification of pedagogical approaches
2. Overview
   a. Module goals
   b. Module activities
3. Background and context notes
   a. Includes research brief concerning math concept and relevant pedagogical issues
   b. Includes discussion of common student errors based on research
   c. Examines NAEP student performance data in context of relevant research
4. Preparing to teach the module (Instructor notes not covered elsewhere)
5. Introductory PowerPoint presentation for the module (to be presented to PSTs)
   a. Specification of the mathematical concept(s) being addressed
   b. Specification of pedagogical issues addressed
6. *Teaching the Module* plan for the university/college instructor that provides:
   a. Goals and objectives of the module
   b. Time required for module
   c. What mathematics is addressed and grade band(s)
   d. How NAEP resources will be used
   e. Materials required
   f. NCTM Principles or Process Standards addressed
   g. NAEP Content Strand Emphasized

h. Description of class activities (Activities should include samples NAEP problems, student work, and performance data)
i. Directions for conducting class activities
j. Student activity sheets
k. Discussion guide
7. References

Each module includes recommended readings and Teaching Notes to help instructors implement the activities. The instructor can access PowerPoint presentations as well as a Moodle-based course shell that includes the instructional materials. Example modules are available on the project website http://ncnaep.rcoe.appstate.edu/. Online and face-to-face professional development opportunities are planned for 2013–15.

Method

Instructional modules based on NAEP data were developed and implemented in mathematics content and methods courses aimed at preservice elementary and middle school teachers who were enrolled at three universities and two community colleges from fall 2008 to spring 2010. Thus far, roughly 750 PSTs have been impacted by the project. External evaluators analyzed three data sources: (1) PSTs' performance on a mathematics knowledge assessment (LMT); (2) PSTs' responses to mathematics teaching beliefs questionnaires, the *Mathematics Teaching Efficacy Beliefs Instrument* (MTEBI) (Enochs, Smith, & Huinker, 2000) or the *Yackel Belief Survey* (Quillen, 2004); and (3) faculty responses to the *NC NAEP* workshop surveys and their reported use of *NC NAEP* modules. The sample included PSTs who were given a mathematics content knowledge test and a teaching self-efficacy questionnaire at the beginning and end of the semester. The project included sections of experimental courses at each university as well as control sections that did not use the project modules. The elementary preservice teachers were given the *LMT: Grades 4–8 Geometry* test or the *LMT: Elementary School Number Concepts and Operations–2004* test, dependent upon their specific course enrollment. The middle school preservice teachers were administered the *LMT: Middle School Number Concepts and Operations* test, as were the community college students. It is significant to note that the LMT tests do not just measure mathematics content knowledge; they measure a teacher's knowledge of mathematics for teaching. Thus, this data helps us learn not only how the PSTs think about mathematics concepts but it also helps us to form a picture of how they interpret possible student responses to certain mathematical scenarios. To ensure comparability across all data collected, the analysis included only students in each group, (e.g., course specific, higher education setting, and grade-level focus) for which evaluators were able to match both the pre-post scores on each instrument. After linking students with their pre and post scores, the evaluators conducted a range of statistical tests including significance and regular multiple regression tests, as well as item response analyses.

Key Findings

The results from the *NC NAEP Project* suggest that the National Assessment of Education Progress can inform instructional practice. This report shares findings based on the evaluators' analysis—using a mix of data from several instruments (i.e., *Mathematics Teaching Efficacy Beliefs Instrument* (MTEBI), the *Yackel Belief Survey* (YBS), and the *Learning Mathematics for Teaching instrument* (LMT)) used at different stages of the project, and with populations of students from 2 to 4-year undergraduates. Three main project components evaluated are discussed below: (1) PSTs' learning in terms of content knowledge and mathematics teaching efficacy beliefs; (2) learning by the college /university faculty impacted by the project; and (3) the quality of the modules and accompanying materials.

Impact on Pre-Service Teachers' Content Knowledge

Finding #1. Project faculty were differentially effective in increasing PSTs' mathematics content knowledge for teaching as measured with an LMT test. Because positive growth varied strongly across students linked to different project faculty, the results suggest overall positive effects. The difference in faculty effectiveness is significant at $p \leq 0.01$. Over half of the project faculty had students who gained, on average, a standard deviation or more in post-test scores.

Finding #2. All PSTs showed improvement in their knowledge of mathematics, with elementary PSTs making the largest gains. Treatment elementary PSTs showed statistically higher gains in their pre-post knowledge of mathematics for teaching as compared to a control.

Elementary Pre-Service Teachers

The average number of correct items on the baseline LMT test for all pre-service elementary teachers was 10, while the average number correct on the post-test was 12.4. There was little variation in the test scores between students in the control and treatment groups—the average pre-test score was 10 for both groups, and the average post-test scores were 12 and 12.50 respectively.

The post-LMT test gain for elementary pre-service teachers corresponds roughly to a 2 to 3-item increase, per student, in the raw number of correct items. Considering that the assessment was not designed exclusively to match the curriculum of all or any particular course, this gain is a promising finding. The standard deviation of the pre and post-test scores for students in the treatment group were .892 and .626, respectively, making this gain a third standard deviation in size, and statistically significant at $p < .001$.

Pre-service teachers pre and post-LMT scores in spring 2010 were higher in the number of overall correct items by 2 than compared to teacher's pre-post scores in fall 2009. An analysis of matched items from the pre-post LMT showed that spring 2010 students performed significantly better on items designed to measure operations content knowledge than other students. Correct responses to items 5 and 8 were positively and strongly predictive of teachers' knowledge of mathematics, and higher raw scores than other matched items. These results suggest that as the project proceeded and the project modules were more effectively integrated within the courses, the benefits became more pronounced.

Middle School Pre-Service Teachers

The number of middle schools pre-service teachers for which there were matched pre-post test scores for was considerably smaller than the sets for the community college and elementary pre-service teachers. This data is reported for comparison purposes, but we suggest the results be viewed with caution because of the relatively high standard error compared to other sub groups. Analysis of the pre-post LMT scores for pre-service middle school teachers revealed a statistically significant increase in post-test scores at the 5 percent level overall, and in both fall 2009 and spring 2010.

Finding #3. Preliminary results indicate a high degree of correlation $r = 0.78$ between PSTs' personal beliefs of math and math instruction and their performance on the LMT. The relationship between knowledge of mathematics teaching was strongest with the personal efficacy sub-scale.

Impact on Pre-Service Teachers' Self-Efficacy

Finding #4. Evidence suggests that the *NC NAEP* modules used in different contexts influence PSTs self-awareness and confidence in their personal efficacy for mathematics and mathematics instruction. We examined the relative effects of instructional environment (2 or 4-year university/college) and instructor with different characteristics on PST outcomes. Four unique pair-wise comparisons of PST beliefs were conducted: (a) 4-year university PSTs relative to community college PSTs, (b) elementary school PSTs relative to middle school PSTs; (c) elementary pre-service treatment teachers relative to elementary pre-service control teachers; and (d) fall 2009 PSTs relative to spring 2010 PSTs.

Among the aggregate results on the MTEBI, PSTs responses indicate changes in nearly every personal efficacy item, with significantly positive changes ($p \leq 0.001$) on three items: (e.g., "I know how to teach mathematics concepts effectively"). In nearly every dimension (e.g., subject matter-knowledge, pedagogy and subject-specific pedagogy), PSTs from spring 2010 had markedly higher self-efficacy beliefs toward mathematics, with elementary PSTs showing dramatic shifts—both experimental and control. Both elementary pre-service and middle school PSTs from 4-year universities, showed a statistically significant differential ($p \leq 0.001$ and $p \leq 0.05$, respectively) intra-group in their post-mathematics efficacy scores—indicating changes in their mathematics content and PCK.

Finding #5. At the end of the semester, PSTs, in general, noted changes in their attitudes that they can positively influence student learning—their belief in outcomes expectancy. Elementary and middle school PSTs from spring 2010 showed significant changes ($p \leq 0.05$) in their outcomes expectancy beliefs when compared to candidates from Fall 2009—both experimental and control.

Impacts on Faculty Instructional Practice

Finding #6. Project faculty found value in using project resources to improve their own instructional effectiveness. *NC NAEP* modules forged connections between mathematics content, instructional practice and assessment, to help faculty better prepare PSTs.

Finding #7. Non-project faculty found the *NC NAEP* materials very useful. They reported that the training and materials helped them form a personal action plan for using *NC NAEP* resources and illustrate concrete resources and strategies for improving students' preparedness.

Finding #8. *NC NAEP* resources helped to challenge participating faculty's preconceptions concerning their teaching of mathematics content and methods. Participating faculty recognized the importance of changing their practice to evaluate their students' preparedness and to emulate authentic classroom activities.

Conclusions

The *NC NAEP* modules had important effects on the development of PSTs' mathematical content knowledge, and improved their personal efficacy, outcomes expectancy, and attitudes toward mathematics. The modules provided a meaningful format from which to draw situated, authentic resources to support critical thinking and reflection about mathematics instruction. These modules have the potential to play a critical role in the preparation of high-quality, well-prepared teachers of mathematics. However, some limitations of the evaluation should be mentioned. While the LMT is a reliable measure of mathematical content knowledge for in-service teachers, its use with PSTs is preliminary (Gleason, 2010). To address this concern, we plan for future evaluations of the modules to validate individual LMT results using either an assessment of PSTs use of mathematics content during situated classroom teaching or using interviews where students explain their thinking and solution process to the test items. Gleason also suggests that the reliability of the LMT with preservice teachers is strengthened through the use of multiple instruments.

In addition to the findings discussed above, the project team submitted the modules to an external mathematics educator from the Pennsylvania State University for evaluation. The evaluator provided detailed feedback concerning the quality and utility of the modules, noting:

> Overall, I can see that the project has worked hard to integrate NAEP items, results, and student work into modules that are intended to be disseminated for use in PST education. Developing meaningful activities for PSTs is challenging; developing accompanying facilitator notes adds levels of difficulty to the task. The developers of the materials are to be commended for their work thus far, particularly in the area of integrating NAEP into your materials.

Some of the evaluator's suggested revisions include: (a) limiting the scope of some of the modules, particularly the community college materials, to make them easier for instructors to implement; (b) addressing the issues associated with making referenced video clips more accessible; and (c) changing some of the facilitator notes to provide more guidance to instructors concerning how to best implement the modules. We are making revisions to the modules based on this helpful feedback.

Another indicator of the quality of the project modules is their adoption for use in selected courses within a new multi-university program in North Carolina for an *Add-on Certificate in Elementary Mathematics* (which is similar to a K–5 mathematics specialist). Evaluation of the pilot add-on certificate program showed improvements in mathematics content knowledge of the teachers enrolled as compared to a control group.

This project provides an example of how different communities of professionals can contribute to the effectiveness of mathematics teacher preparation programs. Mathematicians and mathematics educators, including instructors from various levels of higher education (doctoral institutions, 4-year institutions, and community colleges), and classroom teachers all have a crucial role to play in the development and implementation of authentic instructional resources in mathematics teacher education. Such cooperation among professionals and institutions facilitates transitions across the continuum, including the transition that students make as they progress through a teacher education program and emerge as an effective beginning mathematics teacher.

Acknowledgments

The project team would like to thank the external evaluator of the *NC NAEP* module materials, Dr. Fran Arbaugh, of the Pennsylvania State University, for her thoughtful criticisms and suggestions concerning our modules. We also thank Dr. Lynn Clark of the University of Louisiana–Monroe and Dr. Chris Mathews of Apple, Inc., for their overall project evaluation.

USING A KNOWLEDGE-IN-PIECES APPROACH TO EXPLORE THE ILLUSION OF PROPORTIONALITY IN COVARIANCE SITUATIONS

Erik Jacobson
University of Georgia

Andrew Izsák
University of Georgia
izsak@uga.edu

The non-normative application of proportional strategies in non-proportional covariance situations is widespread and documented in studies conducted in many countries and with participants across a wide range of ages. In the present study, we found that preservice middle-grades teachers have many of the same problems with proportional reasoning as those reported with other populations. We employed diSessa's (1993) knowledge-in-pieces perspective to track how pre-service teachers used knowledge resources before and after a unit on proportional reasoning in their methods course. Past research has often characterized this phenomenon as the result of intuitive or impulsive responses to familiar missing-value problem presentations. Our data show that even a detailed understanding of the relationship between covarying quantities by no means guarantees the normative use of the proportion equation.

Keywords: Teacher Knowledge; Teacher Education–Preservice; Rational Number

Purpose

Meno's slave famously told Socrates that a square of double area is obtained by doubling the side length of the given square. The inappropriate application of proportional reasoning strategies in non-proportional covariance situations (termed here *non-normative*) is widespread and documented in studies from many countries and among participants with a wide range of ages (for a review, see Van Dooren, De Bock, Janssens, & Verschaffel, 2008). However, knowledge of the root psychological sources of this tendency remain tentative and pedagogical remedies unsatisfactory (see the first issue of *Mathematical Teaching and Learning 12*).

In the present study, we found that preservice middle-grades teachers have many of the same problems with proportional reasoning as those reported with other populations. To gain further insight into these difficulties, we employed diSessa's (1993) knowledge-in-pieces perspective to track how pre-service teachers used knowledge resources before and after a unit on proportional and non-proportional reasoning in a methods course. We report two cases in which participants judged non-proportional relationships to be proportional even though they demonstrated clear understanding of the non-proportional covariance relationship.

Perspectives

Teachers and the Illusion of Proportionality

Fruedenthal (1983, p. 267) wrote, "Linearity is such a suggestive property of relations that one readily yields to the seduction to deal with each numerical relation as though it were linear." Teachers, even those certified for mathematics, are not exempt from its lure. Riley (2010) found that in a sample of 80 preservice elementary teachers, less than 50% solved *constant difference* and *inverse proportion* problems correctly. We illustrate these terms with example tasks from other studies with teachers. We used similar tasks in the present study.

Constant difference. Cramer, Post, and Currier (1993) report that 32 out of 33 preservice elementary teachers solved the following task using the proportion $9/3 = x/15$. "Sue and Julie were running equally fast around a track. Sue started first. When she had run 9 laps, Julie had run 3 laps. When Julie completed 15 laps, how many laps had Sue run?" The relationship between these runners' laps is not proportional: They remain an equal distance apart: $9 - 3 = x - 15$.

Inverse proportion. Fisher (1988) reported that 12 out of 20 inservice secondary mathematics teachers did not solve the following problem correctly; "If it takes 9 workers 5 hours to mow a certain lawn, how long would it take 6 workers to mow the same lawn?" The common error was to assume a direct proportion such as $9/5 = x/6$. Instead, the relationship between men and minutes is inversely proportional: The amount of work is constant: $9(5) = 6x$.

Knowledge-in-Pieces and Conceptual Change

Prior work on this problem has been conducted within a traditional knowledge-as-theory perspective (Özdemir & Clark, 2007). Knowledge is understood as a unified and coherent structure and conceptual change is characterized as a paradigm shift: old structures are replaced with new ones. Instead, we use diSessa's (1993) knowledge-in-pieces epistemology that models knowledge as networks of loosely connected knowledge resources that are each highly sensitive to context. Conceptual change from this perspective is characterized as the piecemeal construction and reorganization of knowledge resources (e.g., diSessa & Sherrin, 1998) as learners gradually navigate the continuum from novice to expert.

Within the larger knowledge-in-pieces perspective, diSessa and Sherin (1998) proposed the *coordination class* as an empirically verifiable alternative to the black-box notion of concept in traditional work on conceptual change. A coordination class is made up of *readout strategies* by which one acquires information ("sees") in knowledge-use situations. The *causal net* of a coordination class is made up of the syllogism-like ways of inferring new information not directly available from readout. For example, someone might use the equation $F=ma$ to obtain information about acceleration from a situation that specified only force and mass. Different contexts require different readout strategies and result in different kinds of inferences in the causal net. *Coordination* in an expert's coordination class means (a) that one *integrates* all of the relevant information in a particular context, and (b) that inferences are *aligned* or consistent across the range of applicable contexts.

Under this analytic approach, knowledge and its use are not carefully distinguished, and knowledge per se is empirically linked at a fine grain size to contextual differences across situations of knowledge use. Wagner (2006) applied diSessa's framework and found that conceptual change happened as the participant's knowledge, "came to account for (rather than overlook) contextual differences" (p. 6). We follow Wagner in specifying terms for more precisely discussing the contextual differences that problem solvers encounter in activity. The *type* of a problem is defined by appealing to normative or expert judgment. The *aspects* of a problem are defined separately for each problem solver by obtaining empirical evidence for what features or details are perceived as relevant. The term *context* is broader, including type, aspect, and the cover story for the problem. For example, although the problems reported by Crammer et al. (1993) and Fisher (1988) are of a different type (one describes a constant difference and the other describes an inverse proportion), a problem solver might likely read out a similar aspect in both situations: the women run and the workers mow at equal rates.

Methods

Participants and Context

This study took place in the context of an 18-week content/methods course on number and operations for preservice middle-grades mathematics teachers that met for two 75-minute sessions each week. Students in the course ($N = 28$) were in their third year of college and had taken (at least) a course in introductory calculus prior to the study. Two weeks of the course were devoted to a unit on proportional reasoning. Students worked on tasks in small groups and participated in whole-class discussions. The instructors selected tasks and orchestrated discussion to focus on the big ideas for the unit such as: proportional situations are those in which covarying quantities maintain a constant multiplicative relationship (ratio).

Problem Situations

We gave students problem situations describing both proportional and non-proportional covariation during the unit and on assessments. The present study focuses on the following four problems that are variants of problems used in previous studies (e.g., Cramer et al., 1993; Fisher, 1988). The first two problems describe situations of constant difference. The last two are non-linear as well as being non-proportional. The Work Problem describes an inverse proportion situation, and the Interest Problem describes (an approximation to) an exponential situation.

The Running Problem (used in the pretest, posttest, and interviews). Determine whether the following problem is a *mathematically valid* illustration of the proportion A/B = C/D: Bob and Marty run laps together because they run at the same pace. Today, Marty started running before Bob came out of the locker room. Marty had run A laps by the time Bob had run B laps. How many laps C had Marty run by the time that Bob had run D laps?

The Combine Problem (used in the methods course unit on proportion). Two combines harvest grain at the same rate. The first combine starts harvesting 10 minutes before the second combine. After 20 minutes of operation, the second combine harvests 400 lbs of grain and the first harvests 600 lbs of grain. How many pounds will the second combine harvest by the time the first has harvested 1000 pounds of grain?

The Work Problem (used in the pretest, posttest, and interviews). Determine whether the following problem is a *mathematically valid* illustration of the proportion A/B = C/D: If A men paint the outside of a house in B minutes, then how many minutes D would it take C men to paint the same house, if all the men work at the same rate?

The Interest Problem (used in the methods course unit on proportion). Karl has a savings account that pays interest monthly at a rate of 5%. Three months ago, there was $300 in his account. If he did not withdraw any money from the account, how much is there now?

Data Collection

Each class session was video recorded using two cameras. One camera was stationary and positioned to capture the activity in the whole classroom. The second camera was hand-held and tracked the primary instructor (second author) and the written work of the students' with whom he was interacting. Students also took a pre-test and post-test. The primary data for this study were from video taped interviews (running 60 to 90 minutes) conducted with four pairs of students from the class. During the interviews, each pair was presented with a sequence of tasks and asked to solve the task together while verbally explaining their reasoning. The interviewer encouraged the students to talk freely and occasionally asked clarifying questions.

Analysis

Video data from each class was summarized, and student and instructor comments were time-stamped and supplemented with screen-shots to facilitate review. The interview data were fully transcribed. We watched all of the interview data and wrote summaries comparing each of the students' pre- and post-unit interviews. Then we reviewed the classroom video data for each student and looked for interactions or written work that might inform the observed changes. Finally, we reviewed students' written work on the pre-test and post-test, on the course midterm and final exam, and on the proportional reasoning homework assignments.

Results

We found that students who correctly explained relationships between quantities that were not proportional in the Running and Work problems (given above) still tried to set up and use proportion equations. To understand how this could take place, we examined the knowledge resources that students used to determine whether or not proportions could be set up to solve these problems. Our analysis led us to focus on (a) the consistent use of one knowledge resource (the necessary correspondence between quantities and their position in a proportion equation) by all interviewed students across all tasks, (b) the readout and use of the *same rate/pace* aspect of the tasks which varied among students, and (c) the various aspects of the non-proportional Interest and Combine problems (given above) that students found relevant for inferring proportionality.

First Interview, Work Problem

In this section, we use data from the Work Problem to describe a common aspect of the problems perceived as proportional—correspondence between quantities. *(Note on transcription:* Pauses are indicated by ellipses and interruptions by the em dash; overtalk is within double-slashes and action within square brackets; there are no deletions in the transcript provided.)

Lisa and Tess. These students immediately agreed that the Work Problem was proportional, and Lisa notably recognized the aspect of *same rate*.

Tess: I think [the proportion is] accurate because you have the number of men on top over //*Lisa*: and they're going at the same rate// the number of minutes and the same rate so you have your second number of men over your second number of minutes.

Alice and Clara. After reading the problem, Alice said, "So I guess like you would start off by setting it up like this," and wrote the proportion A/B = C/D. Then Clara used her pencil to point to A and then B while saying, "This amount of men paint a house in this many minutes." Alice touched her pencil to B at the same time as Clara, and then Alice said, "This many men [pointing to C] and minutes [pointing to D]."

Discussion. Across all pairs, students began almost all interview tasks by carefully reading out the correspondence between the quantities represented by variables and the position of these variables in the presumptive proportion equation. This is evident in Tess's initial comments ("... so you have your second number of men over your second number of minutes"). When asked about similar behavior during the second interview, Lisa said, "Proportion has to correspond." Alice and Clara also read out the correspondence between initial and final, men and minutes in the Work Problem, and this shared activity and its result had a shared interpretation: the proportion equation was applicable. Several other students we interviewed noted that a failure of correspondence would rule out the proportion equation in their view.

First Interview, Running Problem

In this section, we report how different interview pairs read out the aspect of *same pace* in the Running Problem, and how they made very different use of it.

Lisa and Tess. Tess established the correspondence between the quantities as she read the problem out loud by pointing to each variable in the proportion as she read its description. After a 30-second pause, Lisa began.

Lisa: Hmm. I mean if they keep on at same pace, //*Tess*: Right// isn't that going to be the same difference between the two //*Tess*: Right// so it would be an equal proportionality I would think ... kind of like equal fractions //*Tess*: Yeah// equivalent fractions?

They tried a numerical example, then both agreed the proportion was valid.

Interviewer: So run me through your reasoning one more time.

Tess: Okay. We just plugged in numbers to make sure that it was accurate and valid. So we said that if Marty had run 4 laps by the time that Bob had run 2 laps, we're looking for how many laps C, Marty ran by the time that Bob had run 8 laps. So we put 4 over 2 equals X over 8. And so our proportion, we're going to do 4 times 8, which is 32 equals 2 times X, just 2X, and then we're going to divide by 2. So we get 16 equals X and [rewriting the proportion] it's going to be 4 over 2 equals 16 over 8 and that is correct because you can simplify ... that's 2, 2 [writes 2=2]. So yes it is valid.

Alice and Clara. After working with a numerical example, the students made a discovery.

Alice: So we're saying by the time Marty had ran 4 laps Bob would have ran 2 //*Clara*: Yes// because I feel like if they run it in the same pace—

Clara: —then it should have been only 1 more lap.

Within a few minutes, they agreed that the proportion equation was not valid.

Interviewer: Why are you questioning its validity?

Clara: Because if they're running the same pace ... if Bob had run 1 more lap than Marty should have run 1 more lap. He just started earlier but they're running at the same pace, so the same speed of 1 lap should just be in Marty's 1 more lap. If Marty went and started and he ran 1 lap and then Bob came and started and ran another lap, Marty is still running so Marty would have run 2 laps by the time Bob ran 1. And then when they run another lap, Marty would have run 3 laps by the time Bob ran 2, but with this proportion it's saying that Marty would have run 4 laps by the time Bob ran 2 because it's doubling.

Discussion. It is clear that the *same pace* aspect of the problem was quite salient for Lisa. She interrupted Tess on the Work Problem to point out a similar aspect of that problem, *same rate*. In the Running Problem, she used the *same pace* information to conclude (normatively) "the same difference." However, the information about *same difference* served as a warrant for Lisa's use of the proportion equation: "so it would be an equal proportionality, I would think." Clara made a different inference, "they're running at the same pace, so the same speed of 1 lap should just be in Marty's 1 more lap." These data are evidence of differences in these students' causal nets. That is, although both pairs had access to the same information about the problem, awareness of a constant difference led them to different conclusions about the applicability of the proportion equation.

The data presented thus far admit the alternative hypothesis that Lisa and Tess did not fully understand the problem situation or were simply failing to be attentive and careful. Certainly, it makes intuitive sense that students who possess or develop the kind of quantitative understanding that Alice and Clara displayed of the Running Problem would not apply the proportion equation in non-proportional situations. The unit on proportional reasoning in the methods course was designed to help students develop just this kind of quantitative understanding for several types of non-proportional covariance that are frequently viewed as proportional.

The Proportion Unit

The first and second interviews bracketed the two-week unit on proportional reasoning that included work distinguishing proportional and non-proportional relationships. The Interest Problem and the Combine Problem received prominent attention as explicit examples of non-proportional situations throughout the unit. Students in the methods course witnessed clear, normative explanations from their peers and had opportunities to work on these and similar tasks in class and on homework (including inverse proportion tasks). They also received feedback on their work from the instructors in class and on homework.

The unit appeared to have little effect on students' tendency to use the proportion equation on the non-proportional Work and Running problems. (These specific problems were not discussed during the unit.) Table 1 shows how many students maintained or changed their responses for the Work and Running problems on the posttest ($N = 27$, one student was absent for the posttest) and serves to contextualize the data from the second interview described in the next section. We used McNemar's (1947) test for matched data and found that there was no statistically significant change in students' responses on these items ($p_{\text{Work}} = 1.00$, $p_{\text{Running}} > .450$). Students were almost entirely agreed on the Work Problem, but the consensus response was non-normative. By contrast, the proportion of normative responses on the Running Problem was not much different than that expected by chance.

Table 1: Student Pretest and Posttest Responses on Two Non-Proportional Problems

	Posttest Response			
	Work Problem		*Running Problem*	
Pretest Response	Proportional	Non-prop.	Proportional	Non-prop.
Proportional	25	1	9 2	
Non-prop.	1	0	5	11

The Second Interview

In this section, we report two cases where students clearly understood quantitative relationships that were not proportional in the problem but still endorsed the proportion equation.

Clara. (Alice did not participate in this interview because of a family obligation.) Clara began the Work Problem with confidence and set out to justify her use of the proportion equation by using a numerical example: 2/15 = 4/? . Then she paused for 35 seconds.

Clara: It is proportional, but it's going to be a proportion going down this way if the men were increasing [draws a line with negative slope] because if more men are working on the house then it's going to take fewer minutes. But if it takes 2 men 15 minutes then it's going to take one man 7.5 minutes so it is going to be proportional. I mean ... not 7.5, that doesn't make sense ... takes one man 30 minutes. It's proportional, it's just a decreasing proportion.

After working for 3 more minutes, Clara rejected her graph but not the proportion equation. A changed tone of voice suggested decreased confidence, but she remained adamant.

Clara: What I'm thinking is that as the amount of people painting the house increases the amount of time it takes to paint the house would decrease. I'm just not sure how to illustrate that. It would be a proportion, I feel it's proportional ... I just don't know how to represent it proportionally [in a graph].

Lisa and Tess. Both Lisa and Tess immediately decided that the Running Problem was proportional.

Interviewer: How do you know it's proportional?
Tess: Because if they run at the same pace this says they run laps together because they run at the same pace. Even if Marty starts before Bob, however many ... they're going to run at the same pace. So it's going to in ... like the amount difference is going to stay the same the whole time because they're running at the same pace.
Lisa: Mm-hmm [yes]. It's a constant increase …
Tess: Right, if Marty starts he runs two laps, and Bob starts. So by the time that he runs 4, by the time Marty runs 4 laps, Bob will have run 2 laps ... then 6, 4 ... 8, 6 ... so the same amount of increase every time.
Lisa: Yeah, and if you know the lap difference between the two then you can give me any value of laps and I can figure out where they are //*Tess*: Right// without having to go step by step like you do with interest problems.
Tess: Right.
Interviewer: So that's what tells you it's proportional?
Lisa: Yeah, because you're not factoring in time or anything. You're like ... I mean if you were to ask at twenty minutes then you'd have to factor in the time difference.

A little later in the interview, during the Work Problem, Tess continued in the same vein.

Tess: Right, or like on interest problems like every month there's five percent interest. She starts with this amount; then she puts this amount in each month, and then you have to also think about your

> interest and how that's affecting your amount. But this is just a same rate you know, like there's nothing adding in.

Discussion. In both cases, the students provide normative reasoning about how the quantities in the situation covary using specific numbers. Clara said, "If it takes 2 men 15 minutes ... [it] takes one man 30 minutes." Tess gave a sequence of example values for the consecutive pairs of laps run; "Marty runs 4 laps, Bob will have run 2 laps ... then 6, 4 ... 8, 6" The students clearly demonstrated accurate knowledge of the relationships among the quantities in the problem situations, yet in both cases the students endorsed the proportion equation.

The data from Clara contrast with her work during the first interview on the Running Problem, where she used similar quantitative understanding to normatively reject the proportion equation. In this case, contextual differences led to non-normative knowledge use. Clara read out the aspect of *more men, fewer minutes* and interpreted the Work Problem as a negative proportion problem like those discussed in class and on the homework.

In the case of Tess and Lisa, some of the data are consistent with the first interview. For example, Tess read out the aspect of *same pace*, and used this to judge that "the amount difference is going to stay the same the whole time." Lisa apparently agreed, saying, "It's a constant increase." But rather than moving directly from the aspect of *constant increase* to the proportion equation (that is, in parallel to how Lisa moved from the aspect of *same difference* to the proportion equation during the first interview), this pair referenced their course experiences with the Interest and Combine problems.

Lisa and Tess read out and used aspects of the Combine and Interest problems that would likely go unnoticed by experts. The Running Problem had a functional aspect for Lisa, "You can give me any value of laps and I can figure out where they are." By contrast, Tess and Lisa's work on the Interest Problem was iterative; they used each monthly total to compute the next. In the class discussion of the Interest Problem, Tess said, "You need to know all of the previous months to find the next month." Several other aspects of the non-proportional problems discussed in class distinguished them from the interview problems. For example, Lisa read out the time interval of 20 minutes specified in the Combine problem and used this as a warrant for non-proportionality. She said that the Running Problem would not be proportional "if you were to ask at twenty minutes." Moreover, both students agreed that to solve the Interest and Combine problems, one had to "factoring in" an extra quantity like time or interest. In the Running and Work problems, Tess observed, "there's nothing adding in." Tess's and Lisa's knowledge resources were evidently refined and reorganized to incorporate their experiences in the course but their judgments remained non-normative.

Implications and Conclusion

The quantitative results of this study provide a partial replication with preservice middle-grades teachers of prior results with elementary and secondary teachers (e.g., Cramer et al., 1993; Fisher, 1988; Riley, 2010) showing that teachers face some of the same challenges as children when reasoning about situations involving non-proportional covariance. Recent research (e.g., Van Dooren, De Bock, Vleugels & Verschaffel, 2010) suggests that thinking about problems rather than answering reflexively is necessary if students are to avoid applying the proportion equation in non-proportional situations. The qualitative data reported here warrant a much stronger claim: Even a detailed understanding of the relationship between covarying quantities may not be sufficient for the normative use of proportionality. These results suggest a sobering assessment of the pedagogical challenge faced by teacher educators. Preservice teachers may need a broad and coordinated collection of fine-grained knowledge resources developed in a wide variety of contexts in order to distinguish between covariance relationships and to apply the proportion equation appropriately across contexts and problem situations.

TOWARDS EXPERT CURRICULUM USE: DEVELOPING A MEASURE OF PRE-SERVICE TEACHERS' CURRICULAR KNOWLEDGE

Tonia Land
Drake University
tonia.land@drake.edu

Corey Drake
Michigan State University
cdrake@msu.edu

The overall purpose of this study is to develop a measure of elementary mathematics teachers' curricular knowledge (Shulman, 1986) and curriculum use practices. In this paper, we present the first step in this larger effort—the piloting of one set of questions that document pre-service teachers' (PSTs') knowledge and practices for reading, evaluating, and adapting a Standards-based curriculum lesson. We present the range of responses elicited from 34 PSTs related to the goals and purposes of the lesson, the strengths and weaknesses of the lesson, and possible changes to the lesson. These survey questions and our findings about the range of PSTs' responses to the questions are intended to help researchers further develop the constructs of curriculum use and curricular knowledge.

Keywords: Curriculum; Elementary School Education, Teacher Education–Preservice, Teacher Knowledge

Introduction

The overall purpose of this study is to develop a measure of elementary mathematics teachers' curricular knowledge (Shulman, 1986) in order to document the development of this knowledge as PSTs move through elementary mathematics methods and then into student and novice teaching. Mathematics curriculum materials are ubiquitous and often mandated in elementary classrooms, yet the field of mathematics education has few tools for developing and measuring teachers' knowledge related to using these materials in productive ways. In this paper, we present the first step in this larger effort—the piloting of one set of questions that document PSTs' knowledge and practices for reading, evaluating, and adapting a *Standards*-based curriculum lesson.

Theoretical Framework

We understand these practices—reading, evaluating, and adapting curriculum materials—to be part of a larger construct of expert curriculum use that incorporates many of the aspects of curricular knowledge described by Shulman (1986). In our work, we have begun to develop a conjectured learning trajectory describing teachers' curriculum use practices from initial curriculum use (beginning of the methods course) to expert curriculum use. Our definition of expert curriculum use draws from a substantial body of work that has been conducted in the past several years, including the work of Remillard (2005; Remillard and Bryans, 2004), Brown (2009), Sherin and Drake (2009), and Taylor (2010).

Taken as a set, this work suggests that the teachers' curriculum use is a dynamic, interpretive, and interactive process in which both teachers and materials contribute resources in the design and enactment of instruction. "Expert" curriculum users seem to have (1) curriculum vision—an understanding of the goals of the curriculum, as well as strategies for using the curriculum materials to reach those goals (Cirillo & Drake, in revision); (2) particular strategies for reading, evaluating, and adapting curriculum materials in productive ways (Sherin & Drake, 2009); (3) practices for using curriculum materials to accomplish instructional goals (Brown, 2009); and (4) strategies for "systematically" adapting curriculum materials to meet the needs of students (Taylor, 2010). The portion of the curriculum use survey that we describe in this paper focuses on the second set of practices—reading, evaluating, and adapting curriculum materials. Our ultimate goal is to develop a measure that reflects all of these components of expert curriculum use, as well as additional features of curricular knowledge as described by Shulman (1986).

Methods and Data Sources

Participants

We piloted the survey with 34 PSTs enrolled in a small liberal arts university located in the Mid-West. Thirty-one participants were female; three were male. Seven took the survey at the beginning of a semester-long elementary mathematics methods course that included a focus on the use of *Standards*-based curriculum materials, and the remaining PSTs took the survey at the end of the course. For this study, responses from the beginning and end of the semester were combined into a single set of responses in order to identify and describe the range of PST responses.

Description of Lesson

The curriculum use questions focus on a first-grade lesson from *Math Trailblazers* (University of Illinois at Chicago, 2008a). The lesson begins by presenting several numbers (e.g., 125) to students and asking them what those numbers mean. In the materials, anticipated student responses are listed (e.g., 5 groups of 25, 12 groups of 10 with 5 left over). During student exploration time, students consider the number 172 and represent it in any way they choose. Next, they share their representations with a partner, and then a whole group discussion occurs.

Data Collection and Analysis

The survey consists of 18 questions. For the purposes of this study, we selected six questions:

<u>Reading</u>

1. As a teacher, what would be your specific goal(s) for your students' learning with this lesson?
2. On page 37 in the first bullet point under the assessment heading, the lesson plan states, "Even though counting by ones is an inefficient strategy, it works if done carefully." What does that mean?

<u>Evaluating</u>

3. Does this lesson have multiple entry points? In other words, is the task accessible to a wide-range of learners? Explain.
4. When thinking about student learning, what are the strengths and weaknesses of this lesson?

<u>Adapting</u>

5. If you would make changes to this lesson, what would they be?
6. Another pair of students represented 172 with 6 groups of 25 and had 22 left over. What would you say to or ask these students after they have shared their solution?

The first two questions were designed to measure PSTs' *reading* of the curriculum materials by asking them to explain the learning goals and meaning of a selected phrase from the materials. The third and fourth questions addressed PSTs' *evaluation* of the materials by asking them to assess the lesson against the concept of "multiple entry points" discussed in class and determine the strengths and weaknesses of the lesson. The last two questions allowed PSTs to describe the ways in which they might *adapt* the lesson after having read and evaluated the curriculum materials and respond to a particular solution strategy.

Each survey question was analyzed separately through a process of open and emergent coding (Strauss & Corbin, 1998). For each question, a set of codes was generated that illustrated the type of survey responses. Codes will be presented in our results section. Our goal at this point in the development of the survey is to capture the range of possible PST responses to each item in order to further refine the survey.

Results

In this section, we present results from the six survey questions in sections related to each of reading, evaluating, and adapting curriculum materials.

Reading Curriculum Materials

PSTs' goals (Question 1) for teaching the 172 Lesson were categorized using three primary codes. Responses were categorized as *procedural* if they focused on counting/grouping; as *conceptual* if they focused on the understanding/meaning of number and/or place value; and as with *connections* if there was explicit mention of making connections across multiple strategies and/or representations. Responses could be any combination or all of the above three codes, which led to six types of goal responses. Table 1 summarizes the response to Question 1.

Table 1: Responses to Question 1 (Goal Question)

Number of PSTs	Type of Response	Example
7	Procedural	Counting and grouping objects that are greater than 100.
11	Procedural with Connections	Students will be able to represent numbers greater then 100 using manipulatives and words. Students will be able to group objects by ones, tens, and hundreds.
3	Conceptual	My goals for this lesson would be for the students to understand what 3 digit numbers mean and to be able to talk about and explain them.
1	Conceptual with Connections	To have students talk about the meaning of a number, represent a number by a picture, and use different objects to represent a number.
5	Procedural and Conceptual	As the teacher, my specific goal for this lesson would be that the students group numbers between 101 and 199 in a way that shows that they understand place value.
6	Procedural and Conceptual with Connections	Understanding place value, hundreds, tens, and ones. Being able to break numbers into parts and recognize they belong to a whole representing numbers with pictures or symbols grouping and counting objects by ones, tens and hundreds.

In the curriculum materials, the goals were listed as the following:

- Representing numbers greater than 100 using manipulatives, pictures, symbols, and words
- Grouping and counting objects by ones, tens, and hundreds. (University of Illinois at Chicago, 2008b, p. 33)

Using our coding scheme, the above goals would be categorized as procedural with connections, which makes these results particularly interesting to us. We conjecture that the curriculum authors had a conceptual purpose in mind when writing these goals, but that purpose was not explicit in the materials. Identifying a conceptual goal for the lesson required a significant amount of interpretive work while reading the lesson, and we found that many of the PSTs (15/33) did engage in that work.

For Question 2, PSTs were asked to interpret the following statement: *Even though counting by ones is an inefficient strategy, it works if done carefully*, there was a wide range of responses. Each response was coded with one or more of the following codes—*better ways* if the PST stated there were "better ways" to count or represent 172 than counting by ones; *specific limitation(s)* if the PST stated one or more limitations of counting by ones; *another strategy* if the PST suggested another strategy that students should use; *it works if careful* if the PST stated the strategy works, but students need to be careful; *count by ones* if the PST discussed that it is expected that some students will counts by ones to represent 172; and *acceptable strategy* if the PST seemingly took a stance for students who wanted to use that strategy. Table 2, along with some text after the table, summarizes the responses to this question.

Table 2: Responses to Question 2 (Interpreting a Phrase)

Number of PSTs	Type of Response	Example
16	Specific Limitations	This means that it takes longer to count three digit numbers by ones, and is more prone to mistakes because of the tediousness of the strategy.
7	Better Ways	Counting by ones is not the quickest way to assess a large number of items. It does work, but there are better ways to do it.
6	Counts by ones	It is expected that some students will count by ones even though the number is so large. When it states, "it works if done carefully," I think they are saying that if is ok that students do that.
4	Acceptable Strategy	The purpose of this lesson is counting 172, not grouping 172. If the student's method is counting by ones and they are getting the correct answer, then they are completing the lesson. From this foundation, you can build with them an understanding of grouping and they may change their method of counting as they grow older.

Of the 16 PSTs who stated one or more specific limitations of the counting by one strategy, five mentioned another strategy (e.g., grouping larger numbers) students could use and six mentioned that the strategy works if it is done carefully. Of the seven PSTs who stated that there are better ways to count 172, three also mentioned specific limitations of the strategy while another mentioned the strategy was OK to use. Of the six PSTs who thought it would be expected for students to count by ones, one PST also said that it was okay to do. In this set of findings, the role of PSTs' beliefs is clear, particularly their beliefs about how children learn mathematics. Many PSTs elaborated the aspect of the statement that counting by ones is an inefficient strategy by describing in one or more ways how counting by ones is inefficient. Others perceived the statement as saying that some students will need to count by ones to solve the problem and/or that strategy is acceptable.

Evaluating Curriculum Materials

Responses to the third question about whether or not the 172 Lesson had multiple entry points were first sorted into yes or no categories. Eight PSTs did not think the lesson had multiple entry points and all eight stated that this was because only one number was given for students, although some of the eight noted that this number could be adjusted by the teacher, as in the example response in Table 3. Twenty-six of the 34 PSTs thought that the lesson *did* have multiple entry points. For those 26 responses, a set of codes was developed to describe PSTs' reasoning. A response was coded as *student develops/uses own strategy* if the PSTs discussed that the students could develop or use their own strategy to represent 172; *number can be changed* if the PST thought the number could be changed to meet the range of learners in the classroom; and *count by ones* if the PSTs discussed the idea that if students could count by ones to represent 172, then the lesson had multiple entry points. Table 3 summarizes these responses.

Table 3: Responses to Question 3 (Multiple Entry Points)

Number of PSTs	Y/N	Type of Response	Example
8	No	Only one number choice	There is only one number choice provided for the students to work with and it is in the high range of the 100's. Thus, I would provide additional number choices of one slightly above 100 like 112 and another number choice in the middle (e.g.132) to provide access to a greater range of ability levels.
14	Yes	Student develops/uses own strategy	There are multiple ways to draw 172 beans, but there really isn't a clear "solution.” They already know there are 172 beans and have to draw them. The only different will be how they drew it.
4	Yes	Number can be changed	For slower or higher learners, you could adjust the number of beans to an easier or more difficult number, and give more or less support to the students as needed.
3	Yes	Students develops/uses own strategy and Number can be changed	I think the lesson has multiple entry points. The lesson doesn’t specifically give a way to illustrate the number. I think students could represent it in a lot of different ways. Because of the number, the lesson may be harder for lower level students. I would adjust the number for a different range of learners.
2	Yes	Count by Ones	As long as students know the number about 100 and can count by ones, then yes it is accessible to wide-range learners.

All but three responses could be sorted into our above codes. Of those three responses, one talked about targeting multiple learning styles, another mentioned the teacher being able to ask students to count in a certain way, and the third suggested that the lesson did a good job of providing manipulatives. Another noteworthy finding was that four PSTs suggested alternative number choices as in the first example above. Many PSTs focused on the idea of offering multiple choices as a way to provide multiple entry points for students, or PSTs focused on the idea that students could develop their own strategies. Three PSTs thought a combination of those two ideas provided multiple entry points.

PSTs were asked to list the strengths and weaknesses of the 172 Lesson in Question 4. For this response, we developed a set of 12 codes that categorized ideas listed as strengths or weaknesses. In Table 4, we list the code and how many times it was mentioned as a strength and weakness.

Although the PSTs listed a wide range of strengths and weaknesses, we can identify some important themes in looking across their evaluations of the lesson. First, the PSTs focused a great deal on the students’ role in the lesson, with “Student-directed” and “Multiple Strategies” as the most common strengths. The most commonly noted weaknesses were in the structure of the lesson (e.g., the lack of an opening routine, the use of worksheets) and that the lesson was perceived as too challenging for some students and not challenging enough for others. Finally, many aspects of the lesson that were viewed as a strength by some PSTs were also viewed as a weakness by other PSTs, suggesting that PSTs vary widely in their evaluations of lessons.

Table 4: Responses to Question 4 (Strengths and Weaknesses)

Code	Frequency as Strength	Frequency as Weakness
Student-directed	14	4
Multiple Strategies	15	1
Lesson Structure	3	10
Interactions	10	2
Too challenging or not challenging enough	0	11
Concrete	8	1 (Abstract)
Differentiation – lack of/can be/cannot be	7	2
Assessment	4	4
Number Choice	1	3
Teacher-directed	2	2 (lack of)
Affective (e.g., enjoyable, comfortable)	3	0
Connection to real-life	1	2 (lack of)
Connection to more advanced mathematics	1	0

Adapting Curriculum Materials

Eleven PSTs would not make any changes to the given lesson. The remaining PST responses fell into three categories—would provide multiple number choices, would change aspects of the lesson that did not affect the overall approach in lesson, and would practice a model beforehand or give example. Table 5 summarizes responses to Question 5.

Table 5: Responses to Question 5 (What changes would you make?)

Number of PSTs	Type of Response
11	Would make no changes
11	Would provide multiple number choices
7	Would change aspects of the lesson (e.g., add opening routine, count something more meaningful to students) that did not affect overall approach in the lesson
4	Would practice a model beforehand or give example

It was not surprising to us that the most frequent adaptation (N = 11) was to provide multiple number choices. The result can be explained, in part, by the fact that these PSTs were in a methods course in which they had many opportunities to observe and reflect on lessons that provided multiple number choices for students. Seven other PSTs thought they would change aspects of the lesson that did not affect the overall approach in the lesson and four wanted to provide a model or example before the students began to work.

Question six pertained to how PSTs might question students as they engaged with the 172 Lesson: *Another pair of students represented 172 with 6 groups of 25 and had 22 left over. What would you say to or ask these students after they have shared their solution?* Responses were categorized according to which aspect of the solution PSTs questioned. In a few instances, a PST questioned multiple aspects of the solution. Table 6 summarizes the foci of PSTs questions.

Table 6: Responses to Question 6 (Questioning students about solution strategy)

Number of PSTs	Foci of Question
8	Questioned if there was another way to group or represent the leftover 22.
7	Questioned students as to why they used groups of 25.
4	Questioned if there was another way to group or represent 172 due to having 22 leftover.
4	Asked another type of question about the strategy (e.g., any patterns)
3	Questioned students as to why they used groups of 25 and if there is another way to group or represent the leftover 22.
2	Questioned if there was another way to group or represent 172.
2	Questioned if there was a way to consolidate the groups of 25.
3	Other

Most interesting to us was how PSTs reacted to the leftover 22 given that the curriculum materials listed the grouping by 25 strategy as an anticipated student response and the connection to money. Nine PSTs (second and sixth rows) asked if there was another way to group or represent the leftover 22 even with the other groups of 25 as in this response: "I would say, "how can we group the leftover 22 in an organized way? How could we split those 22 beans into 5 groups?" Another four PSTs wanted students to regroup the 172 entirely due to the leftover 22 as in the following response: "Could you have made less groups of more beans in order to not have so many left over?" Two others wanted students to consolidate their groups of 25.

Quite opposite from the disdain for the grouping by 25 strategy, was the response from one PST, who fell in the other category, as he/she made the connection (not the students) to money in their response. That response is given below:

> That's another great idea as we know that just like in a dollar there are 4 quarters (25), right? (relating it to a real life situation) then break it down further like 2 quarters in 50 cents, so there would be 22 ones left over (if you are thinking in those terms).

The other responses seemed not to value or dis-value the grouping of 25 strategy, as PSTs are just asking students to explain why they grouped by 25 or if there was another way to group or represent 172. The intent of these responses may be to support or extend student thinking.

Implications

This study is a step towards understanding expert curriculum use. These survey questions and our findings about the range of PSTs' responses to the questions can help researchers further develop the constructs of curriculum use and curricular knowledge, through an understanding of ways in which PSTs read, evaluate, and adapt curriculum materials. At the same time, these findings might support mathematics teacher educators in designing learning experiences for PSTs that contribute to the development of PSTs' curriculum use practices. This study also contributes to the field by providing a measure for documenting growth in teachers' curricular knowledge—an important knowledge base for teaching first identified by Shulman (1986). Ultimately, this measure, and others like it, can be used to understand PSTs' growth in knowledge and practices as they progress through teacher education courses and programs.

This study investigates cognitive difficulties and mathematical ideas that are related to making connections among representations. A three-week intervention was designed and implemented to help prospective secondary mathematics teachers develop understanding of big ideas that are critical to connection of representations in algebra. This study finds that most participants had difficulties with the concept of variable, the Cartesian connection, and its related idea, graph as a locus of points, and held incomplete concept definitions and concept images of conic curves. During the intervention, however, many showed signs of progress. Many who were initially dependent on memorized forms of algebraic formulas made efforts to consider aspects of the Cartesian connection to make sense of their work.

Keywords: Teacher Education–Preservice; Teacher Knowledge; Algebra and Algebraic Thinking; Advanced Mathematical Thinking

Objectives

The purpose of this study was to investigate cognitive obstacles and mathematical ideas related to making connections among representations and how prospective teachers' thinking progressed while they worked on tasks that were designed to bring out these cognitive issues. The importance of representations in mathematical understanding is well documented (Brenner, Mayer, Moseley, et al., 1997; Knuth, 2000; Moschkovich, Schoenfeld, & Acavi, 1993), and students' learning of mathematics through representations is recommended in the Principles and Standards for School Mathematics (NCTM, 2000) and the Common Core State Standards (CCSI, 2010). However, not much is known about cognitive obstacles or ideas that are involved in making connections among representations or how to help students develop mathematical understanding through connection of representations (Bosse, Adu-Gyamfi, & Chetham, 2012; Even, 1998) except that even mathematically capable individuals have compartmentalized understanding of mathematical representations (Gagatsis & Shiakalli, 2004; Hitt, 1998; Vinner, 1989). Making connections among representations is one of the big ideas in mathematics education (Lacampagne, Blair, & Kaput, 1995; Knuth, 2000) and more research is needed to understand this complex, yet critical issue.

This study is a component of a larger project intended to develop and study a mathematics curriculum for prospective secondary mathematics teachers. This report specifically deals with a three-week unit designed to promote understanding of algebra through the connection of representations. Twenty prospective secondary mathematics teachers participated in this study. Qualitative research methods were employed in order to delve into cognitive difficulties and ideas that are related to the connection of representations and to document how student understanding evolved during the unit.

Theoretical Framework

In the mathematics education community, representations are regarded as critical tools for mathematical communications and problem solving (Brenner et al., 1997; Goldin & Shteingold, 2001; Hiebert & Carpenter, 1992; Hollar & Norwood, 1999; Mousoulides & Gagatsis, 2004; Thompson, 1994). However, it has known that mere representation of a mathematical concept in a certain mode of representation is not enough for mathematical understanding. In order to understand mathematical concepts or to be successful in problem solving, learners need to be able to connect representations. They need to be able to not only recognize ideas embedded in various representations but also convert a representation in one form to another and translate ideas from one representation to another within and across various representations (Borko & Eisenhart, 1992; Dufour-Janvier, Bednatz, & Belanger, 1987; Even, 1998; Hitt, 1998; Gagatsis & Shiakalli, 2004; Knuth, 2000; Lesh, Behr, & Post, 1987).

Many researchers have investigated how learners attempt to connect various representations of functions, a concept critical to much of algebra and higher mathematics. For example, Knuth (2000)) showed that the Cartesian connection—"a point is on the graph of the line L if and only if its coordinates satisfy the equation of L" (Moschkovich et al., 1993, p. 73)—is related to students' problem solving ability where they must connect symbolic and graphical representations of linear functions. Hitt (1998), Williams (1998), and Hansson (2005) have shown that teachers' inability to use subconcepts, such as variables and domain/range, affected their problem solving. Following up on the ideas posed by Knuth (2000) and other researchers cited above, a primary focus of this research was to examine how learners' understanding of critical mathematical ideas (that are related to connections among representations), such as the Cartesian connection, interacts with their abilities to connect representations and/or their problem solving ability.

In order to address this issue, we designed a unit focusing on representations in algebra. The unit, indeed the entire course, was developed and implemented along with the educational and philosophical principles of *realistic mathematics education* (Freudenthal, 1991; Gravemeijer, 1999) and *constructivist learning theory* (Cobb, Yackel, & Wood, 1992). As such, mathematical understanding in the course and hence in this study was regarded as social construction (or reconstruction) of ideas through mathematical communications and collaborations while learners are actively engaged with "realistic" (Gravemeijer, 1999) tasks.

For this study, we restrictively use the term, representations, in regard to only four types of representations in algebra—algebraic, spatial, numeric, and verbal representations. We also extended the notion of the Cartesian connection to "a point is on the graph of the mathematical relation, $R(x, y) = 0$ if and only if its coordinates satisfy $R(x, y) = 0$" in order to accommodate this idea to other mathematical relations with two variables, conic curves in this case.

The constructs of *concept definition* and *concept image* (Tall & Vinner, 1981; Vinner, 1991; Vinner & Dreyfus, 1989) are utilized as a tool to understand participants' cognitive structures relating to conic curves. According to Vinner and others, an individual's understanding of a concept is related to her verbal definition of the concept (concept definition) and her non-verbal image of the concept (concept image). When her concept definition and her concept images are aligned with the *formal concept definition* (the one accepted by the mathematics community), she can solve non-routine problems or prove theorems by successfully consulting both the definition and the image (Vinner, 1991). As with other studies concerning learners' understanding of mathematical concepts (Bangi, 2006; Bingolbali & Monaghan, 2008), this construct aided us to understand the mathematical thinking and understanding of the participants.

Methods

Research Setting

This research was conducted in an inquiry-based classroom during the winter quarter, 2009, when a three-week teaching unit focusing on Algebra was implemented. 20 prospective secondary mathematics teachers (PSMTs), mostly juniors and seniors majoring in mathematics, participated in this study. The Algebra unit started with the opening activity, a discussion of symbolic and spatial meanings of the solution of the algebraic equation $x^2 = 2$, followed by the major task, an interpretation of the historical work by Omar Khayyam (1048–1131). PSMTs were asked to figure out how Omar Khayyam's geometric approach to the solution of a cubic equation made sense, i.e., how an intersection point of the parabola $py = x^2$ and the circle $x^2 + y^2 = qx$, with p and q positive integers, determines the solution of the algebraic equation $x^3 + p^2x = p^2q$. This task involved three subtasks: (a) graphing the circle represented by algebraic representation $x^2 + y^2 = qx$ and proving why the formal concept definition of circle defines the equation of circle, (b) deriving the equation of a parabola based on the concept definition of parabola, and (c) explaining how the solution of $x^3 + p^2x = p^2q$ is represented spatially. During the Omar Khayyam task, two quick writes were administered to examine PSMTs' understanding of representations, the one examining PSMTs' abilities to connect the concept definition and the algebraic representation of circle, and the other examining their abilities to connect algebraic and geometric representations.

All sessions were videotaped using two video cameras. PSMTs' responses to quick-writes and group posters that they prepared for the presentations were also collected.

Methods of Analysis

For the analysis, we adopted and modified an analytic method by Powell et al. (2003), designed for research using video data. At first, we viewed the video recordings and prepared a brief, written record of the video content. The written record at this stage included rough transcriptions of some episodes and focused on mathematical activities, situations, and meanings (Powell et al., p. 416). We also roughly viewed PSMTs' quickwrites to get a sense of their responses. We then developed a priori codes, based on the research framework, research questions, and the problematic areas of the mathematical investigations that were found from the viewing of video recordings, quickwrites, and posters (Miles & Huberman, 1994). With these observational codes, we rewatched the video recordings and reexamined the written data. At this stage, we revised the codes by identifying more codes and constantly comparing with the existing codes (Glaser & Strauss, 1967), and identified *critical events*—significant moments showing learners' cognitive difficulties, conceptual leaps from previous understanding, or intuitive mistakes (Powell et al., 2003). At the next stage, we prepared word-to-word transcripts of the portion of the video data, including critical events and other episodes that "provided evidence for important theoretic or analytic matters to our guiding research questions" (Powell et al., 2003, p. 423). The new transcription data, combined with the written data, then, put through another phase of analysis for the accuracy and the consistency of the results.

Results

The Case of Circle

Most PSMTs knew the definition of circle correctly, as "the collection of points equidistant from a point". However, their algebraic concept image of circle, $(x - a)^2 + (y - b)^2 = r^2$, and the spatial concept image of circle were compartmentalized or existed without proper understanding of the roles of variables x and y or constant r.

Only one out of five groups (each group had 4 PSMTs) successfully transferred the algebraic representation, $x^2 + y^2 = qx$, to its graphical representation, the circle with the center $(q/2, 0)$ and the radius $q/2$. Three groups transferred the equation, $x^2 + y^2 = qx$, to a circle centered at the origin, with radius labeled $\sqrt{qx}$, by taking the left part of the equation, $x^2 + y^2 =$, as a process of drawing a circle with center (0, 0) and qx as the square of the radius, without paying attention to the variable x. In subsequent class discussions, they also showed lack of understanding of the Cartesian connection. Although these groups had an understanding that $x = 0$ and $y = 0$ satisfy the equation, $x^2 + y^2 = qx$, they were unable to translate this idea to the graphical representation in that they did not recognize that the graph of $x^2 + y^2 = qx$ had to pass through the origin. One group transferred $x^2 + y^2 = qx$ to a bow-tie figure passing through the origin (see Figure 1). Although this group's graph passes through the origin, they did so because they believed that their "radius" $\sqrt{qx}$ approached 0 as x approached 0. Understanding of the concept of variables in graphical representations or the Cartesian connection was absent in most of these students.

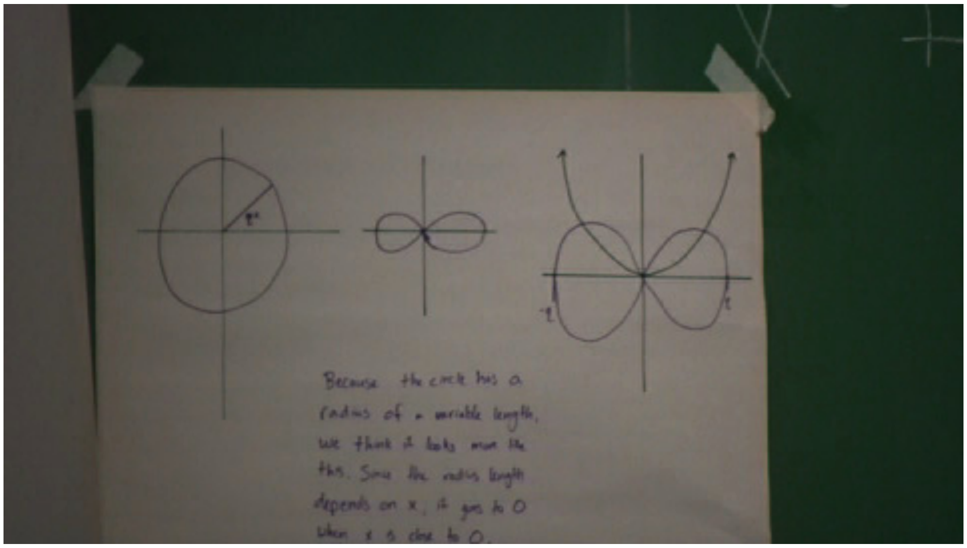

Figure 1: Representation of circle and parabola

The Case of Parabola

Only one out of 20 PSMTs knew the concept definition of parabola—the locus of points equidistant from a point, called focus, and a line, called directrix. When they were asked to find the equation of parabola with the focus $(0, f)$ and the directrix $y = -f$ given, the vast majority had no clue how to start. For them, a parabola was given by the equation $y = ax^2$ or $y = a(x - h)^2 + k$ where the only meaningful information they could draw from these expressions were the vertex (h, k) and the coefficient a, and their discussion was mainly about the concavity of the parabola, how wide the parabola was depending on the value of a, or how to shift $y = ax^2$ to $y = a(x - h)^2 + k$ using vertical and horizontal translations. Only after being reminded by the instructors that their job was to derive the equation of parabola using the definition of parabola and that they could name a random point that is equidistant from the focus and the directrix as (x, y) in the Cartesian plane, did they attempt to interpret the definition of parabola to come up with some kind of algebraic equation. Even then, a lengthy discussion within their group and with the instructors was required to reach to the algebraic representation, $x^2 = 4fy$. Although they seemed to understand that x, y represent variables in an algebraic relationship, $r(x, y) = 0$, they did not understand that (x, y) could represent varying coordinates in the geometric context. Most of them also did not understand or use the idea that a graph of a mathematical relation is a locus of points whose coordinates satisfy the relation even if they had heard the definition multiple times from their classmate and instructors. Many of them had difficulties in translating mathematical concepts, such as distance and equivalence, from verbal/geometric representations to algebraic representations.

Connecting the Solution of the Cubic to the Intersection Point of the Circle and Parabola

For PSMTs, finding the relationship between the real solution of the cubic $x^3 + p^2x = p^2q$ and the point of intersection of the parabola and the circle was difficult as well. Two groups falsely claimed that the solution of the cubic equation was the distance between the point of intersection and the origin or the distance between the point of intersection and the focus of the parabola (The actual solution of the cubic equation was the x-coordinate of the non-origin intersection point of two graphs). The examination of PSMTs' quickwrites also suggested that they fell short in understanding the relationship between algebraic and graphical representations. In one of the two quickwrites, only 5 out of 18 PSMTs specified that the solution of a system of linear equations, $2x + y = 10$, $x + 2y = 8$, was the x, y coordinates of the point of intersection $(4, 2)$, discriminating the point $(4, 2)$ on the plane from its coordinates $x = 4$ and $y = 2$, another evidence for their lack of understanding of the Cartesian connection. For them, splitting a single object, a point (x, y) in the Cartesian plane, into two objects, its coordinates x and y, or using x as a distance between the point (x, y) and the y-axis in their descriptions was very challenging.

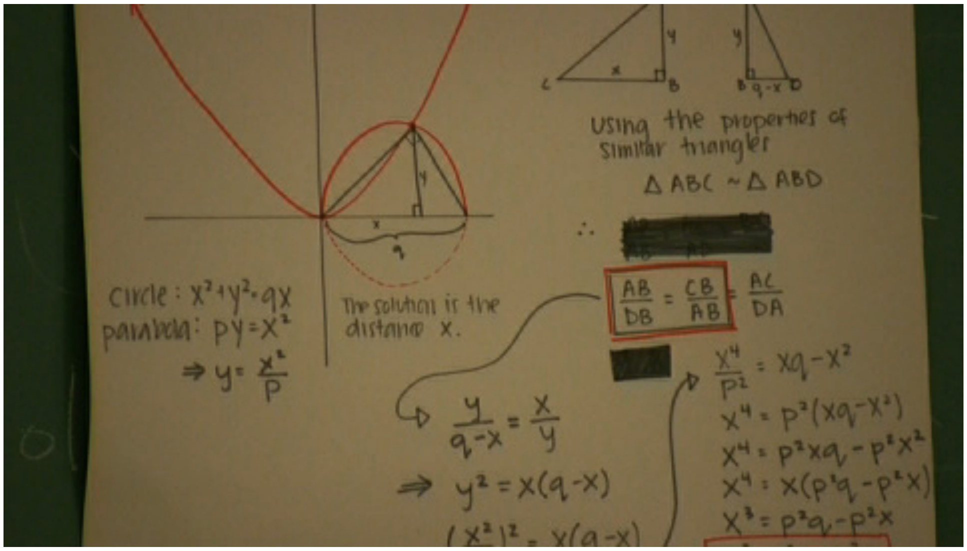

Figure 2: Graphical to algebraic transfer

Toward the end of the Omar Khayyam task, however, there were many signs that PSMTs were making progress in connecting representations. For example, one group showed the relationship between the algebraic representation of a circle $x^2 + y^2 = qx$ and the graph of circle with center (q/2, 0), by incorporating a concept in geometry—the proportionality of similar triangles—into the Cartesian coordinate system (Figure 2). This group first showed that $y/(q - x) = x/y$ and then derived the equation $y^2 = x(q - x)$ by cross-multiplying, which then can be transformed into $x^2 + y^2 = qx$. Their work, finding an analytic expression of circle using geometric properties on the Cartesian plane, as Descartes did, was remarkable progress, compared to their initial work on the Omar Khayyam task. In the beginning, they mostly focused on formulas and algorithms of which they did not make much sense. Two other groups also came up with explanations how Omar Khayyam could have represented his solution and idea in his period. The importance of verbal, spatial, and algebraic representations in understanding algebra was embedded in the groups' work.

Conclusion

This study found that without interventions prospective secondary mathematics teachers were largely dependant on memorized formulas or algorithms rather than focusing on meanings and ideas in connecting algebraic equations and their Cartesian graphs. Their problem solving was handicapped by incomplete concept images and definitions of circles and parabolas, similar to learners in the other studies on the concept of function (Even, 1993, 1998; Vinner, 1991; Vinner & Dreyfus, 1989; Williams, 1998). In the case of circle, although most of them acknowledged the formal definition of a circle, they were unable to prove why the definition gives the equation of circle. In the case of parabola, most of them had no knowledge of the definition of parabola or the subconcepts of focus and directrix. Even after they were reminded of the definition repeatedly by their classmate and by the instructors, they had difficulties in translating the ideas in the definition to an algebraic representation.

This study also affirms that the Cartesian connection, the idea that connects algebraic and graphical representations of a line (Moschkovich et al., 1993; Knuth, 2000), is a critical idea to connect representations in the concept of conic curves. The concept of variable and a graph as a locus of points—an extended idea of the Cartesian connection with the concept of variable intertwined—were also identified as critical ideas in making connections of representations.

Through the intervention, prospective teachers made some progress. During the three-weeks of instruction, we saw some positive changes in prospective teachers' mathematical thinking and behaviors and progress in understanding Omar Khayyam's solution to cubic equations. Many prospective teachers who initially were dependent on memorized forms of algebraic formulas made efforts to consider aspects of the Cartesian connection to make sense of their own work. Their exposure to these critical ideas and concepts also helped them analyze students' thinking. In the subsequent activities that dealt with students' understanding of algebra (which will be documented in a later article) they tried to relate many of these same issues that they experienced to students' cognitive difficulties and understandings in algebra.

An implication of this study is that teacher education programs might have to pay special attention to these critical ideas so that their graduates can better help their future students understand connections among algebraic equations and their Cartesian representations. This study shows one of those examples. Using a historical task of Omar Khayyam in accordance with the principles of realistic mathematics education (Freudenthal, 1991; Gravemeijer, 1999), we provided prospective teachers opportunities to reconstruct these critical ideas that are essential for their own understanding of algebra and for their future instruction. Further, by providing subsequent tasks with which prospective teachers could discuss student mathematical thinking around the same issues that they had experienced, we tried to provide them opportunities to develop pedagogical content knowledge along with subject matter knowledge.

Connection among representations is identified as one of the "big ideas" (Lacampagne, Blair, & Kaput, 1995; Schifter & Fosnot, 1993) in algebra by many researchers (Knuth, 2000). Understanding the role of the Cartesian connection and the idea that a graph is a locus of points that satisfy a relation in sense making about the connections between symbolic and graphical forms is a crucial piece of pedagogical content knowledge that secondary teachers need to be familiar with. Only when a teacher is aware of the importance of this big idea and hold the understanding of the big idea, can she teach for the big idea (Schifter & Fosnot, 1993; Schifter, Russel, & Bastable, 1999).

TEACHER IDENTITY AND TENSIONS OF LEARNING TO LEVERAGE STUDENT THINKING IN MATH TEACHING

Jill Neumayer-DePiper
University of Maryland
j.neumayer.depiper@gmail.com

In mathematics teaching, high-leverage practices include eliciting, analyzing, and responding to students' ideas and reasoning (Kazemi, Franke, & Lampert, 2009). While a focus on student thinking in professional development can be a powerful mechanism for linking pedagogy, mathematics, and student thinking, it is less clear how to support teacher candidates (TCs) to leverage student thinking in their mathematics teaching. Findings suggest developing an understanding of self as mathematics teacher relates to TCs' capacity for leveraging student thinking as a pedagogical practice and for making sense of their relations to the complex dynamics in schools. The tensions TCs experienced when leveraging student thinking in the actual socio-political contexts and constraints of schooling and the influence of their identity on their representations of practice lead to implications for mathematics teacher education.

Keywords: Teacher Identity; Teacher Education–Preservice, Instructional Activities and Practices

There is emerging consensus in education research of importance of teachers' attention to "high-leverage practices" (e.g., Ball & Forzani, 2009). In mathematics teaching, high-leverage practices include eliciting, analyzing, and responding to students' ideas and reasoning (Kazemi, Franke, & Lampert, 2009). By focusing teachers' attention on students' reasoning and then leveraging their thinking in instruction, teachers validate students' mathematical thinking and support all students in making connections, solving authentic problems, and participating in the discipline (Windschitl, Thompson, & Braaten, 2011).

A focus on student thinking in teacher professional development has also been shown to be a powerful mechanism for linking pedagogy, mathematics, and student thinking (e.g., Franke & Kazemi, 2001). As teachers struggled to make sense of students' thinking, they elaborated on how problems were posed, asked each other questions, and learned about their students and their practice. Student work thus promoted collective inquiry into relations between teaching and learning and supported teachers' experimentation in their classrooms (Franke & Kazemi, 2001).

Objectives or Purpose of Study

While research suggests that elementary teacher preparation should support teacher candidates (TCs) in development of practices such as leveraging student thinking, research with TCs is less widely documented. Attention to student thinking in teacher education and inquiry into instructional practices has been hypothesized as a way to support TCs' understanding of teaching and student learning as well as their enactment of practices of leveraging student thinking (Windschitl et al., 2011). I contend that to support TCs in leveraging student thinking, math teacher education must prepare TCs to enact these practices *while* navigating the many social, political, and institutional dynamics in math classrooms and schools that complicate and regulate teacher practice and construct images of being a math teacher.

The following response from Laura, a teacher candidate in an intensive elementary masters' certification program, underlines this point. Laura is a White female in her late-twenties from a middle-income background. While her age, ethnicity, and socioeconomic class are consistent with what educational research labels as the "typical preservice teacher" (Lowenstein, 2009, p. 166), the following discussion is not meant to present TCs as learners who have deficient resources or experiences from which to build on when it comes to learning about issues of mathematics learning or teaching for equity. The goal, instead, is to illustrate the complexity of Laura's positioning as an elementary mathematics teacher and how she understands it.

Laura participated in a seminar on critical self-examination and mathematics teaching in context. In a written response, she described how her self-understanding as a mathematics teacher and her understandings of her students are influenced by the way her institution frames student learning, students' abilities, and mathematics:

> All the time, we refer to students as "above," "on," or "below." In many ways, attaching these labels makes life easier, but it also attaches stigmas about the student's ability and desire to learn…. [In my math class] the students work in separate classrooms and with different teachers to learn the 3rd grade objectives and to practice problem solving…. My impression is that the expectations of their [problem-solving] abilities are low, and as a result, they are given rather simple problems. (May 3, 2010, Positioning statement)

She identified how labels, such as "above-grade-level" and "below-grade-level," which are determined by students' test scores, come to characterize the students' capacity to learn and motivations. The institutional policies of grouping shape teachers' expectations, define mathematics as skills or problem solving, limit students' opportunities to learn, as well as restricted her own teaching practices:

> When I suggested some word problems from the 3rd grade math textbook, I was told the numbers in the problems were too difficult and had to be changed. I recognize that for some of my students, they would really struggle using fractions with different denominators; however, I also know that many of my students could handle the challenge. Since they are not challenged to solve more difficult problems (that are still considered 3rd grade level), they do not have the opportunity to make as much progress as students in other classes who are challenged. (May 3, 2010, Positioning statement)

Teaching mathematics is fundamentally about teaching within this complexity. The consequences of leaving teachers unprepared are damaging, not only for those teachers, but also for students, as teachers who are unprepared for the realities of schooling may be unable to enact ambitious mathematics teaching practices. New teachers need to understand the dynamics mathematics teaching in their school contexts that Laura mentions, and their own relationships to these dynamics. Understandings of self and relations to these dynamics structure teacher identity.

Theoretical Framework

Teacher identity is a complex construct that is conceptualized in a multitude of ways in educational research. To explore teacher identity and teacher practice, I extended Judith Butler's (1999) premise of the performativity of gender and gender identity and sought to conceptualize identity as an agentic act as much as possible within the discourses that concurrently frame identity as a process. TCs' mathematics teacher identities are shaped by the political, social, and institutional *discourses* that provide systems of categories, terms, and beliefs that organize and structure ways of thinking and acting in relation to mathematics, teaching, and learning (St. Pierre, 2000). Prevailing discourses about mathematics teaching and learning that influence TCs' understandings of being a mathematics teacher may include: institutional discourses around curriculum and testing (Brown & McNamara, 2005); social discourses around race, class, and abilities (de Freitas & Zolkower, 2009); discourses about mathematics as skills or as practices of "making sense" (Fuson, Kalchman, & Bransford, 2005); or, discourses of teacher as "savior."

Discourses, as theorized in poststructural feminist discussions of education, constrain and enable what teachers do, say, and even conceive of as appropriate (Britzman, 1993; Walshaw, 1999). For example, test-driven school cultures in the U.S. create institutional discourses about teaching and students, including notions of fixed student abilities and one-sided positive notions about standardization (Apple, 2004). These discourses, norms, and the way they position individuals (e.g., Davies & Harre, 1990) are understood to structure teacher identities, influence how teachers position students, and *interfere* with teachers' authentic teaching and learning relationships with children in their schools (Olson & Craig, 2009). In becoming a math teacher, Laura, for example, wondered how to navigate the ability grouping in her classroom, contest teachers' low expectations, and work within competing discourses of mathematics.

Teacher identities have been shown to shape why people teach (Britzman, 1993), how they understand the mathematics they teach (Gellert, 2000), and how they learn to teach (Horn, Nolen, Ward, & Campbell, 2008). TCs' experiences as students and with mathematics also manifest in practices of attending to student thinking in math teaching as obstacles or resources (Neumayer DePiper & Edwards, 2009). While there are a variety of influences on new teacher practice and how TCs attend to student thinking, the relations between teacher identity and teacher practice need to be better understood and identity work needs to be fostered in teacher education (Ponte & Chapman, 2008). Building from and responding to research on teacher identity, my theoretical stance is that TCs need to understand, on one hand, that how they position themselves as mathematics teachers and are positioned by others (e.g., instructors, mentor teachers, school administration, students, etc.) is shaped by social and political discourses about mathematics and teaching, and, on the other hand, that they can use this understanding to (re)author their positions toward mathematics teaching and learning. Developing TCs' understandings of classroom dynamics may support them in negotiating their multiple positions as elementary mathematics teachers and enacting teaching practices that best support all students in learning with understanding.

Modes of Inquiry

I used design-based research, situating my stance on identity and identity work in action both to support these TCs and to theorize about identity work in mathematics teacher education. The following questions guided this study: For TCs participating in a seminar on critical self-examination and mathematics teaching in context, how are they understanding themselves as mathematics teachers and teaching in context? How are those understandings shifting?

Study Context

The study took place during the last semester of a 15-month master's certification program. Ten female TCs, between the ages of 25 and 35, volunteered to participate in the eight seminar sessions and the study. Eight TCs self-identified as White, one as an immigrant from Argentina, and one as African-American.

Seminar Design

In the seminar design, I operationalized critical pedagogy (e.g., Kumashiro, 2000) and feminist poststructuralist notions of identity in mathematics teacher education. I sought to engage TCs in determining what discourses were present and in understanding how they operate in order to think differently about *themselves* as mathematics teachers and their relations to these dynamics. The objectives of the seminar focused on: identifying and examining the many prevailing social and political discourses that shape mathematics, mathematics teaching, and their positioning; analyzing the implications; rethinking these in relation to self; and problematizing teaching in relation to them. Seminar activities included case analysis, group discussions, and reflective writing prompts about their positioning and teaching experiences.

Data and Analysis

The data included seminar video and transcripts, interviews, and TCs' written work. I used discourse analysis to analyze TCs' identity and understandings of teaching. I analyzed identity as positioning, repositioning (Davies & Harre, 1990), and being reflexive about positioning (Mauthner & Doucet, 2003). Understanding of mathematics teaching was conceptualized as problematizing, that is how TCs took up particular conversational routines that open opportunities for learning about practice (Horn & Little, 2010) and how they negotiated attention to principles of teaching, instructional strategies, and specific practices (Pollock, 2008). In each case study analysis (Yin, 2003), I followed each TCs' discursive participation across seminar sessions. In line-by-line analysis of seminar transcripts, I identified an emergent theme in relation to each TC's self-understanding and followed each TC's discursive participation about herself and her teaching in relation to this theme and TCs' shifts in participation.

Analysis and Results

The following analysis presents TCs' participation in one analytic episode and serves to illustrate TCs' representations of their practice and one of the main findings of this study.

Examining Practices of Grading and Evaluating Student Understanding

In preparation for Session 4 of the seminar, TCs analyzed an artifact of their teaching as situated within the discourses and messages that we had discussed. They submitted this analysis in writing, including their intentions and specific interactions with students, and shared their artifacts and analysis with the group during Session 4. Candice began by describing challenges with judging students' work and tensions between being supportive of "where students are" and also wanting "to get [her students] where [they] need to go" (group discussion, May 18, 2010). Analysis suggests that she felt that the pressure to maintain pace with the curriculum and the standardization of grading (on a scale of 1 to 10) were institutional constraints on her teaching and in tension with an emphasis on attending to students' individual understandings and abilities:

> I don't want a kid to always get a [score of] 1. Like, you know, it's this big thing if you're not a "1 kid." You want to be a "10 boy" or a "10 girl." But if they're not doing 10 work, but they're trying their—like, it's a 10 for them, but it's not a 10 according to our rubric. And I actually had a conference about that because I was giving out too many 10's. And like, "Do you really think this is 10 work? Like on a BCR, you have to do this, this, and this." And I was like, "Okay, that was his 10 and I, he put forth effort, he sat next to me and he tried, so I don't give him a 10 on his best try? So, why would he try again?" (discussion, May 18, 2010)

Candice's comment serves as evidence that she recognized how she was positioned by both the pressures of standardized grading systems and by her desire to attend to and leverage students' thinking and self-confidence. She evidenced problematizing of grading students in her context and repositioning herself by contesting standardized grading and supporting individual learning.

In response, Brooke did not take up Candice's concerns. Rather, she suggested Candice use effort grades, specifically a "star, smiley face, and check" system to "affirm [students'] effort." Brooke stated that this communicated her goals to students: "I want [students] to know that they need to keep going and what they're doing isn't perfect yet. They should just keep working as hard as they can, just like an on-grade or above-grade level student should be pushed the exact same way" (group discussion, May 18, 2010). Analysis suggests that Brooke did not problematize how grades, either for achievement or academic behaviors such as effort, position students, but emphasized individual student responsibility.

Sarah then described how she communicated with students about their writing in language arts by creating facilitated opportunities for her students to read her comments and ask her questions. Sarah articulated a guiding principle, "You have to give them opportunity," emphasizing students' and teachers' responsibilities in grading and assessment. Although her mentor did not approve of her practice of taking class time for individual writing conferences, Sarah stated that she felt that it supported her students' understandings of their grades and their writing and repositioned students in relation to the pressures of grading. In this manner, analysis suggests that she took up some of tensions Candice felt about grading and supporting students' progress while also contesting the pressures of test-based accountability.

When Sarah described how all students "scored an A or a B on these assignments" because there were "multiple points to catch them," Laura questioned what those students' grades meant. Laura felt that there were differences in the understandings evidenced between the students who had received support and those who had completed the assignment independently but that these differences, both in her classroom and Sarah's, were glossed over in the grading system and when supporting students' learning. Laura described an incident with a particular student who had "great math assignments" after working with the assistant teacher and the tensions she felt:

> But it's so hard because then, like, there were other kids that were sort of normally on like his level, that were still like maybe getting low grades, and his grade was like up here, but you knew that she

really like pulled that from him. And, I don't know. Grades are weird, right, but I always just wonder. (group discussion, May 18, 2010)

Laura felt a conflict between supporting her students, standardized grading, and seeking to understand students' independent thinking and skills. In discussion, she identified how grades influenced multiple stakeholders, including parents, next-years' teachers, and administrators, and understandings of students' abilities and progress. Thus, analysis suggests that Laura struggled to make sense of how to attend to students' thinking and differences in understanding in the actual socio-political contexts and institutional constraints of schooling.

How Personal Theories of Teaching and Learning and TC Identity Related to TCs' Analysis of Student Work and Representations of Practice

Across seminar sessions, TCs experienced tensions when seeking to leverage student thinking as a pedagogical practice in their teaching contexts, particularly TCs who demonstrated a belief in and capacity for these practice in methods courses. While the focus and framing of these tensions were different, TCs' personal theories of teaching and learning *and* their identity influenced the ways in which these tensions emerged in their analysis of student work and representations of practice.

Figure 1 presents a framework outlining three stances of how TCs' individual theories of teaching and learning and TC identity relate to analysis of student work and representations of practice. Windschitl et al. (2011) found that in guided discussion about student work, some TCs took an intellectual stance of teaching and learning as problematic and others took a stance of teaching and learning as unproblematic. They suggest that TCs' theories of teaching and learning were underlying their analysis of student work, representations of practice, and the dilemmas they felt in their classroom. Building on the analysis and frameworks of Windschitl et al. (2011), my analysis highlights another dimension, specifically that TCs' understanding of their positioning also influenced framing of practice and the questions they brought to peers.

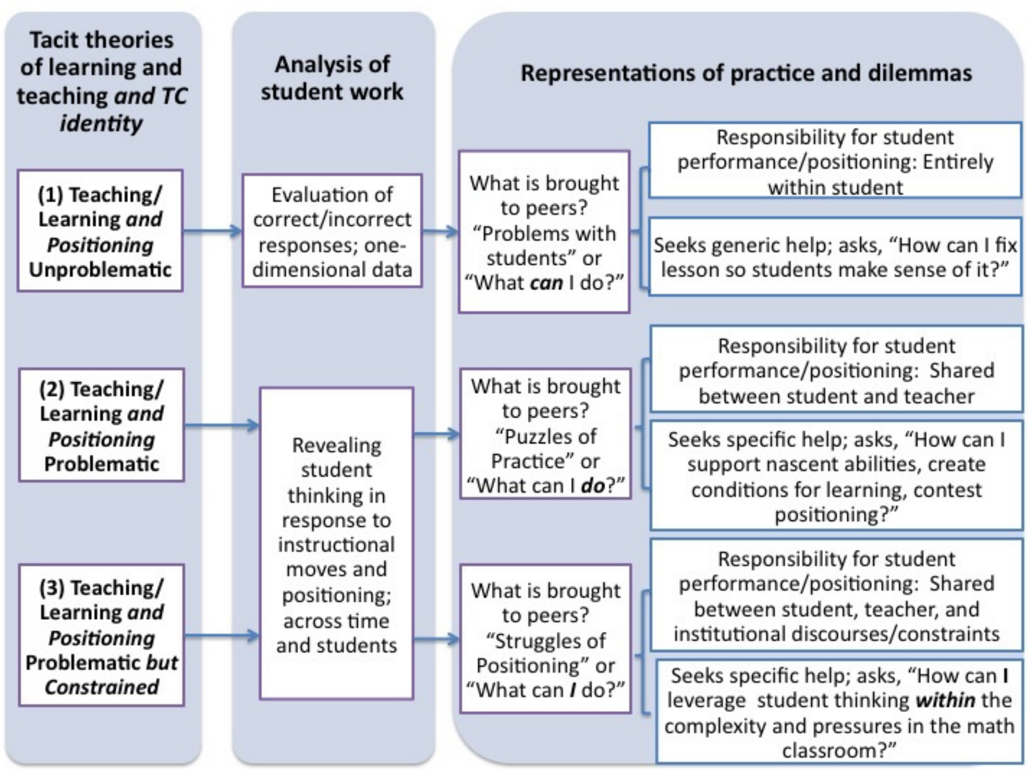

Figure 1: How personal theories of teaching and learning and TC identity related to TCs' analysis of student work and representations of practice

Brooke's participation across sessions is representative of the first intellectual stance emergent in TCs' engagement: Teaching/Learning and Positioning as Unproblematic (Figure 1). In analysis of student work, she focused on correct/incorrect responses and how there were *students* who did and did not get it, would and would not get it, and did not understand their placement in what she called the "math class hierarchy." Her comments suggest beliefs about learning mathematics as a process of skill acquisition as well as the ways in which she did not see students' positioning, her influence on students' positioning, or their positioning by grading practices as problematic.

Analysis of TCs' tensions with mathematics teaching and their representations of practice identified three iterations of the question, "What can I do?" which is also referenced by Pollock et al. (2010) in discussions of teaching teachers about race. Analysis suggests Brooke brought the question, "What *can* I do?" to her peers, questioning what she *could* do, as student performance and positioning were problems of *students* needing to understand the mathematics and take responsible for their performance and positioning. She sought generic help, not specific to students' understanding or thinking. Her positioning, in particular how she understood math abilities and students' responsibilities, framed her analysis of student work, and she struggled to interrogate her positioning towards mathematics, the framing of abilities in mathematics, and how her school framed learning and progress. This case highlights the challenges TCs have with working at the intersections of these issues and their positioning. By not seeing her positioning or her students' positioning as problematic or examining herself in relation to these issues, she struggled to problematize practice and remained focused on fixing students and lessons.

Sarah and Candice's participation is representative of an intellectual stance where both teaching and learning and their positioning were problematic, the second stance articulated in Figure 1. Sarah and Candice both analyzed student work to reveal student thinking and emphasized sense-making in her interactions with students. In analysis of student work and when discussing instruction, they identified their positioning as an intern, how students were positioned, and the discourses of test-based accountability and tensions, where standardized assessments mattered more than what was learned from students' work. In representations of practice and dilemmas, Candice and Sarah asked specific questions of practice; that is, "What can I *do*?" They engaged in puzzles of practice and demonstrated a shared responsibility for working with students to address their positioning and context. Sarah, for example, saw her positioning as problematic and asked questions about supporting students' abilities, creating opportunities to learn, and contesting discourses of test-based accountability, her positioning and her students' positioning. Understanding positioning as problematic and seeking to contest it coincided with bringing puzzles of practice and specific questions about practice to peers.

Laura also represented teaching and learning as problematic, but analysis suggests that she sought to work within how she was positioned and the complexity of institutional pressures in her mathematics classroom. As evidenced in her analysis of student work and representations of dilemmas of practice, her participation is representative of a third stance, Teaching/Learning and Positioning as Problematic but Constrained (Figure 1). During her mathematics methods course and across the seminar, Laura demonstrated a strong belief in and the capacity for attending to student thinking as a critical instructional practice and also that responsibility for student performance was shared between student, teacher, and institution, but analysis suggests that her understandings of herself left her feeling as if her options for her practice in her school context were constrained. Thus, while she problematized practice and brought these puzzles of practice to the group, analysis suggests that she felt limited and struggled with her positioning in context.

As this study and seminar were framed in relation to sociopolitical discourses of teaching, Laura's discursive participation suggests that through this attention to what is framing her positioning, more tensions about enacting this work in context emerged for her. Analysis suggests that she was asking, "What can *I* do?" The self-understanding and awareness that she evidenced may have helped her better understand how teaching context was a critical element of her practice and her positioning and how she could assert agency in choosing a teaching context, but she remained uncertain about how to engage in the instructional practices that were important to her and encouraged by her methods courses. While Windschitl et al. (2011) suggests that TCs' enactments or lack of enactment of ambitious practices related to TCs' beliefs or knowledge, it was Laura's concern about who she was and what she could do, specifically, her understandings of herself and her identity that influenced her representations of practice.

Discussion and Conclusions

This study emphasizes the importance of attending to the many tensions TCs feel in enacting practices of leveraging student thinking in context. As Windschitl and colleagues (2011) suggest that unsophisticated views of teaching and learning underlie analysis of student work, this analysis finds that through attention to the sociopolitical dynamics of teaching, TCs articulate other tensions in their representations of practice and the ways in which they understood enacting practices such as leveraging student thinking. The framework outlining the different stances and TC representations of practice and dilemmas suggests that TCs were asking different questions about themselves, their agency, and instruction. In response, math teacher education needs to respond to the questions and tensions TCs feel about their positioning and enacting specific practices in classrooms. Specific implications are for more activities in math teacher education that help TCs contests one-sided positive notions of standardization and the category systems and grading systems prevalent in math classrooms and for continued discussions about TCs' complex positioning. In seeking to support TCs in their enactment of high-leverage pedagogical practices in context, mathematics teacher education needs to focus on the complexity of math teaching contexts and TCs' understandings of these dynamics as related to practice.

A TENSION IN TEACHING "MATH FOR TEACHERS": MANAGING COGNITIVE AND AFFECTIVE GOALS

Susan Oesterle
Douglas College
oesterles@douglascollege.ca

This paper presents partial results of a completed study which investigated the experience of teaching mathematics content courses to preservice elementary teachers. Interviews with ten mathematics instructors who teach these courses revealed several major tensions, including one that arises as instructors strive to set priorities and balance their affective and cognitive goals for their students. An analysis of three of the instructors' experiences of this particular tension will provide insight into the factors that contribute to it and how it is managed.

Keywords: Teacher Education–Preservice; Affect, Emotion, Beliefs, and Attitudes; Mathematical Knowledge for Teaching

Background

Concern over the mathematics preparation of elementary school teachers has led to increasing calls for prospective teachers to take specialized mathematics content courses, i.e. Math for Teachers (MFT) courses, during their undergraduate programs (Greenburg & Walsh, 2008; Conference Board, 2010). These courses are usually taught by instructors in mathematics departments, and some recent studies have begun to call into question whether these instructors are equipped to meet the needs of MFT students, particularly with respect to affect (Hart & Swars, 2009).

Although there has been some research done into teaching styles of post-secondary mathematics instructors generally (Strickland, 2008), and into the difficulties they face in implementing reform approaches (Wagner, Speer, & Rossa, 2007), there seems to be little information about mathematics instructors in the context of teaching MFT courses. The original study upon which this paper is based sought to address this gap in the literature. Interviews with ten mathematics instructors who teach MFT courses at various post-secondary institutions in British Columbia were analyzed in order to answer questions, including: What are the major tensions they experience? What factors contribute to these tensions and how are they managed?

Given space limitations, this paper will discuss only one of six major tensions revealed in the full study, specifically, the tension related to instructors' efforts to balance their affective and cognitive goals for their students.

Supporting Literature

The research reported in this paper is informed by prior research into the cognitive and affective needs of prospective elementary school teachers (with respect to mathematics), as well as literature on tensions.

Cognitive and Affective Needs

With respect to the students in MFT courses, there is evidence to support concerns that they have poor understanding of the elementary school mathematics topics; Ball's (1990) study of 252 preservice teachers revealed "understandings that tended to be rule-bound and thin" (p. 449). Regarding their beliefs, the elementary preservice teachers in the group "tended to see mathematics as a body of rules and facts, a set of procedures to be followed step by step, and they considered rules as explanations" (p. 464). Preservice elementary teachers often suffer from mathematics anxiety (Hembree, 1990), and some are only enrolled to "fulfill a requirement rather [*sic*] to learn more mathematics" (Kessel & Ma, 2001, p. 477).

Although it is clear that MFT students have much mathematics to learn, and often come in with negative attitudes and beliefs, the literature does not provide specific advice on whether cognitive skills or affect should take precedence in teacher preparation. In fact, there is considerable literature engaged in debate over this issue. While some researchers make a case for the priority of strong mathematics knowledge, pointing out that such knowledge can both boost confidence and make teacher practice (i.e., the implementation of teachers' pedagogical beliefs) more effective (Schwartz & Riedesel, 1994; Goulding, Rowland, & Barber, 2002), a large number advocate for an emphasis on teachers' beliefs in specialized mathematics content (and methods) courses (Kessel & Ma, 2001; Liljedahl, Rolka, & Roesken, 2007), observing that beliefs will affect both students' learning in preservice mathematics courses and their later teaching. Still others promote the view that students' knowledge *and* beliefs need to be challenged in teacher education programs (Borko et al., 1992). This debate in the literature is reflected in the tension experienced by the MFT instructors described in this study.

Tensions

Tensions, often expressed as "dilemmas," have been recognized as an integral part of teaching practice, dating back at least to the early 1980s. In their seminal work, Berlak and Berlak (1981) examined the complex and sometimes contradictory behaviors of teachers in responding to the curriculum within socio-cultural contexts. Their use of the language of dilemmas was taken further by Lampert (1985), who emphasized the personal and practical aspects of dilemmas.

Lampert (1985) observes that tensions in teaching are often "managed" rather than resolved. She characterizes teachers as "dilemma managers" who find ways to cope with conflict between equally undesirable (or desirable but incompatible) options without necessarily coming to a resolution. Faced with a teaching dilemma, the teacher must take action, finding a way to respond to the particular situation, even while the "argument with oneself" (p. 182) that characterizes the dilemma remains. For Lampert, the ongoing internal struggles presented by the tensions arise from and contribute to the developing identity of the teacher, and as such have value in themselves. Furthermore, she comments: "Our understanding of the work of teaching might be enhanced if we explored what teachers do when they choose to endure and make use of conflict" (p. 194).

More recently, Berry (2007) focused on "tensions" in a self-study that examined her own efforts to improve her practice as she made the transition from *teacher* to *teacher educator*, finding that the notion "captured well the feelings of internal turmoil experienced by teacher educators as they found themselves pulled in different directions by competing pedagogical demands in their work and the difficulties they experienced as they learnt to recognize and manage these demands" (p. 119). In the study presented here, the instructors are similarly experiencing a transition between teaching future *users* of mathematics and teaching future *teachers* of mathematics, a situation which influences the tensions they experience.

Methodology

Data for this study were gathered through interviews with ten participants, five male and five female, all instructors in mathematics departments at post-secondary institutions who teach MFT courses. Theoretical sampling (Creswell, 2008) was used to achieve variety in type of post-secondary institution represented, as well as varying degrees of experience in teaching MFT. The ten instructors represented nine different institutions, and their experience teaching the MFT course ranged from novice to 20 years.

The one-hour long interviews were semi-structured, beginning with a set of core questions but allowing for variations and additional questions to be asked as needed. Such an open-ended ("clinical") approach is advocated by Ginsburg (1981) in situations where discovery or identification/description of a phenomenon is the objective. The questions sought to elicit the instructors' conceptions of the MFT course by asking them to examine their goals, describe the approaches they take, compare the teaching of MFT with teaching of other mathematics courses, and reflect on the challenges and the successes they experience.

The interviews were audio-recorded, transcribed, and analyzed using constant comparative analysis (Creswell, 2008). An iterative coding process (Charmaz, 2006) was employed in order to allow concept codes and themes to be identified. Very few new codes emerged after the tenth interview, suggesting saturation of the data. Specific concept codes, including "priorities," "wishes," "doubts," "barriers," and "resistance," helped to locate instances of instructor tensions in the transcripts.

Analysis of the tensions was further facilitated by techniques of discourse analysis (Rowland, 1995) and considerations of positioning (Harré & van Langenhove, 1999). The former helped to locate hesitation, uncertainties and inconsistencies, while the latter supported understanding of contexts and factors contributing to the tensions identified.

Results

One of the major tensions that emerged through the coding and thematic analysis involved instructors' struggles with managing their cognitive and affective goals for their students in the MFT course. Each of the instructors experienced this tension differently, however, due to space limitations, only the cases of Bob, Maria and Alice (all pseudonyms) will be described here. These three cases will suffice to exemplify the diversity and scope of the views expressed.

Bob

Bob's experience of this tension emerged in the contrast between his comments at the beginning of his interview with respect to his primary goals in his MFT course and his later reflections on the ultimate outcomes for his students.

Bob reported that his main emphasis is on building deep conceptual understanding in his students, although affective considerations are also very important to him. His course "focuses on a very sound fundamental ability to appreciate [mathematics], in a theoretical way, why things work," along with having "a secondary by-product of what you do in the classroom is to get the students to enjoy it." The cognitive and affective are closely related for Bob. From his responses to prompts about dealing with students' anxiety, he expresses the view that his students' anxieties are at least in part caused by, and at the same time the cause of, their lack of arithmetic skills. It is his hope that helping his students learn about the structure of mathematics will solidify their understanding, giving them confidence, competence, and enjoyment.

Later in the interview, commenting on what his students leave the course with, Bob observed that his students "have improved most in their technical abilities," along with having gained some problem-solving skills, although these need to continue to be developed. But he is ultimately disappointed, both in his hopes to build deep theoretical understanding, and in his hopes to increase his students' appreciation for, and love of, mathematics.

> *Bob*: In terms of appreciating some of the more subtle aspects of the theory, I think that's another thing that they could do better, if they had better basic arithmetic skills, coming in. So ... yeah, in terms of what I produce, I guess, in terms of the other goal, for love of math? Unfortunately, the course is so packed, that in some ways, I think they do get a little bit beaten by the end, and they're just tired.

He does see some success in improving their technical skills, although their depth of understanding still falls short, but admits with regret that he is less than successful (by his own standards) in terms of affective aims. He is trying to cover too much, to the extent that his students are overwhelmed.

A closer look at this passage, with particular attention to pronoun use, offers some further insights. In the first sentence, he ostensibly places the responsibility on the students, "*they* could do better, if *they* had better basic arithmetic skills." However, as Bob is aware, the prerequisites for the course are not controlled by the students, or by him, but are set by the larger community. Whether it is the fault of this community or the students themselves, he sees the lack of student skills coming into the course as an impediment to his ability to realize his goals for his students.

He then switches to consider what he ("I") produces. Having already mentioned that students have increased their technical abilities, he moves to his "secondary" goal, improving affect. The results here are "unfortunate"; he describes his students as "beaten" and "tired"—not at all what he desired. The phrase, "the course is so packed," is telling. It is offered as an explanation for the students' states of exhaustion;

there is too much material in too little time. Bob's use of the passive voice here suggests that he is not in control of the course content; with it he positions himself as unable to remedy this "unfortunate" situation. The course, as he believes he is expected to deliver it by his institution, demands too much of the students.

Bob is not a new instructor of the MFT course, and so has likely lived with this problem for some time. He is stuck in this dilemma. On one side he has students who are unprepared for the level of mathematics he believes they need in order to "appreciate" the mathematics (both in a cognitive and in an affective sense). On the other side, he has a prescribed curriculum he is expected to "cover." He feels a strong responsibility as a mathematics instructor, seeing himself as being charged with "delivering the content" (Bob's words). From Bob's perspective, the situation could be improved if the students were stronger coming in, but this is not within his immediate power to change. So he manages the tension by adhering to his practice in his other mathematics classes—he focuses on the content, despite his dissatisfaction with the outcomes.

Maria

Similar to Bob, Maria expressed a strong intention to improve students' mathematical understanding, emphasizing cognitive goals. However, Maria's use of the past tense in describing these goals in her interview, even though she was teaching the course at the time, suggested she was having second thoughts about her priorities.

Maria was a first-time instructor of the course at the time of the interview, and was surprised by the needs of her students, not only their weak mathematics skills, but their mathematics anxiety and the barrier to learning it presented.

> *Maria*: So my goal was, primarily, sort of more content, and I [...] knew that there would be some issues of, let's describe it as "math phobia" or anxiety, with math. I just [was] still surprised to see it so strong at this level, that it overrides their learning, that it blocks their learning! That's what I discovered, and it surprised me that it would be this strong.

She went into the course expecting that she would be teaching mathematics and would need to deal with math anxiety, but at a certain point she realized that, at least for some of her students, the affective issues would need to be addressed before they could learn the mathematics. Maria commented that she believed she had lost about a third of her students, and was not sure how to get them back on track.

> *Maria*: For this group of students at this point, content? Forget it. I need an attitude change. I need [their] perception of math to change. And I can't reach it anymore. It was very high, you know, it was a good high in the beginning of the course, because of what I did, free, sort of, problem-solving, open discussion, everybody let's just ... [there was a] fuzzy, cozy atmosphere. But the topic does get difficult, yeah?

Maria seemed to feel that she had missed an opportunity. For this particular group of students, she did not believe it would be possible for them to progress without an attitude change, and this change was not possible to attain "anymore." She spoke nostalgically about a time at the beginning of her course when her approach was different: there was "open discussion," "free" problem solving, and a friendly atmosphere. She seemed to take responsibility for these initial positive feelings; it was good because of "what [she] did," but something changed; her approach changed, and in this excerpt the reason offered for the change was the "topic," i.e., the mathematics, which gets more difficult as the course progresses.

Like Bob, during her interview Maria expressed a sense of obligation to complete the prescribed mathematics content for the course, a disposition that appeared to be in tension with her goals to both promote deep conceptual understanding and address her students' affective needs. Her desire to "cover the content" influenced her choice of teaching methods, leading her to reduce in-class activities, such as open discussions of readings and problem-solving sessions, methods that she described as effective, but not time-efficient. At the same time, she reported that it troubled her that she was leaving students behind, students who would continue to suffer from negative attitudes to math and continue to have weak skills.

An additional consideration for Maria that contributes to this tension is a perception that the MFT course has the potential, if not the responsibility, to act as a filter. Early in her interview, comments with respect to the importance of deep content knowledge for mathematics teachers (not cited here) revealed a strong commitment to ensuring that she does her part in the preparation of future elementary teachers; i.e., if the mathematics skills of the prospective teachers are too weak, they should not be permitted to go on to become teachers.

Maria was far from resigned to living with this tension. At the time of the interview she was still seeking to understand her students better and find methods that would be more effective for them, to find a way to change their attitudes so that the mathematics could be learned.

Alice

In contrast to Bob and Maria, Alice was less concerned about building mathematics knowledge and much more concerned about affect. This also created tension for her, although this was not evident early in her interview. Alice's emphasis was on helping her students see the "fun" of mathematics. She described the many ways she tries to address her students' anxieties and to build their confidence, including striving for a very relaxed classroom atmosphere where questions are encouraged and student interaction and exploration of concepts is the norm.

The tension between her affective and cognitive goals for her students did not emerge until she considered whether her students will be prepared to go on to be teachers of mathematics.

> *Alice*: That's a very good question. That, that's a very deep question. Because we don't teach so much math in that class, you know. We don't drill them on whether they can do those fractions. We kind of believe they have the elementary math, that's how we let them in [...]. But how much above it should they be? You see they always say that you should be significantly above what you want to teach, because then you have the big picture, you see the troubles and all that. I don't know that much about that. [...] Many at least will not be afraid to go for it. But I still think there are people who will be afraid. I still think I let people go in there being afraid.

In this passage, she begins with the admission that improving students' mathematics proficiency is not a major objective in her course. This is followed by a justification that students are presumed to come into the course with sufficient mathematics skills, however the hedge "we kind of believe" and other comments in her interview suggest that she realizes those skills are often lacking. She then considers that even if they could do the arithmetic, perhaps that would not be enough, that teachers of mathematics should have a *deeper* understanding of the subject. She even provides reasons for why this deeper understanding might be helpful, but then quickly dismisses this as education theory, something she is not an expert in. She looks to her goal of improving attitudes next, to see if "at least" her students will no longer be afraid of mathematics, but sadly admits that even in this respect, some of her students are not ready.

A careful parsing of this passage reveals some of the different forces contributing to the tensions that Alice operates under. As she thinks aloud, her pronoun use changes from "we" to "they" to "I." "We" likely represents her institution as she describes what does not happen in the course: there is not much math and no skill drill. Even if she disagrees, the objectives for the course are set by her institution. In the phrase "they always say...," the "they" seems to point to education experts, or at least to those who have an informed opinion, but she disassociates herself from this group, switching to the pronoun "I," and denying any expertise in deciding what students need. Ultimately, responsibility for the content and objectives of the course is deferred to others, her institution and/or the community.

Alice seems to believe that the goals for improving students' attitudes and diminishing their anxiety are important, and this is consistent with the reported aims of her institution. As a result of this local orientation, she does not express the same concern as Bob and Maria with respect to "covering" the course content. But there is still a tension here as she contemplates what she achieves with the course, and what future teachers might need both in terms of mathematics proficiency, which she does not address to a great extent, and attitudes towards mathematics, which she tries to address, but feels she does not entirely succeed in. She deals with this tension by deferring authority for deciding these priorities to others at her institution and within the teacher education system, but remains concerned with the implications for future teachers.

Discussion

Bob, Maria and Alice experience the tensions differently, but all struggle with finding the balance between building students' mathematics proficiency/understanding and fostering positive attitudes, within the parameters set for the course. Bob hopes to improve affect through building cognitive skills (one of the views reflected in the literature), but his affective aims are sabotaged by an emphasis on content that he sees as too much for his students to absorb given their skills coming into the course. He opts in favor of covering the course content, fulfilling his perceived obligation as a post-secondary mathematics instructor, even though this means the students leave the course far less excited about mathematics than he would like. Maria's comments revealed a growing awareness that her cognitive aims cannot be attained, at least for some of her students, until affective barriers have been removed (reflecting the other side of the affective/cognitive debate). She, too, sticks to the course curriculum, even though students are left behind, largely to try to ensure that students who do not have a certain level of understanding will not become teachers before they are ready. For Alice, whose emphasis is already primarily on the affective, there is an uneasiness that what her course provides may not be enough to meet either one of her students' affective or cognitive needs, at least for some of her students.

Both Bob and Maria seem to manage this tension between cognitive and affective aims by staying true to the course syllabus and "covering the material," even though they are unhappy with the consequences. There are indications within the broader study that this commitment to the prescribed course content is a prevalent norm amongst post-secondary mathematics instructors. This may not be surprising given that the traditional calculus-stream mathematics courses that they generally teach tend to be sequential in nature with topics in one course building on knowledge of earlier course content. It is unclear whether instructors are consciously aware of this norm or have considered its appropriateness in the context of MFT courses.

Exceptionally, Alice does not appear to adopt this norm in her MFT course, at least in part because the mandate from her institution is a focus on affective goals. Yet this does not free her from the experience of tension. She manages her situation by deferring to the authority of others at her institution, but she is left uneasy with the mathematics proficiency of some of her students in the context of their role as future teachers, while not being wholly satisfied that her affective goals are being reached. Her comments point to additional factors that contribute to this tension, including the often weak mathematics skills of students coming into the MFT course, also observed by Bob, and the sense that one of the roles of the course is to act as a filter to prevent those with poor mathematics skills from becoming elementary school teachers, also expressed by Maria.

Both of these concerns point to larger problems within the system of teacher preparation, problems with defining the level of mathematics proficiency elementary teachers need, and with clearly defining the role of MFT courses in their preparation.

Conclusion

This tension is not easily resolved. As illustrated by the case of Alice, it is certainly not simply a matter of refocusing priorities on affective rather than cognitive goals—both are important in the development of future teachers of mathematics. Rather than attempt to resolve the tension, in the spirit of Lampert (1985), we consider instead what can be learned from it.

The study by Hart and Swars (2009) suggests that approaches of MFT instructors may negatively impact student affect. This study counters that even when instructors are concerned about students' attitudes and beliefs, their ability to respond to the affective needs may be constrained by normative commitments to course syllabi, beliefs about the level of mathematics proficiency needed by future teachers, and understandings of the role of the MFT course. Maria's comments about reducing in-class activities in order to get through the material suggest that these factors may also be barriers to instructors' adoption of more reform-oriented approaches. Furthermore, a perceived mismatch between students' prior mathematics preparation and course expectations is also implicated.

The question then becomes, how can mathematics instructors best be supported by the mathematics education community as they strive to manage both cognitive and affective aims for MFT courses? This study suggests that identifying norms in post-secondary mathematics instruction that may differ from those in teacher education may bring to light preconceptions that inhibit instructors' transition from teaching future *users* of mathematics to teaching future *teachers*. Furthermore, ongoing research into the knowledge, beliefs and attitudes needed by teachers of mathematics would assist in clearer articulation of goals for MFT courses and a better understanding of their place in the process of teacher preparation. Finally, although the debate between the priority of affective versus cognitive goals in the literature is exemplified within the cases of these instructors, it is worthy of note that the research literature does not play a direct role in informing these instructors' efforts to deal with their tensions. This is even more evident in the larger study. Although the literature to date offers no clear resolution, closer contact with the mathematics education community might expose these instructors to new strategies or alternate perspectives, placing them in a better position to manage their tensions.

This paper describes a synthesis conducted to determine what research says regarding preservice teachers' understanding of fractions and identify the gaps in their existing knowledge basis. Specifically, this paper will address a smaller portion of the synthesis and report the findings from fraction multiplication and division topics. Results indicated that preservice teachers' understanding of fraction multiplication and division is limited and largely based on rote procedures. Implications for teacher education programs and future research studies are provided.

Keywords: Teacher Education–Preservice; Rational Numbers

Objectives

Elementary teachers need a "solid understanding of mathematics so that they can teach it as a coherent, reasoned activity and communicate its elegance and power" (Conference Board of the Mathematical Sciences (CBMS), 2001, p. xi). However, research studies on preservice teachers' mathematics knowledge have shown that many possess a limited knowledge of mathematics in key content areas such as number. For example, Thanheiser (2009) found that only 3 of 15 preservice teachers held a conception of place value that allowed them to explain how and why the subtraction algorithms with three-digit numbers work. The National Mathematics Panel affirmed the "proficiency with fractions" as a major goal for K–8 mathematics education because "such proficiency is foundational for algebra and, at the present time, seems to be severely underdeveloped" (p. xvii). Therefore, developing such proficiency in preservice elementary teachers is a critical task for mathematics educators. As the authors of *The Mathematical Education of Teachers* suggest, "The key to turning even poorly prepared prospective elementary teachers into mathematical thinkers is to work from what they *do* know" (CBMS, 2001, p. 17). There is still much to be learned about preservice teachers' (PST) conceptions in a wider array of topics and how we might use such knowledge in designing mathematics courses for PSTs. In this paper, we discuss the main findings from a research synthesis of existing studies on preservice elementary teachers' fraction knowledge to identify critical directions for future research specifically in the area of fraction multiplication and division.

Theoretical Framework

Shulman (1986) proposed three categories of content knowledge for teachers: (a) subject matter content knowledge, (b) pedagogical content knowledge, and (c) curricular knowledge. For Shulman, subject matter content knowledge includes knowing a variety of ways in which "the basic concepts and principles of the discipline are organized to incorporate its facts" and "truth or falsehood, validity or invalidity, are established" (p. 9). Pedagogical content knowledge refers to the knowledge of useful forms of representations (e.g., analogies, illustrations, explanations) of subject-matter ideas that make it understandable to others, and an understanding of the conceptions and pre-conceptions students bring to the learning processes. The third type of knowledge, curricular knowledge, includes knowledge of a "full range of programs designed for the teaching of particular subjects and topics at a given level, the variety of instructional materials available in relation to those programs, and the set of characteristics that serve as both the indications and contraindications for the use of particular curriculum or program materials in particular circumstances" (p. 10).

Shulman's ideas on pedagogical content knowledge sparked a huge interest in knowledge for teaching, eliciting over a thousand studies throughout a number of content areas with a large number of these studies focusing on teachers' knowledge of mathematics (e.g., Davis & Simmt, 2006; Ball, Thames, & Phelps, 2008; Hiebert, 1986; Ma, 1999). Deborah Ball and her colleagues introduced the term "mathematical knowledge for teaching" (e.g., Hill, Ball, & Schilling, 2008), which focused on the work that teachers do when teaching mathematics.

Building on Shulman's (1986) categories of knowledge, Ball, Thames, and Phelps (2008) introduced a framework for mathematical knowledge for teaching. This framework broke subject matter knowledge into three categories: common content knowledge (CCK), the mathematical knowledge that should be known by everyone; specialized content knowledge (SCK), the knowledge of mathematics content that is specific to the work of teachers; and horizon content knowledge, which involves understanding how different mathematical topics are related. Pedagogical content knowledge was similarly broken into: knowledge of content and students (KCS), which dealt with understanding how students relate to different topics; knowledge of content and teaching (KCT), which involves the sequencing of topics and the use of representations; and knowledge of the curriculum as a whole. While a number of different frameworks look at mathematical knowledge for teaching, this framework proposed by Ball and her colleagues is typically looked at by groups focusing on what teachers know about mathematics and served as a framework for our study as well.

Background and Research Questions

This work was initiated at a PME-NA working group in 2009 and 2010. The members of the working group all taught specially designed mathematics courses for elementary school teachers in the United States and sought to improve their practice by building on PSTs' current knowledge. The working group was formed with a goal of summarizing the prior research addressing PSTs' content knowledge and its development with the idea that we could both improve our teaching and design further research to extend what we know about PSTs' mathematical knowledge. We broke into smaller groups by content area, (whole-numbers, fractions, decimals, geometry, and algebra), and attempted to synthesize the current research in each of these fields.

This paper reports a synthesis of the research that has been done to this point on fraction multiplication and division. These are the areas that came up most frequently in the literature. Our goals for the research synthesis were to: (1) to identify what we already know about preservice elementary teachers' knowledge of fractions in both the domains of subject-matter and pedagogical content knowledge, and (2) to identify the knowledge gap in the existing knowledge basis to help guide future research endeavours.

Methods

The first step of conducting this research synthesis was to identify the existing literature. Initially, we decided to restrict our search to only published research journal articles to maintain the quality of the findings. However, recognizing the time lag required for publication, we decided to expand the search to also include proceeding papers published in 2007, 2008 and 2009, and dissertations published since 2005. With key words such as "preservice teachers," "preservice elementary teachers," "fraction," "fraction concepts," "fraction operations," "fraction multiplication," "fraction division," and "rational numbers," we searched the ERIC, Google Scholar, Dissertation Abstract and Rational Number Reasoning databases (*gismo.fi.ncsu.edu/database)*. We also manually searched through the recent PMENA and PME proceedings because we were not sure about the time lag for a proceeding paper to be included in the above databases. This search yielded 42 journal and proceeding articles and 3 dissertations between 1988 and 2011.

The second step required the research team to locate these papers and skim through them to determine if they had a research question focusing on preservice elementary teachers' fraction knowledge. Fifteen papers were rejected because they did not meet this criterion. For example, some papers were about curriculum sequence or instructional activities that would facilitate preservice elementary teachers' learning of fractions, while others were about preservice elementary teachers' teaching of fractions. So the synthesis we report on in this paper is based on 30 papers and dissertations.

Careful readings of these documents were carried out during the third step. To assist the comparison across these documents, an entry in a synthesis table was filled with information such as “research questions,” “research design,” “descriptions of participants,” “content foci,” “data collection,” “data analysis,” “findings,” and “implications” for each one.

We soon noticed the following main trends in our synthesis table. First, all but two papers were published in two distinct time periods: 1988 to 1994, and 2005 to 2011, with 21 articles falling in the latter time period. This shows a growing interest in preservice elementary teachers’ fraction knowledge. Second, the majority of the papers focused on preservice teachers’ subject matter content knowledge, with a handful on pedagogical content knowledge such as their ability to construct valid fraction story problems and representations, and their ability to predict students’ errors, and none focused on preservice elementary teachers’ fraction curricular knowledge. Third, the majority of the studies (17 of them) focused on preservice elementary teachers’ fraction knowledge in a single sub-concept, for example, fraction multiplication or fraction division, with six studies focused on two or more fraction sub-concepts. Only four focused on the development of fraction knowledge. In the following section, we will report the main findings about preservice elementary teachers’ fraction knowledge related to multiplication and division.

Results

We organized our findings around the major themes that we found in the research. These dealt with PSTs’ common content knowledge of fraction procedures, their specialized content knowledge of being able to write story problems modeling situations with fractions, their knowledge of content and students, in relation to common student errors in regards to fractions, and of different instructional interventions designed to help improve this knowledge.

Preservice Teachers’ Understanding

Research illustrates that preservice elementary teachers are most uncertain about dividing fractions, followed by subtracting, multiplying, and then adding fractions (Newton, 2008). This becomes problematic especially when the ability to represent an operation with diagrams and story contexts has been identified as an important type of specialized mathematics knowledge for teaching (Ball, Thames, & Phelps, 2008). Such ability even becomes more important in the context of the Core State Standards of Mathematics implementation. Grade 5 and 6 students are expected to solve real word problems involving fraction multiplication and division through visual fraction models (e.g., a tape diagram, number line diagram, or area model) and equations to represent them.

However, studies have shown that the majority of preservice elementary teachers do not have a strong ability to represent fraction multiplication and division with story problems (Ball, 1990; Luo, 2009; Simon, 1993). While preservice teachers have an easier time on writing story problems when one of the two numbers involved in multiplication and division computation is a whole number, many of them were not able to do the same when mixed fractions are involved or when both given numbers are fractions. For example, Luo (2009) found that preservice teachers struggled to provide an appropriate context and representation given a symbolic expression of fraction multiplication. In agreement with Goodson-Epsy (2009), Luo concluded that whole number by fraction multiplication is easier than problems with two fractions. Of the 127 preservice early childhood and elementary education students in Luo’s study, only 27% could construct a valid word problem to represent $1/2 \times 1/3$, while 58% could construct a valid word problem to represent $1\ 2/3 \times 4$. In addition, Luo found that the majority of the preservice teachers used a “multiplication as repeated addition” construct which can be problematic when working with non-whole numbers.

Findings from Ball (1990) and Simon (1993) indicated that many preservice teachers were unable to generate a valid story problem for fraction division problems such as $1\ 3/4 \div 1/2$ or $3/4 \div 1/4$. Many of them wrote story problems that were actually for multiplication of fraction by either the given fractions or by the reciprocal of the divisor. It also appeared that preservice teachers who attempted to use measurement division contexts were more successful than those that used partitive division. The field has just began to examine preservice teachers’ proficiency of using diagrams to represent fraction multiplication and division. One study that compares Taiwanese and U.S. preservice elementary teachers' fraction knowledge contains a multiple-choice item asking them to choose the diagram that can not be used to model $3/4 \times 4/5$ or $4/5 \times 3/4$ (Luo, Lo, & Leu, 2011). The finding suggested that the majority of preservice elementary teachers from both populations were unable to identify the correct answer which simply showed a diagram of 3/4 and a diagram of 4/5 with a multiplication sign listed in between.

Preservice Teachers' Knowledge of Student Errors

When teachers enter the classroom, they need to have an understanding of mathematics content as well as student thinking (Ball, Thames, & Phelps, 2008). By understanding how students think, teachers can establish classrooms where discussions focus on the validity of students' responses. Knowing how preservice teachers interpret student responses before they enter a classroom can provide a foundation for the types of activities needed in teacher education programs.

In the context of fraction division, research has shown that preservice teachers' analyze student responses at a surface level (Son & Crespo, 2009; Tirosh, 2000). For example, when shown a correct student's method that included dividing the numerators and denominators, preservice teachers argued that the method works but only because the answer matched to what they got by inverting the second fraction and multiplying (Son & Crespo, 2009). The participants in this study did not delve deeper into the concepts underlying the methods and their beliefs about teaching and learning strongly correlated with their responses toward the non-traditional algorithm.

Other research has shown that similar conceptions hold true when preservice teachers analyze students' incorrect methods for dividing fractions (Tirosh, 2000). Tirosh found that participants were able to identify common problems that students would have, but they generally attributed these errors to students not understanding the algorithm for dividing fractions. Thus, preservice teachers had some understanding of the types of difficulties students may have, but were not able to justify why those methods are incorrect (Tirosh, 2000).

Improving Preservice Teachers' Understanding

Several recent studies have examined the effects of special instructional strategies on preservice teachers' procedural and conceptual knowledge for fraction: for example, use of manipulatives (Green, Piel, & Flowers, 2008); web-based instruction (Lin, 2010) and problem posing (Toluk-Ucar, 2009). All three studies used the experimental design with control and experimental groups. All showed significant better improvement by the preservice teachers in the experimental groups.

For example, in a study conducted by Green, Piel, and Flowers (2008) only 15% of the preservice teachers in the experimental group were able to illustrate the fraction division $1\ 1/2 \div 3/4$ during the pre-test. After working with manipulatives for four weeks, 66% of them were able to do so. These studies also pointed out that it was more difficult for preservice teachers to illustrate fraction multiplication and division situations than it was for them to write story problems. This pattern remained true after the treatment. For example, while the percent of preservice teachers in the experimental group who were able to write story problems for fraction division increased from 2% to 88% between the pre- and post-test in the study by Toluk-Ucar (2009); the corresponding result for drawing diagram for fraction division were 2% and 80%.

Discussion

Research regarding preservice teachers' mathematical content knowledge illustrates that they have a rule-based conception of fraction multiplication and division. Misconceptions result from overgeneralized rules from other number systems, such as multiplication always makes bigger, or result from not understanding algorithms for multiplying and dividing fractions. Other difficulties preservice teachers have with fractions stem from not having a conceptual understanding of the mathematics. Thus, when asked to provide contextualized situations, they tend to create situations not related to the original problem or are unable to generate a situation at all.

Preservice teachers' conception of fraction multiplication is based off of the part-whole meaning of fractions. Studies suggest that in the context of multiplication, preservice teachers are more successful when the problem contains fractions less than one and whole numbers (Goodson-Epsy, 2009; Luo, 2009). Thus, more experiences with fractions greater than one as well as more problems not incorporating whole numbers are needed in teacher preparation programs.

Preservice teachers' conception of fraction division is largely focused on the sharing meaning of division. In addition, fraction division understandings are procedurally or algorithmically based. As a result, preservice teachers have difficulty with interpreting fraction division situations and struggle with representing the situation with an appropriate context.

Recent reports have begun to document the ways in which preservice teachers' develop an understanding of fractions (Tobias, 2012). Tobias (2012) found that their fraction understanding does not develop linearly in that knowledge of one topic may not be fully developed before they start to learn another. Thus, classroom instruction may need to focus on multiple fraction concepts before preservice teachers can develop an understanding of one idea.

Conclusion

By understanding preservice teachers' knowledge of fraction multiplication and division, future studies and improvements in teacher education programs can start to investigate the ways in which preservice teachers overcome their misconceptions to develop the mathematical understandings needed to be an effective teacher. Virtually every study suggests that strong teacher education programs and improvements to teacher education courses are needed, however little has been done to document the types of experiences preservice teachers need. With current recommendations suggesting that mathematics teacher education programs design instruction around what preservice teachers do know, and with the majority of studies focusing on fraction division, research is needed regarding preservice teachers' understanding of other fraction topics. Though there has been a recent increase in the number of publications pertaining to preservice teachers' knowledge of fractions, this is still not enough for teacher educators to have an adequate understanding of how preservice teachers think.

Acknowledgments

The authors would like to thank Cindy Edgington for her work on previous versions of this manuscript.

A critical practice in teaching elementary mathematics is posing problems that build on children's mathematical thinking. As such, teacher educators must provide pre-service teachers (PSTs) with a set of learning experiences to support PSTs in this practice. In this study, we present our analyses of PSTs' responses to a sequence of three methods course activities that engaged them in increasingly complex tasks requiring the PSTs to write problems in response to authentic student work.

Keywords: Children's Thinking; Teacher Education–Preservice; Mathematical Knowledge for Teaching

Introduction

Research suggests that a critical practice in teaching elementary mathematics is posing problems that build on children's mathematical thinking (Carpenter et al., 1999). An implication of this research is that teacher educators must provide pre-service teachers (PSTs) with a set of learning experiences to support PSTs in engaging in this critical practice. However, as a field, we know little about the design, enactment, or sequencing of these kinds of experiences. In this study, we present our analyses of PSTs' responses to a sequence of activities that engaged them in increasingly complex tasks requiring the PSTs to write problems in response to student work.

Theoretical Frame

Shulman (1986) suggested three types of knowledge are important for teaching - subject matter knowledge, pedagogical content knowledge, and curricular knowledge. Since that article, Ball and colleagues (Ball, Hill, et al., 2005; Hill, Sleep, et al., 2007) have built on Shulman's work and have provided the Mathematical Knowledge for Teaching (MKT) framework further defining subject matter knowledge (SMK) and pedagogical content knowledge (PCK) and identifying subsets of these knowledge bases. We are grounding this study in two subsets of PCK—knowledge of content and students, "knowledge that teachers possess about how students learn content" (Hill, Sleep, et al., 2007, p. 133); and knowledge of content and teaching, "mathematical knowledge of the design of instruction, includes how to choose examples and representations, and how to guide student discussions toward accurate mathematical ideas" (Hill, Sleep, et al., 2007, p. 133). These subsets of the PCK construct are useful as we are asking PSTs to think about how students solved particular problems and then use that knowledge of students to design subsequent instruction.

Also relevant to this study is the *professional noticing of children's mathematical thinking* construct (Jacobs, Lamb, & Philip, 2010). Three interrelated skills: *attending* to children's strategies, *interpreting* children's understandings, and deciding how to *respond* on the basis of children's understandings comprise the construct. Within our methods course, we ask PSTs in several instances to talk about what they notice in student work (via video clips and written) and discuss what they think students do or do not understand. Finally, we ask PSTs to use what they know about students to generate a next problem.

Methods

Data were collected from thirty-three, first semester, senior level PSTs (32 female, 1 male) enrolled in an elementary mathematics methods course taught by the first author in fall 2011. The data include PST responses to three different activities, each of which are from a set of methods course materials written by the second and third authors (Drake, Land, et al., 2011). The activities were designed to scaffold and support PSTs as they developed the capacity to make sense of student strategies and to write appropriate subsequent tasks for students. Each of the activities is set in the context of actual classrooms. The three activities were posed over the first six weeks of the course and were sequenced in order to provide PSTs with various experiences analyzing and writing effective tasks based on student thinking. The first activity (Natalie's Class the Next Day) was designed to give PSTs the opportunity to notice and analyze how an experienced teacher used her students' current knowledge of division with fractional remainders to design a subsequent story problem and number choices. The second activity (Counting Sequences) required the PSTs to write an opening number routine (ONR) and problem, including number choices to address a class-wide addition misconception. The third activity (Fishbowl Problem) asked PSTs to analyze 14 students' multiplication strategies and write a subsequent problem with number choices to address the wide range of learners. We organized the activities to form a trajectory along several dimensions – moving from noticing an expert teacher's task design to having PSTs design tasks themselves, moving from designing a task to address a single misconception to writing a task that addressed a wide range of student understandings, and moving from PSTs noticing an expert teacher's number choice to selecting numbers for a pre-written task to writing an entirely new task.

Data Analysis and Results

Natalie's Class the Next Day

Prior to completing the Natalie's Class the Next Day task, PSTs watched a video with transcript of Natalie and her 2nd grade class as they solved two partitive division story problems:

> <u>Problem #1</u> Trisha and Allie are sharing ______ chocolate chip cookies. If they are shared equally, how many will each of them get?
>
> 2 4 5 8 9 12 13
> 30 31 50 51 66 67 83
>
> <u>Problem #2</u> Trisha, Allie, Lance, and Kathy are sharing brownies. If they are sharing _____ brownies equally, how many will each person get?
>
> 4 5 8 9 16 17 20
> 32 33 44 45 48 49 50

Multiple number choices are given to provide for differentiation. Students were to choose the row of number choices "just right" for them. In Problem #1, even numbers were posed followed by the next consecutive number (with the exception of 2 and 83). In Problem #2, multiples of four were posed followed by the next consecutive number. The use of next consecutive numbers was intended to provide a scaffold in that students could use what they knew about one number choice to help with the next. Included in the video are examples of student work, teacher/student interactions, and a sharing session where students explain their various strategies. After discussing the video, PSTs are asked to complete the following activity:

> The next day, Natalie posed the following problem. Solve the problem for a few of the number choices. Then, answer the questions below.
>
> There are ____ miniature candy bars. Dustin, Jose, Sam, and Joe are going to share the candy bars. If they split up the candy bars equally, how many will each of them get?
>
> 11 17 22 35 48
> 65 83 75 99 104

1. Why do you think Natalie posed this particular problem next?
2. What do you notice about the number choices in this problem compared to the number choices given the day before?

Analysis: Natalie's class the next day. As we examined responses from the PSTs, we focused on their responses to question two. The next problem Natalie posed is also a partitive division problem and extends the second problem from the day prior in sharing a set of objects among four people. We analyzed PSTs' responses according to their noticing of three aspects of Natalie's number choices: (1) the numbers in both rows are both *larger* numbers than the day before; (2) the numbers are more *complex* in that students had to think not only about sharing remainders of zero and one, but also two and three as well; (3) the next consecutive number *scaffold* that had been used the day before has now been removed. Two authors independently coded the PSTs' responses for evidence of these three facets with 94.9% agreement (94/99).

Here is a sample response from one of the PSTs, Jaceylyn (all names are pseudonyms):

> The first thing that stood out to me about these number choices was that they were generally larger than the ones offered on the previous day. Next, when I actually started working with them, I found that these number choices granted me with quite different answers than the day before. On the previous day the answers had either been whole numbers, or sometimes involved a half as well, but today the answers came out with remainders of ¾ or ¼.

This response was coded as identifying larger numbers as well as more complex numbers.

Results: Natalie's class the next day. We examined the 33 responses to the Natalie's Class the Next Day activity in two ways: (1) how many of the facets of the number choices were identified by each PST, and (2) number of PSTs that identified each facet. The results are presented in Tables 1 and 2. We interpreted this data through the lens of MKT, specifically as indication of knowledge of content and teaching; knowledge of how to choose examples and design instruction. From the data one can see that ~48% of the PST identified either zero or one facet of the number choices, ~42% identified two of the three facets and only a small percentage (~9%) were able to identify all three. We posited that it might be more likely for PSTs to notice the larger numbers and the lack of scaffolds than recognize the complexity of the numbers, as the first two required less developed knowledge of content and teaching.

Table 1: Number of Facets Identified

# Correctly identified	# PSTs
0	7
1	9
2	14
3	3

Table 2: Percentage of Each Facet Identified

Facet	# PSTs	% PSTs
Larger numbers	13	39.4
More complex numbers	18	54.5
No scaffolds	15	45.5

Counting Sequences

The Counting Sequences activity begins with the PSTs watching a video with transcript of Jenny's first grade class. For her ONR, Jenny poses the following counting sequences to her students that focus on base-ten concepts: 30, 40, 50, ______, ______, ______. 44, 54, 64, ______, ______, ______. 57, 67, 77, ______, ______, ______. 157, 167, 177, ______, ______, ______. Jenny's students are able to solve the tasks by counting by 10. Students also notice the units place remains the same and the tens place number increases by one each time. They are able to solve the sequence that "crosses over" from a 2-digit number to a 3-digit number. The video ends with Jenny posing a story problem about a paleontologist:

> A paleontologist had _____ dinosaur bones. He found some more. Now, the paleontologist has _____ dinosaur bones. How many bones did he find?
> (10, 70), (20, 84), (26, 126), (15, 65), (60, 150), (42, 53)

The activity provides PSTs with a description of student work from the Paleontologist Problem:

> Most of the children solved the paleontologist problem by using a hundreds chart, but many counted by ones when counting up to the second number instead of counting by tens. Some children did count by tens. For 20 and 84, the children who were counting by tens either counted by ones from 20 to 84, or counted by tens to 80, then counted 4 more. Nobody solved for 42 and 53 (Drake, Land et al., 2011).

Following this description, the story problem Jenny used the next day (without number choices) is given, "Today, the paleontologist is looking for fossils. He already had ____ fossils in his collection. He found some more. Now, the paleontologist has ____ fossils. How many fossils did he find?" The counting sequences activity was then posed for the PSTs to complete:

> Now that you have seen the Counting Sequences video (and its transcript), consider these questions related to students' solutions to the Paleontologist Problem.
>
> 1. What is the disconnect between how students counted in the opening routine and the counting strategies they used when solving the problem?
> 2. Why do you think the disconnect exists?
> 3. Considering this disconnect, generate two artifacts for the next day's lesson: an opening number routine and number choices for the Paleontologist problem given below. Briefly justify your choices.

In this activity, we were interested to see if: (1) the PSTs could recognize many children did not see their counting by tens strategy in the sequence activities as applicable in solving the join-change unknown story problem; (2) they could posit reason(s) for the disconnect; (3) they could design an ONR to address the reason(s) stated in 2; and (4) they could select appropriate number choices for the next day's problem. We believe this task was a natural progression from the previous task, as it required PSTs to interpret and respond to a general mathematical misconception within a class of children.

Analysis: Counting sequences. Prior to analyzing this data set, the authors collaboratively examined several responses to this activity from a previous course and through open and emergent coding (Strauss & Corbin, 1998) established a series of codes and operational definitions for: (1) identifying the disconnect explicitly and accurately (yes/no/no response); (2) number of reasons given for the disconnect (0, 1, 2 or more); (3) identifying the degree to which the ONR addressed the reason(s) given (low, medium, high); and (4) classification of the types of number choices we believed were appropriate for Jenny's students (count by 10s from a decade number as given in Jenny's original Paleontologist Problem, count by 10s from a non-decade number, count by 10s and 1s). We operationalize the degree to which the ONR addressed the reasons for the disconnect by examining the approaches the PSTs took in selecting the type of task, structure and/or number choices for their ONR. PSTs who used the same approach as Jenny, or used approaches that did not connect to their reason, were ranked low. PSTs who attempted at least one new type, structure or number choice related to their reason, and did so in a manner we *believed* could be effective, were rated medium. PSTs who made significant changes (more than one new approach) related to their reason, and did so in a way we were *confident* could be effective, were rated high. Reliability percentages for each of the four categories are as follows: Disconnect: 90.9%; Reasons: 75.8%; Degree: 78.8%; Number Choices: 87.1%. We discussed disagreements and reached consensus on the final codes.

Chelsea's response follows. The numbers correlate with the questions given above:

> 1) When students were counting in the counting sequences opening routine, they were counting by tens and realized that the second digit of the number was remaining the same. However, once they tried solving the problem, the students began counting by ones, and it threw them

off to try counting larger numbers by ones.

2) When counting by tens, the second digit of the number remains the same. It creates a pattern and makes it easy to continue in an almost rhythmic-like pattern of repeating “10, 20, 30, 40, 50...” and so on. However, when counting by ones, the second number changes along with the first number and this can be very confusing for kids if they are counting “10, 11, 12, 13, 14, 15, 16, …”

3) Opening Number Routine – Fill in the blanks with the missing numbers.

10, _____, _____, _____, 50, 60, _____, _____, 90, _____
5, _____, 25, 35, _____, _____, 65, 75, _____, _____, 105
100, _____, _____, 130, _____, 150, _____, _____, 180, _____, _____

Problem for the next day
Today, the paleontologist is looking for fossils. He already had ____ fossils in his collection. He found some more. Now, the paleontologist has ____ fossils. How many fossils did he find?
[10, 30]   [5, 25]   [100, 175]   [3, 43]

I chose these numbers because I started out with simpler numbers that they could easily apply their counting sequence strategy to a word problem (10, 20, 30). I then moved on to [5, 25] because starting at 5 and counting by tens is slightly more difficult. Next I did [100, 175] because starting at 100 is difficult, and they also have to count by 5’s once they get to 70. Finally, I placed the hardest number choice last because the students have to count by tens, but they are starting at 3, which will throw them off to see a 3 as the last digit, and they will really need to understand the process of counting by tens to get from 3 to 43.

The above example was coded as (1) *yes* to identifying the disconnect; (2) *0* for not identifying a reason for the disconnect; (3) as *low* for the degree in which he/she addressed the disconnect as it is the same approach used by Jenny; and (4) as having *counting by tens from a decade number, counting by tens from a non-decade, and counting by tens and ones* in the number choices.

Results: Counting sequences. Of the 24 PSTs who attempted to identify the disconnect within Jenny’s class (9 no response), 18 were able to accurately do so (75%). 18 of those 24 (75%) were able to posit at least one reason why the disconnect may have occurred. When it came time, however, to design an opening number routine that would address the disconnect, more than 50% of PSTs simply posed “more of the same” approaches Jenny used. Ten PSTs (30.3%) made an attempt to try something different, but only five PSTs (15.2%) were able to do so in a way we felt confident would afford the children multiple opportunities to make the connection between skip counting by 10s in patterns and using skip counting by 10s as a strategy for solving join-change unknown addition problems. The number choices data were more encouraging. There was a high percentage of PSTs (42.4%, 14/33) who included at least two of the three appropriate number choices or all three of the appropriate number choices (48.5%, 16/33) in the next day’s problem. Three PSTs included only one of the appropriate number choice types. One emerging pattern from these data is our PSTs seem to be able to understand and identify student thinking, but often struggle using this information to effectively address it.

Table 3: Counting Sequences Results

Disconnect			Reasons			Degree			Number Choices		
Y	N	NR	0	1	2+	L	M	H	10sD	10sND	10s1s
18	6	9	15	9	9	18	10	5	25	29	24

Fishbowl Problem

The Fishbowl Problem is set in the context of Molly’s 2nd/3rd mixed age classroom. This task was built around PSTs’ examination of examples of student work from 14 children in Molly’s class in response to the following multiplication problem:

> Sam had ____ fish bowls. He had _____ fish in each bowl. How many fish did Sam have? Molly presented 4 pairs of number choices for her students to pick from: A: (2, 10), (5, 10); B: (4, 20), (8, 20); C: (3, 11), (6, 11); D: (4, 12), 8, 12).

The task for the PSTs was as follows:

1. First, consider Molly's learning goals—what are they?
2. Next, look at the student work on the following pages. What do you find interesting? What evidence can you identify that students are or are not making progress toward the learning goal(s)?
3. Write a problem for the next day along with a rationale. What do you think will be an appropriate problem that will meet the range of needs in Molly's classroom? Reference at least three students or group of students specifically in your rationale.

We believed this activity was an appropriate next task for the PSTs' development as it required them to analyze and make sense of several children's thinking, to write a story problem appropriate for the entire class and simultaneously attend to specific strategies and learning goals when writing number choices. This activity is very similar to the work of teaching and required PSTs to use many different knowledge bases to effectively complete the activity. Molly had different goals for different groups of children in her room. For some children she wanted to see if they were able to skip count by multiples of ten. For others, she wanted to see if they could notice and use the doubling relationship between the pairs of numbers she had chosen for them to solve. She included number choices like 11 and 12, to see if any children would solve using the distributive property and their knowledge of tens.

Analysis: Fishbowl problem. In our analysis of the children's work, we classified their approaches into one of four categories: (1) direct modeling: children in this group either could not solve any of the multiplication tasks, or did so by directly modeling the solution with drawings; (2) skip counting: children in this group skip-counted by 10s and/or multiples of 10; (3) repeated addition/break apart by place: children in this category solved tasks by writing the multiplication problems as repeated addition and then broke the 2-digit numbers like 11 and 12 apart by place value and added the 10s and 1s separately; and (4) doubling: the children in this group also used repeated addition to solve the first number choice in the pair, but were also able to recognize the relationship between doubling the number of groups and doubling the product.

Similar to our analysis of the Counting Sequences Activity, the authors first collaboratively examined several responses to this activity from a previous course and established a series of codes and operational definitions for writing an appropriate story problem (yes/no) and demonstrating understanding of children's strategies (yes/no). In our analysis of the PSTs' number choices, we coded their responses in terms of addressing current student understanding and in terms of addressing Molly's learning goals. As we coded the responses in terms of addressing students' current understanding, we first looked for evidence in the rationale that the PSTs were *attempting* to choose numbers for specific individual's (or groups of children's) strategy. If we found evidence, we then examined the number choices they selected in order to determine if they had *successfully* done so. We coded their number choices in terms of learning goals in a similar manner. If PSTs explicitly mentioned a learning goal in their rationale, we coded it as an *attempt.* If an attempt was made, we then determined if the number choices were appropriate. If so, we coded it as a *success*. Reliability percentages were calculated for each category and ranged from 73.5% – 93.9%. Consensus was reached on all disagreements.

Samantha's response follows as an example. For space purposes only her problem is shared:

> Olivia has ____ drawers. She has ____ pencils in each drawer. How many pencils does Olivia have?
>
> I want to address the same goals, but have structured them so some are easier than her first examples, some the same difficulty, and some harder.

Group A (3, 10) (4,10) (6, 10) (11, 10) *Here I want to practice going over 100 to provide some extra challenge. I also wanted those struggling to recognize the relationship between the 3 and 10 and the 4 and 10.*

Group B (1, 20) (2, 20) (4, 20) (8, 20) *Here I want the students to start on the 20s to focus on the relationship between the first and second number in the problems, but also the first numbers over the sequence.*

Group C (4, 11) (5, 11) (7, 11) (5, 12) *Here I want students to apply their knowledge of counting by 10s and then adding 1s to solving the problem. Hopefully having the second number switch to 12 will have these extend that knowledge.*

Group D (2, 11) (2, 12) (2, 13) (2, 14) *I wanted the students who've really gotten a hang of this 10s and 1s concept to apply it and to see patterns by keeping the 2 consistent.*

In this case, the above problem was coded not attempting, and thus, not successful, in addressing specific student's strategies. However, it was coded as attempting and successful in choosing numbers for specific learning goals.

Results: Fishbowl problem. The data supports the preliminary result from the Counting Sequences activity. We can see by this stage in our sequence a vast majority of the PSTs (31/33, 93.9%) made sense of the student work provided and were able to write an appropriate story problem type (28/33, 84.8%). When it comes to writing number choices for the next story problem however, it becomes evident that: (1) PSTs have difficulty in addressing multiple groups of student thinking simultaneously; (2) when PSTs do attempt to write specific number choices to address or further student thinking, they are not often successful in doing so (9/17, 52.9%; 8/26, ~31%; 7/15, ~47%; 5/12, ~42%); and (3) PSTs have difficulty writing number choices that attend to both student thinking and learning goals.

Table 4: Fishbowl Problem Results

		Number Choices for Students								Number Choices Learning Goals					
		Low/Direct Model		Skip Count		Repeat+ /BABP		Doubling		Skip by 10s		Doubling		Distributive Property	
Story?	Understand?	A?	S?	A?	S?	A?	S?	A?	S?	A?	S?	A?	S?	A?	S?
28	31	17	9	26	8	15	7	12	5	22	11	17	12	14	10

Discussion

As we interpret the results from this sequence of activities through the work of Jacobs and her colleagues (2010), we conclude PSTs have become more adept at *attending* to and *interpreting* student thinking. The activities however, have not helped the PSTs to make similar progress in *responding* to student thinking. One possible reason for this result is that our sequence of tasks does not provide enough educative supports to develop PSTs' ability to respond appropriately to student thinking. We have not explicitly attended to the question, "What makes a number choice appropriate or inappropriate to support/extend a student's current way of thinking?" An activity that presents an example of student thinking and requires PSTs to select and justify an appropriate number choice from a list of possibilities might help to develop PSTs' ability to interpret, evaluate and write appropriate number choices. These conclusions can be explained in terms of the construct of MKT. Our sequence of activities appears to support the development of PSTs' knowledge of content and students. Through repeated exposure to authentic student work (both video and written), PSTs have improved in their ability to make sense of and evaluate students' thinking strategies in a variety of mathematical contexts. This knowledge base is paramount in *attending* to and *interpreting* student thinking. PSTs' knowledge of content and teaching however has not shown similar improvement. Though the PSTs have demonstrated an ability to interpret student thinking and "diagnose" mathematical inconsistencies, they have not yet developed the appropriate content knowledge base to respond effectively in "prescribing" the next treatment.

REPRESENTATIONS OF ALGEBRA INSTRUCTION IN PRESERVICE TEACHER EDUCATION

Jillian N. Wilsey

Deborah A. Moore-Russo
University at Buffalo, The State University of New York
dam29@buffalo.edu

This study examined preservice teachers' reactions to and reflections on a set of five animations as representations of algebra instruction. The results showed that most comments in the preservice teachers' reflections were related to: (a) student learning and motivation, or (b) the classroom and instructional environment. Few comments in the reflections focused on the preservice teachers' reactions to the realistic nature of the animations. The data suggest that animations are a useful alternative to video. Not only do they allow for a condensed format that is free of distractions and focuses on a specific scenario to be analyzed, this study suggests that animations can also promote productive reflection without prior scaffolding.

Keywords: Teacher Education–Preservice

Purpose of the Study

This study examined preservice teachers' reactions to and reflections on animations as representations of algebra instruction. It revolved around the implementation of animations with preservice teachers in a methods course and focused on their responses to the classroom dynamics portrayed in the animations. Since animations are a relatively new medium to represent classroom instruction, we explored preservice teachers' reactions to the animations themselves as well as the extent and quality of the preservice teachers' discussions relative to what they noticed in the animations. More specifically, this study addressed the following research question: What are preservice teachers prompted to discuss after viewing the animations when implemented without prior prompts or scaffolding?

Theoretical Framework

Star and Strickland (2008) define noticing as what preservice teachers identify and deem important or noteworthy when viewing a classroom scenario. Santagata and Guarino (2011) identify what they consider "fundamental skills for reflecting and learning from teaching" as "the ability: (a) to attend to important elements of instruction, (b) to reason about these elements in integrated ways, and (c) to propose alternative instructional strategies" (p. 134). While noticing is important, preservice teachers must also be able to reflect on what they have noticed before they are able to apply what has been observed.

Providing representations of classroom scenarios prompts preservice teachers to consider and discuss the dynamics portrayed thus helping to bridge theory with practice (Harrington & Garrison, 1992). Video is commonly utilized to provide these representations along with guidance from provided prompts or scaffolding to facilitate what is noticed and reflected upon. However, Stockero (2008) points out that preservice teachers "need to move away from a dependence on external prompting if they are to continue to ground their analyses in evidence after a university course is over" (p. 377).

While videos have been a common medium in teacher education, animations are relatively new but provide unique benefits. Although animations represent practice, they are scripted in a manner that allows for a condensed format in terms of both focus and duration. Animations, because they are manufactured representations of instruction, can be pared down to specifically what one wants the viewer to consider in a time-efficient manner. This reduction in complexity removes many of the distractions that naturally accompany video. In fact, Moore-Russo and Viglietti (2011) found in their study of teachers' reflections on animations of geometry instruction that the lack of complexity did not impact the preservice teachers' impressions of the animations as realistic representations of teaching.

Methodology

Participants

Data for this study came from two groups of preservice teachers enrolled in a methods course for secondary mathematics teachers in the fall 2010 and fall 2011 semesters at a large research university in the northeastern United States. All of the preservice teachers held mathematics degrees and were enrolled in a certification program through a graduate school of education. The fall 2010 group of preservice teachers consisted of five females and three males. The fall 2011 group of preservice teachers consisted of four females and four males. Five of the eight preservice teachers in the fall 2010 section and six of the eight preservice teachers in the fall 2011 section were concurrently enrolled in their field observation components.

Setting

The methods course is a three-credit hour, graduate-level course with a primary goal of preparing those with mathematics degrees to be secondary school mathematics teachers. This course is designed to address the aspects of pedagogical content knowledge including: knowledge of content and students, knowledge of content and teaching, and knowledge of content and curriculum (Ball, Thames & Phelps, 2008). The course covers a variety of topics including classroom management, lesson planning, and implications of educational theories (e.g., social constructivism) on the practice of teaching. There is a particular emphasis on the National Council of Teachers of Mathematics' (NCTM's) (2000) vision for mathematics education.

About half way through each semester, the preservice teachers were assigned to view five animations over a period of five weeks, one per week. The instructional intentions were to use the animations as a common reference for collaborative reflection, discussion, and analysis. They provided an opportunity for teachers to engage in reflective discourse grounded in a shared experience, one that represented different secondary algebra classrooms.

The animations used cartoon figures to represent episodes of instruction in various secondary algebra classrooms. The cartoon figures were each colored, and their names corresponded to their colors. For example, one student was Blue, another was Red. All cartoon characters were gender neutral.

Since the preservice teachers were not able to go as a group to observe a classroom, the animations served as condensed, "shared" experiences for the methods class. The animations were from ThEMaT (Thought Experiments in Mathematics Teaching), an NSF-funded program at the University of Maryland, which has developed animations as representations of classroom scenarios to be used in teacher education (for more information on the animations representing algebra instruction that were used, go to http://www.education.umd.edu/MathEd/ThEMaT.html).

The animations were chosen as representations of teaching for two reasons. First, they portrayed secondary classroom instruction—all from different classrooms with different teachers (as noted by the varying voices used for the teachers in the animations). Second, they have been found to be effective in eliciting discussion among experienced teachers often compelling them to project themselves into the stories (Herbst & Chazan, 2006).

Data Collection and Analysis

After viewing each animation, the preservice teachers were required to make three entries (two in response to classmates) to an asynchronous, electronic discussion forum over the course of a week as a part of their homework assignment. The instructor did not contribute to the online discussion boards nor was any feedback to the entries provided. Students were informed that they were to be graded on their entries, considering both the content of their entries and the personal knowledge growth evidenced from the entries over the course of the semester.

Inductive content analysis was used to identify the themes emerging from the discussion board data. This consisted of multiple readings followed by the recording of each researcher's thoughts utilizing theoretical memoing (Glaser, 1998). Once this stage was completed, the researchers revisited the discussion board entries jointly and compared their memos, forming categories. The researchers noted that most notions raised in the memos were mentioned by both researchers and often on more than one animation.

The researchers jointly revisited each animation in light of the identified categories until it was clear that all ideas in the entries would be able to be coded. The research team then jointly conducted a "horizontal" pass through the discussion boards agreeing on themes that emerged from the categories that ran across all five animations. After this, the researchers then independently coded all 248 of the preservice teachers' discussion board entries. Each individual discussion board entry served as the unit of analysis. Each unit of analysis was assigned as many codes as were deemed applicable. The overall percentage of agreement for coding was above 90% for both 2010 and 2011 sets of data. The Cohen's kappa values were at or above 0.80 for each data set, well above the generally accepted 0.60, which represents good agreement (Landis & Koch, 1977; Altman, 1991). The two independent coders reached consensus by means of discussion for each entry that had been assigned a different code. The research team began analysis at this stage.

Results

During the analysis, several themes evolved from the discussion forums. In reviewing and coding the discussion board entries over five animations and two methods courses, six recurrent themes were identified: (a) *supporting student learning and motivation*, (b*) classroom and instructional environment*, (c) *mathematics in the animations*, (d) *reflections on past observations and one's own future practices,* (e) *reality of the classroom*, and (f) *reactions to the animations*.

Table 1 presents the frequency of comments relating to each identified theme, along with the percentage, or relative frequency, for each category. Examining the compiled data, the greatest amount of time was spent in discussing *supporting student learning and motivation* while the least amount of time was spent in discussing the *reactions to the animations*. The *supporting student learning and motivation* theme included categories focused on student learning such as understanding as the goal of instruction, providing positive feedback for students' efforts, building on what the students know, responding to students' questions, and preventing or correcting student misconceptions.

Table 1: Presence of Themes in Discussion Forum

Theme	Frequency	Relative Frequency
Supporting Student Learning and Motivation	461	42
Classroom and Instructional Environment	303	27
Mathematics in the Animations	168	15
Reflections on Past Observations and One's Own Future Practices	81	7
Reality of the Classroom	59	5
Reactions to the Animations	39	4

The theme with the second highest frequency of comments was the *classroom and instructional environment* theme. This theme contained categories that were concerned with the teachers' instructional obligations, preparedness and flexibility, attitude, and the classroom environment in general. Comments in this theme were often related to what a teacher should do such as support and explain ideas presented and provide more direct instruction when it is clear that guiding is not productive. Comments also captured the nature of the classroom environment as one that should be safe and respectful where students are not afraid to ask questions.

The *mathematics in the animations* theme included comments revolving around the mathematics presented in the animations and the use of technology such as calculators. This theme also captured the multiplicity of mathematics in that mathematical concepts can often be represented or considered in multiple ways and often there is more than one solution method that may be applied when solving a problem.

The final three themes that presented were not as frequently noted. The *reality of the classroom* theme focused on the challenges faced in the classroom environment such as time constraints and pressure to cover a certain amount of material or to cover it in a certain way in order to satisfy state assessment requirements. Comments in this theme also addressed the fact that not all students will perform optimally and give forth their best efforts. The *reflections on past observations and one's own future practices* theme included comments that related to individual preservice teachers' reflections on what they believe they will encounter in their classroom and the decisions they may make in response. This theme also included categories that captured the preservice teachers' reflections that compare what was presented in the animation to what they experienced throughout their academic career and in their field observations. The *reactions to the animations* theme captured comments and discussion that focused solely on the nature of the animations themselves, such as comments related to the depiction of the characters in the animations or to the animations as a particular snapshot in time where the viewer does not know what came before or transpired after that featured episode.

Discussion

The data show that the preservice teachers were most likely to post entries on the discussion boards that fell under the *supporting student learning and motivation* theme. This theme had 13 categories; the most frequently evidenced category related to *understanding* as the goal of instruction and issues around promoting deeper student thinking. The *understanding* category represented 21% of the comments under this theme. The following entries exemplify the comments made by the preservice teachers that were assigned to the *understanding* category:

> *The teacher asked a lot of questions to see where the students understanding was, and [did] not move on until they all showed understanding.*

> *The students that have to explain it are forced to have a complete understanding of the material ... This shows a class that is much more focused on a conceptual understanding of what is going on than a simple procedure.*

The second most prominent category was *constructivism*, which was assigned to 16% of the comments under the *supporting student learning and motivation* theme. Comments that mentioned building on what the students know and allowing students' ideas to guide the direction of instruction were assigned to this category. The following entries exemplify the comments made by the preservice teachers under the *constructivism* category:

> *I loved the way that the teacher was able to step back and allow the students to explain their solutions and their reasoning.*

> *I think "tricking" the students into thinking that they are coming up with all of the work is a pretty good strategy to use. In reality, they are actually coming up with most of the work.*

Other categories under the *supporting student learning and motivation* theme also were evidenced in 10% or more of the preservice teachers' comments. The *affective concerns* category, which was assigned comments related to providing positive feedback to students and acknowledging their efforts, represented 13% of the comments under this theme. The *responding to students' questions* and the *addressing student misconceptions* categories each represented 10% of the comments under this theme. The following entries exemplify the comments made by the preservice teachers under the *affective concerns* and *addressing student misconceptions* categories, respectively:

> *Showing them that we care will give them more confidence and make them more successful math students.*

> *Common mistakes, such as when half of the class gets the same wrong answer, need to be addressed, and correct answers need to be shown.*

The prominence of comments assigned to these categories provide evidence that even without direct, prior prompting or scaffolding, the preservice teachers were able to view the animations with a student-centered focus.

The theme that ranked in second place in terms of the number of discussion board entries assigned to categories under it was *classroom and instructional environment.* Under this theme, many comments made it clear that even though the preservice teachers were student-focused, they also were concerned with the teacher's role in the classroom. This theme had nine categories. The most frequently evidenced category related to *teachers' instructional obligations*, which included such things as providing clear, direct explanations. This category represented 21% of the comments under the *classroom and instructional environment* theme. The following entries exemplify the comments under this category:

> *[T]he teacher simply explains that "it isn't appropriate to use [negation] here" and that "time can't be negative anyway." Her first comment is vague at best and does not help the students.*

> *I felt the teacher was ineffective in their [sic] explanation…nothing was being summarized.*

The preservice teachers also posted a number of discussion board entries regarding how: (a) the material was presented, including the pace of the instruction and how the board and other resources are used in instruction (16%); (b) how teachers need to be prepared with the necessary knowledge of content and pedagogy that allows them to have flexibility in their teaching (16%); and (c) how the classroom environment should be a safe and respectful one where students are encouraged to ask questions and share (15%). The following three entries exemplify the comments under *instructional presentation*, *instructor's preparedness and flexibility*, and *safe/respectful environment* categories, respectively:

> *I really liked the use of the balance as an analogy for solving the problem. Many people talk about viewing an algebraic equation as a scale, but I liked how this teacher actually drew out a scale… It gave the equation a very tangible representation.*

> *… the teacher seemed like the type of teacher who is comfortable with one way to solve a problem [who] does not want to open up to the possibilities of other correct options. He is not confident in his understanding of the other ways of looking at the problem…*

> *I believe that it is all about creating an environment in your class where it is okay to be wrong… if I can get as many students as possible to feel comfortable doing this, the better my classroom will be.*

The theme with the third highest frequency was the *mathematics in the animations* theme. While all five of the animations focused on the mathematics inherent in a secondary algebra classroom, the greatest amount (42%) of entries under this theme were assigned to the *multiplicity of mathematics* category. Under this category, preservice teachers' comments frequently dealt with how there are multiple solution methods available for any given mathematical problem and that most, if not all, mathematical concepts may be thought of in multiple ways. The *mathematics in the animations* theme only had two other categories: the *general mathematics* category, which contained general comments about the mathematics in the animations, and the *technology in mathematics* category, which included comments about the use of technology as a tool to help solve mathematical problems or represent mathematical concepts. These categories held 40% and 18%, respectively, of the comments under the *mathematics in the animations* theme. Almost all of the entries assigned to the *technology in mathematics* category were for the fourth animation, which specifically dealt with the utilization of a graphing calculator. The following entries exemplify the comments made by the preservice teachers under the *multiplicity of mathematics* and *technology in mathematics* categories, respectively:

> *… although some students approached the problem differently all of the methods are correct and completely acceptable so its ok to choose the approach that makes the most sense to you as an individual …*

I think it is interesting though, how they were supposed to be doing it on the calculator. We include these technologies in classrooms so that students can get experience using the tools they will have in the workplace.

Reflections on past observations and one's own future practices was the fourth most common theme. Although some of the preservice teachers reflected on their own academic careers as students, most of the entries that were coded under this theme (44%) related to the *future-oriented reflections* category where the preservice teachers pondered what it would be like in their own classrooms and how they would handle situations that arose. The *reflections on past observations and one's own future practices* theme contained two other categories: the *past observations* category, which contained comments that made comparisons between the events in the animation and the preservice teacher's experiences as a student or in field observations, and the *other sources* category, which included comments revolving around comparisons between the animations and what the preservice teachers had been exposed to in courses, readings, and outside educational resources. These categories held 33% and 22%, respectively, of the comments assigned to the *reflections on past observations and one's own future practices* theme. The following entry exemplifies the comments made by the preservice teachers under the *future-oriented reflections* category:

I have always wonder [sic] how and what I should do with students who miss class, do I cross my fingers and hope they can just catch on and move along with the class? Or should I take them aside and help them learn the material they have missed?

The theme with the fifth highest frequency was the *reality of the classroom* theme. This theme also had only three categories. The most frequently evidenced category related to *students are different*, which included such things as recognizing that students often think about things differently and learn differently. Thus, teachers need to be aware that differentiated instruction may be required in order to satisfy the needs of all students. This category represented 46% of the comments under this theme. Other preservice teachers' comments often related to time constraints in the classroom and pressure to cover a certain amount of material or pressure to cover the material in a certain way to satisfy state assessments. This category, *pressure and constraints*, represented 42% of the comments under the *reality of the classroom* theme. The remaining category, *students do not perform optimally*, included such things as students' inability to recall information, minimal student effort, and poor student attitudes. This category represented 12% of the comments under this theme. The following entry exemplifies the comments made by the preservice teachers assigned to the *students are different* category:

There was [sic] definitely different levels of learners in this class, as well as different styles of learners.

Finally, the last theme contained entries that addressed the preservice teachers' *reactions to the animations*. The *animations as snapshots* category represented 38% of the comments under this theme. This category contained comments related to the realization that what transpired before or after the particular episode could have impacted the teacher's actions. By not having knowledge of prior or subsequent events, the preservice teachers recognized that their interpretation of the teacher's actions in the animations could be inaccurate. The *reactions to the animations* theme contained three other categories. The *characters in animation* category contained comments related to the depiction of the cartoon characters in the animations, in particular that the characters were identified without the use of gender, ethnicity, etc., and represented 31% of the comments under this theme. The remaining two categories were the *verifying reality of animations* category which suggested that the animations reflected what actually occurs in classrooms and the *questioning reality of animations* category which suggested that the animations do not reflect what actually occurs in classrooms. These categories held 26% and 5%, respectively, of the comments assigned to the *reactions to the animations* theme. The following entry exemplifies the comments made by the preservice teachers under the *animations as snapshots* category:

I'm not saying this is necessarily what I think, but there's a world of information not presented to us while watching a 2:49 clip.

In light of the fact that the *reactions to the animations* theme presented the least amount of comments overall, this provides evidence that the preservice teachers seemed to think that the animations were reasonable representations of teaching, which corresponds with Moore-Russo and Viglietti's (2011) study findings.

Overall, animations are a useful alternative both to group classroom observations and to video. While reducing the complexity of the classroom, they still provide a sense of the temporality of events and represent the dynamic, often ill-structured, nature of classroom instruction in a time-efficient manner. They focus on what teacher educators might want preservice teachers to notice, reflect upon, and discuss with their peers. In summary, this study suggests that unlike videos where research suggests that guidance is needed to direct preservice teachers' focus to particular events for analysis (Santagata & Angelici, 2010), animations seem not to need instructor scaffolding in order for preservice teachers to be able to productively notice and reflect on the presented classroom instruction.

This qualitative study examines (N = 33) pre-service elementary teachers' disposition toward mathematics. The theoretical framework of the study encompasses a sociotransformative constructivist perspective which best supports research using a positioning theory lens to view human experiences, dispositions and relationships developed through discursive practices. In order to examine discursive practices, we used an open-ended metaphor approach that allowed researchers to identify characteristics of disposition by opening up a "fresh space of truth-telling" and "powerful use of language and image" (Hagstron et al., 2007, p. 27). Through the use of linguistic and deconstruction analysis as well as meaning coding and meaning interpretation techniques (Kvale & Brinkmann, 2009), we found that the participants had a higher than expected productive disposition toward mathematics.

Keywords: Affect, Emotion, Beliefs, and Attitudes; Teacher Beliefs; Teacher Education–Preservice

Purpose of the Study

The purpose of this study is to ascertain affective disposition of pre-service elementary teachers ($N = 33$) towards mathematics and gain a better understanding of the nature of this disposition. The participants were asked to develop their own novel metaphor for mathematics. They were provided with the topic "mathematics" and asked to choose their own vehicle to describe mathematics as well as to provide a rationale for their choice. By eliciting the rationale, we were able to determine which salient aspects of their chosen vehicle are to be ascribed to mathematics.

For purposes of this study, disposition is defined as a habitual inclination on a continuum of feelings, thoughts and behaviors toward mathematics. In this study, disposition toward mathematics is considered by the degree of its productivity. The guiding research questions are: (1) What are the most frequent affective characteristics of pre-service teachers' disposition toward mathematics? (2) To what degree is pre-service teachers' disposition toward mathematics productive?

Theoretical Framework

The theoretical framework of the study is grounded in sociotransformative constructivism and is guided by disposition and positioning theory. Positioning theory, as a framework, guides the study of social phenomena i.e. productive and/or nonproductive dispositions. To further focus and narrow the conceptual framework, the affective domain of disposition theory is used as the basis for examination and evaluation of teacher dispositions. Teacher and student affective disposition characteristics influence mathematical knowledge constructed; thus the importance of identifying and measuring affective dispositional characteristics is in the significance of its role in the learning process (Beyers, 2011). The positioning triad, Figure 1, represents the interactive components of the positioning process and the essence of the theoretical framework applicable to this study.

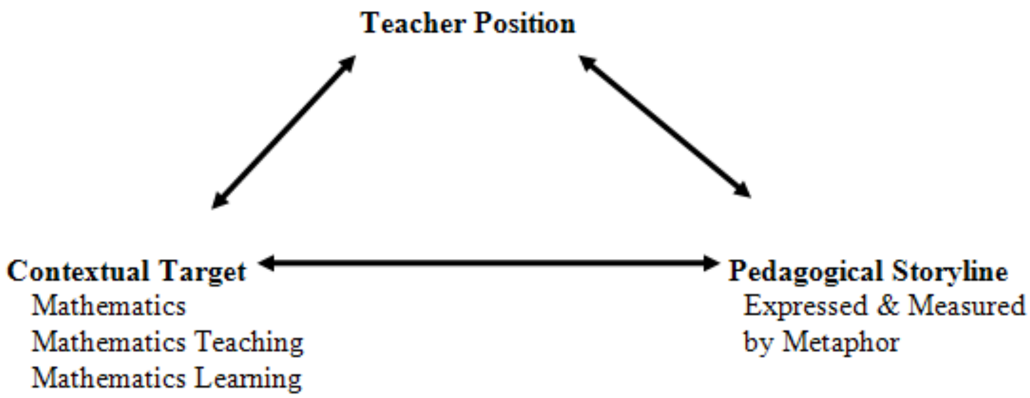

Figure 1: Positioning Triad

Source: (van Langenhove & Harré, 1999, p.18): modified to the framework of the teacher disposition study

Method of Inquiry

Metaphor Methodology in Studying Disposition

One way to gather self-reported assessment of disposition towards mathematics is through the use of a metaphor as a prompt. Metaphors are a vehicle that is easily understood by participants and encourages freedom of expression. In order to distinctly identify characteristics of disposition, the format of metaphors provides an indirect prompt allowing for free expression of feelings, emotions, and thoughts – positive or negative. For this study of disposition towards mathematics, participants were asked to develop a novel conceptual metaphor in response to mathematics (contextual target), such as "*Mathematics is like...*"

Participants

The thirty-three participants in this study were selected based on their membership in an undergraduate course titled *Teaching Mathematics in Elementary School*, offered at a university located in a binational/bicultural, border region of west Texas. All participants are considered to be senior education majors. Based on ethnicity, gender, and language, the sample of thirty-three participants would be considered a homogeneous sampling of pre-service educators.

The participants (self-reported) are predominantly female [94%]. A majority of the participants identified themselves as Hispanics [88%] and as bi-lingual English-Spanish speakers [79%]. Ethnicity and language abilities mirror the demographics of the region. Two participants indicated they are mono-lingual Spanish speakers and four participants indicated they are mono-lingual English speakers. 42% of participants indicated that Spanish was their primary language spoken. Of participants reporting years spent in schools in the United States, the mean number of years attending American schools is 13.7 years, with a range of 3.5 years to 19 years.

Data Collection and Analysis

Participants were asked to respond to an open-ended metaphor "*Mathematics is like ... Explain why.*" To maintain anonymity, each participant was assigned an alphanumeric code. Participants' responses to the open-ended metaphor were coded through linguistic and deconstruction analysis (Kvale & Brinkmann, 2009) and rated by two independent raters with regard to the degree of productivity of the pre-service teachers' disposition toward mathematics. Degree of productivity was measured using a 1–5 scale (1 – lowest productivity, 5 – highest productivity). Spearman's *rho* was calculated to report inter-rater reliability. The value of the reliability coefficient *.686 ($p<.001$)* indicates adequate inter-rater agreement. The participants' responses were also assessed by affective categories that were addressed in the metaphor. The categories are: nature of mathematics, usefulness, worthwhileness, and sensibleness of mathematics, as well as attitude, anxiety, and self-concept. Table 1 provides examples of affective dispositional statements characteristic of categories and levels of intensity.

Table 1: Affective Example Descriptors and Levels of Intensity

Rating Level		Example of *Mathematics is like…*	
		High Intensity	**Low Intensity**
1	**Highly Non-Productive**	*Mathematics is like a dule (dull- inserted) hair brush, because it makes me want to pull out my hair"*	*"Mathematics is like the unknown; not everyone knows math"*
2	**Non-Productive**	*"Mathematics is like a foreign language. Just when I feel like I am grasping it, I am shown something different"*	*"Mathematics is like something you are just not born for. I believe that every person has gifts and defects. Some are born to dance, some can write poetry, and I just believe that even though I can do some math, I wasn't born to be great at it"*
3	**Neutral**	*"Mathematics is like an adventure, because it always takes your mind to exploring different possibilities!"*	*"Mathematics is like a daily routine. There is always problems to resolve and you have to resolve them using the best strategy that you know and have on your hands, you learn from it and use it in future problems."*
4	**Productive**	*"Mathematics is like breathing. You do it every day, sometimes without even thinking."*	*"Mathematics is like second nature. I don't have as much of a difficult time, if I feel confident about it."*
5	**Highly Productive**	*"Mathematics is like air/oxygen. It's all around us and we can't seem to live without it."*	*"Mathematics is like the gateway to a better life. People who understand and do math well have more opportunities and better choices to make in life"*

Results and Discussion

The mean value for elementary pre-service teachers' disposition was at the level *3.41*, which was surprising to the researchers, considering a commonly held belief of elementary teachers' lack of content knowledge and avoidance of teaching and learning mathematics. Researchers believe that the "surprising" effect was due to the nature of the assessment instrument. An open-ended metaphor, as opposed to a closed-ended Likert-type scale question, allowed participants express themselves authentically and not locate their response to a predetermined scale.

The coding process was based on meaning coding and meaning interpretation techniques (Kvale & Brinkmann, 2009). Let's consider the following response from a Hispanic female pre-service elementary teacher (Survey Code # PS7): *"Mathematics is like something you are just not born for. I believe that every person has gifts and defects. Some are born to dance, some can write poetry, and I just believe that even though I can do some math, I wasn't born to be great at it."* Both raters assigned a level of "*2*" (nonproductive) on the (1–5) scale of productivity. This response reflected the stereotypical view of the existence of the "math gene phenomenon" that she refers to as *just not born for*. At the same time, the respondent recognizes the multiple intelligences (*gifts)* as positive characteristics, whereas the absence of "math gene" as a deficit (*defect).* Her final statement suggests a lack of perseverance toward learning success in mathematics by stating *that even though I can do some math, I wasn't born to be great at it.* The first portion of this final statement (*I can do some math)* contains an inclination toward self-efficacy, which deterred the raters from assigning a level of "*1*" (highly nonproductive) to this response. With regard to the affective categories, both raters agreed on the fact that this participant's response overwhelmingly reflected self-concept.

Let's consider another response from a Hispanic female (Survey Code # PS4): "Mathematics is like the gateway to a better life. People who understand and do math well have more opportunities and better choices to make in life." Taking into consideration a high inter-rater reliability coefficient, this response was independently rated at level "4" (productive) by one and "5" (highly productive) by the other. High productivity of this disposition was obvious to both raters because of the worthwhileness of mathematics (the gateway to a better life) as well as its usefulness (more opportunities and better choices). She also believes in sensibleness of mathematics and her self-concept (people who understand and do math well).

Conclusion

Disposition towards mathematics is under-researched in educational arenas, specifically with regard to pre-service elementary teachers' positioning toward the subject they feel less prepared to teach and therefore, avoid any encounter with it. The major intent of the proposed study is to address the gap in the research utilizing the lenses of positioning theory and disposition construct. Findings of this study, specifically a higher than expected productive disposition toward mathematics, may inform mathematics teacher educators in the development of learning cultures that recognize and address the positioning of pre-service teachers, and further guide them in the development of productive mathematical disposition.

Acknowledgments

The authors express their gratitude to Ms. A. Leanna Lucero for assistance in administering the survey with pre-service teachers enrolled in her section of *Teaching Mathematics in Elementary School* course.

STUDYING ABSTRACT ALGEBRA TO TEACH HIGH SCHOOL ALGEBRA

Erin Baldinger
Stanford University
erin.baldinger@stanford.edu

This study explores the transition from studying abstract algebra to teaching high school algebra in the context of an abstract algebra course designed for pre-service teachers. It addresses the question of how teachers develop mathematical knowledge for teaching using a case study approach. This research provides an empirical understanding of the role of mathematical content courses in teacher education programs. A preliminary finding highlights the importance of mathematical practices in the development of mathematical knowledge for teaching. By beginning to establish a research base on how teachers develop mathematical knowledge for teaching at the secondary level, teacher educators can begin to systematically and strategically incorporate these learning opportunities into teacher preparation programs.

Keywords: Mathematical Knowledge for Teaching; Post-Secondary Education; Teacher Education–Preservice, Teacher Knowledge

The transition from thinking about mathematics as a student to thinking about mathematics as a teacher marks a critical place in the trajectory of learning how to teach secondary mathematics. Pre-service teachers must develop mathematical knowledge for teaching (MKT) (Ball, Thames, & Phelps, 2008), which includes learning to use their mathematical content knowledge in ways that are distinct from how other educated adults use mathematics. Research has shown the importance of MKT in furthering student mathematical achievement (Ball, Lubienski, & Mewborn, 2001; Ball et al., 2008; Ma, 1999). However, the way in which secondary teachers successfully develop this knowledge remains an open question.

Developing Mathematical Knowledge for Teaching

Research shows that math majors or teaching licenses do not guarantee a teacher has sufficient mathematical knowledge for teaching (e.g., Ball et al., 2001; Monk, 1994). The German COACTIV study provides evidence that strong mathematical content knowledge (MCK) can support development of pedagogical content knowledge (PCK) in secondary teachers (Baumert et al., 2009). COACTIV uses a natural experimental design to demonstrate not only the importance of developing MKT (which includes MCK and PCK) in pre-service teachers, but also the important role that strong MKT plays in student achievement. There are many different, but complementary, conceptions of MKT (Hill, Sleep, Lewis, & Ball, 2007). This study takes the perspective that mathematical knowledge for teaching encompasses two domains: MCK and PCK (Ball et al., 2008; Baumert et al., 2009; Tatto & Senk, 2011), with strong MCK being a prerequisite for strong PCK (Baumert et al., 2009). MCK can be subdivided into knowledge of secondary and tertiary mathematics (common content knowledge) and specialized content knowledge (SCK). SCK is mathematical knowledge directly related to the practice of teaching (Ball et al., 2008). Both MCK and PCK are necessary parts of a teacher's knowledge.

Many mathematicians and mathematics educators have theorized about how pre-service teachers can develop the mathematical content knowledge they need to teach (Cuoco, 2001; Ferrini-Mundy & Findell, 2010; Hill, 2003; Stanley & Sundström, 2007; Usiskin, 2001; Wu, 2006; Zazkis, 1999). While each takes a slightly different view, they all agree that a traditional math major does not adequately prepare secondary math teachers. They emphasize the lack of connection between typical undergraduate mathematics courses and the mathematics taught in high school. However, these papers take a theoretical perspective and do not support their conclusions through empirical results. Therefore, evidence is still needed to address the question of how pre-service secondary teachers transition to developing MKT.

Mathematics Content Courses for Teachers

There are many possible settings for pre-service secondary teachers to learn and develop MKT. These include high school math courses, undergraduate math courses, math methods courses, and field experiences (Ball et al., 2001; G. Hill, 2003; R. Hill & Senk, 2004; Peterson & Williams, 2008). Learning in undergraduate math courses often suffers from what Cuoco (2001) calls the "vertical disconnect" (p. 3). Pre-service teachers are not able to see how higher level mathematics necessarily connects with the content they will be asked to teach. Learning through field experiences is idiosyncratic, as it is based entirely on the cooperating teacher attending directly to developing MKT (Peterson & Williams, 2008). While mathematics learning may occur in methods courses, focusing specifically on mathematical content is often beyond their scope. Since none of these settings are intentionally designed to emphasize content learning for teaching, MCK learning opportunities vary greatly. Mathematical content courses designed for pre-service secondary teachers potentially offer a focused opportunity to develop MCK.

R. Hill and Senk (2004) describe their process of developing a capstone course in mathematics for secondary teaching, which emphasizes secondary mathematics from an advanced perspective and aims to help pre-service teachers see the depth of content in the high school curriculum. Another style of course focuses on undergraduate mathematics while making explicit links to the high school curriculum. G. Hill (2003) describes how a pre-service teacher used ideas from an abstract algebra course to enhance student understanding of complex numbers in her field placement. Regardless of their form or content, math classes designed for pre-service teachers offer an excellent opportunity to examine the development of MCK.

Math content courses for pre-service teachers provide a possible site for developing MKT in general, and mathematical content knowledge in particular. This study examines one such course to address the following research question: How does a mathematical content course for pre-service secondary teachers influence their mathematical knowledge for teaching?

Methods

This study considers an abstract algebra course that makes explicit connections to high school algebra, a case of teaching undergraduate content specifically to pre-service teachers. Through written MKT measures, course observations, artifacts, and interviews with the professor and students, I will consider both the opportunities for developing MKT and learning outcomes. This case study provides insight into the effectiveness of a specific context in which MKT might develop by allowing for detailed qualitative analysis of opportunities for learning (such as homework problems focusing on "unpacking" a math concept [Ball et al., 2008]) as well as quantitative and qualitative measures of pre-service teacher MKT. The course took place at an east coast university within a teacher preparation program emphasizing mathematical content courses for pre-service teachers.

Data Sources

In order to identify opportunities to develop MKT in the class, I observed each class session and took detailed field notes. I collected artifacts such as the syllabus, assignments, and student work samples. I also interviewed the professor to discuss course goals and plans (if any) for creating opportunities for students to develop MKT. To document the student learning, all participants completed written pre- and post-measures of MCK focusing on algebra and geometry topics. To supplement the written measures, I interviewed participants to investigate their beliefs about teaching and learning math and to unpack their mathematical thinking. These semi-structured interviews help capture both MCK and PCK through the use of a think aloud protocol. Incorporating a range of measures helps form a more complete picture of the role of the course in developing MKT (Hill et al., 2007).

Data Analysis

To understand the opportunities participants have to develop MKT, data were analyzed qualitatively using both MCK and PCK lenses. For example, I coded field notes by identifying the math content (e.g.

algebra, geometry) and the level of content (secondary or tertiary). I categorized each learning segment as an opportunity to develop common or specialized content knowledge. I coded for connections between math and teaching (e.g., how to respond to a student error). I take these two lenses because while the course will primarily provide opportunities to develop MCK, it may also provide some opportunities to develop PCK.

After unpacking the opportunities provided for learning, I looked in greater detail at the changes in MKT that occurred after participation in the course. Data analysis was both quantitative and qualitative. The written MKT measure gave insight into the impact of participation in the math class. Analysis considered changes from pretest to posttest while controlling for factors such as previous math learning opportunities. Qualitative analysis of pre- and post-interviews used line-by-line coding to look for changes in the ways participants talk about and use mathematics. I coded for dimensions such as conceptual understanding and procedural fluency (Kilpatrick, Swafford, & Findell, 2001), as well as using mathematical practices, making connections between high school and college math, and making connections to the practice of teaching. Finally, I coded these interviews for links to the opportunities to learn identified in the analysis of the course itself. This helps clarify how students built on the opportunities to enhance their own mathematical knowledge for teaching.

Preliminary Findings

This research investigates the transition from thinking about mathematics as a student to thinking about mathematics as a teacher by considering how a math content course influences the development of mathematical knowledge for teaching. Participants in the course entered with varying levels of MKT and differing use of mathematical practices. As the class progressed, participants improved their ability to be mathematically precise, particularly in their use of language, construct rigorous mathematical proofs, communicate mathematical ideas, and persevere in problem solving. These improvements can be clearly linked to course emphasis on proof and communication. The professor also emphasized the importance of clear communication when teaching secondary math. To help participants develop these mathematical practices, the professor uses challenging mathematical tasks and a problem-based approach to teaching. This attention to mathematical practices suggests that they play a fundamental role in developing mathematical knowledge for teaching.

Implications and Directions for Future Research

This careful investigation of a mathematics class focused on developing mathematical knowledge for teaching offers an important insight into secondary teacher preparation. The ability to use mathematical practices plays a crucial role in the process of developing mathematical knowledge for teaching. This indicates that content courses should make practices an explicit part of the learning experience. By beginning to establish a research base on how teachers develop MKT at the secondary level, teacher educators can begin to more systematically and strategically incorporate these learning opportunities into teacher preparation programs. Since strong mathematical knowledge is a prerequisite for successful mathematics teaching, attention to its development, along with other aspects of teacher preparation, may improve the quality of mathematics teaching in this country.

While this study presents one case of focused mathematical content instruction, it is clearly only one of many possible cases. Future research might focus on the variety of ways in which teachers develop this knowledge. Other research will take the important step of following teachers with this type of preparation into the classroom, documenting their mathematical quality of instruction and connecting it to student learning. This research represents a first step toward a firmer understanding of where and how mathematical knowledge for teaching is developed.

THE CONTINUUM OF PRE-SERVICE TEACHERS' MKT OF MATH STRINGS

Laura Bofferding
Purdue University
LBofferding@Purdue.edu

Twenty pre-service teachers in a mathematics methods class interpreted patterns embedded in math strings and responded to questions about representing the patterns and anticipating student's solutions. The pre-service teachers' responses fall along a continuum of specialized content knowledge and pedagogical content knowledge; furthermore, their knowledge varies according to whether they are asked to focus on the problems versus representations. These results highlight the types of mathematical content that methods courses must emphasize (along with possible contexts for introducing them) to help pre-service teachers support their students in developing key mathematical practices.

Keywords: Mathematical Knowledge for Teaching; Number Concepts and Operations; Teacher Education–Preservice; Teacher Knowledge

Together with the process standards put forth by the National Council of Teachers of Mathematics (NCTM) and the recent standards for mathematical practice, which are part of the Common Core State Standards for Mathematics (CCSSM), students face increasing pressure to make sense of and interact with the mathematics they learn, rather than memorize procedures. Three standards in particular require that students identify connections among problems (*Look for and make use of structure*, CCSSM; *Connections*, NCTM), model or represent relationships among problems using materials and drawings (*Model with Mathematics*, CCSSM; *Representation*, NCTM), and effectively communicate about mathematical relationships (*Attend to Precision*, CCSSM; *Communication*, NCTM) (National Council for Teachers of Mathematics, 2000; National Governors Association Center for Best Practices & Council of Chief State School Officers, 2010). These mathematical practices are important for teachers to emulate and emphasize in mathematics instruction with students. However, it is challenging for pre-service teachers (PSTs) to learn how to implement student-centered instruction, especially given their own direct-instruction experiences as students.

One instructional method that emphasizes the process standards and that can help teachers make the shift to student-centered teaching is math strings (also referred to as number strings or minilessons) (Fosnot & Dolk, 2001; Parrish, 2011). Math strings are "a structured series of computation problems that are related in such a way as to develop and highlight number relationships and operations" (Fosnot & Dolk, 2001, pp. 105–106). For example, a teacher might choose a series of problems to highlight the distributive property (i.e., $2 \times 5 = 10$; $10 \times 5 = 50$; $12 \times 5 = 60$). During a math string lesson, the teacher puts the first of a series of problems on the board and asks students to solve the problem (usually mentally). Students then share their answers and solution methods. The teacher asks clarifying and prompting questions to ensure that all students understand each other's methods and to help students evaluate the similarities and differences among methods. Further, the teacher represents the students' thinking using models (such as empty number lines, arrays, and branching notation) so that students can reflect on their methods. This process then continues for the rest of the problems.

Although the structure of math strings is centered on patterns among computational problems and ways of solving problems, there is little research on how teachers—especially PSTs who may not be comfortable with multiple ways of thinking about a problem—make sense of the problems. Identifying the continuum of responses that PSTs make in their thinking about and use of math strings will provide teacher educators with insight into challenges and possible scaffolds for helping new teachers understand mathematics in relation to the process standards.

Theoretical Framework

The Mathematical Knowledge for Teaching (MKT) framework, described by Ball, Thames, and Phelps (2008) and which evolved from Shulman's (1986) seminal speech on the types of knowledge that teachers need to be successful, provides a useful lens for identifying the types of knowledge that PSTs need to develop in order to make sense of math strings and successfully foster productive practices in the mathematics classroom. For the purposes of this investigation around the use of math strings, two categories of knowledge are of particular importance: specialized content knowledge (SCK) and pedagogical content knowledge (PCK), which includes knowledge of content and students and knowledge of content and teaching.

Specialized content knowledge involves content knowledge that pertains specifically to mathematics teaching, like knowing how to capture students' strategies using multiple representations or explain mathematical relationships. Pedagogical content knowledge encompasses knowing how students might solve problems, identifying what difficulties they might have, deciding which examples to use in instruction, and weighing the pros and cons of using different materials or representations (Ball, Thames, & Phelps, 2008). In terms of math strings, teachers must move beyond focusing solely on answers and be able to determine the relationship among problems in the math string, including the strategy the string promotes. Further, they need to know for what problems the strategy works. All of these areas draw on teachers' SCK. Regarding PCK, when choosing additional problems for the math string, teachers must pick numbers that their students can handle but which also help draw their attention to the underlying pattern among the problems. Finally, they must understand what strategies students might use to solve the problems and how to use representations to highlight the relationship among problems (high PCK) and not just the problems themselves (low PCK).

The research question guiding this pilot study was as follows: What are pre-service teachers' levels of SCK and PCK regarding and as reflected in their analysis of math strings?

Methods

Participants and Setting

This study took place at a large Midwestern university. All 20 pre-service teachers (all female) from one section of a mathematics methods course participated. The PSTs were in their senior year and most were set to student teach in the semester following the course.

Materials and Data Collection

The pre-service teachers completed two worksheets, which required them to analyze several math strings, create problems to continue the strings, and draw representations to highlight the patterns of the strings. They completed one worksheet before and one after two class periods focused on the use of math strings. Due to the short period of instruction, though, the two worksheets are not likely to reflect significant learning.

Data Analysis

One set of questions from each worksheet was chosen for analysis (see Table 1). These two sets were chosen because they drew on different content knowledge (multiplication versus subtraction) and were likely to elicit different representations. First, I categorized each question according to the type of knowledge it targeted (see Table 1). Then, I categorized PSTs' responses according to whether they were correct, incorrect, or partially correct. I further coded PSTs' responses in each category according to what part of the problem they represented, and then I looked for themes to explain the differences in responses and knowledge of the math strings.

Table 1: Math String Questions and Knowledge Categories

Math String Question	Category
1a. Solve. $3 \times 4 =$ $6 \times 4 =$ $8 \times 6 =$ $8 \times 3 =$ $8 \times 12 =$ What relationship do you notice?	SCK
1b. What strategy or strategies is the math string promoting?	SCK
1c. How might a student solve the last problem (8×12) if he understands the pattern?	PCK
1d. Draw a picture/representation that you could use to help students see the relationships among these problems.	PCK
1e. Write 2 more problems that fit the math string pattern and explain how they fit.	PCK
2a. Solve: $35 - 10 =$ $34 - 9 =$ $37 - 12 =$ $31 - 6 =$ What do you notice? Why does this happen?	SCK
2b. Draw a representation that you could use to help students see why this happens.	PCK
2c. Does this strategy work for addition? Why or why not?	SCK

Results

SCK for Math String Construction

In general, responses that indicated low SCK focused on the patterns of answers for the problems. For problems 1a and 1b, 8 out of 20 PSTs (40%) focused solely on the answer. Common responses included identifying that all of the products are divisible by 12, are factors of 96, or that the answers are double previous answers. The latter response is an important part of a complete answer but fails to identify the pattern among the problems as well. An additional 5 PSTs (25%) focused on patterns in the problems *and* in the answers *without* explicitly connecting the two, moving them along the SCK continuum. For example, one person identified that the answers were all divisible by 12, and in the problems "4 is half of 8 and 3 is half of 6." Finally, 7 PSTs (35%) demonstrated high SCK. Their responses highlighted the relationship between the problems *and* the answers: "When the first number [in the problem] doubled, the answer doubled."

A similar pattern emerged for question 2a. Pre-service teachers with low SCK focused on the answer, indicating that the problems "each are a different way to get to the number 25." The PSTs with medium SCK focused on the relationship among the problems but were vague: "The number being subtracted from went up, so did the number being subtracted." As with the previous problem, PSTs with high SCK made an explicit connection between the relationships among the problems and what that means in terms of the answers: "From the original problem if the first number went up or down a certain way, the second number would too, so the difference stayed the same."

PCK in Relation to Math String Construction

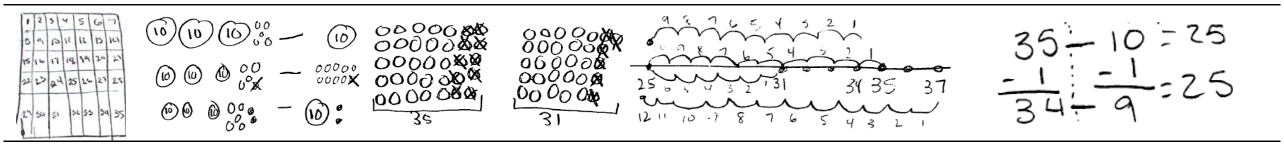
The pre-service teachers' responses to questions 1c and 1e were frequently based on their previous answers. For instance, if they identified that all answers were multiples of twelve in 1a (low SCK), they also thought the student would count by multiples of twelve to find the answer, and they suggested problems for 1e that resulted in a multiple of 12 (low PCK). However, 7 PSTs showed deeper PCK than they did for SCK. One pre-service teacher who said all answers were multiples of 12 on 1a provided much more detail when asked to think about how a student might solve the problem: "The students would double 48 to get the number 96. The student would realize that when one of the numbers in the previous problems is doubled, the answer is doubled."

PCK for Representations

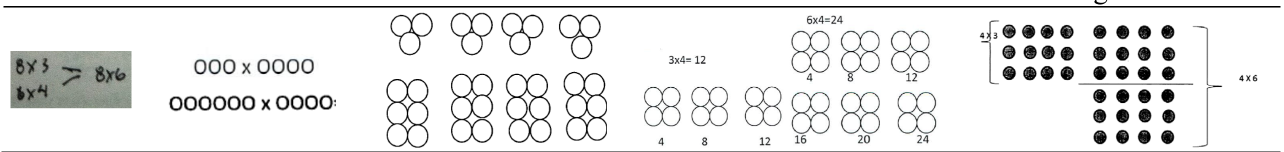
PSTs used a variety of representations for questions 1c and 2b along the PCK continuum. At the lowest level of PCK, pre-service teachers represented one problem instead of the relationship among problems or the relationship between the problem and representation was unclear (see Table 2a). Moving up the continuum, some PSTs substituted pictures for the numerals in the written problem (see Table 2b). Others correctly represented the answers but did not capture the relationship between problems in their representations. Responses in the middle of the continuum had the potential for highlighting relationships, but relationships were not explicit (see Table 2c). Towards the upper end of PCK, pre-service teachers represented the connection among problems (although sometimes focusing on secondary aspects) (see Table 2d & e).

Table 2: Pre-service Teachers' Representations Along a Continuum of PCK

a	b	c	d	e



Low PCK -- High PCK



Discussion

Overall, the math strings context required pre-service teachers to reason about multiple dimensions of SCK and PCK. The results of this study indicate that pre-service teachers have varying levels of SCK and PCK in relation to math strings, and they range in their ability to describe relationships among problems and represent these relationships. However, when asked to interpret the patterns in relation to students, they demonstrated deeper understanding. Future research should investigate the extent to which presenting content through the lens of their future students helps pre-service teachers internalize the mathematical practices they must promote in the classroom. Also, the use of math strings needs to be investigated further, not only in regard to benefits for pre-service teachers and their MKT but also in relation to students' learning.

THE IMPACT OF PROGRAM AND COURSE ON PRESERVICE MIDDLE SCHOOL TEACHERS' MATHEMATICAL KNOWLEDGE FOR TEACHING

Shawn D. Broderick
University of Georgia
sdbroder@uga.edu

This report follows from a study investigating factors that influence preservice middle school teachers' mathematical knowledge for teaching (MKT). Two such factors, with which there has been speculation, include the preservice teachers' certification program type and the college-level mathematics courses they take. Findings include significant statistical differences in MKT for preservice teachers in secondary preparation programs versus all others and for preservice teachers who took axiomatic geometry, the calculus sequence, differential equations, discrete mathematics, and probability versus other courses. I discuss the implications of these findings for mathematics teacher educators.

Keywords: Teacher Education–Preservice; Mathematical Knowledge for Teaching

Navigating the transitions of the professional learning continuum from the beginning preservice teacher to the teacher leader is very important. Preservice teachers are very impressionable as they are learning how to teach and master their subject. In doing so they need the vigilance of teacher educators.

For example, recently the National Governors Association (NGA) and the Council of Chief State School Officers (CCSSO) sponsored an initiative to establish a set of mathematics standards to "ensure that we maintain America's competitive edge, so that all of our students are well prepared with the skills and knowledge necessary to compete with not only their peers here at home, but with students from around the world." (National Governors Association Center for Best Practices & Council of Chief State School Officers, 2010).

There are two areas of middle school teacher education that should be investigated that can significantly influence preservice teachers' mathematical knowledge: (a) the type of certification program they're in, and (b) which college-level mathematics courses they have taken.

As preservice teachers are trained, one would assume that formal mathematics courses should be one important way to increase their content knowledge. However, studies have shown that simply taking college-level mathematics courses does not contribute to the knowledge needed to teach elementary and secondary school (e.g., Ball, 1991; Begle, 1979; Borko et al., 1992). Ball (1991) found that the courses do not provide the preservice teachers with "the opportunity to revisit or extend their understandings of arithmetic, algebra, or geometry, the subjects they will be teaching" (p. 24). Thus, the ways in which college mathematics courses affect U.S. preservice teachers' mathematics content knowledge also need further study.

Research Questions

1. How can preservice teachers' choice of certification program (i.e., elementary, secondary, or middle grades) affect their mathematical content knowledge?
2. How can preservice teachers' choice of college-level mathematics courses affect their mathematical content knowledge?

Perspectives

Three areas in mathematics education give perspective on this study: (a) the idea of mathematical knowledge for teaching, (b) the different types of middle school teacher certification programs, and (c) what constitutes a college-level mathematics course.

Mathematical Knowledge for Teaching (MKT)

Ball, Thames, and Phelps (2008) described MKT as “the mathematical knowledge needed to perform the recurrent tasks of teaching mathematics to students” (p. 399). Their perspective on MKT reflects my view of the areas of mathematical knowledge that preservice teachers need to foster. The MT21 items tap into three types of MKT.

First, Ball et al. (2008) interpreted *common content knowledge* (CCK) as the mathematical knowledge and skill that is used in situations other than teaching. Preservice teachers need to know well the actual mathematics that they were taught in their K–12 education, especially the mathematics at the grade level in which they will teach.

Second, *specialized content knowledge* (SCK) is the mathematical knowledge and skill that is used in teaching situations (Ball et al., 2008). It is the knowledge of mathematics above and beyond what the students need to know. This knowledge is a deeper, specialized, and more abstract version of the content than what is taught to the students.

Third, Ball et al. (2008) described *knowledge of content and students* (KCS) as being a combined knowledge of knowing mathematics and knowing students. This knowledge includes anticipating what students will think about mathematics, including their difficulties and misconceptions.

Certification Programs

With regard to certification programs, I used Schmidt et al.’s (2007) categories. First, middle school teachers of mathematics could be trained in elementary preparation programs and later teach in the (upper) elementary and middle grades. Second, middle school teachers could be prepared in secondary programs and teach sixth through twelfth grades. Third, middle school teachers could be trained in special middle grades programs that focus on sixth- through eighth-grade mathematics. Fourth, I noticed that some preservice teachers certified to teach at all three levels, elementary, middle, and secondary.

Because of the varied nature of these training programs, the required content courses and levels of instruction among these programs differed. Schmidt et al. (2011) showed that preservice teachers who were prepared in secondary programs were those who outperformed those preservice teachers who were prepared in elementary or special middle grades programs on the MT21 items.

College Mathematics Courses

My view of what constitutes a college-level course is also in line with what Schmidt et al. (2007) have designated. They stated that some courses could be considered as a topic of a course in some programs. In this study, I am assuming that the each course is taught similarly among the universities surveyed in the MT21 study.

Methodology

Sample

The sample that I will be using for this study is 381 preservice middle school mathematics teachers in the last year of their preparation program from 12 universities in eight states.

Data Collection

The data that used for this study came from the MT21 study (Schmidt et al., 2007). The data corpus consisted of the preservice teachers’ responses to 18 mathematics items (MT21 items) along with their responses to questions on their background information (e.g., gender, age, certification type, and number of mathematics courses taken).

Methods

To answer my first research question about the differences in the MKT of those in different certification programs, I performed the ANOVA statistical procedure using the preservice teachers’ certification program with their respective averages on all five mathematical domains together and separately.

Then, to answer my second research question about the differences in the MKT of those taking certain college-level mathematics courses, I performed an independent samples *t*-test for each mathematics course, which compared the means, of performance on all domains together and separately, between those who did not take the course and those who did.

Results

Certification Program and MKT

I found that those who were prepared in secondary programs or all levels in fact significantly outperformed those trained in elementary or solely middle school programs. They also significantly outperformed all other preservice teachers in each of the domains separately.

College-Level Mathematics Courses and MKT

The most influential courses on preservice teachers' knowledge of all domains surveyed were: axiomatic geometry, the calculus courses, differential equations, discrete mathematics, and probability because their mean differences were statistically significant in overall domain knowledge between those who did not take those courses versus those who took those courses.

Axiomatic geometry, abstract algebra, and the calculus courses are particularly effective because those who took those courses scored significantly higher means in at least three of the five domains than those who did not.

Other courses in which at least one domain had significantly higher means included: differential geometry for the function domain, topology for the number domain, linear algebra for the data domain, theory of complex functions for the data domain, and differential equations for the data domain.

The courses in analytic/coordinate geometry, non-Euclidean geometry, number theory, functional analysis, statistics, and history of mathematics did not have a significant difference on a preservice teachers' MKT. Additionally, one would think that the number courses would help with number knowledge, the algebra courses would help the algebra knowledge, etc., but for the most part they did not.

More particularly, certain courses had statistically significant higher means for those who did not take the course. Those who did not take differential geometry had a significantly higher knowledge of functions, likewise with abstract algebra and algebra knowledge, and theory of complex functions and data knowledge.

Discussion

In light of these results, we must consider whether or not we should require all our preservice middle school mathematics teachers to go through secondary programs. Experts caution against this action by saying that if we impose such a requirement, we will be left with few middle school mathematics teachers because the mathematics courses would be too demanding (Center for Research in Mathematics and Science Education, 2010). Our next recourse is with the courses taken by the preservice teachers.

With regard to mathematics courses, it seems that there are some courses that can be very beneficial for domain knowledge if one looks at significant differences in mean performance on a mathematical knowledge test. Thus, for example, those who take axiomatic geometry, the calculus courses, differential equations, discrete mathematics, and probability are likely to be better at middle school mathematics than if they did not take those courses.

It seems, however, that there are some courses that can have a negative impact on certain areas of mathematical knowledge at this level if preservice teachers take them. Similarly, Begle (1979) found that some teachers who took a certain number of courses past calculus had a negative effect on student performance. Ball and Bass (2000) attributed this negative effect on the compression of knowledge comes with increasingly advanced mathematical work. This compression is likely to interfere with the unpacking of content that teachers need to do, either for their students or for a test.

Therefore, we must consider the idea to require that preservice middle school teachers take more of the courses that will benefit their MKT. However, here is one area in which I believe we can help preservice teachers. If we ensure they take courses like calculus, geometry, and probability, their MKT should be strengthened. The other kinds of mathematics courses they should take are ones that allow them to revisit and extend their knowledge of arithmetic, algebra, and geometry—the very subjects they will be teaching (Ball, 1991).

Conclusion

As we consider the continuum of the evolution of preservice teachers' MKT as they become ready to teach, we find that there is much work to do. With recommendations for preservice teachers to take courses that increase their MKT the most, be it a combination of college-level mathematics and content-level mathematics, we will help preservice teachers know the mathematics and ensure that they can successfully implement curricula based on the Common Core State Standards.

SUPPORTING TEACHER RETENTION AND DEVELOPMENT THROUGH TEACHING POSSIBLE SELVES

Elizabeth B. Dyer
Northwestern University
elizabethdyer@u.northwestern.edu

It is a challenge of pre-service teacher education programs to prepare beginning teachers for many of the difficulties they will face in the teaching profession inside and outside of the classroom. The possible selves literature from psychology provides a lens for understanding how to help teachers sustain action towards successful classroom practice. In this paper, I will describe how possible selves is distinct from a similar construct, teacher vision, and outline recommendations for teacher education based in the possible selves literature that are absent from the teacher vision literature.

Keywords: Teacher Education–Preservice; Teacher Beliefs; Metacognition

Introduction

Enabling teachers to succeed is a challenge that faces the educational system. Teaching itself is a difficult, complex task that requires a large amount of expertise (Lampert, 2001; Lampert et al., 2010). Teachers are situated in a difficult environment that poses many challenges. One of the ways that the difficulties of the teaching profession manifest themselves is through teacher turnover and attrition. Teacher turnover is highest for beginning and highly experienced (usually retiring) teachers and attrition is found to be the highest during the first five years of teaching (Singer & Willet, 1988; Murnane, 1984). In particular, public schools serving high-poverty and/or low-achieving students are more likely to have higher turnover (Hanushek et al., 2004; Smith & Ingersoll, 2004). Additionally, it is often the best teachers that are likely to leave teaching (Murnane, Singer, & Willett, 1989).

The goal of teacher education programs can be thought of as helping teachers transition from pre-service to in-service teachers by preparing them have a long and successful career. An often overlooked aspect of pre-service teacher education is developing an identity as a teacher. In particular, a large part of the transition to becoming a successful classroom teacher includes developing a teaching identity and the practices associated with that identity. In contexts outside of teacher education, such as weight loss and academic achievement, identity-based interventions have been able to affect self-regulatory behavior (Oyserman et al., 2006; Murru & Martin Ginis, 2010). Given the difficulty associated with persisting in the teaching profession, this literature can help us discover new ways to improve teacher education and ease the transition from pre-service to in-service teacher. In the following section, I will review the literature on possible selves and identity-based interventions and discuss how this literature can supplement current research on teacher vision.

Theoretical Background

Possible selves is one way psychologists view the self-concept. Possible selves are a type of self-knowledge that "pertains to how individuals think about their potential and their future" (Markus & Nurius, 1986, p. 954). As with the dynamic self-concept (Markus & Wurf, 1987), individuals are thought to have multiple possible selves. Some possible selves relate to the people we aspire to be, sometimes referred to as positive possible selves. Other possible selves represent our feared selves, or negative possible selves. Possible selves link identity and motivation together because goals and fears are represented as part of the self-concept. Using this construct can also help us understand changes in actions or practices because “development can be seen as a process of acquiring and then achieving or resisting certain possible selves” (p. 955), which intimately relates possible selves with motivation and self-regulatory processes.

The construct of teacher vision is very similar to *teaching possible selves*. Hammerness (2006) defines teacher vision as “a set of vivid and concrete images of practice” and as “images of ideal classroom practice” (p. 1). She also explains how vision affects teaching practice:

> Vision shapes the way that they feel about their teaching, their students and their school and helps to explain the changes they make in their classrooms, the choices they make in their teaching, and even the decisions they make about their futures as teachers. (Hammerness, 2006, p. 2)

In this way, vision guides the decisions teachers make.

A teacher’s vision is similar to teaching possible selves in many ways. First, both talk about future, possibly achievable selves or roles. Both constructs are seen to have a large impact on the actions that individuals take. However, teacher vision differs by only representing the positive or ideal teaching practice, while possible selves can be both positive and negative. Additionally, an individual is thought to have multiple possible selves, beyond just positive and negative, whereas teacher vision is conceptualized as a singular coherent view of teaching practice. For example, teaching possible selves could include images of practice that are vastly different depending on the context they are working in, but teacher vision would not explain these “inconsistencies.”

Oyserman et al. (2006) assert that possible selves are more likely to be achieved (i.e. sustain self-regulatory action) if they are connected to social identity, linked to concrete strategies to achieve them, cognitively accessible, and balanced between positive and negative. Possible selves that are incongruent with important social identities are less likely to be created and maintained (Oyserman et al., 2006), making possible selves are more achievable when they are connected to social identity. Social identity may include group membership based on race or ethnicity, but may also include professional affiliation. Individuals are also more likely to apply behavior towards a possible self when they have strategies to achieve them, and when those strategies are cued by the context (i.e. the possible selves are cognitively accessible). Finally, both positive and negative possible selves are important for obtaining desired outcomes, but recent research indicates that having balanced possible selves may not be optimal in all contexts. Oyserman and Destin (2011) show that the fit between context and valence of possible selves plays an important role in planned behavior. They argue that in success-prone contexts, positive possible selves and in failure-prone contexts, negative possible selves are more likely to lead to desired self-regulatory behaviors than positive possible selves in failure-prone contexts.

With respect to pre-service teacher education, Hammerness (2006) suggests that teachers have opportunities to surface their visions initially and continually reexamine their vision throughout their teacher preparation program. Pre-service teachers’ visions are somewhat vague, disconnected from the subject matter they will teach, and inconsistent. Commonly, teachers begin pre-service teacher education programs with a vision for instruction that is largely traditional and based on their experience in schools. In the reform context, teacher preparation not only needs to help teachers clarify their existing vision, but it should also challenge teacher vision and provide new possibilities of ideal teaching practice. Hammerness (2006) also argues for the importance of equipping teachers with tools and strategies to manage the gap between their current teaching practice and ability and their vision.

Implications for Teacher Education

Three main differences between the implications from the possible selves literature and the teacher vision literature are discussed below in terms of recommendations for teacher educators.

Congruence with Social Identity

In the possible selves literature we see the importance of relating teaching possible selves to social identity. With teacher vision we do not see explicit mention of ideas related to shared identity. With respect to teaching, various social identities may come into play. Racial and ethnic social identities of teachers may seem relevant to teaching depending on the student and teacher populations found in the school. Social identities related to the teaching profession, such as associating with reform teachers or teachers concerned with social justice. Each of these social identities may be congruent or incongruent with teaching possible selves.

Ideally teaching possible selves would be congruent with all social identities that are relevant in teaching. In the case of teaching possible selves being incongruent with a teacher's racial and ethnic social identities, Oyserman et al. (2006) suggests trying to increase the congruence between possible selves and social identity instead of attempting to disconnect teachers from social identity. Teacher educators may wish to be aware of the different social identities pre-service teachers identify with and attempt to show congruence between these identities and the teaching possible selves they are developing.

Teacher educators can also attempt to relate teaching possible selves and social identities about the teaching profession. Teacher education may already support these links because pre-service teachers often take the same classes and share similar visions. Teacher educators can also help pre-service teachers develop professional social identities in tandem with teaching possible selves by exposing them to professional organizations. Even mentor-student teacher relationships could be leveraged to develop affiliation with reform or other teaching groups.

Incorporating Both Positive and Negative Possible Selves

One significant difference in implications is in considering positive and negative possible selves. In the case of possible selves, a balance (or a context-dependent emphasis) of negative and positive possible selves is ideal. In the case of teacher vision, we only see teacher educators developing ideal visions, or positive possible selves. Because teaching can be considered a failure-prone context, negative teaching possible selves are a useful tool in teacher education.

Pre-service teachers have pre-existing ideas of what good and bad instruction looks like from their experience as a student, which are not likely to give pre-service teachers an example of a reform vision of teaching. Mathematics teacher educators often take part of their mission as helping teachers become familiar with reform teaching and possibly developing a vision of teaching that is consistent with reform principles. Developing new visions is also supported by the possible selves literature, but it may not go far enough.

Teachers are rarely given opportunities to clarify negative or feared visions of teaching. For example, teachers may initially have a positive vision of teaching that incorporates elements teacher educators would hope would not be part of the vision after a teacher preparation program. One could imagine that teachers' vision might include using clear lectures to change student ideas. Without explicitly considering feared visions of teaching, this element may stay associated with positive visions of teaching.

Two mechanisms might be able to explain how developing negative teaching possible selves could lead to more successful teaching practice. Having a clear negative vision of teaching may change teacher noticing (Sherin 2001, 2007) by enabling teachers to notice elements of teaching practice in their negative vision. Teachers may also interpret these practices as something they do not want to do. Additionally, teacher reflection on practice may be influenced. A teacher may focus reflections on elements that are explicit in their visions, whether positive or negative.

Strategies for Achieving Possible Selves

Both constructs examine the need for concrete strategies linked to possible selves or visions, and in the case of teachers this is often conceptualized in terms of strategies to allow teachers to move from their current teaching toward their ideal practice. However, the teacher vision literature does not emphasize that the strategies should be explicitly tied to the vision and be made cognitively accessible, as with the possible selves literature. In addition, making sure that teachers are aware of the entire trajectory of growth toward their vision is not emphasized.

As teacher educators, we often focus only on progress that we would like our teachers to learn by the end of the program, rather than the progress we would like them to make through their beginning years of teaching. Making sure that teachers have concrete strategies for achieving their possible selves could include learning progressions for teachers or progressions of teaching practices that extends beyond teacher preparation programs. These learning progressions should be explicitly tied to teacher vision as well.

Strategies for achieving teacher vision could be seen as strategies for responding to challenges and dilemmas teachers face. As was mentioned in the beginning of the paper, teachers face numerous challenges in the classroom as well as outside the classroom, particularly in low-achieving schools. Having strategies to achieve possible selves can be seen as having strategies for overcoming the specific obstacles that arise when attempting to enact teacher vision.

EXPLORING CHANGES IN PRESERVICE TEACHERS' CONCEPTIONS WITHIN THE CONTEXT OF MATHEMATICS EXPERIENCES

Thomas E. Hodges
University of South Carolina
hodgeste@mailbox.sc.edu

Cindy Jong
University of Kentucky
cindy.jong@uky.edu

This paper reports findings from the Mathematics Experiences and Conceptions Surveys (MECS) implemented at four universities across the United States. Preservice elementary education teachers enrolled in mathematics methods coursework completed pre/post surveys designed to understand the evolution of conceptions towards mathematics teaching and learning. Our overall aim was to determine what, if any, changes occur in conceptions and whether or not particular experiences during the course help explain such change. ANOVAs indicate significant differences in specific aspects of conceptions. These differences are explained using multiple regression analyses, in part, by mathematics methods and field experiences scales within MECS.

Keywords: Affect, Emotion, Beliefs, and Attitudes; Teacher Beliefs; Teacher Education–Preservice

Objectives of the Study

This paper reports preliminary findings from the Mathematics Experiences and Conceptions Surveys (MECS) implemented at four universities across the United States during the fall 2011 semester. Preservice elementary education teachers (PSTs) enrolled in mathematics methods coursework completed pre/post surveys designed to understand the evolution of attitudes, beliefs, and dispositions towards mathematics teaching and learning. The overall aim of this research was to determine what, if any, changes occur in attitudes, beliefs, and dispositions over the duration of a mathematics methods course and whether or not particular experiences during the methods course help explain such changes. While a number of surveys exist that measure beliefs and attitudes, none are contextualized to various points in teacher education, or account for experiences within mathematics teacher preparation to the extent found in the MECS (see Welder, Hodges, & Jong, 2011, for a more detailed account of MECS instrumentation). Consequently, our focus adds to the knowledge base in mathematics teacher education by observing factors within teacher education that influence dispositions, beliefs, and attitudes towards mathematics teaching and learning. This knowledge might then be used to leverage learning opportunities within mathematics teacher preparation.

Perspectives

Decades of mathematics education research suggests the strong role beliefs and attitudes play in influencing the instructional practices teachers use within the classroom (Ball & Cohen, 1999; Ernest, 1989; Richardson, 1996; Wilkins, 2008), and students' opportunities to engage in significant mathematical thinking (Fennema et al., 1996; Staub & Stern, 2002). Given the significant role beliefs and attitudes play, researchers and teacher educators often look for opportunities to bring into focus conceptions of mathematics within methods courses and other important experiences within the continuum of teacher education (e.g., Charalambous, Panaoura, & Philippou, 2009; Quinn, 1997). We use the term *conceptions* as an umbrella to represent three central and interrelated subconstructs: dispositions, beliefs, and attitudes (cf. Welder, Hodges, & Jong, 2011).

Prior research indicates mathematics methods coursework may in fact shift attitudes and beliefs about mathematics teaching and learning to better align with aspects of reform-oriented recommendations in mathematics education (Connor, Edenfield, Gleason, & Ersoz, 2011; Philipp et al., 2007; Roscoe & Sriraman, 2011). Perhaps the most detailed account of experiences in teacher education and their relationship to beliefs about mathematics teaching and learning comes from Philipp et al. (2007), who observed that PSTs with field experiences that focused more on children's mathematical thinking developed more sophisticated beliefs about mathematics teaching and learning than PSTs whose field experiences did not focus on children's mathematical thinking. From our perspective, this is only one, albeit critical, aspect often present in mathematics methods coursework. Taylor and Ronau's (2006) investigation of mathematics methods syllabi indicates a wide array of goals and activities present in methods courses, with varying degrees of empirical evidence supporting such emphases. Consequently, we seek to better understand the relationship between particular mathematical experiences in elementary teacher preparation and the evolution of beliefs, attitudes, and dispositions towards mathematics teaching and learning.

Methods

The data presented here include ninety-one PSTs enrolled in mathematics methods courses at four universities in the Eastern United States during fall 2011. MECS-M1, a survey designed to be taken at the beginning of mathematics methods coursework, was administered during the first week of class in each of the mathematics methods courses and MECS-M2, a survey designed to be taken at the end of mathematics methods coursework, was administered during the final week of each of the same courses.

MECS-M1 is designed to measure constructs related to preservice teachers' past K–12 experiences in mathematics, entering beliefs about mathematics, dispositions toward teaching mathematics, and attitudes toward mathematics. MECS-M2 is designed to measure constructs related to preservice teachers' fieldwork experiences in mathematics, experiences in the mathematics methods coursework, beliefs about mathematics, dispositions toward teaching mathematics, and attitudes toward mathematics. The two instruments, which primarily consist of five-point scale Likert items and a few open-ended questions, were created with similar constructs to avoid a form of single-method bias and to measure growth after a mathematics methods course and over time. Exploratory factor analyses were completed to examine psychometric properties of the instruments. Reliability was examined in terms of the instruments' internal consistency using Cronbach's alpha. Table 1 provides alpha levels for MECS-M1 on beliefs, attitudes, and dispositions. Alpha levels for mathematics methods course experiences and field experiences are reported from MECS-M2. While other MECS subscales exist, we focus explicitly on the subscales in these analyses.

Table 1: Reliability of Subscales

Construct	*α-level*	*Instrument*
Attitudes toward Mathematics	.875	MECS-M1
Beliefs about Mathematics	.732	
Dispositions toward Teaching Mathematics	.870	
Dispositions: Instruction	.659	
Mathematics Methods Course Experiences	.938	MECS-M2
Mathematics Methods: Students	.850	
Mathematics Methods: Materials	.693	
Mathematics Methods: Pedagogy	.748	
Field Experiences	.825	

To determine change in attitudes, beliefs, and dispositions from MECS-M1 to MECS-M2, an analysis of variance (ANOVA) was conducted on each of the three subscales. To examine whether significant relationships existed among the subscales in Table 1, Pearson correlations were used (but not included here) to help determine which explanatory variables to include in the multiple regression models. Then we developed multiple regression models to examine which factors could explain the variation in attitudes, beliefs, and dispositions towards instruction.

Results

There was a statistically significant difference between *attitudes_pre* and *attitudes_post* as determined by an ANOVA (F (3,86) = 1.03, p = .001). There was not a statistically significant difference between *beliefs_pre* and *beliefs_post* (F (3,86) = 1.25, p = .266). The dispositions subscale was disaggregated to three separate scales related to dispositions, but our analysis focused on dispositions towards instruction (*disp_inst*) because it is an indication of PSTs' stance on reform-oriented practices. However, there was not a statistically significant difference between *disp_inst_pre* and *disp_inst_post* (F (3,86) = 0.15, p = .704).

Using the significant correlations and our understanding of the literature on mathematics methods courses and field experiences, multiple regression models for attitudes_post, beliefs_post, and disp_inst_post were developed. The overall regression of *attitudes_post* on *attitudes_pre*, *field_exp*, and *MM_mat* was statistically significant [R^2 = 0.59, F (3,87) = 44.93, p < 0.001]. The three factors accounted for 59% of the variance in PSTs' attitudes following the mathematics methods course, but 52% of that variance was accounted by *attitudes_pre*. The overall regression of *beliefs_post* on *beliefs_pre* and *MM_mat* was statistically significant [R^2 = 0.30, F (2,88) = 20.27, p < 0.001]. The two factors accounted for 30% of the variance in PSTs' beliefs following the methods course, but 23% of that variance was accounted by *beliefs_pre*. The overall regression of *disp_inst_post* on *disp_inst_pre*, *field_exp*, and *MM_mat* was statistically significant [R^2 = 0.42, F (3,87) = 20.96, p < 0.001]. The three factors accounted for 42% of the variance in PSTs' instructional dispositions following the methods course with 20% of that variance accounted by *disp_inst_pre.* The mathematics methods materials (*MM_mat*) subscale included items about resources that promote the development of students' mathematical thinking; thus, it is not surprising to see that it accounted for significant changes in PSTs' conceptions toward mathematics teaching and learning. We acknowledge that this subscale had a lower reliability and that further analyses are needed to accurately detect whether the relationship is important and remove noise in the results.

Discussion

Beliefs are felt more intensely and tend to be more cognitive than attitudes (Philipp, 2007); thus, it is anticipated that changes in attitudes might occur over a shorter time interval than beliefs or dispositions. Dispositions are tendencies to act in specified ways and take on particular positions (Bourdieu, 1986), such as how PSTs position themselves in relation to reform-oriented recommendations in mathematics education. Given the shortened timeframe between MECS-M1 and MECS-M2 (one semester), we were encouraged by a significant growth in attitudes, while not surprised that beliefs and dispositions toward instruction changed little over the course of the semester. Clearly, it is critical that participants continue to complete future iterations of MECS instrumentation to determine if in fact beliefs and dispositions change longitudinally within teacher education and whether or not attitudes serve as a precursor to changes in beliefs and dispositions. A longitudinal approach will allow us to capture the evolution of PSTs' conceptions as they transition along the continuum of teacher education. In the future, we plan to continue gathering MECS data on participants as they enter into the early induction phase of teaching to further examine conceptions during such an important period.

While the variation in attitudes, beliefs, and dispositions towards instruction apparent in the regression models is strongly tied to entering attitudes, beliefs, and dispositions, it is hopeful that we are beginning to understand the relationship between mathematics methods course experiences, field experiences, and their connection to conceptions. In particular, significant relationships between PSTs that perceive an emphasis on materials for mathematics instruction focused on developing students' mathematical thinking and the constructs of attitudes and dispositions is an important first step in understanding what types of experiences bring conceptions into focus. The implications of such work is two-fold: (a) MECS instrumentation has proven useful for understanding changes in conceptions in relation to benchmark mathematical experiences within teacher education programs; and (b) MECS might well serve as a useful tool for programmatic assessment, comparisons between institutions, and in the context of design experiments within teacher education.

TURNING BELIEFS INTO ACTIONS: A TEACHER'S ROLE IN THE CLASSROOM TO SUPPORT DEVELOPING MATHEMATICAL LEARNING

Limin Jao
Ontario Institute for Studies in Education of the University of Toronto
limin.jao@utoronto.ca

Although teacher beliefs have a positive impact on student learning and achievement, it is the teacher's practice that makes the difference. Student communication through dialogue is an effective strategy to encourage mathematical understanding. Qualitative data from teacher interviews and classroom observations of a Grade One teacher uncover how this teacher viewed her role in the mathematics classroom and how she enacted upon these beliefs in her practice. Findings show that the teacher viewed her role as a guide, created a positive learning environment and encouraged student dialogue by modeling mathematical communication and empowering students to participate in classroom activities.

Keywords: Classroom Discourse; Elementary School Education; Instructional Activities and Practices; Teacher Beliefs

Objectives

In the reform-based classroom, teachers move away from the traditional role of knowledge-provider and transform their classroom into a student-centered environment. Teachers, especially those who have been teaching for many years or those who were taught using traditional methods, may not know what the current role of the teacher should be and how they fit into today's student-centered learning environment (Ball, 1996; Raymond, 1997; Tzur, Martine, Heinz, & Kinzel, 2001). The purpose of this study is descriptive: it focuses on a teacher's beliefs about her role as a teacher of mathematics and how she acts on these beliefs in the classroom.

Perspectives

Teacher perception can affect student learning and student achievement (Bruce & Ross, 2008). Teachers who believe that their teaching practices affect student learning and achievement positively are more willing to implement new teaching strategies, take risks with their instructional practices and work to achieve student goals (Bruce & Ross, 2008). Research has shown that this type of teacher contributes to an increase in student achievement (e.g., Bandura, 1997; Brouwers & Tomic, 2001; Henson, 2002; Ross, Bruce, & Hogaboam-Gray, 2006; Tschannen-Moran & Hoy, 2001). These teachers also affect student perceptions of their own abilities (Ross, 1998).

In the reformed classroom, the role of the teacher is very important. Instead of solely being the knowledge provider, they are now seen to be guides helping navigate their students in the discovery of knowledge (Zack & Graves, 2001). Students need to create their own understanding by linking new ideas to previous personal experiences, thus, teachers cannot impose their own comprehension of ideas onto their students. As guides, they can take a step back and encourage students to reach back to their prior knowledge to form the connections for themselves (Alagic, 2003).

Teachers must also facilitate student thinking by encouraging dialogue. They should ask students to talk through their ideas, sort through confusions and explain their understanding of a concept (Alagic, 2003). If students have difficulty with this, teachers should be able to give suitable prompts or even model the appropriate behaviour themselves (Jansen, 2006). Students should also be expected to listen to other students and reflect upon the comments that are shared. Teachers can encourage students by asking probing questions and leading students to look for patterns (Reys, Suydam, Lindquist, & Smith, 1998).

The teacher needs to develop a sense of community within the walls of their classroom, so that the students feel safe and able to explore freely. Without this climate, students will not reach out to the teacher to ask for help nor will they be able to completely immerse themselves in the variety of tasks presented to them (Zack, 1993). If the students do not feel comfortable in the classroom or in classroom discussions, they will not be as willing to take risks and try different approaches to solving problems (Pape, Bell, & Yetkin, 2003).

Method

This paper is built upon work from the School Improvement in Mathematics study (McDougall, Jao, Yan, Kwan, 2011) for teachers wishing to improve their mathematics teaching practices through the lens of the Ten Dimensions of Mathematics Education conceptual framework (McDougall, 2004). In this study, teachers engaged in a peer coaching model of professional development to collaboratively improve self-selected elements of their teaching practice (McDougall et al., 2011). Alice was chosen as a case study (Stake, 1995) about teacher beliefs and practices because of her enthusiasm to improve her professional practice, willingness to reflect on her intentions as an educator and openness to having researchers in the classroom.

Alice is a Grade One teacher with 25 years of teaching experience at the Kindergarten, Grade One and Grade Two levels. All of her teaching experience has taken place in Canada, first starting in Central Canada and later moving to Western Canada.

Data Collection and Analysis

The School Improvement in Mathematics study took place between September 2006 and June 2008. Data was collected for the study through teacher interviews, peer coaching sessions and classroom observations. Alice was interviewed at the beginning of the study to determine her background as en educator, beliefs about teaching, goals as an educator and ideas of success for her students. Peer coaching sessions involved classroom observations and pre- and post-lesson interviews. Classroom observations allowed the researchers to see the types of teaching strategies that Alice used. Following each classroom observation, Alice was interviewed and questions were asked about teaching strategies observed and her rationale for using these strategies. A final interview asked questions about her teaching practices and final reflections as a participant of the School Improvement in Mathematics study.

There were six sets of interviews in total. All interviews were audio-recorded and transcribed. These transcripts were then coded using a series of coding cycles. An open coding (Strauss & Corbin, 1990) format was used for this study. Initial data was coded using two general categories (teacher beliefs and teacher practices) and subcategories were chosen based on emerging themes from subsequent data.

Findings

The data indicate that Alice's beliefs about her role as a teacher of mathematics is closely aligned with her practices. The findings show that Alice is cognizant of her role as a teacher in the classroom and has come to realize the effect that she has on her students. Her belief is that she is a role-model to her students. She believes that her students will pick up on any cues that she gives regarding how to interact with materials and learn a concept. She enacts on her beliefs by using modeling to demonstrate appropriate classroom behaviour and foster mathematical understanding among her students.

Alice uses modeling to support student learning in two different ways. Sometimes, she models an approach to solving the problem in hopes that her approach will be enough of a push to get them to think creatively and to come up with their own ideas. Other times, she asks the students to act as the modeler. If Alice sees that a student has come up their own connection or strategy, she will often ask the student to share their idea with the rest of the class. Alice states that, by having one student share with the entire group, "you may have some more encouragement to get other kids to give their ideas" (Teacher interview, January 23, 2008). By sharing their ideas, students also have the chance to clarify their learning. By getting the students to express their ideas, the students will have to organize and clarify their thoughts and this creates a deeper understanding of the material. The students will have had to truly learn the mathematics concepts to be able to share and voice their ideas.

Giving students a voice is a teaching strategy that Alice often applies to help her students learn mathematics concepts. By empowering students and giving students a chance to have their voice to be heard, students take ownership of their learning, are eager to learn and help make mathematics meaningful. Alice believes that it is important to empower her students and to give them a feeling that “I contributed to that, that was my contribution” (Teacher interview, January 23, 2008). Sharing also gives students a chance to hear the ideas of their peers. These ideas may be ones that the students have not considered themselves. Activities where student tell stories, act out scenarios and incorporate their own drawings into the activity are all examples of how Alice involves her students and gives them ownership of their learning.

Alice creates an environment in her classroom where students can concentrate on learning mathematics. She has developed a level of respect amongst the students by positively reinforcing good behaviour and modeling appreciation statements. Alice encourages her students by giving them praise or doing something as simple as giving them a handshake for doing good work. Alice also models behaviour for the students in the class to follow. She will often applaud a student after they have shared their idea and towards the end of a lesson the students often applaud their peers without being prompted to do so. The students feel safe to experiment and take risks to create their mathematical understanding. She also wants her students to view mathematics and the learning of mathematics as something fun.

Conclusion

This case study is one example of how a veteran teacher views her role in the mathematics classroom to meet reform-based trends. Although teacher beliefs and perception has a positive impact on student learning and achievement (Bandura, 1997), it is the teacher’s practice that makes the difference. The case of Alice shows that she chose to use teaching strategies to align with her beliefs that she is a role-model for her students.

Alice’s Grade One students are in an early stage in their mathematical education. They are still learning the language of mathematics and need help to communicate their understanding. Alice’s actions echo the work of Zack and Graves (2001). She acts as a guide by modeling mathematical communication to encourage her students to begin to communicate their own emerging mathematical understanding. In parallel with Osterman (2000), by creating a safe environment, Alice’s students feel comfortable to participate in classroom activities. Additionally, the opportunity that Alice provides for her students to talk through their understanding supports their mathematical learning (Jansen, 2006).

In conjunction with her ongoing professional development to improve her teaching practices, this study allowed Alice to reflect on her role and how she could best facilitate student learning (McDougall et al., 2011). This case study allows others in the field to learn from Alice’s story to further improve their own mathematics programs.

LEARNING TO LEAD MATHEMATICALLY PRODUCTIVE DISCUSSIONS

Pamela Edwards Johnson
George Mason University
pjohns13@gmu.edu

Jennifer Suh
George Mason University
jsuh4@gmu.edu

Five practices are thought to help preservice teachers learn to facilitate mathematically productive discussions in elementary classrooms: anticipating student responses, monitoring student work, selecting responses to share, purposefully sequencing the sharing of those responses, and connecting responses to other mathematical ideas (Stein, Engle, Smith, & Hughes, 2008). This paper describes a self-study in which the authors encouraged teachers to use the five strategies as a framework for instruction. Data from one representative participant show that she developed the ability to anticipate student responses and identify key ideas to highlight during the discussion, but did not enact effective monitoring, sequencing, or connecting responses to other mathematical ideas. We conclude that specific changes to our instructional practices might help our students strengthen their understanding and use of the five strategies.

Keywords: Teacher Education–Preservice; Teacher Knowledge; Instructional Activities and Practices; Classroom Discourse

Mathematics teachers in the United States typically follow a conventional lesson structure that includes showing students how to solve a particular type of problem, providing time for individual practice, and then checking students' answers in a short discussion (Stigler et al., 1999). Though the *Common Core State Standards for Mathematical Practice* recommend that students engage with mathematics through problem solving, modeling, and reasoning (Common Core State Standards Initiative, 2010) many teachers continue to rely on the conventional script. Achieving the Common Core's vision for instruction can be especially challenging for preservice and novice teachers who have not yet developed strong pedagogical content knowledge (Shulman, 1986) or specialized mathematical knowledge for teaching (Ball, Hill, & Bass, 2005). As instructors of preservice teachers in a graduate-level math methods class, we model and encourage problem-based teaching but recognize the difficulties many preservice teachers face when attempting to implement this kind of instruction during school-based fieldwork. Inspired by Stein, Engle, Smith, and Hughes' (2008) belief that preservice teachers can learn explicit practices for facilitating productive mathematical discussions, we integrated the practices into our own teaching and for the first time in our math methods courses, we asked our preservice teachers to use the strategies when planning and teaching three focus lessons.

Learning to Teach Mathematics

To address predictable difficulties that arise as preservice teachers learn to implement discussion-based teaching, Stein et al. (2008) developed a model to explicitly teach novice practitioners how to lead productive discussions about challenging tasks. By emphasizing components of this type of teaching that can be planned in advance, the model is designed decrease the difficult and sometimes intimidating improvisational nature of leading such discussions. Briefly, the five practices are

> (1) anticipating likely student responses to cognitively demanding mathematical tasks, (2) monitoring students' responses to the tasks during the explore phase, (3) selecting particular students to present their mathematical responses during the discuss-and-summarize phase, (4) purposefully sequencing the student responses that will be displayed, and (5) helping the class make mathematical connections between different students' responses and between students' responses and the key ideas. (p. 321)

We selected this frame because it unpacks the strategies that are implicit in the instructional examples of master teachers that we share with our students (i.e., Ball, 1993; Burns, 2002; Lambert, 2001; Toliver, 1995). When our students read descriptions or watched videos of master teachers at work, the gulf between what they observed and the reality of their own math teaching was wide. With the intent of examining that divide, our guiding question for this study was, in what ways did our preservice teachers describe using the five practices? We hoped the answer to that question would help us understand, transform, and reform our own practice to ultimately improve our students' teaching.

Methodology

The participants in this qualitative study were graduate students in the second of four semesters in an elementary education licensure and masters degree program. Of the 22 students enrolled in a math methods course taught by one of the authors, 12 (11 women and one man) gave consent for analysis of their written work. Participants' ages ranged from approximately 22 to 55, and their ethnicities include white (10), Asian American (1), and Arab American (1).

The data for this study consist of assignments submitted for the course, including in-class writing prompts, summaries of three lesson plans, and reflective narratives. Due to limitations in the program model that did not allow us to observe preservice teachers in the classroom, we relied on written descriptions of their teaching as evidence of their understanding and use of the target strategies. To ensure participant anonymity, papers were relabeled with pseudonyms.

Data were coded using the five target strategies as categories and mapped to show how (or if) individuals changed over time. From the coded data, we drew conclusions about how the participants envisioned and used the practices at several points in the semester. The limitations of this method are potential researcher bias, as we hoped that the students would describe using and identifying with the five practices. To minimize the bias in analysis, we analyzed the data separately and compared our findings, grounding our conclusions in the participants' comments.

We used faculty self-study (Samaras & Freese, 2006) as a methodology for examining our own teaching practices. Through this self-study cycle of planning and revising a lesson plan assignment, we aimed to improve our own understanding of how our preservice teachers conceptualized and incorporated the five strategies into their practice. Analysis of our data will inform the next self-study cycle, during which we will modify our teaching based on what we learned in this initial cycle.

Findings

The findings described below are from an analysis of one representative participant, Tara, who was selected because her descriptions were typical of most respondents.

Anticipating Likely Responses to Cognitively Demanding Tasks

One month into the semester, Tara incorrectly listed this strategy as the third step in the sequence, "so that you can be ready to answer or use them to pose new questions to the class." Her first lesson plan reflected inaccurate anticipations about students' engagement with the task, the parts that would need scaffolding, and how to keep the lesson moving, but included little mention of math content. In the second lesson plan, she anticipated that students would have difficulty understanding the game she had selected and planned to scaffold for related mathematical concepts, including providing multiple representations of the target content and making explicit connections to prior activities. She anticipated cognitive dissonance in the opening activity and actually hoped that the students would be "a little bit confused." In the third lesson plan, she noted that students needed certain mathematical understanding in order to complete the task. She also reflected that she noticed steady improvement in her ability to anticipate students' responses during the course of the semester.

Monitoring Students' Responses to the Tasks

In all three lesson plans, Tara envisioned herself helping students as they worked on the task and "asking leading questions." By the third lesson, she acknowledged that it would be okay for students to make mistakes and "search for the answer themselves." She monitored by discussing students' strategies with them, assisting those having difficulty, and making anecdotal records of their proficiency with the task. She planned to ask questions like, "How did you know…?" or "How did you find…" to encourage them to explain their thinking. Early in the semester, she described this strategy as "use the information to choose students you want to share their ideas with the class," but her lesson plan summaries do not include evidence that she did that while monitoring.

Selecting Students to Present Responses During Discussion and Summary

Tara first described this practice as "monitor and listen" and explained the purpose is to "use the information to choose students you want to share their ideas with the class." There was no evidence in her first lesson plan that she purposefully selected students to share ideas, but students did "share different strategies and explained the steps they used in those strategies." In the second lesson, she planned to share comments from her anecdotal records, and she anticipated asking students to "share a problem they solved, a strategy they used, or a problem they found difficult." The extent to which this happened was unclear. In the third lesson, she planned to "showcase" certain responses and anticipated asking students to share approaches that linked to prior strategies, were new, or were "surprises." She reflected that in reality, the discussion was rushed, seemed jumbled, and that the students were restless.

Purposefully Sequencing Student Responses

Tara developed an awareness of this strategy late in the semester. Her first two assignments do not mention the sequencing of responses. In the second lesson plan, she wanted to save the big idea—how addition and subtraction are related—until the end of the discussion, as a kind of finale. It was not clear in her reflection if this happened as planned. Her third lesson plan included a detailed sequence for sharing: "difficulties first, surprises next, then those who discovered new or interesting strategies…" She noted that a summary discussion did take place, with a few students sharing fact families and others asking questions about doubles.

Making Connections Between Responses and Key Ideas

In Tara's final reflection of the semester, she wrote that one of her ongoing goals is to include more real-life connections to the math curriculum to increase student interest in math. She also thought it was important to link new strategies to students' prior knowledge. In the third lesson plan, she reflected that she would have liked to link the content to a number line representation or to ponder how to solve more difficult problems using fact families. Those connections were made in the lesson reflection rather than in the lesson implementation.

Discussion and Conclusion

Tara grew in her use of one of the practices (anticipating responses) during the course of the semester and described heightened awareness of the others. She moved from anticipating management-related issues to recognizing mathematical content and representations that students would need to understand or might find difficult. She even hoped that students would not understand the problem right away in her third lesson, showing that she was becoming confident in her ability to choose and manage stimulating and challenging tasks.

Nevertheless, leading a mathematically productive discussion remained an elusive goal for Tara. She included plans for discussions in her second and third lessons, but described only one such conversation about fact families. Her focus on helping students and asking leading question during the monitoring phase probably made it difficult to select students to share their responses because she did not have a detailed understanding of the ideas they might share. She stated the importance of connecting a lesson to students' prior knowledge or to real-world problems, but did not plan to illuminate those connections in a summary discussion. Rather, she used those features to engage students early in the lesson.

Though Tara's descriptions did not show that she led mathematically productive discussions as envisioned by Stein et al. (2008), she began to lay the groundwork for such instruction. Based on these findings, we hope to modify our teaching so that students interact with these strategies in more and deeper ways than occurred during this cycle. First, we will continue to model the practices in class while preservice teachers engage in mathematical problem-solving as learners. Second, we will revise the lesson plan template to highlight the importance of planning for each of the five areas, and emphasize only one or two strategies for each of the three lesson plans. Third, we will ask the students to engage explicitly with the practices during their fieldwork. As a precursor to writing their lesson plans, students will analyze their cooperating teachers' use of the five practices, highlighting evidence of their usage or offering suggestions of ways in which they could have been incorporated into the lesson. Lastly, before students teach their lessons, we would like them to observe instruction about a similar topic to help them anticipate student responses, recognize mathematically productive ideas, and envision themselves leading a summary discussion. True to the self-study model, we hope that our next cycle of reflection will further improve our instruction and also make our students better teachers.

A SURVEY OF TEXTS AND CORRESPONDING ASSIGNMENTS USED IN SECONDARY MATHEMATICS METHODS COURSES

Sarah Kasten
Northern Kentucky University
kastens1@nku.edu

Jill Newton
Purdue University
janewton@purdue.edu

This paper presents preliminary findings of a study aimed at summarizing the curriculum of a set of secondary mathematics methods courses at universities in the United States. The analysis began with the identification of texts and related assignments from a survey of secondary mathematics methods syllabi. The findings indicate that a variety of topics are addressed in the texts and that the accompanying assignments represent varying levels of engagement with the texts.

Keywords: Teacher Education–Preservice; Curriculum Analysis; Instructional Activities and Practices

Background

Broad recommendations have been made about the knowledge needed for teaching mathematics, as well as desired characteristics of mathematics teacher education programs (National Research Council, 2001; Conference Board of Mathematical Sciences, 2012). However, we do not yet have research-based recommendations regarding the mathematics pedagogy content of these programs.

> We do not understand well enough how mathematics and teaching, as inter-related objects, come to produce and constitute each other in teacher education practice. We lack adequate knowledge about what and how this happens inside a teacher education program, and then across ranging or contrasting programs, contexts and conditions. (Adler et al., 2005, p. 378)

Before we can design research studies to investigate which aspects of current secondary mathematics teacher education courses are productive, we must first unearth what mathematics teacher educators are currently doing in secondary teacher education programs across the United States, specifically in their methods courses where mathematics pedagogy is the focus. In a recent study of MMC syllabi in the United States, Taylor and Ronau (2006) examined the assessments and stated goals and objectives in mathematics methods course syllabi and found considerable variability among them. The purpose of this paper is to present preliminary results from a study of syllabi that focused on the texts and accompanying assignments in secondary mathematics methods courses (MMCs). We began our exploration of secondary MMC syllabi with the following questions: How does the focus of texts used in secondary MMCs align with standards outlined by NCTM? How are students asked to engage with these texts in the courses?

Studying Intended Curriculum via Analysis of Syllabi

In attempting to gain insight into what is happening in secondary MMCs in the United States we examined the *intended curriculum* of the courses (Remillard, 2005). We agree with Gorski (2009) who also conducted a syllabus analysis and pointed out that "as a teacher educator, I often have diverted from an official course design once the classroom door was closed. As teacher educators, we bring our philosophies, strengths, and limitations into our teaching. Therefore, I cannot claim to have discerned what, exactly, occurred in any particular course by examining its syllabus" (p. 309). Thus we are not attempting to characterize the teaching or the experiences that took place in these courses. Instead we are seeking to gain a picture of the landscape of texts and how they are used in secondary MMCs as they are represented in the syllabi.

Methods

The preliminary analysis presented here included the syllabi from secondary mathematics methods courses from 17 universities across the United States. Some of the collected syllabi contained full reading lists and others did not. In cases in which the reading list was not included, the authors contacted the course instructors to request these lists. We began by identifying the specific texts (e.g., books, articles, curricula) that appeared in more than one syllabus (n = 30 texts). The National Council of Teachers of Mathematics' (NCTM) *Principles and Standards for School Mathematics (PSSM)* (2000) was referenced in at least one syllabus from each university; therefore, we used the NCTM content and process standards as a frame to conduct an analysis of the texts. The topics of the readings were coded as corresponding to one or more areas within this framework (e.g., Problem Solving). Texts were coded only when the major focus represented one of the content or process standards. For example, Driscoll's (1996) book *Fostering Algebraic Thinking: A Guide for Teachers Grades 6–10* was coded with the content standard *algebra* because that was the primary focus of the book. After identifying and coding the content of the texts we then identified and coded the assignments corresponding to the readings in order to determine how students were being asked to engage with these texts (e.g., read, reflect, analyze). Following Larnell and Smith's (2011) recent analysis of verbs in curriculum standards to "describe the character of mental work that students must carry out" (p. 96), we used Bloom's Taxonomy in an attempt to capture the cognitive demand suggested in the assignments.

Findings

Our analysis revealed that the universities used a variety of types of texts in their courses, including secondary MMC textbooks, journal articles, and curricular documents. This included 32 specific texts which are the focus of this analysis.

Content Areas of Focus

Of the texts that did attend to specific content areas the greatest number focused on Number and Operation (see Table 1). We found that not all texts were related to specific content standards, for example several texts addressed the topic of assessment but not in a particular content area.

Table 1: Number of Texts Focused on Specific Content Standards (n = 30)

	PSSM Content Standards				
	Number and Operations	Algebra	Geometry	Measurement	Data Analysis and Probability
Number of Texts	8	6	5	4	3

This finding is particularly interesting given that *PSSM* recommends that Algebra should receive the most instructional attention in the secondary grades while Number and Operations should receive considerably less. Also noteworthy is the fact that three of the texts, *PSSM,* the *Curriculum Focal Points for Prekindergarten through Grade 8 Mathematics* (NCTM, 2006), and Brahier's (2005) MMC textbook, addressed all five content standards.

Process Areas of Focus

Problem Solving appeared the greatest number of times in the texts (see Table 2).

Table 2: Number of Texts with Emphases on Specific Process Standards (*n* = 30)

	PSSM Process Standards				
	Problem Solving	Reasoning and Proof	Communication	Connections	Representations
Number of Texts	7	5	5	2	3

The relative lack of focus on Connections represents a mismatch with NCTM's recommendation for incorporating the process standards into high school: "With the experience proposed here in making connections and solving problems from a wide range of contexts, students will learn to adapt flexibly to the changing needs of the workplace" (NCTM, 2000, p. 288).

Assignments Related to Readings

All levels of Bloom's Taxonomy were represented in the assignments (see Table 3).

Table 3: Number of Universities with Assignments at Each Level and Examples

	Bloom's Taxonomy Level					
	Knowledge	Comprehend	Apply	Analyze	Synthesize	Evaluate
Number of Universities	17	15	9	10	7	14
Example	Read…	Summarize…	Write a related problem…	Analyze readings…	Draw connections…	Reflect critically…

All of the universities had required assignments in their syllabi in at least two of the levels. The two universities with only two levels had assignments at the *knowledge* and *evaluate* levels, indicating a broad range of expectations in their syllabi. Fourteen of the 17 universities had at least one assignment at the *synthesize* and/or *evaluate* level.

Conclusion

This paper presents the findings of a preliminary analysis of secondary mathematics methods course syllabi with attention on the course texts and accompanying assignments. The evidence suggests that outside of *PSSM* there are not commonly accepted texts used in the secondary MMCs at these universities. Despite the fact that all institutions made use of *PSSM*, the relative emphasis of particular content and process standards did not mirror NCTM's recommendations. A similar statement could be made about the content standards of the *Common Core State Standards for Mathematics* (2010) which also has a decreased focus on number in the secondary grades and an increased focus on Algebra. Our preliminary findings of assignments indicate that secondary MMCs are asking students to engage with their texts on a variety of levels. This finding differs somewhat from previously held notions of the role of texts in university courses. That is, "the traditional form of the textbook is largely one that assumes and perpetrates a 'received knowledge, passive consumption' pedagogical model" (Issitt, 2004, p. 689).

Discussion

Our use of syllabi limits the conclusions we can draw about the content of methods courses in general, but our findings do suggest several important areas for future discussion and research. First, the sheer number of different readings employed by the 17 universities provides evidence of the wide range of text resources available to secondary mathematics teacher educators for use with preservice teachers. This is perhaps both a blessing and a curse for new secondary mathematics teacher educators. Discussion of appropriate texts has the potential to benefit new mathematics educators who are often asked to teach courses (e.g., methods) in which they have no experience. Second, the discussion of how secondary mathematics teacher educators are making use of their readings could be helpful both within and outside of the mathematics education community. Our findings may indicate that secondary MMCs are making use of texts in novel ways that merit further inquiry, discussion, and dissemination.

AN INVESTIGATION OF FACTORS INFLUENCING PRESERVICE MATHEMATICS TEACHERS' PREFERENCES TO TEACH IN URBAN SETTINGS

Deena Khalil
Rutgers, The State University of New Jersey
Khalil.deena@gmail.com

Matt Griffin
University of Maryland
griff23@umd.edu

Policymakers and educators have recently focused on the challenges associated with staffing qualified and effective mathematics teachers, especially in urban schools serving predominantly low-income and minority students. Social experiences and working conditions have been linked to teacher turnover and job satisfaction and have been theorized to influence teacher recruitment and retention in urban settings. However, very little is known about how prospective teachers' social experiences and perceptions of working conditions may influence where they choose to teach. The purpose of this study is to describe the background and perceptions of a sample of New Jersey mathematics and STEM-area teacher candidates enrolled in traditional and alternate route programs, and to investigate the factors that impact the candidates' preference to teach (or not teach) in urban districts.

Keywords: Equity and Diversity; Educational Policy; Teacher Education–Preservice

Purpose

The issue of teacher quality has risen to the top of the school reform agenda; research has found that the quality of a child's teacher is the most important in-school predictor of his or her achievement (Wright et al., 1997). Consequently, teacher supply and the initial distribution of teachers into classrooms are important educational policy issues. Of particular concern is the challenge of staffing the nation's schools with qualified mathematics teachers, especially in urban schools serving predominantly low-income and minority students (Ingersoll et al., 2010).

To better understand and address the challenges faced by urban districts in recruiting and retaining quality teachers, it is beneficial to consider not only the perspectives of those already in the teacher workforce, but also the beliefs and viewpoints of preservice teachers. In this study, survey responses were analyzed to investigate the factors that impact teacher candidates' preference to teach in urban schools.

Perspectives

A review of the literature illustrates several factors that contribute to the difficulties involved in the recruitment and retention of mathematics teachers, and more generally of teachers in the STEM content areas (science, technology, mathematics, and engineering). Some researchers argue that the levels and configurations of teacher pay structures contribute to an inadequate supply of math and science teacher candidates, as individuals with strong STEM content-area backgrounds frequently have other career options available offering more generous levels of compensation (Ballou & Podgursky, 1997). Others focus on factors related to heightened demand for qualified teachers; particularly the demand that is a result of high non-retiring turnover, often due to job dissatisfaction. The potential factors that influence teachers' career satisfaction, and by extension, their decisions to remain or leave teaching, can be understood by applying social learning theory, first utilized by in Krumboltz (1979) and later Chapman (1983) as a theoretical framework to review the literature on attrition. Through the social learning theory lens, social learning experiences could represent a relevant and valuable mechanism in addressing the quality of the mathematics teacher workforce. Social experiences, and their impact on one's perception of the environment/working conditions, have been linked to teacher effectiveness and to attracting and retaining sufficient numbers of qualified individuals to the profession despite its relatively low pay (Johnson et al., 2004).

Teacher shortages are frequently more pronounced in urban, high-needs settings. Haberman (1988) suggested that most traditionally-prepared teachers desire to teach in suburban environments, a preference

Van Zoest, L. R., Lo, J.-J., & Kratky, J. L. (Eds.). (2012). *Proceedings of the 34th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Kalamazoo, MI: Western Michigan University.

that may reflect the area in which those teachers grew up (Boyd et al., 2005). Even within urban districts, there can be an inequitable distribution of qualified teachers where teachers were found to transfer out of schools with relatively higher percentages of poor minority students into schools with generally less poor and higher performing students (Hanushek et al., 2004; Liu, Rosenstein, Swan, & Khalil, 2008). Accordingly, many researchers view student demographics, especially socioeconomic status and race/ ethnicity, as characteristics of schools that can lead to teacher turnover (Grissmer & Kirby, 1997).

The lack of retention of newly hired teachers in high-poverty schools can be often related to organizational factors, frequently referred to as "working conditions." Working conditions include unsupportive leadership style, inadequate salary/benefits, insufficient resources and support, and poor hiring practices (Johnson et al., 2004). Working conditions have been linked to teacher effectiveness and to the attraction and retention of qualified teachers into the profession despite its relatively low pay, especially regarding teachers in STEM fields (Johnson et al., 2004). While working conditions have been linked to teacher retention, relatively few researchers have examined how prospective teachers weigh the working conditions of schools in their considerations of where to seek employment.

This study takes an organizational approach (Ingersoll, 2001) to examine how social and professional backgrounds, perceived working conditions, and facets of teacher preparation might influence mathematics and STEM teacher candidates' preference of the type of district they want to teach in. To date, there is a lack of consensus in the literature around the factors that predict teachers' decisions to remain in or exit instructional contexts, which factors may be more or less important to those decisions, and how those factors might be related to teacher attributes or school characteristics (Ingersoll, 2001; Useem & Neild, 2005).

Data and Methods

The research reported here is part of a larger study investigating the challenges in recruiting and hiring teacher candidates in New Jersey. Data for this study were collected via survey from 696 teacher candidates enrolled in traditional and alternate route teacher education programs. Survey items were designed to measure the possible relationships between teacher candidates' perspectives and their future career plans. Survey items were constructed from the National Center for Education Statistics School and Staffing Survey and the NYC Teacher Pathways Project Survey, with additional items tailored to the specific New Jersey context.

For the analyses presented in this document, analytic samples of 199 STEM-area teacher candidates and 116 mathematics teacher candidates were utilized. We included teacher candidates who intended to pursue any STEM-area certification because these candidates may qualify for and potentially be motivated to become mathematics teachers. The samples consist of approximately 56% to 61% female teachers, and of these prospective teachers, about 75% are White, 8% are Black, 9% are of Asian origin, and about 8% are Hispanic. Of the total analytic samples, almost half were enrolled in teacher education colleges and/or programs, about 37% were completing New Jersey's alternate route programs, and 14% were from TFA or TNTP.

The outcome variable of interest was whether or not teacher candidates' indicated a preference to teach in urban schools. Approximately 39% of the participants in our samples indicated this preference. A binary logistic regression model was utilized to examine the impact of personal and professional characteristics, social experiences and preferences of perceived working conditions on teacher candidates' preference to teach in urban schools. Our final model included 11 predictor variables and the single nominally scaled dependent variable.

Results

Logistic regression models were run for both the STEM-area sample and the mathematics sample. Based on these data, we found that teacher candidates' perceived working conditions, previous experiences, and preparation route are significantly associated with their preference to teach in urban schools. The strongest predictor for both samples, in terms of statistical significance, was a scale that emerged from principal component analysis of survey items related to candidates' preferred school characteristics. This scale, which we refer to as the "High-Needs School factor" measures the tendency of a candidate to prefer to work in schools with a diverse population (student and teacher) and with many students of poverty, English Language Learners, and low achieving students. Teacher candidates scoring high on this scale were significantly more likely ($p < .001$ for STEM, $p = .002$ for math) to want to teach in urban schools. In addition, for both analytic samples, study participants who either attended high school or grew up in urban settings were significantly more likely ($p < .001$ for STEM, $p = .005$ for math) to want to teach in urban schools, when compared to their counterparts from suburban backgrounds. Teacher candidates who completed their field experience in an urban school were also significantly more likely ($p = .001$ for STEM, $p = .002$ for math) to prefer to teach in urban schools.

Based on our chosen level of significance ($\alpha = .05$), the other statistically significant predictors for the STEM sample included a flag indicating candidates enrolled in either Teach for America (TFA) or The New Teacher Project (TNTP), an indicator for candidates who were enrolled in teacher preparation programs located in a low-SES districts (identified in this study as District Factor Groups A or B), and a flag for "first-career late starting teachers," or teacher candidates who were 25 to 29 years old when the survey was administered. The only other statistically significant predictor for the mathematics sample was whether a participant was enrolled in TFA or TNTP. Lastly, for both samples, non-White teacher candidates were not significantly more likely to want to teach in urban settings as compared to their White counterparts, after controlling for the other analytic variables.

Discussion and Implications

These results suggest that teacher candidates' perceptions, experiences, and characteristics are important considerations when conceptualizing teacher recruitment policies. Just as Chapman (1984) utilized social learning theory to empirically examine factors influencing teacher career satisfaction and retention, this study found those factors were all positively associated with candidates' preferences to teach in an urban district.

As previously noted, the only factor measuring perceptions of preferred environmental factors/working conditions that was a significant predictor of teacher candidates' preference to teach in urban districts was the High-Needs School factor. In other words, factors tapping into some of the aforementioned working conditions of interest to Liu and his colleagues were not significant predictors in our analyses. This could be due to the high demand for STEM-certified teachers; thus, candidates may feel as if they can choose a position with optimal non-monetary benefits (or perceived working conditions). On the other hand, many STEM-certified candidates may be beneficiaries of pipeline subsidies (such as NOYCE, AmeriCorp, loan forgiveness) that require candidates to work in high-needs districts, resulting in their proclivity for such school characteristics.

Teacher preparation programs are a major investment at the local, state, and national levels. Urban teacher preparation programs are designed to recruit teachers prepared for the rigors of teaching in an urban environment, and to ensure a good fit in such an environment (Haberman, 2005; Ladson-Billings, 1994). Our findings provide evidence that the completion of an urban field experience, as well as the locale of the teacher producing institution, are important influences on teacher candidates' preference for urban teaching. Thus, we contend that teacher preparation programs could make better use of their surrounding urban areas to assist teacher candidates in the facilitation of practical field experiences.

For both of our analytic samples, another significant predictor of candidates' preference to teach in an urban district was whether they grew up or attended high school in an urban area. This is consistent with a finding of Boyd et al. (2005) that 34% of their teachers began their first teaching job near their high school, 61% chose a school within 15 miles of their home, and 85% stayed within 40 miles of their hometown. Taken together, these results support community-based Grow Your Own (GYO) models for teacher pipelines, to produce more committed, culturally aware teachers recruited from the local community (Skinner et al., 2011). Local recruits are more likely to remain in the workforce for longer periods of time, and know more about the students, parents, schools, and the communities where they teach.

ASSESSING ELEMENTARY TEACHER CANDIDATES' KNOWLEDGE FOR TEACHING MATHEMATICS

Jennifer Kosiak
University of Wisconsin–La Crosse
jkosiak@uwlax.edu

Jenni K. McCool
University of Wisconsin–La Crosse
jmccool@uwlax.edu

The purpose of this study was to describe the application of the Mathematical Knowledge for Teaching-Think Aloud Rubric (MKT-TAR) to assess and quantify elementary teacher candidates' (ETCs') common content knowledge and specialized content knowledge for teaching mathematics. The rubric was used to score over 100 think aloud podcasts created by teacher candidates at various stages of their academic coursework. The results indicated that the MKT-TAR was an effective tool to characterize the quality of ETCs' mathematical knowledge for teaching.

Keywords: Mathematical Knowledge for Teaching; Teacher Education–Preservice; Assessment and Evaluation; Technology

Purpose of the Study

The examination of inservice and preservice elementary teachers' mathematical knowledge for teaching (MKT) has been a focus for many years (Ball, Thames, & Phelps, 2008). Researchers have used a variety of tools to examine MKT including written protocols and interviews (Thanheiser, 2009; Ma, 1999; Tirosh, 2000). To extend this research, the authors chose to focus on how elementary teacher candidates (ETCs) would demonstrate MKT through think-aloud podcasts that simultaneously captured their voice and written work. The authors sought to capture and understand ETCs' MKT as it related to not only the types of strategies they used, but also their use of mathematical language and the depth of their explanations specifically related to whole number subtraction and the division of fractions. In order to describe the nature and quality of ETCs' MKT the authors developed the Mathematical Knowledge for Teaching-Think Aloud Rubric (MKT-TAR). Therefore, the purpose of this brief report is to document the development and refinement of this rubric and provide specific examples of how the rubric was applied to ETCs' think-aloud podcasts.

Theoretical Framework

Building on a practice-based theory of mathematical knowledge for teaching, Ball and her colleagues (e.g., Ball, Thames, & Phelps, 2008) identified and defined subsets of subject matter knowledge and pedagogical content knowledge. Relevant to the development of the MKT-TAR are the two distinguishable domains of subject matter knowledge. The first domain is associated with the knowledge of mathematics that is commonly used in settings other than the classroom. This common content knowledge (CCK) encompasses "being able to do particular calculations, knowing the definition of a concept, or making a simple representation" (Thames & Ball, 2010, p. 223). The second domain is comprised of the mathematical knowledge that is used in teaching tasks. This specialized content knowledge (SCK) involves knowing different representations of mathematical procedures and concepts, using appropriate mathematical vocabulary and providing robust mathematical explanations of common rules and procedures.

Methods

The participants for the study and rubric development were ETCs attending a Midwestern university who were at various stages of their academic program. During the initial pilot of the rubric, over 100 teacher candidates were active participants in the project. Similar to the tasks from Ma (1999), participants were asked to create think-aloud podcasts based on the following situations. "Present the following problems as though you were explaining them to a student: $452 - 286$ and $1\frac{3}{4} \div \frac{1}{2}$."

Rubric Development

Similar to coding methods established by Miles and Huberman (1994), the development of the MKT-TAR began with a list of common types of teaching tasks derived from research. These common tasks included using and choosing representations, attending to and using math language, defining terms mathematically and accessibly, and giving explanations (Thames & Ball, 2010). The researchers analyzed a subset of think-aloud podcasts in order to collapse and cluster these teaching tasks into the domains of CCK and SCK.

During this initial development of the MKT-TAR, CCK was further subdivided into three categories. These categories included *Computational Accuracy,* use of *Representations,* and *Strategies Used*. The second domain, SCK, was divided into the categories of use of appropriate mathematical *Vocabulary* and *Depth of Explanation*. In the initial iteration of the MKT-TAR all domains utilized a 3-point scale.

The process of developing the MKT-TAR was cyclical. The researchers used the initial version of the MKT-TAR to assess five think-aloud podcasts for each task in order to discuss scoring procedures and further refine the rubric. The MKT-TAR was then modified to address discrepancies in scores. One such discrepancy was the use of a 3-point scale for *Depth of Explanation* where it became apparent that there existed two distinct situations that were coded at a Level 1. The first situation was that an ETC utilized a coherent explanation to demonstrate their CCK (e.g., they could do the procedure), but did not explain why the procedure worked. The second situation involved an ETC providing evidence of CCK and limited understanding of SCK. That is, they were able to address the need for regrouping in multi-digit subtraction by discussing place value concepts, but their explanation contained minor errors such as “borrow a group of ten” or “you can’t take six from two”. To account for these distinct situations, the second iteration of the MKT-TAR utilized a four-point scale for coding *Depth of Explanation*. To determine inter-rater reliability, a second iteration of the MKT-TAR was used by two researchers to individually code twenty think-aloud podcasts for each task. Cohen’s Kappa correlation coefficients of .682, 1.00, .674, and .896 ($p < 0.001$) were calculated in each of the four domains (Computational Accuracy, Representations, Vocabulary, and Depth of Explanation).

Results

For the purposes of this brief report, we will discuss results related to the SCK subdomain, *Depth of Explanation*. Table 1 highlights specific think-aloud examples that were coded according to the 4-point scale for this subdomain. This table includes a final screenshot of the ECT’s work as well as a partial transcript of their explanation where emphasis has been added to areas of concern (italics) and areas of understanding (underscored).

Example A, exemplifies a Level 0 because the ETC said, “you invert and multiply” and then proceeded to “invert” both fractions. This example shows a novice level of CCK and a limited understanding of SCK. A Level 1 score was given when participants provided a coherent explanation of the procedure, but provided little to no evidence of the mathematical meaning underlying the procedure as shown in Example B. At this level, statements like “borrow a one from the tens place” or “invert and multiply” exemplify common phrases for think-alouds that received scores of 1. In both cases, ETCs document a more practiced CCK than a Level 0, but still exhibit a limited understanding of SCK. A Level 2 indicates that the explanation provided mathematical meaning to the procedure, but further clarification was needed. As shown in Example C, phrases such as “we can’t take away six from two” or “we need to borrow a ten from the tens place in order to subtract” do indicate an attempt to explain the need to regroup however, the explanation could be more refined by saying “we can’t take away six ones from two ones” or “we need to regroup a group of ten into ten ones” which are phrases consistent with a Level 3 score. In Example D, a Level 3 indicates an explanation was both coherent and provided mathematical meaning to the procedure. At this level the ETC demonstrated a practiced CCK and deep SCK by showing multiple representations to solve the division of fractions task.

Table 1: Examples of Depth of Knowledge Coding

Example A 	**Level 0: Inappropriate explanation that distracts from understanding** “Ok now we will be doing fractions. The problem is one and three-fourths divided by one-half. With fractions *you invert and multiply*, so that would be one and *four-thirds times two over one*. Four times two is eight. Three times one. Over three. And that is all you have for fractions.”
Example B 	**Level 1: Explanation provides little to no evidence of the mathematical meaning underlying the procedure** **“**So what we want is we want the *numbers on top to be larger than the numbers on the bottom so we can subtract them*. Looking at the two and the six, the two is smaller than the six, so what we need to do is *borrow from the number before it*. So what we’re going to do is borrow from the five we’re going to make that a four and then we’re going to borrow what we’re adding onto the two and <u>we’re going to make that a twelve by adding ten</u>. Now the twelve is larger than the six, and that’s what we want, so we can subtract that. So we can do *twelve minus six* and that’s going to give us six, so we can put that right there…”
Example C 	**Level 2: Explanation provides mathematical meaning to the procedure but needs further development** **“**Now to begin to help us to understand place values, I might tell them to add little zeros in here, in the hundreds place and in the tens place. So that they can get a better idea when we start to borrow what kind of numbers they are dealing with… *And since we can’t take away six from two*, we’ll need to begin borrowing so we’ll tell the student that we’ll need to <u>borrow ten from the tens place</u> here. So fifty, we’ll take ten over here and that means we’ll have to subtract ten from fifty and now we’ll have forty. And then we add the ten to the two, plus ten is twelve. So now we have six, twelve minus six…”
Example D 	**Level 3: Explanation is coherent and provides mathematical meaning to the procedure** **“**I’m going to do the problem one, one and three-fourths divided by one-half. I’m going to do fraction tiles so we’ll start off by doing, that’s one whole and that’s one whole. Then do the one and three-fourths and then <u>how many halves can I get from the three-fourths</u>. So then, oops that’s one-half another half, then another half. So then it’s three and since there is two parts of each half there is one piece left over so there would be one-half left so the answer would be *three-halves*.”

Discussion

Analysis of the data demonstrated that the MKT-TAR was able to capture distinct levels of both CCK and SCK for teaching. Extending on the work of Hasenbank and Hodgson (2007) who examined levels of procedural knowledge, these domains could be further classified into novice versus practiced CCK and limited versus deep SCK. Therefore, further research will focus on determining what instructional materials are best suited for moving ETCs towards practiced CCK and deep SCK.

NAVIGATING THROUGH PRE-SERVICE TEACHERS' PROFESSIONAL VISION IN FIELD EXPERIENCES

Ji-Eun Lee
Oakland University
lee2345@oakland.edu

This study investigates the aspects of learning/teaching that pre-service teachers examine at distinct time periods while taking on different roles. Pre-service teacher participants (N=76) reported on what they noticed from past teachers' and current field teachers' teaching as well as their own teaching in the field setting around loosely structured themes. Results showed that participants mainly focused on the factors of teachers and tasks. Their attention to the student factor was weak. Also, they tended to avoid making critical reflections when they were in the field compared to their reflection on previous learning experiences. It would be desirable to consider more structured observation/reflection activities in collaboration between the teacher education program and the field setting to support pre-service teachers' appreciation and development of the full range of teaching and learning of mathematics.

Keywords: Teacher Education–Preservice; Instructional Activities and Practices

Objectives

One of the common features of teacher preparation programs around the world is the field experience component that aims to provide pre-service teachers with firsthand experience in classrooms and to support their smooth transitions into classroom teaching. While the specifics of field experiences vary, one common characteristic is that pre-service teachers spend substantive time in the field setting '*observing*' their cooperating teachers' teaching and other events happening in the field. Recent research in mathematics education has drawn attention to effective professional development, realizing the importance of understanding what and how teachers are attending to in their classroom events (e.g., Mason, 2002; Jacobs et al., 2007; Sherin, Jacobs, & Philipp, 2011). While the main body of research focuses mostly on in-service teachers' professional growth, little is reported on how these ideas can be incorporated in teacher preparation programs. In this regard, this study focuses on what pre-service teachers attend to during their field observation and how they interpret what they observed. The purpose of this study is to share the aspects of learning and teaching which a group of pre-service teachers perceived while taking on distinct roles (e.g., as students in past experiences, as teacher candidates in the university course, as student teachers in field settings), how their patterns of noticing changed, and, ultimately, to open further discussion on how to utilize field experiences to support the development of pre-service teachers' professional vision. Specifically, this study examines the following questions:

1. What events do pre-service teachers recall from their past mathematics learning experience?
2. What events from the field settings do pre-service teachers pay attention to?
3. Do the noted past/present events influence pre-service teachers' planning and implementation of mathematics lessons? What are pre-service teachers' justifications of incorporating or not incorporating what they noticed into their actual teaching?

Theoretical Framework

It is the role of teacher educators to consider ways to engage teachers/teacher candidates in authentic aspects of practice so that they can learn to utilize teaching practice as a source of inquiry and a way to develop a professional vision. Mason (2002) frames this professional vision as developing the sensitivity to "notice" things in the beliefs of "teaching as disciplined" inquiry. Mason (2011) states the discipline of noticing as a collection of techniques for (a) *pre-paring* to notice in the moment, and (b) *post-paring* by reflecting on the recent past to select what to notice in order to act freshly rather than habitually. Similarly, Endsley (2000) defined situation awareness, which is the term that embodies a theory of noticing, as involving three factors: (a) perception of meaningful elements in an environment, (b) comprehension of their meaning, and (c) projection of their status in the near future. Most of the other studies also characterize teacher noticing as consisting of three aspects: (a) attending to noteworthy events, (b) reasoning about such events, and (c) making informed teaching decisions on the basis of the analysis of these observations (van Es, 2011). One of the key considerations provided by the previous research is its continuous, cyclic sequence, which emphasizes the component of reflective practice. Informed by these previous works, this study offers similar professional development contexts to pre-service teachers by providing the following opportunities: (a) noticing critical events in their past/current learning experiences from the observer's perspective; (b) incorporating/implementing the noticed areas into their teaching plan; and (c) reflecting upon their teaching.

Methodology

Context

This study was conducted in multiple sections of a K–8 mathematics methods course in a Midwestern university in the USA. A total of 76 pre-service teachers engaged in the following phases throughout the semester: (a) reflection on what their past teachers taught by reporting episodic events, (b) reflection on what their current field cooperating teachers taught by reporting the event they noticed, (c) creating/implementing a lesson in the field based on what they had noticed, and (d) reflection on the results of their own teaching implemented in the field. To help encourage participants' engagement, participants were asked to report on their experience around a loosely structured format of observation: (a) what should be *lessened*, (b) what should be *expanded*, (c) what should be *altered*, and (d) what should be *dropped.* In each phase, written episodic memories, called 'LEAD' reports, were collected as data. In the LEAD report, participants described their learning/teaching experiences and their tentative disposition (e.g., Lessened/Expanded/Altered/Dropped) along with personal justifications. The table below shows the phases of study.

Table 1: Phases of Study

Phase	Phase 1	Phase 2	Phase 3
What is the teaching/learning context involved?	Past learning experiences	Current learning experience	Lesson planning/ Post-teaching reflection for future teaching
Whose teaching is the LEAD report based on?	Past mathematics teachers	Current field cooperating teacher	Self
What is the rationale of each LEAD phase?	* Identifying/noticing the satisfaction/dissatisfaction with others' teaching practice that potentially produce the motivation to move toward the ideal state * Getting a more profound level of reflection under the frame of LEAD * Learning to see important features of classroom practice		* Changing perspective from 'information receiver'/ 'observer' to a more active leading role * Connecting with what is noticed from others' teaching practice with own teaching practice * Finding important results that influence future teaching

Data Source/Analysis

Multiple and primarily qualitative methods were utilized. Major data sources were participants' personal narratives (LEAD reports) documented via an online depository (Moodle). Qualitative data obtained from participants were analyzed with aspects of a double-coding procedure suggested by Miles and Huberman (1994). Multiple people jointly developed a coding scheme and coded the data. The interrater reliability, about 83-85%, was calculated as the number of agreements divided by the number of sample items coded.

Results

Initially, the researcher and a research assistant reviewed all entries and identified emerging themes, independently focusing on significant features participants revealed. Then, the themes each person identified were compared and combined. Since each participant demonstrated multiple thoughts on the same topic over time, demonstrating multiple dimensions of their thinking of the given examples and related strategies, the coding process focused on whether the specific theme was present or absent in each participant's statements. The final coding scheme used and the frequencies are shown in the following table.

Table 2: Coding Scheme and Frequencies

	Phase 1	Phase 2	Phase 3
A. Class environment/set-up *(A1. Materials; A2. Curriculum/Textbook)*	19.3%	14.1%	20.7%
B. Teacher *(B1. Teacher preparation; B2. Classroom management; B3. Communication with students; B4. Modes of representation used; B5. Teacher knowledge/attitude; B6. Grouping strategies; B7. Flexibility/pacing)*	24.2%	41.2%	45.3%
C. Students *(C1. Understanding; C2. Emotions/Attitude; C3. Engagement; C4. Strengths/Abilities)*	10.3%	2.5%	4.4%
D. Tasks *(D1. Types of tasks; D2. Types of instruction)*	36.5%	34.5%	28.1%
E. Assessment *(E1. Types of assessment; E2. Grading/Purpose of assessment)*	9.7%	7.7%	1.5%

Notes: (1) Frequencies are calculated based on the total number of meaningful entries of events described in each phase [Phase 1: 518 entries, Phase 2: 1,252 entries, Phase 3: 135 entries] (2) Frequencies for each sub-category are calculated, but not reported in this proposal due to the limited space.

The frequencies of participants' disposition on their learning/teaching experiences in the LEAD report along with personal justifications are shown in the following table.

Table 3: Frequencies of Participants' Disposition

Phase 1					Phase 2					Phase 3				
L	E	A	D	N	L	E	A	D	N	L	E	A	D	N
20.3%	28.7%	27.2%	17.0%	6.8%	3.4%	26.1%	20.0%	3.2%	47.3%	3.6%	53.3%	42.4%	0.7%	0.0%

Notes: L (Lessen), E (Expand), A (Alter), D (Drop), N (no clear dispositions/justifications)

Some noteworthy findings from this study are listed below:

- In all phases, participants mostly attended to the themes related to "Teacher" and "Tasks". Participants gave more attention to the theme of "Teacher" in Phases 2 and 3 during the field experiences compared to Phase 1.
- Overall, participants demonstrated weak attention to the theme of "Student". In Phases 2 and 3, it became much weaker than Phase 1.
- Overall, two dispositions, *Expand, Alter*, were dominant.
- In Phase 1, there were relatively high number of reports related to *Lessen* and *Drop*, representing negative past learning experiences.
- In Phase 2, almost half of the reports did not indicate specific dispositions. These reports only described what participants observed without judgment.

Possible Conclusions

This study showed that what participants attended to in the field setting is somewhat unbalanced, missing many important aspects in classroom teaching (e.g., less noticing on students). Also, it was shown that many participants did not provide any reflective dispositions on what they noticed in the field setting, even though a loosely designed reflection format (LEAD report) was provided. This may imply that pre-service teachers considered field experiences as the context to learn solely from those in authority (e.g., cooperating teachers) rather than as the opportunity to actively generate their own ideas and thoughts. If teacher education programs continue to provide field experiences as a context to help pre-service teachers have holistic views and critically reflect on teaching/learning in the classroom, it would be important to know what pre-service teachers observe, think, and do in the field setting in order to create conditions that are conducive to both creating a holistic view and reflecting critically. To do so, it would be desirable to consider more structured observation/reflection activities in collaboration between the teacher education program and the field setting. It is hoped that this study brings attention to the creative ways teacher educators can support pre-service teachers' appreciation and development of the full range of teaching and learning of mathematics.

In this paper we share initial findings from an investigation of the similarities in challenges faced by new K–12 mathematics teachers with those faced by new mathematics teacher educators. Data about the challenges faced by new mathematics teacher educators were collected through a survey, and data about the challenges faced by new K–12 mathematics teachers were collected by reviewing relevant literature. Themes from both sources were identified and compared. One goal of this project is to improve the preparation of both groups of teachers by applying principles of successful preparation and professional development from one domain to the other.

Keywords: Teacher Education–Preservice

Purpose of the Study

For decades researchers have investigated the experiences of pre- and in-service K–12 schoolteachers, often focusing on the struggles of new teachers (e.g., Moir, 2009). Within this body of research, there has also been a dedicated effort to understand the experiences of new mathematics schoolteachers (e.g., Sowder, 2007). In contrast, little is known about the experiences of new mathematics teacher educators (Goos, 2009). New mathematics teacher educators face unique challenges, as they are expected to strike a balance between the demands of their work, including their responsibilities for preparing pre-service teachers. Whereas others (e.g., Golde & Walker, 2006) have looked to these challenges to help understand how doctoral education could provide better preparation for careers in academe, the aspect of our research project reported here looks for similarities between the challenges faced by two groups of new teachers (fewer than four years of teaching experience): those teaching mathematics education courses at universities and those teaching K–12 mathematics. Here we focus our attention on addressing the following questions: (1) How prepared do new mathematics teacher educators feel to begin teaching pre-service teachers? and (2) How are the transitional challenges faced by new mathematics teacher educators similar to those of new K–12 mathematics teachers?

Methods of Inquiry

Participants

A National Science Foundation (NSF)-funded program to mentor recent graduates of mathematics education doctoral programs, within their first four years of post-doctoral work, began in 2010. From a national pool of applicants, 46 participants were selected. All program participants were invited to complete our survey with a resulting sample of n = 40 participants (87% response rate).

Instrumentation

The research team constructed a pool of survey items based on existing literature on the responsibilities, expectations, and challenges often faced by new faculty as they transition into a career in academe. A pilot test of the survey instrument was conducted with six mathematics education faculty members who have served as mentors for new mathematics teacher educators. These faculty members were chosen for the pilot because they have knowledge about the challenges faced by new mathematics teacher educators. Based on responses to the pilot test, the research team revised the survey instrument. The final survey instrument, consisting of 27 questions partitioned into demographics and open response items, focused on new mathematics teacher educators' beliefs about their doctoral program experiences regarding: (1) their transition to becoming faculty, and (2) the preparation, support, and resources they received for their teaching responsibilities.

Data Collection and Analysis

New mathematics teacher educators were contacted via email with an explanation of the research study and its purpose. A link to the online survey was provided through email. Participants were informed that participation was voluntary and their responses would be aggregated, so that no one individual could be readily identified. Additionally, participants were informed that their candid responses would be used for research purposes only, and their participation in the survey would be an indication of consent for their data to be used.

The survey data were analyzed using a two-tiered analytic method. We first analyzed the responses to identify patterns and commonalities in describing the struggles, challenges, successes, resources, and reflections on what did and did not prepare the participants well for their work. Two team members read the open response questions independently, used open coding to code responses, and then compared their codes. Differences were discussed and consensus was reached on each code. The constant comparative method was then used to compare these codes across questions to reduce similar codes to categories (Glaser & Strauss, 1967). These categories were then compared across all questions to finalize descriptive themes (Bogdan & Biklen, 1998).

Results

Initial Findings: Challenges for New Mathematics Teacher Educators

Mentoring. While institutional support was fairly common—58% of participants said their institutions offered seminars on assessing student learning, and 65% said their colleagues openly shared student assessment materials—the results for individual mentoring were not as strong. Thirty percent were assigned an official mentor at the start of their academic position with whom they have been steadily working. Twenty-three percent were assigned an official mentor but have not been working with them or have found their interactions ineffective. Forty percent were not assigned an official mentor but have found their own informal mentor. One representative quote spoke to the need for strong research mentoring at the graduate level: "I felt unprepared for independent research in mathematics education. I feel that my program needed more active, publishing faculty members in mathematics education to mentor me and guide me through the early years of my career." Participants also indicated difficulties in striking a balance between research, teaching, and service and sought advice from their faculty mentors, such as by "Talking with them about their jobs, how they're managing their time, etc." Many participants indicated that they found it quite challenging to transition from being a graduate student to a faculty member, recommending the importance of "Having a strong mentor or mentors who will help you navigate through your first few years. There are so many 'opportunities' that come your way. It's good to have some trustworthy advice regarding what to steer away from."

Lack of teaching experience. Participants felt they had good knowledge of mathematics education literature, which satisfies Jaworski's (2008) call for "strong knowledge of the professional and research literature relating to the learning and teaching of mathematics" (p. 1). However, participants felt less prepared for their roles as teachers. Responses included leaving a doctoral program without a comprehensive tool kit for teaching. For example, one participant stated, "My program did not include any training on teaching—how to lead a discussion, construct a syllabus, or create assignments. Some faculty may have discussed this in passing. I didn't teach at all in graduate school." Another representative response: "I did not graduate with any resources for teaching. I had taught one course during one semester (a methods course), but had nothing from which to create courses on my own." Furthermore, one participant did not feel well versed in K–12 mathematics:

> My program didn't help me understand the world of K–12 math education in general, such as NCTM Principles & Standards, state curriculum standards, teacher certification requirements, education associations like AMTE, math ed conferences/other professional development opportunities, etc. I felt like it was assumed that we knew these things as a first year professor.

These findings, while similar to those cited by Prewitt (2006) and Golde (2006), are unfortunately out of sync with Jaworski's suggestion that new mathematics teacher educators know "pedagogy related to mathematics [and] mathematical didactics in transforming mathematics into activity for learners in classrooms" (2008, p. 1). This may be due in part to the variation in programs for preparing future mathematics teacher educators as many new faculty do not have K–12 or post-secondary teaching experience.

Initial Findings: Challenges for New K–12 Mathematics Teachers

Researchers have investigated the challenges faced by beginning K–12 teachers, typically using surveys and interviews to learn from the teachers themselves. Similar to the challenges reported by new mathematics teacher educators (as described above), new K–12 teachers describe difficulty in establishing relationships that provide community, guidance, and mentoring as a challenging aspect of career induction (e.g., Chappell, Choppin, & Salls, 2004; Roehrig & Pressley, 2002; Rust, 1994). Another theme that emerged from our investigation of the literature is the "disconnect" that beginning K–12 teachers perceive between their preparation programs and the "realities" of classroom teaching. This perception is often accompanied by a suggestion that teacher preparation programs include more frequent and more authentic teaching experiences (e.g., Cady, Meier, & Lubinski, 2006; Gleason, 2011; Luft, Roehrig, & Patterson, 2003; Olson & Osborne, 1991; Rust, 1994). Both of these challenges resonate with those reported by participating new mathematics teacher educators.

Discussion

We, the authors of this brief report and new mathematics teacher educators ourselves, took as the premise of this study the recognition that there is value in reflecting on our own experiences transitioning into careers in mathematics teacher education. By comparing our transitions with what we know about the struggles that new K–12 teachers face (based on our own experiences, those reported by our students, and those reported in literature), we think we can become more thoughtful about how we prepare both groups. The research reported in this paper is ongoing. We are currently collecting more data in the form of surveys from additional cohorts of new mathematics teacher educators, and we are continuing to examine reports from other research projects that have sought to investigate the experiences of new K–12 mathematics teachers. Nevertheless, our initial findings as shared here confirm our hunch that becoming a new teacher in any setting—higher education or K–12—is not easy and is far from automatic. We are confirming, in other words, that we must help all new teachers, no matter where they fall on the continuum, to navigate that transition. Experiences from one domain may well apply to the other. For example, much is known about characteristics of effective professional development for K–12 mathematics teaching. How can those principles inform professional development of new faculty members who work in mathematics teacher preparation? Can promising aspects of the student teaching experience, so common in K–12 teaching preparation, be replicated in the preparation of mathematics teacher educators? Similarly, some participants reported that their universities were able to provide effective mentoring and had successful structures in place. Can K–12 teachers benefit from similar models? The next step of our research project considers these and other questions. By viewing our work as not so different from the population we serve (pre-service teachers), we may be able to be more empathetic in our personal interactions and more thoughtful and responsive in our teacher preparation courses and programs.

PRE-SERVICE TEACHERS' ABILITIES TO INTEGRATE A SOCIAL JUSTICE PEDAGOGY IN MATHEMATICS

Maggie Lee McHugh
University of Wisconsin–La Crosse
mmchugh@uwlax.edu

Jennifer Kosiak
University of Wisconsin–La Crosse
jkosiak@uwlax.edu

The purpose of this study was to examine pre-service educators' abilities to integrate social justice *into mathematics. The study examined the change in their abilities to describe and create a social justice lesson over the course of a semester-long study of mathematics taught through a critical, social justice lens. Lessons were coded based on their social justice connection (real world, cultural integration, change agency) as well as the context in which mathematics was used (connected versus critical).*

Keywords: Teacher Education–Preservice; Equity and Diversity

Purpose of the Study

What is the purpose of teaching mathematics using a social justice framework? Adams, Bell and Griffin (2003) define social justice as the "full and equal participation of all groups in a society that is mutually shaped to meet their needs" (p. 1). In education, social justice themes are enacted to enhance students' learning and their life chances by challenging the inequities of school and society (Michelli & Keiser, 2005).

The literature provides multiple definitions of social justice mathematics. This study operationalizes social justice mathematics as a teaching and learning environment where students are introduced to the various issues of equity, diversity, and social injustices as they increase and strengthen their mathematical content knowledge. Additionally, students learn to use mathematics to identify and examine social issues with the intent to enact change. As such, students can begin to see math as a dynamic base of knowledge that can be used to "to create meaning and make sense of human and social experiences" (Gutstein, 2006, p. 4).

With the growing movement of social justice mathematics, various studies have been conducted with in-service educators (Gutiérrez, 2007); however, fewer studies have been conducted with pre-service educators, marking their abilities to integrate social justice (Muller, 2008). This study adds to the emerging literature on teaching a social justice pedagogy by addressing the following research question: What are elementary pre-service teachers' abilities to integrate social justice into mathematics?

Theoretical Framework

One opportunity for teachers to learn about being critical educators is during their teacher education programs. Therefore, it is important to understand how pre-service educators' integrate social justice pedagogy into the math classroom. Cochran-Smith (2004) writes, "In most of their pre-service programs, the role of the teacher as an agent for change is not emphasized" (p. 29). Price and Ball (1998) found that prospective teachers struggled "with learning to see classrooms from new perspectives, to reconsider the roles of teachers and students, issues of power and opportunity, and knowledge itself" (p. 262).

One key aspect of creating a socially just mathematics classroom is to include issues of inequities found in our local and global society. Teachers can integrate information about social injustices in order for students to begin breaking down stereotypes found in society and promoting change of inequities. Gutiérrez (2007) refers to this integration as critical math, one that "acknowledges the positioning of students as members of a society rife with issues of power and domination and which furthermore, takes students' cultural identities and builds mathematics around them in ways that address social and political issues in society" (p. 40).

Overview of the Study

This study was placed into the context of three elementary math methods sections ($n = 66$) which met for two hours weekly over the course of 15 weeks. Each week, the instructor modeled social justice connections that could be integrated into elementary math. During the course of the semester, pre-service educators were administered a pre- and post- survey regarding their understanding of and ability to enact a social justice curriculum in mathematics. As part of a final assessment, pre-service teachers developed a concept plan, a set of lessons focused on one particular topic, which incorporated an aspect of social justice.

A grounded theory approach was utilized to find themes within the pre-service educators' surveys and concept plans through text-based coding. This type of coding is defined as "a progressive process of sorting and defining those scraps of collected data that are applicable to your research purpose" (Glesne, 1999, p. 135). The coding of data was done in such a way as to be open to themes that emerged from the data, while at the same time working within a framework of codes that were consistent with the research question.

Results

Abilities Survey

A question on the pre- and post-survey asked pre-service educators to describe an activity or lesson that could be implemented into the math classroom that addresses social justice. On the pre-survey, 23 of the 66 pre-service educators commented that they were unsure of how to complete this integration. Sixteen others included the aspect of differentiating a lesson to accommodate all learners. The remaining pre-service educators included a connection to social justice into their initial activity. Some of these lessons incorporated diversity into math problem, such as this pre-service educator who wrote, "Including Hmong cultural traditions in math problems would illustrate a diverse approach." It is unclear, though, how fully infused these diverse cultural traditions would be into the problems. Mills (2008) contends we must move away from superficial treatments of diversity; this should also be done in the math classroom where diversity is not an add-on to questions but rather an integral part of a problem.

By the post-survey, all pre-service educators described a social justice math lesson that they would implement. In order to fully analyze the pre-service educators' abilities, this survey item was coded into three hierarchical categories as operationally defined in Table 1 below.

Table 1: Social Justice Survey Coding

Describe a mathematics activity or lesson you could implement into the elementary/middle mathematics classroom that addresses a social justice issue.		
Code & Operational Definition	**Pre-Survey Example**	**Post-Survey Example**
Social Justice as Real World Responses indicated a lesson that addressed a real-life situation	You could relate a lesson to school funding and student population. Determining how much money is invested for each student.	Analyze what students eat in terms of processed food and different nutritional levels—create graphs and statistical examples out of this.
Social Justice as Cultural Integration Responses indicated a lesson that addressed the culture and identity of students or a cultural awareness	I believe having a lesson based on different forms of money, for example the U.S. dollar, peso, euro and bartering. Discuss the different forms of payment then have the children set up a market and use the forms of payment to buy "cookies, pencils, drawings" and other objects for sale.	A teacher could have students create their own survey questions and ask peers about their culture, family life, and favorite ethnic food. Data can be collected and a bar graph or pie chart can be created to show similarities and differences within their own classroom community.

Code & Operational Definition	**Pre-Survey Example**	**Post-Survey Example**
Social Justice as Change Agency Responses indicated a lesson that addressed a social inequity and/or a way to enact change	Students could find out how much it costs to purchase one net (malaria nets) for children in Africa. They could be given a budget and work out how many nets they could buy and how many children's lives would be saved.	Students could compare wages of child labor to that of adult wages. Students can find the injustice in this and graph data on a bar graph. Students can then discuss plans on how to pass laws against child labor.

Social Justice Concept Plan

As part of a final assessment, pre-service educators developed a concept plan, which required the incorporation of social justice. These educators completed the concept plan individually or in small groups of two or three. The concepts plans were initially sorted into one of three main codes as shown in Table 1 above. Each concept plan was further coded based the utilization of mathematics. The mathematics usage fell into one of two categories: *Connected* versus *Critical*. A total of 29 concepts plans into one of the six possible themes as given in Table 2.

Table 2: Concept Plan Operational Definitions

	Connected Mathematics	**Critical Mathematics**
Social Justice as Real World	Concept plan integrates a real world issue yet does not enhance the student understanding of the concept through mathematics. (N = 10)	Concept plan integrates a real world issue and critically engages students in understanding the concept through mathematics. (N = 3)
Social Justice as Cultural Integration	Concept plan integrates a cultural concept yet does not enhance student understanding of the concept through mathematics. (N = 5)	Concept plan integrates a cultural concept and critically engages students in understanding the concept through mathematics. (N = 1)
Social Justice as Change Agency	Concept plan integrates a social justice inequity yet does not enhance student understanding of the concept through mathematics only sometimes leading students to enact change in their society or world. (N = 4)	Concept plan integrates a social justice inequity and critically engages students in understanding the concept through mathematics often leading students to enact change in their society or world. (N = 6)

For the purposes of this brief research report, we will further clarify the coding of the *Social Justice as Change Agency* concept plans. Pre-service educators who created a concept plan that was coded under *Social Justice as Change Agency* needed to have chosen a topic that reflected an inequity of societal, national, or global implication, as well as actively encourage critical analysis of that inequity, with the even greater intent of creating change.

Two pre-service educators created a *Social Justice and Connected Math* lesson centered on creating a global community dinner. These pre-service educators began their lesson by reading the book *If the World Were a Village* by D. Smith followed by a list of probing questions they would have their students discuss regarding the inequities expressed in the book, such as "What statistics were the most interesting? How does this book change the way you think about the world?" These questions led to the activity of creating a community dinner for a village of 100 people. Fifth grade students would use multiplication concepts to predict how much food might be needed and how much the dinner would cost. This concept plan was coded as connected math versus critical math because the math was not used to examine or analyze an inequity.

Pre-service educators created a *Social Justice and Critical Math* lesson centered on the injustice of child labor. Linking the lesson to Social Studies, these pre-service educators provided a historical context for child labor in the United States as well as current working conditions. They expanded their lesson to include child labor at a global scale citing "in Sub-Saharan Africa around one in three children are engaged in child labor, representing 69 million children. In South Asia, another 44 million are engaged in child labor." To incorporate mathematics, students would determine what fraction of the workers are children in areas such as Sub-Saharan Africa or South Asia. This lesson critically incorporated mathematics as the fractions were utilized to analyze the inequity. As an extension to social justice as a change agency, this lesson would "have students formally present their findings through graphs and charts, and explain their thoughts and opinions on child labor laws."

Conclusion

After participating in their mathematics methods class focused on social justice, all pre-service educators were able to create a social justice lesson plan. Their abilities to integrate social justice in the mathematics class ranged from using social justice to connect to the real world, promote cultural integration, or serve as an agent of change. Depending on the usage of mathematics, this integration was further defined to be connected or critical. Further research is needed to determine how this ability as a pre-service educator translates into the classroom as an in-service educator.

THE EQUAL SIGN: AN OPERATIONAL TENDENCY DOES NOT MEAN AN OPERATIONAL VIEW

Briana Mills
Portland State University
millsbl@pdx.edu

Literature concerning pre-service teachers' (PSTs') content knowledge is not as developed as one might want (Thanheiser & Roy, 2011); this includes the equal sign. This paper considers one PST, Betsy, who has a strong tendency toward an operational view—that is, as an operator where the answer immediately follows the equal sign. Betsy also holds some relational ideas where she treats expressions on opposite sides of the equal sign as equivalent. Betsy serves as an example of a PST with a strong operational view of the equal sign. Her example also demonstrates that a PST with a strong operational view may hold some relational understanding. Reworking or modification of the current framework for equal sign understanding may be useful in light of her case.

Keywords: Teacher Education–Preservice; Algebra and Algebraic Thinking; Mathematical Knowledge for Teaching; Teacher Knowledge

Rationale and Background Literature

Consider one pre-service teacher's (PST's) solution to the box problem (see Figure 1).

Betsy: So 54 and 37 is 91 so that would go in the box, and then how that I know that it is 91 is that you do a check by taking 91 and subtracting one of the numbers… and I don't know what the 55 would mean.

What is the number that goes in the box? How do you know? 37+54= $\square$ +55

Figure 1: The box problem

This PST has gotten an incorrect answer by making use of the equal sign as an operator instead of an equivalence relation. She would like to teach children, but, based on her solution, she would not be ready to help children develop an understanding of the equal sign as a relation.

Equivalence underlies many aspects of mathematics (e.g., algebra, geometry). This suggests that a strong understanding of the equal sign would aid in a deep understanding of mathematics as suggested necessary by organizations and researchers within the mathematics education field (e.g., National Council of Teachers of Mathematics, 2000; Kilpatrick, Swafford, & Findell, 2001). Past researchers have focused on four views of the equal sign: operational, substitutive, basic relational, and full relational (e.g., Jones & Pratt, 2012). Some studies (e.g., Knuth, Alibali, McNeil, Weinberg, & Stephens, 2005) lump the two relational views together and focus only on the distinction between operational and relational. A student holding an operational view uses the equal sign as an arithmetic operator or a place indicator where the answer immediately follows. A student holding a relational view knows that the expressions on each side of the equal sign are the same. Using this framework, Knuth et al. (2005) categorized students as holding an operational or relational understanding; students were credited with a relational understanding if a relational definition was given regardless of the presence of an operational definition. They found the majority of middle school students (n = 373) held an operational view. Those with a relational view tended to be more successful on problems involving the equal sign, such as the box problem (Knuth et al., 2005). Thus, the equal sign may be one way to help bridge ideas from arithmetic to algebra, aiding students in making it through the algebra "gateway" (Moses & Cobb, 2001). In order to aid in this process, teachers must have a relational view themselves.

Although there is a lot of literature concerning PSTs, a recent working group found that literature specific to PSTs' content knowledge is not as developed as one might want (Thanheiser & Roy, 2011). Stephens (2006) found the majority of PSTs in her study, all half way through their program, were able to interpret student solutions involving a relational use of the equal sign. More recently, Kinach (2011) found PSTs in a methods course self-reported a move from an operational view to a relational view, even if the operational "do something" meant to "solve for a variable" (p. 1420). The literature appears to focus on what PSTs are capable of developing, but does not identify what PSTs understand about the equal sign as they begin their first courses. This paper begins exploring this gap by examining one PST with a strong tendency toward an operational view of the equal sign.

The goal of this paper is two-fold. First, this paper will explicitly demonstrate that PSTs with a strong tendency toward an operational view exist by describing what one PST with this view does and says. Second, this PST will serve to demonstrate that a reworking of the current framework may be useful in further analyzing PSTs' knowledge.

Methods

One PST, Betsy (a pseudonym), near the end of her first content course (including place value and whole number operations) was interviewed for 70 minutes. The interview was videotaped, transcribed, and analyzed in light of the four views of the equal sign. Her responses to the first, second, and fourth interview questions (Figure 2) are the focus of this analysis.

Betsy's math background most recently includes calculus, in which she received a D. During the time of the interview, she was taking a trigonometry course in addition to the content course. Betsy identifies herself as strong in basic math and algebra, but weak in math beyond algebra.

1. Consider the following symbol:=
   What is the name of this symbol? What does it mean? Can it mean anything else? (If yes, what?)
   Give one example of how you might use this symbol. Can you give a different example of how you might use this symbol? If so, give the example and describe what makes it different. If not, state why not?
2. Box Problem: What is the number that goes in the box? How do you know?
   37+54= +55
4. Can you think of alternate solution strategies for the box task

Figure 2: The first, second, and fourth interview questions

Results and Discussion

The results will be broken into two larger sections: (1) Betsy's dominant operational view, and (2) Betsy's relational understandings.

Betsy's Dominant Operational View

When Betsy was asked what the equal sign meant, it was unclear whether she was thinking about the equal sign relationally or operationally. "Uhh, it's the symbol, I don't know, *is* is one of the meanings for it… or equivalent to." She was then asked for examples using the equal sign. In Betsy's first example, she writes *7+7=14* and says, "so [the equal sign] can be that the answering an equation or putting seven together." She implies that the equal sign produces an answer and that it is the operator to put the two numbers together, the embodiment of an operational view. Betsy also discusses the use of the equal sign in a formula (Figure 3). "Let's see, so like uhh area, let's say the area of a rectangle, for example, is the height times the width equals area." Betsy's written version of this formula is different from how formulas are typically presented ($A = l \cdot w$). In her verbalization of the formula, she both begins and ends with the area. She also labels the formula with the area and then leaves the area as the answer on the right of the equal sign suggesting a tendency toward an operational view.

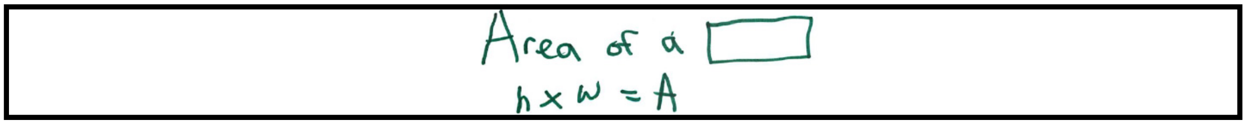

Figure 3: Betsy's work for the formula for the area of a rectangle

The operational tendency here coincides with the quotation at the start of this paper. In this initial quotation, Betsy uses the equal sign as an operator giving her the result of the left side (37+54) instead of making both sides equal. Further, Betsy's confusion with the 55 on the right hand side demonstrates that she is not considering the equal sign as a relation but as an operator. Thus, Betsy's operational view appears dominant.

Bits of Relational Understanding

Later in the interview, Betsy was prompted for alternate solutions to the box task where she demonstrates that she has access to a relational view. During this discussion, Betsy was able to express her confusion with the 55 as well as discuss a second interpretation of the question.

Betsy: Well, I'm not sure what you want me to do with the 55. Is this supposed to mean that this answer plus 55 is supposed to equal this side, umm, that's what I'm confused about… Like, if it's an equation, both side have to be equal and this side [left] equals 91 and this side [right] equals 91 plus 55 and those are not the same… a different way to interpret that… is to try to make them satisfy the other side…this side [right] you can do a bunch of things with because you have a blank spot. So if we wanted them to be equal to each other, we could take umm 91 minus 55 umm and put that in the spot, box

Betsy demonstrates the existence of both her operational—confusion with the 55—and relational—awareness that *37+54* and *91+55* does not hold the same value and is not equal—views. Additionally, she was successful at finding a number to put in the box that would make both sides equal by trying to make them "satisfy the other side" and she views the blank spot as something "you can do a bunch of things with."

The idea of satisfying the "other side" and that many things can go in the blank are in contrast to a third solution strategy that Betsy offers for the box problem.

Betsy: I wonder if maybe you could do a add something to one side type of thing, type of issue like algebra… I have no idea if it would work, but if we take the same thing and say 37 plus 54 equals and then just say *x* instead of the box, it's our unknown plus 55. If we wanted to do this algebraic way, we would want to find this out by isolating the *x*, so the first step would be to subtract 55 from both sides… and this is another rule in math, in algebra, that as long as you do it to one side, you can do it to the other if it's an [equation]

Interviewer: So why, why is that?

Betsy: Umm, well because this 55 minus 55 is umm is zero and so as long as you're not adding anything to the problem itself, the problem doesn't change… so we'll see how this works, so here's *x* and so now what we have to do is we have to come up with what this is… 36 which is what we got there

In this third strategy, Betsy offers an algebraic solution. Although she is not confident in this strategy, she notes at the end that the solution matched her second strategy. Betsy had to solve for *x* using pre-defined rules which she recalled but could not justify, and her notion of "many options" for what could go in the box becomes a single option for what *x* could be.

Betsy is a PST in her first content course with a strong tendency toward an operational view of the equal sign. Her discussion, examples, and solution strategies, give insight to how a PST with this view may think about and understand the equal sign. Nevertheless, Betsy does have some relational understanding available, and it is possible that activities building on those ideas will help her transition to a relational understanding of the equal sign.

Conclusions, Limitations, and Future Research

Betsy serves as an example of the knowledge a PST with a strong tendency toward an operational view of the equal sign may be able to communicate. Further, Betsy demonstrates that even PSTs who tend toward an operational view may hold some relational understanding of the equal sign and, when put in the right situation, be able to draw on, expand on, and use that view. This demonstrates that PSTs may not fit cleanly within the confines of the currently defined framework of equal sign understanding. A more refined framework, such as one including a clear transitional stage where students *tend* to draw on an operational view but are *able* to draw on a relational view, may better serve teacher educators in understanding the knowledge of PSTs.

There are at least two limitations to this study. First, Betsy is just one PST. Second, Betsy may not be a typical PST. In the future, more PSTs' knowledge should be studied to determine the proportion of PSTs with a tendency toward an operational view as well as create situations where their operational view is not sufficient. Four suggestions for future research follow.

1. Modify the current framework of equal sign understanding to aid in understanding what PSTs understand about the equal sign.
2. Analyze the proportion of PSTs with a strong tendency toward an operational view. Is it large enough that teacher educators should address the equal sign explicitly in classes?
3. Investigate whether it is common for PSTs demonstrating a strong tendency toward an operational view of the equal sign also have a relational understanding, which they can draw upon given the right situation.
4. Identify problem types/experiences aiding in development of a relational understanding.

PRE-SERVICE TEACHERS' PERSPECTIVES OF 0.999… = 1

Marnie Phipps
North Georgia College & State University
marnie.phipps@northgeorgia.edu

This research highlights pre-service teachers' perspectives of repeating digits and specifically investigates the equality $0.\overline{9} = 1$. *Previous literature and reports indicate that some prospective teachers have misconceptions about this relationship. The researcher argues that understanding equivalence and magnitude of repeating digits is a key component for all teachers who are tasked with teaching these concepts to students in elementary and middle grades. Presented in this paper are pre-service teachers who demonstrate a fragile and undeveloped notion of single- digit repetends. The data presents evidence from prospective elementary and middle school teachers' journals that reveals their belief is* $0.\overline{9} \neq 1$. *Questions are raised and concerns are voiced about the implication of these findings.*

Keywords: Mathematical Knowledge for Teaching; Teacher Education–Preservice

Introduction

The concept of 0.999… = 1 has merited the attention of mathematicians and mathematics educators in the form of proof and students' understanding; however, the contexts of these studies have been confined to mathematics students (in calculus) or fields of study heavily laden with mathematics that use concepts such as limits. Only recently has concept of students' understanding of single-digit repetends been investigated using both prospective and in-service teachers. The Burroughs and Yopp (2010) study of five prospective teachers finds "deep-rooted" misconceptions about repeating digits that they claim originated from elementary school concepts such as whole number, fractions, and decimals. The Yopp, Burroughs, and Lindaman (2011) study of in-service teachers demonstrates the participants' misconception of 0.999…. Furthermore, they argue single repeating digits in equivalence statements, such as 0.333… = 1/3 and 0.666… = 2/3, are common in the middle school curriculum specifically in fifth grade and they should not be dismissed as trivial. They are careful to assume that their study does not generalize to others.

Justification

In light of the Common Core State Standards Initiative (2010), teachers are expected to help elementary students develop a full understanding of non-terminating decimals. Specifically, the standards require a student to develop computational fluency and number sense of decimals and fractions. For example in fifth grade, students are to understand 1/3 can be conceptualized as 1 divided by 3. In eighth grade, students are to comprehend the relationship between rational numbers and repeating decimals. Ni and Zhou (2005) point out that a typical middle school student does not view the distinction of rational numbers as important. They argue that the students' perceptions are skewed by concrete discrete numbers. The researcher suspects prospective elementary school teachers exhibit behavior similar to middle school students who do not acknowledge the significance of the 0.999… = 1.

Purpose and Research Questions

The purpose of this study was to investigate the understanding and the relevance of single-digit repetends in pre-service teachers. What knowledge do pre-service teachers possess about 0.999… and its relationship to one? How do they value that knowledge?

Methodology

Participants

This research was conducted at a small institution in the United States. The participants were undergraduate students seeking Bachelor of Science degrees in elementary education. After the successful completion of six hours of collegiate mathematics courses, these students enroll in a Numbers and Operations course. The Numbers and Operations course is designed to focus on mathematical content knowledge and pedagogical content knowledge specific to elementary mathematics. The course includes a deep understanding of fractions, decimals, and relationships that exist between them. Data were collected from 36 volunteers in multiple sections of the described course. Most were juniors in their programs of study and only five were males.

Data

The students are required to learn how to represent repeating decimals as fractions and vice versa. The instructor had embedded journal prompts throughout the course as a means to promote deep and reflective thinking about mathematics. As reported from the instructor, the topic of the journal prompts was usually mathematical in nature and required the students to reflect on the activities in class. At the time of data collection, interviews with the instructor suggest that the participants had been exposed to the statement, 0.999…= 1, without specific attention to its meaning or origin. Furthermore, the instructor reports that the statement was made when guiding the class through an activity that demonstrates how to turn a repeating decimal into a fraction and vice versa. The data for this study were collected from the routine journal prompt that the instructor assigned. The journal prompt is given below.

Are you convinced that 0.999…= 1? Write a few sentences that explain your thoughts.
Show two different ways to explain 0.999…= 1 to a future middle school student.

Results and Analysis

The researcher used thematic coding as the basis for the data analysis of the students' writing (Merriam, 2001). Thematic coding involved first coding categorically, based on evolving data, and then was defined in terms of broader properties that depict a continuum of dimensions. This type of technique allowed for open data exploration. A few of the common categories in coding included: equal due to rounding, decontextualized, and external authority. Thirty-two students (out of 36) reported in their journals that the two representations were not equal. Below typical responses and reasoning are given to signify the cognitive difficultly experienced by the participants.

Equal Due to Rounding

The three words most frequently included in students' responses were *rounding*, *estimation*, and *approximation.* Journal segments with these identifying descriptors demonstrated the students' internal conflicts stating that obviously these two quantities are equal by rounding. The researcher posits that students are unaware that rounding numerical values is a different subject matter than equivalent magnitudes. Furthermore, many students went on to say the person making the calculations could use as many decimal places as they deemed necessary and then estimate appropriately. For example, one student wrote, "Even though the number is 0.99999…., the only way I would call it 1 would be if I were asked to round the number. But logically, I would still call it 0.999999." Another student scripted, "It's true because basically you would round up to the next number. The only thing I don't understand is when do we [*sic*] know to round up."

Decontextualized

Other students referenced the context or lack of context for the given prompt. The students wrote about their desire for a concrete tangible model to use in making connections to an abstract idea. For these students magnitude of numbers has greater meaning in context when measuring specific concrete items no matter how large or how small the quantity. One student actually calls the two numbers *practically equivalent* citing the insignificantly small difference between them. The researcher argues that for this student she is not making claims about the mathematical magnitude or numeric value but rather the use of numbers in the context of everyday-life examples. Another student wrote, "This concept is very hard for me to wrap my brain around because it is not very visibly concrete. I feel as though at some point there is still a fraction of a point that is missing and contributing to inequivalency [*sic*]." Yet, another compared the subject matter to science writing, "I believe no, I feel like math is a set of numbers where as if you were doing science then it could be a little different. In science you estimate."

External Authority

Students defer the topic to an external authority, usually the course instructor, to inform them of the content they are required to know rather than engaging in the complexity of mathematics and self-discovery. They show resistance to engage in reflective thought about the nontrivial concept. According to the instructor, these participants have worked with decimals and fractions separately before they examined relationships between the two representations. To exacerbate this point students are not seeking understanding for themselves but rather an explanation that they can reiterate to their future students. One student's journal revealed, "I do not think it (0.999…) equals 1. How would you explain this to students? I am unclear on this reasoning." In this example, the student admits that she believes the statement is not true. Additionally, she does not seek clarification but rather for a recallable argument that she could use to convince her own students at some future time.

Mathematical Understanding

Only four students demonstrated sound mathematical reasoning or provided evidence that the statement $0.\overline{9} = 1$ was a fact that they personally believed to be true. These students had convinced themselves without creating any formal mathematical proof. All of the students who made such a statement reported taking action to investigate this claim outside of class. One student's journal revealed his interesting thought process.

> I did not believe you [the instructor]. I did a quick on-line search and revealed several proofs…. After some thought, I realized that if .999….. And 1 were not equal, I should be able to do things with them that I am not able to do, like find the difference, or their average, or name a number between them. It's funny how I was convinced more by the things that I could not do rather than the mathematical proofs. (journal entry student #5)

Although this student's statement addresses their personal conviction, it does not address how to discuss and teach such topics to fifth graders.

Conclusions and Implications

The purpose of the study was to demonstrate the variations of prospective teachers' understanding of 0.999… = 1. Participants revealed a gross lack of understanding and focused on the concrete, finite, tangible numbers rather than on the magnitude that the numbers represent. These results have broader implications. First, the researcher encourages others to consider the consequences, for middle school students if these results were true for most pre-service teachers. Will these pre-service teachers pass this deficiency to their students? Further research is warranted to determine the general state of teachers' understanding and how this knowledge is disseminated in the classroom. Secondly, these results demonstrate the participants' misconceptions of the equal sign. They are missing the precision that accompanies the representation. How do the misinterpretations of the symbol impact the foundational knowledge base in algebra?

We present the cases of 2 pairs of teachers who entered their teacher education programs with similar beliefs but whose teaching practices were substantially different by the end of their second year of teaching. We describe their beliefs and the evolution of their teaching practices across 2 years of a teacher education program and 2 years of teaching in their own classrooms. We then identify factors that contributed to the differences in these teachers' practices.

Keywords: Teacher Beliefs, Teacher Education–Preservice

The goal of this paper is to describe two pairs of elementary school teachers who started the teacher education program with similar belief profiles but whose teaching practices diverged significantly over time. We use Ernest's classification of beliefs to describe the teachers' beliefs and practices as they navigated the transition from preservice to inservice teacher, and we posit the factors that led to or inhibited change over time.

Theoretical Framework

The study of beliefs and practices in mathematics teaching has been a topic of scholarly interest for over 3 decades now with studies designed to articulate teachers' beliefs, identify and explain links or gaps between beliefs and practice, and posit means of changing beliefs. Ernest (1989) provided a scheme for making sense of relationships between teachers' beliefs and instructional practice, arguing that teachers' views of the nature of mathematics influence their models of learning and teaching mathematics. These models are then mitigated by the contexts in which the teachers work and lead to enacted models of learning and teaching. Ernest classified teachers' beliefs about mathematics as instrumentalist, Platonist, or problem solving. He described teachers' views of the teacher's role as instructor, explainer, or facilitator. Related to a teacher's view of teaching is a view of learning as active or passive. Ernest suggested that there are logical links among a teacher's beliefs about mathematics, views of learning, and enacted classroom practices. For instance, he posited that a teacher with a Platonist view of mathematics would likely act as an explainer, viewing learning as the passive reception of knowledge. Ernest noted that teachers are socialized by the context in which they work by the expectations of students, parents, fellow teachers, administrators, and the larger community. Further, a teacher's actions in the classroom are affected by the level of consciousness about the beliefs held and the degree of reflection on what happens in the classroom. When teachers are aware of their views, can justify them, identify viable alternatives, make deliberate choices, and actively reconcile conflicting beliefs and practices, they are more likely to adopt a problem solving orientation to mathematics, a facilitator role in teaching, and an active view of learning

Methods

The data corpus for this study included data collected on 15 participants across a 4-year period from their first year in a teacher education program through the end of their second year of teaching. For purposes of this paper we analyzed a subset of the data from 4 participants.

Participants

We identified 2 pairs of participants who entered the teacher education program with similar belief profiles but whose teaching practices differed markedly. They had taken one mathematics content course for elementary education majors prior to the study. During the study, they completed 2 mathematics methods courses for elementary education majors, the first of which included a mathematics-specific field experience. During the second and third semesters they participated in 4-week field experiences in local schools; the fourth semester was a traditional student teaching experience.

Data Collection and Analysis

Data on participants' initial beliefs were collected using the Integrating Mathematics and Pedagogy (IMAP) web-based beliefs survey (Ambrose, Philipp, Chauvot, & Clement, 2003). In addition, participants were interviewed once per semester for 4 years. Each participant was observed once during an early field experience, twice during student teaching and 4 times during each of the first two years of teaching. Data from the IMAP instrument were analyzed using the protocol provided by the developers. We then classified the teachers' beliefs about mathematics, the teachers' role, and learning based on IMAP data and interview data according to Ernest's scheme (1989). We further analyzed classroom observation data to characterize the teachers' practice according to Ernest's frame as well.

Findings

Comparing Laura and Jennifer

Laura and Jennifer began the teacher education program with beliefs about mathematics consistent with Ernest's description of an instrumentalist. Both equated finding a correct answer with fully "understanding" the mathematics, although both believed that children had the ability to construct novel approaches to problems that differ from adults' thinking. They believed that students should be actively engaged in learning and should have opportunities to create and express their own ideas. Their beliefs about active learning diverged, however, in their end goals. Laura wanted to understand students' thinking and strategies, while Jennifer wanted to make mathematics fun by letting students be "creative." Laura and Jennifer interpreted their teacher education experiences in different ways. For instance, during their first methods course, they had a chance to work one-on-one with an elementary school pupil weekly for 2 months on problem solving tasks. Because of her interest in making sense of students' thinking, Laura learned how to scaffold her pupil's learning process without giving away the answers to problems. Jennifer, on the other hand, was heavily influenced by her desire to make mathematics fun for her pupil, so she tried to provide her pupil with easier problems so that he would enjoy their time together.

For student teaching Laura was placed with a mentor teacher with an instructor orientation toward teaching and adhered to her mentor's expectations, although she occasionally used tasks that put her more in the role of a facilitator. Once she had her own classroom, however, she functioned more as a facilitator and used tasks that enabled her students to be active learners. As she created her own teaching style, she was able to reconcile her previous beliefs about teaching for the right answer with her new beliefs about how students learned and to mediate the context in which she was teaching. By her second year of teaching, Laura actively disregarded some school policies and used her textbook as more of a guide as she took on a facilitator role. Her orientation toward mathematics tended more toward problem solving, and her students were actively engaged intellectually in constructing mathematical ideas. Jennifer's beliefs led her to adopt an instructor orientation to teaching during student teaching and her first year of teaching. She frequently engaged students in using manipulatives and hands on activities, but this portion of the lesson generally had a playful, rather than mathematical, orientation. Jennifer was still developing her time management and classroom management skills, and this seemed to lead her to a more directive instructional style. She rarely asked students to talk about what they were doing; when she did, she asked for short answers to procedural questions. In her second year of teaching, Jennifer gained more control of her classroom, and she took on more of an explainer role, occasionally asking students to explain their thinking but still looking for a "correct" answer.

Although these two teachers began with similar beliefs, they became dramatically different teachers. Laura changed her belief about mathematics learning as a result of her experiences and used what she learned to become a confident facilitator of pupils' mathematical learning. Jennifer was strongly influenced by her view of mathematics as difficult and boring and her desire for students to have fun while learning. She filtered what she learned through these beliefs and selected pieces of what she learned to give her tools to implement these beliefs.

Comparing Jayne and Alex

Both Jayne and Alex initially exhibited a Platonist of view of mathematics, and they subscribed to an explainer view of the teacher's role, even though both of them valued listening to children. When working one-on-one with children during their first mathematics methods course, they both drew on their belief that it is important for teachers to listen to children to learn how to use children's mathematical thinking to alter their instruction. Thus, they both began to enact more of a facilitator orientation toward the teacher's role.

As they began their teaching careers Jayne and Alex shared a commitment to respecting and listening to children. Jayne maintained her facilitator role, engaged her students as active learners, modified curriculum materials to suit her students' needs, and focused on students' understanding, reflecting a Platonist view of mathematics. Jayne asked a lot of higher order questions and appeared to be moving toward a problem solving view of mathematics by the end of her second year of teaching. In contrast, Alex tended toward more of an explainer role, demonstrating procedures for students to emulate and often using manipulatives to illustrate the procedures. Alex's teaching practice was heavily influenced by the context of his school district, which required teachers to adhere tightly to a district level curriculum guide. This conflicted with Alex's views, and he was very articulate about this conflict between what he wanted to do as a teacher, what he was required to do by his district, and his decision to honor the wishes of his school administrators. He was likely moved in the direction of adopting an explainer teaching mode because he believed he needed to model mathematics first for his students.

Comparing Jayne and Laura

Although Jayne and Laura began their teacher education program with different beliefs, their teaching practices were similar by the end of their second year of teaching. Both exhibited internal authority and the capacity to make decisions that were in the best interests of their students despite administrative pressure to do otherwise. Jayne's beliefs about the importance of students as active learners and her role as a facilitator enabled her to resist administrative pressure, close her door, and teach the way she wanted to teach. After trying to follow an explainer model of teaching with passive learning and close adherence to the textbook, Laura concluded that her students were not learning mathematics. Thus, she crafted her own style of teaching, blending some of what was expected of her with some of what she learned in her teacher education program. Jayne and Laura both cared deeply about their students' mathematical learning, which seemed to empower them to internalize authority and craft lessons that actively engaged students in making sense of mathematics.

Discussion

Beliefs and Context Act as Filters

Both Alex and Jennifer used their beliefs as a filter when interpreting their methods courses. Jennifer believed that mathematics was boring and therefore looked for ideas that would help her make mathematics fun. In contrast, Jayne filtered her experiences through her belief in the importance of encouraging and building on students' thinking and adopted practices from her methods course that supported this belief. For Alex, context was a filter that affected his teaching practice. He believed that it was important to satisfy the demands of his administrators by teaching to the test, which led to demands on his instructional time that precluded a more facilitative style of teaching.

Teacher Education Makes a Difference

Some literature has reported that teacher education programs have minimal impact on preservice teachers' future teaching styles. Laura, in particular, provides a contrast to these findings as her beliefs and subsequent practice were clearly affected by her experiences in the program. All of the preservice teachers came to realize that mathematics can and does make sense and that the use of particular teaching practices and materials can help pupils make sense of mathematics. During the field experience, pre-service teachers were surprised by students' creative mathematical thinking and recognized that each student's thinking was different. From this they learned the importance of focusing on students' mathematical thinking and listening to children. Moreover, they began to see their role as facilitating student's mathematical thinking.

Reflection

As noted by Ernest (1989), reflection plays a key role in the ways that teachers enact their beliefs in the classroom. Jennifer was not inclined to reflect on her beliefs, and in fact was not able to articulate her beliefs clearly, suggesting that she may not have been aware of them. Therefore, she did not make deliberate choices about teaching actions. In contrast, Alex was able to articulate his beliefs as well as his concerns about the context in which he was teaching and was able to explicitly reconcile the conflicts between his beliefs and practices. Laura, on the other hand, became aware of her beliefs and the influence on her practices during her teacher education program. As she articulated her beliefs, she realized that they resulted in teaching practices that she did not condone, and she made a deliberate effort to change her teaching practices. Jayne was also very reflective, and although her beliefs did not change much, she was able to articulate her beliefs clearly from the start of her program, and she made deliberate decisions about instruction in light of her beliefs.

Conclusion

The data from this study provides further evidence of the importance of teachers' beliefs in shaping their teaching practices, although those practices can be mitigated by school contexts. A key finding of this study is that the preservice teachers' ability to articulate their beliefs was central to their deliberate and informed decision-making regarding teaching practices. This finding suggests that teacher education programs need to continue to work to help preservice teachers become aware of their beliefs, as they are an important filter of new experiences.

The Common Core State Standards for Mathematics (CCSS-M) place heavy emphasis on eight Mathematical practices consistent with development of social and sociomathematical norms. Present teacher preparation prepares candidates to work on these norms with students, but their field experiences too often acculturate them to traditional teaching practices. This research begins to develop a way to induct teacher candidates into the planning and reflecting practices of a master teacher who is using reinvention teaching to encourage children to re-invent mathematical ideas. The master teacher includes the candidates in her thinking about the sequence of activities children will take part in, candidates observe the lessons while focusing on student learning, and then together they reflect on what happened as students engaged in the activities and on the implications for the next day's lesson.

Keywords: Teacher Education–Preservice; Learning Trajectories; Instructional Activities and Practices

Purpose

The purpose of this research is to develop a model for mentoring undergraduate elementary teacher candidates into what we are calling the *reinvention approach to mathematics teaching*. The reinvention approach to teaching is a blend of standards-based instruction and Realistic Mathematics Education (RME) instructional design theory. In an RME approach, instructional materials are designed so that students re-invent important mathematical concepts. In the reinvention approach to mathematics teaching, the teacher's challenge is to create a standards-based environment that encourages students to actually do this *re-invention*. A reinvention approach to teaching requires highly specialized knowledge about mathematics teaching and learning and can be associated with a number of sophisticated planning and classroom practices. Our purpose in this research is to learn how to provide opportunities for new teachers to appropriate these practices as they engage in a variety of teaching and mentoring activities.

Theoretical Perspectives

In developing a model for understanding mathematics classrooms that take a reinvention approach, we ground our work in the *emergent perspective* (Cobb & Yackel, 1996). The emergent perspective is a theoretical position stating that learning is both a social and individual accomplishment simultaneously, with neither taking primacy over the other. An individual's cognitive reorganizations are made as she participates in and contributes to the emerging mathematical practices of the community of which she is a member. The framework that emerges as a result of this perspective coordinates both social and psychological perspectives of learning.

Table 1: Emergent Perspective

Social Perspective	Psychological Perspective
Classroom social norms	Beliefs about own role, others' roles, and the general nature of mathematical activity in school
Sociomathematical norms	Mathematical beliefs and values
Classroom mathematical practices	Mathematical conceptions and activities

The framework above has been used to orient both our analysis of classroom interactions as well as our discussions with teachers who are attempting to incorporate a reinvention approach in their teaching practice. One of the main components of our teaching approach is that the teacher and students interactively establish the *social norms* that are productive for engaging in the mathematical discourse necessary for the reinvention of ideas. During discussions, the teacher is charged with facilitating turn-taking, encouraging students to explain their thinking, prompting students to ask questions when they do not understand, and asking for agreement or disagreement. In addition, the teacher and students negotiate productive *sociomathematical norms* when they talk about the *nature* of the mathematical arguments they are giving. Are the solutions different? Which ones are more sophisticated and efficient? Have students given an adequate explanation and what is our class criterion for acceptable? (Yackel & Cobb, 1996)

It is our contention that most approaches to "standards-based" or "inquiry math" can often be equated with establishing the social norms and the sociomathematical norms described above. While these are inarguably foundational to establishing classroom environments based on mathematical justification and argumentation, in order to guide students in reinvention of mathematical ideas, careful consideration must be given to the mathematical activity of the learner and the instructional tasks that support the students' learning. To this end, we have found that instructional materials developed using the ***Realistic Mathematic Education*** (RME) instructional design theory can be used to create mathematics instruction that guides students, together with their teacher, to re-invent important mathematical concepts. In an RME design experiment, the researcher begins by first reading research on students' cognitive development of the mathematics and uses these findings to design a hypothetical learning trajectory. This trajectory is comprised of the mathematical learning goals of the sequence along with the means of supporting it, including whatever *classroom mathematical practices* might emerge and whatever discourse, notation, gestures, tools and tasks can support these practices. These are tested in classrooms and revised as needed. Well-designed RME sequences are those that have gone through several iterations of such development.

Akyuz (2010) analyzed the *planning* (Table 2) and *teaching* practices (Table 3) of an expert reinvention teacher over the course of approximately six weeks. She documented the teacher's pedagogical practices in two broad categories, each consisting of five practices and associated teacher actions. The first category comprises the teacher's planning practices below.

Table 2: Planning Practices of Reinvention Teachers Using RME Sequences

1. Preparation. The teacher familiarizes herself with the mathematical content to be learned, students' preconceptions, and the conceptual mathematical ideas to be learned. The teacher also works through the instructional activities to unpack the intent of the tasks and to create a hypothetical image of the variety of pathways that can emerge as a result of the diversity of her students' reasoning.
2. Reflection (looking back). This includes a daily reflection on a) student strategies, b) the big ideas for the following day, c) the status of the social and sociomathematical norms, and d) student thinking. These allow the teacher to determine the status of the classroom mathematical practices.
3. Anticipation (looking forward). The teacher attempts to anticipate the best ways to introduce tasks the next day, works out problems to anticipate possible student thinking, and uses anticipated student thinking to imagine discussion topics.
4. Assessment. The teacher creates and implements formative assessments to ascertain the daily evolution of the classroom mathematical practices (i.e., learning) as well as summative assessments to document the finalized learning of the students.
5. Revising. The teacher revises instruction based upon the formative and/or summative assessments.

Not only does the expert reinvention teacher engage in planning practices outside the classroom, she also adopts practices *during* classroom instruction. This second category of pedagogical practices comprises the teacher's ***teaching*** practices:

Table 3: Teaching Practices of Reinvention Teachers Using RME Sequences

1. Creating and Sustaining Social Norms. This involves creating and sustaining environments that are conducive to children's reinvention in whole class and small group settings.
2. Facilitating Genuine Mathematical Discourse. This is characterized by introducing mathematical vocabulary when students have invented an idea, asking questions that promote higher thinking, restating students' solutions in clearer or more advanced ways, and using solutions to engineer a summary discussion during which mathematical practices are established.
3. Supporting the Development of Sociomathematical norms. These involve establishing the criteria for what counts as an acceptable mathematical argument, and as an efficient or elegant solution.
4. Capitalizing on Students' Imagery to Create Inscriptions and Notations. This is directly related to the rich imagery and tool development that are part of the RME instructional design.

As can be seen from above, the reinvention teacher has highly specialized knowledge and skills. The question is, what mentoring experiences best help novice teachers to appropriate the practices of reinvention teachers? Unfortunately, the most prevalent model for teaching practicums involves placing novice teachers in classrooms with experienced school mathematics teachers for 30–45 classroom hours. Under the best circumstances, novice teachers become acculturated into the practices of good *traditional* teachers. With this model, there is little hope that school mathematics teaching traditions will change. Even among the small number of pre-service teachers who have host teachers that are proficient at standards-based teaching, their host teachers typically have little, if any, training as a mentor. The primary goal of this project is to develop a model for apprenticing future teachers into a re-invention teaching tradition.

Modes of Inquiry

In order for future teachers to become experts in the reinvention approach to teaching, we argue novice teachers must be engaged in activities that focus them on the planning and classroom practices that are unique to this teaching method. During Summer 2012, we will begin the first step in our program designed to develop elementary school math reinvention teachers. Eight to twelve pre-service teachers (PSTs) who have already successfully completed at least two math courses for elementary school teachers will be enrolled in a new course designed to deepen their mathematical content knowledge and begin their acculturation into the practices of the reinvention teacher. The course will consist of an intensive two week field experience led by a master reinvention teacher, who is also a member of the research team and was the teacher Akyuz (2010) studied. The master teacher will teach a unit on ratio and proportion to a group of students entering 7th grade during the 2012–13 school year. PSTs will meet with the expert teacher both before and after the class and will be present during teaching in order to participate in Planning Practices and observe the Teaching Practices of the teacher. PSTs will have opportunities to interact intensively with the expert teacher as well as reflect on the actions and decision-making processes that accompany this approach. The research team will use the *cognitive apprenticeship* model (Collins, Brown, & Newman, 1989) as the framework for designing mentoring activities for the PSTs. The interactions and reasoning of the novice teachers will be documented.

Discussion

Standard-based teaching has been gaining momentum in this country with most didactic discussion involving the establishment of social environments conducive to problem solving. The Common Core State Standards place heavy emphasis on eight Mathematical practices that should be encouraged in students. These practices are consistent with social and sociomathematical norms for standards-based classrooms. Less emphasis, however, has focused on the nature of the problem solving that is to take place among students. This is where the reinvention approach provides more detailed practices for teachers. The goal of the instructional materials used in our summer program is for students to re-invent mathematics in a logical and meaningful way with guidance from a well-researched instruction theory (Gravemeijer &

Stephan, 2002, Yackel and Cobb, 1996). Teaching practices associated with the reinvention approach are sophisticated and, we posit, require specialized mentoring experiences for teachers. We expect our data to show that placing a cohort of pre-service teachers in a classroom situation in which they will co-plan mathematics lessons with an expert reinvention teacher enhances their ability to listen to students with more than an evaluative ear. We expect, through various mentoring experiences and observations of the expert teacher in action, that pre-service teachers will learn to use student thinking as the basis for their decisions and that co-planning will provide opportunities for the teacher candidates to construct deeper content knowledge. Our brief report will outline the mentoring experiences used, illustrate our findings and discuss implications for future teacher preparation.

TRANSITIONS IN PROSPECTIVE MATHEMATICS TEACHER NOTICING

Shari L. Stockero
Michigan Technological University
stockero@mtu.edu

Erin M. Thomas

ethomas@mtu.edu

Teacher noticing is key to student-centered instruction, but it cannot be assumed that teachers automatically know how to notice productively. This study engaged prospective mathematics teachers in targeted activities, including research-like analysis of unedited classroom video and group discussions of their analysis, for the purpose of helping them notice mathematically important moments during a lesson. The data revealed several transitions in the participants' noticing, including shifts in who and what they noticed, as well as in the specificity of their noticing. These shifts, as well as initial conjectures about what facilitated them and directions for future research, are discussed.

Keywords: Teacher Education–Preservice; High School Education; Middle School Education

Student-centered instruction requires teachers to carefully attend to, assess the potential of, and respond to student ideas during instruction. To support such instruction, one important transition that prospective teachers (PTs) need to make is in how they view classroom instruction—transitioning from a student to a teacher perspective. School-based field experiences might be a venue for supporting this transition, but it has been found that many PTs cannot meaningfully make sense of classroom interactions (Masingila & Doerr, 2002) and that the goals of such experiences are often ill-defined, with little connection to mathematical content or student understanding (Leatham & Peterson, 2010). Thus, meaningful learning from such experiences requires substantial teacher educator involvement (Oliveira & Hannula, 2008).

Teacher noticing has emerged as central to student-centered mathematics instruction (e.g., Sherin, Jacobs, & Philipp, 2011). Novice teachers, however, often fail to notice or act upon instances that experienced educators intuitively recognize and respond to (Peterson & Leatham, 2010). Fortunately, noticing is a skill that can be learned, with video cases found to be one effective method of supporting such learning (e.g., Sherin & van Es, 2005; Stockero, 2008). Many interventions use video clips that have been purposefully selected by experienced teacher educators, eliminating the opportunity for teachers to determine which instances are worthy of analysis. This is problematic since teachers need to learn to recognize instances that can be capitalized on to support mathematical learning.

This paper reports on findings from the first iteration of a design experiment in which prospective mathematics teachers engaged in research-like analysis of unedited videos of mathematics instruction during an early field experience. The purpose was to support their ability to notice, analyze and consider how to capitalize upon important mathematical moments that occur during instruction. We discuss transitions in the PTs' noticing that resulted from this work.

Theoretical Perspectives

Teacher noticing is defined in a variety of ways in the literature (e.g., Sherin et al., 2011). We follow Sherin and van Es (2005) in defining noticing to include three components—noticing, analyzing and deciding. We limit our study of noticing to *mathematical noticing.* This stems from a perspective that not all instructional events are equally important to notice in order to support mathematical learning. For instance, not all student thinking is equally valuable in supporting the goals of a lesson and, thus, should not be pursued in similar ways. We aim to focus teacher noticing on high-leverage instances of student mathematical thinking that provide rich opportunities for developing important mathematical ideas—those instances that have been conceptualized as Mathematically Important Pedagogical Opportunities (MIPOs) (e.g., Leatham, Peterson, Stockero, & Van Zoest, 2011).

Methodology

The participants were four secondary mathematics PTs; each was paired with an experienced mathematics teacher at a local school during a 14-week field experience. Each week, one PT video recorded a mathematics lesson. The instructional portions of each video were left unedited for the PTs' analysis. The PTs used the Studiocode video analysis software (SportsTec, 2011) to individually code the classroom video, tagging "mathematically important moments (MIM) that a teacher needs to notice during a lesson" and writing a brief explanation of their reasoning. The PI and a graduate research assistant (GRA) independently coded the same video and then met to discuss their own and the PTs' coding and decide which instances to discuss in a weekly meeting with the PTs. The PTs coded eight videos and met with the PI ten times.

Data for this analysis included the PTs' coded video timelines and video recordings of the weekly meetings. Building from coding frameworks used in previous research (Stockero, 2008; van Es, 2011), each MIM that a PT identified was coded by the PI and GRA for agent (who was noticed), topic (what was noticed) and specificity (whether noticing was mathematical or non-mathematical/general or specific). The meeting videos were used to help with the coding if a written comment was unclear. During this process, the researchers met regularly to discuss, refine and verify the coding. The codes were analyzed to characterize shifts in the PTs' noticing.

Results and Discussion

The data revealed that the PTs' noticing transitioned within all three coding categories. These shifts in noticing, as well as initial conjectures about what facilitated them, are discussed below.

Agent

The agent coding analysis revealed two shifts in noticing: (a) from student groups to individual students, and (b) from teacher moves to teacher-student interactions. In Video 1, when the PTs focused on students, it was largely on groups of students (76%), rather than individuals. For example,*"Students struggle to give a definition for [quadrilateral]"* (PT3) was coded as group-focused, while *"[The student] was able to see the connection, which led to finding an equation"* (PT4) was coded as an individual focus. The shift began in Video 2 and 3, with only about 50% of comments focused on groups of students. By the last three videos, the percent of student-centered comments focused on groups of students ranged from 25–31%. The cause of this shift is difficult to determine with certainty, but we conjecture that it may be the result of targeted facilitator moves that included replaying the video during meetings to focus on specific student comments and detailed discussions about student ideas. This shift is significant in that it supports the careful listening necessary to teach in a way that is responsive to student thinking.

The second shift—from teacher to teacher-student interactions—provided evidence that the PTs were starting to think about how teacher actions support student learning, rather than on teacher moves independent of students. When focused on the teacher in the early videos, the PTs considered how the teacher action was likely to support learning less than half the time. Starting with Video 5, a shift occurred, with over 70% of teacher-focused comments considering teacher-student interactions. The timing of this shift suggests that it was at least partly facilitated by an assignment in which the PTs read a portion of a paper about MIPOs (Leatham et al., 2011) that defined such moments as the intersection of important mathematics, student thinking, and pedagogical opportunity. In particular, the pedagogical opportunity component seemed to prompt the PTs to think about how a teacher might be responsive to student ideas.

Topic

Several noteworthy shifts in topic were noted. First, the PTs transitioned from noticing when students gave correct answers, to noticing incomplete answers (e.g., *"His definition was close but missing an important part—only 1 pair of parallel sides,"* PT4), incorrect answers, and student questions and confusion. They also learned to listen more carefully, as they noticed the teacher making incorrect assumptions about what a student had said (e.g., *"I think there might be some miscommunication here. I* *heard the student say 3, but the teacher heard 30,"* PT1) and described specific student thinking (e.g., *"[The student] gives an answer that [the teacher] finds interesting and never heard before. Instead of the simple splitting [of] either a or b, he used both addition and subtraction,*" PT2). Together, these shifts indicate that the PTs became more attentive to a range of student comments and to the details of them, along with what they might indicate about student understanding—important foci for student-centered instruction.

Directly related to the agent shift discussed above, a third shift was a decrease in claims about the understanding of groups of students, as the PTs became more focused on individuals. A fourth shift was from focusing on the mathematics itself (e.g., *"Order of vertices is important,"* PT4), to focusing on students' understanding of it. Finally, affective noticing, such as student participation, decreased as the PTs became more attentive to issues directly related to students' mathematical learning.

These findings are tentative because we conjecture that the topic of noticing may be more context-specific—dependent on what takes place during a lesson—than agent or specificity. It is also unclear what triggered the shifts in topic. They may be related to facilitator moves during the group discussion, or to other activities, such as asking the PTs to label each coded instance. Additional data are needed to better understand and verify these shifts and their causes.

Specificity

The PTs became both more focused on mathematical instances and more specific in their noticing. Despite the fact that the PTs were given instructions to code mathematically important moments (MIMs), some of their early noticing was focused on non-mathematical instances. For example, one PT noticed that the teacher incorporated exercise into her lesson. The shift to mathematical noticing was fairly easy to facilitate by pushing the PTs to discuss the mathematics in each coded instance; thus, no non-mathematical noticing was documented after Video 2.

A second shift, from general to specific mathematical noticing, is important because it indicates that the PTs were engaged in more detailed analysis, rather than making general observations about a lesson. For example, *"The student gave the wrong answer to the teacher's question"* (PT3) is general in nature, while*"The student asks a question about the placement of negative signs and the order [of the points] in finding slopes"* (PT1) is specific. In the first three videos, about 30% of noticing was specific. Collectively, the PTs' noticing became more specific than general in Video 4, but individuals shifted at different times. Two of the PTs transitioned to primarily specific noticing (over 66% of coding) beginning with Video 4, while the others did so in Video 6. In the last two videos, over 90% of all instances were specific in nature.

An analysis of the facilitator moves gives some indication of what triggered this shift. Throughout the weekly discussions, the facilitator intentionally focused on specific student comments and asked what it was that the teacher had to notice, often replaying a video segment so that the PTs could listen to what was being said. This is the likely cause of the earlier PT shifts. The later shifts, however, were likely also influenced by reading the MIPO paper, which highlighted student thinking about important mathematics as criteria for such an instance.

Conclusions

The results indicate that it is possible to facilitate transitions in mathematics teacher noticing, even early in a teacher education program. The data revealed that the PTs in this study became more focused on individual students and how teacher-student interactions affect learning, and better able to attend to specific details of mathematically important instances that surfaced during a lesson. These transitions are significant because teacher noticing of important mathematical ideas is central to student-centered instruction.

The intervention in this study included many elements that are often missing from field experiences: structured analysis, substantial mathematics teacher educator support, and clear mathematical goals. Together, these elements appear to have been effective in supporting desired transitions in noticing. Although the results are promising, more work is needed to fully understand the transitions, as well as what activities supported them. Understanding the details of transitions in noticing has the potential to inform interventions for supporting mathematics teachers in a range of contexts to more productively notice during instruction.

POSITIVE TURNING POINTS FOR GIRLS IN MATHEMATICS: DO THEY STAND THE TEST OF TIME?

Kathleen Jablon Stoehr
The University of Arizona
kjstoehr@email.arizona.edu

Kathy Carter
The University of Arizona
kcarter@email.arizona.edu

The purpose of this study is to examine the equity issue in mathematics from perspectives not traditionally included in equity claims. This study offers a close up view of personal experiences that female preservice teachers have encountered in their own journey as students of mathematics as well as how they make sense of their experiences, especially as they learn to teach. Different themes that arise in this issue of mathematics equity were examined in a study conducted by Stoehr and Carter (2011). This paper extends the previous study by examining and discussing the data-derived theme that centers on girls who experienced positive turning points in mathematics.

Keywords: Gender; Teacher Education–Preservice

Literature Review and Theoretical Framework

Girls enter the mathematics classroom with just as much potential to excel as boys (Boaler, 2008; Huebner, 2009). However, the stories that some girls tell about their mathematical experiences in the classroom suggest that they do not believe that this is true (Stoehr & Carter, 2011). This can lead to girls bowing out or not pursuing higher-level mathematics classes in high school and college, which are required for the more lucrative careers in science, technology, mathematics, and engineering (Else-Quest, Hyde, & Linn, 2010).

Sometimes girls experience a positive turning point in their mathematics journey that puts them on a path to believing they can do well in mathematics. This generally occurs because of the efforts of caring and helpful mathematics teachers. It is these positive moments in time that can lead to a substantial change in how girls view their mathematical abilities, as teachers empower students to succeed (Drake, 2006). These events exemplify the belief in the power of education to truly change a person's life. Turning point stories in education give credit to educators being able to make a real difference in a student's life (Yair, 2009).

Teachers involved in the day-to-day school lives of students have the capacity to effect compelling turning points (Yair, 2009). Often this occurs in a student's educational career when a previously failing student is met with a new teacher. Suddenly someone new sees merit in the failing student and views the student as capable. The belief that the new teacher has in the student can lead to the student believing in herself. Trusting a new teacher is powerful and can lead to a turning point in a student's educational journey (Bryk & Schneider, 2002).

Lemke (2002) makes several valid points regarding the power of turning points events. He argues that fundamental changes in attitudes or habits of reasoning cannot happen on short timescales. What has to be evaluated is whether the turning point event fades away or gets erased by events that occur afterwards. The question to ponder is whether these turning points are in reality just pleasant anecdotes that occur rarely and are unable to be planned for and put into practice. Or are turning points that occur in the lives of students significant enough to lead to personal transformation and empowerment? (Yair, 2009). It is these events that must be examined in an effort to evaluate if the change has a longer-term agenda.

It is also the influence that one person has over another that is important to consider when looking at positive turning point events. If pre-service teachers who have experienced a positive turning point event due to the efforts of a teacher they had in their K–12 years, can identify and emulate in their own teaching the characteristics of the positive turning point teacher, then perhaps strides can be made to break down the barriers that often prevent girls from believing they are capable mathematic students.

Methods

Participants and Setting

This preliminary study focused on women who experienced positive turning points in mathematics during their K–12 school years. This theme was derived from a larger qualitative study currently being conducted at a Research I University in the Southwestern United States. One hundred forty-nine narrative stories were prepared by a diverse group of female elementary pre-service teachers primarily in their early twenties. Twenty-one narratives revolved around the theme of positive turning points in mathematics.

Data Collection

The participants all wrote a mathematics narrative as part of a requirement for an introductory teacher education course. In these narratives, termed "Well-Remembered Events," the preservice teacher candidates were asked to describe and analyze a particularly salient mathematics event from their own experiences as students in K–12. This genre of personal narrative was derived from Carter's (1994) work on well-remembered events as windows into the understandings preservice teachers have of teaching. The task consisted of a 2–3 page paper organized around the following parts (1) the selection of a particularly salient mathematics event from one's past experiences in mathematics as a K–12 student; (2) a detailed description of the event; (3) an explanation of why the mathematics event was memorable; and (4) a statement of what impact this turning point experience might have on the writer's understanding of what it means to be a teacher and how she perceives it will affect her future teaching of mathematics.

Findings

This paper will briefly touch on the narrative writings of the stories told by the participants that related to a positive turning point experience in mathematics they recalled during their K–12 years. The research to date includes five main patterns and themes. They are as follows:

Theme 1: Thank You for Caring About Me

Nine participants wrote about how a caring and understanding teacher helped them work through the struggles they were having in mathematics. They described the impact it made on their mathematical performance. One participant who was struggling to learn how to add and subtract negative numbers in seventh grade wrote:

> I was too afraid to speak up and ask questions because I did not want to be the only student in the class who did not understand this concept. Mrs. Brown must have realized I was struggling and asked me to stay after school with her for a little while. Mrs. Brown was willing to give up her time after school to make sure that I understood the topic. We went through each problem and to this day, I can remember the feeling of accomplishment that I finally understood not only how to add and subtract negative numbers, but I also understood the concept of it. This gave me a ray of hope for my future math career.

Theme 2: My Teacher Believed in Me

> Panic attack was the first thing that popped into my head when Mr. Granger informed my AP Calculus class that we were to have our first test at the end of the next class period. I stayed after class and explained that I was very overwhelmed with the fast pace. Mr. Granger told me I should attempt the homework study guide to the best of my ability, and come into his classroom at lunch for help. After going over the homework the next day, he assured me I had nothing to worry about. When Mr. Granger passed out the tests, I went into panic-mode. He reassured me that I knew what I was doing. He had me take slow breaths to calm myself down. After putting a smiley face on each page, I dove right into the test and received my first A in the course. By believing in me Mr. Granger helped me to be more confident in my knowledge of the subject.

This participant's response is shared and reflected in the writings of three other women who wrote about how having their mathematics teacher believe in them changed how they viewed their mathematical abilities. One participant said, “Teachers have the ability to make students believe in themselves like no other person can.”

Theme 3: My Teacher Showed Me How To “Do Math”

Four participants recalled successful mathematics experiences as a result of a teacher’s ability to show them how to do a particular mathematics problem. This led to positive mathematical feelings. One participant talked about how her sixth grade teacher drew pictures so that she could visually see the math. She wrote:

> I was working on mathematical story problems and I was feeling anxious and worried because I knew I was not going to get the assignment finished before the bell rang.
>
> As Mr. West was walking through mathematical story problems and I was feeling anxious and worried because I knew I was not going to get the assignment the rows of desks to check on our progress, he noticed that I was having some trouble. I remember him asking me to walk back to his desk with him. It was there that Mr. West taught me one of the ways that I could go about solving story problems. We read the problem together and then he asked me to draw a picture of what I thought was occurring in the problem. From there we walked through each step of the problem, each with little drawings. I will never forget him saying to me that I was a concrete thinker that needed to see things for them to make sense. I remember feeling more confident with math after this point in the school year.

Theme 4: Math Does Not Need to be Scary

Two preservice teachers recalled mathematics stories that revolved around mathematics being scary and something they could not master. With the help of a teacher they were able to see mathematics in a positive and accessible manner. One participant wrote about a third grade mathematics experience:

> It was after lunch that we worked on mathematics. I dreaded it during recess wondering what was wrong with me and why I could not comprehend it. In fact I felt like a failure. Long division was getting the best of me. The student teacher, Mrs. Allen, noticed how I struggled with it. She asked me to come back to the classroom after lunch instead of going to recess. I remember sitting there looking at the board as we worked on long division problems and being so terrified. She helped me to understand that long division was simply backwards multiplication. More importantly, she allowed a young girl with glasses to see that mathematics is not a scary subject.

Theme 5: A Calm and Approachable Mathematics Teacher Makes a Difference

Two participants wrote about how having a teacher who was calm and who offered extra support helped them to see they could be successful in mathematics. As one participant said, “My teacher gave me the courage and strength to succeed in mathematics. If it wasn’t for her, I would still be the student sitting in the third row of the class in fear of asking for help.”

Discussion

The preliminary results of this study revealed promising findings in relation to positive turning point events in mathematics. All participants reported a surge of confidence and a more positive attitude in mathematics as a result of a teacher’s supportive efforts. The amount of detail these preservice teachers can remember years after the turning point experience took place exemplifies the power that these experiences can have on girls and how they view mathematics. Allowing girls to see themselves as capable mathematics students through the eyes of a positive turning point teacher offers a glimpse of how important and significant these experiences can be.

All participants in the study wrote about how significant it was that their teachers believed in them and gave them opportunities to be successful mathematics students in their class. Teachers empower students in these magical types of moments (Yair, 2009). This pilot study seems to suggest that positive turning point events in mathematics can make an impact on some individuals who experience them.

Conclusion

There is great optimism for girls in mathematics (Huebner, 2009). This pilot study suggests that girls who have struggled in mathematics can be positively affected by teachers who believe they can be successful mathematics students. The participants in the study identified characteristics that are important for mathematics teachers to possess in order to successfully meet the learning needs of their students as well as have confidence in their students and offer them the chance to succeed in their class. Identifying positive factors and teaching characteristics that this study uncovered is a step in the right direction. Teachers must embrace the critical role of encouraging girls in mathematics (Gavin & Reis, 2003). It is important for mathematics teacher "to help girls to find the spark" that can lead to success in mathematics (James, 2009, p. 158).

USING INTERVIEWS TO MOTIVATE TEACHERS TO LEARN MATHEMATICS AND REFLECT ON THEIR LEARNING

Eva Thanheiser
Portland State University
evat@pdx.edu

Randy Philipp
San Diego State University
rphilipp@mail.sdsu.edu

Jodi Fasteen
Portland State University
jfasteen@pdx.edu

Helping preservice elementary school teachers (PSTs) recognize that they have something useful to learn from university mathematics courses remains a constant challenge. We found that an initial content interview with the PSTs—deeply probing a mathematics concept—motivates PSTs to learn by (a) showing them the limits of their own understanding, (b) helping them recognize that knowing more than just procedures is worthwhile, and (c) helping them recognize that participating in mathematical activities during the course helps them learn. In addition, viewing the video of their initial interviews at the end of the course to reflect on their knowledge at the beginning of the course helps PSTs appreciate the content they learned and, thus, motivates them for future courses.

Background/Rationale

Preservice teachers (PSTs) often approach mathematics assuming that knowing how to apply procedures is synonymous with understanding (Graeber, 1999), a view that affects PSTs' views not only of children but also of themselves. With recent calls for a focus on having students in the United States develop conceptual understanding (Common Core State Standards Initiative, 2010; Kilpatrick, Swafford, & Findell, 2001), U.S. mathematics teacher educators need to focus on how to help their PSTs develop such knowledge. Although most PSTs and teachers can execute algorithms, many struggle when asked to explain them conceptually (Ball, 1988/1989; Ma, 1999; Thanheiser, 2009). PSTs often do not know that there is a rationale behind the procedures and thus equate procedural proficiency with understanding. Thus PSTs often approach mathematics courses for elementary school teachers in a perfunctory manner (Philipp et al., 2007), assuming that if they already know something they need not relearn it, and if they do not know something, they certainly cannot imagine having to teach it to elementary school students. We need, therefore, to help PSTs recognize the knowledge they are lacking and the value in learning mathematics beyond procedures.

Another challenge in teacher education relates to the "I-knew-it-all-along effect," or *hindsight bias* (Kahneman, 2011), which is the tendency of people after they learn something to lose their ability to recall what they knew or believed *before* they learned. The hindsight bias is problematic for preservice mathematics education because PSTs who forget how little conceptual understanding they held at the beginning of a course may not recognize what they learned, leading to their undervaluing the learning experience and failing to recognize the difference between knowing only procedures and understanding the underlying concepts. Consequently, we need to help PSTs establish a baseline of knowledge at the beginning of the course to which they can compare their learning while they move through the course.

Theoretical Framework

If we want PSTs to value their content courses for elementary school teachers and grapple more deeply with the content, then we believe that we need to first help PSTs

1. Recognize the limitations of their own understanding.
2. Recognize that knowing more than mathematical procedures is worthwhile.
3. See that engaging in mathematical sense making during the content course helps them learn the mathematics they need.

In addition we need to help PSTs

4. Reflect on what they have learned in their content courses.

Our assumption is that if PSTs realize #1–3, they will be motivated to learn mathematics in our content courses and that through #4, reflection, they will recognize what was learned. Our hypothesis is that these four goals can be realized by including particular kinds of experiences at the beginning and end of the course, combined with experiencing a sense-making approach throughout the class. In this study we conducted a videotaped content interview with each PST at the beginning of the course and then arranged for the PSTs to watch and reflect upon their interviews during a second interview at the end of the course.

Because interviews provide opportunities for instructors to ask probing follow-up questions to assess the depth of a PST's understanding, the instructor can give immediate and personal feedback and assessment. Furthermore, interviews enable both the instructor and PST to develop awareness of what the PST knows and does not know. By becoming aware of their own understandings, PSTs begin to develop intellectual integrity (Chamberlin & Powers, 2007). Furthermore, the PSTs are also aware that their interviews have made public to their teacher what they do and do not understand, thereby encouraging PSTs to more openly address their knowledge gaps during class, rather than concealing them from their instructor, their classmates, and even themselves.

Viewing the videotaped interview at the end of the course enables PSTs to (a) compare their knowledge at the end of the course to their knowledge at the beginning, and (b) reflect on their learning and the experiences that engendered the learning.

Methods

Participants in the study were 23 PSTs enrolled in a 10-week mathematics course for preservice elementary school teachers at a large state university. The course met for two 110-minute class sessions per week. The class was focused on whole numbers and operations.

The data analyzed were drawn from two 10–15-minute videotaped individual interviews with the 23 PSTs conducted at the beginning and at the end of the course and student reflections collected at the beginning of the course (immediately after the first interview), in the middle of the course (week 6), and at the end of the course (before the last interview). The first and last reflections were collected via web surveys and the middle one via e-mail. Sample reflection questions are listed in Figure 1. Because little is known about how PSTs experience such an interview, we analyzed the data using a grounded theoretical approach with *open coding* (Strauss & Corbin, 1990). In reading all PST responses, we identified four themes. Next, two coders coded all the data by theme and then met to resolve disagreements through discussion. We share those themes in this paper.

Sample reflection question from the middle of the course (collected via e-mail)

- Thinking back to the interview at the beginning of class, how do you think that interview affected your learning in this class? Please try to be as specific as you can in this response.
  Sample end-of-course question, posed after PSTs had viewed their initial interviews
- Watch your first interview and give your general reactions to the interview; we are very interested in your reactions, so feel free to share.

Figure 1: Sample reflection questions

The instructor probed the students' understanding of regrouping in the context of addition and subtraction using Thanheiser's (2009) interview protocol and framework. This framework was then used to categorize the PSTs' conceptions in the two interviews. Each interview was independently coded by two coders with 86% agreement. All disagreements were resolved through discussion.

Results and Discussion

Consistent with previous research (Thanheiser, 2009), at the beginning of the course, 17 PSTs held an incorrect conception of number and 6 held a correct conception. At the end of the course, 21 PSTs held a correct conception; only 2 PSTs held an incorrect conception. In this section we (a) briefly review the themes that emerged from the PSTs' reflections on their interview experiences, and (b) discuss the themes that emerged from PSTs' viewing their initial interviews at the end of the term and reflecting on viewing the interviews.

Four themes emerged throughout the interview reflections (see Table 1). For an in-depth description of the themes, see Thanheiser et al. (2012). These themes, taken together, indicate that PSTs feel motivated to learn mathematics in their content courses as a result of the initial interview and the reflections on that experience.

Table 1: Themes Identified in 23 PSTs' Reflections

Theme	# of PSTs
1. PSTs are not typically asked to think about or explain mathematics beyond procedures.	5
2. The PSTs recognized the limitations of their own understanding, the value of knowing more than the procedures, or both.	15
3. The PSTs stated that they were motivated to learn the mathematics of the course.	21
4. The PSTs reflected on their own knowledge and learning.	19

At the end of the course, when PSTs watched their interviews from the beginning of the course and reflected on that experience, two themes emerged (see Table 2).

Table 2: Two Themes Identified in the 23 PSTs' Reflections After Watching the Interviews

Theme	# of PSTs
Theme A. Recognition of their limited mathematics knowledge at the beginning of the course (akin to Theme 2 above but in stronger language). PSTs explicitly acknowledged feeling embarrassment, shock, or surprise at their own lack of knowledge and noted how confusing and unorganized their explanations had been.	18
Theme B. Recognition of what they learned in the course. PSTs expressed pride in their correct explanations and feelings of accomplishment and recognition or pride at what they had learned in the course.	13

Kendra, for example, reflected on viewing her interview:

> I was shocked at the level of understanding of math I had. I am surprised that it did not occur to me to think about the ones that were being carried over were tens or hundreds, not just one. My understanding of numbers was the idea that the number represented one value. For example, I did not know that the one carried to the tens place was not a 1 but a group of ten ones. Overall, I am surprised by my thinking at the time.

The notion of experiencing shock at their own understanding was prevalent in many reflections. A characteristic of elementary-mathematics learners is that after learning an idea, one had difficulty imagining not knowing it. Consider, for example, the fact that $345 = 300 + 40 + 5$. This fact, once understood, seems obvious; however, it is a fact with which many people struggle. A result of this phenomenon is that PSTs often leave their content courses thinking that they learned nothing because now that they do understand the mathematics, not knowing it seems unimaginable. The interview (and the fact that it is recorded so that PSTs can watch it later) enables PSTs to remember what it is that they knew and did not know at the beginning of the course and thus to appreciate what they learned in the course. This knowledge, in turn, can serve as a motivational tool for future courses.

Several students commented that, in addition to being shocked, they recognized what they had learned. Aubrie, for example, stated, "After watching my first interview, I was really shocked, to say the least. I couldn't help but laugh at myself at how little I actually knew, and now, realizing how far I have come. If I had only knew [*sic*] then what I know now."

As a result of participating in an initial content interview and viewing that interview at the end of the term, PSTs were motivated to attend carefully to the activities in the content course and to engage with them more deeply than they otherwise would have. In addition, PSTs were aware of and proud of what they had learned. Thus PSTs valued their course/learning and were motivated for future courses.

EXAMINING CONNECTIONS BETWEEN MATHEMATICAL KNOWLEDGE FOR TEACHING AND CONCEPTIONS ABOUT MATHEMATICS TEACHING AND LEARNING

Rachael M. Welder
Hunter College–CUNY
rwelder@hunter.cuny.edu

Cindy Jong
University of Kentucky
cindy.jong@uky.edu

This study explores connections between preservice elementary teachers' mathematical knowledge for teaching (MKT) and their conceptions about the teaching and learning of mathematics. Researchers administered the MKT measures developed by the Learning Mathematics for Teaching Project and used the Mathematics Experiences and Conceptions Surveys (MECS) to measure attitudes, beliefs, and dispositions. Preliminary findings from data collected at two universities show significant gains in MKT and attitudes about teaching mathematics over the duration of an elementary mathematics methods course. Regression models indicate that factors within the course did not account for a significant portion of the growth in MKT. However, changes in MKT, along with course and fieldwork factors, helped explain a significant portion of the preservice teachers' changes in attitudes.

Keywords: Mathematical Knowledge for Teaching; Teacher Education–Preservice; Teacher Beliefs

Purpose of the Study

This paper reports preliminary findings from an exploration of elementary teachers' development of Mathematical Knowledge for Teaching (MKT) and the connection between MKT and conceptions (defined as attitudes, beliefs, and dispositions) about mathematics teaching and learning. During the fall 2011 semester, preservice elementary teachers (PSTs) enrolled in mathematics methods courses at two U.S. universities completed pre- and post-iterations of the Learning Mathematics for Teaching (LMT) Project's MKT measures (Hill, Schilling, & Ball, 2004) and the Mathematics Experiences and Conceptions Surveys (MECS) (see Welder, Hodges, & Jong (2011) for details regarding MECS instrumentation). The purpose of this study was to examine changes in MKT over the duration of a mathematics methods course and to explore potential relationships between PSTs' MKT, experiences afforded in mathematics methods courses and related fieldwork, and the attitudes, beliefs, and dispositions PSTs hold towards mathematics teaching and learning. This investigation is part of a larger research agenda to understand how teacher educators can foster student achievement by facilitating the development of teachers' MKT and conceptions about mathematics.

Perspectives

The process of learning to teach mathematics is multifaceted and includes a number of domains known to influence the instructional practices teachers employ and thus the learning opportunities provided to their students. In this study, we focus on two domains: MKT and conceptions about mathematics teaching and learning. We argue that the development of PSTs in each of these domains is a critical aspect of mathematics teacher education.

Over the years, research has identified content knowledge as a significant factor in the pedagogical decisions of mathematics teachers and the achievement of their students (Graeber, 1999; Hill et al., 2008). However, the work of the LMT project has confirmed that the content knowledge needed for teaching mathematics requires more than general mathematical ability (Ball, Thames, & Phelps, 2008; Hill et al., 2004). The daily tasks of teachers, such as interpreting a child's work or developing an alternative explanation, require skills beyond those needed to perform a mathematical procedure. These responsibilities require *unpacked* mathematical knowledge, in addition to pedagogical knowledge, demanding teachers to know *more* and *different* mathematics than their non-teaching counterparts. For years, LMT researchers have worked to conceptualize and measure the various domains of what they have coined Mathematical Knowledge for Teaching (Ball et al., 2008); our study is grounded in their conceptual framework. Studies have indicated that MKT plays an important role in the practices employed by mathematics teachers and have identified a strong relationship between teachers' MKT and the mathematical quality of their instruction (Hill et al., 2008). Therefore, we argue that teacher educators can support PSTs by attending to the development of their MKT. This initiative aims to understand of how MKT is affected by factors within teacher education.

In addition to MKT, Ball, Lubienski, and Mewborn (2001) suggest that efforts to improve teacher quality should consider the ways in which teachers think about the processes of teaching and learning. Supporting research has shown that teachers' beliefs and attitudes heavily influence their instructional practices (Ball & Cohen, 1999; Wilkins, 2008) and the opportunities their students have to engage in significant mathematical thinking (Staub & Stern, 2002). For example, Wilkins (2008) found a strong link between beliefs, attitudes, and the extent to which teachers employ reform practices in their classrooms. In the current study, we use the term *conceptions* to encompass beliefs, attitudes, and dispositions, three central and interrelated subconstructs of how one thinks about the teaching and learning of mathematics (cf. Welder et al., 2011). Although researchers vary in their definitions of these subconstructs, consensus exists on the critical importance of aligning PSTs' conceptions with effective mathematics teaching practices within teacher education (Metzger & Wu, 2008).

The preparation of PSTs must be multidimensional to support the development of robust MKT and a set of beliefs, attitudes, and dispositions towards mathematics that will foster student learning. However, little is known about how these vital domains of learning to teach mathematics co-evolve over time. Furthermore, there is a dearth of research explicitly investigating relationships between the domains. In one study, Philipp et al. (2007) found connections between teachers' knowledge and beliefs about mathematics to have significant impact on instructional practices. These results are promising and offer support to our hypothesis that teachers' knowledge and conceptions about teaching and learning are interrelated.

Methods

Participants and Context

The results of this study are based on data collected on 59 elementary PSTs within two universities in the Eastern United States. Participants were enrolled in an elementary mathematics methods course as part of a teacher education program for initial licensure during the fall semester of 2011. Participants at University A were first-semester graduate students enrolled in a non-traditional, two-year elementary certification program. These students complete one three-credit mathematics methods course and a co-requisite field experience requiring them to observe ten hours of elementary mathematics instruction. Participants at University B were undergraduates, enrolled in a traditional, four-year elementary certification program where students complete one three-credit mathematics methods course during the semester prior to full-time student teaching. The co-requisite field experience for this course places PSTs in a classroom full-time for five weeks, where they teach a minimum of twelve mathematics lessons.

Data Analysis

The mathematics methods course served as a common point of interest for the researchers to examine PSTs' MKT and conceptions. Data were collected at the beginning and end of the course using the LMT Project's MKT measures and the MECS, under development by Welder et al. (2011). PSTs completed computer-adaptive pre- and post-administrations of the 2001 Number Concepts and Operations MKT measure using the LMT online assessment system. The MKT measures have undergone a rigorous validation process with the application of item response theory and are used extensively in mathematics education research (Hill et al., 2004). Concurrent with MKT administrations, participants completed two iterations of the MECS, being developed to study the evolution of PSTs' conceptions over time. MECS instruments correspond with significant benchmarks in teacher education programs. Participants in this study completed MECS-M1 and MECS-M2, designed to be pre- and post-surveys for mathematics methods courses and co-requisite fieldwork experiences. The subscales within MECS-M1 and MECS-M2 have been found to be highly reliable (Welder et al., 2011) and the surveys continue to undergo rigorous validation. We began our analyses by conducting an analysis of variance (ANOVA) to examine changes in MKT, attitudes, beliefs, and dispositions over the course of the semester. We then created multiple regression models to examine factors accounting for the variance noted in MKT and attitudes about mathematics teaching.

Results

An ANOVA of the aggregate data showed a statistically significant difference in PSTs' MKT scores from pre to post ($F(2, 56) = 6.24$, $p = .015$). However, ANOVA results of the disaggregate data indicated a significant gain in MKT scores for University A ($F(1, 40) = 5.97$, $p = .019$) but not University B ($F(1, 15) = 1.97$, $p = .179$). A significant change in attitudes was also noted for University A ($F(1, 40) = 11.69$, $p = .001$) but not for University B. No significant changes were found in beliefs or dispositions for either group. This could be due to the small sample sizes included in these preliminary analyses.

To examine changes in MKT scores and attitudes, we developed regression models in search of explanatory variables for University A. The overall regression of *MKT_post* on *MKT_pre* and *field_exp* was statistically significant [$R^2 = 0.24$, $F(2, 39) = 5.32$, $p < 0.027$]. The two factors accounted for 24% of the variance in PSTs' change in MKT scores following the methods course, but 14% of that variance was accounted for by initial MKT scores. It is surprising that field experiences accounted for the remaining 10%, considering the minimal fieldwork requirements at University A. However, since their methods course is graduate-level and tends to be taken in the program's first semester, this is commonly the PSTs' first elementary classroom experience in years. Thus, the influence of this fieldwork may be explained by the PSTs' lack of recent exposure to elementary education and a potentially more advanced level of maturity.

The overall regression of *attitudes_change* on *MKT_change*, *MM_mat,* and *field_exp* was also statistically significant [$R^2 = 0.37$, $F(3, 38) = 4.31$, $p < 0.045$] for University A. The three factors together explained 37% of the variance in PSTs' change in attitudes towards mathematics following the mathematics methods course. Change in MKT scores accounted for 15% of this variance, methods course materials accounted for another 15%, and field experiences accounted for an additional 7%. It is not surprising that the three variables entered into the model explained a significant portion of PSTs' positive change in attitudes given that attitudes typically have a positive or negative orientation and can shift more easily than beliefs (Philipp, 2007).

Conclusion

To capture a more holistic picture of the process of learning to teach, it is critical that research co-examines the development of content knowledge and conceptions about teaching and learning. Our results suggest that teacher education can significantly influence PSTs' MKT and attitudes about teaching, simultaneously, over the course of only one semester. Interestingly, when the data from the two universities was disaggregated, significant changes were noted only for the PSTs in the graduate certification program. We realize that our analyses focused on relationships; hence, no causal claims can be made. Additional research will be necessary to explore the variables accounting for this difference and examine the co-development of these constructs. We suspect a number of factors, including the context of the program, course instructor(s), and maturity level of the students, might be influential.

While small sample sizes were a clear limitation in this preliminary study, we are beginning to find evidence that links MKT and conceptions about mathematics teaching and learning. It is promising that, for University A, MKT accounted for a significant portion of PSTs' changes in attitudes alongside the mathematics methods course and fieldwork experiences. Continued research is needed to validate our findings with larger data sets and to longitudinally examine the development of PSTs. This study is a small, first step towards an understanding of how teacher educators can facilitate the interrelated development of MKT and conceptions about the teaching and learning of mathematics.

PROSPECTIVE ELEMENTARY TEACHERS' JUSTIFICATIONS FOR THEIR NONSTANDARD MENTAL COMPUTATION STRATEGIES

Ian Whitacre
San Diego State University
ianwhitacre@yahoo.com

Susan D. Nickerson
San Diego State University
snickers@sciences.sdsu.edu

We report on the justifications that prospective elementary teachers offered for their nonstandard mental computation strategies. Seven participants were interviewed before and after a whole-number unit in a mathematics course designed to promote number sense development. We investigated the sense that the participants made of their new non-standard strategies (one invalid) for addition and subtraction by examining their justifications.

Keywords: Number Concepts and Operations; Teacher Education–Preservice

We briefly describe the number sense of prospective elementary teachers, focusing on how they reason in mental computation. Mental computation is closely linked to number sense (Sowder, 1992). Teachers need good number sense in order to support students' inquiry learning because a teacher whose understanding of numbers and operations is bound to standard algorithms is not equipped to make sense of children's often-unorthodox solution strategies (Ball, 1990; Ma, 1999; Sowder, 1992; Yang, Reys, & Reys, 2009). Yet, studies of preservice elementary teachers have found that this population tends to exhibit poor number sense even after having completed required college mathematics courses and that their understanding is tied to the standard algorithms (Tsao, 2005; Yang, 2007; Yang, Reys, & Reys, 2009).

Good number sense is exhibited in the use of a variety of computational strategies, which are selected based on the particular numbers at hand, rather than using an automatic procedure for the given operation. Inflexibility manifests as overreliance on the mental analogues of the standard paper-and-pencil algorithms. Flexible individuals use strategies that often stray far from standard, as in reformulating computations or rounding and compensating (Carraher, Carraher, & Schliemann, 1987; Heirdsfield & Cooper, 2002; Markovits & Sowder, 1994; Sowder, 1992; Yang, Reys, & Reys, 2009). Our focus is on investigating prospective teachers' understanding of the computational strategies they use, so that we can better design instruction.

Setting

We report on the second iteration of a classroom teaching experiment (CTE) in a mathematics course for prospective elementary teachers. Topics in the curriculum include quantitative reasoning, place value, meanings for operations, children's thinking, meanings for algorithms, representations of rational numbers, and operations involving fractions. In the CTE, intended to foster number sense, we identified in the curriculum particular opportunities to engage students in activities such as authentic mental computation, as well as to facilitate rich discussions concerning students' strategies and ways of reasoning. Over time, a shared set of strategies was established via mathematical argumentation. These strategies were given agreed-upon names, and the class maintained a list with examples of each.

Methods

This study took place at a large, urban university in the Southwestern U.S. The participants in were students enrolled in a first mathematics content course for prospective elementary teachers, belonging to a four-course sequence. The second author was the instructor of the course.

Seven of the students, all female undergraduates participated in pre/post mental computation interviews. Participants were asked to solve story problems for each of the four basic operations. These problems were presented verbally and written. For example, participants were asked, *If Bobo buys an oboe for $49 and then sells it for $125, how much is his profit?* The participants were asked to solve each story problem mentally and to describe the steps that they had performed. They were not allowed to do any written work during these interviews. Whenever a participant used a strategy that departed from the mental analogue of the standard algorithm, she was asked to justify this strategy (e.g., “Why does that work?”).

For each problem posed, the participant’s strategy was coded, using a previously developed scheme (Whitacre, 2007). Once the strategy coding had been completed, we identified the justifications that had been given for each nonstandard strategy. Through a process of open coding, we generated mathematical idea codes to describe the ideas that students had used to justify their strategies. The set of codes and operational definitions was refined through a process of constant comparative analysis (Strauss & Corbin, 1998). Our sensitivity to ideas of interest and our descriptions were informed by the literature, especially Carraher et al. (1987), Heirdsfield and Cooper (2002), and Thanheiser (2010).

Results

In this paper, we focus on addition and subtraction. We report on the nonstandard strategies that participants used in the interviews, together with the ideas that they offered as justification. We give examples and discuss nuances in the participants’ reasoning. There were four distinct nonstandard addition strategies used, and all of these were valid. (See Table 1.)

Table 1: Participants’ Nonstandard Addition Strategies and Justifications

Strategy	Mathematical Ideas used in Justification
Left to Right Separation. Added place-value wise from left to right. Decomposed the addends, added ones, tens, and hundreds separately, and then combined.	*Tens and Ones.* Gave a decomposition justification, describing the addends and their sum as composed of tens and ones and hundreds.
Leveling. Altered the problem such that part of one addend was taken and given to the other prior to finding their sum.	*Addition is Associative*. Expressed, either formally or informally, the associative property of addition.
Single Compensation. Rounded one of the two addends up or down, then compensated by adding or subtracting appropriately.	*Inverse Operations.* Reasoned about compensation in terms of the inverse operation: addition undoes subtraction; subtraction undoes addition.
Double Compensation. Rounded both addends prior to computing. Typically, one was rounded up and the other down. Added and then compensated by adding or subtracting, taking into account the net effect of her two rounding moves.	*Inverse Operations.* As with Single Compensation but compensation applied to the balance of the two rounding moves. *Compensation Balance.* Adding an amount to one addend and subtracting from the other resulted in a net change to sum.

Example 1

In her second interview, Val used Single Compensation to find the sum of 38 and 99. She quickly answered that this was 137. Val explained her reasoning to the interviewer:

Val: Um, I made ninety-nine into a hundred by adding one. Uh, and then a hundred plus thirty-eight equals one thirty-eight. And I just subtracted the one and got one thirty-seven.
Interviewer: So, the one that you added, where did it come from?
Val: Well, I just added ‘cause I know I can add one to make it a hundred. And so, if I add one to make it a hundred, I know I have to subtract one from the final answer to make it even.

Val thought about rounding in terms of adding one to the sum. In contrast to a Leveling strategy, the one that she added originated outside of the given computation. Val reasoned that because she had added 1 to 99 before computing, she needed to subtract 1 from the sum of 100 and 38 “to make it even.”

There were four distinct nonstandard subtraction strategies used. Three of these were valid, and one was invalid. (See Table 2.) We offer two specific examples of participants' reasoning.

Table 2: Participants' Nonstandard Subtraction Arguments and Justifications

Strategy	Mathematical Ideas used in Justification
Aggregation. Either began with the (a) subtrahend and added onto it in convenient chunks until the minuend was reached or (b) minuend and subtracted off the subtrahend in convenient chunks.	*Difference as Distance Between.* Described the difference between the minuend and subtrahend as a distance between number-locations.
Minuend Compensation. Rounded the minuend prior to computing and found the difference between the subtrahend and rounded minuend. Compensated appropriately for rounding.	*Inverse Operations.* Reasoned about compensation in terms of the inverse operation: addition undoes subtraction; subtraction undoes addition.
Invalid Subtrahend Compensation. Rounded the subtrahend and found the difference between the minuend and rounded subtrahend and then subtracted from or added to the difference to compensate for change to the subtrahend.	*Inverse Operations.* Reasoned about compensation in terms of the inverse operation: addition undoes subtraction; subtraction undoes addition.
Valid Subtrahend Compensation. Rounded the subtrahend and found the difference between the minuend and rounded subtrahend and then added to the difference or subtracted from the difference to compensate.	*Compensating for Effect.* Reasoned about compensation on the basis of the effect of a rounding step, as opposed to the action itself. Understood how increasing or decreasing the subtrahend decreases or increases the difference.

Example 2

Trina and Natalie were both presented with the following story problem: *If Bobo buys an oboe for $49 and then sells it for $125, how much is his profit?* Trina solved the problem by Valid Subtrahend Compensation. She added 1 to 49 to make 50. She knew that 125 – 50 was 75. Then she added 1 to 75 to get her answer of 76. Trina's justification was contextualized. She said that by changing 49 to 50, she had "pretended [Bobo] used more money than he did." Because Bobo had actually purchased the oboe for $1 less than $50, this meant that his profit was $1 greater than $75.

Natalie also rounded 49 up to 50. She subtracted 50 from 125, obtaining 75. She then decided that she needed to subtract 1 from 75 to compensate for the fact that she had added 1 to 49 initially. So, she arrived at an answer of $74. Natalie explained, "I'm technically adding a one to the problem. But then I have to subtract the one again in order to correct what I did originally." Natalie's approach is an example of Invalid Subtrahend Compensation. In her view, she had added 1 "to the problem," and she had to remove that 1 in the end.

Discussion and Conclusion

As MTEs, we find it important to consider students' justifications for their nonstandard strategies because these reveal their understanding of key mathematical ideas. Understanding the reasoning of students like Natalie and Trina helps to inform the design of instruction to support prospective elementary teachers' mental computation strategies and number sense development. In the case of Natalie and Trina's subtraction strategies, the key idea lacking concerns the distinct roles played by the subtrahend and minuend and, as a result, how each affects the difference. When students understand difference as distance between number locations, they apply aggregation strategies or understand compensation in terms of maintaining that distance.

PROSPECTIVE TEACHERS' MATHEMATICAL KNOWLEDGE FOR TEACHING ALGEBRA AND GEOMETRY

Kristen N. Bieda
Michigan State University
kbieda@msu.edu

Xueying Ji
Michigan State University
jixueyin@msu.edu

Relatively little research exists on prospective secondary mathematics teachers (PST-Ms) MKT and how it is developed. This paper discusses preliminary findings from a project investigating the characteristics of PST-Ms' MKT in the domains of algebra and geometry, and how participating in lesson study with mentor teachers correlates with change in their MKT.

Background

MKT is the "mathematical knowledge needed to perform the recurrent tasks of teaching mathematics to students" (Ball, Thames & Phelps, 2008, p. 399). PST-Ms may develop MKT through participating in lesson studies with mentor teachers, which involve planning, enacting, debriefing, revising, and re-teaching a research lesson in a mentor's classroom. The research questions that guided this study were: *What are the characteristics of PST-M's MKT in the domains of algebra and geometry? To what extent does engaging lesson study with mentor teachers influence the development of PST-M's MKT?* This poster presents findings to address the first question.

Methods

Thirty-five students, completing two university-based mathematics pedagogy courses (A and B) prior to student teaching placement, participated in the study. Course A focused on MKT for algebra and Course B focused on MKT for geometry. There were two sections (a treatment and a control group). The treatment group completed two mentor-guided lesson study cycles during Course B while the control group completed two Plan-Teach-Reflect assignments in field placements. All 35 students completed two written MKT exams in both Course A and Course B (4 exams), which included items from the Knowledge for Algebra Teaching measures.[1] Other sources of data from the lesson study cycles included reflective logs and audio-recorded lesson study meetings. This poster reports only results from analysis of exam responses.

Results

The results suggest that there are no significant differences between the content knowledge and specialized content knowledge portions of PST-Ms' algebra and geometry MKT. There were significant differences in the dispersion of the scores, suggesting that PST-Ms' geometry MKT may be slightly stronger. However, differences between the MKT measured in the items may account for the differences in the dispersion. Two potentially significant findings did emerge: (1) PST-Ms common content knowledge for algebra appears to be stronger than for geometry; and (2) lesson study may support the development of PST-Ms MKT, particularly aspects of pedagogical content knowledge.

Endnote

PRE-SERVICE TEACHERS' INTERPRETATIONS OF THE COMMON CORE STANDARDS: A COMPARATIVE STUDY ALONG THREE DIMENSIONS

Janet Bowers	Michael Fredenberg	John Gruver
San Diego State University	San Diego State University	San Diego State University
jbowers@math.sdsu.edu	mikefredenberg@yahoo.com	jgruve@gmail.com

This report describes the second phase of an ongoing study designed to analyze the ways in which pre-service teachers (PSTs) interpret the *Common Core State Standards for Mathematics* (CCSSI, 2010). During phase I, our goal was to identify which of the eight math practices were most comprehensible to PSTs and those which subjects found most difficult to interpret and implement (see Bowers & Fredenberg, 2011). The methodology for both studies involved asking PSTs to create scripts depicting tutoring scenarios that target any two of eight math practices. When analyzing the results from study 1, researchers coded students' scripts on a scale of 1–4, with 1 representing the least sophisticated interpretation of the practice, and 4 representing a well-defined interpretation. Results from phase one of the study revealed three critical findings:

- The two most targeted (and most understandable) practices were 1 (Persevere) and 2 (Argumentation), while the two least targeted (and least understood) were 7 (Patterns) and 8 (Structure).
- A statistical analysis of the PSTs' descriptions indicated that the average rating of 1.8 (on a scale of 1–4) revealed no significant differences between the levels of sophistication among descriptions of all eight practices. This suggests that PSTs had equal difficulty describing all of the practices without any formal introduction to their intent and wording.
- Many of the PSTs' descriptions of the math practices reflected everyday interpretations of words that have specific meaning in the mathematics education community.

Target Dimensions for Phase II

Based on the findings from Phase 1, we have identified three dimensions that need to be addressed in order to improve PSTs' understanding of the math practices: (1) Communication (specifically the role of argumentation and precision); (2) Classroom Roles (specifically the student practices and the teacher moves that supported the emergence of those practices); and (3) Enculturation into mathematics education community (specifically, the ways in which various everyday terms are interpreted by students and teachers learning the CCSS as well).

Subjects, Setting, and Data Collection

The subjects in this study were, once again, all undergraduate students enrolled in a capstone mathematics class for prospective middle school teachers at a large southwestern university. After discussing the importance of teacher questioning and the intent of the CCSS, subjects were asked again to write scripted videos that featured a teacher and student solving a proportional reasoning problem and again asked to target two of the eight practices. Once the videos were created, subjects were asked to watch three randomly assigned videos and describe which practices they believed the authors were targeting. These ratings, along with those from the previous year, will be analyzed along the three dimensions described above. Results from this round will be compared with the results from phase I of this study to determine if the revised treatment approach was more effective for promoting PSTs' appreciation of the practices described in the CCSS-M.

PRE-SERVICE ELEMENTARY TEACHERS' DEVELOPING UNDERSTANDING OF ELEMENTARY NUMBER THEORY

Ziv Feldman
Boston University
zfeld@bu.edu

Keywords: Teacher Education–Preservice; Teacher Knowledge

In order to be effective, teachers must develop a deep understanding of the mathematics that they will teach their future students (Ball, Thames, & Phelps, 2008). Moreover, the mathematical knowledge needed for teaching is shown to be positively associated with elementary students' mathematics achievement (Hill, Rowan, & Ball, 2005). Research shows, however, that many pre-service and in-service elementary teachers struggle to make sense of the mathematics that they must teach (Ma, 1999; Ball, 1990). One branch of mathematics that is important for all teachers to understand is elementary number theory, which includes topics in divisibility, prime factorization, factors, and multiples. Teacher preparation is critical in this area because number theory is closely connected to topics in number and operations and has recently taken a more prominent role in elementary curricula and standards documents.

Unfortunately, little is currently known about pre-service teachers' understanding of number theory. Only a handful of studies (Zazkis & Campbell, 1996a, 1996b) have begun to identify pre-service teachers' knowledge of divisibility and prime factorization, and even fewer have provided detail about how such knowledge changes during teacher preparation coursework. However, if teacher educators are to help pre-service teachers learn with understanding, they must first determine how pre-service teachers come to make sense of such topics.

This poster presentation will detail the results of a mixed methods study whose goal was to describe pre-service elementary teachers' developing understanding of number theory during a three-week instructional unit within a mathematics education content course. Using elements of the *action-process-object-schema* theory of understanding (Dubinsky, 1991), qualitative analysis of six individual clinical pre- and post-interviews identified participants transitioning from concrete to abstract levels of understanding. Additionally, statistical analysis of fifty-nine participants' pre- and post-test results revealed changes in their achievement across questions requiring procedural and conceptual understanding of number theory. Using both analyses, the presentation will describe participants' transitions between levels of mathematical understanding of number theory topics, as well as report on the details and structure of the research project.

LEARNING TO TEACH TEACHERS: MAKING A TRANSITION

Ryan D. Fox
Pennsylvania State University–Abington College
rdf16@psu.edu

As I transition from mathematics teacher to mathematics teacher educator, I wonder how I can support the mathematical development of future teachers. Like Ball (1988), I wanted to accomplish two objectives at once: "learning about prospective teachers and developing strategies for working with them" (p. 40). Toward these ends, I began a study where I interview several students aspiring to become elementary school teachers, while they are still in their pre-service preparation program. This poster focuses on the preliminary findings with one particular student. The question guiding this particular study is: how does a pre-service teacher apply his/her knowledge of proportional reasoning and fractions to a sequence of contextual problems? In the poster, I answer this question and determine how those answers guide my own development as a teacher of future teachers.

I set up a sequence of four interviews with each participant. The first interview allowed me to learn about the student's background, and to pose five word problems. The middle two interviews involved the participant responding to ten word problems in each interview. In the three interviews, participants identified proportional relationships, using whole numbers, unit fractions, and composite fractions respectively in the three interviews. The final interview allowed the participant to reflect on his/her experiences. The interviews match Steffe and Thompson's (2000) description of exploratory teaching, where my goal as teacher-researcher is to "become thoroughly acquainted, at an experimental level, with students' ways and means of operating in whatever domain of mathematical concepts and operations are of interest" (p. 274).

Stephanie (a pseudonym) possessed the content knowledge necessary to answer all of the word problems correctly. To achieve her goal to "make things [solutions] clearer," Stephanie began each response with the same two activities, eventually writing out as detailed a solution as she could create. During the interviews, Stephanie recognized the need to acquire additional knowledge of some form to identify different solutions or representations to the same question, as in Ball (1993). I believe Stephanie wrote as complete a solution as she could create, so that she could reduce, or eliminate, any confusion a student might have answering a similar problem. However, Stephanie recognizes that students could accurately answer one problem in a variety of ways that she is not familiar with. As I develop as a teacher educator, I feel the desire to balance two concerns in my own work with future teachers: supporting pre-service teachers' own mathematical knowledge and translating mathematical knowledge to useful explanations for younger students. In my future work with Stephanie, my intention is to support the translation of her established content knowledge into a specialized knowledge base meaningful for her future teaching of mathematics.

Keywords: Curriculum Analysis; Teacher Education–Preservice/ Inservice

The contemporary social, economic, and political changes that have occurred in the Russian Federation as a result of the breakdown of the Soviet Union have imposed new reforms in education during the last two decades. Currently, Russia is in the process of transitioning from a traditional teacher preparation model to a restructured progressive model led by new standards, which abide by the commitment to the European Bologna Declaration in 2003. These significant changes are reshaping the higher education system and curricula in a radical, and perhaps, contentious manner. The underlying principle of this research is to offer a comprehensive analysis of the changes that have occurred regarding secondary mathematics teacher preparation in Russia, due to these developments, as a way to advocate for reforms to improve teacher preparation programs. Teacher training curricula and degree plans from several Russian pedagogical universities were used to support the analysis.

The findings uncovered that the system of secondary mathematics teacher preparation in Russia within the framework of the new model includes the following distinctive characteristics: greater importance is placed on general educational goals over professional goals at the first tier of the teacher preparation; inclusion of a research component in the content of the teacher preparation, which becomes increasingly important with transition from the Baccalaureate to the Master's program; and a distinction between professional accreditation of graduates of Baccalaureate and Master's programs with regard to grade level teaching assignment (Stefanova, 2010).

From a comparative perspective, the secondary mathematics teacher preparation in Russia is more extensive than it is in the U.S., with higher emphasis placed on the content and pedagogical content preparation of teachers along with increasing attention to its research component. The comparison between the Master's programs in Mathematics Education in Russia and the U.S. shows that there is a significant difference in the professional specialization component of the Russian curriculum compared to the U.S. curriculum. Secondary Mathematics teacher training programs in Russia, particularly at the upper secondary school level, also offer double content majors, which is not the case in most of the U.S. teacher preparation programs (Ministry of Education and Science of Russian Federation, 2000). Learning about secondary mathematics teacher preparation in Russia presents diverse view on teacher education and pedagogical approaches that are used in other countries. With this diversity, mathematics teacher educators could reflect on their own practices and re-evaluate strategies that can be incorporated in their own teacher preparation system. However, further studies in exploring the impact of different teacher preparation curriculum on teacher quality characteristics, such as teacher knowledge, are needed.

EXPERIENCES FILTERED BY BELIEFS: THE EFFECTS OF A PROFESSIONAL DEVELOPMENT SCHOOL SECONDARY MATHEMATICS METHODS COURSE

Alyson E. Lischka
Kennesaw State University
alischka@kennesaw.edu

In a Professional Development School (PDS) setting, the preparation of mathematics teachers is a collaborative effort between university faculty, high school faculty, and the pre-service teachers (PST). All PDS participants can experience transitions through their work with PSTs as they explore research-based best practices in mathematics teaching. In this study, the impact of one such collaborative effort on the beliefs and practices of the methods course co-instructor (a high school faculty member) and one PST and his collaborating teacher (CT) were explored.

This study was framed by the view that teachers' beliefs are sensible systems (Green, 1971; Leatham, 2006) through which they filter research and suggestions to employ reform-oriented teaching practices as envisioned by NCTM. Classroom practices were characterized through the use of research-based classroom discourse practices (Hufferd-Ackles, Fuson, & Sherin, 2004; Smith & Stein, 2011). Data gathered in this qualitative case study included a pre and post belief survey, interviews, classroom teaching observations, and methods class observations and assignments. This report is drawn from the findings from the first year of a two-year study.

Findings indicate that participants with differing beliefs were impacted in different ways. The methods course co-instructor began the collaboration with stable beliefs that were more reform-oriented than the other participants and classroom practices that clearly displayed those beliefs. She was conflicted as she compared her practice to the research-based practices described in course readings and said "I found myself really evaluating myself" (Interview 1). Though her beliefs measure did not change, she implemented new pedagogical tools in order to more closely align with research-based practices. The CT's original measure of beliefs was less reform-oriented than the co-instructor's measure by a statistically significant amount. His beliefs were found to be context specific based on comments such as ". . . [the role of student discourse] might be constantly changing depending on the topic that we're talking about" (Interview 5). Although he did not, as requested, read the course readings or participate in methods discussions, he was open to new ideas brought in by the PST. He did not express conflict between research and practice. However, his beliefs measured substantially more reform-oriented on his post-survey than on his pre-survey. The PST also exhibited a shift in the measure of his beliefs toward more reform-oriented beliefs. His beliefs were in transition throughout the year as he struggled to construct a vision of reform-oriented practices within the application of day-to-day teaching.

Exposing these PDS participants to best practices during a methods course and through classroom instruction had varying impacts. This indicates the need for future investigation into the trajectories along which teachers at all levels move as they make changes in their practice and for understanding of how beliefs interact with these trajectories.

WHO TEACHES MATHEMATICS CONTENT COURSES FOR PROSPECTIVE ELEMENTARY TEACHERS? RESULTS OF A NATIONAL SURVEY

Joanna O. Masingila
Syracuse University
jomasing@syr.edu

Dana E. Olanoff
Widener University
deolanof@syr.edu

The mathematical experiences that prospective elementary teachers have during their teacher preparation are vitally important. However, there is evidence that many prospective teachers do not receive adequate experiences from their teacher education programs in order to develop deep, conceptual knowledge of the mathematics that they will teach (Ball & Bass, 2000; Greenberg & Walsh, 2008). Teachers of mathematics content courses for prospective elementary teachers play an important role in helping prospective teachers acquire the knowledge they need for teaching, however, not much research has been done on this important group of educators.

This research reports on a national survey of higher education institutions in the United States to answer the question, "Who teaches mathematics content courses for prospective elementary teachers, and what are these instructors' academic and teaching backgrounds." We surveyed 1,926 institutions and a faculty member from each of 825 institutions (42.8%) participated in the survey. The survey results demonstrate that the majority of institutions are not meeting the recommendations of the CBMS (2001), the NCTM (2005), and the NCTQ (2008) for prospective elementary teachers to take at least nine credits of mathematics content designed for them. Additionally, most instructors for these courses do not have elementary teaching experience and have likely not had opportunities to think deeply about the important ideas in elementary mathematics, and most institutions do not provide training and/or support for these instructors. If nothing changes with the preparation and professional development of these instructors, the cycle of unprepared prospective teachers whose college experience has little effect on their mathematical understanding (CBMS, 2001) will continue.

In order to change this situation, we first suggest that all institutions preparing elementary teachers offer and require at least nine credits of mathematics content courses designed for this population, and prepare and support the instructors who teach these courses. We also suggest that there be collaboration among instructors. Institutions with multiple instructors can form communities of practice at their sites. Instructors who are alone in teaching these courses at their institutions can seek out instructors at other institutions for support. Professional organizations, such as the Association of Mathematics Teacher Educators (AMTE), offer resources through membership, conference sessions, and pre-conference workshops. Finally, our survey results, combined with other research on prospective elementary teachers' achievement, may help the mathematics education community develop standards for the teacher educators who teach mathematics content courses for this population.

GENERATING A PEER MENTORING CULTURE THROUGH MATHEMATICS CAMPS

Gabriel Matney
Bowling Green State University
gmatney@bgsu.edu

One of the hallmarks of a preservice teachers' transition into the profession is their aptitude and desire for sharing ideas and overcoming difficulties faced by the community of teachers. Teacher educators strive to design programs that address the many facets necessary to foster preservice teachers through the transition from student to professional educator. In many cases preservice teachers move according to a prescribed program of study in which they learn from professors, engage in tutoring and/or field experiences with students, and apply their knowledge in an internship with an experienced mentor teacher. During the program of study there is typically cooperation with peers for group work on designing lessons, units, pedagogical strategies and portfolio development (Davis & Honan, 1998; Freidus, 1998), but there is not a significant and prolonged collaboration among preservice teachers in solving the immediate problems presented by issues such as disengaged students, struggling students, or students with behavior problems. What would it mean for a program to increase expectations and transition from peer collaboration to peer mentoring by enacting teaching in mathematics camps?

In this poster I will describe an *exploratory evaluation* study (Patton, 1987) of a mathematics teacher program at a university in Southeast Asia. The program in the study incorporated mathematics camps with public school children from grades K–12 each semester. Preservice teachers in the program were expected to design, implement, assess, discuss, and redesign mathematics camp curriculum and processes. The mathematics camps were enacted for many different grade levels and schools in the local community. The preservice teachers applied their learning from mentors and their experiences from each camp to become more effective at engaging students in enjoyable learning of mathematics. First-year preservice teachers are mentored by the second- and third-year preservice teachers. In the first year they learn about the camp structure and participate as students in a large camp experience. Second-year preservice teachers are mentored by the third-year preservice teachers in the design, implementation, assessment, discussion, and redesign process. The second-year students work alongside the third year to enact the camps in several schools each academic semester. Third-year students are in authority at the camps and must ensure their success. They may consult their fourth- and fifth-year elders and their professors on issues that arise, but during the camp, they must make the decision they feel is best and then reflect on that decision with others later.

The resulting descriptions from the study suggest the program has a rich and endearing peer mentoring culture that has been established through the teaching of mathematics camps with local school students. These descriptions reveal that through the peer mentoring and the teaching during the mathematics camps preservice teachers have a strong bond to others within the profession and the mathematics unit. Preservice teachers also appear to operate with increasing pride and efficacy in their teaching of mathematics. Lastly, there is evidence of significant development of the preservice teachers social, organization, and leadership skills as they progress through the program.

EXAMINING PRESERVICE TEACHERS' PERSPECTIVES ON WRITING IN THE MATHEMATICS CLASSROOM

David Norris
Purdue University
norris@purdue.edu

Rachael Kenney
Purdue University
rhkenney@purdue.edu

Melanie Shoffner
Purdue University
shoffner@purdue.edu

Secondary mathematics preservice teachers (PSTs) are typically well grounded in content knowledge; however, the development of their ability to teach mathematics is not an automatic outgrowth of their content knowledge, as it may be impeded by issues such as the influence of past experiences and an inability to recall their own developing conceptions of mathematics.. Our research objective was to examine how engagement in two activities: *writing to learn mathematics* (WTLM) and *reflection,* can broaden perspectives on what it means to teach and learn mathematics . Through writing, learners can monitor strategies used in problem solving (Countryman, 1992), while reflection engages existing understandings of mathematics and supports the development of new understandings about teaching and learning (Shoffner, 2009).

Data for this study consisted of PSTs' in-class WTLM activities and discussions and reflective writings posted in a wiki during a six-week mathematics methods course. The PSTs reflected on their experiences with WTLM and answered specific prompts about their conceptions of the use of writing as tool for teaching and learning in mathematics. We analyzed these reflections to examine teachers' growing perspectives on the use of this tool.

Initially, PSTs explained that, in their experiences, writing in mathematics was limited to geometry or proof. Many PSTs could not recall writing in mathematics in high school, and felt that it was "kept to a minimum." Those that did recall writing in mathematics considered it "pointless" or "tedious." Inexperience with writing influenced PST's ideas about how students might view WTLM and often led to initial reluctance toward using it in their future classroom. Many felt that writing in mathematics classroom would "distract" from the "real" mathematics.

Following their engagement in multiple WTLM tasks and reflective discussions on the course wiki pages, we were able to identify several changes in PSTs' perceptions on the use and role of writing in a mathematics classroom. Many PSTs now mentioned teacher benefits in their final posts, lauding WTLM's usefulness for knowing how different students think about mathematics. One suggested that "verbalizing helps make more connections to the concepts and may be helpful in clearing up any discrepancy that the student might have." The PSTs' reflections to their own responses to the WTLM prompts seemed to frame their content knowledge in a pedagogical context. Upon completing the WTLM tasks, some PSTs focused their reflections on the students that they would be teaching and some issues that they may need to consider. After considering how students might view a problem they worked on, the PSTs began to consider pedagogical decisions that they might make to build on students' thinking.

This research suggests that many PSTs are willing to accept WTLM as a useful tool to help students understand mathematics after engaging in WTLM tasks themselves. Teachers must be able to understand and explain mathematics in multiple ways in order to reach all students. By diversifying and expanding approaches to mathematics, teachers may support multiple learning styles and address diverse learners.

PRESERVICE TEACHERS' PERCEPTIONS WHERE INSTRUCTION IN COLLEGE COURSES EMPHASIZES CONNECTIONS TO MIDDLE GRADES MATHEMATICS

Travis A. Olson
University of Nevada, Las Vegas
travis.olson@unlv.edu

Melfried Olson
University of Hawai‘i at Mānoa
melfried@hawaii.edu

The Conference Board of the Mathematical Sciences (CBMS) (2001, 2012) and Wu (2011) suggest that instruction in mathematics courses for preservice secondary mathematics teachers (PSMTs) should emphasize a connection between the mathematics they are learning and that which they will teach. In this poster we will present the results of a survey given to PSMTs in which they identified college mathematics courses that specifically addressed the content in the Common Core State Standards for Mathematics (CCSSM) (2010) to be taught in grades 7–9.

Keywords: Teacher Education–Preservice; Mathematical Knowledge for Teaching

One CBMS recommendation is that in their preparation PSMTs should have the opportunity to develop, "Knowledge of the mathematical understandings and skills that students acquire in their elementary and middle school experiences, and how they affect learning in high school" (CBMS, 2001, p. 39). For more than a decade, there has been increased interest from the mathematics community to address this issue. With respect to the need to deeply understand K–12 mathematics, Wu (2011) notes that, "Because of the teacher preparation programs' failure to teach content knowledge relevant to K–12 classrooms, the vast majority of preservice teachers do not acquire a correct understanding of K–12 mathematics while in college" (p. 9).

To understand PSMTs experiences in mathematics coursework, a survey was developed to investigate in what college mathematics courses the instruction received mentioned that the mathematical ideas being taught pertain to them as future teachers of mathematics in grades 7-12. Twenty-three key mathematical content standards in the 7th grade, 8th grade, and parts of the Algebra strand of the CCSSM were chosen for the survey.

Programs of study for PSMTs at four institutions of higher education in four different states were examined and compared to the suggestions by CBMS (2001). After considering titles of courses or content included in courses, the comprehensive list of courses developed reflected the required content in the proposed courses of study for PSMTs in each of these universities.

Methods courses were identified at nine institutions of higher education and instructors were sent an electronic survey link to provide to their students. In total, 33 PSMTs at five institutions responded. Among the data to be shared is that from the courses available, PSMTs identified *Calculus or Advanced Calculus*, *Probability and Statistics*, *Linear Algebra*, *Abstract Algebra*, and *Discrete Mathematics/Computer Science*, in order, as the courses where the content was at some point taught with regard to their future as a secondary mathematics teacher.

USING CLASSROOM PHOTOGRAPHS TO SUPPORT PRESERVICE TEACHERS' NARRATIVES OF MATHEMATICS TEACHING

Joy Oslund
University of Michigan
oslund@umich.edu

Sandra Crespo
Michigan State University
crespo@msu.edu

Keywords: Teacher Education–Preservice; Instructional Activities and Practices; Elementary School Education; Design Experiments

On this poster we explore classroom photos as tools for eliciting and supporting pre-service teachers' (PSTs') narratives of math teaching and learning. Because narratives are the primary means for making sense of and learning from life experiences, they are useful in supporting teacher candidates' sensemaking and transitions from college students-to preservice teacher-to teacher intern-to beginning teacher. Our work with photographs was inspired by Carter and colleagues' (1988) use of photographs as prompts to research expert-novice teacher knowledge and by Chazan and Herbst's (2006) use of cartoon representations of mathematics teaching in their TheMat Project. It brings into relation research on representations of practice as a means to improve teachers' attention to and reflection on critical features of mathematics instruction (e.g., Herbst & Chazan, 2006; VanEs & Sherin, 2006) and the teacher learning literature that conceptualizes narrative as a sensemaking activity (e.g., Carter, 1988; Drake, 2006; Lloyd, 2006).

In our case, groups of four PSTs were each given one of six different sets of approximately twenty classroom photos and asked to create a flip book, including thought and speech bubbles and captions. Each set of pictures represented classroom scenes from the launch, explore, and debrief sections of a math lesson. After constructing a flipbook that organized the set of photos visually, preservice teachers were then asked to write a plausible mathematics teaching story to describe their flip book. We provide an analysis of these artifacts using an emerging analytic frame participants in this study used to describe and interpret classroom events in terms of teaching—*moments, perspectives, and settings*—within and across classroom photographs while constructing mathematics lesson stories. We describe how participants depicted and narrated teaching *moments*, meaning that they spent significant time unpacking instructional moments of varying time scales in the lesson. They noticed *perspectives*, often narrating the story from different points of view (e.g., students or third-person). They noted the *settings*, meaning that they discussed details of physical materials and space and the role these play in the lesson. We argue that this expanded frame is important, and that photographs and narratives have particular affordances for supporting its development during and beyond teacher preparation.

ANALYZING THE EVOLUTION OF THE FIELD OF MATHEMATICS EDUCATION: A HISTORICAL PERSPECTIVE

Farshid Safi
The College of New Jersey
safi@tcnj.edu

Keywords: Post-Secondary Education; Teacher Education; Technology

Due to the interdisciplinary nature of mathematics education which intersects areas of mathematics, learning theory, educational psychology and others; research efforts have struggled to document the development and evolution of the field (Stanic & Kilpatrick, 2003). Several reviews of doctoral programs and their history of producing mathematics education doctorates have been compiled which have positioned this research effort to develop a systemic, data-driven way to analyze a progression of the field over the course of the past century (Reys & Kilpatrick, 2001; Reys, Glasgow, Tuescher, & Nevels, 2008). This on-going research project aims to dynamically illustrate the evolution of mathematics education since 1906 and demonstrates the impact of academic institutions, and certain influential figures that have helped to mentor and develop future generations of mathematics educators. Some doctoral programs in mathematics education have produced a significantly greater number of leaders who have been vital in advancing teaching, research, curriculum efforts; have shaped educational policies, and contributed to the success of the discipline through committees and professional organizations. Utilizing an innovative and extensive data-driven approach (see Table 1), some of the primary research objectives and initial findings of this project have been illustrated.

Table 1: Goals and Results

MATHEMATICAL KNOWLEDGE FOR TEACHING: THE CASES OF TWO PRE-SERVICE TEACHERS WITH ENGINEERING BACKGROUNDS

Ravi B. Somayajulu
The Ohio State University
somayajulu.1@osu.edu

Reports of studies documenting sources of secondary mathematics teachers' pedagogical decision making or the nature of their Mathematical Knowledge for Teaching (MKT) are rare (Goos, 2010). Efforts towards establishing a framework for capturing and measuring MKT for teaching high school Algebra are currently ongoing (McCrory et al., 2010). In this work I adapted the Knowledge for Algebra Teaching (KAT) to examine pre-service teachers' mathematical knowledge pertaining to the framework's tasks of teaching as manifested during episodes of bridging, decompressing, and trimming when making instructional decisions in an attempt to answer the following question: *What factors do pre-service teachers consider when judging students' mathematical work and thinking?*

The proposed poster offers an analysis of two specific cases studied as they assessed instances of children's geometric work and/or their questions concerning geometry content. I examined factors they considered when conceptualizing instructional plans in the presence of these episodes. The two focus participants were from engineering backgrounds (computer engineering and industrial engineering). The decision to focus on these two participants was deliberate. On one hand, initiatives to recruit individuals from non-mathematical backgrounds into the profession of teaching are now widespread. It is crucial to gain a better understanding of the orientations they bring into teaching and teacher education so to design environments conducive to their learning. On the other hand, an examination of the two cases offer valuable insight into how expert practitioners in one field, engineering in this instance, who are also novice to teaching, might attempt to make sense of tasks of practice.

At the time of data collection, both participants were enrolled in a Master of Education program. Each participant completed written surveys which included case based illustrations of children's work for analysis. Each participant was also interviewed. The goal of the surveys and the accompanying interviews was to capture knowledge sources from which they drew when assessing students' work, factors most influential on their thinking about ways to design instruction based on students' ideas/questions, and resources they found most valuable when navigating these demands.

The two pre-service teachers differed in their methods of judging student work based on their level of understanding of geometry. For both the participants, their analysis of student work was influenced by curriculum. The interviews with the participants revealed that while one participant attempted to use learning progressions to analyze student work and plan instruction, the other participant did not perceive learning progressions as useful while making in the moment pedagogical decisions.

ASSESSING PROSPECTIVE ELEMENTARY TEACHERS' ABILITY TO MAKE LINKS BETWEEN TEACHING AND LEARNING

Sandy M. Spitzer
Towson University
sspitzer@towson.edu

Christine Phelps
Central Michigan University
phelp1cm@cmich.edu

Teacher education represents a key milestone in the professional learning continuum, as it is during this time that teacher candidates must transition from student to teacher. Part of successfully making this transition is gaining an analytical approach to teaching. One model for *the systematic analysis of teaching* (Hiebert, Morris, Berk, & Jansen, 2007) proposes four analytic skills which support continuous teacher learning from practice: specifying learning goals, gathering and analyzing evidence of student learning, constructing hypotheses which link the effects of teaching to students' learning, and revising lessons. By using these skills, PTs can understand teaching in terms of students' mathematical learning outcomes, a critical transition in their development as teachers.

The ability to construct hypotheses linking teaching and learning (the third skill in this model) is especially critical to improving instruction over time because it can lead to productive lesson revisions and build general knowledge about effective teaching (Hiebert et al., 2007). However, little current research has examined how PTs construct these hypotheses. This study represents a first look at PTs' initial ability to link teaching and learning in a mathematics lesson. PTs read a transcript of a lesson and were prompted to describe what aspects of the lesson and teacher actions might have led to student learning outcomes. Data were analyzed based on theoretical criteria for useful cause-effect hypotheses as outlined by Hiebert et al. (2007). These criteria include whether hypotheses: (a) were focused on the mathematical learning goal; (b) cited or followed from evidence of student learning; (c) included specific detail; (d) were appropriately cautious; (e) made a link between teaching and learning; and (f) were based on pedagogical principles.

Results indicate that while PTs demonstrate some skill in hypothesizing before instruction, this skill requires further development along specific dimensions. Across the sample, PTs cited student understanding of least some aspect of the mathematical goal in approximately half of their hypotheses. PTs were less likely to mention mathematical aspects of the teacher's actions (cited in approximately one-third of hypotheses). Unfortunately, even when describing students' understanding of the learning goal, PTs did not always cite evidence to support their claims. Only about one-third of hypotheses included supporting evidence. Over 60% of PTs' hypotheses were inappropriately vague or general about lesson features or outcomes. Finally, PTs were rarely cautious in their claims, with approximately 80% of hypotheses stated as fact.

In terms of making links, wide variation existed between individual PTs, with some PTs consistently making links between teaching and learning and others making few or no links. Although nearly all PTs drew on pedagogical principles when constructing at least some of their hypotheses, the fact that they often cited beliefs that were not in alignment with a conceptual learning goal made some of their hypotheses problematic. Interventions aiming to improve PTs' ability to write hypotheses linking teaching and learning could be built upon this description of their baseline skills.

PEDAGOGICAL CONTENT KNOWLEDGE FOR TEACHER EDUCATING

Scott Zollinger
The Ohio State University
zollinger.4@buckeyemail.osu.edu

Azita Manouchehri
The Ohio State University
manouchehri.1@osu.edu

Keywords: Post-Secondary Education; Teacher Knowledge

Research concerning the practice of mathematics teacher educating, and knowledge bases used in such a practice is lacking (Speer, Smith, & Horvath, 2010). As a result, a shared knowledge base regarding mathematics teacher educators is yet to be developed. To address this need our study was conceptualized to investigate: (1) What knowledge domains do mathematics teacher educators draw from and use when providing content specific pedagogical experiences for teachers? and (2) How do these knowledge domains influence the activities of mathematics teacher educators as they design and implement pedagogical experiences for teachers? This presentation will report preliminary results from the pilot study.

Data were collected using in-depth interviews, classroom and professional development session observations, and existing documents prepared and used by the participants when organizing activities around teacher educating. Participants included faculty members in mathematics and science education, and school mathematics leaders involved in a PD program.

Data analysis consisted of three levels. At the first level of analysis, a case profile for each of the participants was developed. The framework for analysis of each case included the domains of knowledge referenced by the participants use of mathematical knowledge for teaching (Ball, Thames, & Phelps, 2008), Shulman's (1986) categories of pedagogical content knowledge, knowledge of algebra for teaching (Ferrini-Mundy, McCrory, & Floden, in revision), and constructs identified as crucial to educating adult learners (Marquardt & Waddill, 2004; Mezirow, 1981). Participants' comments, both during the interviews as well as observation sessions were coded according to indicators of knowledge identified by each construct. At the second level of analysis we conducted a cross examination of all cases as a means to generate a comprehensive list of knowledge domains expressed to be used, or used in practice by the participants. This cross analysis allowed us to isolate unique aspects of knowledge for teacher educating in various fields and according to other variables of concern. The final analysis included careful categorization of the referenced and enacted knowledge domains by mathematics teacher educators.

THE MAKING OF A MEANING MAKER: AN ENGLISH LEARNER'S PARTICIPATION IN MATHEMATICS

Higinio Dominguez
Michigan State University
higinio@msu.edu

This paper focuses on meaning making as a process that can transform English learners' participation in mathematics. Using selected video transcripts from a one year long project in a fourth grade bilingual classroom, the paper documents the development of participation along a continuum of meaning making, from preparing students to transform their participation to creating meaning eliciting tasks to showcasing students in meaning making interactions. Findings suggest that the problem of participation in mathematics by English learners—and other students as well—is a problem rooted in the absence of meaning making practices in mathematics classrooms.

Keywords: Meaning Making; Participation; English Learners; Elementary School Education

Purpose

The purpose of this paper is to contribute an understanding of English learners' participation in mathematical discussions as a deliberate meaning-making process that is initiated by the teacher, interpreted by an English learner, and reinterpreted by peers. The paper documents the development of meaning making practices with a focus on an English learner's participation in a Latino classroom. The focus on this student serves to illustrate the intricacies of meaning making and how it transforms and is transformed by participants. Through this analysis, the paper highlights the importance of re-envisioning student participation in mathematics not as an individual act but rather as a continuum of meaning making moments. Along this continuum, participation emerges as a meaning-oriented, other-oriented process.

Theoretical Foundation

The issue of who participates in mathematics has been explored from an equity perspective (Gutiérrez, 2010; Khisty & Chval, 2002), a status and domination perspective (Cohen & Lotan, 1995, Pierson Bishop, 2012, JRME), a racial perspective (Martin, 2007; Stinson, 2010), and a sociocultural perspective (Moschkovich, 2002), among others. This paper focuses on a meaning-making perspective to understand English learners' participation in mathematics. I view meaning making as foundational to student participation in mathematics. The critical need for bringing meaning making into teaching and learning mathematics has been highlighted in research (Schoenfeld, 1991). A view of participation as rooted in meaning making affords a critique of participation as individual and behavioristic and shifts our attention to participation as a continuum of various forms of participation, none of which can stand alone in a significant manner. As Sfard (1998) explains her metaphor of learning as participation, "[f]rom a lone entrepreneur, the learner turns into an integral part of a team" (p. 6).

I start this theoretical foundation with a definition of meaning making as "the translation of one sign into another system of signs" (Jakobson, 1985, p. 251). By translation I refer to the interpretive and continual process of recreating signs (e.g., 9 is also 5 and 4), reconstructing images (e.g., the area of an irregular shape is also the sum of the areas of regular shapes), social representations (Gorgorió & de Abreu, 2009) (e.g., an English learner can solve problem *a* but not problem *b*), and task adaptations (e.g., 272 divided by 8 can be transformed into an open ended task). The expression of meaning is only possible through signs (Radford, Schubring, & Seeger, 2011). However, signs alone refer to objects that are meaningless (e.g., a 9 remains as a 9, or an English learner can remain as someone who can only solve problem *a*) unless participants translate them along a continuum of possible meanings (Otte, 2011). The active translations and interpretations of signs—meaning making—characterize rich participation in mathematics. For example, the number 9 is a sign that, by itself, has no meaning. It requires a student's interpretation as “1 less than 10,” or as “5+4,” or as “3 × 3,” etc. An open-ended task in this framework is a powerful sign in that it invites multiple interpretations from students. A teacher who uses open-ended tasks is primarily interested in the meaning that students will make.

Methods (Participants, Context, Data Collection, Analysis)

Data collection consisted of video taping of the problem of the day in a bilingual Latino fourth grade classroom, four times a week, for an entire school year. At the time of the data collection, the teacher was in her first year of practice. At the beginning of the project, the problem of the day consisted of low-level mathematics tasks, often copied from the school’s adopted textbook. However, she was interested in increasing student participation but did not know how to make it happen. Students, including Sam the English learner who is the focus of this paper, came to her classroom with a history of traditional mathematics instruction from the previous three years. Students were used to the Initiation-Response-Evaluation pattern of participation (Mehan, 1985) found in most U.S. classrooms. For example, Sam would only participate when called on by the teacher, and his ideas would not travel outside the teacher-student interaction. Another form of data collection consisted of reflection and co-planning sessions with the teacher, usually at the end of the school day, and on weekends. The problem of the day used in this analysis was developed during one of these reflection and co-planning sessions.

To analyze data, I selected interactions from video recordings produced at the beginning of the school year, when students were showing resistance to the teacher’s new plan for participation. I also selected interactions toward the end of the school year to illustrate how students were relearning new ways of participation. I transcribed these selected videos. Then I applied the ideas from the theoretical foundation to document how participation emerged as a continuum of meaning making.

Results

Results are intended to illustrate the arduous process of making meaning makers. Years of being denied opportunities to participate in meaning making result in this arduous process of reminding, convincing, and preparing students to participate as meaning makers. Results illustrate moments of tension as students learned to transition from older ways into new ways. An important meditational tool in this evolution of participation was the transformation of mathematical tasks and the roles, norms for participation, and expectations that these tasks required.

Preparing Students to Transform their Participation

At the beginning of the school year, students were used to working in mathematics individually. The prevalent participation pattern was between individual students and the teacher, with the rest of the group acting as passive spectators. How comfortable students were in this participation structure became apparent as the teacher introduced the new norms of participation. These new norms met students’ strong resistance. Their reaction evokes Sherin, Louis, and Mendez’s (2000) comment about how hard it is to make students participate in mathematical discussions. Students were initially participating *for* the teacher, as evidenced by the kinds of questions they were asking the teacher:

“Ms. R, do we take out our math journal?”
“Do we need to copy that?”

Students were also challenging the new rules of participation with expressions of resistance:

“What does this have to do with math?”
“Ms. R, why are we doing all this? Can you explain it to me?”
“Ms. R, are we learning anything here?”

In the midst of these complaints, the teacher and I also noted that students were noticing something about the tasks. For example, when the teacher was explaining the new rules of participation, hearing the teacher say “problem of the day,” three students suggested:

"Why can't there be a problem of the week? Or the month?"
"Yeah, like a really, really hard good question."
"Yeah. That would be good."

Translating the Mathematical Task

In our initial conversations, the teacher and I had a clear goal: We wanted students to participate by responding to each other's contributions instead of responding only to the teacher. We were confident that strong, open-ended mathematical tasks—or as students suggested, "like a really, really hard good question"—could be our ally in achieving our goal. The problem I use in this paper was originally conceived as a single version that the teacher and I translated into two related versions. One version was a measurement division problem; the other was a partitive division (see Table 1).

Table 1: Measurement and Partitive Division Tasks

Measurement Division (size of group known; number of groups unknown)	Partitive Division (size of groups unknown; number of groups known)
1. Ortega Elementary has 272 students. For the fire drill, students were placed in rows of 34 students. How many rows did they form?	2. Sanchez Elementary has 272 students. For the fire drill, students were placed in 8 rows. How many students were in each row?

We split the group in half and each group received one of these two problems. On the back of their problem, we included a discussion question: Explain which school has a better fire drill, Ortega or Sanchez. The teacher instructed students to save this question for a final discussion. One student, however, could not resist the curiosity of reading the question, and he exclaimed:

Rolando: "But this doesn't make any sense!"
Teacher: (touches Rolando on the shoulder): "But it'll make sense whenever you hear what the other problem (points to other group) is about."
Rolando: "Oh!"

Rolando was not finding meaning in the question. For him, the question was a sign disconnected from other signs, therefore lacking meaning. The teacher, however, reminded Rolando that meaning was about to emerge as soon as all participants translated this question along a continuum of ideas. The teacher's reply to Rolando is consistent with a view of meaning as other-oriented (Dominguez, López Leiva, & Khisty, 2012), and it may be difficult to emerge in the sole act of Rolando reading the question.

Making an English Learner a Meaning Maker

The teacher asked each group to read their version of the problem to the other group to establish a common understanding that they had been working on different problems. Some students claimed that the problems were the same, only that the words were different. The teacher helped students with this initial translation of each other's signs (the problem) by emphasizing that one problem was asking for the number of groups, whereas the other was asking for the number of student in each group. But the important part of this interaction came next, when Sam, an English learner, raised his hand to participate, in English. What follows is the process of the teacher and peers collectively making Sam a meaning maker.

Sam: "Ms. Ramos, I did a picture of eight, eight…"
Teacher: "Can you stand up and show what you did?"
(Sam stands up, holding his notebook high up for the other group to see) (See Figure 1.)
Teacher: "Can you explain it to them?"
Sam: "I put 8 rows, 8, 8 lines, and I did it like this, it's the, it's the, it's the rows, and then I put 34 in each row, the number, and then I knew that 34 × 8 is 272."
Teacher: "OK, go ahead and show them what you did (signals to go to the other group's table) 'cause I don't think they can see that when you are standing way over here."

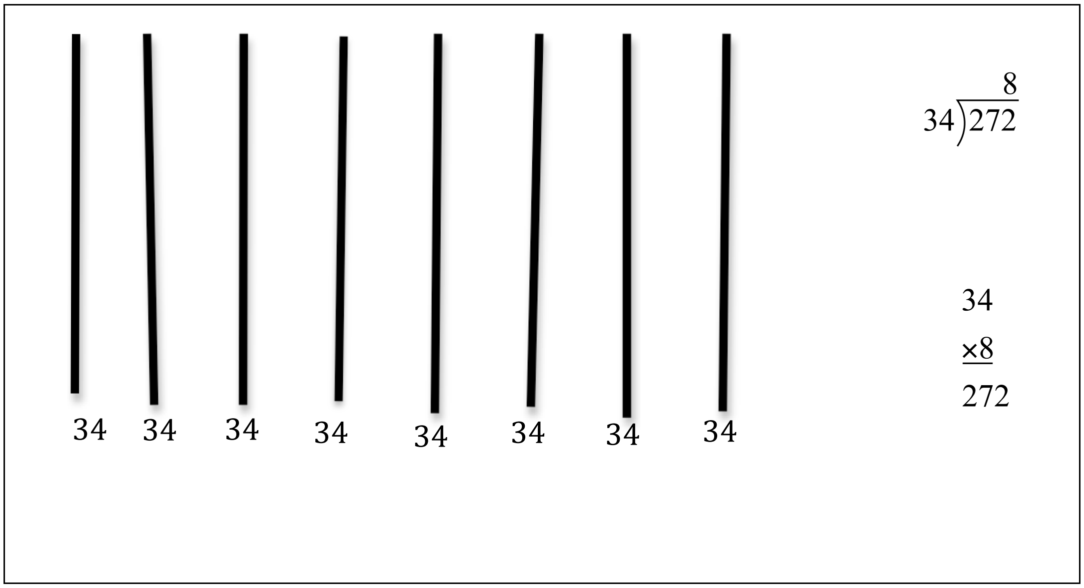

Figure 1: Sam's strategy

When the teacher asked Sam to stand up, she is translating Sam as capable of explaining his strategy to others. By asking Sam to explain his strategy, she is establishing the conditions for the creation of a continuum of meanings, as meaning depends on others to grow. Sam takes up the teacher's translation of him, but his standing up and showing his work has not yet created a continuum of meanings. The teacher seems to be interested in seeing this continuum, as she asks Sam to explain what he did to his audience. In the act of explaining, Sam may find the possibility of refining his translation of the problem (his strategy) for himself and for others. Although Sam accepts the teacher's new translation of him as a capable explainer, he performs this new role from where he is standing distance. The teacher wants to ensure that everyone hears Sam's translation, so she asks Sam to approach the group. Here, the teacher is interested in Sam's audience and their ability to interpret Sam's translation. The teacher is establishing the conditions for making every student a participant in the process of making meaning. She picked Sam as the carrier of a sign to be translated first by him and then to be interpreted by his peers. In the following section, Sam will encounter multiple interpretations of his work as he interacts with peers. The continuum of meanings at this point begins to take shape.

Students Interpret an English Learner's Strategy

Sam walks toward the other group. At the same time that he starts walking, Joel, the same student who, in the beginning of the year, was questioning the new way of participating in mathematics, initiates a student-student interaction focused on Sam's mathematical strategy.

Joel: "What was that for?" (pointing to Sam's drawing)
Sam: "The rows!" (points to his 8 rows)
Joel: "Why did you need it? Why did you do that?"
Sam: "So I can show my strategies. So, some people do believe me. Like this!" (points to Joel's strategy, who drew 8 circles on his notebook instead of 8 lines like Sam did) (See Figure 2)
Joel: "Oh, Oh, every line means a row?"
Sam: "Yeah!" (turns palm of his hand up, as if indicating the obviousness of his meaning)
Joel: "Oh!"
Student: "Duh, dude!" (teasing Joel)
(Sam walks around the table, holding his notebook by his chest so peers can see).

Jennie: “Wait, don’t go so fast! Wait, why did you put 34 in each row? The way you put that.”
Sam: “Because it says right there in the question, that there’s 34 students in one row.” Jennifer: “Oh.”
Liz: “Ah, hey! Wait! How did you know that 34x8 is 272?”
Sam: “Because I did this and then I did this.” (points to his division, then to his multiplication, and finally to his drawing)

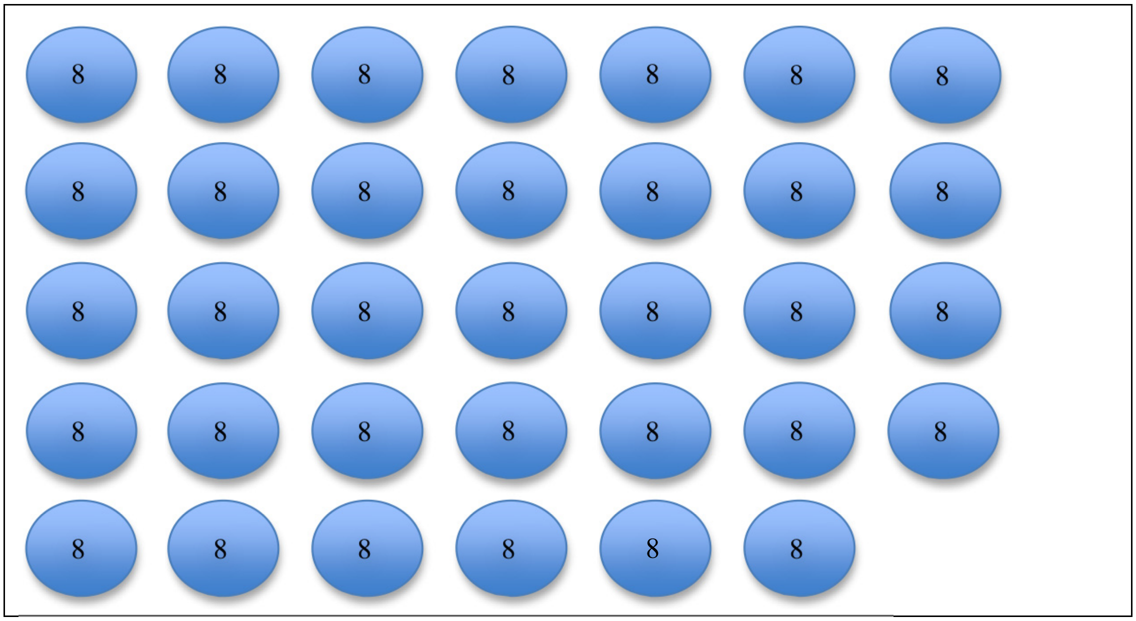

Figure 2: Joel’s strategy

In this interaction, peers are translating Sam as a meaning maker. First, Joel demonstrates interest in Sam’s strategy. Sam responds by placing his strategy (his own translation) along his peer’s strategy (Joel’s own translation), thus establishing a student-generated continuum of meanings. Sam’s strategy in itself reflects his sensitivity to this emerging continuum of meanings, as he represented his strategy in different ways. For example, his response to Joel, “So, some people do believe me” is consistent with the multimodality of his strategy, which includes iconic representations (8 vertical lines representing 8 rows) and also symbolic representations (multiplication and division). Sam has in other words recreated signs for multiple interpreters (so some people would believe him) and has maintained these translations of signs meaningfully connected.

At this point in the interaction, Sam does not need the teacher’s prompts any more. Instead, he shows his strategy to peers spontaneously. At the same time, peers continue asking him questions, in what exemplifies the rarest form of whole group discussion in mathematics, one in which students themselves mediate and control their own participation. The teacher was sitting in one corner of the room, enjoying the unfolding of this discussion. It is important to note that Jennie’s question is a request for an explanation (*why*) and Liz’s question is a request for a justification (*how did you know*). The caliber of these questions, and the fact that they are the building blocks in a discussion for learning mathematics (NCTM, 2000) demonstrate that as a whole, Sam’s peers have helped the teacher to effectively construct an English learner as a meaning maker. And in this collective act, all participants constructed themselves as meaning makers as well.

Discussion: The Making of Meaning Makers

Teachers, students, tasks, and instructional strategies, all contribute to make different kinds of meaning makers. Prior to the interaction reported in this paper, particularly at the beginning of the school year, students were making meaning for and by themselves, sharing it occasionally with the teacher. As one student frankly put it,

Josh: "But this is the first time we've done it in groups. We've always doing it by ourselves."

Similarly, when the teacher asked whether all students had found a group to be in, two students replied:

Mandy: "No! Not all of us."
Joel: "It's more like, per person."

I chose the case of Sam, an English learner, for several reasons. First, Sam illustrates how status in classrooms can shape who gets to participate (Cohen & Lotan, 1995). Second, when tasks offer students the possibility of making meaning in multiple ways, students like Sam can be motivated to share with others their understandings and strategies. Third, the fact that the teacher selected Sam as the representative of his group, was a powerful instructional strategy that served to achieve multiple goals: sharing meanings, creating a continuum of ideas, and translating low status students as active and capable participants in the process of making mathematical meaning.

LEARNING TRAJECTORIES AS A TOOL FOR MATHEMATICS LESSON PLANNING

Cyndi Edgington
North Carolina State University
cpedging@ncsu.edu

In this paper, I examine the utility of a mathematics learning trajectory as a tool to support teachers' attention to students' mathematical thinking. I present findings from one second grade teacher's use of a learning trajectory as she planned a sequence of three mathematics lessons. Findings suggest learning trajectories support teachers in choosing appropriate tasks and learning goals, and in anticipating students' likely approaches and difficulties. Learning trajectories, as representations of student thinking, provide teachers with a means of evaluating evidence of student learning of intended goals and afford them with a range of instructional moves based on their students' current conceptions.

Keywords: Learning Trajectories; Instructional Activities and Practices

Attention to student thinking has been identified as a critical tool to initiate changes in teachers' knowledge for teaching and improvements in classroom instruction (Fennema, Carpenter, Franke, Levi, Jacobs, & Empson, 1996; Franke, Carpenter, Levi, & Fennema, 2001; Kazemi & Franke, 2004; Sherin & van Es, 2009). Moreover, an emerging hypothesis in the field is that the construct of a *learning trajectory* (LT) has the potential to support teachers in making sense of and use student thinking to improve teaching and learning. The authors of the Common Core State Standards (2010) emphasized the use of research-based LTs in the development of the new standards and committed to using research and evidence of student learning to inform future revisions. Daro, Mosher, and Corcoran (2011) state that LTs serve "as a basis for informing teachers about the (sometimes wide) range of student understanding they are likely to encounter, and the kinds of pedagogical responses that are likely to help students move along" (p. 12). However, little is known about how teachers come to learn about LTs and appropriate them into their instruction. In this study, I identify the ways in which one elementary teacher used a LT to support attention to her students' mathematical thinking during instruction. In particular, the teacher's use of the LT as she planned her math lessons, identified learning goals, and anticipated likely student responses will be highlighted.

Background

Learning trajectories utilize research on student learning to describe probable pathways of learning over time. Researchers that have studied the implications of LTs for teachers have found that LTs provide a framework for making instructional decisions (Bardsley, 2006; Sztajn, Wilson, Confrey, & Edgington, 2011b; Wilson, 2009) and afford teachers with a means to focus on their students' mathematical thinking (Clements, Sarama, Spitler, Lange, & Wolfe, 2011; Edgington, Sztajn, & Wilson, 2011; McKool, 2009; Mojica, 2010). As teachers increasingly attend to student thinking in lesson planning and instruction, research must consider the role of LTs in supporting teachers' complex work. Research has yet to address how teachers adjust their lesson planning and instruction when they have information about the progression of more sophisticated levels of thinking inherent in LTs, or how teachers use evidence of student thinking to inform future instruction in light of LTs. This study contributes to the research on teachers' uses of LTs to support attention to student thinking in planning for mathematics instruction.

For the purposes of this paper, I am reporting one teacher's use of a LT in lesson planning through three different processes: identification of learning goals, choice of instructional tasks, and anticipation of students' work. Often considered a core routine of teaching, lesson planning refers to the time teachers spend preparing for instruction before students enter the classroom. Grossman and colleagues (2005) refer to this as the "preactive" aspect of practice, where teachers focus on lesson planning, unit planning, or even planning for classroom management.

Studies on what teachers attend to in planning their lessons indicated that teachers focus on ideas such as content, activities or tasks, materials, textbooks, routines, as well as students' needs and backgrounds (Fernandez & Cannon, 2005; McCutcheon, 1980; Yinger, 1980; Zahorik, 1975). In his 1975 study of teacher planning, Zahorik showed that teachers attended to content more often than objectives, followed by activities. In a study of 12 elementary school teachers, McCutcheon (1980) found that teachers used their textbook as a main source for activities and depended heavily upon suggestions from the teachers' guide. In a later study, Brown (1988) examined the lesson planning practices of 12 middle school teachers in various content areas. She found that teachers relied heavily on curriculum materials, building their lessons off of objectives expressly stated in the curriculum resources.

More recently, Superfine (2008) studied three teachers' lesson planning with respect to a specific mathematics curriculum. Her study revealed two planning problems: difficulty anticipating student work, misconceptions, and potential errors for a given task, and understanding the treatment of the content in the curriculum. She concluded that the conceptions teachers hold with respect to the teaching and learning of mathematics as well as years of experience mediated their management of the planning problems.

Conceptual Framework

In light of reform efforts to improve the teaching and learning of mathematics, one may question what *should* be the focus of planning when instruction attends to students' mathematical thinking. Teachers must consider how to construct lessons that address specific learning goals and allow teachers to gather evidence of their students' understanding towards the chosen goals. Moreover, as student learning progresses over time, teachers must be able to consider how to build students' current conceptions to reach intended learning goals.

The conceptual framework for this study draws upon the work of Hiebert, Morris, Berk, and Jansen (2007) as well as that of Stein, Engle, Smith, and Hughes (2008). Hiebert et al. (2007) proposed a framework for competencies necessary to analyze teaching with the goal of improving on instruction. Stein et al. (2008) presented five practices to support productive mathematical discourse structured around students' responses to mathematical tasks. These two frameworks were chosen because of their emphasis on student thinking as a central feature. During lesson planning, teachers not only *choose intended learning goals*, but they decompose learning goals into smaller sub-concepts that comprise larger goals (Hiebert et al., 2007). In *considering mathematical tasks* proposed in a lesson, teachers use their own content knowledge as well as their knowledge of how students are likely to approach the task to *anticipate students' responses* and likely areas of difficulty. In this way, teachers can consider how students' responses, both correct and incorrect, can lead to the intended learning goals (Stein et al., 2008). By comparing evidence of student learning to the intended learning goals, teachers can determine what aspects of their instruction helped or hindered their students' understandings (Hiebert et al., 2007). Once instruction has been evaluated, careful planning is important so that teachers consider new learning goals and instructional tasks that build on students' current conceptions and move students to more complex mathematical understanding.

Attending to student thinking can support teachers as they engage in lesson planning. This attention allows teachers to acknowledge their students' current conceptions and design lessons that build on prior knowledge. Furthermore, as teachers consider evidence of students' thinking, they can more explicitly connect students' conceptions to important mathematical ideas. As representations of student thinking, learning trajectories are tools which help advance teachers ability to make sense of this evidence and use it to develop instruction that addresses their students' existing conceptions and moves learning forward.

Method

This study seeks to understand how teachers use the construct of a LT to support attention to students' mathematical thinking and addresses the following research question: *In what ways do teachers use LTs during lesson planning to choose learning goals and instructional tasks, and anticipate students' approaches to intended instructional tasks?* A qualitative approach is appropriate in order to understand participants' created meaning of their use of one particular LT in mathematics instruction. Specifically, case studies allow the researcher to uncover and examine significant interactions that are characteristic of the phenomenon under study as well as provide concrete and contextual knowledge as evident in the end product (Merriam, 1998).

Context

Learning Trajectory-Based Instruction (LTBI) is a research project with a strong professional development component for elementary school teachers (Sztajn, Wilson, Confrey, & Edgington, 2011a). The project was motivated by the adoption of the Common Core State Standards (2010) and current research on learning trajectories in mathematics education (Battista, 2004; Clements & Sarama, 2009; Confrey et al., 2009), with the goals of examining the ways in which teachers learn about learning trajectories and use them in their classrooms to define the concept of learning trajectory-based instruction.

As the context for the professional development, teachers learned about one LT: the equipartitioning LT (EPLT). Based on a synthesis of research and clinical interviews, Confrey and her colleagues developed the EPLT that describes how children use their informal knowledge of fair sharing as a resource to build an understanding of partitive division that unifies ratio reasoning and fractions (Confrey, in press).

The EPLT begins with experiences of fairly sharing collections of items or single wholes. In equipartitioning, students must learn to coordinate three criteria: (1) creating equal sized groups or parts, (2) creating the correct number of groups or parts, and (3) exhaust the entire collection or whole. As students enact strategies to complete these tasks, they gain proficiency in mathematical reasoning practices such as justification and naming (e.g., as a count, fraction, or ratio) and begin to develop understandings of fundamental mathematical properties that later influence the ways that they fairly share multiple wholes (Confrey, Maloney, Wilson, & Nguyen, 2010). The trajectory describes how these strategies, practices, and properties ultimately unify as a generalization of partitive division that relates ratio reasoning and fractions. Important to the trajectory are not only the levels of sophistication of reasoning but parameters associated with the tasks, including the number of wholes and number of sharers. Beginning with equipartitioning collections, the next task parameters address equipartitioning single wholes (rectangles and circles), building on primitive splits such as halves and powers of two, to eventually include arbitrary integer splits. The upper levels of the trajectory address tasks that involve multiple wholes and multiple sharers when the number of wholes is both less than and greater than the number of sharers.

Participants

LTBI is a four-year project and, in its first year, involved 22 kindergarten through fifth grade teachers from one elementary school in a mid-sized urban school district in the Southeastern United States. Project participants were offered the opportunity to continue working with the research team in some respect in the second year of the project. The second grade team, consisting of five teachers, expressed an interest in developing a set of equipartitioning lessons based on the EPLT. The findings presented here are from the analysis of one particular case, Bianca. Bianca is a Hispanic female and had been teaching second grade for five years. For her, LTs represented "a continuum of learning where there are key stopping points and also major misconceptions."

Data Sources and Analysis

The primary sources of data for this study are transcripts from grade level planning meetings, pre-lesson questionnaires, classroom observations of teachers' instruction, and transcripts of teacher interviews. Each data cycle began with a grade level lesson planning meeting, followed by individual classroom observations, and concluded with individual post-lesson interviews. Prior to each lesson, each participant completed a pre-lesson questionnaire to obtain information about the teachers' learning goals and any adaptations they may have made to the lesson plan. Observations took place in each participant's classroom during her regularly scheduled math instructional time and were video recorded. Following each lesson, a semi-structured interview was conducted with the participant to discuss the teacher's perceptions of what learning took place as well as evidence of that learning, and how the teacher used that evidence to inform future learning goals.

Data were analyzed using ATLAS.ti (2012) qualitative data analysis software. Evidence from the grade level meetings and pre-lesson questionnaires were used to examine the ways in which teachers used the EPLT to select learning goals and tasks, and anticipate students' responses. Evidence from post-lesson interviews and grade level meetings were considered to determine the ways in which the EPLT was used to reflect on the impact of instruction on student learning, evaluate evidence of student learning, and to inform future instruction. Using a constant comparative method to build and refine categories (Strauss & Corbin, 1998), open coding and pre-determined codes were utilized. The findings reported here focus on the use of the EPLT to choose learning goals, select tasks, and anticipate likely student responses for three sequenced lessons.

Results

Lesson #1: Sharing a Collection for 2, 4, and 3 Friends

During the first grade-level planning meeting, Bianca initiated the discussion of ideas for their first equipartitioning lesson by suggesting they use an activity they created and tried out the previous year where students engaged in fairly sharing a collection of 24 counters among 2, 4, and then 3 friends, justify their work, and name the resulting shares. In considering her own students, Bianca stated that she was interested in knowing if her students knew the three criteria for equipartitioning and thought that sharing collections would be a reasonable place to start since it is low on the trajectory. She stated, "I mean, for me my objective is to see do they know the three criteria. Which you can see, but you can't fully see. Because they may, with a two split, they may or may not do that right, even if they don't know all three [criteria]." After observing her students' work in the first few weeks of school, she used the nature of the task parameters of the EPLT as a justification for adapting the lesson to increasing the size of the collection from 24 to 36 counters: "that's why I went to the higher number because I know that, you know, that's going to increase the level of difficulty."

Bianca anticipated how her students would engage with the first lesson, expecting them to use dealing strategies along with number facts and doubles facts to help them determine fair shares of collections. She used the EPLT to also anticipate obstacles her students might have by saying, "I think one difficulty will definitely be naming the shares. I know that it is a more difficult task on the learning trajectory and they haven't had many experiences doing so."

After the first lesson, Bianca confirmed the difficulties her students had with naming a share and stated, "I feel as if the naming is the hardest part…Because when we teach fractions explicitly, I feel like they get to the wholes and they get to the actual sharing of things. But I feel as if we'd be doing our kids a disservice if we didn't hit on what they are most needing. Which I, from my class, I definitely think the naming thing. I definitely would not recommend sharing collections with higher numbers. I know that shouldn't be your next step, because that is what I thought."

Lesson #2: Sharing a Rectangle and a Collection for 2 Friends

Bianca used what she knew about her students' understanding and the structure of the LT to consider possible follow-up activities. She recognized that a next instructional step could be to change the task parameters but still focus on naming. Based on her teaching experience, she hypothesized that naming would be easier with a whole so in the second grade-level planning meeting, she suggested starting with sharing a rectangle for two and naming the resulting share to help scaffold students' ability to name the resulting share from equipartitioning a collection for two. She also recognized from the first lesson that students readily made connections to doubles facts, so that could potentially scaffold students' ability to name 2-splits. "What if we went, this is, I'm just throwing this out there, this could be, you know. But what if we went to wholes and just worked on halving to see if a name came out of that? And then we went back to doubles with collections and see, saw if the, you know if the vernacular, if the vocabulary came out with a whole, if they would transfer it then to collections."

The group agreed to begin the lesson by having students share two different sized rectangles fairly for two people and discuss naming the share as "one half," or "one out of two pieces" with respect to the different sized rectangles. Then, students would work to fairly share small collections as represented in drawings of arrays of 6, 8, and 10 counters and name the resulting share for each collection. Bianca identified "naming a share as 'half'" for both rectangular wholes and for collections as the goal for the lesson. She anticipated that the structure of the arrays in the second activity would help her students make a connection between "half" of the rectangle and "half" of the collection of counters. After the second lesson, Bianca considered that a possible follow up activity could be to increase the size of the collection to 12 or 14, but still share for two people, or move to sharing small collections or single wholes for four or three people and continue to focus on naming the resulting share. She attended to the interactions between the proficiency levels of the EPLT (*strategies* for sharing a collection or whole and *naming* the resulting share) and the task parameters (changing the size of the collection or the number of people sharing) to consider follow up activities for her students.

Lesson #3: Sharing a Rectangle for 2, 4, and 8 Friends

During the third lesson planning meeting, the teachers agreed to use a task they called "the wrapping paper task" where they used the context of fairly sharing wrapping paper to wrap holiday gifts. Bianca again attended to the task parameters as a way to address naming with her students. Her specific learning goals were for students to "share a whole fairly for 2, 4, and 8 people. Students will focus on how they might name the share in relation to the whole, for example each person got 'one of 8 pieces.'" She also considered that because her focus was on naming, which is higher in the trajectory, that keeping the task parameters lower would allow her students to focus more easily on the name rather than on the strategy for equipartitioning. When asked why she chose 2, 4 and 8, she stated, "Yeah, so I wanted to keep with repeated halving just knowing the trajectory. You know, I know that that's easier and since naming is a little bit harder, I didn't want the sharing to be as diff—too difficult for them … I wanted them to be able to feel successful sharing so that they could focus on what do we call what we've just shared."

Bianca anticipated that her students would make connections from the previous lesson to sharing the wrapping paper for two people. Because she purposefully chose powers of two, she also predicted that her students would use a repeated halving strategy: "I hope that a few of them notice the repeated halving and give their own language and explanation as we go from 2 to 4 to 8." Bianca also used the EPLT to expect different mathematical names such as "one out of four, or one part of the four whole parts, or one part out of eight parts, etc."

After the third lesson, Bianca again considered the task parameters in relation to her students' learning. She believed they were successful with equipartitioning a rectangle and naming the share for 2, 4, and 8 people and considering changing the task parameter from rectangles to circles for a follow up lesson:

> Well, I think—I mean I would like to see—I would probably do something the same, maybe with circles. And still focus on naming because we've kind of gotten there. But I know we're taking it down a—I would still do two, four and eight, but let's do circles and see can we still name them, but are our shares—but, like, at the side be like, "okay, what's going to happen when we get a circle? Can we share it?" Because here, they were successful sharing it and so they could be successful naming it, all right so now we're just going to take a circle and we're going to try to share it fairly.

She recognized that in changing the task parameter to a circle, she would first need to investigate if her students could use successful strategies to equipartition a circle and then move higher up the trajectory to address naming the resulting shares.

Discussion

Overall, Bianca coordinated the proficiency levels and task parameters of the EPLT to design tasks that focused on the learning goals that she chose for her students related to naming. She was able to bring together the existing curriculum with aspects of the trajectory, such as relating doubles facts with sharing for two people and naming fractional parts of halves and fourths. Bianca was also able to use the structure of the EPLT to consider possible follow up activities based on her students' learning. In considering the planning problems identified by Superfine (2008), Bianca offers evidence that the structure of LTs can support teachers in anticipating student work and in making connections between mathematical content and existing curricula.

For each lesson, Bianca was very clear about the specific learning goals she chose and used information from the trajectory to anticipate how her students would engage with tasks she selected. In light of the LT, Bianca was able to anticipate a variety of students' approaches and difficulties and consider how these related to her students' current conceptions and the intended learning goals. The LT was a tool to gauge the appropriateness of the tasks based on the understandings her students exhibited with the intention of moving students towards more sophisticated conceptions.

The tasks and goals she chose were in service of the larger, long-term goal of understanding the relationship between equipartitioning collections and wholes to naming the resulting share using a fractional name in relation to the collection or whole. Moreover, Bianca used open tasks that provided evidence of her students' thinking with respect to multiple proficiency levels of the EPLT, supporting the engagement of students with various conceptions of development along the trajectory (Sztajn, Confrey, Wilson, & Edgington, in press). Her ability to coordinate the levels of the EPLT with the task parameters supported her in considering follow-up activities based on the learning she observed from her students.

Because LTs describe concepts from less formal to more sophisticated ideas, LTs can aid teachers in selecting appropriate learning goals and provide information about what sub-goals are associated with larger conceptual goals. Hiebert and colleagues (2007) contended that learning goals are the basis for gauging the effectiveness of particular instructional activities and for measuring evidence of student learning. LTs afford teachers with information about likely strategies, misconceptions and important milestones that teachers can then anticipate as they plan instructional activities. Anticipating students' approaches to a task prior to instruction allows teachers to begin to think about how students' work relates to the intended mathematical goals (Stein et al., 2008). The knowledge of student learning inherent in LTs provides teachers with more detail as they compare evidence of student learning to learning goals, and gives them a repertoire of instructional moves based on the understandings their students' exhibit. Bianca was able to use the LT to better understand her students' mathematical thinking and target her lesson planning to her students' needs. Considering the fact that the Common Core State Standards were developed using LTs, it is important for the field to continue to explore the utility of LTs as a tool to aid teachers in attending to their students' mathematical thinking not only in lesson planning, but also during classroom instruction.

EVALUATING TEACHERS' DECISIONS IN POSING A PROOF PROBLEM

Karl W. Kosko

pgherbst@umich.edu

When Geometry teachers pose proof problems to students, it is the teacher who provides the givens and the statement to be proven; we hypothesize that teachers of geometry recognize this to be the norm. This study examined teachers' decision-making in regards to the posing of a proof problem, and whether recognition of this norm accounted for the decision made. Results of a multinomial regression indicated that the more participants recognized that norm of posing proof problems, the less likely they were to select an action that breached the norm.

Keywords: Instructional Activities and Practices; Reasoning and Proof; Teacher Beliefs; Research Methods

Background and Objectives

During the early 1970s, teachers' decision-making became a focus of educational research through parallel investigations led by Alan Bishop, Lee Shulman, and Richard Shavelson (Borko, Roberts, & Shavelson, 2008). Each initiative viewed the examination of teacher decision-making as a means to better understand teaching. For Shulman (1986), this research on teachers' decision-making exemplified how research on teaching had brought attention to teachers' cognition to a field that had up to then only considered teachers' characteristics and behaviors. Accordingly, much of this early research posited individual resources such as beliefs, goals, knowledge, or schemas as resources for decision-making (Schoenfeld, 2010). But another of the paradigms for the study of teaching that Shulman (1986) described, the classroom ecology paradigm spearheaded by Doyle, had undertaken to improve the study of teaching by attending carefully to its activity structures. Contributing to this approach, Herbst and Chazan (2011) have addressed teachers' decision-making by proposing that teachers draw upon resources of a different kind to justify their pedagogical moves. "Combined with the personal assets (including knowledge, skills, and beliefs) that an individual teacher brings with them to that position and that role, [instructional norms and professional obligations] can help explain teacher action and decision-making" (p. 417). As described by Herbst and Chazan, professional obligations are resources of the profession that regulate the position of a mathematics teacher while instructional norms are resources embedded within the various activity structures in which the teacher plays a role. Thus, in this perspective, the justification of a teacher's decision depends not solely on the individual teacher's personal resources but also on their recognition of those norms and obligations (a recognition that could be tacit). Yet, what remains unclear is the degree to which an individual teacher's resources and their recognition of instructional norms account for the decision that a teacher makes in the moment. The purpose of the current study is to examine this phenomenon in a specific decision-making context.

Personal Resources for Decision-Making

In their review of early literature on teachers' decision-making, Shavelson and Stern (1981) suggest that teachers "make judgments and decisions, and carry them out on the basis of their psychological model of reality" (p. 461), which, in turn, is composed of various beliefs such as those concerning pedagogy and the subject matter. Shulman and Elstein (1975) also suggested that personal resources of the teacher influence judgments. Shulman (1987) later restated this relationship in terms of particular types of knowledge professional teachers hold, and how such knowledge influences teachers' decision-making. In the past several years, Deborah Ball and colleagues have expanded this idea to describe their conception of Mathematical Knowledge for Teaching (MKT) (Ball, Thames, & Phelps, 2008). Like Shulman (1987), Ball et al. (2008) suggest that teachers' in-the-moment decisions require "…coordination between the mathematics at stake and the instructional options and purposes at play" (p. 401).

The literature suggests that one clear resource teachers use in making pedagogical decisions appears to be their pedagogical content knowledge (PCK) (e.g., Ogletree, 2007). Yet, Bishop's (1976) account of decision making made a strong argument for the importance of teaching experience in the development of the schemas that may be associated with decision making. Osam and Balbay (2004) provide additional evidence for this, finding that surveyed novice teachers were more concerned with technical details of a lesson in their decisions while experienced teachers were more concerned with the way students behaved during the lesson.

Another potential resource that may influence teachers' decisions is their degree of autonomy to make decisions about their instructional practices. Behm and Lloyd (2007) observed that while different student teachers were provided different resources, the degree of autonomy afforded those student teachers was a critical indicator of what they were able to do with the materials at hand. Examining decision-making in science classrooms, Gess-Newsome and Lederman (1995) found that teachers' autonomy was a highly influential factor in the types of instructional decisions made. With these considerations in mind, we consider teacher autonomy, along with PCK and teaching experience, to be critical personal resources of teachers in their decision-making.

A Professional Resource for Decision-Making

Aho et al. (2010) note that more than teachers' own personal resources influence their decision-making. Rather, "teaching is influenced by the surrounding society, culture and traditions" (p. 400). Teachers interviewed by Aho et al. noted that some pedagogical decisions they made were agreed upon with school colleagues. Further, these types of collective decisions over time work their way into the routines of the teacher. We argue that while such routines are operationalized by individual teachers, their genesis are social in origin and therefore may be more characteristic of actions normative of a group than of particular individuals: In this case we are interested in the obligations that bind a professional group and the norms of the activities in which they play a role. Herbst et al. (2009) provide an example of one such type of norm. Observing similarities in how proof was facilitated across different teachers' classrooms, Herbst et al. note that "these similarities can be expressed by a common system of implicit norms regulating the events on the surface" (p. 266). Such norms appear to influence teacher decisions in the classrooms particularly shaping the division of labor, or who does what, when the situation is one of doing proofs.

Situational norms and professional obligations on the one hand and individual resources of teacher autonomy, experience, and knowledge are thus two kinds of constructs that might account for the decisions teachers make (e.g., Ball et al., 2008; Bishop, 1976; Gess-Newsome & Lederman, 1995). Given these various resources, it is prudent to investigate the degree to which they influence teachers' decision-making. We focus on the instructional situation of doing proofs (Herbst et al., 2009), and on a particular norm of doing proofs (*when posing proof problems, the teacher provides students with the given information and the statement to be proved*). With this situation-specific focus, we sought to answer the following research question:

> *To what degree do teachers' recognition of an instructional norm account for their decision-making in posing a proof problem, and to what degree do the individual resources of PCK, teaching experience, and perceived teaching autonomy contribute to their decision.*

Methods

Sample and Measures

Data were collected from 55 secondary mathematics teachers (grades 8 to 12) in a Midwestern state. The sample included 43.6% male and 56.4% female teachers. Participants were sampled from a wide range of districts, both urban and rural, and of varying levels of socio-economic status. For example, some participating teachers taught in schools with 4% of the population eligible for free and reduced lunch, while others came from schools where 59% of students were eligible. Of the 55 sampled participants, 44 (80%) completed all assessments that we include in the current analysis, and represent our effective sample.

Participants were invited to complete a series of assessments on an online platform (LessonSketch.org), of which we include data from four of the assessments. LessonSketch allowed for the incorporation of multimedia survey instruments in which participants viewed and answered questions concerning representations of teaching, of which was particularly useful in assessing teachers' situation-specific decision-making.

Dependent Variable

We assessed participants' decision-making based on their multiple-choice responses to a representation of teaching. Participants were presented with a cartoon-based, two-frame teaching representation, preceded with a brief overview of the lesson as one taking place in a high school geometry class in which the teacher was going to assign a proof problem. The representation depicted the teacher drawing a diagram and reviewing with students that to write a proof they would need a set of givens and a statement to prove. Participants were then presented with four potential actions that could follow and were asked to select which they would be most likely to do next following the scenario. Each action was a single-frame depiction representing either compliance or breach with the normative action: *when posing a proof problem, the teacher provides the givens and prove statement to students*. Participants were asked "which action would you be most likely to take in the teaching scenario?" and then to "please explain your reasoning for choosing this action."

Choice A depicted a breach of the norm where the teacher instructs students they will have a discussion to decide, as a class, what the givens and the prove statement will be. Choice B is another breach of the norm where the teacher asks students to work individually, decide what the givens and prove statement are, and then do the proof. The students would later compare their proofs to their peers'. Choice C is a breach where the teacher provides the prove statement, but instructs the class that they will discuss, as a class, what givens they will need to do the proof successfully. Choice D is compliant with the norm where the teacher provides both the givens and "prove" statement, and then asks an initial question for class discussion on how to do the proof. Responses were well distributed with 22.7% selecting Choice A, 18.2% selecting Choice B, 31.8% selecting Choice C, and 27.3% selecting Choice D.

Independent Variables

We included four independent variables in our analysis. The independent variable of interest (*normativity*) was a score representing participants' endorsement of the norm: *when posing a proof problem, the teacher provides the givens and prove statement to students*. The variable, described in detail below, was designed as an indicator of participants' recognition of an instructional norm. Specifically, scores for *normativity* were interpreted to assess the degree to which individual participants recognized the identified norm in the situation 'doing proofs' in Geometry instruction.

We assessed this recognition with a 10-item survey that presented participants with explicit statements regarding the norm of focus. A sample item and available responses is presented in Figure 1. Items were written to assess participants' view of how appropriate it was for the professional group of Geometry teachers to provide students with the givens and prove statement in posing proof problems. Interpretation of the items was validated through cognitive interviews prior to collection of the current data, with results suggesting that items were interpreted as intended. Additionally, we calculated an alpha coefficient of .89, suggesting the items had sufficient reliability as well as validity. Participant responses were averaged into a composite score, *normativity* (M = 3.46, SD = 1.08), for inclusion in the present analysis. Higher scores represented a greater recognition of the norm, and vice versa.

When starting a proof problem, how appropriate is it for teachers to have students decide upon the 'prove' statement (conclusion)?

1	2	3	4	5	6
Very Inappropriate	Inappropriate	Somewhat Inappropriate	Somewhat Appropriate	Appropriate	Very Appropriate

Figure 1: Sample item assessing participants' recognition of the norm

The next independent variable included was a measure of participants' perceived autonomy in their mathematics teaching (*autonomy*). As noted in our literature review, teachers' autonomy has the potential to regulate the effect of teacher beliefs, and therefore represented a useful factor for investigation. Items measuring *autonomy* were adapted from multiple sources to focus both on the content of mathematics and the role of teacher (Deci & Ryan, 2011; Kosko & Wilkins, in review; NCES, 1998; Reeve et al., 2003). Teachers were asked to rate their agreement with statements such as the following: *I am discouraged from teaching mathematics in the way I would like to* (reverse-coded sample item). Available responses were on a 6-point Likert-scale (1–Strongly Disagree; 2–Disagree; 3–Somewhat Disagree; 4–Somewhat Agree; 5–Agree; 6–Strongly Agree). Items showed sufficient reliability (α = .89) and responses were averaged into the composite score *autonomy* (M = 4.62, SD = .81).

The third variable included for analysis was years of teaching experience (*Years*). Teachers in the sample taught an average of 13 years (SD = 7.30). While Bishop (1976) noted that it was schemas developed through experience that influenced teachers' decision-making, we used *Years* as an indicator of having more sophisticated forms of such schemas.

The final independent variable included was a measure of pedagogical content knowledge in geometry (*PCKG*). The assessment included 10 items covering various Geometry topics and addressing teachers' *knowledge of content and teaching* and *knowledge of content and students* (see Ball et al., 2008 for a detailed description of these domains of mathematical knowledge for teaching). Items were validated through cognitive interviews before collection of the present data. Item analysis of present data showed biserial correlations of .30 or higher, and a Cronbach's alpha coefficient of .70, suggesting the construct had sufficient reliability. Scores were based on percentage of items answered correctly, with a possible range of 0 to 1 (M = 0.46, SD = .23). Herbst and Kosko (2012) provide more details on the development of this instrument.

Analysis and Results

We used multinomial logistic regression (MLR) to examine participants' decision-making. Specifically, participants were asked to select one of four potential actions following a depicted teaching scenario. While one of these actions was considered compliant with the norm and the other three breaches of the norm, we did not consider one action as necessarily better than any other. Further, the participant choices could not be ordered in any natural way. Therefore, the responses represent nominal data suitable for an MLR. MLR is a form of logistic regression which uses one category (one of the choices available) as a reference outcome, and creates separate logistic regression comparisons between the reference outcome and each other classification (see Hosmer & Lemeshow, 2000 for a detailed description).

The model examined in the current analysis is presented in the equation below. The outcome of reference is the normative action, Choice D, and is designated by 0 in the equation. Each alternative choice (breaches of the norm in Choices A, B, and C) are represented in variable m, such that we have three distinct regression equations; one for each comparison. So, we evaluated the degree to which each independent variable contributes to participants choosing Action A rather than Action D, Action B instead of Action D, and Action C instead of Action D.

$$g_m(x) = ln\left[\frac{P(Y = m \mid x)}{P(Y = 0 \mid x)}\right]$$
$$= \beta_{m0} + \beta_{m1}(normativity)_1 + \beta_{m2}(autonomy)_2 + \beta_{m3}(Years)_3 + \beta_{m4}(PCKG)_4$$

Customary in performing MLR is an initial checking of model fit, both for the model as a whole as well as for particular variables within it. While the model represented in the above equation had overall model fit ($\chi^2 = 39.34$ (df = 12), $p < .01$), the variable PCKG was found to not have a statistically significant relationship with participants' choices ($\chi^2 = 3.91$ (df = 3), $p = .271$). This initial finding suggests that there was little relationship between participants' *PCKG* scores and their chosen action following the scenario and, therefore, *PCKG* should be considered for removal in the analysis to provide a more parsimonious model. The standard errors associated with *PCKG* were also high (above 2.0), suggesting potential collinearity. Also, a separate MLR with only *PCKG* in the model still suggested no statistical relationship with choice of action. However, an examination of the descriptive statistics suggest that while participants selecting the normative action tended to have higher *PCKG* scores, there was a large degree of variance in these scores, further justifying the removal of *PCKG*. The new model, which includes *normativity*, *autonomy*, and *Years* as predictors, was found to have good overall fit ($\chi^2 = 35.43$ (df = 9), $p < .001$), with no need for further simplification of the model.

Results from the MLR analysis are presented in Table 1, with coefficients represented in logits. In each model comparison, *normativity* scores were found to be a statistically significant predictor of choice at the .10 level, when accounting for participants' perceived teaching autonomy and years of teaching experience. Using the conversion:

$$\frac{e^{\beta_{m0}+\beta_{m1}(normativity)_3+\beta_{m2}(autonomy)_2+\beta_{m3}(Years)_3}}{1+e^{(normativity)_3+\beta_{m2}(autonomy)_2+\beta_{m3}(Years)_3}}$$

we can determine the probability that a participant in our sample would select a particular choice rather than the normative action represented in Choice D. For example, a participant with an average *autonomy* score ($M = 4.62$) and years of teaching ($M = 13$) for the sample, a low *normativity* score of 1.00 would suggest such a participant is 99.9% more likely to select Choice A over Choice D. However, if a similar participant had a high *normativity* score of 6.00, there is a practically zero probability that they would select Choice A over Choice D. These and similar calculations are illustrated, for convenience, in Figure 2.

Table 1: Results from Multinomial Logistic Regression.

Comparison		β (logits)	S.E.	Wald Statistic
Choice A | Choice D	Intercept	12.75	5.27	5.13**
	normativity	-5.35	1.83	8.56**
	autonomy	1.59	1.00	2.55
	Years	-.29	.11	6.52**
Choice B | Choice D	Intercept	-4.17	4.90	.72
	normativity	-1.51	.79	3.68*
	autonomy	2.21	.98	5.15**
	Years	-.10	.08	1.71
Choice C | Choice D	Intercept	2.20	3.13	.49
	normativity	-1.08	.60	3.20*
	autonomy	.57	.57	1.00
	Years	-.04	.06	.48

**p < .10. **p < .05.*

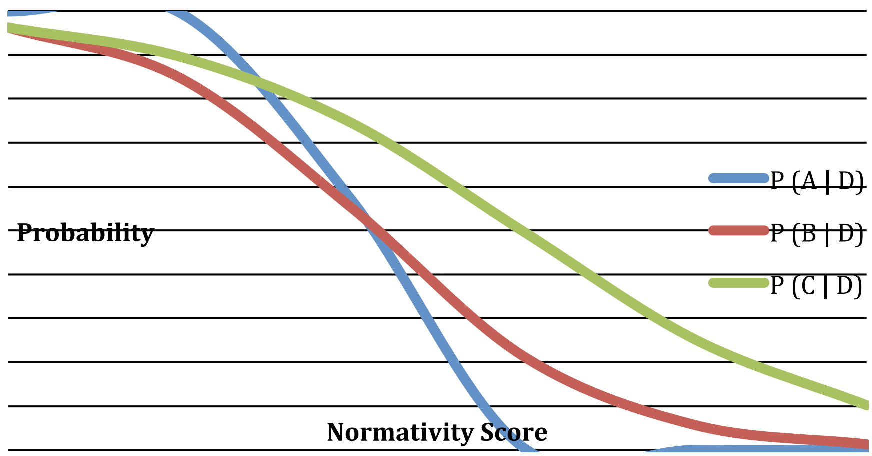

Figure 2: Effect of normativity score on probability of selecting an option other than choice D, with average *autonomy* and *Years* for the sample

These findings indicate that, for each comparison, the degree to which participants recognized the norm was a consistent determiner of how likely they were to select Choice D or an alternative. Additionally, it appears that the more participants recognized the norm, the more likely they were to select the normative action, Choice D, instead of an action that included a breach of the norm. Further, while perceived autonomy and years of teaching experience did influence whether participants would choose one action over another for some comparisons, *normativity* consistently did so and generally at larger magnitudes.

Discussion and Conclusion

The findings from our analysis are preliminary, in that they represent the decision-making regarding the teaching norm of focus for only one particular teaching scenario. Yet, examination of participants' choices suggests that participants who recognize the norm tend to act according to that norm. Additionally, participants' perceived teaching autonomy influenced decision-making in a manner that contrasted *normativity*. Specifically, a higher perception of autonomy was shown to increase the likelihood a participant chose Action B over the normative action, while a higher *normativity* score decreased the likelihood those participants would choose Action B over the normative action (see Table 1). This statistical conflict between *autonomy* and *normativity* is representative of what Pepitone (1989) described as the conflict between rights and obligations. Pepitone noted that "the reaction to the violation of an obligation may be tempered by an internalized right that is in opposition to the obligation, perhaps the very same right claimed and exercised by the 'violator'" (p. 14). Applied to the context of this study, participants' 'violation' or breach of the norm through selecting Action B may have been tempered by their sense of autonomy, which in turn can represent any number of internalized beliefs about mathematics teaching and learning.

The conflict between *autonomy* and *normativity* discovered in the present analysis suggests that for the particular scenario examined, *normativity* wins the conflict. While *autonomy* was shown to have a larger logit size for P(Action B | Action D), *normativity* consistently predicted the decision-making patterns for all actions relative to Action D (the normative action). While this pattern may vary given differing scenarios and options for decisions, the main claim from our analysis suggests that participants' recognition of situational norms in teaching are an important influence in their pedagogical decision-making. Therefore, if we wish to better understand teachers' decision-making, more attention should be given to the characteristics of the situations in which teachers act, as well as to the resources of individual teachers.

Third- through fifth-grade students participating in a classroom teaching experiment investigating the impact of an Early Algebra Learning Progression completed pre- and post-assessment items addressing their abilities to engage in functional thinking. We found that after a sustained early algebra intervention, students grew in their abilities to shift from recursive to covariational thinking about linear functions and to represent correspondence rules in both words and variables.

Keywords: Algebra and Algebraic Thinking; Elementary School Education

Algebra has historically served as a gateway course to higher mathematics that—due to high failure rates—has been closed for many students. More recent initiatives have identified algebra as playing a central role throughout mathematics education and re-framed it as a longitudinal strand of thinking across grades K-12 rather than as an isolated eighth- or ninth-grade topic (e.g., Common Core State Standards Initiative, 2010; National Council of Teachers of Mathematics, 2000). This is not to be interpreted as a call to shift traditional algebra instruction to earlier grades, but rather as one to introduce elementary school students to algebraic thinking in the context of age-appropriate activities.

In response to this call, we drew from research findings, curricular resources, and standards documents in the area of early algebra to develop an Early Algebra Learning Progression [EALP] organized around five "big ideas": (1) Generalized Arithmetic; (2) Equations, Expressions, Equality, and Inequality; (3) Functional Thinking; (4) Proportional Reasoning; and (5) Variable.

We conducted a one-year classroom-based study in grades 3–5 to gather efficacy data regarding the impact of EALP-based classroom experiences on elementary students' developing understandings of these big ideas. The focus of this paper will be our findings regarding the development of students' functional thinking. We will share pre/post assessment data and representative excerpts from student work and briefly discuss the classroom intervention we believe contributed to the growth we observed.

Theoretical Perspective

Functional thinking has been identified as one of the key strands of algebraic thinking (Kaput, 2008) and one of the core content domains in early algebra research (Blanton, Levi, Crites, & Dougherty, 2011). Blanton et al. (2011) characterize functional thinking as "generalizing relationships between covarying quantities, expressing those relationships in words, symbols, tables, or graphs, and reasoning with these various representations to analyze function behavior" (p. 47).

Elementary curricula often include a focus on simple patterning activities in which the change in only one variable is observed. However, an exclusive focus on this type of activity is suggested to hinder the development of students' reasoning about how two or more quantities vary simultaneously (Blanton & Kaput, 2004). A deeper understanding of change and the modeling of behavior in real world phenomena requires students to look beyond recursive patterns and consider covariation in their study of functions (Blanton et al., 2011). Confrey and Smith (1994) furthermore argue that a covariational approach establishes a good foundation for the development of correspondence rules.

Evidence exists that children in elementary grades are in fact capable of reasoning about covarying quantities and developing correspondence rules. Blanton and Kaput (2004) found that students could construct and reason with function tables and identify covariational relationships and primitive correspondence rules as early as first grade, while older elementary students could successfully transition from using natural language to using symbols to represent correspondence rules more formally. Based on these findings, Blanton and Kaput argue that elementary curricula should go beyond recursive pattern finding to include a focus on relationships between variables.

Martinez and Brizuela (2006) likewise found that third-grade students could successfully reason with linear function tables but sometimes struggled to make the transition from focusing on recursive patterns to identifying general correspondence rules that would apply to all cases. They identified "hybrid" approaches, in which students examined the relationship between input and output as required in a covariational approach while simultaneously relying on a recursive pattern. For example, one student observed in her table that "the number that you add to get from the input to the output is always one more than it was in the previous row" (p. 292). This is a limited approach in terms of generalizing and making far predictions, but it does indicate progress in considering the relationship between two variables.

The study of functions in the elementary grades can lay the foundation for success in later grades. Teachers can nurture students' functional thinking by helping them develop algebraic habits of mind that encourage building patterns, making conjectures, generalizing, and justifying mathematical relationships (Blanton & Kaput, 2011; Moss, Beatty, Barkin, & Shillolo, 2008; Moss & McNab, 2010). Martinez and Brizuela (2006) call for carefully designed interventions that consider the relationship between "what students *know* and what we want them to *learn"* (p. 293). In this study, we aimed to move beyond the patterning experiences elementary curricula and standards documents (e.g., National Council of Teachers of Mathematics, 2000) propose students should have and push students to consider covariational relationships and develop correspondence rules. Specifically, this paper addresses the following research question:

How does the functional thinking of grades 3–5 students who have had a year-long focus on early algebra (including functions) compare to that of students who have had more traditional arithmetic-based experiences? Specifically, how does student performance compare across the following aspects of functional thinking:

a) Constructing a function table?
b) Identifying a recursive pattern?
c) Identifying a covariational relationship?
d) Representing a correspondence rule in words and symbols?
e) Making "far" data predictions?

Method

Participants

Participants included approximately 300 students from two elementary schools in southeastern Massachusetts. The school district in which these schools reside is largely white (91%) and middle class, with 17% of students qualifying for free or reduced lunch. Six classrooms (two from each of grades 3–5 and all from one school) served as experimental sites and 10 classrooms (four grade 3, four grade 4, and two grade 5, from both schools) served as control sites.

Classroom Intervention

Students in the experimental condition participated in an EALP-based classroom teaching experiment [CTE] for approximately one hour each week for one school year. A member of our research team—a former elementary school teacher—served as the teacher during these interventions. A typical one-hour lesson consisted of a "jumpstart" at the beginning of class to review previously discussed concepts, followed by group work centered on research-based tasks aligned with our EALP. These tasks were designed to encourage students to reason algebraically in a variety of ways and justify their thinking to themselves and their classmates.

The last five weeks of the CTE focused on functional thinking, in particular, problem situations in which students investigated linear patterns and relationships. In most of these tasks, students were presented with a scenario in words or pictures and were asked to record and organize data, identify and describe recursive patterns and covariational relationships, express correspondence rules in words and symbols, and make near and far predictions. Multiple representations—verbal, pictorial, tabular, graphical, and symbolic—were typically generated from a given problem context. Students were encouraged to discuss connections among representations (e.g., to identify the meaning of the slope and intercept in a symbolic correspondence rule by referring to the function table or by referring back to the original problem context).

Students in the control condition participated in their usual classroom activity with their regular classroom teachers. District-wide, all classroom teachers used "Growing with Mathematics" (Iron, 2003) curriculum materials. This curriculum does not include a focus on early algebra.

Data Collection

A pretest and (identical) posttest were designed to measure students' understandings of algebraic topics identified across the five "big ideas" of the EALP. The majority of tasks were research-based, adapted from tasks used in our or others' prior studies. In total, 290 students completed the pretest (117 experimental, 173 control) and 293 students completed the posttest (126 experimental, 167 control). We also conducted individual interviews with ten students (6 experimental, 4 control) across grades 3–5 at the conclusion of the study to gain deeper insight into their thinking about a subset of the assessment tasks.[1]

From the pre/post assessment, we will focus in this paper on one task—the *Brady task* (see Figure 1)—that investigated students' functional thinking around a situation involving linear growth.

Data Analysis

Each part of the *Brady task* was first scored dichotomously (i.e., correct or incorrect). For all but part a (which required no explanation), student strategies were also coded.

For parts b, c, and d, student responses were categorized according to the type of relationship described: *recursive*, *covariational*, or *functional*. For example, the most prevalent response to part b was for students to provide a description of a recursive pattern (e.g., "The people column goes up by 2s."). We anticipated students would respond in this way, given the focus of typical elementary curricula, and thus designed parts c and d to try to push students beyond recursive thinking. Part c required students to consider the relationship between two variables, thus requiring either a description of a covariational relationship (e.g., "When the number of tables goes up by 1, the numbers of people goes up by 2") or a correspondence relationship (e.g., "The number of people is 2 more than 2 times the number of tables"). In part d, students were expected to describe the correspondence relationship symbolically (e.g., "$2n + 2 = p$ where n = number of tables and p = number of people").

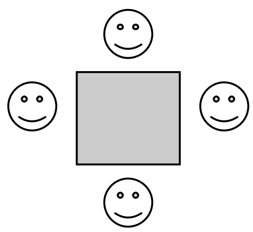
Student responses to part e were coded according to the strategy used to determine the number of people who could sit at 10 tables: *drawing* indicated that students drew 10 tables and counted the number of people who could be seated, *recursive* indicated that students extended the pattern found in the table in part a to 10 tables, and *functional* indicated that students used the correspondence relationship between the two variables to find the solution (i.e., $2 \times 10 + 2 = 22$ people). Student responses to part e that included no work or explanation were placed into an *answer only* category.

Across all of the items, responses that students left blank, or for which they responded "I don't know" were grouped into a *no response* category, and responses that were not sufficiently frequent to constitute their own codes were placed into an *other* category.

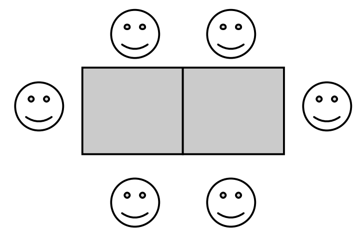
To assess reliability of the coding procedure, a second member of the research team coded a randomly selected 20% sample of the data. Initial agreement between coders was at least 74% for each item. All differences in scoring were discussed by the coders and resolved.

Brady is having his friends over for a birthday party. He wants to make sure he has a seat for everyone. He has square tables.

He can seat 4 people at one square table in the following way:



If he joins another square table to the first one, he can seat 6 people:



a) If Brady keeps joining square tables in this way, how many people can sit at 3 tables? 4 tables? 5 tables? Record your responses in the table below and fill in any missing information:

Number of tables	Number of people
1	
2	
3	
4	
5	
6	
7	

b) Do you see any patterns in the table? Describe them.

c) Find a relationship between the number of tables and the number of people who can sit at the tables. Describe your relationship in words.

d) Describe your relationship using variables. What do your variables represent?

e) If Brady has 10 tables, how many people can he seat? Show how you got your answer.

Figure 1: The *Brady Task*

Results and Discussion

In this section, we report pre/post results from the *Brady Task* and offer representative excerpts from the written assessment to illustrate particular categories of responses.

Completing a Table (Part a)

In the first part of the *Brady task*, students were asked to complete a function table using the given description of the problem situation and accompanying pictures. Third- and fourth-grade students struggled with this task at pretest (see Table 1), while fifth-grade students were already fairly successful prior to the intervention. Grades 3–4 experimental students made significant improvements over the course of the intervention and outperformed control students at posttest.

Table 1: Proportion of Students Who Successfully Completed the Table in Response to Part a

	Grade 3		Grade 4		Grade 5	
	Pre	Post	Pre	Post	Pre	Post
Control	.379	.524	.449	.716	.816	.946
Experimental	.359	.868*	.512	.932*	.857	.955

*Experimental group outperformed control group at posttest ($p < 0.01$).

These findings are consistent with Blanton and Kaput's (2004) and Martinez and Brizuela's (2006) assertions that provided the appropriate experiences, elementary students can learn to construct function tables to represent covarying data. While those students with an arithmetic-based curriculum could successfully construct tables by fifth grade, those students with early algebra experiences could do so sooner.

Recognizing and Describing a Pattern (Part b)

Students were next asked to identify any patterns they saw in the table. This is a task with which we expected students to be fairly successful as only the identification of a recursive pattern was required. One third-grade student stated at pretest, for example, "You count by 2's every time." Most students took this recursive approach; however, some students identified a covariational relationship. A fourth-grade student, for example, wrote "plus 1 table = plus 2 more people" at pretest, indicating attention to the relationship between two variables. One fifth-grade student in the experimental group wrote "× 2 + 2" at posttest, indicating he or she was attending to the functional relationship between the number of tables and the number of people. Table 2 shows the proportion of students who provided a correct pattern or relationship to describe the data in the table. Overall posttest differences were only marginally significant at grade 3.

Table 2: Proportion of Students Who Provided a Correct Recursive, Covariational, or Functional Table Description in Response to Part b

	Grade 3				Grade 4				Grade 5			
	Control		Experimental		Control		Experimental		Control		Experimental	
	Pre	Post	Pre	Post	Pre	Post	Pre	Post	Pre	Post	Pre	Post
Recursive	.182	.333	.205	.579	.275	.418	.415	.341	.579	.541	.476	.386
Covariational	.015	.079	.103	.211	.130	.254	.098	.296	.237	.351	.214	.409
Functional	.000	.000	.000	.000	.000	.000	.000	.000	.000	.000	.000	.023
Total correct	.197	.412	.308	.790*	.405	.672	.513	.637	.816	.892	.690	.818

*Experimental group outperformed control group at posttest ($p < 0.01$).

That students had some initial success with this task—especially by grade 5—is not surprising given the fact that elementary curricula typically focus on identifying recursive patterns in their work with number sequences and data tables. It is interesting to note, however, that an increasing proportion of students provided descriptions of the covariational relationship involved. Note that by fifth grade, more students in the experimental group were providing such responses than were identifying recursive patterns, suggesting the CTE successfully encouraged them to consider relationships between variables.

Expressing a Functional Relationship Using Words and Variables (Parts c and d)

Students were next explicitly asked to move beyond recursive patterning to consider the covariational or functional relationship between the number of tables and the number of people. We initially anticipated this would be very difficult for students given the lack of focus on these concepts in typical elementary curricula. Table 3 shows the proportion of students who provided a correct description of the covariational or functional relationship in words (Part c) and the functional relationship in symbols (Part d).

Table 3: Proportion of Students Who Provided a Correct Covariational or Functional Relationship in Words (in Response to Part c) and Symbols (in Response to Part d)

	Grade 3				Grade 4				Grade 5			
	Control		Experimental		Control		Experimental		Control		Experimental	
	Pre	Post	Pre	Post	Pre	Post	Pre	Post	Pre	Post	Pre	Post
Relationship in words (part c)												
Covariational	.015	.079	.026	.237	.101	.164	.146	.136	.316	.487	.119	.182
Functional	.000	.000	.000	.079	.000	.000	.000	.273	.026	.027	.000	.341
Total correct	.015	.079	.026	.316*	.101	.164	.146	.409*	.342	.514	.119	.523
Relationship in symbols (part d)												
Functional	.000	.000	.000	.158*	.000	.000	.000	.295*	.000	.000	.000	.455*

*Experimental group outperformed control group at posttest ($p < 0.01$).

As Table 3 shows, students struggled with these tasks at pretest. Only one student wrote a correct correspondence (i.e., functional) rule in words at that time. All other correct responses to part c at pretest involved describing in words the covariational relationship between the number of tables and the number of people. A fifth-grade student wrote, for example, “The rule is if you add a table two more people can sit.” No students wrote a correct symbolic functional rule in response to part d at pretest. Experimental students improved in this area quite a bit over the course of the intervention, with over 30% of fourth graders and almost half of fifth graders producing correct symbolic rules at posttest. For example,

$A \times 2 + 2 = B$; A for the number of tables, B for the number of people (grade 3)

$x \cdot 2 + 2 = y$; x represents the number of tables, y represents the number of people who sit at the tables (grade 4)

$p \times 2 + 2 = m$; p = # of tables, m = # of people (grade 5)

We attribute this performance to experimental students’ ongoing experience working with variables in a variety of contexts and to the connections continuously made among various representations and the original problem context in the CTE.

Making a “Far” Prediction (Part e)

Finally, students were asked how many people Brady could seat at his party if he had ten tables. As described in the data analysis section, students took three main approaches: drawing ten tables and counting the number of people who could be seated, extending the pattern found in the table in part a to ten tables, or using the functional relationship between the two variables. See Table 4 for the proportion of students who correctly used each approach. “Answer only” refers to students who only answered “22,” with no work shown to indicate strategy use.

Table 4: Proportion of Students Who Correctly Applied a Drawing, Recursive, Functional, or "Answer Only" Strategy to Make a "Far" Prediction in Response to Part e

	Grade 3				Grade 4				Grade 5			
	Con		Exp		Con		Exp		Con		Exp	
	Pre	Post	Pre	Post	Pre	Post	Pre	Post	Pre	Post	Pre	Post
Drawing	.167	.143	.077	.132	.203	.284	.220	.296	.368	.324	.333	.091
Recursive	.076	.191	.128	.237	.188	.224	.220	.205	.237	.487	.286	.296
Functional	.000	.000	.000	.079	.000	.000	.024	.273	.026	.027	.024	.364
Answer only	.030	.079	.128	.105	.073	.119	.073	.000	.053	.054	.048	.068
Other	.000	.000	.000	.000	.000	.045	.000	.023	.000	.054	.000	.046
Total correct	.243	.413	.333	.553	.464	.672	.537	.797	.684	.946	.691	.865

Students in both control and experimental conditions showed improvement with this task, but there were no significant posttest differences between groups in terms of correctness. This is not entirely surprising given that the "far" prediction—to 10 tables—is not actually that far. Thus drawing and recursive strategies are not all that inefficient. In subsequent administrations of this task, we plan to ask students how many people could sit at 100 tables. Note, however, the experimental group's increasing use of a function rule to help them solve this problem. We again attribute this difference to the CTE's focus on moving beyond recursive patterning to consider covariational relationships and correspondence rules.

Conclusion

Experimental students showed significant improvement in this study in their abilities to construct function tables (in grades 3 and 4), identify patterns or relationships in tables (in grade 3), and represent a functional rule verbally (in grades 3 and 4) and symbolically (in all grades). These findings support the work of others (e.g., Blanton & Kaput, 2004; Martinez & Brizuela, 2006) who assert that elementary students are capable of sophisticated functional thinking and call into question the lack of focus on relationships between co-varying quantities in many elementary curricula and recent standards documents.

Endnote

In this paper we articulate an approach, termed culturally-mathematically relevant pedagogy (CMRP), for fostering urban English language learners' mathematical progression. CMRP integrates three aspects, the use of (1) adaptive teaching to build on students' funds of knowledge for mathematics, (2) tasks that make sense to students given their current mathematical conceptions, and (3) manipulatives and representations that, for the students, meaningfully signify quantities linked to numbers and operations used in a task. To situate CMRP, we use a continuum of conceptual transitions in multiplicative reasoning, which are critical for supporting students' development of algebraic reasoning.

Keywords: Culturally Relevant Pedagogy; Learning Trajectories; Number Concepts and Operations; Instructional Activities and Practices (Adaptive Teaching)

In this theoretical paper, we argue for the need to expand pedagogical perspectives so they integrate, build on, and are relevant to *both* cultural and mathematical aspects of students' prior experiences and knowledge. Our expansion draws on the core notion of *Culturally Relevant Pedagogy (CRP)* (Ladson-Billings, 1995). This notion has greatly enhanced sensitivity to issues of congruency between student experiences of educative processes at their home/community and in schools. The thrust to augment such congruency for diverse student populations was proposed in place of deficit views of students from underserved populations (e.g., lack of family support), which essentially blame the victims for their poor achievements (e.g., Sleeter, 1997).

For English Language Learners (ELLs), CRP entails addressing the complex interactions between their mathematical communication and understandings, while engaging them in work on cognitively challenging tasks (Moschkovich, 2002). CRP encourages ELLs' use of multiple languages as it enables more complex mathematical activity than when using just English (Moschkovich, 2007). We argue that sensitivity to students' cultures and languages is necessary but insufficient to foster their mathematical progressions. This is supported by research findings suggesting that language fluency does not fully account for differences in ELLs' mathematical proficiency (e.g., Abedi et al., 2006). Our thesis is that to foster students' mathematics learning pedagogy has to be relevant to *both* their cultural and mathematical resources.

To realize mathematics teaching for equity an integrated, *Culturally-Mathematically Relevant Pedagogy (CMRP)* is needed. We suggest that being ***M***athematically relevant entails: (1) Using adaptive teaching to build on students' funds of knowledge *for mathematics*, (2) Using tasks that make sense to students given *their* prior conceptions, and (3) Using manipulatives and representations that, *for the students*, meaningfully signify quantities linked to numbers and operations used in a task. Below, we elaborate on each of these three aspects of CMRP.

Adaptive Teaching

By adaptive teaching we refer to pedagogical methods that are tailored, *every mathematics lesson*, to students' resources—conceptions and experiences they have and bring to a learning situation, termed *funds of knowledge* (Moll et al., 1992). These resources *afford and constrain* advances to rigorous mathematical understandings expected of each young person. We set out to identify students' resources, relevant for lesson goals, and design instruction (tasks, activities, materials) that methodically builds on these resources as a means to engender learning of the intended mathematics. We emphasize that adaptive teaching is *not just* student-centered, or standard- (content) informed, or activity- (problem) based. Rather, it integrates all of these into what Tzur (2010) has termed the "*Teaching Triad*" (Figure 1), which stresses the need to analyze, begin at, and build on developmental continua in student available conceptions. This adaptive approach, depicted by the Teaching Triad, is rooted in Simon's (1995) idea of a teaching cycle revolving around hypothetical learning trajectories (HLT).

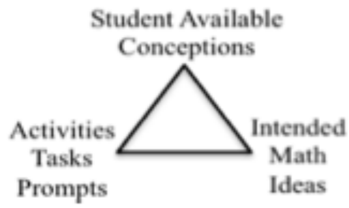

Figure 1: The Teaching Triad

Adaptive teaching, as depicted by the Teaching Triad, includes three principal activities. The first, which ties teaching to students' resources, is the ongoing analysis of students' available mathematical conceptions: goals they might set, activities they might use, contexts familiar to them, objects they might operate on, and effects of their activities that they might notice. The second principal activity is deciphering the intended mathematics into underlying, goal-directed activities. The third principal activity is articulating paths between students' extant thinking and the mathematics they are to learn. The teacher (a) hypothesizes how students' activities and reflections may bring forth the intended learning and (b) designs specific task sequences that can promote the advancement sought (Simon & Tzur, 2004). These three principal activities address five key points proposed by Bransford, Brown, and Cocking (1999): engaging students in tasks, tailoring interaction to students' sense of tasks, motivating students' pursuit of goal, adjusting tasks to students' level of frustration, and possibly modeling execution of a new activity.

Adaptive teaching is consistent with the notion of co-learning (Jaworski, 2001, Tzur, 2004). A teacher selects and uses tasks, guides goal setting, and orients student reflections, while students set their goals, initiate activities, notice effects, and abstract new mathematical relationships. This co-learning approach supports emergence of norms that can increase learning opportunities for ELLs. One critical norm is the constant need to explain various solutions to one another. Another is the expectation to collaboratively solve challenging mathematical tasks, including posing tasks to peers and sharing solution strategies (Boaler, 2006). Such collaboration is coupled with appreciation for diversity and the expectation that every student will participate and share different solutions (errors included!) while not limiting others' participation. Another norm includes awareness that there are many viewpoints, and promote respect for those viewpoints that differ from one's own (Moschkovich & Nelsen-Barber, 2009).

Using Tasks that Make Sense to Students Given *Their* Current Knowledge

CMRP, by engaging every student in solving tasks that are constantly challenging her or his available mathematical thinking, can provide the backbone for equitable lesson/unit design (Simon, 2011). Essential to CMRP is the distinction *between task features and children's thinking*. That is, we contend that the structure of a task as seen by an adult does not, in and of itself, determine the way a child makes sense of and acts to solve it. Rather, implementing a task integrates both—a child's current conceptions and sense making (goal-directed actions, units acted upon), and *task features* designed by adults to promote learning of intended mathematics (Tzur & Lambert, 2011). The need for such a combination is seen in the following example.

Consider the task: Enrique has 3 boxes of cookies. Each box contains 5 cookies. How many cookies does Enrique have in all? Students could solve this task in various ways, such as: (1) using a single cube to signify a cookie and counting, one-by-one, the number of cubes in 3 towers of 5 cubes each to arrive at 15 cookies, (2) counting by 5's, using each finger to signify a tower of cubes (which signifies a box of cookies), and stopping at 15 because 3 fingers have been accrued, and (3) multiplying 3 by 5 to arrive at (a retrieved fact of) 15 cookies.

In the first method, the child needs to count single items—units of 1, but she can use other items, in this case cubes, to stand for these units. In the second method, the child can consider each group of 5 cookies as a "thing," a composite unit. She can continue to accumulate those 5s, anticipating she would be finished when she has accumulated three such units of 5s. In the third method, the child can use a known operation, in this case multiplication, to determine an amount of cookies. As these different methods suggest, although an adult might see a structure in the task and intend for it to elicit a particular operation, the child solving the task engages in operations rooted in her existing conceptions. When implementing mathematical tasks using CMRP, it is necessary to integrate task features with children's sense of the task (e.g., by allowing children to solve the problem in whichever method and language that suit their current ways of making sense of the task). Whereas in this example task features are designed to accentuate coordination of two types of units, a child's solution (e.g., method 1) may include no such coordination.

Using Manipulatives and Representations that Signify Meaningful Quantities for Students

To be adaptive to students' available conceptions, teaching needs to recognize how, when solving tasks, *students* make sense of and use manipulatives and representations, which can signify different quantities for different students. For example, the student who used method (1) above to determine the amount of cookies seemed to be engaging in a one-by-one operation on figural (semi-concrete) objects. That student was able to use a physical object, in this case a cube, to represent an unseen physical object (a cookie). For the student who used method (2), however, a tower (and a finger) represented a composite unit—a box consisting of 5 cookies.

A key feature of adaptive teaching for promoting abstraction of mathematical ideas is therefore identification of how students currently use and interpret particular manipulatives and representations. In turn, teachers need to strategically and gradually promote students' shift from operating on concrete objects, to operating on figural objects (e.g., finger replaces a tower that replaces a box), to operating on abstract (imagined) objects. Students might begin counting only what is visible to them. Next, students could use a different physical object and then figural objects to represent unseen physical objects (e.g., drawing a small square to stand for a box of cookies). Eventually, students could work in the abstract (e.g., using their number sequence to *simultaneously* count the boxes and the cookies—one is 5, two is 10, and three is 15).

Situating CMRP in a Developmental Continuum of Multiplicative Reasoning

In this section, we illustrate a CMRP approach by focusing on multiplicative reasoning—a mathematical prerequisite for advancing to algebraic reasoning (e.g., Mason, 2008; Smith & Thompson, 2008). Rather than focusing on particular topics for students to acquire (e.g., "multiplication of 2-digit by 1-digit numbers"), we target essential ways of reasoning that can underlie students' development of more advanced understandings.

Composite Unit: A Key Distinction between Multiplicative and Additive Reasoning

A key construct we use to distinguish multiplicative from additive reasoning is *number as a composite unit* (Steffe, 1992). When number is conceived of as composite unit, children can anticipate *decomposing* units into "nested" sub-units. For example, a child can decompose 7 into 5+2 because, *for her*, 5 and 2 are "nested" within 7. Key to additive reasoning is that the referent unit is *preserved* (Schwartz, 1991): 11 *cookies* – 7 *cookies* = 4 *cookies*. In contrast, multiplicative reasoning requires a conceptual transformation—a coordination of operations *on* composite units (Behr, 1994). Consider placing 3 cookies into each of 4 boxes; 3 is one composite unit (*cookies per box*) and 4 is another (*boxes*).

Multiplicative reasoning entails distributing one unit over items of another (e.g., 3 cookies into each box) and finding the total via a *coordinated (double) count* (Steffe, 1992): 1 (box) is *1-2-3* (cookies), 2 (boxes) are *4-5-6* (cookies), and so on. C*oordinated* counting involves keeping track of the composite units while accruing the total of 1s based on the size of the distributed composite unit (3 cookies-per-box). As this example indicates, in multiplicative reasoning the referent unit is *transformed* (Schwartz, 1991), and the product has to be conceptualized as a unit of units of units (Steffe & Cobb, 1998): here, "6 cookies" is a unit composed of 3 units (boxes) of 2 units (cookies-per-box). The *simultaneous count* of two composite units and the resulting *unit transformation* constitute the conceptual advance from additive reasoning. Children have difficulty developing multiplicative reasoning, and impoverished conception of number as a composite unit might contribute to that difficulty (Tzur et al., 2010). For example, a student like the one who used method (1) above seemed unable to conceive of a composite unit as a "thing" and thus must have counted individual items to determine the product.

Scheme-and-Task Continuum to Support Students' Multiplicative Reasoning

To foster students' progression in multiplicative reasoning, our CMRP approach follows a sequence of six schemes—goal-directed ways of acting and reasoning (von Glasersfeld, 1995). Below, examples follow each scheme to illustrate tasks on which students work during instruction, to help them advance from prior scheme to the next. A task corresponds to but is not identical with a scheme. For fostering each scheme, we begin by engaging students in operating on tangible objects (e.g., putting cubes together to make a tower). We then proceed to tasks in which students produce the composite units and cover them before figuring out the total. This leads to students' use of figural (substitute) items. Initially these figural items may be physical objects such as fingers. Subsequently students may draw schematic diagrams of the objects. At first, students may draw all single items (1s) in a composite unit. For example, students may draw each of 3 cookies in 5 boxes. Next, we promote a shift to the drawing of only the composite units. For example, students may draw only the 5 boxes and write the number 3 in each box to represent the number of cookies in each box. Finally, we support students' use of numbers to replace the individual items. For example, students may record the numbers 3, 6, 9, 12, 15 to stand for the 5 boxes each containing 3 cookies. To make tasks relevant to children, *we ask them* about and select units and contexts that fit with *their daily experiences* (e.g., shirts and buttons, families and family members, pets and legs, packages and food items, etc.).

For each task we also select numbers that allow gradual progress from "easy" ones (e.g., composite units of 2, 5, or 10 items) to intermediate (units of 3 or 4) and larger/difficult ones (6, 7, 8, and 9, and beyond). The point is quite simple: students are better positioned to construct a new scheme by operating on composite units with which they are familiar. Once the new scheme is evolving, changing to more challenging numbers fosters repeated use and recognition of the invariant nature of that new way of reasoning across any similar situation.

We initiate transition from additive to multiplicative reasoning by fostering students' construction of a ***Multiplicative Double Counting (mDC)*** scheme—the simultaneous counting of composite units and 1s described above. Once students construct mDC, they can anticipate that a total of 1s (say, 24 buttons) is itself a composite unit made of another composite unit (4 shirts), each a composite unit itself (6 buttons). They may solve tasks such as "Enrique has 3 boxes of cookies. Each box contains 5 cookies. How many cookies does Enrique have in all?" Tasks supporting ***mDC*** require students to determine a total number of 1s such that the amount is a composite unit made up of groups of composite units. A solution entails not only figuring out the number of 1s but also and most importantly justifying why this *must* be the total. Typically, we engage students in working on such tasks in pairs, and their justifications often serve to determine which of two different answers is the correct one (including checking their answers by counting the tangible objects).

Next, students can construct a ***Same-Unit Coordination (SUC)*** scheme, in which they learn to apply their additive operations to sets (units) of composite units. They may solve tasks such as, "You had 5 vases, each containing 10 flowers. Now you have 9 vases, each containing 10 flowers. How many *vases* did you gain?" Tasks supporting ***SUC*** require students to reason about a *set* of composite units as made of sub-units, each of which is a set of composite units, without losing sight of their being composed of a particular numerosity. Initially, they may respond to such tasks by mistakenly attempting to count, or calculate, the total of 1s in the set. Gradually, with teaching emphasis on the unit being asked about in a task, they shift their focus to operations on the composite units. Such operations can, for example, support students' learning of adding/subtracting units of 10 (e.g., 90–50 means subtracting five 10s from nine 10s, hence four 10s which are forty 1s).

Next, we promote students' construction of a ***Unit Differentiation and Selection (UDS)*** scheme (McClintock et al., 2011), in which they further separate operations on 1s and composite units. They may solve tasks such as, "You have 7 boxes, each containing 5 pencils. I have 4 boxes, each containing 5 pencils. How are our collections similar? Different? How many more pencils do you have?" Tasks supporting ***UDS*** foster students to conceive of two sets of composite units in terms of sub-units that constitute each, and operate multiplicatively *on the difference* between the two sets. Such operations can, for example, support students' learning of the distributive property of multiplication over addition (e.g., to solve the above problem they can either find the totals first, 35 and 20, and then subtract to obtain 15, or find the difference of 7-4 first, and then multiply it by 5 to obtain 15).

Then, we promote students construction of a ***Mixed-Unit Coordination (MUC)*** scheme (Tzur et al., 2009), in which they operate on two collections—one consisting of composite units and the other of 1s. They may solve tasks such as, "You have 7 boxes, each containing 3 candies. I'll give you 6 more *candies*. If you put these 6 candies into boxes containing 3 each, how many *boxes* will you have in all?" Tasks supporting ***MUC*** foster students' selecting the distributed composite unit (e.g., 3 cookies-per-box), imposing that unit on the singletons (e.g., 6 candies) to yield 2 composite units (e.g., boxes), and then adding these to the initial set (e.g., 7+2=9 boxes). Such operations can, for example, support students' learning of algebra-like mathematics that involves both additive and multiplicative operations on different-but-related units (e.g., 3*10+15=4*10+1*5=45, and later solving for the number 'x' that will make the equation 3x+15=45 a true statement).

From ***MUC*** we proceed to fostering students' construction of a ***Quotitive Division (QD)*** scheme as an inverse operation to multiplicative double counting. They double count to solve tasks like: "I counted 60 legs of chairs in the class. Each chair has 4 legs. How many chairs are in the class?" Tasks supporting ***QD*** require students to operate on a total of 1s and use the size of each composite unit to determine (keep track of) how many such units can be made. Such operations can, for example, support students' learning to use a single structure (equation) to represent, and solve, multiplicative situations by identifying which two of three quantities are given, which needs to be figured out, and what operation is required (e.g., 4x?=60 leads to dividing 60÷4, whereas 4x15=? leads to multiplying the two numbers).

Later, we move on to fostering students' construction of a ***Partitive Division (PD)*** scheme, in which they operate on a total of 1s by distributing it equally into a given number of composite units. They solve tasks such as "Our class has 24 students. We want to place them into 3 groups. How many students will be in each group?" Tasks supporting ***PD*** require students to figure out the size of each distributed composite unit, given the amount of composite units and the total of 1s. Such operations can, for example, support students' learning to meaningfully use the long-division algorithm, as a process in which units of units (etc.) of 10s are distributed into the given number of groups (divisor), while exchanges to smaller units enable such distribution when there are not enough larger units (e.g., to divide 294 into 7 equal groups one exchanges two 100s into twenty 10s, adds the nine 10s, and distribute those twenty-nine 10s by placing four such units in each of the groups, leaving one 10 that needs to be further exchanged, etc.).

Enacting CMRP with Urban ELLs

We have begun to enact a CMRP approach through piloting instruction designed to promote the aforementioned conceptual transitions in multiplicative reasoning in urban ELLs. This pilot work was conducted at an elementary school with over 85% of students whose native language is Spanish. It included work with individual 4th graders who were identified as having disabilities in mathematics, and with K–5 teachers in the school. The latter included workshops with teachers that focused on their own mathematical understandings (e.g., of the place-value, base-ten number system), on children's developmental pathways to mathematical conceptions (from rote-counting, through cardinality and counting-all to counting-on, and to additive and multiplicative reasoning with whole numbers), and on the

CMRP, adaptive teaching approach. Besides the workshops, we have been partnering with two teachers (grade 3 and grade 4) to co-plan and co-teach their students as a medium for enacting and demonstrating the adaptive teaching.

Our pilot work highlights how a CMRP may provide ELLs with instruction that gives them the opportunity to work on cognitively challenging mathematical tasks (e.g., Brown et al., 2011; Campbell, Adams, & Davis, 2007; Moschkovich, 2007). Moschkovich (2002) asserted that equitable mathematics instruction for ELLs must move beyond focusing on acquiring mathematical vocabulary and recognizing multiple meanings for terms. By analyzing students' available conceptions and fostering their problem solving in conceptually tailored tasks, CMRP seems to enable engaging in and linking mathematical processes and expressions. In particular, by fostering students' movement from concrete to figurative to abstract representations, CMRP seemed to promote a focus on *their* mathematical reasoning and justifying. When students justified their solutions, they had an opportunity to do so in multiple ways—in English and in one's native language. Thus, students were highly engaged in discussions with their peers as they shared their strategies. Further, when justifying their results, students have used physical objects and/or diagrams to represent the composite units (e.g., boxes of cookies) involved in the problem. Strategic use of representations supported students' development of more advanced mathematical structures and fostered their productive participation in mathematical practices. Preliminary results of enacting CMRP to promote ELLs' advancement from additive to multiplicative reasoning indicated substantial impact.

Discussion

In this paper we proposed a Culturally-Mathematically Relevant Pedagogy (CMRP) approach, including three key aspects: adaptive teaching, sensible tasks, and meaningful manipulatives. Central to all three aspects is students' engagement in mathematical practices they can make sense of via their prior conceptions. The three aspects of CMRP are interrelated, as indicated by the Teaching Triad. That is, a CMRP approach links instructional goals to funds of knowledge that low SES and ELLs bring to a lesson. If traditional lessons focused on one vertex of the *Teaching Triad* (mathematics), reform lessons on two (tasks/activities and mathematics), CMRP lessons are innovative in that the focus is on all three vertices (student resources/conceptions, tasks/activities, and intended mathematics). Each CMRP lesson begins with tasks that build on student mathematics. This supports gradual use of challenging tasks by making sure the tasks are tailored to students for whom the instruction is being designed.

In essence, CMRP is a mathematically focused implementation of Culturally Relevant Pedagogy (CRP). When implementing challenging tasks, CMRP uses situations that are supposedly meaningful to the students. These tasks build on students' abilities rather than deficiencies and allow for multiple pathways to their success. The "M" part of this approach focuses on strategic tailoring of problem situations and representations that make sense to students given their current understandings. The goal of this strategic tailoring is to promote students' mathematical progression, in our case to promote transition along our six-scheme continuum of multiplicative reasoning. For example, if a student has developed multiplicative double counting (mDC) only for visible items, the student would engage in tasks that would support her development of mDC for *hidden* items. Another student who had developed mDC for abstract items could engage in tasks that foster Same Unit Coordination (SUC) with visible composite units. The articulation of the schemes involved in multiplicative reasoning augments our sensitivity to students' mathematical progression. By linking the operation of division with the operation of multiplication, students can meaningfully solve problems that they otherwise may have been able to solve only with the use of an algorithm. In turn, we foster bringing forth each of the schemes to support its use for more advanced algebraic reasoning.

TEACHERS' AND STUDENTS' PERCEPTIONS OF CLASSROOM DISCUSSIONS

Wendy Rose Aaron
Oregon State University
wendyaar@umich.edu

Patricio Herbst
University of Michigan
pgherbst@umich.edu

We argue that teachers and students view classroom discussions differently. Teachers view the work of facilitating discussions weaving students' contributions together into a coherent discussion of the subject at hand. Students, on the other hand, view the work of participating in discussions as negotiating relationships with their peers. We support these claims with analysis of the appreciation and judgment (Martin & White, 2005) made by high school geometry students and teachers in conversations around an animated representation of instruction.

Keywords: Classroom Discourse; High School Education; Reasoning and Proof

Objectives or Purposes of the Study

In this paper we support the hypothesis that teachers and students view classroom discussions differently from each other, in particular, they view different difficulties involved with engaging in classroom discussions. From the point of view of the teacher the work of facilitating discussions involves weaving students' contributions together into a coherent discussion of the subject at hand, while from the point of view of the students, the work of participating in discussions is much more relational and involves negotiating relationships with their peers.

We have collected teacher and student responses to an animated classroom episode, The Square (which can be viewed at lessonsketch.org), in which a class engages with the question, What can one say about the angle bisectors of a quadrilateral? In the full paper we examine the different ways that teachers and students interpret discursive moves visible in this episode. Here we present examples showcasing the ways that teachers and students interpret a canonical teacher discourse move, revoicing (O'Connor & Michaels, 1993).

Perspective(s) or Theoretical Framework

Within the educational research and reform communities, teachers are encouraged to facilitate discussions in class, building on student contributions (Chapin, O'Connor, & Anderson, 2003; Inagaki, Hatano, & Morita, 1998; Kazemi, 1998; NCTM, 2000; White, 2003; Yackel, Cobb, & Wood, 1999). When researchers examine the difficulties of this work they often focus on the difficulties of listening to and understanding student contributions, responding to unexpected student contributions, choosing the most appropriate discourse move in response to students contributions, and weaving together a coherent argument from student contributions (Even & Gottlib, 2011; Sherin, 2002; Stein et al., 2008). If researchers were aware of students' experience their account of the teacher's challenges would be more complete.

Methods or Modes of Inquiry

To analyze the data in this study we look at the way that the participants used appraisal resources (Martin & Rose, 2003; Martin & White, 2005) in their talk about instructional scenarios. We look at two dimensions of appraisal, appreciation and judgment. Appreciation resources are used to appraise the worth of things in the world and judgment resources are used to appraise the deeds of people. These resources operate at the level of the text rather than the clause because, while they rely on word choice and sentential structure, they cannot be reduced to one or the other. Using these linguistic tools we compare teacher and student talk around an animated instructional episode involving revoicing. This comparison highlights the different ways that teachers and students evaluate the instructional episode, either in terms of the mathematical ideas at play or the people who voice those ideas.

We pull from two data sources; study group sessions with experienced geometry teachers and focus group sessions with classes of high school geometry students. The data collection with each group centered on gathering the group's reaction to an animated episode of geometry instruction. These data sources provide the opportunity to compare the reactions of teachers and students to the same instructional episode.

In the animated episode, The Square, the class is working on the problem, What can one say about the angle bisectors of a quadrilateral. In particular, a student, Alpha, has brought up the case of a square and claimed that the diagonals bisect each other. The teacher picked up this claim and reminds Alpha that the problem is about angle bisectors, not diagonals. In response to this Alpha revises his claim to say that the diagonals cut the square in half. The teacher revoices Alpha's revised claim and asks the class to elaborate on it. Another student, Beta, makes the claim that diagonals are also angle bisectors. The teacher revoices this claim and asks the class if they agree with Beta's statement. Gamma replies that the claim is obviously false since it is not true for the case of rectangles.

Below we describe examples of reactions that the two groups of participants had to this exchange. In the full paper we present analysis of all the conversations that participants had in response to this animated episode. In this proposal we limit our analysis to two examples. In the transcripts below, text in bold shows appreciations and text in italics shows judgments.

The first example comes from a study group session with experienced geometry teachers. The participants were viewing The Square and had just seen the excerpt described above. Tabitha paused the viewing and began a conversation about how the animated teacher handled the students' contributions. In the transcript below, another participant, Tina, questioned how the animated teacher dealt with Beta's contribution by suggesting that the animated teacher should have stressed the condition that the quadrilateral is a square. Tabitha agreed with Tina and Tina made the recommendation that the animated teacher redirect the discussion to focus on squares and the distinction between angle bisectors and diagonals.

Table 1: Transcript from Study Group with Experienced Geometry Teachers

1057	Tina	But see I think *she was* ***wrong*** **in stating it how she said it**. I think the teacher said "listen-" *she* ***should have said*** **something about "listen to what Beta just said. Diagonals are also the angle bisectors of a square."**
1058	Tabitha	**Of a square**.
1059	Tina	***I would've added*** **"of a square."**
		…
1061	Tina	Right. **"So let's think about it as a square. Are the angle bisectors and the diagonals the same?"**

In Table 1 the participants negatively appreciate the teacher's response to Beta's contribution, as well as negatively judge the teacher. By providing alternative responses to Beta's contribution they make tacit, negative appreciations on the response given by the animated teacher. Each alternative provided is in contrast to the animated teacher's comment, "Listen to what Beta has just said. That the diagonals are also the angle bisectors. Do people agree with that?" The contrast between the animated teacher's comment and the participants' rephrasing is set up in turn 1057, when Tina referred the animated teacher's response as "how she said it." Through the use of grammatical resources Tina made a negative appreciation of the animated teacher's statement of the type composition/distortion (Martin & White, 2005, p. 56). Tabitha's comment in turn 1058 strengthens this appreciation, by reiterating the piece of information that was missing from the animated teacher's comment, "of a square." In turn 1061 Tina reiterates the appreciation by providing a new alternative response to Beta's comment that is further from the animated teacher's response. In this turn Tina suggests that the animated teacher abandon the revoicing move and ask students to think about a new question.

The second example comes from a focus group with a class of high school geometry students. The participants had just watched the clip from The Square that is described above. In the transcript in Table 2 participants brought up the interpretation that Alpha might be annoyed by Beta's restatement of his contribution. Tasha saw that Beta could be annoying to Alpha because Alpha knew that he had the right idea, but that Beta was going to be the one to get the credit for the idea since she said it more clearly. Jack expanded on this interpretation by pointing out that other students admire students who share correct answers. The researcher asked if students are concerned about having their ideas heard in class and Nissim pointed out that students see this as a kind of theft when a student rewords another student's answer.

Table 2: Transcript from Focus Group with High School Geometry Students

149	Researcher	So say more about Alpha being annoyed.
		…
155	Tasha	I can kind of agree with that because um like you just know that you *have it* ***right*** too but they're kinda *the one that's going to get the credit for it* but I mean *you had the same idea*, you *just didn't have the words to say it*.
156	Researcher	Yeah it's like someone *stole your idea*.
		…
165	Jack	When you answer a question it makes people be like "*oh they knew that, they're smart*" and then so when someone else answers the question they're like "*oh my I did not get to like explain my [inaudible]*."
166		[students laugh]
167	Researcher	Yeah so that's what you want to do, you want to make sure your ideas are heard that's the only thing you care about?
168	Nissim	I think it's sort of like a [inaudible] when you go up to answer the question yeah [inaudible] answer it, then if you *word it* ***wrong*** then someone else *words it* ***correctly*** the whole class kinda feels like they *stole your answer*.

In Table 2, the participants discussed the increased social status that students associate with contributing correct ideas to the conversation. They did this through lexical judgment resources of the security ("correctly"), capacity ("smart") and inclination ("credit") types to positively judge students who contribute correct ideas and negatively judge students who are unable to communicate their ideas. They mention students who "have it right," "get the credit," "had the same idea," "[are] smart," "did not get to … explain," "word it wrong," and "[word] it correctly." Students who have correct ideas, get credit, and are able to communicate their ideas are judged positively, while students who cannot communicate their ideas are judged negatively.

Results

From the analysis of these two examples, and the other discussions which we do not have room to report on here, it can be seen that teachers are more likely to appraise the ideas that are at play in the classroom discussion while students are more likely to appraise the people involved in the discussion. We contend that these different appraisal patterns reflect the different professional obligations (Herbst, 2010) or commitments that teachers and students are responding to. While teachers seems to be concerned with the mathematical content of the discussion, in response to the disciplinary obligation, students seem to be concerned with the interactions between students around content, related to the interpersonal obligation. This suggests that students' instructional experiences, and the quality of mathematical discussions, would improve if teachers were positioned to attend to the students' interpersonal concerns.

Discussion and/or Conclusions

Mathematical discussions in classrooms are often justified by claims that could be seen to appeal to teachers' individual and disciplinary professional obligations (to attend to students' cognition or motivation, or to attend to the features of the ideas at stake). However, in this study we show that, in the students' experience, this work has a large interpersonal dimension. Within discussions, students not only deepen their own understandings and construct shared mathematical knowledge, but they also relate to each other around the mathematical ideas that are being shared. We argue for a more nuanced way of examining discourse moves that pays attention not only to the impact that they have on individual student learning, or the shaping of the content, but also to how it invites students to interact with each other around the content.

Author Note

Research reported had the support of the National Science Foundation through grant ESI-0353285 to P. Herbst. All opinions are those of the authors and don't necessarily reflect the views of the Foundation.

SECONDARY MATHEMATICS TEACHERS' ENACTMENT OF CONTENT LITERACY STRATEGIES

Anne E. Adams
University of Idaho
aeadams@uidaho.edu

Jerine Pegg
University of Alberta
jerine.pegg@ualberta.ca

Content literacy strategies offer teachers another set of tools for developing student reasoning and sense making, ongoing goals of mathematics education. However, the nature of strategy use determines whether these goals will be met. This paper presents the results of a qualitative inquiry into the content literacy practices of 17 mathematics teachers engaged in an ongoing content literacy professional development. We analyzed classroom observations, lesson plans, and online discussions to determine the nature of mathematics teachers' use of content literacy strategies. We describe contrasting ways teachers enacted content literacy strategies, provide examples of the varying approaches, and describe influences on implementation.

Keywords: Instructional Activities and Practices; Teacher Education–Inservice/Professional Development

Purpose

Content literacy is "the ability to use reading, writing, talking, listening, and viewing to learn subject matter in a given discipline" (Vacca & Vacca, 2005, p. 184). Incorporating content literacy instruction into content courses can improve student learning and support learners in developing understanding of knowledge accepted by the discipline, enabling them to critique and influence that knowledge (Draper, 2002; Moje, 2008). Previous studies have examined teachers' beliefs about use of content literacy strategies in content courses, amount of strategy use, and influences on amount of use, but not the specific nature of teachers' incorporation of content literacy strategies into their instruction (Alvermann, O'Brien, & Dillon, 1990). This study examined the nature of mathematics teachers' implementation of content literacy strategies.

Perspectives

Focus in the use of literacy strategies in the content areas has shifted from the use of strategies for memorization and exposition of knowledge and the development of technical reading and writing skills towards a more constructivist view in which students construct meaning through discussion, reading, and writing activities. Current content literacy approaches incorporate strategies that use a reasoning and sense making approach to actively engage students in learning content (Fisher & Ivey, 2005; Moje, 2008).

Previous research has shown that teachers' decisions to use content literacy strategies are influenced by a variety of factors. Preservice teachers' use was influenced by views of the content, their philosophy of teaching, relevant curriculum materials, administrative policies, and their cooperating teacher's desires and teaching style (Bean, 1997; Sturtevant, 1996). Strategy use was also constrained by limited time, large class sizes, students with academic or personal problems, and instability in teaching assignments (Sturtevant, 1996). Cantrell and Callaway (2008) found that inservice teachers' self-efficacy influenced their use of content literacy strategies.

There is little research that specifically examines the nature of teachers' use of literacy in secondary classrooms. Alvermann et al. (1990) examined the nature of teachers' discussions of content area readings in science, social studies, language arts, and health classes. They found the type of discussion depended upon the teachers' purpose for the lesson and that there was often a discrepancy between teachers' definitions of discussions and their actual practices. This study suggests the importance of examining whether or not teachers incorporate literacy instruction and the need to understand the nature of implementation. Our study extends previous work by examining the nature of content literacy strategy use by secondary mathematics teachers engaged in a long term professional development project specifically focused on content area literacy.

Methodology

This study examined the practice of 17 secondary mathematics teachers in a project on integrating literacy strategies into secondary science and mathematics courses. Project activities consisted of a week-long summer workshop, three follow-on workshops, classroom visits by project staff, and online discussion. Workshops introduced the role of language in content learning and instructional strategies for integrating literacy into instruction. Teachers engaged in activities that modeled specific research-based strategies for vocabulary, writing, and reading in mathematics and science. These strategies were chosen for their ability to support development of student understanding and reasoning in mathematics and science. In order to understand the nature of teachers' literacy strategy use, yearly data were collected from three classroom observations, two lesson plans, reflections, student work, and discussion posts from each teacher. Two researchers independently examined data and coded strategy use. This paper presents findings from the mathematics teachers' lessons from the first two years of the project.

Findings

Although all teachers incorporated new content literacy strategies into their instruction, they did so in varying ways. Upon analysis of teachers' use of content literacy strategies, typical features of strategy use were discerned. Two contrasting approaches to the incorporation of literacy were identified: Rehearsal and Reorganization. In the Rehearsal approach, teachers primarily used literacy strategies to revisit and rehearse content. In the Reorganization approach, teachers used literacy strategies to support students in developing deeper conceptual understanding. We also identified a third Transitional pattern of use that contained components of the other patterns. While teachers seemed to predominately exhibit one pattern, some teachers at various times used a Rehearsal pattern, and at other times a Reorganization pattern. Table 1 presents characteristics of the Rehearsal and Reorganization approaches.

Table1: Rehearsal and Reorganization Approaches to Content Literacy Strategy Use

	Rehearsal Approach Emphasizes:	**Reorganization Approach** Emphasizes:
Vocabulary	• Memorize formal definitions • Definitions taught first, followed by concept development	• Engage in constructing meaning of terms • Integrate vocabulary and conceptual development
Reading	• Decode, vocabulary, and text structure • Acquire information/facts/ vocabulary	• Draw on background knowledge and text structure to support comprehension • Active interaction with text supporting conceptual understanding
Writing	• Write formal reports • Take notes/record information • Support memorization or reinforcement of knowledge • Assess student knowledge	• Process/construct new knowledge • Reflect on prior learning/clarify thinking • Explain and justify one's steps/process to further understanding • Support students in making thinking explicit

Implementation of Content Literacy Strategies

This section presents examples of how teachers used specific vocabulary, reading, and writing strategies with either a Rehearsal or a Reorganization approach.

Vocabulary development. The Frayer Model and Verbal Visual Word Association (VVWA) are word categorization activities designed to develop concept understanding (Billmeyer & Barton, 1998). With the Frayer Model, students write their own definition for the concept, describe its characteristics, and provide examples and non-examples. In the similar VVWA students write their definition, provide a visual representation and a personal association. A teacher who used the Frayer Model with a Rehearsal approach described making sure to "give an answer for each of the four sections of the Frayer Model during my lecture." He then had students copy these during the lecture or transcribe them from their notes. In contrast, a teacher using a Reorganization approach described how she used the VVWA strategy to develop understanding of the concepts, providing "some activity where they 'discover' the concept. … Then we fill out the VVWA, but I ask them to tell me what a good definition would be."

Reading. Anticipation Guides support students in thoughtful reading and interpretation of text (Forget, 2004). When presented with a set of statements that rephrase ideas in the text, students initially read each statement and conclude whether it is true or false. After discussing their choices with a partner, students are motivated to read and interpret the related text, seeking evidence that supports their previous decisions, and then justify their choices with evidence from the text. Anticipation Guide uses identified as Rehearsal focused student attention on finding facts from the reading. Statements required little thought to answer. Anticipation Guide uses that were classified as Reorganization involved students in reading text carefully, making inferences from the text, or engaged students in examining misconceptions. In one such example, the statement "3.14 is an irrational number" engaged a class in a long discussion as students distinguished an irrational number from its common decimal approximation.

Writing. Writing can be used in many ways to support understanding of mathematical ideas. Students might respond to a statement, summarize learning, or describe or justify their problem solving approach or their solution. Such writing leads students to reflect on experiences, organize thoughts, and consolidate understanding (Burns, 2004; Forget, 2004). When writing consisted of recalling information or recording what was presented, it was coded as Rehearsal. In one such example, students were asked to describe steps for solving an inequality and provide an example. In doing so, they needed to recall or look up the rules they had been given, providing an opportunity to reexamine this process. In an example characterized as Reorganization, students conducted a probability experiment. They calculated their own experimental probability and that of the entire class and wrote a paragraph describing results and proposing an explanation for the differences in experimental probability. In this example, writing led students to reconsider the results of the probility activity, make meaning of the situation, and propose an explanation.

Discussion

The data from this study show that teachers tended to use content literacy strategies in ways that aligned with their current practices and instructional goals. As O'Brien, Stewart, and Moje (1995) suggested, this tendency sometimes resulted in a mismatch between content literacy strategies based on socioconstructivist theories and teachers' goals and practices. We found this discrepancy did not necessarily result in a failure to use content literacy strategies, but rather in some teachers modifying the strategies in ways that focused more on transmission of knowledge than on the development of conceptual understanding. All teachers incorporated content literacy strategies into their instruction, but modified them in ways that fit their own teaching approach.

When strategies were implemented according to a Rehearsal approach, the teachers' instructional goals were typically for students to learn procedures or facts or to review specific information. Teachers with such learning goals used strategies that helped students take in and retain information and implemented learning activities in ways to maximize opportunities to do so. When teachers described learning goals of developing conceptual understanding, they used literacy strategies in a Transitional or a Reorganization pattern. In the Reorganization pattern, the strategies were often integrated with instructional activities focused on a common conceptual goal, with time provided for student reflection and discussion.

In strategy use identified as Transitional, the teacher's goals were aligned with conceptual understanding, but aspects of lesson design or implementation resulted in not accomplishing these goals. There are multiple challenges for teachers adopting literacy strategies in content area teaching. For some teachers the incorporation of content literacy strategies required shifts in previous instructional patterns, such as in the amount of time allotted for particular instructional activities, connections between lesson activities, and the role of discussion. Our findings suggest that if related instructional activities are not already in place in a teacher's practice, considerable learning and rethinking of the learning process may be necessary for a teacher to use literacy strategies to support meaningful understanding of mathematics concepts.

Conclusion

Content literacy strategies offer teachers of mathematics another set of tools for use in developing student reasoning and sense making, ongoing goals of mathematics education. However, the ways the strategies are used determines whether these goals will be met. We found teachers' implementation of content literacy strategies to be variable and adaptable. Teachers' use of literacy strategies was influenced by multiple factors, including learning goals, prior teaching practices, and pressures from limited class time. These findings suggest that it may not be enough for teachers to value literacy use in mathematics instruction. They must understand the importance of reasoning and the role of literacy in supporting understanding of mathematics**.**

Algebra instruction should help students navigate the transition from executing procedures to a more robust understanding of algebra. There is little empirical evidence, however, linking promising instructional practices to such understandings. The Algebra Teaching Study seeks to develop tools for measuring connections between algebra teaching and students' learning outcomes. To demonstrate the use of these tools, we present a comparison of two algebra classrooms, where instructional differences were related to differences in student outcomes.

Keywords: Algebra and Algebraic Thinking; Instructional Activities and Practices; Middle School Education; Problem Solving

Introduction

While growing attention has been given to algebra teaching and learning, there is still a lack of empirical evidence linking teachers' instruction and students' understanding of algebra. The purpose of the Algebra Teaching Study is to develop measurement tools to determine which classroom practices help students navigate the transition from executing procedures to the development of robust understanding of algebra. Our classroom observation scheme, Teaching for Robust Understanding in Mathematics (TRU Math), is being developed using classroom observations in Michigan and California. To measure students' gains in robust understanding, we articulated a set of dimensions defining robust understanding of algebra, which we call Robustness Criteria (RC). We adapted and constructed tasks to measure student understanding along these dimensions. We illustrate these tools by presenting comparative cases in which differences in instructional practices of two classes related to differences in gains in algebra achievement. For this paper, we focused on algebraic representations, due to their central role in algebra. We first present our framework for measuring robust understanding of algebra.

Theoretical Framework

The study focused on student understanding of algebra word problems. This is due to their central role in the algebra curriculum, as well as students' struggles with them. Focusing on word problems enabled us to examine a range of student skills related to robust understanding, including: sense making, modeling, representational and procedural skills. In this section, we will elaborate our definition of robust understanding.

Robustness Criteria Framework

The robustness criteria were developed in consultation with a large body of literature, including: the *Principles and Standards for School Mathematics* (NCTM, 2000), the Common Core State Standards for Mathematics (2010), studies of how students solve problems (e.g., Schoenfeld, 2004), and algebraic habits of mind (Driscoll, 1999). The robustness criteria (RCs) serve two major purposes in our project: guiding task selection and analysis, and focusing our attention during classroom observations, for example, on teacher actions that might promote fluency with algebraic representations. Below, we list our five criteria. We elaborate RC3 because it is the focus of this paper.

RC #1: Navigate language to make sense of the problem situation.

RC #2: Identify relevant quantities and relationships between them.

RC #3: Represent quantitative relationships. Relating and representing multiple varying quantities is a core feature of a functions-based approach to algebra (e.g., Chazan, 2000). Algebraic representations include coordinate graphs, bivariate tables, diagram or pictures, and variable equations (or systems of equations). Further, the Understanding Patterns, Relations, and Functions Standard states that students should be able to "represent, analyze, and generalize a variety of patterns and tables, graphs, words, and when possible, symbolic rules" (NCTM, 2000, p. 222). Schoenfeld (2004) identified building a situation model and building a diagram or other appropriate representations as being important aspects of student knowledge for solving word problems. The use of multiple representations facilitates students' development of mathematical concepts (e.g., Stein et al., 2009) and their efforts to carry out problem solving tasks (e.g., Greeno & Hall, 1997). Tasks with high cognitive demand should have the potential to be represented in multiple ways (Stein et al., 2009). Therefore, students should be given the opportunity to use multiple representations in problem solving activities.

RC #4: Executing algebraic procedures and checking solutions.

RC #5: Explain and justify reasoning.

These criteria represent the proficiencies required to solve rich, contextual algebraic word problems (Wernet et al., 2011), which we henceforth refer to as contextual algebraic tasks.

Method

Over the course of two years, we have collected data from ten 8th-grade algebra classrooms. We administered pre-tests at the beginning of the school year to document students' initial proficiencies with contextual algebraic tasks. During the school year, we observed each classroom eight times, capturing lessons involving contextual algebraic tasks whenever possible. We then administered post-tests at the end of the school year to document students' growth in understanding as a result of a year of classroom instruction.

The pre- and post-test assessments were comprised of three, multi-part tasks drawn largely from the Mathematics Assessment Resource Service (MARS) assessments. Students' work received two types of scores: a holistic score based on rubrics that aligned with the MARS rubrics, and RC-specific scores, with points awarded related to each of the robustness criteria.

For the purposes of scoring, RC3 (interpreting quantitative relationships) was further elaborated to RC3a (generating representations) and RC3b (interpreting and making connections between representations). The RC 3a scores reflect, in part, students' spontaneous generation of a representation to complete a task in addition to the correctness of the representation generated. These scores were then compiled to provide overall class scores, allowing us to capture student growth, at the classroom level, in robust understanding of algebra across the school year.

Across the observed classrooms, teachers used a variety of curricula (four of the classrooms used an NSF-funded curriculum while the others used a traditional, district adopted text). Thus, the videos we have collected provide a range of lessons from those focusing on traditional story problems to those using more open-ended tasks. This collection of videos has been used both to identify teaching moves warranting attention in our observational tool, as well as to test the observational tool during the development process.

For the purposes of this paper we made a holistic characterization of the instructional practices around representations. We focused on five randomly selected students from each of two classrooms, A and B, in a comparative case study. Class A was comprised of low-tracked students in a suburban school in the Midwest and used an NSF-funded curriculum. Class B included de-tracked students and used a traditional text in a large urban setting on the West Coast. The case study addressed the following questions:

1. How does student use of representations in written algebraic tasks differ between two 8th grade algebra classrooms?
2. How do teachers' approaches to supporting students' use of representations differ between these two classrooms?
3. How does variation in student performance on tasks involving representations relate to the differences in instructional practices?

Illustrative Results

In our observations of Class A and Class B, we noticed significant differences in classroom practices. Students in Class A interacted with representations on a regular basis. Using a functions-based approach to learning algebra (cf. Chazan, 2000), tasks in the curriculum regularly asked students to generate equations, tables, and graphs, and to make connections between these representations. Additionally, Teacher A consistently pressed and supported students to make explicit their generation of representations and make connections between them through questioning, re-voicing, drawing attention to context and other visual cues, and building on previous knowledge.

In contrast, students in Class B spent much of their time taking notes on specific procedures, working on exercises and showing steps in their work. During independent or partner work time, students were primarily engaged in practicing procedures demonstrated in class lecture. Students had few opportunities to generate or interpret representations.

There were differences in students' learning growth both in terms of overall scores and in terms of students' use of representations, measured by RCs 3a (generating representations) and 3b (interpreting and making connections between representations). Table 1 shows the average total scores across the two classrooms on the pre- and post-assessments and the performance in understanding the use of the algebraic representations. Recall that students in Class A were placed in a low-tracked classroom and scored lower than Class B on the pre-assessment. By the end of the study, however, the performance gap had closed; Class A showed evidence of greater growth in RC3. Although students in Class B correctly generated and interpreted representations more frequently on the pre-assessment, the students in Class A finished the school year with higher scores on tasks involving representations.

Thus, initial evidence indicates that there are differences in students' growth in RC3 across classrooms, and that our assessments can capture differential growth.

Table 1: Scores across Two Classrooms

	RC3a		RC3b		Total score		Difference
	Pre	Post	Pre	Post	Pretest	Post-test	
Class A	0.6	4	3.6	6	20%	41%	21%
Class B	1.6	3	4.4	5	26%	32%	6%

The results shown illustrate the potential to document the relationship between students' learning with factors related to teachers' specific instructional practices.

Discussion

National discussions increasingly emphasize the importance of all students studying algebra by eighth or ninth grade. If the push for all students to study algebra is to lead to robust understanding, rather than only superficial skill with algorithms, mathematics educators must have a better understanding of which classroom processes will help build robust understanding.

Our Algebra Teaching Study has developed a system for classroom observation and task-based forms for student assessment that can be used for research linking differences among patterns of activity in classrooms to differences in student acquisition of robust understanding. The cross-case comparison presented here shows that our measures document such differences. Although a comparison across two classrooms is only suggestive of connections between teaching and learning, future work with larger numbers of classrooms can reveal whether such connections are typical. Development of these tools is a significant first step in an important line of research that is scant in the literature.

DO STUDENTS FLIP OVER THE "FLIPPED CLASSROOM" MODEL FOR LEARNING COLLEGE CALCULUS?

Janet Bowers
San Diego State University
Jbowers@math.sdsu.edu

Dov Zazkis
San Diego State University
zazkis@gmail.com

The "flipped" classroom model, wherein students watch online lectures for homework and do traditional homework sets in class, has fueled significant role transitions for both teachers and students. In this ongoing study of one flipped college calculus course, the role of the teacher transitioned from lecturer to problem set designer. The role of the students is still in flux: Initial reports indicate students prefer their role as collaborators but many indicate their uneasiness regarding the first exam. We are currently investigating the stages of several transitions including the students' changing views and the ongoing reflections of the TAs and instructor.

Keywords: Technology; Flipped Classroom; Calculus

Online video sharing websites have fueled major transitions in the ways students learn about the world, the culture, and mathematics. Thanks to innovative mathematics instructors such as Saul Khan, whose Khan Academy currently boasts over 11 million lessons delivered, some teachers have begun implementing a "flipped" (or inverted) model of instruction wherein students are expected to watch online lectures out of class and spend in-class time working in groups to solve problems related to the lecture content. Many students are enthusiastically embracing this chance to shift from non-engaged stenographers in large lecture classes to self-paced collaborative learners. The goal of this ongoing investigation is to examine the stages of this student transition in the context of one college calculus course. The presentation will discuss the results of five surveys that will be given to the students over the course of the semester. The present proposal describes the results from the first of these reports which measures students' initial views of the flipped approach to teaching and their time allocation patterns.

Theoretical Perspective: Finding the "Sweet Spot" Between Teaching for Procedural and Conceptual Understanding

Despite the huge range of topics displayed in online mathematical instruction videos, there is surprising uniformity in presentation: Either a learned instructor or a set of talking hands demonstrates a single, step-by-step procedure for solving a given problem in, on average, 5.5 minutes. Our current hypothesis is that such presentations implicitly promote procedural skills, but are not designed to support the development of overall conceptual understanding. Following current reform initiatives for grades K–12 (cf., NGA, 2011; NRC, 2001; NCTM 2000), we seek to determine if the method devised by this college instructor defines the sweet spot that promotes both procedural fluency and conceptual understanding.

As Star (2005) suggests, one could argue that the procedural/conceptual debate may be seen as promoting a false dichotomy based on the view that there is a good deal of conceptual understanding that underlies *procedural fluency.* For example, when solving novel problems, students with procedural fluency are able to first choose an appropriate algorithm and then persevere in applying it. In this view, procedural fluency can be seen as using various heuristics (Polya, 1957) and being metacognitively aware of how they relate to the problems at hand (Schoenfeld, 1994). Thus, the overall questions for this study focus on determining (a) the degree to which students learned to teach themselves both procedural fluency and the conceptual understanding that underlies algorithm selection, (b), their affective reaction to this class, and (c) the paths they traversed as they transitioned from passive students to active peer collaborators and internet sleuths.

Methods

Subjects and Data Sources

The subjects for this study are the 27 students enrolled in the "flipped" Calculus I course at a large, southwestern university. Of the population, 41% were engineering majors, 25% were computer science majors, and the remaining students spanning a variety of other majors. Sources of data include the five sets of survey results, notes from interviews with the instructor and the three TAs, and students' scores on the daily problem sets and exams.

Setting

At the outset of the course, the instructor had set up a full outline of topics that would be covered each day along with some question and solutions. He also provided a list of online resources including an interactive tutorial, an online textbook, and links to five to seven suggested work in groups to solve a series of roughly ten increasingly complicated problems, one of which is collected and graded at the end of the 50-minute period. Although the instructor is never present during classes, the Teaching Assistants (TAs) are available to answer questions relating to how a particular problem is solved.

Results and Discussion

The two questions posed at the beginning of this semester study have now come into clearer focus. The first question, regarding procedural versus conceptual fluency, can be answered by noting that while the entire exam consisted of difficult procedural items, the average grade for this class was 52%. This indicates that students were most likely not prepared for the rigor of the exam, which involved understanding and applying skills such as application of trig inverses (based on a strong knowledge of trig), inverse functions (which required a strong understanding of inverses) and other "tricky" questions such piecewise function shown in Figure 1.

Consider the function $\mathrm{f(x)} = \begin{cases} 1 & x \text{ is positive and irrational} \\ 0 & x \text{ is positive and rational} \\ x^2 & \text{otherwise.} \end{cases}$

Determine whether $f(x)$ is continuous and/or differentiable at $x = 0$.

Figure 1: "Tricky" exam question

Despite the low exam average, the overall average semester grade assigned was a C. This was affected by the instructor's "C policy" which basically maintained that if students attended each class (as evidenced by their homework quiz), then they would earn at least a C. Therefore, we will use the final exam, rather than the final grade, as a gauge of the educative nature of this particular approach.

In order to determine the degree to which students were developing conceptual knowledge, we interviewed a few students and followed two pairs of students over the course of the entire semester. What we found was not surprising: students were able to perform the procedures of differentiation and integration for the very basic functions, but they had not developed a conceptual understanding of why these procedures mattered. As just one example, a student in one of the focus groups was given a sheet that included several related rates problems. The student's reaction, after discussing how to solve the problems was, "Why are we still on derivatives? We have been on them for the past week!" To us, this indicates that asking students to view short, 10-minute videos and then only do problems during class time negatives the ability for the instructor to help the students make critical connections. For example, how does what we were studying before relate to what we are studying now? Is the concept of rate of change a sub- or super set of questions in calculus 1?

The second question is, how did students adapt their study habits over the course of the semester? As shown in Figure 3, there was a dramatic shift after the first test (survey 2 was given just before test 1). Prior to taking the first test, the students relied most heavily on online texts and other references provided. However, these declined in use and, after exam 1, the students came to believe that the interactive lesson (a narrated video describing calculus ideas with some interactive components) and the instructor's posted sample problems were most educative and useful to study for the exam.

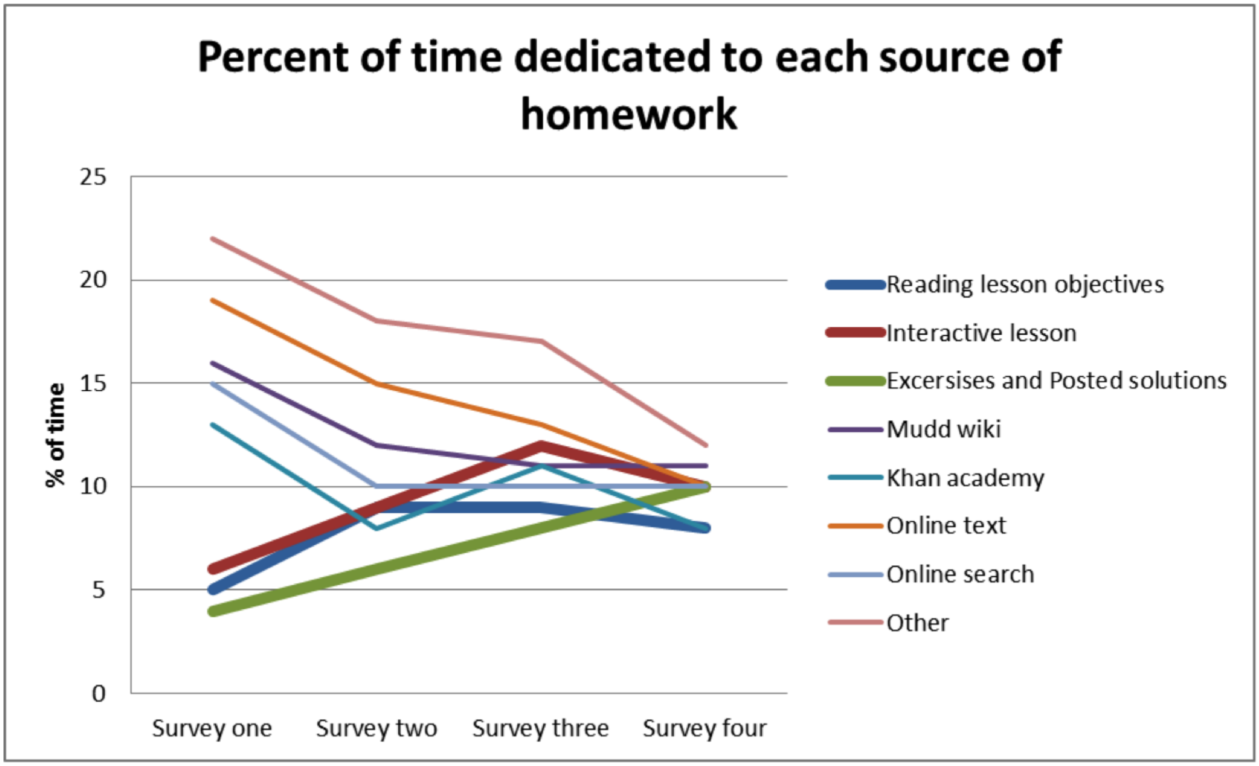

Figure 2: Homework time allotment trends

To answer the question regarding affect in general, we asked the student to rate their enjoinment (enthusiasm) and effort dedicated to this class versus that dedicated to others. To our surprise, the results, shown in Figure 3, indicate that, except for a short dip before the first test, students indicated that they were just a bit more enthusiastic about this set up than a traditional lecture (since the $n = 30$, we cannot claim that these results are significant); however, we can claim that the students' enthusiasm and effort remained very consistent over the course for the entire semester. This continually positive reaction to a class where the professor does not even show up once (and leaves any explaining to the TAs) is alarming. One hypothesis is that the students in our university are very busy; therefore, they appreciate any chance they can get to work on homework. Furthermore, they indicate that even though they are aware that they may not have the most comprehensive grip of the material, they still found the active engagement model to be a more *enjoyable* form of learning.

INTEGRATING INSTRUCTION AND PLAY IN A K–2 LESSON STUDY PROJECT

Catherine D. Bruce
Trent University
cathybruce@trentu.ca

Tara Flynn
Trent University
tara.c.flynn@gmail.com

Researchers in a lesson study project in Ontario, Canada, facilitated lesson study with nine teacher teams (n = 63) with young children (ages 3–8). This innovative project involves teacher selection of topics of concern, with a focus on content learning (such as spatial reasoning and patterning). Together, teachers and researchers planned and implemented exploratory and public lessons. One unexpected outcome of the project was a heightened attention on the interaction between mathematics instruction and play. Instruction was informed by student play, and was simultaneously being used to inform the design and structures of play-based activities, leading to an integration of instruction and play that questions the assumption that these approaches exist at opposite ends of a continuum of instructional approaches for young children.

Keywords: Elementary School Education; Teacher Education–Inservice/Professional Development; Number Concepts and Operations

Objectives and Background of the Study

Previous research has demonstrated that the goals of kindergarten programs have shifted from a focus on social and psychological development to an academic model with predetermined standards of student performance (Russell, 2011). By engaging in in-depth, sustained professional learning activities known as lesson study, teachers and researchers collaborate to learn more about student capability in mathematics (Fernandez, 2002; Lewis, Perry & Murata, 2006). By engaging with teachers, researchers learn more about what mathematics instruction looks like in the early childhood classroom. The purpose of this study was to: (a) identify the strategies that kindergarten-grade 2 teachers use for exploring mathematics concepts with students, (b) identify how play-based programming supports student understanding, (c) investigate the teacher content knowledge required to support this learning, and (d) develop a greater understanding of student learning trajectories in mathematics for young children. We questioned whether play-based contexts and mathematics instruction need be mutually exclusive and examined how these pedagogies informed one another through an integrated approach with close attention to observing, documenting, and enabling student learning.

Theoretical Framework

The education of young children, especially in the area of mathematics, has never been without contention. In the 180 years since the introduction of publicly funded schooling for young children in North America (the first kindergarten programs), the education community has fluctuated between two opposing views: (1) that children are capable of and enjoy rich mathematical thinking, or (2) that early instruction in mathematics is unnecessary or even harmful to child development (Balfanz, 1999). In parallel, and further dividing the proponents of mathematics education for young children, is the argument over the most suitable and developmentally appropriate approach to mathematics instruction for young children. This argument oscillates between extremes of a teacher-directed or direct-instruction approaches associated with the memorization of rules and algorithms, to student- and/or play-centred approaches fostering exploration with concrete objects and ideas associated with the discovery of patterns and rules along with deep conceptual understanding (Balfanz, 1999).

Why Is Math for Young Children Important?

Research over the past 25 years has shown that "nearly from birth to age 5, young children develop an *everyday or informal mathematics*—including informal ideas of more and less, taking away, shape, size, location, pattern and position—that is surprisingly broad, complex, and sometimes sophisticated" (Ginsburg, Lee & Boyd, 2008, p. 3). Furthermore, young children have a "spontaneous and sometimes explicit interest in mathematical ideas"; Ginsburg, Lee, and Boyd (2008) cite research results from the observation of children at play showing that young children spontaneously count (even up to relatively large numbers) and show interest in quantities ("how many" or "how much") (Saxe, Guberman & Gearhart, 1987; Irwin & Bergham, 1992; Gelman, 1980). They argue that children are capable of handling learning content far more complex than the typically limited curriculum implemented in primary and early elementary school. Baroody, Bajwa, and Eiland (2009) found that the primary cause of problems with basic number combinations among young children "is the lack of opportunities to develop number sense during the preschool and early school years" (p. 69).

Importance of Play

Perry and Dockett (2008) stress the importance of play in the mathematical development of young children. Bergen (2009) describes play as a "medium for learning" that provides opportunities for communicating (even before verbal skills are fully developed), risk taking, confidence building, as well as for developing self-regulation and social skills (p. 416). Play, including imaginative pretense, construction play, and games with rules, promote and enhance logico-mathematical reasoning as well as social understanding and metacognition (Bergen, 2009). As a disposition, play is closely linked to other characteristics valued in mathematics education, including creativity, curiosity, problem posing and problem solving (Ginsburg, 2006; NAEYC/NCTM, 2002; Dockett & Perry, 2007). As Thomas, Warren, & de Vries (2010) write: "play is a pedagogical tool that can enable learning and this learning can be maximized with appropriate, timely and effective adult input" (p. 719). Balfanz (1999) "proposes that intentional teaching of mathematics to young children is both appropriate and desirable" (p. 10). The value of play is not under question. However, play alone does not guarantee mathematical learning will take place. As Seo and Ginsburg (2004) acknowledge: "children do learn from play, but it appears that they can learn much more with artful guidance and challenging activities provided by their teachers" (p. 103). What might this artful guidance look like in classrooms for young children?

Methods of Inquiry

Participants in the lesson study project in Ontario, Canada, included teachers of junior kindergarten through grade 2 (ages 3–8). Nine small groups of teachers (*n* = 63) participated in lesson study, an adaptation of Japanese Lesson Study, which is a professional learning approach where teachers plan lessons and closely observe children's mathematics thinking (Perry, Lewis, & Murata, 2006). As part of this collaborative inquiry approach, we observed key structures in mathematics learning situations, and the intersections of play and instruction. Researchers collected video data of students in three contexts: (a) at play, (b) during small group activities related to mathematics, and (c) during mathematics lessons. Field notes from teacher planning sessions also provided interesting data on teachers' shifting and expanding conceptions of play and instruction.

Based on joint teacher-researcher video viewing and analysis, teams examined the role of play, instruction and the teacher in these contexts, with an action-oriented framework to learn more about the research question: How do play and instruction complement one another to support student learning in mathematics?

Table 1: Data Collection Per Teacher Team (× 9 teams)

	Clinical interviews	Teacher meetings	Observations of free play	Classroom observations
Nature of the Data	Video of clinical interviews: 6 students/ class (pre & post)	Field notes from 8 team meetings of 7 hours each	10 minutes of video per classroom (camera stationed at centre)	Video & field notes from exploratory lessons and public lesson
Quantity	20 hours	50 pgs	50-60 minutes	8 hrs, 30 pgs

We used a design research approach (Brown 1992; Collins, Joseph, & Bielaczyc, 2004; Lamberg & Middleton, 2009) that enabled teachers and researchers to test and refine both theoretical models and products based on observations in classroom contexts. Analysis of data is still underway, and involves coding all data sets using open and axial coding (Charmaz, 2003), and developing matrices to search for patterns in the movements between play and instruction.

Results

Baroody et al. (2006) developed a continuum of four types of teaching: traditional direct-instruction, guided discovery learning via an adult-initiated task, flexible guided discovery learning via a child-initiated task, and unguided discovery learning via a child-initiated task. Guided and flexible guided discovery learning were the most promising according to Baroody et al. In order to test these categories, we analysed teachers and students in math learning situations in their classrooms during lesson study activity. We also asked teachers to describe their practice and their mathematics goals for students. Keeping Baroody's framework in mind, we then focused video and field note data analysis on the two middle categories: guided discovery learning (what we call guided inquiry) and flexible guided discovery learning via a child-initiated task (what we call structured play). Our data revealed that Baroody's continuum was not actually a sequence of locked strategies or even stages, but rather a set of approaches that can be drawn on, and flexibly arranged to maximize student learning in mathematics. Figure 1 represents our analysis of these interconnected approaches to teaching in mathematics classrooms for young children.

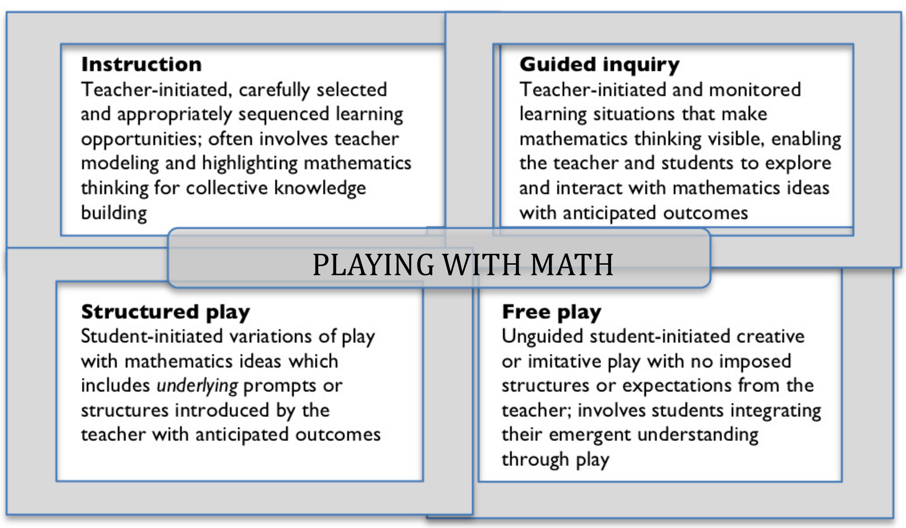

Figure 1: Teaching approaches that supported young children in mathematics

An illustrative example of the intentional yet fluid movement between play and instruction was documented with one team of teacher-researchers inquiring into the composition and decomposition of numbers. To begin, the teachers observed students playing (*free play*) and gathered additional information through clinical interviews which showed that children were able to count (ordinality) but had greater difficulty understanding more and less than five (relative quantity), and how to make five. Subsequently, the team designed some lessons (*instruction with guided inquiry*) to engage children in composing and decomposing five with fingers on two hands as well as five frames with two colours of counters. As an extension, a play station was designed (*guided inquiry*) called "The 5 Bakery," where "customers" ordered a cookie with five toppings. The students coloured a 5 frame with 2 colours to represent toppings and then "bakers" created these cookies using play dough and two colours of glass beads. The five frame was embedded in the activity at the bakery to support both mathematical play. Because of familiarity with this underlying structure, students independently played at the bakery with peers (without adult intervention) to further explore quantities of five (*structured play*). This oscillation between free play, structured play, guided inquiry, and instruction occurred over weeks, and relied on teacher attention to the underlying mathematics content they were encouraging students to play with. These learning experiences also provided a foundation for later variations that capitalized on student interest as well as the now-familiar mathematical structures. For example, on a class walk, the students noticed flowers at bloom. Students improvised to co-create a new play station called “The 10-in-a-pot Flower Shop,” which combined yellow and red tulips to “make 10.” The students recorded their orders on 10 frames, made their flower arrangements and wrote a related number sentence. In focus group interviews, teachers attributed the mathematization of play to their own explicit investigation of mathematics concepts and structures throughout the lesson study professional learning program.

Contributions and Future Research

Next steps include systematic video analysis to count and define *transitions* between the approaches to teaching with the lesson acting as the unit of analysis, connected to longer learning sequences. Cross-case analyses will be generated to further test, refine and amplify a play-instruction framework and to populate the framework with examples from classrooms in the Ontario early childhood context. Practical products of cross-case analyses include a series of short videos on play, instruction and the interaction between approaches to support young children’s mathematics understandings.

PERSONAL KNOWLEDGE AND ENACTED KNOWLEDGE: EXPLORING THE TRANSITION FROM UNDERSTANDING TO TEACHING PROPORTIONS

James Burke
University of Massachusetts Dartmouth
james.burke@umassd.edu

Chandra Hawley Orrill
University of Massachusetts Dartmouth
corrill@umassd.edu

This exploratory study considers how a single teacher's understanding of proportions shapes the experience in his classroom. We built from the knowledge in pieces perspective to consider the teacher's knowledge organization as a way of making sense of his understanding. Then, we considered how his understanding shaped his teaching. We end with a discussion of implications for pursuing this line of research.

Keywords: Teacher Knowledge; Number Concepts; Middle School Education; Mathematical Knowledge for Teaching

Purpose

Teachers' knowledge is instrumental for supporting mathematics learning in classrooms (e.g., Baumert et al., 2010; Hill, Rowan, & Ball, 2005). In standards-based classrooms, teachers are faced with an unlimited range of mathematical ideas as students engage in the valued processes of communicating, arguing, representing, and problem-solving (National Council of Teachers of Mathematics, 2000), thus making mathematics classes more diverse and less predictable as student contributions drive the conversation (Kennedy, 1998). Teachers who lack coherent understandings of the mathematics they teach have only the possibility of teaching disconnected facts (Thompson, Carlson, & Silverman, 2007). Additionally, teachers may find themselves avoiding situations of high intellectual engagement if they cannot accommodate students' unusual or half-formed ideas in the course of a lesson (Kennedy, 2005).

As part of our larger study of teacher knowledge, in this study we are interested in understanding how one teacher made sense of concepts in professional development and, subsequently, how his enactment of his understanding compared in an interview situation and in his 6th grade classroom. Specifically, we wondered whether the teacher's knowledge organization impacted the ways in which he taught the concepts in this own classroom. This exploratory study contributes to the teacher knowledge literature by stepping away from simply quantifying the amount of knowledge the teacher has, to actually seeing how that knowledge is used to drive the implementation of a single lesson.

Theoretical Framework

We rely on the knowledge in pieces epistemology (diSessa, 2006). Knowledge in pieces asserts that each of us has a variety of fine-grained understandings that work in concert with each other to make sense of complex situations. For any given problem situation, we are likely to invoke some number of these pieces to create a more complex, synergistic knowledge. Thus, learning can be seen as (a) developing more fine-grained knowledge pieces, and (b) refining existing pieces so they have more connections between them, allowing a more coherent understanding. Learning occurs when a perturbation causes the learner to reassess an understanding in ways that lead to new understandings or new connections among existing understandings. For example, if a student only understands fractions as *n* pieces of an *m*-sized whole, (e.g., 3 pieces of a 4-piece cake is ¾) that student cannot use that understanding to make sense of 7/4. The student needs to both add a new piece of knowledge about fractions and reassess the existing piece of knowledge to better understand how and when it is appropriate. The development of expertise from this perspective involves building connections and refinements that allow appropriate pieces of knowledge to be invoked in various situations. Knowledge in pieces is important both because it provides a lens for making sense of how a teacher might understand a concept and for understanding that the knowledge invoked in any given situation may or may not reflect the total body of knowledge a person has.

Methods

Walt was a 6th grade teacher with six years of teaching experience after a career in another field. Walt taught at an urban school with a 98% poverty rate. For this study, we considered his implementation of a single lesson on proportional reasoning conducted with his 6th grade students.

Data were collected through two related projects. For one project, we videotaped Walt's 6th grade class as they participated in a one-hour lesson about proportions. The lesson took place in the weeks of the school year. We used two cameras to capture the lesson: one directed at capturing written work on the board or on students' desks and one focused on the teacher or other people talking. As part of a second project, we conducted a 90-minute clinical interview with Walt the following November, immediately after his retirement from the school system, to explore how he understood the concepts of ratio and proportion. The interview prompts consisted of items intended to elicit different aspects of reasoning about ratio and proportion. The items were all situated in the work of teachers, thus asking our participants to respond to sample responses from students or from other teachers.

To understand how content was organized and discussed for Walt and in the PD, we created content maps (Empson, Greenstein, Muldonado, & Roschelle, in preparation) from the videos. To do this, we considered relationships among lexical content to compare what mathematical language is explicitly linked within the two situations. Phrases representing concepts or objects became nodes of our maps. When we noted Walt using two words in similar ways, we recorded that connection as a line connecting the nodes. When Walt described a relationship, we recorded the description of the relationship as an annotation to the line (e.g., a proportion *can be* set-up).

For Walt's clinical interview, this mapping showed Walt's use of language while reasoning about mathematical tasks requiring knowledge of ratio and proportion. The maps of the classroom video show how Walt linked these key concepts in his instructional practice, making those linkages explicit and available for students in his class.

We analyzed each mapping for notable groupings and connections between and among concepts relevant to proportional reasoning. We then compared the mapping of Walt's understanding to the mapping of his teaching to understand how his knowledge was enacted in the classroom.

Results

Due to space constraints, we explore only one key aspect of Walt's proportional reasoning as it related to his classroom. Specifically, we noticed that Walt seemed to have a conceptual separation between the processes of reasoning about relationships and the calculations involved with proportions. This manifested itself in both his interview and his teaching as language about "relationship" and "proportion" formed the center of separate sub-maps within the interview and classroom data. We discuss implications of this for conceptualizing specialized mathematics knowledge for teaching and further research in the Discussion.

In his interview, Walt spoke of contextualized situations involving proportions as being "relationships." Within this realm, he was able to discuss ideas of concrete, real-world quantities being doubled or halved. He related this to street knowledge and used descriptors like "intuitive" and "makes sense" to describe how he was reasoning about the quantities in the tasks. He described proportional relationships in terms of the relationships. For example, he noted that he was looking for how many of one quantity might be in another quantity (multiplicative relationships) and describing the intensive quantity in terms of both its attribute (e.g., flavor) and its equivalence to other ratios in the proportion. However, when he spoke of "proportions" rather than "relationships," Walt's focus shifted to calculating correct answers, creating graphs, and writing equations. This focus elicited more confusing language such as his description that "… what I want them to understand is that we want to maintain an equal amount … we want the ratio always to be equal, that we increase that ratio proportionally." His discussion of proportion also included a relatively large focus on finding a correct amount.

We saw this separation of proportion and relationship in Walt's class as well. In his class, Walt focused extensively on each individual variable in $y = kx$ without tying them together. He expressed to the students that proportions can be graphed, can be gotten done, can be set-up, can be in the form $y = kx$, and can be used to solve problems. There was never any discussion of any definition for proportion nor was there attention paid to the relationships between the *x* and *y*. However, Walt used a number of contextualized situations in which to have students solve proportions. He built much of the lesson around a book called *If You Hopped Like a Frog* (Schwartz, 1999) that featured proportional relationships between frog body length and jump length as well as between chameleon tongue and body length. He also pulled in other real world examples. In the context of discussing these examples, he raised issues of using multiplication to calculate results, using graphs that represented various attributes (e.g., tongue length and body length) and ratios. Unfortunately, with all of the contextualized situations used in class, the focus quickly changed from understanding that there was a relationship between two variables to calculating a single unknown that happened to fit that situation. Thus, there seemed to be a privileging of calculation over reasoning about relationships.

While Walt taught the lesson without explicitly tying the relationships within the contextual situations to the calculations for solving proportions, it was clear, at times, that he was working to convey some kind of connection to his students. Most notably, he repeated multiple times as they worked that the chameleon tongue was ½ the length of its body. This clearly had some kind of proportional meaning for Walt that he was not able to convey in any other way to his students, thus leaving that phrase as the only connection between his contextualized explanations and his calculation-based explanations.

Discussion and Conclusions

We set out to understand how a teacher's organization of knowledge compared to his enactment of a lesson in his classroom. Our hypothesis was that the teacher's knowledge organization would shape the implementation of the lesson. In this case, we noted that Walt had separated his understanding of "relationship" from his understanding of "proportion." In our interview with Walt, he described that relationships were more often contextualized and could be reasoned about using intuitive street knowledge. In contrast, his discussion of proportions was very heavily tied to calculating and graphing to determine correct answers. There was little focus on contextualized reasoning in his discussion of proportions.

In Walt's classroom, we saw a mirror of this reasoning. Walt focused much of the class period on finding a missing value for a given situation. He did raise issues of the relationship between values within the contexts presented, but quickly moved on from those relationships to focus on the calculations. His focus on missing value was consistent with how Walt talked about proportion in the interview. Walt's emphasis on proportions in class was a reflection of his own connection of proportion to the process of calculation rather than the relationship between quantities.

This case study suggests that the organization of teacher knowledge, in fact, may impact the way in which concepts are developed in their classrooms. This is an extension on the research trying to tie teacher knowledge to student learning in that it considers how a teacher understood his content and what that looked like in practice. Clearly a larger body of data as well as empirical results about the implications of the teaching would strengthen this case. But, as an exploratory study, this case raises interesting questions about how teachers might transition between their knowledge of mathematics and their teaching of mathematics.

INSTRUCTIONAL COHERENCE IN THE MATHEMATICS CLASSROOM: A CROSS-NATIONAL STUDY

Jinfa Cai
University of Delaware
jcai@math.udel.edu

The University of Tulsa
tao-wang@utulsa.edu

This cross-national study explored instructional coherence by integrating research on discourse and coherence. U.S. teachers referred to instructional coherence as the surface connections between teaching activities, lessons, and topics, and they non-differentially embraced such coherence. In contrast, the Chinese teachers differentiated between surface and real coherence. For real coherence, Chinese teachers emphasized the interconnected mathematical concepts and student thinking. They stressed that only real coherence facilitates learning.

Keywords: Classroom Discourse; Instructional Activities and Practices; Teacher Beliefs; Teacher Knowledge

Purpose of the Study

Although instructional coherence has been recently identified as an important feature of effective classroom instruction (Cai, Kaiser, Perry, & Wong, 2009; Stigler & Hiebert, 1999), thus far, we do not have a clear understanding about the meaning of instructional coherence. In addition, even though prior studies have observed differences in instructional coherence between U.S. and East Asian classrooms (Leung, 2005; Wang & Murphy, 2004), we know little about how teachers themselves view instructional coherence (Cai et al., 2009). The purpose of this cross-cultural study is to examine, from an integrated perspective of discourse and coherence, how U.S. and Chinese teachers view instructional coherence in the classroom.

Theoretical Basis of the Study

Discourse coherence reflects the degree of meaning related to topics that affects readers or listeners' understanding (Dore, 1985). van Dijk (1977) proposed a two-level model for analyzing discourse coherence: micro and macro. Regardless of its level, the eventual goal of discourse is to enable the readers or listeners to process and comprehend it. van Dijk and Kintsch (1983), proposed that for the same *text* (what was read or heard), one might either comprehend its semantic content, resulting in a mental model called a *text base*, or one might actively make inferences and integrate the content of the text into one's existing knowledge system, resulting in a *situation model*. A coherent text contributes to the formation of a text base, which may improve one's ability to remember that text (Kintsch, 1986; Mannes & Kinstch, 1987). Yet, a coherent text with full information may reduce one's active processing of a text. Thus an incoherent text may better facilitate the formation of situation models, which are the keys to learning from a text.

Comparative studies have revealed two main features of instructional coherence that distinguish mathematical teaching in China (and other Asian countries) from teaching in the U.S.: (a) connected topics and (b) using transitional discourses (Chen & Li, 2010; Leung, 2005; Stigler & Hiebert, 1999). However, few studies (e.g., Cai & Wang, 2010) have directly explored how teachers from different cultures view instructional coherence. Explicit discussion is needed about what instructional coherence actually entails and whether teachers hold culturally different views on it. We hope to fill in some of these gaps through this cross-cultural comparative study.

Method

Subjects and Data Collection

A total of 20 Chinese teachers and 16 U.S. teachers participated in our study. All of these teachers were considered excellent mathematics teachers (e.g., all of the teachers won national or regional teaching awards or recognitions). Chinese teachers taught at the elementary level while the U.S. teachers taught at the secondary level. In addition, all of the U.S. teachers had a master's degree while all but one of the Chinese teachers had a bachelor's degree.

Survey Questions, Data Coding, and Data Analysis

Each of the teachers was given a set of questions: (1) *When people say a lesson is very coherent, what does the word "coherent" mean to you? What are the characteristics of a coherent lesson?* (2) *If you were mentoring a new teacher, how would you guide the new teacher to achieve coherence in her or his teaching?* and (3) *Some people say that a coherent lesson can foster students' learning. Do you agree with this statement? Why?* We analyzed teachers' written responses to each question using a constant comparison method (Gay & Airasian, 2000). The detailed codes of each teacher's responses were sorted and combined into broader categories of content, teaching, and learning. We then triangulated teachers' responses across questions and compared Chinese and U.S. teachers' responses. To ensure reliability, two independent coders went through the complete data sets and the general consistency in coding was confirmed.

Results

Static Nature of Instructional Coherence

Both groups of teachers interweaved static and dynamic aspects of instructional coherence in their responses. Regarding the static nature of instructional coherence, both groups discussed it at the micro and macro levels, arguing that content within and between lessons should be connected respectively (See Table 1).

Table 1: Content Coherence in U.S. and Chinese Teachers' Views

	Macro		Micro	
	U.S.	CH	U.S.	CH
Connection of activities/lessons/topics	3, 5, 6, 8, 9, 10, 12, 13	15	1, 3, 4, 5, 6, 7, 8, 11, 12, 13	4, 12, 13, 16
Connection of knowledge pieces	16	2, 5, 10, 15, 19	2, 14, 15, 16	1, 3, 5, 6, 7, 8, 9, 10, 14, 15, 18, 19, 20

Macro level. As indicated by Table 1, eight U.S. teachers (50%) referred to instructional coherence as connected topics that aligned with content standards. In contrast, five Chinese teachers (25%) considered the coherent nature of the mathematical knowledge system.

Micro level. Ten of the U.S. teachers (62.5%) argued that a coherent lesson should flow logically from one component/activity/thing to the next. To elaborate, they described the *beginning, middle, and end* (BME) of a lesson. Chinese teachers also acknowledged the teaching flow. However, 13 Chinese teachers (65%) emphasized the importance of the interconnection of mathematical ideas within a lesson, which was similar to the pattern observed at the macro level. In order to obtain an understanding of interconnected knowledge pieces, Chinese teachers uniquely stressed studying textbooks, along with studying students, before teaching a lesson.

Dynamic Process of Instructional Coherence

Table 2 summarizes teachers' different emphases on key features of a coherent lesson.

Table 2: Teachers' Different Emphases on the Key Features of Instructional Coherence

	U.S. Teachers	*Chinese Teachers*
Setting up teaching objectives	1, 2, 3, 4, 5, 6, 8, 11, 13, 14	1, 2, 3, 4, 7, 9, 10, 14, 18, 19,20
Managing lesson structures	1, 2, 3, 4, 5, 6, 7, 8, 10, 11, 12, 13, 14, 15,	1, 3, 4, 5, 6, 7, 8, 9, 10. 11, 12, 14, 15, 16, 17, 18, 19, 20
Designing appropriate teaching sequence	N/A	3, 5, 9, 11, 12 14, 15, 19
Designing teaching language/questions	10	1, 5, 6, 7, 9, 15, 16, 19, 20
Challenging student thinking	3, 6, 10	1, 3, 7, 10, 11, 14, 17, 18, 19
Dealing with emerging events	13	4, 7, 9, 10, 13, 14, 17, 18, 20

Setting up teaching objectives. Ten U.S. teachers (63%) and eleven Chinese teachers (55%) emphasized that a coherent lesson should have a clear goal or teaching focus, which served as a direction for coherence (see Table 2). Some Chinese teachers discussed "essential and difficult teaching points."

Designing teaching with a progressive sequence. Eight Chinese teachers (40%) stressed that the teaching content should be designed and arranged progressively (see Table 2). CH9 suggested arranging tasks from easy to hard so as to align with students' development. None of the U.S. teachers discussed this aspect.

Designing teaching language/questions. Eight Chinese teachers (40%) emphasized the teacher's language coherence including the use of transitional language (see Table 2). In addition, seven Chinese teachers (35%) stressed careful design of teachers' questions. None of the U.S. teachers mentioned transitional language. Only one U.S. teacher mentioned questioning.

Challenging student thinking. Nine Chinese teachers (45%) argued for challenging students' thinking (see Table 2). Chinese teachers consider a smooth teaching flow without challenging student thinking to be surface coherence, but a smooth flow that challenges student thinking to be real coherence. Although three U.S. teachers (20%) stressed challenging student thinking, none of them differentiated between surface and real coherence.

Dealing with emerging events. Nine Chinese teachers (45%) discussed dealing with unexpected student responses, questions, and difficulties. Most Chinese teachers saw them both as a threat and an opportunity, and thus termed them as "emerging resources." Only one U.S. teacher (6%) discussed dealing with emerging events.

The Impact of Instructional Coherence on Student Learning

When explicitly asked whether a coherent lesson fosters student learning, the majority of Chinese teachers (75%) held very conservative views (5 agreed, 2 disagreed, and 13 partially agreed). The Chinese teachers argued that only *real coherence,* not surface coherence, may foster learning. In contrast, the majority of U.S. teachers (87.5%) expressed unreserved agreement that coherent lessons foster student learning (14 agreed, 1 partially agreed, 1 not sure). U.S. and Chinese teachers' different responses seemed to relate to their different views of the purpose of instructional coherence. Many Chinese teachers pointed out that instructional coherence should serve student thinking (e.g., coherence of students' thinking, gradually deepened thinking) while many U.S. teachers viewed it as a way to facilitate students' completion of tasks.

Discussion

What Does Instructional Coherence Entail? Surface versus Real

This study explored teachers' views of instructional coherence from a cross-cultural comparative perspective. U.S. teachers mainly referred to instructional coherence as the connections between teaching activities, lessons, or topics, which appeared to align with some of the "features" of coherent lessons reported by prior studies (e.g., Chen & Li, 2010; Wang & Murphy, 2004). U.S. teachers' emphases on a complete BME lesson structure also aligned with the levels and the structure of classroom discourse (van

Dijk, 1977). Connected activities and a complete lesson structure may help students construct a text base that may be useful for remembering what was taught (Kintsch, 1986; Mannes & Kinstch, 1987). However, such coherence, in Chinese teachers' eyes, was indeed only surface coherence and not real coherence. Chinese teachers emphasized the interconnected nature of the content and they also stressed gradually deepened student thinking. Chinese teachers' differentiation between surface and real coherence is insightful and invites rethinking of what instructional coherence actually entails.

The Tension between Scripted Plan and Generative Actions

To reach real instructional coherence, Chinese teachers advocated careful design of various aspects of a lesson. Although prior studies have observed important features such as transitional language (Wang & Murphy, 2004), our study reveals that these features mainly result from intentional design rather than in-the-moment decisions. In contrast, U.S. teachers rarely discussed designing lessons. Since teaching is complex, it is hard to imagine how a teacher can achieve a coherent lesson, especially *real coherence,* just by thinking on their feet.

Although Chinese teachers emphasized pre-designed lesson plans, they also highly valued capturing generative, emerging events during teaching. These emerging events often bring unpredictability to the teaching flow. Why, then, do Chinese teachers bother to design a lesson plan beforehand if the designed plan will be inevitably disrupted by emerging events? According to discourse theory (van Dijk & Kintsch, 1983), effective discourse should start from "design" even though unpredictable factors exist.

The significance of this study is threefold. Methodologically, it contributes an analytic framework of instructional coherence, integrating two well-established lines of research on discourse and coherence. Theoretically, our findings encourage a rethinking of the existing literature, particularly regarding the essence of instructional coherence. Practically, our findings have direct implications for classroom instruction and teacher professional development. Future studies may include detailed analyses of classroom instruction to show prototypes of lessons with surface and real coherence and to explore strategies to help teachers achieve instructional coherence.

EXAMINING THE COGNITIVE DEMAND OF TASKS IN THREE TECHNOLOGY INTENSIVE HIGH SCHOOL ALGEBRA 1 CLASSROOMS

Charity Cayton
North Carolina State University
cscayton@ncsu.edu

This brief research report uses frameworks and analytic tools found in current research regarding cognitive demand of mathematical tasks to examine the cognitive demand of technology-based tasks in three 1:1 laptop learning environments. Current frameworks and analytic tools were productive in assessing potential and implemented level of cognitive demand and for indicating factors related to level of implementation. Growth in teachers' ability to create and successfully implement high level tasks was demonstrated, and factors related to decreasing or increasing the level of cognitive demand during implementation are reported.

Keywords: Algebra and Algebraic Thinking; Instructional Activities and Practices; Technology; Teacher Education–Inservice/Professional Development

The *Principles and Standards for School Mathematics* (NCTM, 2000) presents a vision of learning where every student has access to technology to facilitate mathematics learning under the instruction of a skilled teacher. Technologies, including calculators and computers, are viewed as integral tools of learning mathematics that provide visual images of mathematical ideas, facilitate the organization and analysis of data, provide efficient and accurate computations, and support student investigation in all areas of mathematics by allowing students to focus on decision making, reflecting, reasoning, and problem solving. "The existence, versatility, and power of technology make it possible and necessary to reexamine what mathematics students should learn as well as how they can best learn it" (NCTM, 2000, p. 24). One learning context that has the potential to match this vision is a 1:1 laptop learning environment. Within this environment, individual teachers and students are provided with access to laptop computers both during and after the school day. Argueta, Huff, Tingen, and Corn (2011) performed a meta-analysis using state executive reports from six major statewide 1:1 laptop initiatives throughout the United States, and their findings support that 1:1 laptop initiatives have the potential to positively influence the instructional practice of teachers and student outcomes. Specifically, when provided with high quality professional development, teachers increased their use of technology to develop learning materials and their use of higher order questioning. Further, their instructional practices began to shift away from more traditional approaches toward teaching with more reform-oriented approaches. This description of learning is consistent with the *Professional Standards for Teaching Mathematics* (NCTM, 1991), the *Professional Standards for School Mathematics* (NCTM, 2000), and matches the context of the teachers participating in this study.

Context

All three teachers participating in this study work within the same school district at two different high schools. The school system has participated in a 1:1 laptop computing initiative for approximately four years. Both schools are located in rural communities and serve high minority populations. The teachers came to be part of this study through their participation in a larger on-going professional development project focused on Algebra instruction within 1:1 laptop learning environments.

As part of the Algebra component of the professional development project, each Algebra teacher participated in a week long institute where the focus of the institute was to develop teachers' knowledge of algebra, Geometer's Sketchpad, and pedagogical practices. The main technological tool incorporated during the summer institute was The Geometer's Sketchpad (Version 5.0). Pedagogical aspects of the institute focused on practices designed to assist teachers in facilitating mathematical discussions in their classrooms (e.g., Smith & Stein, 2011), and Algebra content from the Common Core State Standards for

Mathematics (CCSSI, 2010) served as the mathematical content. On-going support included twelve hours of online professional development throughout the 2011–2012 school year and three observations per semester when teaching Algebra 1.

Methods

The framework and analytic methods that guided this study were derived from research conducted by Boston and Smith (2009), Smith and Stein (1998, 2011), and Stein, Engle, Smith, and Hughes (2008). The Mathematical Task Framework (Smith & Stein, 1998) served as the overall framework for analysis. Similar to Boston and Smith (2009), the Task Analysis Guide (Smith & Stein, 1998), the Instructional Quality Assessment Academic Rigor in Mathematics rubrics for Potential of the Task and Overall Implementation, as well as the Lesson Checklist (Boston & Wolf, 2006; Matsumura, Slater, Garnier, & Boston, 2008) served as the tools for analysis of tasks. However, what distinguishes this study from the previous research is the technology-intensive environment. The purpose of this study was to examine the cognitive demand of technology-based tasks used by teachers' in 1:1 laptop learning environments.

Tasks included dynamic sketches created by the teacher using The Geometer's Sketchpad and any accompanying worksheets or assignments used during each of three teaching sets conducted with the teachers. According to Simon, Tzur, Heinz, Kinzel, and Smith (2000):

> A teaching set consisted of two classroom observations and three interviews: a pre-lesson interview with the teacher about the first lesson to be observed, an observation of the first mathematics lesson, a second interview in which the teacher was asked about the first lesson and about plans for the second lesson, an observation of the second lesson, and an interview about the second lesson. (p. 583)

All tasks were evaluated for Potential of the Task prior to analyzing the Overall Implementation of the task utilizing video from the teaching sets. Then the average Potential score for each teaching set was compared to the Implementation Score. A Lesson Checklist was also completed for each observation. The findings reported include only the first two teaching sets, which focused on introducing linear and quadratic functions. Exponential functions served as the topic for the third teaching set, but that data is still being analyzed at this time.

Results

Table 1 shows the Potential and Implementation scores for each of the three teachers during the first two teaching sets.

Table 1: Potential and Implementation Scores for Participants

	Teaching Set 1		Teaching Set 2	
Teacher	Potential	Implementation	Potential	Implementation
Mrs. Lewis	3.4	2.6	3.5	4
Mrs. Patterson	2.67	2.33	3.5	3.5
Mr. Phelps	3	1.5	4	3.25

Mrs. Lewis

During the first teaching set, the tasks designed by Mrs. Lewis had the potential to engage the students at a high level of cognitive demand during instruction (3.4). However, the actual implementation score of the tasks (2.6) meant that the tasks did not reach their potential. Based on the Lesson Checklist that was filled out, the level of cognitive demand was diminished because the teacher provided a set procedure, the focus shifted to procedural aspects or correct answers, students were not pressed for high level products and processes. Also, the teacher's modeling during the lesson became directive, and students were not allowed enough time to effectively engage in the task.

For the second teaching set, Mrs. Lewis created tasks that demonstrated the potential for a high level of cognitive demand (3.5), and during implementation the level of cognitive demand increased (4). Several factors that influenced the increase in cognitive demand were based on appropriate time for students to engage with the task, the teacher held students accountable to high level products and processes, and the teacher provided consistent presses for explanation and meaning.

Mrs. Patterson

The tasks designed by Mrs. Patterson for the first teaching set fell just below a high level of cognitive demand (2.67), and the level of cognitive demand decreased during implementation (2.33). Based on the Lesson Checklist several factors contributed to the decrease in cognitive demand. The tasks were not complex enough to sustain student engagement in a high level of thinking, the teacher provided a set procedure, and the focus shifted to procedural aspects of the task or obtaining correct answers.

The potential for cognitive demand of the tasks increased for the second teaching set to a high level (3.5) and were maintained during implementation (3.5). During this teaching set, students had the opportunity to serve as the mathematical authority during the lesson, the teacher held them accountable for high level products and processes, and the teacher made consistent presses for explanation and meaning. All of which helped maintain the level of cognitive demand.

Mr. Phelps

Mr. Phelps demonstrated the greatest difference in potential (3) and implemented (1.5) level of cognitive demand during the first teaching set. Despite the potential for a high level of cognitive demand, the teacher provided a set procedure for solving tasks, focused on the procedural aspects of the task and correct answers, and did not hold students accountable for high level products and processes.

The tasks used by Mr. Phelps in the second teaching set scored the highest potential (4) among all the teachers. While the cognitive demand decreased during implementation (3.5), his use of the tasks with students remained at a high level of cognitive demand. During the second teaching set, Mr. Phelps gave students sufficient time to grapple with the high level of demand of the tasks, provided opportunities for the students to share in the mathematical authority of the class, and consistently pressed for high level products and processes from the students.

Conclusions

Two trends were noted regarding teachers' use of technology-based tasks in technology-intensive Algebra 1 classrooms. First, all teachers demonstrated growth in the potential level of cognitive demand from the first teaching set to the second teaching set. Second, all teachers were able to achieve a high level of cognitive demand during implementation of tasks for the second teaching set. This is a stark comparison to low level of cognitive demand achieved during implementation of tasks during the first teaching set. Taken together, these two trends indicate the potential for growth in teachers' design of cognitively demanding tasks, as well as growth in their ability to implement tasks at a high level in technology-intensive learning environments. These findings are consistent with Argueta et al. (2011) regarding teacher changes in 1:1computing environments when provided with quality professional development. Also, the framework and analytic tools from previous research on tasks and cognitive demand (e.g., Boston & Smith, 2009; Boston & Wolf, 2006; Matsumura et al., 2008; Smith & Stein, 1998, 2011; and Stein et al., 2008) proved to be applicable to technology-intensive environments. Future work as part of this study will include analysis and comparison of results from the third teaching set (exponential functions) to see if current trends hold, examining teachers' use of pedagogical practices to facilitate mathematical discussions, and discourse analysis of the resulting discussions. Another area of exploration may be to examine how the presence of technology influenced the resulting mathematical discussions.

The purpose of this study was to examine how special education teachers make the transition from procedural thinking to making meaning in the mathematics classroom. Teaching and making meaning of difficult mathematics concepts can be influenced by the interaction of technological, pedagogical and content knowledge (TPACK). Special Education credential candidates learn to make meaning through a communal classroom activity system in which the university instructor creates zones of proximal development where candidates begin to make meaning. Dynabook, a Web-based tool to help college faculty, including special education faculty, instruct teacher candidates how to teach proportional reasoning to children in middle school was the foundation for this communal classroom activity system.

Keywords: Proportional Reasoning; TPACK; Special Education

Introduction

The purpose of this study was to examine how special education teachers make the transition from procedural thinking to making meaning in the mathematics classroom. Teaching and making meaning of difficult mathematics concepts can be influenced by the interaction of technological, pedagogical and content knowledge (TPACK; Mishra & Koehler, 2006). Special Education credential candidates learn to make meaning through a communal classroom activity system in which the university instructor creates zones of proximal development where candidates begin to make connections between past knowledge and new information. *Dynabook*, a web-based tool to help college faculty instruct teacher candidates how to teach proportional reasoning to children in middle school, was the foundation for this communal classroom activity system. The *Dynabook* includes dynamic representations, videos of children solving problems, and examples of practice problems. These features are intended to help teacher educators teach middle school teachers about how children think about proportionality, including their misconceptions and the strategies they use when solving problems. In addition, university instructors can create a social learning environment with teacher candidates as they work on math content and share work and ideas through a shared-work space. They model how middle school teachers should build discourse into their classrooms so their students can collaboratively build a deeper understanding of math content.

Theoretical Framework

Boyd and Bargerhuff (2009) completed an extensive literature review exploring research that intersects middle school mathematics with special education. They claim that in special education, college faculty are still instructing pre-service teachers to teach children to solve problems procedurally; in mathematics education, college faculty are working with pre-service teachers in student-centered, constructivist ways to teach children to solve problems more conceptually. These researchers admit that learning explicit procedures in mathematics is important, but that special education teachers tend to focus on procedures too much. Special education methodology is more likely to emphasize task analysis and specific, measurable objectives, often targeting procedural rather than conceptual skills. The propensity of special education to use these approaches is not surprising, given some of the common characteristics of students with disabilities, who often struggle in areas such as short-term memory, visual and auditory processing, and executive functions. Furthermore, past research in the field of special education has demonstrated more effective outcomes for students with disabilities when teacher-directed instruction is used (Kroesbergen & Van Luit, 2003).

Those who write about special education teachers and mathematics instruction come to the conclusions that it is important for teachers to not only know mathematics content, but they also need to know mathematics content pedagogy (Griffen, Jitendra, & League, 2009). Special education teachers need to provide children with opportunities to elaborate their ideas to make their reasoning explicit through the use of why and how questions, to engage more deeply in their ideas through deep discussions, and to use visuals and interactive materials to help make abstract concepts more concrete.

Boyd and Bargerhuff (2009) suggest teacher preparation programs provide a mathematics methods and intervention course that includes both a general and special education focus. As pre-service mathematics and special education teacher candidates develop their understanding of mathematics content, and explore teaching tools and strategies for teaching this content, they should also consider the accommodations and other interventions students with learning differences require to support them in mastering challenging content. Boyd and Bargerhuff insist that candidates enrich their own understanding of proportional reasoning beyond the over-simplified notion of cross-multiplication. While cross-multiplication is important and valuable, this narrow view provides an insufficient basis for later algebra learning.

To learn about proportional reasoning more meaningfully, teacher candidates need to build connections through a coherent learning progression with adequate support for the challenges of maintaining interest and engagement (Stein, Engle, Smith, & Hughes, 2008). Engagement with meaningful mathematical ideas depends on the kinds of tasks candidates are given (Schoenfeld, 1985), the tools and representations they are able to use (Sfard & McClain, 2002), available supports when they get stuck, and of course on the pedagogical talent of their instructor. Additionally, technology can support new more engaging tasks, better tools and representations, and can provide layered supports when students need them. Technology cannot substitute for good pedagogy, but it can encourage and support good pedagogy.

Emerging technological advances combined with Shulman's (1987) work on pedagogical content knowledge (PCK) have lead to the technological pedagogical and content knowledge (TPACK) framework (Mishra & Koehler, 2006). Shulman (1987) defined PCK as the professional understanding of teaching, or "how particular topics, problems, or issues are organized, represented, and adapted to the diverse interests and abilities of learners, and presented for instruction" (p. 8). TPACK extends this definition to how a teacher utilizes the dynamic interplay of technology, pedagogical skills, and content knowledge to represent concepts in different ways to engage learners. It represents the corpus of knowledge that an expert teacher utilizes to create an effective learning environment.

Method

Participants

A purposive sample of 13 students was recruited from the Mild to Moderate Special Education Program at a California State University in Fall of 2011.

Design

Researchers used a mixed-methods design to explore how special education teachers developed knowledge in the area of mathematics in an advanced curriculum class focused on preparing teacher candidates to teach junior high children with learning differences in math and reading. A chain of evidence is needed to establish that certain kinds of content knowledge support useful practices and that those practices support more positive outcomes for children (Darling-Hammond et al., 2005). For this research project, we planned to implement research methods that provided links for this chain of evidence. First, we recognize that teachers must gain knowledge and develop competencies. Second, they must translate their knowledge and competencies into effective practices. To this end, we collected the following types of data: pre- and post-surveys, pre- and posttest of pedagogical content knowledge, and video observations of class sessions.

Instruction

Thirteen pre-service and intern special education teacher candidates participated in two three-hour classes dedicated to interacting with the ratio section of the *Dynabook*. Participants had varying levels of mathematics proficiency and teaching experience. Over two class periods, teacher candidates utilized the *Dynabook* as part of a neatly choreographed classroom assignment designed by the university instructors and outlined on the assignment page in the *Dynabook*. First, candidates were asked to complete a ten-minute pretest on pedagogy and proportional reasoning. Prior to the first *Dynabook* class session, each candidate had completed an on-line survey about his or her teaching efficacy. Second, candidates logged into *Dynabook* with individualized passcodes that allowed them to save the work they completed and post it onto the shared workspace. On the assignment page, candidates were directed to watch embedded video of how the *Dynabook* is utilized at the university level and how aspects of UDL are embedded and modeled throughout the software. This particular activity helped situate and define the candidates' role within this classroom activity system, as it was important for candidates to take on the role of a teacher who was preparing to teach ratio during the next class session. Third, candidates were asked to solve a ratio word problem with a partner, discuss answers, and post solutions to the shared workspace. The university instructor opened the shared workspace so all anonymously posted solutions could be viewed and discussed by the entire class. Fourth, after the class discussion, candidates watched instructional videos that provided a framework for discussing conceptual shifts in proportional reasoning (Khoury, 2002; Labato, Ellis, Charles, & Zbiek, 2010; Lamon, 1999).

During the second session, candidates began the class by watching a video of a student incorrectly solving the problem that the candidates solved and discussed during the previous class. The student in the video made a typical procedural error by inappropriately applying cross multiplication without checking if her answer made sense. Second, after watching the student attempt to solve the problem, candidates worked in pairs to discuss the student's level of proportional understanding and how they could help the student reach the next level of proportional reasoning. Third, to demonstrate how each pair would teach the student in a way that addresses her misconception, candidates wrote teaching scripts using *Xtranormal,* a Web-based software to create animated teaching videos. Finally, videos were shared with the class and discussed in terms of content and pedagogy.

Research Question

1. How did teacher candidates' content and pedagogical knowledge of ratio change after using *Dynabook*?

Results

Early into the first class session, teacher candidates were reluctant to discuss math reasoning and evasive when asked discussion questions. By the end of the *Dynabook* sessions, they were sharing their mathematical thinking by discussing their own solutions to problems and remarking on the mathematical thinking represented by the videos. Participants were beginning to understand the idea that there are many ways to explain ratio problems and they would need conceptual understanding to reach students who may need multiple means of instruction. For example, one candidate said that she was impressed how the variety of explanations in the shared-work space really demonstrated how many different ways a person could solve one problem:

> I was just thinking it is really cool how everyone is describing it in a different way, and we can point out to students how there is not just one way to explain this problem, it is a really cool example—look at all these teachers in the room, and they all came up with 20 different ways to explain it.

They showed an increased understanding of student thinking by creating and discussing scripts to address a student's misconceptions. Teacher candidates were surveyed about their attitudes toward teaching proportionality and familiarity with terms such as TPACK. On average, they showed increases in self-efficacy for teaching ratio conceptually to struggling learners. They were also more confident with addressing the Common Core standards for teaching ratio, such as generalizing from patterns and making sense of word problems.

Conclusion

In past iterations of the *Dynabook*, credential candidates were only interested in learning the one "best" way to teach ratio and requested a video of a teacher explaining ratio to a student. After working with the *Dynabook* and creating scripts to teach a student with misconceptions, they were all willing and enthusiastic to discuss the mathematical thinking behind the videos.

After utilizing *Dynabook* in a well-designed curricular activity system, these teacher candidates were reintroduced to concepts such as ratio and were better able to recognize and understand the math content. The candidates realized that they needed to go back to this curriculum to review and remember what they learned in those grades. Following their use of the *Dynabook*, they were able to talk more precisely about ratio and how to assess students' understanding of ratio. They were more confident in their ability to teach the subject. After a relatively quick review, candidates were able to discuss their solutions to ratio problems and analyze other perspectives that they may not have considered. Moreover, the candidates were enthusiastic during the discussions, often carrying them over into breaks and after class. They reported increases in understanding TPACK and felt more confident teaching ratio using principles of TPACK. Also, the *Dynabook* activities and discussions led them to think about their ability to solve proportionality problems and recognize misconceptions in children.

EXPLORING THE IMPACT OF PROFESSIONAL DEVELOPMENT ON K–3 TEACHERS' PRACTICES AND THEIR STUDENTS' UNDERSTANDING

Ya-Shu Yang
University of Nebraska–Lincoln
yyang5@unl.edu

The purpose of this study is to develop paired case studies of K–3 teachers and subsets of their students to explore how teachers shape their teaching practices to develop students' mathematical habits of mind after participating in Primarily Math, a program for K–3 mathematics specialists. Data were collected from classroom observations and interviews across 2011/12 from three K–2 classrooms in one school, and focused on teachers' uses of representations, questions, and examples, as observable instances of mathematical knowledge for teaching. Teachers credit Primarily Math with helping them become more reflective and with equipping them to more intentionally design lessons that deepen student understanding.

Keywords: Teacher Education–Inservice/Professional Development; Elementary School Education; Mathematical Knowledge for Teaching; Instructional Activities and Practices

While much is known about the effects of professional development on mathematics teachers' knowledge and beliefs about mathematics, less is known about the impact of professional development on teaching practices, and even less about the impact on students. The purpose of this study is to develop paired case studies of K–3 teachers and subsets of their students to investigate how teachers shape their teaching practices to develop students' mathematical habits of mind after participating in a longitudinal professional development program for K–3 mathematics specialists. This study is part of a much larger study, whose central research questions is: How do teachers translate the mathematical attitudes, knowledge, and habits of mind emphasized during Primarily Math into measurable changes in teaching practice?

Primarily Math is part of NebraskaMATH, a $9.2 million NSF targeted partnership, and includes an 18-credit-hour program for K–3 mathematics specialist certification. The coursework includes three courses each focused on mathematics and pedagogy. The overall purpose of Primarily Math is to improve achievement in mathematics for all students and to narrow achievement gaps of at-risk populations.

A main focus of Primarily Math courses is to develop teachers' *habits of mind as mathematical thinkers*, and in turn to help them consider how to develop similar habits in their students. Habits of mind of mathematical thinkers include ways of productive mathematical thinking that are creative and persistent in solving problems; people with effective mathematical habits of mind are good at solving problems and communicating their reasoning to others. Children's mathematical habits of mind include "curiosity, imagination, inventiveness, risk-taking, creativity, and persistence…[viewing] mathematics as sensible, useful and worthwhile and… themselves as capable of thinking mathematically… appreciate the beauty and creativity that is at the heart of mathematics" (Sarama & Clements, 2009, pp. 6–7). The National Council of Teachers of Mathematics (2006) and the Common Core State Standards for Mathematics call for an increase in developing students' reasoning and sense-making skills. Focusing on developing teachers' and students' mathematical habits of mind is our approach to this.

Beyond habits of mind, Primarily Math also focused on teacher noticing (Sherin, Jacobs, & Philipp, 2011), and attending to student understanding. Together, these are a main vehicle for teachers to develop students' mathematical habits of mind. Kilpatrick, Swafford, and Findell (2001) define quality instruction as, "a function of teacher's knowledge and use of mathematical content and a teachers' attention to and handling of students" (p. 315). Teachers can attend to their students in a number of ways, including attempting to understand a student's developing understandings. Attempting to understand means a teacher needs to find a way to see the mathematics through the child's eyes. This is not an easy task for a teacher, as student understanding often occurs in a non-linear manner, is variable, and tumultuous in nature (Edwards, Gandini, & Forman, 2011). The lack of visible student understanding is sometimes attributed to a variety of factors including language and culture (Sarama & Clements, 2009). However, knowing the factors that make students' developing understandings invisible does not help the teacher to deepen their students developing understandings and mathematical habits of mind. Examples of how teachers make developing understandings visible are limited; one contribution of this study to the field is to describe how three K–2 teachers make the developing understandings of their students visible, as teachers work to develop their students' mathematical habits of mind.

Methods

This brief research report focuses on three paired cases. The three teachers were chosen from their cohort of 35 to represent strong and average mathematics achievement; these choices were made following extensive qualitative and quantitative analysis of teachers' trajectories across their Primarily Math coursework (Smith & Shen, under review). The three teachers all teach at the same school (Bluebird Elementary School [all names are pseudonyms]), and took courses June 2009 to June 2010, and participated in ongoing professional learning community meetings through spring 2012. Fifteen observations of each classroom were collected during the 2011/12 school year, with pre- and post-observation teacher interviews conducted around each set of two to three consecutive observations. During observations, researchers regularly interacted with students to ask them about their thinking and understanding, and to capture selected copies of student work. This research project is guided by several questions, including:

- Within each teacher's mathematical teaching practices, what types of questions does she ask, what types of examples (e.g., worked examples) does she use, and what types of representations does she demonstrate or elicit with students during math lessons to develop students' mathematical habits of mind?
- What do children's mathematical habits of mind look like in classrooms of Primarily Math participant teachers? What connections can be observed between teachers' and students' mathematical habits of mind?

Bluebird Elementary School is a Title 1 School. There are 650 multicultural students in prekindergarten through 5th grade. 75.6% of students qualify for free or reduced lunch, 18.4% of the students participate in the English Language Learner program, and the school has a 20% mobility rate. The teachers involved in this study are Ms. Summer, Ms. Spring, and Ms. Autumn (see Table 1); all were Caucasian females. During the year of data collection, the school district was in its first year of implementation of new mathematics textbooks: *Math Expressions*.

Preliminary data analysis conducted includes coding transcripts of interviews and videotaped observations of Ms. Spring; analyses of data from Ms. Summer and Ms. Autumn will during summer 2012. Researchers used MAXQDA10 to code transcripts in vivo (Creswell, 1998), focusing on questions, representations, examples, and observed mathematical habits of mind. Codes were then grouped into broader themes as patterns emerged across observations and teachers.

Table 1: Teacher Demographics

Teacher	Grade	Years of Experience	Class size
Ms. Summer	Kindergarten	9	18-23
Ms. Spring	First grade	33	18-20
Ms. Autumn	Second Grade	10	18-22

Findings

Four themes emerged during preliminary analyses, related to choices teachers make to develop mathematical habits of mind in students and make developing understandings visible: instructional choices, teacher moves, use of representations, and reflection. These themes spanned both interviews and observations, across all three teachers and grade levels.

Teachers making intentional instructional choices to develop students' mathematical habits of mind was marked by instances of teachers making choices about the design of the lesson or task, the representations being used and the design of the classroom. During observations, researchers noted apparent instructional choices, and then asked about these during the post-observation interviews. Teachers then could confirm the intentionality of these decisions.

Teacher moves that develop students' mathematical habits of mind include repeating, revoicing, defining and asking clarifying questions. In one example, the class is trying to come to an understanding of how a total is defined. Ms. Spring calls on several students to ask, "What is a total?" and then repeats what the student says. Through this process the class is beginning to create a definition for total.

A second move that Ms. Spring uses is revoicing, in which she adds mathematical precision or clarity to a student utterance.

Victor: Because 9 is at the bottom and 10 is at the top.
Ms. Spring: And 10 plus 9 makes 19 together.

Victor is referring to a chart with 2 rows of 10 envelopes. Ms. Spring makes a slight change to what Victor said to make a more complete mathematical statement.

Adding mathematical clarity and precision also occurred in the form of clarifying questions. Clarifying questions occurred often and are one of the tools that Ms. Spring uses to make a students' developing understanding visible to other students, and thus develop students' mathematical habits of mind.

Ms. Spring: Would it go at the top of the mountain or at the bottom? How do you know it goes at the bottom?
Kiya (points to the bottom of the mountain): Because it is not the biggest number.
Ms. Spring: And is it always the biggest number that has to go at the top? If it is the biggest than how come 5 didn't go at the top?

In this conversation, Ms. Spring is trying to help Kiya clarify her understanding about why a number is considered either a partner (addend) or total.

Use of representations to develop students' mathematical habits of mind and make developing understandings visible was seen both by the teachers providing students with representations and the students creating representations in different situations. Evidence of this was found throughout all observations. One example is in student solutions to daily math problems. For example, one problem being solved was: I have 1 nickel. I have 7 pennies. I buy a car for 10¢. How much money do I have left? José used drawings of coins to display how he solved the problem, first by drawing all the coins, then by crossing out those needed to purchase the toy car to see how much is left.

Teachers being reflective develop the mathematical habits of mind of their students is a theme that emerged from the interviews. For instance, Ms. Spring spent considerable time during the interviews reflecting on her district's new textbook series (*Math Expressions*). She discussed how before her Primarily Math participation, she would not have known words like "partners" and "totals" and she would not have combined her instruction of addition and subtraction. Many of Ms. Spring's reflective statements intertwined what she was noticing about her students and the mathematics about which they were developing understandings and habits of mind.

Discussion and Conclusion

During interviews, teachers reflected on the impact of their Primarily Math participation on their teaching practices. Since their district was implementing a new, much less traditional, textbook during the year of observations, teachers saw firsthand how their Primarily Math experiences gave them advantages over their peers, especially in understanding the language, representations, and examples provided in the textbook. Teachers saw deeper levels of student understanding and mathematical habits of mind developing as a result of their intentionality in planning representations, examples, and questions. All three teachers reflected about their levels of understanding of student understanding and mathematical habits of mind, and planned instruction to include examples and representations they thought would best support deeper student understanding and development of mathematical habits of mind.

Further analyses will include coding Ms. Summer and Ms. Autumn's videos and interviews, and include cross-case analyses. Since the teachers were chosen to represent strong and average learning trajectories across Primarily Math courses, data will be examined to determine if similar patterns emerge in their teaching practices and attempts to understand student thinking and mathematical habits of mind. Connections among student work, conversations and interviews with students, and teacher data will support conclusions about connections among teachers' and students' observed mathematical habits of mind.

PREDICTION QUESTIONS IN THE ELEMENTARY CLASSROOM: TRANSITIONING FROM A PROFESSIONAL DEVELOPMENT EXPERIENCE TO CLASSROOM ENACTMENT

Lisa Kasmer
Grand Valley State University
kasmerl@gvsu.edu

Esther Billings
Grand Valley State University
billinge@gvsu.edu

In this study, we use prediction questions as a vehicle for professional development and share factors that hinder and promote experienced elementary school teachers' transfer of these professional development experiences into their classroom practice.

Keywords: Teacher Education–Inservice/Professional Development

Purpose

There is a burgeoning concern among researchers, educators, and policymakers to develop teacher capacities through professional development (PD) as a means for improving instructional practices to increase student learning and achievement. In this paper we share results of a study, investigating how teachers transition their knowledge from a PD experience into classroom practice; in particular, how does use of prediction questions serve as a catalyst for promoting reform-teaching practice?

Perspective

The goal of PD initiatives is to improve instructional practice as research confirms the significance of instructional practice on student learning (McLaughlin & Talbert, 1993). Three characteristics of effective PD are summarized by Edmondson (2009): (a) PD is *content-focused*, (b) teachers are provided with *opportunities for active practice*, and (c) PD is *embedded in teachers' daily work*. But, in order for PD to have a tangible impact on practice, teachers must find ways to transition from methodologies explored within a PD context to meaningful enactment into their classroom. Yet, the ways in which teachers may transfer and implement knowledge varies; Joyce and Showers (2002, p. 102) outline a continuum of "levels of transfer" (see Table 1).

Table 1: Levels of Transfer

Level	Description
1: Imitative	Exact replication of what was demonstrated in a training session
2: Mechanical	Applies an idea or strategy learned to other similar contexts, but in a way that varies little from how it was presented.
3: Routine	Activities become identified with specific models of teaching." At this level, lower-order and concrete curriculum objectives are often noted.
4: Integrated	Begins to integrate methods used in multiple contexts and can understand when and why it is appropriate to use.
5: Executive	Complete understanding of theories underlying various models learned, a comfortable level of appropriate use for varieties of models of teaching

This pilot study is designed around Edmondson's three characteristics and uses prediction questions as the catalyst for monitoring student learning and adjusting teaching to meet students' needs. We define prediction as reasoning about the mathematical ideas using previous knowledge or patterns *prior* to formal instruction (Kasmer, 2009). Prediction does not imply a simple premature guess; it is a sophisticated reasoning process in which students must activate their prior knowledge and connect concepts from previous learning. This study specifically investigated the following research question: In what ways does a teacher's use of prediction questions transfer from a PD experience to classroom practice?

Modes of Inquiry

Professional Development Teacher Intervention

Three teachers are highlighted in this section (Susan, 4th grade; Derrick, 5th grade; and Judy, 6th grade). Their teaching experiences were 15 years, 12 years, and 30 years, respectively. Since none of the teachers previously used prediction questions, the researcher initially met with each teacher to share the purpose and research supporting the effectiveness of this paradigm. Then the researcher taught a model lesson incorporating the use of prediction questions in each of the teacher's classrooms followed by a debriefing session. Each teacher taught 8–10 lessons incorporating prediction questions developed by the researcher based on the mathematical content of the lessons.

The teachers were asked to use the following lesson protocol throughout the study. At the onset of the lesson, the teacher poses one or two prediction questions. Students respond in writing, providing both an answer and explanation. After previewing each student's paper the teacher then elicits a variety of prediction responses with supportive reasoning. At this point, the teacher does not confirm the accuracy of the responses and should assess students' thinking in order to make instructional decisions pertaining to how to address ill-formed ideas and misconceptions and proceed with the lesson. At the end of the lesson, key mathematical ideas are coalesced and misconceptions revealed as the teacher encourages students to resolve discrepancies between initial prediction responses and outcomes.

Data Collection and Analysis

Data were drawn from various sources in order to triangulate the data (Denzin, 2006) and enhance the validity of research findings. These data sources reveal information about how the teachers transferred the practice of using prediction questions into their classroom.

Classroom observations. Classroom observations, collected monthly and augmented by field notes and video episodes, documented the ways in which the teachers transferred the use of prediction questions into their classrooms. In this study, we examined videos from Susan's classroom and observations from Derrick and Judy's classroom.

Teacher journals and debriefing sessions. The teachers submitted a weekly journal, reflecting upon their experiences with prediction questions, responding to questions such as: *What aspects of using prediction in your classroom, if any, have been beneficial to your teaching in terms of gauging students' understanding/misunderstandings? What instructional decisions did you make based on students' prediction responses?*

Our analysis focuses on the qualitative characteristics of each teacher's use and integration of prediction questions with an emphasis on a subset of the RTOP (Reform Teaching Observation Protocol) indicators (Pilburn & Sawada, 2000) that focus on monitoring student learning. Indicators we chose to guide our analysis includes: (a) Instructional strategies and activities respected students' prior knowledge and the pre-conceptions inherent therein; (b) Student questions and comments often determined the focus and direction of classroom discourse.

Results

In this section, we share snapshots of classroom interactions during the sixth week of the study that seem to be typical of each teacher's use of prediction questions.

Susan

Susan did not even demonstrate an imitative use of prediction questions when introducing probability. She asked her students to make predictions and had them look at these questions at the end of the lesson, yet she did not use her students' responses to either inform her own instruction nor have students reflect about their own initial misconceptions, resolve discrepancies or make connections. Susan's lesson was teacher-directed. She encouraged students to share their thinking; however, the focus and direction of the lesson was not determined by ideas originating from the students. Neither Susan nor the students made explicit connections between the prediction questions and newly learned information.

Derrick

In Derrick's fifth grade classroom, students completed a lesson on ordering decimals. Initially, Derrick asked his students to predict whether 3.07 or 3.4 would cover more or less area on a 10×10 grid. A number of students responded that 3.07 would cover more area than 3.4 because there were more digits past the decimal point. One student remarked that two zeros could be added to 3.4 (3.400), and there would now be more digits past the decimal point. Another student responded that two zeros could be added to 3.07 (3.0700) and there would now be more digits in 3.07. He commented during the post-lesson debriefing, "I knew I had to make an instructional decision based on their responses, but I could only show them on a 10×10 grid the difference between 3.07 and 3.4, but I couldn't think of any other way to explain it to them. I really didn't know what else to do." Derrick proceeded with the lesson as he originally planned, unable to make instructional adjustments to directly respond to his students' needs. At the end of the lesson, he only asked "is everyone clear now about the difference in shading between 3.07 and 3.4?"

Derrick's transfer of the use of prediction questions appears mechanical. He respected his students' knowledge and actively encouraged his students to share their strategies and conjectures. Derrick understood the rationale and intent of asking prediction questions both as a means for confronting students' misconceptions and to focus the lesson based on students' current understanding. Though he desired to use his students' thinking to direct the lesson, Derrick was unable to do so; he lacked the pedagogical content knowledge necessary to provide additional ways for his students to visualize, conceptualize, and compare decimals to confront their ill-formed ideas.

Judy

In Judy's sixth grade class, students were exploring strategies for representing fraction amounts larger than one (both mixed numbers and improper fractions). Judy posed this prediction question to begin her lesson: *Can you predict how many ¼ are in 7¼? Explain your reasoning.* A number of students suggested that there would be 7 fourths in 7 since the ¼ was the same in both numbers (¼ and 7¼) and 7 was different. Some students responded 28, reasoning that there are 4 fourths in 1 and since they have 7, multiply 7×4 to get 28. Others thought 11; reasoning that $7 \times 1 = 7$ and $7 + 4 = 11$. A few students suggested 29, stating they remembered the procedure. During this time, Judy wrote the students' responses on the board and summarized their reasoning. Then she told the students, "let's begin a new problem and we will revisit your predictions once you finish." Next, students worked in groups to represent numbers as improper fractions and mixed numbers on a number line. Judy circulated among groups, listening to students' explanations, interacting and questioning students who demonstrated misconceptions revealed through the prediction questions. For example, Judy asked a student whose response to the prediction question was 28, "Can you show me how many ¼s are in 7¼ using a picture?" The student drew seven circles and divided them into quarters. Judy encouraged the student to count the number of fourths; as the student counted, she realized she had forgotten the extra ¼ in 7¼ concluding there were actually 28 + 1 or 29 fourths. At the end of the lesson Judy restated the prediction question, "How many ¼s are in 7 ¼? Do you still want to stick with your original prediction? This is your opportunity to make a change if you want." Judy then led a discussion to help students make connections and resolve the discrepancies in their thinking prior to the lesson.

Judy's transfer of the use of prediction questions is integrated. She used prediction questions to solicit students' thinking and strategies, representing this thinking in an organized way for the entire class. Judy used students' responses to focus the classroom lesson and actively confront student misconceptions. She intentionally asked her students to make connections among concepts and strategies. Judy internalized how prediction questions could be used as a powerful tool for anticipating and building student thinking.

Conclusions

Through this professional development opportunity, teachers did transfer the practice of integrating prediction questions at various levels into their mathematics lessons. It was hoped that the prediction questions would provide an instructional focus and enable teachers to actively assess what the students already knew and misconceptions or ill-formed ideas that would need to be addressed during the lesson, as was illustrated through Judy's enactment of this instructional practice. Susan was unable to incorporate the use of prediction questions in a non-literal way. For Derrick, an incomplete understanding of pedagogical content knowledge interfered with his ability to confront students' misunderstandings.

This study suggests the need for sustained PD that explicitly provides more support for teachers' pedagogical content knowledge. In order for teachers to gather evidence of the student's knowledge and make well-informed instructional decisions based on this knowledge, teachers need additional experiences anticipating students' responses and explicitly connecting student thinking to related mathematical and pedagogical knowledge prior to instruction. In addition, involving teachers in the writing of the prediction questions may help teachers plan for their lessons more effectively as they anticipate students' responses and potential ways to adapt the lesson to address these responses ahead of time. The use of prediction questions has merit and is worthy of inclusion into PD opportunities.

We report on research conducted within a large NSF-funded curriculum project which has resulted in a new fourth-year high school mathematics curriculum. Teachers were engaged in the development process in that they provided ideas for content, contributed materials, and provided significant critique of the materials. We find that teachers who have participated in the project indicate they have improved knowledge and skills in mathematics, that their students made changes in their participation in the classroom, and, most significantly, that teachers have made substantial changes to their teaching practice. We claim these changes are evidence of teacher agency, a crucial element of successful professional development.

Keywords: Teacher Education–Inservice/Professional Development; Curriculum

Introduction

Recently, mathematics educators have called for new and focused studies of professional development as a way to improve mathematics teaching at the K–12 level (e.g., Darling-Hammond, Chung Wei, Andree, Richardson, & Orphanos, 2009). Often teacher change is an explicit goal of professional development. In this report, we address teacher change with the intention of connecting and using it to support the notion of teacher agency. This focus on agency has been studied extensively in other educational and psychological venues (e.g., Ray, 2009), but there is very little research on teacher agency in the mathematics education body of research. In this paper, we report on a research study conducted within a large curriculum project [CP] to examine an innovative type of professional development. In particular, we examine teacher-reported change and how this change relates to teacher agency.

Curriculum Development Project

Currently, many states require, or will require, high school students to complete a mathematics course beyond Algebra II in their fourth year (Cavenaugh, 2008). Additionally, there is a growing movement among schools to integrate mathematics with science, engineering, and technology (National Center on Education and the Economy [NCEE], 2007). As a result of these policies, mathematics educators and engineers are collaborating on an NSF-funded project with the objective of creating, implementing, and evaluating a new high school curriculum that integrates mathematics and engineering concepts (Young, Keene, Norwood, Chelst, Edwards, & Pugalee, 2012). The curriculum provides the venue for students to make decisions concerning contextual problems using mathematical methods; hence, the curriculum is called “mathematics for decision-making” [MDM]. The curriculum is intended for high school seniors who have completed two years of algebra and one year of geometry. During the summers of 2008–2011, 232 teachers participated in 11 workshops where they learned the content of the MDM curriculum and ways to teach it.

Research Background

Previously, we showed that the CP is an effective form of professional development (Keene, Dietz, & Holstein, 2011). Here, we extend this research by examining teacher agency because we believe agency is an important element of professional development. In the larger sociocultural structure, human agency is defined as “the process through which people intentionally change themselves or their situations through their own actions” (Ray, 2009, p. 116). When applied to teachers, agency is the belief that teachers have the ability to influence their environment while being shaped by social and individual factors (Lasky, 2005, p. 900). Thus, teacher agency is the desire and ability of teachers to take an active role in making important decisions for their classrooms and their students. Teachers are also shaped by social factors, like their schools, peers, and districts, and by individual factors such as elements of their own teacher identity.

Under this definition, the CP presents a situation where teachers can exercise their own agency. In the CP, teachers have the ability to choose whether or not to teach the curriculum, how much of it to teach, how they teach it, how many workshops to attend, how active they are in the CP, and whether or not they would like to give feedback. The CP teachers assert their own agency repeatedly throughout this process.

Methodology

Participants

The participants in this study came from the group of teachers who participated in a summer workshop (108 teachers at the time of this study). The project team developed and facilitated workshops for the purpose of introducing the volunteering teachers to the MDM curriculum. Participation following summer workshops included: (a) piloting the materials, (b) providing feedback on the materials, and/or (c) contributing to online forums.

Teacher Change Survey and Teacher Artifacts

A survey was utilized as one way to study how teachers reported change. The survey was adapted from a portion of Garet, Porter, Desimone, Birman, and Yoon (2001) Teacher Activity Survey. The CP teachers were given questions from the survey that specifically asked about the effectiveness of their involvement in the CP. The adapted survey consisted of 40 Likert-scale items to collect information about teacher change. In this paper, we report only on the items studying teachers’ perceived change of their practice because we believe that these items most closely relate to teacher agency. Of the 108 teachers who were a part of the CP at the time of this study, 39 (36%) completed the survey. In addition, throughout 2008–2010, we collected a number of teacher artifacts from the summer workshops as well as from throughout the school year. For this paper, we only discuss the teacher change survey results and supporting quotes from teachers’ daily journals from the summer workshops.

Results

We feel attending to teacher agency is an important element of successful professional development, and as Ray (2009) suggests, agency is the process to intentional change. Table 1 details teachers’ responses to the survey items regarding teachers’ perceived change in their practices. Table 1 also shows the results of hypothesis testing on the results. We use an approximate *z*-test to check if the means of the response values are significantly different from 2 (minor change). As the table shows, all but the last question showed a significant difference from 2. Note that the last question’s mean was significantly different from 1 (no change).

Table 1: Summary Data of Teacher Responses to Part 3 of Teacher Survey

To what extent have you made each of the following changes in your teaching practices as a result of being part of the CP?

			No Change (1)		Minor Change (2)		Moderate Change (3)		Significant Change (4)	
	N	Mean	*n*	%	*n*	%	*n*	%	*n*	%
The mathematics curriculum content	34	2.82*	4	11.8%	8	23.5%	12	35.3%	10	29.4%
The cognitive challenge of math classroom activities	35	2.86*	3	8.6%	7	20.0%	17	48.6%	8	22.9%
The instructional methods I employ	34	2.65*	4	11.8%	10	29.4%	14	41.1%	6	17.7%
The types or mix of assessments I use to evaluate students	34	2.56*	3	8.9%	14	41.2%	12	35.3%	5	14.7%
The ways I use technology in instruction (calculator or computer)	34	2.79*	4	11.8%	10	29.4%	9	26.5%	11	32.4%
The approaches I take to student diversity	33	2.09	7	21.2%	17	51.5%	8	24.2%	1	3.0%

*$p < 0.001$

The results from this set of questions show that teachers perceive that they have taken action and changed their teaching practice. For all but the last question, at least 50% of the teachers answered that they made either moderate or significant changes in their practice. We discuss two of the questions whose mean values were significantly higher than 2 in the survey (due to space constraints) and support these results with quotes from the teachers' workshop journals.

The Instructional Methods I Employ

Of the teachers who completed the survey, 58% (20 of 34) said they made at least moderate change in the instructional methods they use. One teacher explained why the MDM curriculum helps foster this change: "It is very tempting to continue business as usual… teach, homework, quiz repeat… Implementing this kind of curriculum at a school will take a teacher who is willing to change their mindset… If the teachers can't change the students never will." Another teacher explained how the MDM curriculum fosters this change by promoting "a problem based learning environment in the classroom. My life does not have to consist of worksheets. Students will ultimately get more out of the problem if we let them do it and not always walk them through step by step." The results from the survey coupled with these teachers' quotes from their journals are interesting particularly because the summer workshops and any further support given to the teachers focus primarily on content and not classroom instruction. The fact that the teachers decided to take action and change their teaching methods is noteworthy.

The Ways I Use Technology in Instruction (Calculator or Computer)

As a result of participating in the CP, teachers reported substantial changes in the ways they used technology in their instruction. This survey prompt received the most "significant change" responses of any of our survey questions (11 of 34). Implementation of the MDM curriculum requires computers on a regular basis and many of the chapters require students to employ Microsoft® Excel. We find teachers' interest in and commitment to incorporating Excel into instruction notable because it is difficult for teachers to introduce this type of technology in traditional mathematics classrooms. This introduction is the biggest indicator of teacher agency, as it takes significant effort for teachers to incorporate this technology. Teachers' journal entries indicate that many were very concerned about the technology required to teach portions of the MDM curriculum as well as the challenge of instructing students on how to use the software. For example, one teacher wrote, "My biggest concern at this point is the availability of computers when I start teaching this." Another teacher shared the same concern, but also offered a way to handle it: "I am very concerned about the amount of technology used because I know I can't get into a computer lab every day. I would definitely need some 'work by hand' material (more so than technology material)." The survey showed that many teachers have made changes in their technology use even though they faced these challenges, indicating that their desire to act on their decisions and effect change.

Conclusions and Implications

We have presented the results of a research study on teacher change which support our hypothesis that teacher-author partnering is an effective form of professional development that supports teacher agency. A relatively large sample of the participating teachers reported at least a minor change, and often a moderate or significant change in their teaching practice in several different areas. By participating in the CP, teachers illuminate their desire to take action in their practice and then actually change their practice. We believe that this is an important professional quality for teachers to have.

However, a large majority of the U.S. is in the process of implementing the Common Core State Standards (CCSSI, 2010). With this new opportunity comes the possibility that teachers will be required to employ a narrowed curriculum, outside-mandated instructional strategies (possibly scripts), and external assessments, all of which may lead to less autonomy and reduced teacher agency. We suggest actively involving teachers in a curriculum project, like the one described here, provides an avenue for teachers to choose action and make choices in their teaching and thus increase their sense of agency and improving instruction in the classroom.

INVESTIGATING COMMUNITY COLLEGE MATHEMATICS INSTRUCTORS' PRACTICAL RATIONALITY THROUGH PROFESSIONAL DEVELOPMENT

Elaine Lande
University of Michigan
elande@umich.edu

This study explores community college mathematics instructors' rationales for their teaching decisions. Using Herbst and Chazan's theory of the practical rationality of mathematics teaching, conversations among faculty during professional development sessions for teaching trigonometry are analyzed to better understand the norms of the classroom and influences on instructional decisions. This knowledge can be instrumental in developing sustainable strategies to assist teachers in improving their teaching.

Keywords: Teacher Education–Inservice/Professional Development; Post-Secondary Education; Instructional Activities and Practices

This study explores community college mathematics instructors' rationales for their teaching decisions. Using Herbst and Chazan's (2011) theory of the practical rationality of mathematics teaching, I analyze conversations among faculty during professional development sessions targeting trigonometry or pre-calculus instructors. The sessions also sought to probe the norms of teaching mathematics in community colleges and to establish how community college instructors' professional obligations influence their teaching decisions. This knowledge can be instrumental in developing strategies to assist teachers in improving their teaching.

More concretely I seek answers to the following questions:

1. Why do community college trigonometry instructors teach in the way that they do?
2. What are the norms in these instructional situations?
3. What are the reasons they give for the instructional decisions they talk about in professional development?
4. How do professional obligations (from Herbst and Chazan's theory of the practical rationality of mathematics teaching) influence their instructional decisions? Where in these obligations do their justifications fall?

Rationale

Mathematics courses at community colleges comprise 51% of the total enrolment of undergraduates in mathematics. A large portion of this enrolment is in developmental mathematics (57%) and college level mathematics which is a pre-requisite for calculus (19%, Lutzer, Rodi, Kirkman, & Maxwell, 2007). Thus community colleges play a large role in preparing students who plan to pursue STEM fields, but do not enter college prepared to take calculus. While community colleges emphasize the importance of good teaching and are organized in a way that suggests a commitment to teaching (e.g., faculty are devoted almost entirely to teaching, classes are typically small, Cohen & Brawer, 2008), there is little empirical research on teaching that occurs in community colleges and even less on improving the teaching (Mesa, Celis, & Lande, 2011).

Most community college mathematics faculty hold their highest degree in mathematics (70% of full-time and 49% of part-time faculty), with a smaller portion of faculty holding their highest degree in mathematics education (18% & 27%, Lutzer et al., 2007). Thus unlike K–12 teachers, most community college mathematics instructors have little or no formal education in teaching. As a result much of the instruction that takes place in these classrooms is based on how the instructors themselves learned mathematics—providing information in a teacher-centered classroom (Mesa, Celis, & Lande, 2011; Anderson, 2011)—with an estimated 78% of pre-calculus level mathematics in community colleges taught using standard lecture methods (Lutzer et al., 2007).

While there have been efforts to reform mathematics instruction in community colleges (Blair, 2006), there is no system in place to educate the faculty about reform-oriented teaching practices. This study approaches the improvement of mathematics instruction by looking at a professional development sessions for community college faculty teaching trigonometry or pre-calculus as a means to better understand their reasons for making the teaching decisions.

Conceptual Framework

Drawing on Herbst and Chazan's (2011) theory of the practical rationality of mathematics teaching, I explore the norms of teaching mathematics in community colleges and community college instructor's professional obligations. This theory of practical rationality views teaching as a natural phenomenon; teachers' actions are in response to the conditions and constraints of the environment.

This theory holds that teaching decisions are shaped by the presence of two sets of regulatory elements: norms and professional obligations. The norms of an instructional situation are mutual expectations between the teacher and students of who can do what and when. Norms are in part shaped by the professional obligations that are specific to an individual holding the position of a mathematics teacher. Professional obligations can be divided into four categories—*disciplinary*, *individual*, *interpersonal* (to the class a whole), and *institutional*—which aid in organizing the justifications that instructors make about their teaching decisions.

Context

Throughout a series of five three-hour professional development sessions for trigonometry and pre-calculus instructors from regional community colleges, I explore how teachers talk about their instructional decisions and identify—through their justifications of these choices—the professional obligations that influence these decisions.

Two sections of the professional development were conducted with a total of twenty instructors of trigonometry and pre-calculus from community colleges in the region. The participants were both full-time and part-time instructors with a wide range of backgrounds and years of experience teaching.

Each session included exploration of a trigonometric topic and involved the use of either an animation depicting a community college trigonometry classroom or other video to encourage discussion about instruction. Throughout the sessions the participants were asked questions and encouraged to talk about their reasons for making instructional decisions. Each session was audio and video recorded. The recordings and transcripts of these recordings for each session are the data used for this research.

Analysis

This study uses two methods to analyze the discourse in these professional development sessions. The first analysis aims to better understand the norms, professional obligations, and instructional decisions while the second aims to gain a more nuanced understanding of the tensions instructors face when making instructional decisions.

Analysis 1

This analysis uses open coding with special attention being given to the norms, breaches of the norms, and professional obligations used when justifying instructional decisions. Each justification is also categorized as the result of a breached norm or as one or more of the four professional obligations, with the goal of creating sub-categories within the four professional obligations. The intended result of this analysis is the creation of a *decision space*—the compilation of the influences on instructional decisions.

Analysis 2

To gain a more nuanced understanding of the tensions instructors face when making instructional decisions, the instructors' justifications will be further analyzed using Systemic Functional Linguistics (SFL, Eggins, 2004). SFL was chosen because of its theoretical grounding and comprehensive approach to discourse analysis; SFL focuses on the relationship between language and the context in which the language is being used.

This analysis will make it possible to look at the *position* of an instructor in the decision space when making a specific decision in a given context at a certain point in time. This position would indicate both the professional obligations that are included in their decision making and which professional obligations are driving the decision.

Discussion

Based on the data analyzed so far, I theorize that there exists a *decision space* that the instructor uses (not necessarily consciously) to make their instructional decisions and while this decision space remains constant, there are many variables locating an instructor's current *position* in that space—what obligations are more or less influential for a specific decision at a certain point in time in a given context. Being located in a different position may result in different justifications for their choices or different choices entirely.

For example, instructors talk about using or not using group work in their classroom. Some instructors justify using group work as a way to get students to communicate about and explore the mathematics as a means to better develop their mathematical ideas (obligations to the individual, the class as a whole, and the discipline). Whereas other instructors justify not using group work on the basis that not all students participate equally and therefore not all students get anything out of group work (obligation to the individual and class as a whole); that when the mathematics is not presented correctly it may just confuse the students more or the student may walk away with an incorrect notion of the mathematics (obligation to the individual and the discipline); and that it takes too much class time given the amount of content that needs to be covered in the course (obligation to the institution).

After viewing a clip of a student interview on a topic that had just been covered in class, which showed that the student was still struggling with many of the concepts presented, one faculty member reconsidered his earlier position of not using group work in class based on the realization that students may not be getting out of the traditional lecture what that faculty member would have expected.

This example illustrates the instructors' acknowledgement of their professional obligations as well as the potential for a change of position in the decision space. Because instructional decisions may have competing obligations, an instructor having more awareness or knowledge may influence the weight of a certain obligation in a given situation. In this case the instructor realized that students may leave a traditional lecture without having the expected knowledge, and began to question if lecturing is in fact fulfilling their obligation to the individual student in the way he expected. As a result instructors may begin to consider other methods of teaching that are more student-centered. While student-centered teaching methods were not previously considered an option—in part because of classroom norms and his or her professional obligations—this instructor began to discuss how the individual student may benefit from more student-centered practices, which may either outweigh or better contribute to their other professional obligations.

This example illustrates how knowledge of instructors' justifications for teaching decisions can better inform the design of professional development. Interventions can then be chosen to help instructors realize—rather than be told—ways of improving their teaching. Changes that occur in this manner are much more likely to lead to sustainable change.

LIMITING STUDENTS' TRANSITIONS IN MATHEMATICAL COMMUNICATION

Carlos A. López Leiva
University of New Mexico
callopez@unm.edu

This paper describes how facilitators' assumptions during mathematical communication—about the unconventional mathematical discourse practices of some bilingual Latina students—limited attention given to these students' semiotic resources preventing them from transitioning into greater understanding mathematical concepts although students' initial ideas were correct.

Keywords: Equity and Diversity; Instructional Activities and Practices; Reasoning and Proof

Communication in mathematics has become one of the major goals of and learning processes in mathematics education (Chapin, O'Connor, & Anderson, 2009; Sfard, 2008). Learning mathematics is deemed as an active process, closely connected to receptive, expressive, and interpersonal communicative actions (Bereiteer & Scandamalia, 2003). Appropriation of mathematical concepts is facilitated through using one's own terms to express own ideas— languaging (Wittgenstein, 1965) and even tensional, transformative processes that promote understanding (Razfar, Khisty, & Chval, 2010). These communicative perspectives are delineated in the standards. For example, the National Council of Teachers of Mathematics (2000) recommends problem solving and a focus on communication in the teaching mathematics to develop expertise in mathematical practice students need to make sense of problems, construct viable arguments, and look for and express their reasoning. Then teaching and learning of mathematics encompasses the appropriation of mathematical discourse practices, which reach far beyond using operations and terms (Moschkovich, 2004), so students become "mathematically powerful" by blending their understandings with mathematical knowledge and practices (Romberg, 1994). Though, discourse defines what is acceptable and marginalizes viewpoints central to other discourses (Gee, 1990), a situation that challenges an equitable promotion of the communicative process in mathematics.

This study centers on Latina students in mainstream classrooms that are not receiving special services, but still who struggle in mathematics. I believe this population is often overlooked but needs more attention. The U.S. NCES (2011) reports 18% of 4th graders and 27% of 8th graders are performing below the basic level in mathematics; 28% of 4th-grade and 39% of 8th-grade Hispanic or Latina/o students perform at below the basic level in mathematics. Among students reported as ELLs, 41% of 4th graders and 71% of 8th graders perform at this level also. Therefore, the students deemed as struggling in mathematics represent a high percentage of the general student population, the Hispanic/Latina/o, and the ELL student populations.

Focus, Setting, and Methods of the Study

This paper describes how some communication processes limited opportunities for some Latina students to participate and understand mathematics (Gutierrez, 2008). Although they were initially correct, the low expectations, assumptions, and lack of attention they encountered stifled their own understandings and perspectives and forced them to acquiesce and adapt their learning according to the instructor' ways and expectations. The context of the study comprises a math club (Khisty, 2004) where the participating Latina/o students were all bilingual (Spanish and English) and mostly U.S.-born and from a Mexican background. They met twice a week, ninety minutes each time, and the program ran for over three years (2006–2009), having an average of 17 students per semester. The program began with their 3rd and ended with their 6th grade.

Students had a self-selected enrollment. The hosting school has a dual-language program and is located in a low-income neighborhood in a Midwestern urban area where the student population is nearly 100% Latina/o, low income, and over 60% English Language Learners (ELLs). From the pool of participating students, I selected two focal students—Betty and Nora—with low mathematics performance in their regular classroom and examined the quality of their participation in small groups around the mathematics problem solving tasks during the entire program. I focused on the opportunities that each student had to express her ideas and how these were taken up by both the rest of peers in the group and the instructors or facilitators, who were Latina/o bilingual pre-service teachers. The data included videotaped interactions, fieldnotes, and student work. I selected 30 episodes showing focal students' interactions. Through a comparative and contrastive process (Miles & Huberman, 1994), I explored recurrent interaction patterns regarding the level of support that the facilitators and peers provided to different students in the different groups. These patterns were originally sorted in categories either as communicatively supportive interactions—or not. Because of the emphasis of this paper, the examples presented here relate to interactions with limited communicative interactions.

Using a framework based on Wittgenstein's (1965) idea of "languaging" and Vygotsky's (1978) concepts of language interpersonal and intrapersonal functions, I explored the following question: *How do social interactions around students with low mathematics performance mediate their opportunities to understand and participate in mathematics?*

Findings

Results from analysis show that 56% of Betty's and 52% of Nora's communicative interactions were limiting (i.e., students ideas were rarely elaborated on or acknowledged). In contrast, students with high mathematics performance within the same groups had over 75% supportive (i.e., students' ideas and struggles received attention and support) communicative interactions. These results indicate that students with low performance seem to have less support during communicative interactions around mathematics than students with higher mathematics performance. The following selected examples portray limiting communicative interactions.

The first example comes from Betty's group while interacting with Fabiola, Candy, Elsita and a facilitator. They worked on a task naming fractions in order to solve a word puzzle. At first, the facilitator asked students to describe the task and reacted differently to each student.

Betty's explanation was not elaborated by the facilitator. Perhaps it seemed unclear to her. Betty mostly relied on gestures to describe her ideas. Her narrative itself was imprecise compared to Fabiola's. Betty used general terms such as "it," "this," "here," and "there," which made the content of her message ambiguous, as in the following example:

> *Betty*: We need like, this one's already cuz maybe there's three right here [*points to pie charts*]; and then the thing is, there's like three and two [*points to numbers, keeps hand there*]; so, like if there's three and there's two right here [*points to charts with pen in right hand*], then that's a fraction.

Betty used gestures as an important part of her explanation, while Fabiola used gestures to complement her idea. Fabiola used specific terms, which made her message more direct.

> *Fabiola*: Yeah, because the fractions are here (points to circles). So, I think we need to put the letter in here [*taps empty boxes and numbers*], that we see the fraction here [*points to circles and holds pen there with right hand*], and we put the letter up here [*points to boxes with left index*].

Despite these differences, Betty's explanation helped another peer start understanding the task. These alternate ways of providing explanations may depict different levels at which meaning is constructed. For Betty and her peer, having gestures accompanied with a few general terms seemed to help their understanding; for the others, the use of more specific terms accompanied by few gestures worked better. At this point, the reception of Betty's "unconventional" explanation had been ignored and no attempt was made to understand what she meant.

Later, Betty understood the illustrations in the task differently, and the facilitator and peers did not attempt to adapt to this form. This fact forced Betty to change her perspective (although correct) without understanding why. While the group solved the task, Betty focused her attention on the white sectors of the pie chart (M), which led her to name it 1/8 (see Figure 1). This selection differed from everyone else's and what the task asked, which focused on the black sectors instead. Although Betty explained: "*It's one covered. It's one out of eight,*" which was a correct description, her idea was rejected without elaboration. The conflict arose from the difference in how the participants paid attention to the illustrations. The facilitator and the group corrected Betty, claiming that there was only one correct answer (O) to complete the phrase.

Emphasis on the "only" correct answer to overshadowed the possibility of understanding the representations in divergent, but equally correct ways. It is not clear whether Betty understood the differences between the two answers, but she accepted what the facilitator determined as correct. The facilitator and most peers focused on solving the puzzle, and there was no chance of negotiating mathematical meaning. Therefore, this process limited Betty's and the group's transitioning onto deeper understanding of fractions.

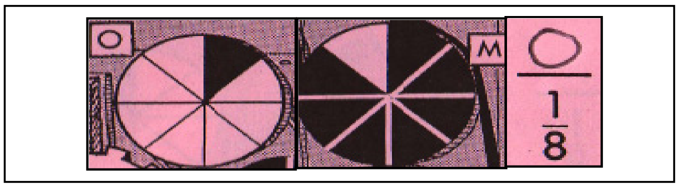

Figure 1: What is 1/8?

In the second example, Nora worked with Yolanda, Pilar, and a facilitator on a probability task called "Bubble Gum." Stressing conceptual understanding, the problem included the following question: "*Why do you think that three cents would be the most that Mrs. Hernández would spend to please her little twins?*" The problem first presented a gum machine with only red and white balls. Since the group was confused, Nora, however, reread and explained:

> Nora: [*extending left arm and holding up three fingers*] Ella tiene tres chanzas de sacar dos bolas con el mismo color./*She has three chanzas to pull out two balls of the same color*.
>
> Nora: Y si echa uno. Entonces tiene, ahí va una chanza. Y si echa el otro penny, ahí tiene otra chanza! /*And if she puts in one, then she has, that was one chanza* [points up as if making a tally mark twice] *And if she puts in another penny, there goes another chanza*!

The facilitator, although impressed by Nora's explanation, moved on to other peers who still seemed confused. Chanza is a term that is neither English nor Spanish, but it corresponds to the English "chance." Nora's explanation was neither used nor brought up again. This suggests that even though the facilitator seemed impressed by Nora's answer, she did not pay close attention to it. After this interchange, the facilitator supported the other students solve the problem.

As Nora's idea was not elaborated on, she was forced to tackle the task in procedural ways following the facilitator's directives. Confused by the process she took longer than her peers. The facilitator explained in a rather condescending way. Nora was the first in the group to have an insight with great potential to promote better understanding of the task. Her Spanglish term *chanza* was a powerful discursive resource that was ignored and perhaps not understood, but the lack of negotiation of this term promoted a limiting communicative mathematical interaction and forced Nora to follow sequential steps to an answer, but not to transition to understanding deeper the mathematical concept embedded in the term *chanza*.

Discussion

Unsuccessful communicative processes became evident when quality attention was not equitably distributed. It seems that students' mathematical status transfers beyond classroom settings. Assumptions about what is "correct" affected how facilitators noticed students. Students with more conventional ways of talking seemed to have greater support. If we believe students should develop understanding from their own perspective and move to more "efficient" ways of doing mathematics, it is crucial that we also make substantial effort to understand students' ideas before discounting or ignoring them. If something we hear or see seems unclear, then that is the point we need to work on, so we can see and listen to what students are saying to help us move with them in the transition onto deeper understandings. This means to build a common platform of understanding to build on collaboratively. Communicative approaches must validate different sources of communication. Unconventional or hybrid terms are not necessarily incorrect; instead, they might already be infused with rich mathematical content that we ought to include in order to strengthen the meaning-making process and equitable communicative opportunities for all, especially for those students with least conventional mathematical discursive practices, which stem from transitions moving along the continuum of understanding mathematics.

SECONDARY MATHEMATICS TEACHERS' EXPERIENCES WITH HIGH-STAKES EXAMINATIONS IN A TIME OF CURRICULUM CHANGE

Richelle Marynowski
University of Alberta, University of Lethbridge
richelle.marynowski@uleth.ca

This paper presents preliminary findings on research concerned with understanding secondary mathematics teachers' experiences teaching mathematics courses that have a provincially mandated high-stakes examination at the end of the course. The timing of the research project was such that the secondary mathematics teachers were also experiencing a curriculum change. Three experienced secondary mathematics teachers from three different schools and contexts were interviewed and philosophical hermeneutics was used as a theoretical framework to develop the method and analyze the secondary mathematics teachers' narratives of their experiences. Preliminary findings indicate that the secondary mathematics teachers' emotions, assessment, and teaching practices are influenced by both the high-stakes examination and the curriculum change.

Keywords: Affect, Emotion, Beliefs, and Attitudes; Assessment and Evaluation; High School Education

This paper presents early findings of research inquiring into the ways in which secondary mathematics teachers experience teaching mathematics courses where the final assessment is a provincially mandated examination. The research is being conducted in Alberta where grade 12 students write diploma examinations worth 50% of their final mark in the course. Research (Dager Wilson, 2007; Volante, 2006; Webber, Aitken, Lupart, & Scott, 2009) has indicated that the high weighting of diploma examinations leads them to be considered high-stakes examinations for students. This research asks whether the educators teaching theses courses also see the diploma examinations as being high-stakes for themselves. While the study was not initially focused on examining the impact of curricular change on the teachers' experiences with diploma examinations, new secondary mathematics curricula are being implemented in Alberta in the 2011–2013 school years, thus managing that change is on secondary mathematics teachers' minds.

Purpose of the Inquiry

The purpose of this inquiry is to inquire into and develop an understanding of secondary mathematics educators' experiences teaching a course that involves the students writing a diploma examination. Understanding secondary mathematics teachers' experiences can provide insight into high-stakes examination development and implementation. Their experiences can also highlight policies that schools and school boards have in place that affect teachers both positively and negatively. Media attention to the results of student performance on the diploma examinations also shapes how secondary mathematics teachers experience teaching grade 12 mathematics courses in Alberta.

Having been a teacher and an examination developer, seeing both sides of what can sometimes be a wide gulf, led to me want to delve deeper into secondary mathematics teachers' experiences to understand how they are experiencing teaching courses that involve students writing a provincially mandated high-stakes examination. Clandinin, Murphy, Huber, and Orr (2009) comment that

> stories of school are increasingly driven by standardized achievement plotlines. Present accountability policies in Canadian schools place increased emphasis on achievement testing and mandated assessment practices reflected in provincial policies on yearly testing across the country. (p. 81)

Large-scale testing in Alberta, in Canada, and in the United States has a long and controversial history. Understanding how teachers experience these high-stakes examinations is crucial to administrators and policy makers.

Methodology

This research uses a philosophical hermeneutic framework to develop a personal understanding of others' experiences. Gadamer (1975/2004) said that "[u]nderstanding and interpretation are indissolubly bound together" (p. 400). As I am developing my understanding of others' experiences, I am also interpreting them within the context of my experiences. Like Gadamer, I believe that I cannot separate myself from my experiences, but I can work towards extending my horizon of understanding to that of whom and what I am trying to understand. D. G. Smith (1991) writes

> we can only made sense of the world from within a particular 'horizon' which provides the starting point for our thoughts and actions. Understanding between persons is possible only to the degree that people can initiate a conversation between themselves and bring about a 'fusion' of their different horizons into a new understanding which they can hold in common. (p. 193)

The understanding that I develop is then a shared one between the participants in the inquiry and me. From the fusion of horizons, I do not experience what the participants have experienced, but I understand how they would have experienced an event they way they did based on their history. Philosophical hermeneutics helped me develop an understanding of another's experiences while recognizing my own experiences.

I engage in questioning how I understand something by coming back to the participants to either confirm or challenge my understanding. This process of questioning my developed understanding is engaging in the hermeneutic circle (Ellis, 1998; Gadamer, 1975/2004; D. G. Smith, 1991; J. K. Smith, 1993). The hermeneutic circle involves considering an experience or an understanding within the context and the history of the person who had the experience. As a researcher working within the hermeneutic tradition, I consider the part of the experience within the whole of the participants' lives and within the larger context that they are working and living.

Participants

Participants in this research project are three experienced secondary mathematics educators who are teaching one or more secondary mathematics courses requiring the students to write a diploma examination. Susan has been teaching for approximately ten years and, at the time of the research, teaching at an online school in a large city. Susan has taught in four different schools in the same city and has taught a variety of secondary mathematics courses. Marla has been teaching for approximately eight years with all of her teaching experience at a large urban school. Marla has taught mostly what is considered the non-academic mathematics courses throughout her career. Vanessa has been teaching for approximately nine years and has experience teaching mathematics from grades five through twelve. Vanessa is currently teaching at a secondary school in a smaller, affluent city and teaches mostly the higher academic mathematics courses.

Method

Each of the participants was provided with a general written invitation to participate in the research project and an invitation to complete a pre-interview activity (Ellis, 2006) to bring to our first meeting. The purpose of the pre-interview activity was to provide our conversation a place to start, a way to get to know each other and for me to find out more about what was important to whom I was interviewing. Ellis (2006) writes "a conversational relationship can be established through discussions of the pre-interview activity products, thus building rapport for remaining parts of the interview" (p. 121). Marla was the only participant to complete the pre-interview activity and her response to the prompt "Draw a good day for you as a secondary mathematics teacher, and a bad day for you as a secondary mathematics teacher" provided the basis for much of our first conversation.

The interviews were unstructured and the conversations that we had did not follow a specific pathway but flowed as ideas came to us. As I planned to interview each participant more than once and over a period of eight months, I felt free to let them and I explore ideas and threads as they came to us. Gadamer

(1975/2004) writes, “the more genuine a conversation is, the less its conduct lies within the will of either partner. Thus a genuine conversation is never the one we wanted to conduct…No one knows in advance what will ‘come out’ of a conversation” (p. 385). Each of the conversations was different and focused on different aspects of mathematics education and teaching in general. As Ellis (2006) writes, I was learning “what the topic of the research [was] about for the participant” (p. 113) not pushing a particular agenda. Though the topic of research was identified to the participants, I chose not to direct the conversation to a specific set of experiences and the theme of change appeared in all interviews.

The interviews took place at a location and time of the participant’s choosing. The interviews were conducted both in person and over a distance. The interviews were transcribed and then reviewed for accuracy. The participants had an opportunity to review the transcript and make corrections, deletions, or additions as they saw fit.

At the time of this paper, I have interviewed both Vanessa and Marla on three different occasions, several weeks apart, and interviewed Susan once. Several more interviews with each of the participants are planned through the end of the 2011–2012 school year.

Discussion

During our interviews, each teacher expressed concern, frustration and a desire to not want to be teaching a grade 12 mathematics course in the first year of curriculum implementation. Both Marla and Susan, indicated an uneasiness regarding the diploma examinations adjusting to a change in curricular focus from content to process, though their concern was not stated explicitly. Vanessa, on the other hand, explicitly commented on her concern and what I interpreted as distrust of the government agency responsible for producing the examinations in providing information regarding the examination in a timely fashion so that she could adequately “prepare” her students for the upcoming examination.

Vanessa commented on recent change to the examinations that occurred in the fall of 2009 where the decision was made by the minister of education at the time to remove the written portions of the mathematics and science diploma examinations that left the questions on the examination to be machine scoreable only. She said:

> So I thought, all right I’ll teach them how to write a multiple-choice test. So now I actually spend days teaching them how to write a multiple-choice test it’s kind of my big whatever, you pulled my written, I’ll teach them how to write this. I’ll teach them how to graph it … You’re going to make it 50% of their mark on a multiple choice 40-question test, I’ll teach them how to write multiple-choice test.

Vanessa had earlier in the conversation stated a confidence in her ability to predict what was going to be the focus of the questions on the diploma examination, and this radical change in examination format shook her confidence. She responded to the change in the examination format by changing some of her teaching styles and strategies. Vanessa has not changed her classroom examinations to model the format of the diploma exam as her examinations contain questions where students have to explain their thinking. Vanessa indicated that she believes that communication and explaining mathematical process is important even though the diploma examination does not explicitly assess mathematical communication.

As the school year continued and the end of the term got nearer, each conversation focused more and more on the upcoming curriculum change and the ‘new’ diploma examination. Vanessa expressed a concern regarding the style of the question that was being asked on the examination. Her concern was that if the style of the question, or what was being asked of the students, does not change, her teaching focus would not change. For Vanessa, the diploma examination format and content was influential on her teaching practice. And for all three participants, teaching a course with a diploma examination at the end without knowing what the examination would look like before beginning teaching the course was a source of worry and concern.

TEACHING AND LEARNING OF MATHEMATICS THROUGH PROBLEM-SOLVING ACTIVITIES IN KENYAN SECONDARY SCHOOLS

Fred O. Odindo
Syracuse University
foodindo@syr.edu

Joanna O. Masingila
Syracuse University
jomasing@syr.edu

The study sought to determine the effect that teaching through problem-solving activities has on students' performance in mathematics, their attitude, their perception on the teaching approach and the effect the approach has on syllabus coverage. About 420 form two (tenth grade) students from four high schools in Siaya County, Kenya participated in the research in 2011. The study used a quantitative research method that followed a control quasi-experimental design with pre-test and post-test measurements of attitude, confidence and classroom interaction; and a baseline, post-test for students' achievement. Results showed combined control variables of students' attitude, perception on teaching approach, and parents' level of education having effect on students' performance. Also, experimental group had higher performance on post achievement test items that demanded high-order reasoning.

Keywords: Problem Solving; Experimental Design; Attitude towards Mathematics

Introduction

Background of the Study

Past Kenya Certificate of Secondary Education (KCSE) examination results have shown that more than 70% of students attain failing grades of D-E in mathematics each year. For instance, in the years 1979, 1983, 2002, and 2006, students who attained D-E grades were 72.7%, 63%, 71.56%, and 79.2%, respectively (Miheso-O'Connor, 2011). KCSE is graded on a descending scale of A. Kenya National Examinations Council (KNEC) reports for 2005 and 2006 revealed that most mistakes made by students in mathematics are misconceptions and misunderstandings on the application of algorithms in various topics. The Government of Kenya has made attempts to improve the performance; however, it has not significantly improved in mathematics.

Purpose of the Study

The purpose was to examine the effects that problem-solving approach to teaching and learning of mathematics have on students' performance in mathematics in the Kenyan secondary schools, their attitude towards mathematics, confidence in mathematics and classroom interaction; also to asses syllabus coverage within the stipulated time.

Research questions: (a) how does a problem-solving teaching approach influence students' performance in mathematics? (b) What effect does a problem-solving teaching approach have on students' attitude towards mathematics? (c) What are students' perceptions of a problem-solving teaching approach? (d) What effect does this approach have on syllabus coverage?

Framing of Teaching through Problem Solving

Lesh and Zawojewski (2007) defined problem solving as: "A task, or goal-directed activity, becomes a problem when the 'problem solver' needs to develop a more productive way of thinking about the given situation" (p. 782). This study modeled problem-solving teaching approach where students carried out activities as individuals, then discussed their findings in small groups. Teachers, with the help of the students, harmonized the reports from various groups and made conclusions on the concept of the lesson. This approach, involved all students in the lesson as mathematics should be communicated as an active construction rather than inert body of delivered facts and skills (Swan, 2007).

I put students at the center of learning and encouraged planning of the activities that focused students to the concept, in line with the observations by Hiebert, Morris, Berk, and Jansen (2007) who noted that teachers should focus teaching in terms of students' learning.

Methodology

Research Design

I used a quantitative quasi experimental research design (Kazdin, 1998; Trochim, 2006), which followed pre-test and post-test measurements of attitude, confidence and classroom interaction; and a baseline, post-test for students' achievement on control group design approach.

Sampling and Participants

I conducted the study in four public schools (two girls' and two boys') in Siaya County, one of the 47 counties in Kenya in May-July, 2011. The participants comprised form two (10th grade) students in the four high schools and eight trained mathematics teachers of the chosen classes.

I used a total of eight classes (two from each school) with a total of 429 students out of about 12,800 students in the county. Schools were selected through purposive non-proportional quota sampling to get two girls' and two boys' schools. The two classes per school were conveniently sampled as per the sampled teachers whom I selected through purposive expert sampling.

Variables

The independent variables included a problem-solving teaching approach and parental education. Dependent variables were: (a) students' conceptual and cognitive knowledge growth, (b) students' attitude towards teaching of mathematics, (c) students' perception on the use of the approach, and (d) rate of syllabus coverage.

Instrumentation and Measures

For students' conceptual growth, a Centre for Mathematics Science and Technology Education in Africa [CEMASTEA] (2004) 40-item multiple choice mathematics achievement test instrument was adapted and used. The items were tested for both construct and content validities, with a reliability coefficient of 0.81 from statistical internal consistency reliability test.

Perception was operationalized by two indicators of confidence and classroom interaction subscales. A Fennema-Sherman (1986) Mathematics Attitudes Scale (MAS) was adapted for the subscales and attitude towards mathematics. It is a five-point scale Likert-type questionnaire with 30 items. A KIE (2002) guideline was used for the syllabus coverage.

Procedures

Pre-test and baseline items were administered to both groups on the first day of the classroom observation period that lasted for four weeks. Post-test items were administered to both groups on the last day of the intervention period.

Data Analysis

The data were analyzed using Data Analysis and Statistical Software (STATA) version 12 for both descriptive and inferential analyses. A *t*-test and multiple regressions (MR) analysis were used at $P < 0.05$.

Findings

Conceptual and Cognitive Growth

Conceptual and cognitive growth was determined by the achievement test. The intervention topics were applications of gradients in equations of straight lines, areas of quadrilaterals and triangles, and trigonometry I (i.e., sines, cosines and tangents of angles less than 90°). Analyses of post-test results showed consistencies in the higher mean scores for the experimental group on intervention items (i.e. 39 to

42) as shown in Figure 1. These were from the application of gradients in equations of straight lines and trigonometry I.

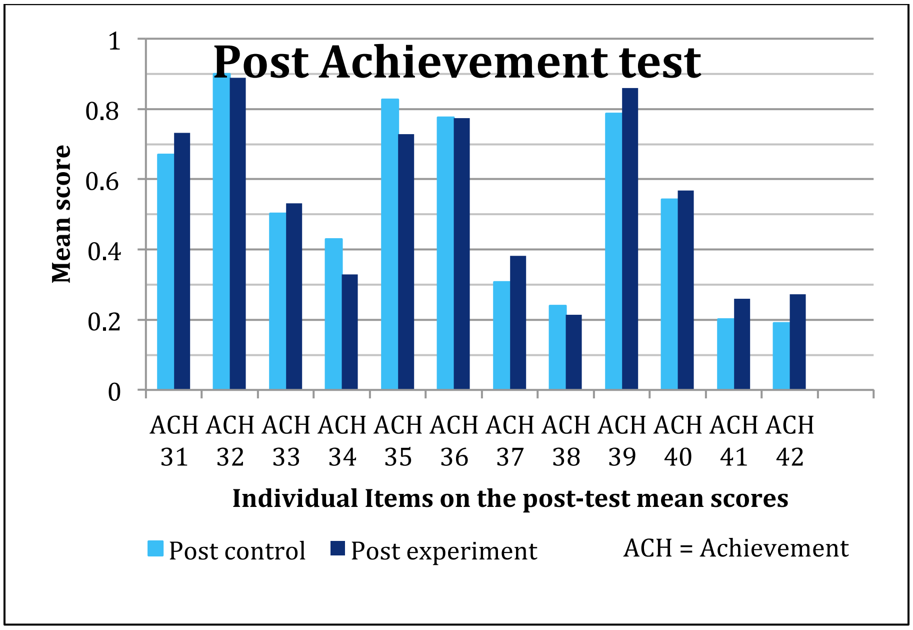

Figure 1: Bar graph on the distribution of the post-test individual items means score on achievement test for the experimental and control groups

These results show that the teaching approach used—that is, teaching through a problem-solving approach—may have contributed to this outcome since the students had no prior experience with these topics unlike the other two topics. Further analysis on these items showed significant differences on items 39 and 42 with $t = 1.96$ and 1.98 respectively at $\alpha = 0.05$. Items 39 and 42 assessed synthesis and evaluation levels respectively, according to Bloom's (1956) taxonomy of cognitive objectives categorization, (i.e. high order thinking skills).

Attitude towards Mathematics, Confidence in Mathematics and Classroom Interactions

Regression analysis showed a significant difference on the combined control variables and confidence over performance as dependent variable as shown in Table 1 below.

Table 1: Regression Analysis Table of the Predictors over the Dependent Variable

Predictors	Coefficient	Standard Error	Beta	t-test	P>|t|
Parents' level of education	-0.24	0.13	-0.12	-1.85	0.07
Attitude	-0.03	0.06	-0.04	-0.45	0.65
Confidence	0.11	0.04	0.29	2.98	0.00
Classroom Interaction	-0.02	0.04	-0.05	-0.57	0.57
Constants	5.50	1.72		3.21	0.00

Dependent Variable = Posttest scores on Achievement

Discussion and Conclusion

Discussion

The experimental group students outperformed the control group on the post-test, and particularly on the items that required creativity and deep understanding of the concept, that is high-order thinking skills (HOTS). It is in support of the research by Lesh and Zawojewski, (2007) that revealed that engaging learners in problem solving with mathematics concepts supports them in developing HOTS and also of research by Cohen, Lotan, Scarloss, and Arellano (1999) that showed that students who were taught through classroom activities gained significantly more than students in comparison classes on questions requiring HOTS.

The attitude change of the students did not show statistical significance and this could be an instrument issue in which a ceiling effect resulted from a pre-test, and it was in line with the findings of the Third International Mathematics and Science Study [TIMSS] (1999) that showed that most students from developing countries, in which Kenya belongs, had higher mean scores on positive attitude towards mathematics than students from developed countries.

The students' confidences in mathematics had low scores in both pre-test and pot-test. The low scores may explain the poor performance in mathematics in KCSE examinations, since findings revealed a significant correlation between students' achievement in mathematics and their confidence in mathematics. Both experimental and control groups taught the topics and completed one week earlier than the suggested time by KIE.

Conclusion

The findings have shown that there was better performance from experimental group on questions that demanded reasoning than the control group. This is an indication that continuous practice of a problem-solving teaching approach could improve performance of mathematics in Kenyan secondary schools.

A PROCESS OF CHANGE IN TEACHERS: EXPERIENCE IN A PROFESSIONAL DEVELOPMENT PROGRAM

Mirela Rigo-Lemini
Centro de Investigación y de Estudios Avanzados del I. P. N.
mrigo@cinvestav.mx

The paper documents and analyzes the changes in the vision of mathematics that a group of teachers experienced as a result of their participation in a professional development program. The paper further explains the process through which they were able to emigrate from a purely "computational" interpretation of the mathematics contents to a more conceptual type of signification, and evidence is provided to attest that said change had a bearing on some of their didactic practices in the classroom. The change process—basically made up of three moments (learning of mathematics contents by way of problem resolution, where justification of strategies and results and metacognitive practices were emphasized; the study of the children's learning difficulties; and the design, application and analysis of didactic material)—can serve as a model for future professional development.

Keywords: Teacher Education–Inservice/Professional Development; Teacher Beliefs; Rational Numbers; Reasoning and Proof

Background and Interpretative Framework

Recently the attention of research has been focused on the changes produced in teachers as a result of their participation in professional development (Sowder, 2007). In specific terms, the experts—e.g., such as Schifter (1998)—have studied the transformation in the conception of the nature of mathematics that takes place among teachers involved in those programs. In her lessons, the researcher referenced seeks to help the teachers learn how to think in conceptual terms in mathematics, as well as for them to learn that their own mathematics learning experience can become food for thought. According to testimonials given by participants in her program, this has renewed the teacher's comprehension of mathematics as well as their beliefs concerning the discipline. Reid and Zack (2010), also interested in understanding the about turn in the mathematics perspectives of teachers-in-training, albeit by way of exploring their attitudes and beliefs, have revealed that said changes have a bearing on their teaching.

Complementarily, specialists in teacher professional development have suggested models to document their didactic evolution during their professional re-training (e.g., Guskey, 2002). One of such models consists of examining the manners in which the teachers question their students: a mentor with a calculational orientation will focus on procedures to obtain answers; those with a conceptual orientation will take into account a "rich conception of situations, ideas, and relationships among ideas" (Sowder, 2007, p. 194). While still other researchers (e.g., Fennema et al, 1996, and Schifter, 1995, quoted in Sowder, 2007, p. 195) have suggested models based on phases.

In order to evaluate the depth and breadth of mathematics conceptualization attained by the teachers who took part in the study, as well as the evolution of their didactic practices, below is a model—made up of four phases—that will act as the interpretative framework and that was formulated on the basis of the models cited above.

First Phase. The teacher focuses on teaching computational definitions and routines.
Second Phase. The teacher explores new ways of teaching, albeit using fixed routines.
Third Phase. The teacher focuses on the student and delves into his/her learning difficulties.
Fourth Phase. The teacher systematically investigates his students' learning difficulties, as well as the "great mathematics ideas," and takes said information into consideration in making his didactic decisions (in the classroom or in planning his lessons).

Methodology and Data Recovery

The changes reported here arose within the framework of a program, whose objective was to professionalize the mathematics teaching of teachers in practice. The program lasted for four years and sixty teachers participated. The study plans were articulated around two guiding axis, as follows: one of a theoretical nature that was consolidated in the courses; and another of a methodologico-practical nature that was consolidated by way of ten Development Projects (Dp), each of which covered six teachers.

The author was responsible for one of the Dps in which the objectives were: for participating teachers to re-signify mathematics contents; for them to recognize the children's thought processes and reasoning; and for them to experience the design, application and evaluation of didactic materials. The following activities were undertaken in order to achieve the objectives: (a) systematic study of the mathematics contents that was undertaken in a Problem Resolution Workshop; (b) definition of a classroom problem; (c) exploratory study and diagnosis (among students and teachers) of the mathematics contents associated with the classroom problem; (d) design of a didactic material whose purpose was to aid in the solution of the classroom problem; (e) application of the didactic material in the teacher's "experimental classroom"; (f) analysis of the intervention; (g) modification of the didactic material; and (h) teacher self-reflection.

This paper reports partial findings concerning the conceptual and didactic transformation process experienced by the group of six teachers attached to the Dp.

The empirical data for the study were recovered by different means, namely, for the Workshop there are documents written by the teachers—homework, exams and personal testimonials; for the diagnostic work, documentation concerning the instruments applied and analysis of results were maintained; for the classroom intervention, the results of the pre-test and post-test applied to the children, as well as the comparative analysis of those productions are also on file; moreover, video records, teacher field notes and the final assignment report were also kept; there are also three videotaped interviews of each of the teachers who took part in the PD.

Empirical Findings: Inflection Points in the Process of Change

The transformation of the mathematics ideas and of their didactics, which it was possible to see among the teachers attached to the Dp, arose in keeping with a lengthy process (cf Sowder, 2007) of four years in which three Moments stood out. Said Moments are described and analyzed below using the Phases described at the end of the first section as guidance. The evolution process is illustrated through the case of one of the teachers attached to the PD, Miss Luisa Ramos (see Ramos, 2009) (case studies are very often included in the reports that deal with changes in teachers, cf. Sowder, 2007).

When they first began the program, the six teachers in the Dp possessed a purely operational or "computational" interpretation of mathematics (Harel & Behr, 1995, quoted in Sowder et al., 1998, p. 128), pursuant to which the algorithms are their prototypical and unique objects, very much like what is described in the First Phase. The latter was verified in their interventions in the Courses and in the PD, and can be clearly perceived in Luisa's Workshop testimonial (see 2009):

> At the beginning of the Workshop, I resolved the exercise without doing any analysis. I felt that the rule of three applied to all missing value problems. I did not personally have a need to resolve problems using different methods; I was only interested in finding the result. (p. 18)

The first Moment of change arose during the Workshop. Focused on the search for re-signification and reinforcement of teacher mathematics knowledge, like in many other instruction proposals aimed at teachers (Schifter, 1998; Sowder et al., 1998), the Workshop—of one year duration—dealt with resolution of ratio and proportion tasks. It methodically promoted the explanation and (locally) deductive justification of the mathematics definitions and processes involved; metacognitive practices were systematically fostered (e.g., by way of writing a testimonial in which each teacher reflected individually upon his/her difficulties in learning mathematics and the changes of his/her mathematics beliefs and conceptions); and collaborative work was also promoted.

These practices raised a dual challenge for Workshop participants. On the one hand they had to provide support for a great number of algorithms and other mathematics resources that they used to accept as unquestionable truths in their daily teaching activities; while on the other, they had to become aware of the difficulties and changes that this represented for them, in addition to socializing their thoughts. In her testimonial, Miss Luisa shares the manner in which she faced those challenges toward the end of the Workshop, when she speaks of her resolution of the following task: “Laura has some pictures in the computer to which she applied a scalar factor of 6/5. She now wants to return them to their original size. [To do this, she only has to] subtract 1/5 from them. Is that solution correct? Justify the answer.” In her testimonial (Ramos, 2009, p. 18), Luisa offers the following proposed resolution and justification for the task:

> I considered the initial unit to be 5/5. Since the picture was increased by 1/5, it became 6/5, which is the new unit. So our new figure has 6 equal parts and to reduce it we have to take one piece away, which would be 1/6. So we would have: 6/6 – 1/6 = 5/6, which is our operator that will be applied to return the picture to its original size. In this resolution [I was able to] understand the problem and analyze it in depth [and] justify the fraction as an operator. [With respect to the group work, I had difficulty] believing that my method is the correct method and to establish which method has the most meaning for what was being requested; and as a group we had trouble reaching an agreement and common convincement.

One can see that Luisa understood the re-unitization process that was brought into play as a result of the successive application of scalar factor. She also understood the effects of the operativity implied in the problem resolution. In her self-reflection, she attests to her conceptual comprehension of the mathematics notions involved and to the fact that she became aware of the advantages that stem from the culture of justification fostered in the Workshop. She furthermore identified the obstacles that must necessarily be overcome in order to truly work in a team.

Like other professional development (such as that of Schifter, 1998, p. 56), the program presented here was based on the principle that “the teachers have to build their instruction around the children’s thoughts,” a principle that became reality through the diagnostic work described in c). Said work marked another Moment of change among the teachers. Miss Luisa carried out her diagnostic work with two groups of secondary school students and their teachers, and it was on the basis of that work that she typified in detail the following categories: “without proportional reasoning”; “traces of proportional reasoning” and “with proportional reasoning,” for which she based herself on operational considerations albeit especially of a conceptual handling. These categories served as a guide to analyze the results of the written instruments that she applied to the children before and after her intervention in the classroom, and they account for her evolution toward a vision of mathematics that is conceptually broader, richer and more meaningful, and that coincides with what is described in the Third Phase of the interpretative model.

The third turning point Moment that definitively marked the course of change in Miss Luisa arose during the application of her didactic material. It was there that she saw for herself and was able to assess her students’ achievements as of when she began to modify her visions of mathematics and her ways of teaching it (cf. Guskey, 2002). The objective of her didactic sequence was to enable her students to carry out processes of transferring knowledge between science and mathematics, and she based it on the idea that the “cross-cutting” condition of the contents, and of situationality and of collaborative work, can foster said processes of transfer in the classroom setting. Her new conceptualization of mathematics and of their didactics, very much akin to what is described in the Fourth Phase, is clearly revealed in the notes that she wrote after her intervention in her “experimental classroom”:

> In the class we spoke of mathematics while referring to other subjects, like nutrition, health, economics or chemistry. Mathematics topics were raised and discussed on an equal footing with other topics from other fields of knowledge. During the third class session, for instance, we spoke of the health impact of ingesting the sugars contained in soft drinks, and many of the students reflected on what foods are nutritional and which are not and on a balanced diet. As such during the intervention we broke away from the traditional teaching scheme (in which the teacher begins the class by giving

mathematics definitions and algorithms, after which the students do some exercises and possibly some applications), and resorted to another scheme based on a more contextualized and situated teaching. In the latter the idea was to promote different ways of resolving a problem, as well as positive and distant transfer [of proportionality themes] by handling knowledge in a cross-cutting fashion and by working collaboratively. (Ramos, 2009, p. 103)

Final Remarks and Possible Contributions

The paper presents a trajectory of professional development of mathematics teachers. Although that trajectory is partially supported by others, proposed by experts, the conjunction of all of its components and some of its specific practices, such as metacognitive practices, make it singular. To demonstrate its feasibility, a description is given of critical moments that arose during the evolution process of the conceptions and didactic practices of said trajectory's participants. This evidence provides the criteria for broadening the model used to evaluate the changes in teachers, described in the first section, including a new phase in which the teacher is considered in her role as a scholar of mathematics emphasizing justification, metacognitive and group collaboration practices that the teacher can implement during the process of resolving mathematics tasks.

TRANSITION IN LIMBO: HOW COMPETING PROFESSIONAL OBLIGATIONS CAN LEAD TO PEDAGOGICAL INERTIA

Corey Webel
Montclair State University
webelc@mail.montclair.edu

Douglas M. Platt
Montclair State University
plattd1@mail.montclair.edu

We describe a high school geometry teacher who perceives a need for change, expresses a desire to change, and yet finds herself struggling to enact change in her practice. Rather than focusing on beliefs or knowledge, we examine the professional obligations underlying her expressed intentions, and suggest that competing obligations made it difficult for her to make progress towards her expressed goals. We share implications for professional development.

Keywords: Teacher Change; Practical Rationality; Teacher Goals; Teacher Beliefs

Purpose

The purpose of this case study is to examine the factors that make transitions in teaching difficult, focusing particularly on the professional obligations inherent in the position of high school mathematics teacher.

Framework

The difficulties surrounding teacher change are often explained as resulting from deficiencies in mathematical knowledge or divergence in beliefs about teaching (e.g., Manouchehri & Goodman, 2000; Wilson & Lloyd, 2000). These explanations have been problematized by the notion that teachers do not operate as free willing individuals; they take *positions* in systems and take on *roles* which come with constraints, often tacit, on possible actions that they are able to take (Herbst, 2010; Herbst & Chazan, 2003). This perspective emphasizes that the decisions and actions of teachers are driven not only by their personal beliefs and knowledge, but also by the rationality demanded by the practice of teaching itself. This *practical rationality* consists of deeply ingrained norms of teaching and obligations to stakeholders such as the student(s) in the classroom, the institution (school), and the discipline of mathematics (Herbst, 2010; Herbst & Chazan, 2003). Obligations in particular present dilemmas for teachers, as teaching actions often favor one obligation at the expense of another, resulting in dilemmas of practice (Ball, 1993).

Methods

Participants and Context

This ongoing study is being conducted through a professional development project involving two high school teachers, a university professor (the lead author), and a graduate student (the second author). The professional development is being provided as a follow-up to a two-week long summer institute which included over 60 K–12 science and mathematics teachers. The follow-up professional development involves a series of meetings in which the two participating teachers are asked to make explicit their goals for teaching and examine their practice in light of those goals through the analysis of video captured in one of their classes (van Es & Sherin, 2010). The role of the professional development leaders is to elicit teachers' beliefs and goals, facilitate discussions, and provide the teachers with exposure to research related to a self-identified "performance gap." During the first meeting, the teachers were asked to create a "goals mapping" where they identified what was "closest to the heart" of their teaching (Herbel-Eisenmann & Cirillo, 2009). Afterwards they shared and described this mapping with the rest of the group. During the second meeting, the teachers had a chance to revise their goals mapping and reflect on their current teaching practices with respect to their self-identified performance gap. Then the teachers were asked to share a lesson plan for an upcoming lesson, which was discussed in the group in an effort to support each teacher in addressing her performance gap.

The teachers both worked a suburban school on the East Coast of the United States. The teacher featured in this article, Becky (a pseudonym), chose to study her practice in a self-contained special education geometry class with twelve students.

Data Analysis

In this paper we examine transcribed audio recordings of the first two meetings with the teachers. We used a grounded theory approach (Corbin & Strauss, 2008) to code and analyze the data. After an initial pass through the data, we separated initial codes into emerging theoretical categories: goals, previous experiences, teaching moves/norms, and obligations. "Goals" consisted of utterances where Becky described what she wanted to achieve with her teaching (but not necessarily what practices would achieve these goals). "Previous experiences" consisted of utterances where Becky described a specific past episode or gave a general description of typical experiences from past teaching. "Teaching moves/norms" consisted of utterances where Becky self-identified with, expressed appreciation for, or implied that she would engage in a particular teaching practice. "Obligations" consisted of utterances where Becky either justified a teaching action or described a constraint or her teaching by explicitly or implicitly appealing to duties derived from her position as a mathematics teacher. In some cases, Becky voiced obligations that we considered to be inherent to the profession of teaching mathematics, such as helping students understand mathematics. In other cases, obligations were inferred from the use of the words "have to" or "need to" with respect to a particular teaching practice.

Subcodes within each of these categories were established through a constant comparison process (Corbin & Strauss, 2008). Multiple codes were allowed for the same utterance; in some cases a single utterance was considered to represent both a goal and an obligation (it is reasonable that teachers, who choose their own profession, will have many goals which coincide with their obligations). Each author separately coded the data. Codes were refined through discussion, a portion of the data was recoded separately (inter-rater reliability was .66), and remaining discrepancies were resolved through discussion.

Results

The goals, experiences, teaching moves/norms, and obligations we inferred from Becky's statements are provided in Table 1. (The limited number of disciplinary obligations voiced by Becky may be attributed to the fact that during the second meeting Becky was discussing a particular geometry lesson that emphasized mathematical vocabulary).

One can see the conflicts among and within the categories. Becky's performance gap, as she described it, was "to do less talking and repeating myself and I want them to do more talking." She expressed the goal of engaging her students in active learning: "I want my classroom to be a place where learning is not just jammed down their throat. I want them to be active in their learning." However, in her previous experiences, she saw students as not wanting to talk about math ("If I am not talking everyone will just sit there and stare").

Becky's described obligations also appeared to make it difficult for her to put her goal of promoting active learning into practice. In the second meeting, Becky brought a plan for an upcoming lesson on parallel lines crossed by a transversal. Prior to describing the lesson, Becky referenced experiences in which students struggled with vocabulary: "words like adjacent, supplementary, complementary, linear pair, vertical, they are just in a cloud in their brain." She also expressed a disciplinary obligation for teaching those words, saying, "They have to be able to use big-people words, grown up words…. They can't just say 'across from,' 'next to.'" She struggled to envision a lesson in which students could engage in active learning and still learn the standard mathematical terminology. When asked why the students could not use "across," Becky hesitated and said, "I don't think I'm allowed," a statement that suggests that teaching the standard terminology was an obligation that did in fact guide her instruction.

Table 1: Subcodes in Each Theoretical Category

Goals	Previous Experiences	Teaching Moves/Norms	Obligations
• Promote active learning • Promote interaction • Reach all students • Motivate students • Make students comfortable • Learn to get better through experience	• Explaining and repeating isn't working • Students **do not** understand math terms or notation • Students **do** understand angle measurement • Students do not like to talk about math • Students are confused with multiple terms for the same idea	• Use nonstandard terms • Give specific instructions on process • Scaffold if necessary • Connect nonstandard and standard terms • Use multiple representations • Keep it simple (only explain one way) • Activate prior knowledge	To school: • Cover material (ensure mastery) To students: • help them make sense of ideas • make them comfortable • do not confuse them • provide a safe/respectful environment • prepare them for citizenship To discipline: • teach standard terms

In response to Becky's expressed desire to turn over more of the math talk to her students, the university professor described a research project where elementary students collectively defined "even numbers" through a nonlinear class discussion (Ball, 1993). This discussion involved the use of nonstandard terms but also actively engaged students in the mathematical act of defining a new set of numbers called "Sean Numbers." Becky did not seem to appreciate the impact of the approach on the active learning of the students and instead appeals to disciplinary obligations: "Well, I would want them to know [the definition of even numbers]…. 'Cause they are important." Becky maintained that multiple terms for the same concept would be confusing, and that allowing the students to come up with nonstandard terms "doesn't seem helpful" and would interfere with learning the standard terms later.

In these statements, we see an obligation that recurred in both meetings: an obligation to not confuse her students. For example, Becky wanted to minimize variation in explanations, saying, "I think about the type of kids these are, if I say something differently it might confuse them." This obligation, coupled with the obligation to teach standard terminology, made it difficult for Becky to enact practices that might have led to attaining her goal of promoting active learning.

Discussion

We believe that the tensions between the different obligations described by Becky present obstacles to substantial changes in her practice. While she wants to promote active learning and provide more opportunities for students to talk, she doubts whether her students will be capable of negotiating the different meanings and terms that might arise if they are allowed more freedom. She is bound both by the obligation not to confuse them and her disciplinary obligations to teach the standard terminology (see Pimm, 1987, for a description of tensions surrounding the development of a mathematics register). These are not unlike the tensions described by Ball (1993) in the Sean Numbers episode, and show that Becky's conflict comes not from a deficiency of knowledge or a lack of appropriate goals for her students, but from the competing obligations she perceives as inherent in her practice.

Becky's case is valuable because it shows that changes to instruction are not likely to result from changes in knowledge and beliefs alone. Becky has goals that she is unable to enact. Understanding the constraints implied by the practical rationality of teaching is important because "durable change in instruction will need not only to provide new and better resources but also to be able to deal with the inertia and possible reactions from established practice" (Herbst, 2010, p. 50). Professional development must anticipate these reactions.

For example, while there is much research which describes the necessity of confusion and struggle in the learning process (Hiebert & Grouws, 2007), Becky seems to operate within the obligation that the teacher should not confuse students. This is an obligation which has value and cannot simply be dismissed, but it can also be understood to operate at different levels and time frames. It may be acceptable for a teacher to introduce confusion if she is reasonably confident that the confusion will be temporary and will ultimately help meet her other obligations. Likewise, allowing students to initially invent their own terms before providing the conventional terminology might help promote active learning, but Becky was unsure whether this was "allowed." She needed reassurance that this strategy would not conflict with obligations to teach the standard terms and to help students make sense of ideas. The ongoing challenge for us as professional development providers is to help teachers like Becky explore paths of transition in her teaching while still honoring her perceived professional obligations.

Poster Summary

The poster includes a synopsis of some relevant results of prior research in this area. These findings prompted the design of this research study, the goal of which is to investigate the impact of teachers' gestures on students' mathematical understanding. The main focus of the poster is on the process and rationale behind the gesture design. The topic of slope was chosen. We wanted to create gestures that demonstrated the kinetic dimension of slope rather than the static graphical representation often used on the blackboard. The preliminary findings support the hypothesis and suggest a need for further research.

THE INFLUENCE OF A TEACHER'S ORIENTATION ON HER MATHEMATICAL KNOWLEDGE FOR TEACHING AND GOALS

Frank S. Marfai
Arizona State University
Frank.Marfai@asu.edu

Marilyn P. Carlson
Arizona State University
Marilyn.Carlson@asu.edu

Keywords: Mathematical Knowledge for Teaching; Teacher Knowledge; Teacher Education–Inservice/Professional Development; Instructional Activities and Practices

Mathematics instruction in the United States has been described as procedural and disconnected, with a primary focus on developing students' calculational abilities rather than their understanding of concepts and how they are connected (Ma, 1999; Stigler & Hiebert, 1999). Researchers have identified mathematical knowledge for teaching (MKT) as a key link between content knowledge and support of student learning (Hill, Ball, & Schilling, 2008; Silverman & Thompson, 2008). Earlier research has also shown that a teacher's image of mathematics, referred to as a mathematical teaching orientation, influences her classroom practice (A. G. Thompson, Philipp, Thompson, & Boyd, 1994). Other research (Webb, 2011) have revealed the interaction of a teacher's goals and pedagogical powerful content knowledge.

In this presentation, we provide findings that illustrate how images of mathematics that result from a teacher's experiences as a mathematics student can be adapted in the context of professional development designed to confront their prior conceptions of instruction and support their ability to implement a conceptually oriented curriculum. We also examine how a teacher's instructional goals might adapt as the teacher advances in her understandings and images of what students are capable of learning. We describe our emergent theoretical framework for examining these shifts, and then illustrate how this framework is used to analyze a teacher's classroom practice.

This poster examines sustained growth in teachers' knowledge of and self-efficacy in using formative assessment over a three-year period. Teachers were randomly assigned to the FA-then-NAV *group, who received professional development in formative assessment in the first year and in using networked classroom technology to implement formative assessment in the second year, or the* FA-and-NAV *group, who received professional development in using networked technology to implement formative assessment in two consecutive years. Teachers in each group reported gains in knowledge and self-efficacy each year, and these gains were sustained in the year following, when no professional development was received.*

Keywords: Assessment and Evaluation; Technology

The poster report on data collected in a research project, *The Effects of Formative Assessment in a Networked Classroom on Student Learning of Algebraic Concepts (FANC)* funded by the National Science Foundation. The working definition of formative assessment was taken from two sources: "the process used by teachers to recognize, and respond to, student learning in order to enhance that learning, during learning" (Cowie & Bell, 1999, p. 32), and "interactive process between teaching and learning where teachers collect evidence about student achievement in order to adjust instruction to better meet students learning needs, in real time" (Wiliam, 2007). In Project FANC technology was paired with formative assessment because technology may provide a solution to the problems encountered when using formative assessment.

Instruments on seven teacher constructs—knowledge about general assessment, knowledge about formative assessment, self-efficacy in formative assessment, the perceived value of technology, interest in technology, self-efficacy in general technology, and confidence in classroom technology—were used to gather data from teachers in Project FANC over the two years they participated in professional development activities and a year after the conclusion of the training. This poster focuses on the collected information on the constructs of knowledge about formative assessment and self-efficacy in using formative assessment.

Within each model, teachers gained in their knowledge of formative assessment and self-efficacy in using formative assessment each year they participated in the professional development. What is more striking is that they also continued to gain in their knowledge of formative assessment and their self-efficacy in using formative assessment in the year following the completion of the professional development. That is, regardless of how the professional development emphasized formative assessment, after three years both groups had gained, and had gained approximately the same amount, even though the trajectories were different.

COLLEGE MATHEMATICS STUDENTS' PERCEPTIONS OF JOURNAL WRITING

Alexis Stevens
James Madison University
lexilarissa@gmail.com

Jesse L. M. Wilkins
Virginia Tech
wilkins@vt.edu

Keywords: Instructional Activities and Practices; Post-Secondary Education

Purpose and Methods

Current literature describes many benefits of writing in mathematics, such as more powerful learning (Borasi & Rose, 1989) and deeper procedural and conceptual understandings (Jurdak & Zein, 1998). However, most college mathematics students have not had a previous experience with writing in mathematics (Borasi & Rose, 1989). Therefore, the purpose of this study was to determine if college mathematics students' perceptions of writing in mathematics align with the benefits outlined in the literature.

The participants of this study were the students enrolled in two sections of "Elementary Calculus with Trigonometry." There were 60 students in one section and 59 students in the other section. Data for this study were collected through an open-ended questionnaire and analyzed using code mapping (Anfara, Brown, & Mangione, 2002).

Results and Conclusions

Fifty-two students (43%) believed that writing in mathematics afforded benefits to their learning. The three most common benefits mentioned were helping students engage in critical thinking, building procedural knowledge, and deepening conceptual understandings of the mathematical content, which is consistent with previous literature (Jurdak & Zein, 1998; Borasi & Rose, 1989). From the students' descriptions, engaging in critical thinking encompasses actively and skillfully conceptualizing, analyzing, and synthesizing information. Students also reported that writing in a mathematics course would be beneficial to their learning because it would allow them to understand, remember, or make sense of mathematical procedures as well as to gain a better conceptual understanding of those mathematics procedures. On the other hand, 67 students (57%) reported disadvantages to writing in mathematics. Students reported that writing in mathematics was a waste of time, was not important, and was not an appropriate task in a mathematics course. These were also consistent with previous literature (Williams & Wynne, 2001; Powell, 1997). These findings offer a basis for further investigation to better understand how these perceptions limit or enhance the benefits of writing in mathematics as well as how to aid students in transitioning along a continuum of learning mathematics.

TWO COLLEGE MATHEMATICS TEACHERS' INTERACTIONS WITH STUDENTS IN DIFFERENTIAL CALCULUS CLASSROOMS AND OFFICE HOURS

Jun-ichi Yamaguchi
The University of Georgia
yamajun@uga.edu

***Rationale*:** Since face-to-face interactions are a very common situation for teachers to help students learn mathematics, it is important for mathematics teachers to facilitate meaningful interactions with their students. In fact, there is an increasing expectation that mathematics teachers engage their students in certain kinds of discourse as a means of increasing student learning (Webb, Nemer, & Ing, 2006). However, few researchers have examined, especially at the college level, how mathematics teachers facilitate classroom interactions when they "make sense of students' reasoning, respond to unexpected questions, analyze students' errors, develop meaningful assessments of student learning, and provide on-the-spot representations, examples, or explanations for ideas that arise spontaneously in the real-time practice of teaching" (Wagner, Speer, & Rossa, 2007, p. 250). This study is designed to contribute in this area of research and extend our understanding of mathematics interactions. I applied conversation analysis (CA) on video recorded data of two college calculus teachers' interactions in their classrooms and during office hours. In particular, I examined what sequential structures around the teachers' questions engage students in a meaningful mathematics discussion.

***Findings*:** I found that most observed lessons were characterized as teacher-centered instruction—the teachers' talk dominated the classroom interactions. CA on the video data revealed that the teachers' domination was attributed to their ways of turn-taking (Ten Have, 2007). The teachers did most of the talking and occasionally provided conversational cues that allowed students to take a turn to speak. For example, when the teachers made a pause after a question, it was students' turn to talk. In contrast, when the teachers did not make a pause after a question, no responses were expected. In fact, students did not respond to such questions and therefore the teachers kept talking. Overall, in the teacher-centered classroom environment, teachers have the power to implicitly decide when the students have opportunities to talk; and the students on the other hand have a good sense of when they are given those opportunities. However, during office hours, the students were more engaged and took an active role in the discussion, especially when they decided how to proceed in their solution. This difference was found in the turn-taking patterns of interactions such as overlaps of talk and pausing.

Significance: Because CA is not widely applied in mathematics education research, the details of mathematics interactions, as described here, have mostly been unexamined. This study plots a new direction in investigating mathematical interactions in classrooms or other instructional situations. For example, if the classroom activities are student-centered or inquiry-oriented, patterns of teacher–student interactions will be illustrated in different ways. This study suggests that we need to further examine conversational structures such as turn-taking and question design across different types of instruction.

EXPONENTIATION IS NOT REPEATED MULTIPLICATION: DEVELOPING EXPONENTIATION AS A CONTINUOUS OPERATION

Arnon Avitzur
New York University
arnon.avitzur@nyu.edu

The concept of exponents has been shown to be problematic for students, especially when expanding it from the domain of positive whole numbers to that of exponents that are negative and later rational. This paper presents a theoretical analysis of the concept of exponentiation as a continuous operation and examines the deficiencies of existing approaches to teaching it. Two complementary theoretical frameworks are used to suggest an alternative definition for exponentiation and guiding principles for the development of a teaching trajectory, and then to analyze an example of the hypothetical learning of a student who goes through the first task in the trajectory. The paper concludes with some possible implications on curriculum and task design, as well as on the development of mathematical operations.

The Problem with Exponents

Research has found the concept of exponents problematic for both students and teachers of all levels (Confrey & Smith, 1994; Elstak, 2007; Goldin & Herscovics, 1991; Weber, 2002). The most common definition that students have for exponents is that of repeated multiplication, for example $2^5 = 2 \cdot 2 \cdot 2 \cdot 2 \cdot 2$ which is two multiplied by itself five times. This limited view of exponentiation, although simple to understand, prevents students from understanding the behavior of exponents in non-natural-number powers. For example, if exponentiation is repeated multiplication then something to the power of zero might be seen as ambiguous—should it be zero or one? Moreover, there is no meaning to multiplying something by itself a negative number of times. An extension to fractional powers that preserves the sense of repeated multiplication is an impossible task, and often fractional exponents are presented as "a different way to write radicals" and connected to repeated multiplication in an artificial way. As they finish their high school unit on exponents, student end up not being able to look at exponentiation as a *continuous* process (in terms of the exponent value) and, in the best case scenario, have a few different models connected to one another through loose logic.

Although it is possible to develop the concept of exponentiation as a case-based operation, this approach may result in various negative implications, such as the perception that exponentiation is always an increasing operation, an inability to work with exponents as continuous functions later in the curriculum and difficulties in understanding the rate of change of an exponential function and its derivative. One other problem that is rarely addressed in the mathematics education literature lies in the fact that students do not have any qualitative sense of the changing growth rate of an exponential function that results in an inability to explain such ideas as compounding or population growth without having to calculate its value numerically.

Existing Approaches

There have been cases of teachers who tried to develop students' understanding of the exponents' rules through the process of proof and mathematical consistency by moving from one rule to another in deductive manner with the goal of allowing the students to see the connection between them. This, however, does not create a single view of exponents that students can work with across domains, and it always remains as a sequence of logical operations that explains the various cases of exponents (positive, negative, zero, and rational). The research community has made several attempts at developing a conceptual understanding of the concept of exponents while at the same time aiming at building a single view of the operation across domains.

The Functional Approach

The teaching of algebra in a functional-based approach was first suggested by Goldin and Herscovics (1991), later to be tested by Elstak (2007) in a teaching experiment. In this approach, the understanding of negative, zero and rational exponents comes from constructing the definition of an exponential function starting from natural exponents, and later investigating this function to expand the notion to other domains. In Elstak's teaching experiment, some of his students were able to logically connect the different cases of exponents, but could not give a single definition for all of them.

Developing Algorithms

Weber (2002) suggested that students be presented with a description of an algorithm to compute exponents, which later they express formally. The students wrote the exponential expressions as products of factors, and then completed activities in which they debated about the nature of rational exponents. Although Weber explained the expected learning path using APOS theory (Dubinsky, 1991), it was not clear how the "debate" stage helped the students develop a conceptual understanding of rational exponents that aligned with their original definition of the operation.

Exponents as Splitting

Confrey and Smith (1994, 1995) suggested that exponents be developed through the idea of splitting. Basing their design on students' familiarity with the idea of fair share and splitting, they gave special attention to the rate of change of the function, which was not given by other researchers. They aimed at developing in students the multiplicative comparison between the sizes of the quantity at different stages, with a focus on a multiplicative rate of change as being fixed throughout the work with exponents, in contrast to the varying additive rate of change. This basis allows students to develop a comprehensive view of exponents of positive base with integer powers (positive, negative, and zero). To extend the domain to rational bases and exponents, they relied on the contrast between the counting and the splitting worlds and offered a logical explanation that accounts for rational exponents. In contrast to their initial work that relied on splitting, the expansion to rational exponents does not offer a cognitively intuitive model to work with, and the case-based view is left unresolved.

What Is Missing?

Although some of those studies contain valuable insights, each has its own drawbacks with regards to the development of a comprehensive conceptualization of exponentiation as a continuous operation relying on a single image. One shared limitation of all of the above approaches is that they begin working in natural numbers and give the students a limited concept of exponents, later to be expanded in one way or another. Expansion to the real number domain is accomplished through formal explanations, definition or logical reasoning, but is not based on the original image the students have. Even in the splitting world, which is an extremely powerful idea based on students' own experience, there is no real meaning to the exponent itself that accounts for both positive and negative values. It ends up being a logical process explaining to the students that in the new "multiplicative" world negative exponents result in division. Rational powers are similarly not well addressed in the splitting world ending up being understood empirically through the identification of patterns. It is extremely hard to think of doing three and a half split operations since the splitting is done on countable sets. In essence, trying to build students' understanding based on a limited domain (natural number) as a starting point requires that students adjust their definition of exponents for every new domain extension, sometimes conflicting with the original one they had, resulting in a disconnected set of definitions.

Another limitation of the approaches is an overuse of calculations as a way to "understand" exponents, indicating a move towards an empirical instead of conceptual understanding. This is evident in the algorithmic and functional approaches, and even in the work based on splitting, there is still some emphasis on generating sample values in order to understand rate of change.

Theoretical Frameworks

One goal when designing the following teaching trajectory is that it will allow students to develop a coherent understanding of the concept of exponentiation as a continuous operation with no contradictions as the domain of the exponent expands from positive whole numbers, to negative whole numbers (and zero), to fractional exponents, and finally to all real numbers. In order to design such a trajectory and to analyze its usefulness, I am using two different theoretical frameworks, which I argue to be complementary (Simon, 2009), and offer principles for the arrangement of the content and provide constructs that explain the learning of the student.

For the overall content organization approach and the analysis of the core understandings that are the foundation of the concept of exponents, I used the design principles as laid out by Davydov (1975). One of Davydov's main points is that the material should be organized, moving from the general to the specific. That is, the students should move from learning about the concept in its most general form and later to work through different cases which are manifestations of it in such a way that they develop a complete understanding of the concept. A principal goal in designing the teaching trajectory was to develop an image of exponents that students can repeatedly use in different cases without ever having to deal with contradictions. This is significantly different than building on the specific case of positive whole numbers and later expanding it to negative and fractional exponents.

A guiding example of the development of a concept from general to specific is the development of multiplication (Davydov, 1992). Davydov asserted that multiplication should not be viewed as repeated addition, raising similar issues to the ones described earlier with exponentiation being viewed as repeated multiplication. In his measurement-based approach, he distinguished between the way one *calculates* the value of a multiplication expression and the *image* of multiplication. Creating an image of multiplication as a change of unit of measurement allows Davydov to develop with his students a more general view of multiplication that also includes multiplication of fractions. My work builds on the previous work not because it is intended to address the issue of teaching multiplication, but because this example is used to demonstrate how it is possible to create a single image of a concept that can be used across cases.

However, Davydov's framework cannot be used to analyze the learning of the students from a cognitive perspective, and to complement it I used Simon et al's (2010) framework for learning through activity, building on Piaget's (2001) concept of reflective abstraction. This framework seeks to explain the transition from the point at which a student did not understand something to the point at which he or she does understand it (p. 77). The following are three principles I used from Simon et al's framework: the importance of a learner's activity, the importance of the learner's reflection, and the distinction between reflective abstractions and empirical learning processes (p. 74). I also note the goal-directed nature of the student's activity, as well as the development of the logical necessity that brings the student to anticipate the relevant results.

Principles in Developing the Concept of Exponents

The development of a single image of exponentiation is the key to developing a *continuous* concept of exponents, including natural and rational bases, as well as real numbers as exponents. The following are guiding principles for designing a trajectory that leads to such concept:

Separating the Image and the Calculation

Students should be able to consider the calculation of any exponential expression separately from the image of exponentiation. Whereas the calculation of positive, negative and rational exponents may involve different operations, creating a single image of exponents will allow them to reason about those as one concept and not as a disconnected set, and carry the same image they expand their domain of operation.

Beginning with a Qualitative Understanding of Exponents

One of the challenges in working with exponents is that the resulting values of the operation quickly become too big (or too small). This does not allow students to develop a real sense of the rate of change since they need to manipulate large numbers at the same time. Beginning with a qualitative (vs. quantitative) experience of exponents that builds on a visual representation will allow the students to build an understanding of the operation's effects and develop an expectation for the result of using different bases, without ever calculating the numerical value of the operation.

Using Physical Quantities of a Continuous Nature

In order to develop in students the understanding of exponents in the integer and rational domains, students should not be limited to working with discrete quantities. Quantities such as length, area, and volume allow them to perform the operation of exponentiation using any value for the exponent and experience the change in a continuous way. Moreover, these quantities are also measureable and visible so they lend themselves to the use of multiple representations.

Using Whole Numbers as a Case within the Continuous Domain

Beginning the calculations of exponents with whole numbers is a way for students to find the result of the operation. The suggested approach introduces whole numbers only once the *image* of exponents is established and without changing it moves to whole numbers as a particular case of *calculating* the result.

Building on Students' Intuitive Models

Confrey and Smith used a concept from the students' world that can be used intuitively as a basis for developing the mathematical concept, and it provides a strong foundation and an important entry point for the teaching trajectory.

Applying several of these principles together poses a great challenge. Continuous models in nature (e.g., temperature change, decay of matter) tend not to be directly measurable which means they cannot be used in a physical activity. The other models are mostly discrete (similar to the ones shown in the splitting approach). An activity that uses a quantity such as length and requires the students to change its size by, for example, stretching it, does not result in an exponential change. In order to create a true exponential change in a quantity, the students have to consistently change the power/speed they use while stretching the quantity, which is not a natural thing to do. In order to overcome such difficulties the suggested teaching trajectory relies on a technological environment that allows the students to change the exponent *continuously* and observe the change in the quantity.

What Is Exponentiation?

The starting point for building a continuous view of exponentiation is accepting that repeated multiplication is only a way to *calculate* exponents in the case of whole numbers, and not the *image* of it. This was understood by previous researchers—Confrey and Smith, for example, developed the image of exponentiation as a splitting operation and repeated multiplication was a way to calculate the number of elements after a sequence of splits. Even though exponentiation is a multiplicative idea at its core, this idea is not enough for building a mental model that students can relate to as they expand the concept and learn to calculate it in different cases.

One of the main differences between addition, multiplication and exponentiation is that the last one is an operation which produces a changing growth/reduction rate. It is also the basis for understanding the extreme changes that happen when exponentiation is repeated.

The basis for understanding the changing rate of exponentiation is that the growth/reduction in exponentiation is always *relative* to the quantity it operates on. Building on that understanding, I define the following *image* of exponentiation as the goal for the trajectory:

Exponentiation is an operation that *changes* a given quantity *multiplicatively* based on the *current size* of the quantity.

A few notes with regards to this image of exponentiation:

1. Through defining exponentiation as a general changing operation, students are not limited to thinking that "exponentiation makes bigger" which is sometimes assumed from the definition of repeated multiplication. The image can be used in the cases of positive as well as negative and fractional exponents.
2. The multiplicative rate as the change factor allows for fractional rate bases, which is important for building the single view across bases that was the goal of the instruction.
3. There is an underlying assumption, although not explicit, that the students can think of a change as related to a given size, meaning a proportional change.
4. The question of calculating the value of the exponential expression is left unanswered in this definition. It is essential that the students have a single model to build on, and that they see the calculations as based on specific cases within that image.

Developing the image of exponentiation is a first step in helping the students to construct the different cases of this image (in the various domains for bases and exponents). The image of exponentiation is reinforced by the use of symbolic language in a more formal mathematical definition and model which includes the following components:

1. Q_0 – the quantity being operated on, at the initial stage (time=0)
2. a – the multiplicative rate of change (natural or fractional) in a given time unit
3. x – the change in time units (as related to the time of the initial stage)
4. Q_x – the resulting quantity at time=x (this can be at any point in time)
5. a^x – the accumulated multiplicative change of the initial quantity (Q_x divided by Q_0).

Representation Model

The use of multiple representations and the utilization of dynamic control and manipulation, made possible using technology, can have a positive impact on students' learning in algebra (Kieran, 2006) and these are incorporated as part of the representational model. In addition, the representation must allow the use of continuous quantities and make it possible for the students to engage with the image without relying on specific calculations.

The Context of the Problem

Based on the desired characteristics of the image of the concept of exponentiation as described earlier, it is essential that the change described in the problem is one that is based on the current size of the quantity being changed. The suggested context problem (other variations exist of course) is the following:

Magic caterpillars need to eat a certain amount of leaves. The length (amount) that each caterpillar needs to eat is proportional to the caterpillar's length. The eating transforms the caterpillar - they end up being as long as the length of the leaves they ate (for simplification they "eat" in straight lines). We will examine the changes in the length of the caterpillars.

The context was chosen to support the development of a complete view of exponentiation:

1. It provides freedom in the selection of the initial quantity to be operated on, as well as the introduction of various bases, in the form of different types of caterpillars that change differently, being more (or less) hungry
2. Its structure allows for the introduction of both growth and decay, since the proportion of the food they need might be smaller or bigger than the caterpillars themselves
3. In the general form of the problem there is no mention of any period of time in which the food needs to be consumed. It will be introduced as a "feeding cycle" later as the students move to the quantitative section in which they calculate the values of the growth. This also allows for the use

of multiple-size feeding cycles, which is the basis for working with any rational exponents, and developing a continuous view of the operation

The Visual Representation

The representation includes two critical components:

(a) Dynamic graphical representation of the caterpillar. Using a narrow rectangle as a representation of the caterpillar allows the students to focus on the length as the relevant quantity. Also, using the length representation answers the need for a continuous quantity, which can grow or shrink dynamically. This eliminates the problem caused by using discrete properties.

(b) Horizontal time axis with a slide bar. The use of a slide bar represents a continuous view of the exponent value allowing the students to work in fractional and integer values. Offering a dynamic manipulation of one element, the use of a slide bar is a known representation for time progression which is familiar to students (consider YouTube for example).

Bringing all the pieces together, and using the elements of the mathematical model with the representation model and the problem context, we have the following:

1. Q_0 is the size of the caterpillar at the given initial state (when the observation begins)
2. "a" is the property of the caterpillar which defines how much food it eat at each time unit
3. "x" is the change in time represented by the slide bar. The location of the marker on the slide bar shows how far they are (and in which direction) from the initial state
4. Q_x is the size of the caterpillar (the rectangular bar) at any point in time (the slide bar)
5. a^x is the result of calculating (or predicting) the change from the initial to the current state

Analysis of the Hypothetical Learning

The affordances of the definition and model described above are best demonstrated through an analysis of a student's *hypothetical* learning process. What follows is a description of the *hypothesized* learning of a student who performs two activities from the first task in a teaching trajectory which is based on the principles above. A full description of the teaching trajectory and analysis of the hypothesized learning as for each step is beyond the scope of this paper.

During the first three activities of the trajectory (not detailed here), the students work with quantities (the length property of the caterpillars, with no particular numerical value but of a comparable magnitude) that change in either exponential or linear form and understand that exponential growth (or decay) is faster than linear one, once the quantity reaches a certain size. They can explain the relationship between the size of the caterpillar and its growth (or decay) and focus on the fact that the bigger the given quantity is, the bigger the change is. Also, students are introduced to the formal mathematical notation. They now move to the fourth activity.

Activity 4: Comparing Different Quantities

In this activity, the student works with two caterpillars with the same base for the exponent and compares their growth, in absolute (additive) and proportional terms. Working in the same base and the same time period with different-sized caterpillars focuses the student on the initial size of the caterpillars. In reflecting on his activity he is expected to understand the logical necessity of the initial quantity explaining the difference in the resulting quantity, building on his prior knowledge of the relationship between the quantity and the change, and knowing that the initial quantity is the only attribute in which the caterpillars vary. I describe now the steps in the activity that lead to this understanding.

In the first step of this process, the student works with one caterpillar and establishes its growth rate, as in previously activities. He does this by using the slide bar marked with units as before to change the time value and compare the resulting size. From this, he can see that the growth is based on a particular base rate. For example, he might observe that the caterpillar grows by a multiple of 3 for every time unit in the case of a base of 3. He does this by comparing the quantity after one time unit, with the quantity at the beginning, or the quantity after x+1 units, with that of after x units.

Once the growth rate is determined, another quantity of a bigger size is introduced and placed next to the original one. The student is told it needs to eat the same proportion as the previous one, and is asked to predict which one will grow more. The student is expected to develop an understanding that the growth of a caterpillar is proportional to its original quantity, and is assumed to know that when multiplying two numbers by the same factor, the larger number will result in a larger product. Building on these two, the student will anticipate that the larger caterpillar will grow more, because "3 times a bigger number is bigger." This understanding is powerful since the student learns about a relationship which is not dependant on whether the given quantity is of a whole or fractional size. At the end of this activity the student concludes that for an equal amount of time units and the same growth rate, the larger quantity will grow by a larger amount. It is important to note that the student generalizes about exponents *without* looking for a numerical pattern, and that the process he goes through is based on reflection about the general process and the understandings developed about the nature of this activity.

Activity 5: Moving Forward and Backward in Time, Only Until the Present

In this activity students can move the scroll bar forward and backward between the present time and a particular point in the future (just to avoid infinite growth/decay in the future). They begin with a quantity of a particular size and are asked to explain whether it is growing (eating more than its size) or shrinking (eating less than its size), based on their observation of the behavior. This should be a simple question for the students, knowing they completed the previous activities in which they learned that when a caterpillar eats more than its size, it grows every day (towards the future) and the opposite in decay. The students are then asked to explain whether the quantity grows bigger or smaller if you move forward in time. The students are then asked to move the bar to a random point on the time line and answer the following question "in order to reach this state and from what you know of the behavior of the caterpillar, would the quantity had to be bigger or smaller before this point in time." Students, building on their "forward" thinking and activity of moving the bar forward from before, see the logical necessity that in order to reach a certain quantity, when a caterpillar is growing, it had to be smaller before (and similarly for decay it had to be bigger before). They are then asked "Knowing that a caterpillar is 'growing' caterpillar, if you look back in time, would that caterpillar be bigger or smaller?" and "how would it look if you move forward in time?" Although this can be checked by the students through the representation, at this point they already see the necessity of the caterpillar being smaller, since it had to grow to reach the given size (in the case of growth). The students learn to anticipate that if the caterpillar is of a growth type ($a>1$), then when moving forward in time (increasing the exponent) the quantity grows, and when moving backward in time (decreasing the exponent) it becomes smaller.

At the end of those five activities, students develop the concept of exponentiation as a change which has a rate proportional to the current size of the quantity, as a factor of time. Also, students can explain the change in a quantity when moving both forward and backward in time, which will serve as a precursor for the development of zero and negative exponents as places on the time line. Moreover, the use of a continuous time line sets the stage for other "time points" which will not be whole numbers. Students never used particular values for quantities so they never calculated the exponential change, and that supports the development of a continuous view of exponentiation and keeping the image of exponentiation separate from the calculation process.

Developing Continuous Concepts in Mathematics

The development of mathematical operations such as addition, multiplication and exponentiation usually begins with the positive whole number case and expands later to negative and rational numbers. I began this paper presenting the implications such an approach might have on the student and suggested principles for designing a teaching sequence for the development of one of those concepts in a continuous manner. Although focused on exponentiation, the importance of the work might be beyond a particular content area, and perhaps also it can serve as an example of how other continuous concepts might be thought of in such fields as calculus and operations in algebra.

Moreover, the approach laid out here might also serve as basis for designing the development of continuous concepts in general. The value of using two different theoretical frameworks is revealed through the examination of the hypothetical learning sequence in which the student on the one hand begins with the general image of exponentiation, as suggested by Davydov, coming from a socio-cultural perspective, but at the same time, develops the understanding which is explained from a constructivist perspective. The use of one framework as the leading one for the overall design of the sequence and another framework to design the activities within the sequence might have applications in other conceptual areas.

THE IMPACT OF ONLINE ACTIVITIES ON STUDENTS' GENERALIZING STRATEGIES AND JUSTIFICATIONS FOR LINEAR GROWING PATTERNS

Ruth Beatty
Lakehead University
rbeatty@lakeheadu.ca

This study explores the impact of working with online learning activities of linear growing patterns (CLIPS) on students transitioning into Grade 9. Fifty students were interviewed about their understanding of linear growing patterns. Twenty-five students had participated in a study involving an experimental instructional approach that emphasized exploration of multiple representations of linear relationships when they were in Grade 8. They were then assessed five months later, and their reasoning compared to twenty-five students who did not take part in the study. Results indicate that students who worked with CLIPS were able to find explicit, generalized rules for patterns and offered higher levels of justifications than their counterparts. These students were also more likely to refine their thinking.

Keywords: Algebra and Algebraic Thinking; Instructional Activities and Practices; Technology

Context

Studies have shown that the transition from primarily arithmetic thinking in elementary school, to algebraic thinking in high school, is difficult for most students (Kieran, 1992). This transition entails moving from a focus on mathematical operations (addition, subtraction, multiplication, division) to thinking about relationships between sets of numbers, and identifying generalized mathematical structures with or without specific numeric values. Traditional algebra is often initially presented in high school as a pre-determined syntax of rules and symbolic language to be memorized by students. Students are expected to master the skills of symbolic manipulation before learning about the purpose and the use of these symbols. In other words, algebra is presented to students with no opportunity for exploration or for meaning making (Kaput, 2000).

In response, a series of online learning objects was designed as an alternative way to introduce the concepts of algebraic relations, specifically linear relations, to Grade 8 students prior to formal algebraic instruction in Grade 9. The activities are based on an approach that emphasizes the observation of relationships among quantities, and among multiple representations, which allows for the construction of understanding rather than rote memorization of procedures. As part of a larger long-term study, I have been investigating the affordances of this instructional approach that prioritizes visual representations of linear relationships – specifically, the building of linear growing patterns and the construction of graphs (e.g., Beatty 2010). Previous research on the lesson sequence has shown that it supports students' progression from working with linear growing patterns as an anchoring representation to considering graphical representations of linear relationships. Students also make connections among different representations – pattern rules, patterns and graphs (Figure 1).

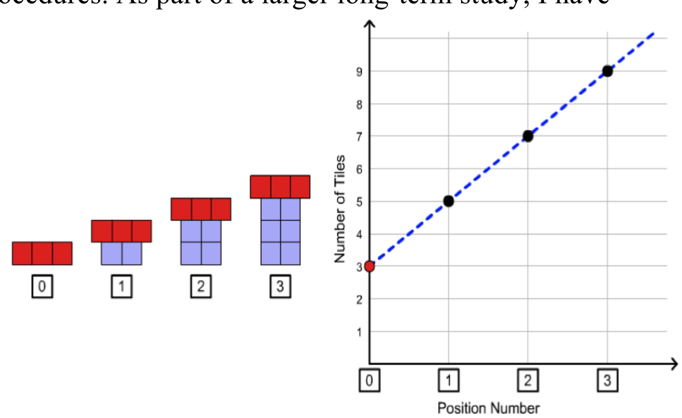

Figure 1: Representations of the rule y=2x+3

The online activities, called CLIPS LGP (Critical Learning Instructional Paths Supports – Linear Growing Patterns) were designed using Flash technology and offered the possibility of combining a proven instructional sequence with unique properties of digital technology. The online activities were integrated into the instruction in five classes of Grade 8 students. The students accessed the online activities for 2 months in order to develop an understanding of linear relationships via linear growing patterns. As part of the instruction, students were supported to develop sophisticated generalizing strategies by considering the explicit relationship between the term number of a pattern and the number of tiles in the pattern, and to express this relationship using pattern rules such as "the number of tiles is equal to the term number x2+3" or "tiles = term number x2+3." Students also engaged in classroom discussions based on the online activities, and developed a disposition for providing justifications for their pattern rules.

In this study we wanted to assess how much content material was retained by these Grade 8 students as they transitioned into Grade 9. We also wanted to compare the problem-solving processes of Grade 9 students who had been part of the CLIPS study in Grade 8 with those who had not in order to determine whether there was a difference in students' generalizing strategies and justifications.

Developing Generalizing Strategies

A main component of algebraic reasoning is the ability to generalize. In the domain of linear relations, particularly when thinking about linear growing patterns, a generalization can be thought of as the articulation of a pattern rule that applies across all cases in the situation (for example figure numbers and number of toothpicks in a linear growing pattern.) Studies have shown that students have difficult moving from particular examples (for instance, focusing on particular iterations of a pattern) towards creating generalizations (a generalized pattern rule that holds for infinite iterations of the pattern). Numerous researchers have reported that the route from working with liner growing patterns to finding generalized rules (and later, algebraic expressions for those rules) is difficult (Kieran, 1992; Orton, Orton & Roper, 1999; Noss et al., 1997). However, we have found in our previous studies that the instructional approach that underpins the CLIPS activities has facilitated students' abilities to find and articulate general rules for linear growing patterns (Beatty & Bruce 2012).

Researchers have identified many generalizing strategies that students adopt when working with problems involving linear relations, including problems based on linear growing patterns (Lannin, 2005; Mason, 1996; Lee, 1996). Below we identify three of these strategies from the least to the most sophisticated. They are presented with reference to a well-known generalizing problem (one that we used in our study), the Toothpick Trees problem (Figure 2). In this problem, students are shown a series of Toothpick Trees and asked to predict how many toothpicks would be needed to build the 10th figure, and how many would be needed to build the 100th figure.

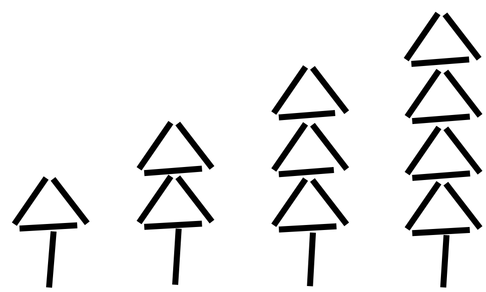

Figure 2: The toothpick trees problem

Counting strategy. Students draw a picture or constructing a model to represent the situation in order to count the desired attributes. For example, students draw the 10th figure and count the number of toothpicks required. The limitation of this strategy is evident to students when they are asked to predict the number of toothpicks for the 100th figure.

Recursive reasoning strategy. Students build on the previous term in the sequence to determine subsequent terms. In our example, students would state that the rule for the pattern is "add 3 each time." To find the 10th figure they add three to the 4th figure, then three more to the 5th figure etc. This strategy generally results in the correct answer to predict the number of toothpicks for "near" terms of a pattern (for example, figure 10) but is problematic for finding the 100th term. It also does not allow for the articulation of the rule, which would allow for the prediction of the number of toothpicks for *any* figure.

Explicit reasoning strategy. Students construct the explicit rule that expresses the co-variation of two sets of data, based on information provided in the situation. An explicit rule can allow for the prediction of any term number in the pattern. An example of an explicit rule would be, "the number of toothpicks is equal to the figure number x3+1."

Research suggests that when working linear relationships and linear growing patterns it is rare for students to go beyond limited kinds of mathematical generalizations – namely counting or recursive reasoning – primarily because these are the strategies that are supported by traditional approaches to teaching patterning and algebra (Noss et al., 1997). However, the instructional approach in CLIPS prioritizes explicit reasoning in order for students to determine and articulate the mathematical structure of linear growing patterns.

Importance of Justification

When students justify their solutions strategies they are able to provide reasoning and evidence to validate their generalization. This has been found to be challenging for most students (Lannin, 2005). However, providing a justification for a generalized rule helps students to see the generalized relationships that exist in the problem context. Just as there is a framework for generalization strategies, there is also a five-level framework for justification strategies (Table 1) (Simon and Blume, 1996). Higher levels of justification have been shown to support higher levels of generalization (Lannin, 2005).

Table 1: Levels of Justification

Level	Descriptions
0	No justification.
1	Appeal to external authority. Reference is made to the fact that a solution is correct because it is stated by some other individual (teacher or a peer who is regarded as more successful) or some other reference material.
2	Empirical evidence. A justification is provided through the correctness of particular example but with no indication of an understanding of <u>why</u> the rule is correct. For instance, "The rule is 'add 3' because for the first figure there are four toothpicks, then you add 3 more for figure 2."
3	Generic example. Deductive justification is expressed for a particular instance, a generic example, which the students uses as a proxy for "any" instance. For example, "I know the rule is "toothpicks = figure number x3+1" because for, say, the fifth figure, there are five triangles, and five times three is fifteen. And then there is one more, so plus one is sixteen."
4	Deductive justification. Validity is given through a deductive argument that is independent of particular instances. For example, "At any figure number, the number of triangles equals the figure number, so that means multiplying the figure number by three, and then there's always an additional one for the trunk."

When working with CLIPS, students engaged in classroom discussions during which they were encouraged to justify their solutions by making connections between their solutions and the context of the problem, with a focus on deductive reasoning.

Methodology

Participants

Fifty Grade 9 students participated. Of these, 25 students had been part of the CLIPS study and 25 had not. The students were drawn from 8 different classrooms in two different school boards with equal number of CLIPS and non-CLIPS students selected from each classroom. Students were interviewed individually for approximately 30 – 35 minutes.

Data Sources and Analysis

In order to track the content knowledge and algebraic reasoning of students, we chose to conduct task-based clinical interviews during which students were asked to describe what they were thinking while solving ten linear relationship problems. This form of interview opens a window into the participants' content knowledge, problem-solving behaviours and reasoning (Koichu & Harel, 2007; Schoenfeld, 2002). In this study, the clinical interviews were semi-structured, which allowed for prompting or questioning students in order to clarify our understanding of the students' reasoning. Validity of the subjects' verbal report corresponds to the extent to which the subjects' talk represents the actual sequence of thoughts mediating solving an interview task (Clement, 2000; Ericsson & Simon, 1993). Therefore, all interviews were digitally video recorded so that verbal report and non-verbal gestures were captured in order to develop a comprehensive analysis of student thinking.

Overall students answered five items that were taken directly from the CLIPS activities, which we termed "near transfer" items because they test the retention of understanding of items that are similar to items students experienced while working with CLIPS. The other five items came from sources such as TIMSS (Third International Math and Science Survey) and NAEP (National Assessment of Educational Progress). We termed these "far transfer" items because they are dissimilar to the CLIPS content, and so assess understanding of underlying conceptual concepts. For this report we will focus on students' responses to one "far transfer" item – the Toothpick Trees problem described above. The students were asked to predict how many toothpicks would be needed for the 10^{th} and 100^{th} figure, and to explain their thinking. However, we did not explicitly ask for a pattern rule in order to determine whether students would use the information presented in the patterns to formulate a general rule that would give the number of toothpicks required for any figure of the pattern.

The scoring guide for these items, based on the generalization framework, is given below.

Table 2: Scoring Guide for Generalization Strategies

Score	Description
0	Incorrect answer
1	Counting strategy. The student drew out the figure(s) and then counted the number of matchsticks/toothpicks (drew out the 10^{th} figure, drew out the 4^{th} to the 10^{th} figure).
2	Recursive strategy. The student has articulated the rule as "add three more each time" or created an ordered table of values that increased by three each time.
3	Explicit strategy. The student has articulated the explicit rule as "matchsticks = figure number x3 + 3" and "toothpicks = figure number x3+1"

Video recordings of task-based interviews were transcribed and coded. Codes were based on the generalization and justification frameworks outlined above.

Results

Generalizing Strategies

Table three shows the level of generalizing strategy demonstrated by students who had experienced CLIPS and those who had not.

Table 3: Generalization Strategies Used by CLIPS and Non-CLIPS Students

	Score 0	Score 1	Score 2	Score 3
CLIPS	0	0	7	18
Non CLIPS	11	8	4	0

Most CLIPS students used an explicit generalizing strategy to find a general rule using the context of the problem in order to find the correct solution. In contrast, many non-CLIPS students did not find a viable solution, and those that did used a counting strategy or recursive reasoning strategy, rather than finding an explicit pattern rule.

Counting strategy. Eight of the 25 non-CLIPS students used a counting strategy for this problem, meaning that they drew the 10th figure and then counted the number of toothpicks. A striking finding was that all eight of the students who used a counting strategy could not make the connection between counting by threes, and multiplying by three. For example, in the transcript below the student is not able to transition to multiplicative thinking in order to predict the 100th term.

Malinda: Well I drew it out and counted and found out that it just kept adding three. So I drew it to the tenth and then counted them to find the right number of toothpicks.
Interviewer: How are you counting? Can you count out loud?
Malinda: Three, six, nine, twelve, like that?
Interviewer: Yeah.
Malinda: (pointing to each triangle as she counts) Three, six, nine, twelve, fifteen, eighteen, twenty-one, twenty-four, twenty-seven, thirty plus one is thirty-one. I was counting by three's.
Interviewer: Could that help you think about how many toothpicks you'd need for any figure number? Like the 100^{th} figure?
Malinda: Um…well…I know that I would draw out three more for each figure. So I would just keep drawing three for each next figure, and then count by threes.

It should be noted that Malinda, like most of the students we interviewed, was considered to be, and considered herself to be, capable of engaging in mathematical operations like multiplication. However, the majority of students who were not part of the CLIPS study could not make the connection between "counting by threes" and multiplying the term number by three.

Differences in recursive thinking. The seven CLIPS students who used recursive thinking created a generalized rule "add three each time plus the one for the trunk" that took into account both the multiplier and the constant of the rule with reference to the figural context of the problem.

> I added three toothpicks every time, like one triangle every time up to the tenth one and got thirty toothpicks and then you have to add the stump part to it. So it's always going up by three each time, but with the little stump so you add one for that. So for 100 you'd add 3 100 times and then add 1.

The two non-CLIPS students who used recursive thinking articulated their pattern rule as "start with four and add three." This is a common way that students are taught to articulate linear growing rules. Students were able to find the number of toothpicks for the 10th tree, but then simply guessed for the 100th term.

> Ok so I started at the first tree with four toothpicks. Then as it added we still had the four and I added it to each new tree every time. So then every time I'd get an answer with three more. I'd added 4 and three and three and three and keep count of where I was until I hit the tenth figure. Then that was my answer. For 100 it would be…maybe 101? I don't know.

Explicit thinking. Eighteen CLIPS students found a generalized rule for this pattern. Most of the students used language and concepts that are part of the CLIPS LGP instruction.

> I looked for the rule. So I could see the triangles were growing, so that meant the multiplier would be times 3. And then the one that stays the same, that's the constant. So for 10 it would be 10x3+1, which is 31. And for 100 it would be 100 x 3 is 300 plus 1 is 301.

Justification Strategies

Transcripts were coded for the level of justification offered by students as they articulated their thinking during the task-based clinical interview. Justifications were scored from Level 0 to Level 4, based on the framework outlined above. Table 4 below shows the level of justification provided by students who had experienced CLIPS and those who had not.

Table 4: Levels of Justification Given by CLIPS and Non-CLIPS Students

	Level 0	Level 1	Level 2	Level 3	Level 4
CLIPS	0	0	2	7	16
Non CLIPS	11	2	8	0	0

Seven CLIPS students offered a Level 3 justification for their rules. An example of a Level 3 justification is as follows: "The tenth tree would have three triangles, which is 3 times 10 or 30. And then you add the one, so it's 31."In this example the student refers to a particular figure number to describe how each component of her rule relates to how her rule determines the number of toothpicks. She notes the ten groups of 3 for the ten triangles in the tenth figure and explains the need to add the one extra for the trunk. In this case a particular example is used to communicate generality across all cases.

Sixteen CLIPS students offered a level 4 justification: "I know my rule is correct because you just multiply the figure number by the group of three for the triangles because the figure number tells how many triangles there are, and triangles are always going to be 3 toothpicks. And then the little trunk means you always add one more." Students clearly explain why the rule applies to all cases of the situation by relating it to the context of the pattern. The students describe the "groups of three" they see in each of the patterns, so the multiplier x3 represents the number of toothpicks in these groups. The extra 1 toothpick (for the trunk) is added to the rule to express the total number of toothpicks needed for any figure number. Unlike a generic example, this justification does not describe a particular instance. Instead, it describes a general relationship that would apply to any case.

In contrast, the majority of non-CLIPS students did not offer a justification, and when asked why their rule worked replied, "I'm not sure" or "because it just does." Two students offered justification that were scored as Level 2, empirical reasoning based on the correctness of one specific example, but with no demonstrated understanding of why this was correct, or how their solution was related to the context of the problem. "From the first to the second tree you add three more so the rule is plus three."

Students' Refining Their Own Thinking

One of the most striking results revealed by an analysis of the interview transcripts is the extent to which students who had been part of the CLIPS project refined their thinking during the course of the interview as a result of explaining their solution process. Overall, there were 28 such episodes coded in the interview transcripts for the 25 CLIPS students. However, there were no such episodes coded for the transcripts of the non-CLIPS students. Non-CLIPS students did not revise their thinking, and when they discovered an error between their rule and the problem context (their rule would lead to an incorrect number of toothpicks) they either gave up or were not aware of the disconnect between their rule and the values given in the problem.

The CLIPS students were more likely to try to find an alternative solution strategy, or to refine their answer based on new evidence. In this example, Deepak had briefly looked at the first figure of the pattern and written "x4." He was then asked to explain his rule. During his explanation, Deepak realized that he had misperceived the structure of the pattern, and that his perception did not coincide with the numerical value of the pattern for each figure number. Rather than dismiss this discrepancy, Deepak went to work to try to discern a rule that would work with all iterations of the pattern.

Deepak: Well I just looked at figure 1, and found that the tree is made up of 4 toothpicks, so the rule is figure number times 4 So, if you look at figure 2, it would be 2 times 4 which is 8, and there are…wait…oh that's not right.

[Deepak spent 54 seconds working on a new rule.]

Deepak: Ok I see what I did wrong. I didn't see it right, I thought the whole tree was made of 4 not 3. But if you check the numbers, it's growing by 3, so the three that are growing are these three that make up the triangles so it's times 3. And then the trunk is made of one, so it's plus 1. And that works with all the figures. So figure 3 is 3 times 3, 9, and then plus 1, 10. So the 10^{th} figure would have 31.

Interviewer: So how many toothpicks would be needed for the 100th figure?
Deepak: Easy! I can just use the rule! 301!

Conclusions

One focus of this study was to assess the enduring understandings students developed while working with the CLIPS activities, and how much of this understanding was retained during the five months from the end of the instructional intervention (June, 2010) to the time of the interviews. The interviews were held near the end of the first semester of school, during November and December 2010. The students had not yet had any formal instruction in linear relations. Given that our intervention was relatively short, these results indicate that students retained a great deal of understanding both of content material, and of the importance of providing justifications for their answers.

Another focus of the study was to compare the thinking of Grade 9 students who had been part of the CLIPS study with those who had not. There were two main areas of algebraic thinking that we assessed – the level of generalizing strategy used by students when solving linear problems, and the level of justification offered for their solutions. We found differences in the kinds of generalization strategies used by CLIPS and non-CLIPS students. In this study, students who had not been part of CLIPS, but who had experienced traditional approaches of instruction, had great difficulty in finding generalized rules for patterns. For those who did find a correct solution for the tenth figure of a linear growing pattern, their solutions were based on counting or, less frequently, recursive reasoning. These limited solutions strategies allowed students to find the number of toothpicks for the tenth figure (a near generalization), but did not aid them in finding the number for the one hundredth figure (a far generalization).

In addition, few students who had not been part of the CLIPS study offered any kind of justification for their solutions. In contrast, students who had been part of CLIPS tended to offer level 3 and 4 justifications. They explained their solutions using the context of the problem, and could articulate why their general rule would work for any case.

Finally, there was the unexpected, yet striking result, of the extent to which CLIPS students revised their thinking. This happened numerous times with the CLIPS students, who, during the course of explaining their solutions, caught and corrected their own mistakes. Past research suggests that students typically do not attempt to revise their rules (Bednarz, Kieran, and Lee, 1996; Mason, 1996; Stacey, 1989). In fact, Cooper and Sakane (1986) suggest that once students select a rule for a pattern, they tend to persist in their claims even when finding a counter example to their hypothesis. Students would rather refute the data presented than modify their original rule. This was the behaviour we observed with the non-CLIPS students, who had no interest in revising their rules.

TRANSITIONING FROM WHOLE NUMBERS TO INTEGERS

Laura Bofferding
Purdue University
LBofferding@Purdue.edu

This paper presents the results of a pre-test, instruction, post-test study that investigated students' integer mental models and how their models changed based on instruction. Sixty-one first graders' responses to questions about the values and order of negative numbers were categorized according to a series of mental models. The models reveal that initially, students over-rely on the values and/or order of whole numbers to varying degrees when working with negative numbers. Focused exploration on the properties of negative numbers helped students transition to more sophisticated mental models compared to only learning about moving in positive and negative directions on number lines.

Keywords: Number Concepts and Operations; Elementary School Education

Purposes of the Study

During students' progression through early elementary school, one of the foundational mathematical understandings they must develop is that of numbers (National Research Council, 2001; National Council of Teachers of Mathematics, 2000). During this time, students learn the counting sequence, numeral names, and numerical values. In particular, students must coordinate their knowledge of number values and order—understanding that moving one number forward in the counting sequence corresponds to a one-unit increase in value—so that they can use this information to solve addition and subtraction problems (Griffin, Case, & Capodilupo, 1995; Fuson, 2004). As students move along the continuum of numerical understanding, difficulty arises when they must expand their number knowledge to include negative numbers and rethink how numerals relate to numerical values: 10 is big in terms of positive numbers but small when made negative; the inclusion of negative numbers also requires students to reevaluate the meanings of addition and subtraction (e.g., adding no longer always results in a larger number) (Bruno & Martinon, 1999; Küchemann, 1980; Murray, 1985). Further, students must navigate the changing meanings of the minus sign (it can mean an operation, a negative sign, or an indication to take the opposite), which later interferes with students' ability to reduce polynomials and manipulate algebra problems (Gallardo & Rojano, 1994; Vlassis, 2004, 2008).

Past research on negative number instruction and student learning explored whether students could learn how to solve integer addition and subtraction problems from a particular method of instruction (Linchevski & Williams, 1999; Schwarz, Kohn, & Resnick, 1993; Thompson & Dreyfus, 1988) or whether one method of instruction is more effective than another (Liebeck, 1990; Janvier, 1985). Results from these and other studies highlight strategies students use to solve integer problems. For example, to solve $-4 + -3$, a student might add $4 + 3 = 7$ and then add a negative sign to get -7 (Bofferding, 2010). Another student might treat negatives as worth zero and get an answer of -4 because adding zero will not change the answer (Bofferding, 2011).

What might account for these differences? One influence on students' solutions to integer addition and subtraction problems is how they think about the values and order of negative numbers in comparison to positive numbers. However, research does not provide a clear picture of what the transition from whole number to integer understanding looks like. This study contributes to this area by addressing the following research questions: (1) What are first grade students' mental models of negative integers in relation to order and value (the elements underlying the central conceptual structure of numbers)? (2) How do students' mental models change based on integer instruction?

Theoretical Framework

The *central conceptual structure of number* (CCSN) or *mental number line* is a mental model or internal structure hypothesized to support numerical thinking (Case, 1996; Griffin, Case, & Capodilupo, 1995). This structure involves four components: number word order (i.e., the counting sequence), a tagging routine for counting objects, numerical values, and written symbols. Although young children may learn how to say the number names in order, they do not initially use this process to quantify sets; similarly, they might compare two sets of objects visually instead of counting and comparing them numerically (Sophian, 1987). Eventually children coordinate the four components, creating the fully integrated CCSN. By referring to this mental model and counting up and down their mental number line, students can add and subtract single-digit numbers (Case, 1996; Griffin, Case, & Capodilupo, 1995).

As students learn about negative numbers, they need to modify their CCSN. Because there are no true physical manifestations of negative numbers, students need to reason that numbers further to the left on the mental number line are smaller than numbers to their right, even if before zero and even if they contain the same numerals. Therefore, while -2 and 2 look similar and are equally far away from zero, the number further to right on the number line is greater. Students must also wrestle with the changing meaning of the minus sign; for example, –4 – –3 does not mean subtract 3 twice (Murray, 1985) but take away –3 from –4.

Situations, such as this one, where students must reorganize their knowledge structures, involve conceptual change. In the context of numbers, students have *initial* mental models that numbers are discrete, which arise from their experiences with objects (Gallistel & Gelman, 1992; Vamvakoussi & Vosniadou, 2004). Students who have an initial mental model for negative numbers might ignore the negative signs and treat the numbers as if they are positive; for example, they might place negative numbers next to their positive counterparts when ordering them (Peled, Mukhopadhyay, & Resnick, 1989). As children have more experiences with a concept, they begin to restructure their initial mental models in order to deal with new, conflicting information; this process results in one of many *synthetic* or *intermediary* mental models. For example, when students learn that negatives exist, they might think that –7 is greater than –3 because 7 is greater than 3 (Stavy, Tsamir, & Tirosh, 2002). With time and experience students will eventually develop the *formal* mental model, where negatives are ordered opposite their positive counterparts on the number line—with zero separating positive and negative values—and numbers decreasing in value to the left and increasing in value to the right. The goal of this study is to address the research questions by using the lens of conceptual change to investigate how students' mental models for the CCSN change during the transition from whole number to integer understanding.

Methods

Participants and Site

This study took place at the end of the school year in a diverse elementary school in California. It was important to recruit students who had initial mental models for negative numbers so that I could explore the transitions they make as they learn about the topic. Based on pilot work, I selected and recruited students at the end of their first grade year. Overall, 61 first graders participated.

Materials and Data Collection

Interviews. The study consisted of a pre-test, instructional intervention, and a post-test. Both pre- and post-tests were conducted as individual interviews by a trained graduate student and me. Additionally, the two tests had the same questions, although with different numbers. The goal of the questions was to determine students' understanding of negative number values, order, and symbols (see Table 1). Although we also asked students arithmetic questions, results for those data are not discussed here. After students solved a question, we asked them to explain how they solved it, and students did not receive feedback on whether they answered correctly.

Table 1: All Pre-Test and Post-Test Questions for Each Category

Category	Number	Pre-Test Questions	Post-Test Questions
Counting	1	*Start at five and count backwards as far as you can. Can you count back any further? Is there anything less than <last number said>?*	
Number Line	1	*Fill in the missing numbers on the number line.* 	
Ordering	2	*Put these number cards in order from the least to the greatest. Which is the least? Which is the greatest?*	
		a. $\boxed{2}$, $\boxed{-3}$, $\boxed{0}$, -$\boxed{9}$, $\boxed{3}$, $\boxed{8}$, $\boxed{-5}$	a. $\boxed{5}$, $\boxed{-2}$, $\boxed{-8}$, $\boxed{1}$, $\boxed{7}$, $\boxed{-4}$
		b. $\boxed{6}$, $\boxed{-6}$, $\boxed{4}$, $\boxed{-7}$, $\boxed{3}$, $\boxed{-1}$	b. $\boxed{3}$, $\boxed{8}$, $\boxed{-9}$, $\boxed{-7}$, $\boxed{0}$, -$\boxed{5}$
Greater	7	*What are these two numbers? Circle the one that is greater.*	
		a. 8 vs. 6	a. 6 vs. 4
		b. 3 vs. –9	b. 5 vs. –7
		c. –2 vs. –7	c. –3 vs. –1
		d. –5 vs. 3	d. –8 vs. 4
		e. –8 vs. –2	e. –6 vs. –2
		Two children are playing a game and trying to get the highest score. Circle who is winning.	
		f. Abigail: 4 vs. Joseph: –7	f. Amy: 5 vs. Ken: –9
		g. Crystal: –7 vs. Leon: –3	g. Dan: –8 vs. Will: –6

Instructional intervention. Based on their performance on the pre-test, students were stratified and randomly assigned to one of three instructional groups. The groups were designed to provide students with differing levels of exposure to negative numbers so that I could explore the ways in which their mental models change. I taught each instructional group for eight, 45-minute sessions and followed strict lesson plans to maintain proper instructional treatments.

The *Integer Operations* group only had exposure to negatives. They learned how to use a number line to move *more positive, more negative, less positive, and less negative,* but they did not learn specifics about negative numbers. The *Integer Properties* group learned about the values and order of negative numbers as well as how to tell the difference between positive and negative numbers and minus and negative signs. Finally, the *Combined Integer Instruction* group had three lessons in common with the *Integer Properties* group and five in common with the *Integer Operations* group. Therefore, they learned the order and value of negatives as well how to use movements of more and less on a number line to add and subtract integers.

Data Analysis

To analyze the data, I first transcribed students' responses to the pre- and post-test questions and classified them as correct or incorrect. The counting and number line tasks needed to include negative numbers to be considered correct. Based on the methods employed by Vosniadou and Brewer (1992) to identify mental models of the Earth, I first formulated possible integer mental models using previous results from the literature (Peled et al., 1989) and the CCSN as a guide. For each test, I then coded students according to the mental model that would account for the pattern of their responses to the interview questions. As I coded, I created additional mental model categories when necessary to capture differences in students' responses that were not depicted by the initial mental models hypothesized from the literature. As found by Vosniadou and Brewer, some students fell into categories that were mixed versions of two other categories, which suggests they have inconsistent mental models. Once all students were categorized according to an integer mental model, I compared the percentage of students with each mental model in each instructional group before and after instruction.

Results

Overall, across the pre-test and post-test, students demonstrated a variety of mental models for integers, reflecting initial, intermediary, or formal understanding of the concept.

Initial Mental Models (in ascending order)

Whole number mental model. Students with a whole number mental model treated all negatives as if they were positive. When counting backward they stopped at zero or one, their number lines only included whole numbers, they ordered negative numbers next to positive numbers (e.g., 0, 3, –5, –7, 8, –9) and choose greater integers based on absolute value (e.g., –9 > 3).

Continuous zero mental model. Although students with a continuous zero mental model also treated negatives as if they were positive, these students used repeating zeroes on their number lines and/or when counting backward as demonstrated by Student 403: "Five, four, three, two, one, zero, zero, zero." Similarly, Bishop, Lamb, Philipp, Schappelle, and Whitacre (2011) had three first graders label multiple zeroes when playing a number line game. Their treatment of zero suggests that these students have some idea that the mental number line continues indefinitely less than one.

Absolute value mental model. The absolute value mental model is the first which involves students noticing a difference between positive and negative numbers. Students with this mental model separated the negative numbers from the positive numbers when ordering them (sometimes correctly) but continued to claim that negative numbers have the same values as their positive counterparts. Therefore, while they might have correctly ordered negatives before zero, they still claimed that –9 is greater than 3 and –7 is greater than –2.

Symbolic mental model. Students with the symbolic mental model correctly counted into the negatives. Additionally, when filling in the number line, they often did so correctly but used their own notation to indicate negative numbers. For example, one student wrote "N3" for negative three, while another student used an "X" instead of "N." Consequently, when ordering and determining which integer was greater, they treated all negative numbers as if they were whole numbers because the problem notation did not match their invented notation. This result highlights the importance of the role of symbols in the central conceptual structure of integers. It is possible they could have ordered the numbers using their own notation, but, unfortunately, this was not tested. Therefore, the students' understanding in this category may be understated.

Ordered nothings mental model. A few students not only separated negative numbers from positive numbers when ordering them but also treated negatives as worth zero. One student justified her order of the numbers (–3, –5, –9, 0, 2, 3, 8) explaining that "nine minus nine is zero," as is five minus five and three minus three. Later, when comparing –2 and –7 she explained that although 7 is greater than 2, both of these numbers were zero.

Intermediary Mental Models (in ascending order)

Separated value mental model. The separated value model is the first example of a mental model where students start to add to their CCSN instead of trying to fit negative numbers into positive number rules. Students with this mental model could correctly order integers and could determine the larger of two negative integers *or* the larger of two positive integers. However, when given a group of positive and negative integers, the students ignored the negative numbers when determining which number in the group was greatest or least. Therefore, a student in this category might say that –3 is greater than –5 and 2 is greater than –3 but when given –5, –3, 2, and 8 would say that 2 is the least. This behavior may arise from students thinking that anything less than zero is not a real quantity.

Equal/Unequal magnitude (mixed) mental model. Students with this mixed model gave responses consistent with having a whole number mental model for some order and value questions and a magnitude mental model for others.

Magnitude mental model. Students with a magnitude mental model ordered negatives before zero but either reversed their order (e.g., –1, –6, –7, 3, 4, 6) and claimed that –7 is greater than –2 or ordered the negatives correctly but thought that numbers further away from zero were larger, again claiming that –7 is greater than –2.

Equal/Unequal integer (mixed) mental model. Several students treated negatives as positive while ordering them but then correctly determined the greater of two integers for all combinations of integer pairs. These students had both whole number and integer mental models.

Dual value (mixed) mental model. Students with the dual value mixed mental model always identified negatives as smaller than positive numbers but sometimes treated negatives further away from zero (e.g., –9) as larger and sometimes correctly identified them as smaller than negative numbers closer to zero (e.g., –1). It is possible that students with these mixed mental models were in the process of transitioning from relying on one mental model to the other. On the other hand, their responses could have been influenced by the context of the question.

Formal Integer Mental Model

Students with a formal integer mental model correctly ordered negative numbers in relation to positive numbers and consistently identified the greater integer regardless of whether two or several integers were presented.

Changes in Integer Mental Models

While students across instructional groups had a similar spread of mental models on the pre-test (15–17 students in each group started with initial mental models), there were several changes by the post-test. Table 2 shows how students' mental models shifted in each instructional group. The cells show the percentages of students in each instructional group who started with a particular integer mental model (initial, intermediary, or formal) on the pre-test and ended with a particular mental model on the post-test. Students who started with initial mental models and shifted to formal mental models made the greatest transition.

As shown in Table 2, most students in the Integer Operations group (who did not learn about the properties of negatives) started with initial mental models on the pre-test and still had initial mental models on the post-test. On the contrary, most students in the other two groups transitioned from having initial mental models on the pre-test to having intermediary or formal mental models of integers on the post-test.

Table 2: Percentage of Students with each Mental Model on Pretest and Post-test by Instructional Group

		Mental Models on (Pretest, Post-Test)					
Group	***n***	**(I, I)**	**(M, M)**	**(F, F)**	**(I, M)**	**(M, F)**	**(I, F)**
Combined Instruction	20	20%	0%	10%	**35%**	5%	**30%**
Integer Properties	20	5%	5%	10%	**35%**	10%	**35%**
Integer Operations	21	**62%**	5%	14%	10%	0%	10%

Note. I = Initial Mental Model; M = Intermediary Mental Model; F = Formal Mental Model. A student who falls in the (I, I) category demonstrated an initial mental model on both tests.

To test whether the average differences in mental model advancement were due to the instructional treatments versus chance, I used the Kruskal-Wallis 1-way ANOVA by ranks (Shavelson, 1996). Students who had reached ceiling (i.e., had formal mental models) on the pre-test were eliminated from the analysis, which resulted in 18 people per instructional group. Results indicate a significant effect for instructional group ($H_{observed}$=9.8064, $H_{critical}$=5.99, α<.05). Pairwise comparisons reveal that the Combined Instruction (mean rank = 31) and Integer Properties (mean rank = 34) groups improved significantly in terms of developing more formal mental models for negative numbers than the Integer Operations group (mean rank = 17) (HSD = 7.76, α < .05). There was no significant difference between the Combined Instruction and Integer Properties groups.

Students in the Combined Instruction and Integer Properties groups both had instruction on the properties of negative numbers; however, only one student from the Integer Properties group continued to have an initial mental model for integers at the post-test. Furthermore, this student progressed from treating all negatives as positive (Whole Number Mental Model) to interpreting the value of negative numbers as different from positive numbers (Ordered Nothing Mental Model). On the other hand, four students in the Combined Instruction group continued to have initial mental models for integers at the post-test, and all four treated negative numbers as if they were positive (Absolute Value and Continuous Zero Mental Models). This difference is suggestive that spending focused time (more than 3 days) on integer properties helped students in the Integer Properties group develop more advanced mental models. This result would need to be studied further, though, to determine how generalizable it is and whether it can be replicated.

Discussion and Implications

The results of this study highlight mental models that students develop for integers and provide insight into the process through which students, who have developed the central conceptual structure of number, expand or restructure their conceptual structure to include integers. As found in other research on conceptual change (Vosniadou & Brewer, 1992), the students' initial mental models for integers were constrained based on their current knowledge (in this case, their knowledge of whole numbers). Their understanding of how order, values, and numerical symbols relate led students to interpret negative numbers as a different type of positive number. Some students with initial mental models ordered negatives apart from positive numbers but did not use this information to reason that the values would also be different; meanwhile, others sorted them separately and considered negatives as amounts taken away, equivalent to zero. Further, students with intermediary mental models knew that negatives were less than zero but had not associated them with the order of numbers definitively.

Identifying students' integer mental models can help teachers better understand students' incorrect solutions to integer arithmetic problems. Further, the results of this study have implications for how curricula and instruction could support students' learning of abstract concepts and help move them along the continuum of numerical understanding. Based on the integer mental models identified, several concepts to emphasize in integer instruction over several lessons include distinguishing between the negative sign and the minus sign, understanding the symmetrical nature of the number line, distinguishing between greater distances from zero versus greater numerical values, and identifying the difference between negative numbers and zero. As with other notation and representations, students need formal explorations with negatives because exposure to them does not make their structure obvious. Students in the Integer Operations group did not learn the structure and values of negative numbers through hearing the words "positive" and "negative" without associating the words with their symbols and meaning. Instruction on negatives (and other abstract ideas) needs to help students see the structure of the concept: there is symmetry in the number sequence when zero separates the positive from the negative numbers, numbers increase as we count up through the sequence, and the minus sign takes on new roles (Vlassis, 2008). Furthermore, teachers can use familiar representations to extend students' thinking; classroom number lines or number paths should continue beyond zero into negatives (even in the younger grades), so that as students learn about negative numbers, they receive constant visual feedback of their existence.

Although curriculum developers, researchers, and policymakers continue to place negative numbers late in the curriculum—6th and 7th grades (National Governors Association Center for Best Practices & Council of Chief State School Officers, 2010)—this study demonstrates that students are quite capable of learning about integers much earlier than fifth grade. In fact, students in this study were able to learn about negatives as early as the end of first grade, although whether this would be beneficial in the long term remains to be investigated.

PRE-FRACTIONAL MIDDLE SCHOOL STUDENTS' ALGEBRAIC REASONING

Amy J. Hackenberg
Indiana University–Bloomington
ahackenb@indiana.edu

Mi Yeon Lee
Indiana University–Bloomington
miyelee@umail.iu.edu

To understand relationships between students' quantitative reasoning with fractions and their algebraic reasoning, a clinical interview study was conducted with 18 middle and high school students. Six students with each of 3 different multiplicative concepts participated. This paper reports on the 6 students with the most basic multiplicative concept, who were also pre-fractional in that they had yet to construct the first genuine fraction scheme. These students' emerging iterating operations facilitated their algebraic activity, but the lack of a disembedding operation was a significant constraint in developing algebraic equations and expressions.

Keywords: Algebra and Algebraic Thinking, Cognition, Rational Numbers

Based in part on recommendations that improved fractional knowledge is critical for success in learning algebra (National Mathematics Advisory Panel [NMAP], 2008), researchers are starting to investigate how students' fractional knowledge is related to their algebraic reasoning (e.g., Hackenberg & Lee, 2011; Empson, Levi, & Carpenter, 2011). Since this research is in its infancy, there are numerous unexplored issues. One issue is how students who conceive of fractions primarily as parts *within* wholes may be challenged when working on algebra problems. These students' challenges may extend beyond the limitations of their fractional knowledge. However, little is known about how these students' fractional knowledge may assist or limit them in building basic algebraic ideas, such as making generalizations from quantitative relationships (Ellis, 2007; Kieran, 2007) and operating on unknowns (Hackenberg, 2010).

To understand relationships between students' fractional knowledge and their algebraic reasoning in the area of equation writing, a clinical interview study was conducted with 18 middle and high school students. Six students with each of three multiplicative concepts (Steffe, 1994) were invited to participate. These concepts have been found to significantly influence students' fractional knowledge (Hackenberg, 2010; Steffe & Olive, 2010), and they are based on how students produce and coordinate composite units (units of units).

The six students with the most basic multiplicative concept also conceived of fractions primarily as parts within wholes and had not yet constructed the first "genuine" fraction scheme, a *partitive fraction scheme* (Steffe, 2002, p. 305). So, these six students could be considered pre-fractional. That meant that the students did *not* conceive of a fraction like three-fifths as three one-fifths, related to but distinct from the whole. Instead, they thought of three-fifths as embedded within the whole—as five parts with three shaded. This view of fractions relies on being able to separate a quantity represented by a segment or rectangle into parts, a mental action we refer to as *partitioning*. However, it also relies on *not* being able to disembed a part from the whole while keeping the whole mentally intact, a mental action we refer to as *disembedding*. In general, pre-fractional students can learn to partition, but they do not yet disembed.

The purpose of this paper is to investigate relationships between the fractional knowledge and equation writing of the six pre-fractional students in the study. The research questions are:

1. How do pre-fractional students solve algebra problems that involve writing equations to represent relationships among unknowns?
2. How do pre-fractional students solve algebra problems that involve generalizing activity?
3. How are students' pre-fractional ways of operating related to their equation writing and generalizing activity?

A Quantitative and Operational Approach

Quantitative Reasoning

We conceive of students' quantitative reasoning as a basis for building fractional knowledge and algebraic reasoning (Smith & Thompson, 2008; Steffe & Olive, 2012). Approaching fractions as quantities means that we pose problems to students in which fractions are measureable extents, or lengths; these lengths may represent other quantities as well (e.g., weight). Approaching algebraic reasoning from a quantitative perspective means that unknowns are quantities for which a value is not known, but for which a value could be determined. So unknowns are potential values of quantities. In working with students we routinely ask them to make drawings of quantitative relationships, and we aim for students' fraction and algebraic notation to trace the quantitative reasoning in which students engage.

Operations, Schemes, and Concepts

Our work is also based on conceiving of mathematical thinking in terms of people's mental actions, or *operations* (Piaget, 1970; von Glasersfeld, 1995). Operations critical for fractional knowledge include *partitioning* and *disembedding* as mentioned above, as well as *iterating*, which is repeatedly instantiating a fractional part to make a larger fraction. Operations such as these are *interiorized* physical actions—that is, they arise from re-processing physical actions in such a way that they can be performed mentally, without having to be carried out materially.

Operations are the components of *schemes*, goal-directed ways of operating that consist of three parts: an assimilated situation, activity, and a result (von Glasersfeld, 1995). For example, if a student has constructed a partitive fraction scheme, then a situation of the scheme is a request to make a new length that is 3/5 of a foot. The activity of the scheme involves partitioning the foot into five equal parts, disembedding one of those parts, and iterating the part to make three such parts. The student then assesses the result of her activity in relation to her expectations.

For us, a *concept* is the result of a scheme that people have interiorized. For example, a student who has interiorized the result of her partitive fraction scheme can take that result, three-fifths consisting of three one-fifths, as a basis for carrying out more activity. This student could engage in problems such as determining what the result of partitioning each of the fifths into two equal parts would be, or how to re-make the whole if the given length is three-fifths of the whole.

Characteristics of Pre-Fractional Students

Students who are pre-fractional struggle in a variety of ways. For example, Olive and Vomvoridi (2006) have analyzed the case of Tim, who had not constructed a partitive fraction scheme by his sixth grade year. At that time, one feature of Tim's fraction scheme was that both a unit fraction and the whole referred to the same partitioned image: One-sixth meant a whole partitioned into six equal parts, and six-sixths meant the same partitioned whole. This idea about fractions led Tim to add up parts regardless of size. For example, in adding ½ and ¼, Tim said the answer would be 1/5 because ½ was one part and ¼ was four parts.

In short, pre-fractional students can engage in equal-partitioning of lengths (Biddlecomb, 2002; Steffe & Olive, 2010), but they cannot take a partitioned length as given prior to engaging in activity. For example, to share a 1-foot length of licorice fairly among five people, these students have to actually partition—they cannot imagine the partitioned length prior to making it. Research also shows that constructing a disembedding operation requires a significant reorganization of these students' ways of operating that can take as long as two years (Steffe & Cobb, 1988; Steffe & Olive, 2010).

Methods

Seven seventh grade students, 10 eighth grade students, and one tenth grade student participated in this clinical interview study. Participant selection occurred via classroom observations, consultation with students' teachers, and one-on-one, task-based selection interviews to assess students' multiplicative concepts. Six students with each multiplicative concept were invited to participate; this paper focuses on the six students with the most basic multiplicative concept. Three of these students were enrolled in a seventh grade mathematics class for struggling students; the other three students were taking an eighth grade pre-algebra class. The three seventh grade students and one of the eighth grade students received special education support for one period per day. All pre-fractional students had received some instruction in their mathematics classes on unknowns and equation solving.

Students participated in two 45-minute, semi-structured interviews, a fractions interview and an algebra interview. All students completed the fractions interview prior to the algebra interview, but the time between interviews varied from 3 weeks to 4 months. The interview protocols were refined in a prior pilot study (Hackenberg, 2009) and were designed so that the reasoning involved in the fractions interview was a foundation for solving problems in the algebra interview. For example, one fractions interview task was the following: “A 65-cm stack of CDs is 5 times the height of another stack. Can you make a drawing of the situation and determine the height of the other stack?” In the algebra interview, students were posed a similar situation but both heights were unknown. Students were asked to make a drawing and write equations to represent the situation. In addition, students completed a written fractions assessment (Norton & Wilkins, 2009) to triangulate claims about their fractional knowledge. This assessment confirmed that the students identified as pre-fractional were pre-fractional.

Each interview was video-recorded with two cameras, one focused on the interaction between the researcher and student, and one focused on the student’s written work. The videos were mixed into one file for analysis, which occurred in three overlapping phases. The first phase of the analysis was to formulate a model (Steffe & Thompson, 2000) of each student’s fraction operations, schemes, and concepts; equation writing and solving; and generalizing activity, to the extent possible over two interactions. Toward this end, the researchers viewed videofiles and took detailed analytic notes (Cobb & Gravemeijer, 2008), which included transcriptions, data summaries, memos, and conjectures. The resultant models provided the basis for responding to the first two research questions for this paper.

In the second phase of the analysis, the researchers looked across the students to articulate differences in how students with different multiplicative concepts solved the problems in each interview. Products of this phase included written syntheses of the ways of operating of students with a particular multiplicative concept, which provided an important backdrop for responding to the three research questions in this paper. Finally, in the third phase of analysis researchers examined how the operations, schemes, and concepts that constituted students’ fractional knowledge were involved in students’ equation writing and generalizing activity. This phase was the basis for responding to the third research question for this paper.

Analysis and Findings

Equation Writing and Multiplicative Relationships

Two of the six pre-fractional students, with significant coaching, wrote equations to represent multiplicative relationships between unknowns that were correct from the researchers’ perspectives. Our analysis suggests that the students’ emerging iterating operations were one reason these students were successful, but that the lack of a disembedding operation was a major source of the difficulties that even these two students experienced in conceiving of unknowns in multiplicative contexts. In this section we present one student’s work on the first problem in the algebra interview to substantiate these claims.

The first problem in the algebra interview was the following:

> A1. *Cord Problem.* Stephen has a cord for his iPod that is some number of feet long. His cord is five times the length of Rebecca’s cord. Could you draw a picture of this situation? Can you write an equation for this situation? Can you write another equation?

Initially all pre-fractional students made a drawing for A1 in which one of the lengths (represented by a segment or rectangle) was a little more than half of the other. Only two students refined their pictures to make a more accurate representation by iterating a shorter segment five times to make a longer segment. Only one of these two students, 7th grader Henry, wrote a multiplicative equation for A1 that was correct from the researchers’ perspectives.

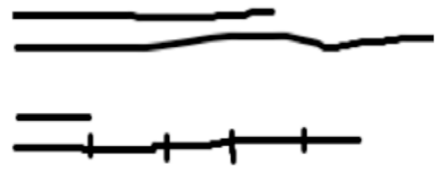

Figure 1: Henry's work on A1

In Henry's initial picture for A1, the segment representing Rebecca's cord length was longer than Stephen's, and Stephen's segment was a little more than half of Rebecca's (Figure 1, top two segments). Without any intervention from the interviewer, Henry reinitiated his activity and drew a small segment. Then he drew a copy of that segment below, and he proceeded to draw four more copies, pausing after each copy (but not lifting his pen). So he repeated one cord length five times, and this new segment represented the other cord length (Figure 1, lower two segments; hash marks have been added for clarity). Henry called the long segment Rebecca's and the short segment Stephen's. However, Henry switched these meanings when the interviewer restated the problem. Spontaneously initiating the repeating of a segment was novel, and it suggested that Henry had constructed an iterating operation that he would need for constructing more advanced fractional knowledge.

Henry's initial equation for A1 was "$S \cdot$ O = Rcord," which he said meant "Stephen's cord times what Rebecca's cord is, equals Rebecca's cord." He said that he wrote an "O" to "leave it open," since he did not know the length of Rebecca's cord. Then, in discussion with the interviewer about how many of Rebecca's segments would fit into Stephen's in Henry's picture, Henry generated a correct equation, "$R \cdot 5$ = Stephens cord." In explanation, he changed the 5 to a 4, saying, "No, Rebecca's times four equals Stephen's cord, 'cause she already has one [of the segments]." This conflation suggests the lack of a disembedding operation: Rather than consider Rebecca's cord as one part of Stephen's, Henry appeared to think of Stephen's as five parts, one of which had to be Rebecca's, leaving Stephen with only four parts.

The researcher then posed a numerical example in order to test the equation: "Let's say Stephen's cord length is 15 feet; how long is Rebecca's cord?" Henry spent nearly 6 minutes determining Rebecca's cord length. He initially thought it would be 10 feet. Then he tried 5 feet and arrived at 15 feet. He appeared to be iterating an amount three times, because then he said "three, 9 feet." In this process, Henry extended the segment for Stephen's cord length by another segment the size of Rebecca's cord length, so Stephen's length then consisted of six segments (later Henry crossed off this part following questioning from the interviewer). We note that confusing "five times" and "five more than" is a sign of not having constructed iteration (Steffe & Olive, 2010, p. 182). So, despite Henry's later correction of his drawing, this work throws some doubt on whether Henry had indeed constructed an iterating operation for segments.

To explain his answer of 9 feet for Rebecca's length, Henry counted by threes along the first four parts of Stephen's segment, and then counted by ones ("13, 14, 15") along the fifth part. When the interviewer repeated back to Henry how he had counted along Stephen's segment, Henry changed his mind. "Yeah, hers is like three feet," he said.

Finally, the interviewer asked Henry about his equation—whether he wanted to use 4 or 5. Henry said four, although under questioning he agreed that 3 x 4 was not 15. Following that exchange, Henry changed his equation back to "$R \cdot 5$ = Stephens cord." When asked for any other equations he could write for the situation, he wrote "$5 \cdot 3 = 15$, $3 \cdot 5 = 15$, and $3 \div 15 = 5$."

Our current interpretation of Henry's work relies on the fractional operations we could attribute to him. Although the evidence is not incontrovertible regarding Henry's operation of iteration, Henry appeared to have something like iteration available—or becoming available—based on how he made his drawing for A1. The spontaneous change that he independently made in his drawing allowed him to create a quantitative foundation for his algebraic work that was a key reference during the rest of his activity. Since only one other pre-fractional student in the study made a similar drawing, we infer that creating this kind of drawing to show one segment and another that is five times longer is not a trivial achievement for a pre-fractional student.

In addition, although Henry received significant support from the interviewer in order to write a correct equation, we suggest that his emerging operation of iteration allowed him to make sense of the support that the interviewer offered in terms of questions about his picture. In contrast, none of the other pre-fractional students wrote a similar equation with similar questions—not even the pre-fractional student who generated a drawing similar to Henry's.

However, we suggest that Henry's lack of a disembedding operation, as shown most clearly in him changing the 5 to a 4 in his equation, was a constraint for him. That is, although with the support of the interviewer's questions Henry did return to a correct equation, it's not clear whether using 5 was a logical necessity for him. Indeed, without a disembedding operation it would be unlikely for Henry to make sense of a segment that is five times another, because that relationship appears to require thinking about the other segment as both embedded in and disembedded from the longer segment. So, without that operation, it would be more natural for Henry to think of the longer segment as "four more" than the original segment. This analysis indicates that writing equations representing multiplicative relationships between quantities would be quite challenging for students without disembedding operations.

Making Generalizations: Solving The Border Problem

In contrast to their work on A1, five pre-fractional students solved parts (a), (c), and (d) of the Border Problem, which has been used to introduce ideas of unknowns and variables to middle school students (Boaler & Humphreys, 2005):

A7. *Border Problem.* Below is a 10 by 10 grid with the squares on the border shaded.

(a) Without counting one-by-one, and without writing anything down, can you find a way to determine how many squares are on the border?
(b) Can you find another method?
(c) Can you apply your first method to a 6 by 6 grid?
(d) How would you describe in words how to use your first method on any grid?
(e) How would you use algebra to write an expression to communicate your first method to someone?

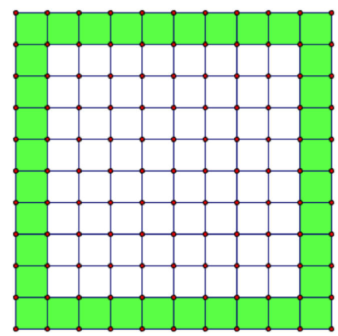

Figure 2: Border problem

All six pre-fractional students initially thought that there were 40 squares. Upon counting to check, five students adjusted their initial idea based on observations about counting the corner squares of the grid twice. Two students adjusted by subtracting 4 from 40. Three students, including Henry, adjusted by adding 10 and 10 for the top and bottom sides, and then adding 8 and 8 for the left and right sides (eliminating both corner squares from these sides). All five students applied their method to a new grid, a 6 by 6 grid, and verbally described their method to some degree. The two most detailed verbalizations were from Henry and another 7th grade student, Courtney, which we state below.

Due to time constraints, only these two students were asked to use algebra to communicate their methods (part (e)). Courtney said she did not know how to do that, even after discussion with the interviewer about using a letter to represent the number of unit squares in one row of the grid. However, Courtney did then apply her method correctly to a 15 by 15 grid without drawing that grid. Henry also had a discussion about part (e) with the interviewer, who suggested that x could represent the number of unit squares in one row. After asking Henry what x was in each of the first two grids (the 10 by 10 and 6 by 6), the interviewer asked if Henry could use x to write down an expression for the number of squares on the border. Henry wrote "x = top row 10" and then underneath "x = top row 6." Then he added the 10 and the 6 to get 16. So, no student made a correct solution to part (e) from the perspectives of the researchers.

Yet the five students who solved parts (a), (c), and (d) did generate a method for determining the number of squares on the border, used it on a grid of different size, and verbalized the patterns they observed. We assess that in doing so, they engaged in two forms of generalizing activity (Ellis, 2007): They extended their reasoning beyond the range in which it originated, and they began to identify commonalities across cases. However, we propose that the students' lack of a disembedding operation constrained the nature of their generalizations and prevented them from writing an algebraic expression. Although these conclusions were made from analysis of all data, we use Henry and Courtney as examples for explaining them, in part because these two students demonstrated some of the more advanced thinking of the pre-fractional students.

Henry's generalizing activity. In describing in words how to use his method on any size grid (part (d)), Henry said, "I'd tell them to do the top first, see how much in a row it would be [pointing at a row]. And then do the bottom, which is the same. And then after that, like, whatever number's at the end [corner], go to the next box [down] on the other side and put, like, put how much it is. Don't use the same number two times." When asked if by his last statement he meant "don't count a corner square again if you've already counted it," Henry agreed. The interviewer then asked how Henry knew, in the 6 by 6 grid, that the other side had to be four, and whether the four had any relationship to the six. Henry's response was inaudible. When the interviewer asked the same question about 8 and 10 in the 10 by 10 grid, Henry said "Huh?" and proceeded to label his drawing with numerals.

From this data excerpt, we conclude that Henry did not articulate the relationship between the 4 and the 6 and the 8 and the 10 structurally. In other words, he did not appear to see 4 as embedded in 6 and also separate from the 6 in terms of the side lengths of the grid (and similarly for 8 and 10). This means that in thinking about the grid he did not disembed 4 from 6 (or 2 from 6) while leaving the 6 intact—and we infer he did not do so because he had not constructed a disembedding operation. His comments do provide evidence that he knew two different numbers should be involved—that a person can't just add the same number four times as he initially did. But the lack of a disembedding operation contributed to Henry's generalization about adding the number of unit squares in the top and bottom rows, and then adding a different pair of numbers for the other sides of the grid. This generalization might lead to writing something like $x + x + y + y$ as an algebraic expression, but it would not lead to something like $x + x + x - 2 + x - 2$.

Courtney's generalizing activity. In contrast with Henry, Courtney subtracted 4 from 40 in solving the Border Problem. In writing down her method, she first wrote multiplication signs in between each of the four tens, changing them to addition signs under questioning from the interviewer. In verbally describing her method, she said, "Since a square has ten [sic] sides, on each one, I'd add ten plus ten four times and then I subtracted four 'cause I counted all four ends [corners], and I counted them twice. So I subtracted four since there are four sides. For the 10 by 10 I got 40 and then I subtracted 4 and I got 36." To clarify, the interviewer asked Courtney why she added 10 four times, and Courtney said it was because the square had four sides. At this point the interviewer did not probe for clarity about reasons for subtracting four. However, prior to this data excerpt and within it, Courtney said she subtracted four in order to not count corner unit squares twice. In fact, except for stating that she subtracted four due to there being four sides, her generalization does not seem problematic in any obvious way.

Yet based on our model of Courtney, we claim that she did not write an algebraic expression for her generalization in part because of how she thought about the "ten plus ten four times" and the 40. Since we knew Courtney had not constructed a disembedding operation, we knew that taking a number (such as 10) some number of times was a significant cognitive load for her (Steffe, 1994). When students like Courtney take a number (10) and repeat it, they do not consider these numbers (four 10s) as both embedded in and disembedded from the result (40). Instead, it's like the tens disappear after they have been used. In short, Courtney's method really was not 10 + 10 + 10 + 10 – 4, structurally; we infer she did not generate awareness of the 10s as segments of the 40 in the process of and after computation. This conclusion is supported by Courtney's multiple ways of describing and notating the use of 10s to make 40. This analysis indicates that it was quite reasonable for Courtney *not* to know how to use the interviewer's suggestion to let x represent the number of squares in one row in writing an expression for her method, since the relationship between the number of unit squares on each side and the total number of border squares was rather ephemeral for her.

Discussions and Conclusions

This study contributes to understanding why pre-fractional students struggle with algebra. In particular, it suggests that these students' iterating operations may facilitate their representation of multiplicative relationships between quantities, and that these students' lack of a disembedding operation is a significant constraint in developing algebraic equations and expressions. It also suggests that students' fractional operations shape the generalizing activity in which they engage. For example, without a disembedding operation, pre-fractional students will be unlikely to distinguish amounts that are both contained within and separate from other amounts in a quantitative situation—and doing so is critical for creating a structural view of many situations that can be represented with algebraic notation.

Implications for algebra instruction for pre-fractional middle school students include the pressing need to develop curricular materials that provide support for helping these students advance their fractional and algebraic knowledge simultaneously. These materials need to be based on the ways and means of operating of the students so that these students will not be left out of making mathematical progress, and so that their mathematical thinking will not remain invisible or under-valued in an environment where extant curricular materials assume operations that these students are yet to construct.

FRACTION OPERATION ALGORITHMIC THINKING: LEVERAGING STUDENTS' USE OF EQUIVALENCE AS A TOOL

Debra I. Johanning
University of Toledo

Kimberly.Shockey@utoledo.edu

The data used for the qualitative analysis reported here were generated as part of a larger study to understand and characterize teacher practice related to engaging students in algorithmic thinking associated with the fraction operations of addition, subtraction, multiplication and division. This paper presents ways in which teachers used students' emergent ideas to leverage the use of equivalence as a tool, rather than a procedure, to support students as they work to develop algorithms for operating with fractions.

Keywords: Rational Numbers; Instructional Activities and Practices; Middle School Education

Purpose

Prior work on teacher practice acknowledges the complexity of instruction when teachers aim to engage students in authentic mathematical activity where the instructional path is not specified and teachers themselves engage in sense-making as they make instructional decisions (Ball & Bass, 2003; Kazemi & Stipek, 2001; Stein, Smith, Henningsen, & Silver, 2000). In their review of the collective literature on teaching and classroom practice, Franke, Kazemi and Battey (2007) offer that effective teaching involves more than having a rich task or eliciting students' thinking. They argue that the field would benefit if the complexity of teacher practice were examined using a domain-specific approach leading to the identification of routines of practice, or core activities, that should occur regularly within particular mathematical domains.

From an instructional perspective, fraction operations are especially complex (Lamon, 2005; Ma, 1999; Borko et al., 1992). The literature (e.g., Kamii & Warrington, 1999) has documented that students can invent, or reinvent, procedures for operating with fractions. However, there has been little consideration of the role that a teacher might play in supporting students to construct such strategies and procedures. In this paper we draw from our work with four experienced and "skillful" teachers whose approach to teaching fraction operations involves positioning student to invent, or reinvent, their own procedures for operating with fractions. It is argued that the ways in which the teachers leveraged student reasoning to draw out perspectives on equivalence is an important aspect of teacher practice associated with instruction that emphasizes a *guided-reinvention* approach to fraction-based algorithm development (Gravemeijer & van Galen, 2003).

Theoretical Framework

In their discussion of a *guided-reinvention* approach to algorithm development, Gravemeijer and van Galen (2003) emphasize that instead of concretizing mathematical algorithms for students, teachers can use an instructional approach where students develop or reinvent algorithms for themselves. Given the opportunity to reinvent mathematics in somewhat the manner that it played out historically, students can experience mathematical knowledge as a product of their own activity. "The core idea is that students develop mathematical concepts, notations, and procedures as organizing tools when solving problems" (Gravemeijer & van Galen, 2003, p. 117). Related to guided-reinvention is the notion of emergent-modeling (Gravemeijer, 2004). When instruction is designed to support emergent-modeling, instead of trying to concretize mathematical knowledge, the objective is to help students model their own informal mathematical ideas. From this informal modeling, more formal ways of reasoning can emerge. The teacher plays a role in supporting this development. This work characterizes practice where teachers supported students' mathematical activity related to fraction operations, and the role of equivalence, without taking over the guided-reinvention process or reducing the cognitive demands of the work.

Equivalence concepts are fundamental if students are going to be able to operate meaningfully with fractional quantities. The flexibility to understand and view fractional quantities as having many names all representing the same number, the ability to generate equivalent fractions meaningfully, and the ability to perceive the relationship between equivalent fraction representations, are important features in algorithm development (Lamon, 2005). The students in this study explored equivalence as a conceptual idea and as a skill in an instructional unit that preceded the unit where data was collected for the study reported here. In the data we focus on ways in which teachers drew from students' informal reasoning in order to support the notion of equivalence as a tool when operating with fractions. It was not suggested to students in advance that they needed to have or use equivalent fractions. It emerged from their mathematical activity. It was present in their informal work when making sense of and solving problems that would lead to adding, subtracting, multiplying and dividing fractions.

Methodology

The settings for this study were the classrooms of four sixth-grade teachers and their students. Each of the teachers used the Connected Mathematics Project (CMP) II instructional unit *Bits and Pieces II: Using Fraction Operations* (Lappan, Fey, Fitzgerald, Friel, & Phillips, 2006a) as their primary curriculum source. This unit uses a guided-reinvention approach to developing meaning for fraction operations. It allows algorithms to arise through student engagement with both contextual and number-based situations. In this setting, assumptions can be made about the tasks used and about the fraction-related concepts that were developed prior to, and during the unit on fraction operations. In the timeline for the sixth graders who are part of this study, students came to the fraction operation unit with previous experiences that supported their understanding and ability to use equivalent fractions. Prior to implementing the *Bits and Pieces II* unit, the *Bits and Pieces I: Understanding Fractions, Decimals and Percents* (Lappan, Fey, Fitzgerald, Friel & Phillips, 2006b) unit was also implemented.

This study used a qualitative design. During the teaching of the *Bits and Pieces II* unit, classroom lessons were videotaped each day during the 5–6 weeks it took to cover the unit. In addition, the teachers wore an audio recorder during each lesson. The audio recorder was used to record the small group conversations teachers had with students. When a teacher completed a lesson, they also audio recorded a short 5-minute reflection on the lesson. When visiting, the researchers engaged in participant observation. This included observing, taking field notes, interacting with students during small group work time, and meeting with the teacher after the lesson to seek their perspectives on the lesson. During the summer the researchers and teachers came together for three days to discuss their teaching. The three days of summer work were also videotaped for data analysis. Ways teachers purposefully leveraged the use of equivalence as a mathematical reasoning tool was one of the topics discussed.

Data analysis was guided by Erickson's (1986) interpretive methods and participant observational fieldwork, which addresses the need to understand the social actions that take place in a setting. The multiple data sources allowed for triangulation. The school-year data was transcribed and analyzed for emerging themes. The analysis led to characterizations for leveraging equivalence as a tool. It focused on themes related to what teacher elicited from students during whole class discussions when they were sharing strategies for solving problems, and how these elicitations positioned students to move from informal to formal mathematical reasoning.

Findings

In order to capture how a teacher might leverage students' informal reasoning with equivalence in support of helping them articulate strategies for operating with fractions, characterizations of practice are provided for each addition/subtraction, multiplication, and division. Specific project teachers are not identified in the dialogue. These findings are presented as a collective view of what was observed in the classroom data and what emerged in the collaborative work that took place during the summer workshop.

Addition/Subtraction

The work on addition and subtraction began with a task where students drew on past work that involved partitioning and naming fractional quantities. The problem, referred to here as The Land Problem (see Lappan et al., 2006a, pp. 17–19 for full problem), used an area model where square sections of land where divided into smaller sections for farming. Initially, the task asked students to determine what fraction of a section of land each farmer owned. Depending upon how students partitioned the land, various equivalent fractional names emerge for different farmers. As part of their arguments, students visually partitioned their map into equal-size parts and showed, for example, that Bouck owned 1/16 of a section or Foley owned 5/16 of a section. Some students would cut out a farmer's section, for example a Kreb's piece, and then show 32 Krebs-size pieces filled Section 18 and that Bouck's land could also be called two 32nds of the section. Figure 1a shows a map where a teacher recorded the fractional values that emerged from students' work. An important idea that emerged from this part of the problem was that collectively students offered more than one possible fractional name for each section.

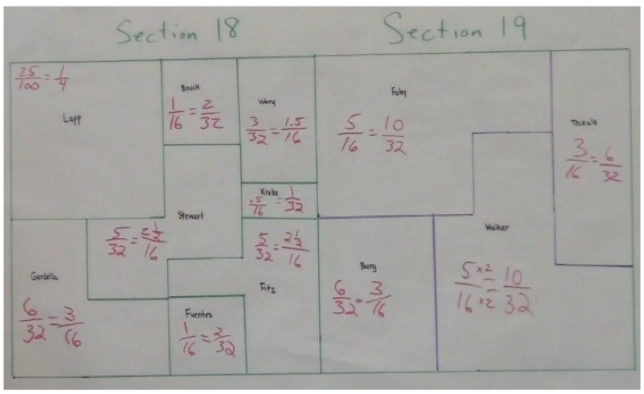

Figure 1a. Land map solutions

(1) 5/16 + 3/16 = 8/16 = ½

(2) 10/32 + 6/32 = 16/32

(3) 10/32 + 6/32 = 16/32 = ½

(4) 5/16 + 6/32 = 16/32

(5) 5/16 + 3/16 = 8/16

Figure 1b. Number sentences

The next part of the Land Problem asked students to combine various sections of land and write a number sentence for their solution. One problem posed was: *Lapp and Bouck combine their land. What fractions of a section do they now own together?* These number sentences were offered by students during discussion: 4/16 + 1/16 = 5/16 and 8/32 + 2/32 = 10/32. Here, as is typical of students who solve this problem, they used fractions with common denominators to write their number sentences. This emerges intuitively. Students did not do this because they were prompted to. When presenting their number sentences, students were asked to show on the map, how they knew their number sentences were true. The teacher then extended students' ideas to draw upon equivalence as a tool by asking them to consider ideas like the following:

- When we put Lapp plus Bouck together some of you said the answer was 10/32 and some of you said the answer is 5/16. Are those amounts the same? Or are they different?
- I am going to throw up another example. I have some kids who look at Lapp and say that Lapp is ¼ of Section 18. Is Lapp ¼ of that section? [class says "yes"] And we are supposed to add Bouck to it. So for example, I could say that Bouck is 1/16. Is Bouck 1/16? [class says "yes"] So I am going to write the number sentence ¼ + 1/16 = 5/16. Is that a true statement?

In response to the later scenario, some said "yes" and others said "no." The teacher asked students to talk to their groups and prove if it was true. The class conversation then went:

T: Tara I heard you say something. Would you share it?
Tara: It is right but if you wanted to make it an easier addition problem to do, you could change the ¼ into 4/16. Then you would have the same denominators.
T: Would that make it easier?
Class: Yes.
T: How many of you agree with that?
Class: [Most students raise hand.]
T: Is this sentence right here [1/4 + 1/16 = 5/16] a true sentence?
Class: Yes.
T: Can someone say what it is about this sentence [1/4 + 1/16 = 5/16] that makes it hard to say if that is right or wrong?
Sam: Because the denominators are different?
T: What does that tell us about the size of the pieces.
Liam: They are different.
T: We are talking about a unit here [points to Lapp on map] that is fourths and then a unit here [points to Bouck on map] that is sixteenths. And it is kind of hard to put that together and say what it is.

There was a similar discussion when the teacher posed the following: *Foley and Burg combine their land. What fraction of a section will they now own together?* Figure 1b contains a string of number sentences that emerged during this discussion. Again, students were asked to use the Land Problem map to argue that their solutions were sensible. A student offered number sentence 1 in Figure 1b. Another student then offered number sentence 2 in Figure 1b.

T: You didn't get the same fraction that the other group had…Can someone talk to us about that? One is 8/16 and one is 16/32. Who is right?
Drew: They are both equal.
T: How do you know they are both equal?
Kayla: Because 8 times 2 is 16 and 16 times 2 is 32.
T: So if you have 16/32 of the whole section, how much to you have?
Kayla: ½. [Writes number sentence 3 in Figure 1b.]
T: So, Isabel, what does that say about both answers?
Isabel: They are both equal.
T: Let me ask another question. I had a kid last year that did it a different way. He said Foley was 5/16. Then he looked at Burg [on map] and wrote 6/32. Then for the answer, he wrote 16/32. [See number sentence 4 in Figure 1b.] Would that number sentence work?
Class: [There were both yes and no responses.]
T: Talk with your table. [Students talk.] Daniel.
Daniel: The answer works but not the sentence. But the answer is the right answer.
T: Oh. So the answer works but not the sentence.
Leah: If it gives the right answer then it is true.
Others: No.
Tara: Really, you can change 6/32 to 3/16 and 16/32 is 8/16…[this gets recapped and number sentence 5 in Figure 1b is recorded.]
T: Let me ask again, is this sentence [5/16 + 6/32 = 16/32] a true sentence?
Class: [some said yes and some said no]
T: Yes. This is a true sentence. Because we know that Foley really is 5/16. We know Burg really is 5/32. But, what helps us think about it? Daniel, I heard you say you don't like this sentence. What is it about that sentence that made it hard for you?
Daniel: There are different denominators

T: Yeah. The pieces are not the same size. So what were you guys doing to make these easier for you? So they weren't confusing.
Lacey: Changing the denominators.
T: Yeah. You were changing the denominators and then adding the amounts.

Using equivalence as a tool, the teacher leveraged students' reasoning to draw out several ideas. One idea was to make explicit why students were choosing fractions with common denominators. They were doing this intuitively. By leveraging equivalence as a tool, students were able to explain why this was helpful. This is a key component of the algorithm they are working toward. A second idea involved using equivalence to compare three different solutions (i.e., 8/16, 16/32, and ½) in order to verify they were all correct. This supported students' ability to read and work with mathematical symbolism. When students move on to problems that do not have a context, they will need to use equivalence as a tool to show others how they are working with and manipulating quantities.

Multiplication

There were opportunities to leverage equivalence as a tool when working with fraction multiplication. In one conversation students were finding fractional sections of fractional parts (parts of parts) in a scenario that involved brownie pans (see Lappan et al., 2006a, pp. 32–33 for full problem). For example, *What fraction of a pan will I have if I buy ¾ of a pan that is ½ full?* In these scenarios, the problems were presented as "part of part" problems. At this point in the work, an algorithm was not established nor pushed for explicitly. When modeling ¼ of 2/3, two different diagrammatic approaches were used leading to two different number sentences: ¼ of 2/3 = 2/12 and ¼ of 2/3 = 1/6. Students were asked to consider whether these were both true and how they knew. Students used their diagrams and equivalence as a tool to argue that both 2/12 of a pan and 1/6 of a pan were the same amount.

After working through numerous brownie pan problems, a student offered that when she wrote her number sentences she noticed that it looked like you could just multiply the numerators across and the denominators across and it would work too. Many students were still trying to understand what ¼ of 2/3 meant and so the teacher suggested that this student continue to draw her brownie pan models and test her idea to see if worked across numerous problems.

On the second day of the unit, students were introduced to multiplication symbolism where ¾ of ½ is formally written as ¾ × ½. They were also asked to use estimation and number sense to consider whether the following problems would lead to products greater than or less than one whole: 5/6 × ½, 5/6 × 1, 5/6 × 2, and 3/7 × 2. The student who had been contemplating how to operate symbolically started the following discussion.

Libby: When there is a whole number, not so much when estimating, but remember how I told you before [referring to her idea to multiply numerators and multiply denominators]. For 5/6 × 2, couldn't you turn the two into 12/6 and do it my way and I could figure it out?"
T: [Rewrites 5/6 × 2 as 5/6 × 12/6 on board.] Change this into 12/6?
Libby: Yeah.
T: I don't know why not. It is another name for 2. Right?
Libby: Then I could do 5 times 12 and 6 times 6.
T: If that way works. It seems like every time you tried it, it has matched your model. I don't know if I would want to draw all those things but you could. For 2 you would have to draw two whole pans.
Ginny: I agree with Libby on her way but I think you could do it in a simpler way. You could turn two into two halves.
T: Would that be one? [writes 2/2 = 1].
Ginny: No.
T: So that is not equal. That seems like I would be finding 3/7 of 1 instead of 3/7 of 2 if I made it 2 halves. This is an excellent discussion and it is exactly what I want everyone to be doing…You are thinking and I love it. Keep thinking.

Here the teacher prompted students to draw upon equivalence as a tool. We also saw the student, Libby, inquiring about the use of equivalence as a tool. In her understanding of fractions, she recognized that a fraction can have many names. She was also starting to realize that by choosing a specific equivalent name, she could use her theory about how to multiply fractions symbolically. This is an idea the entire class would eventually explore together.

Division

With division the long-term goal was to support development of the common denominator algorithm for fraction division. Most of the work used quotative division problem contexts. For example: *You have 7/8 of a pound of hamburger. If you make patties that are each 3/8 of a pound, how many patties can you make?* The initial problems involved simple fractions with common denominators, then simple fractions with unlike denominators, and finally mixed numbers with both common and unlike denominators. In the initial days of the work on division, the focus was on creating a picture or visual representation for the problem and writing a corresponding number sentence. Students were using drawings, rate tables, and number sentences to talk about why 7/8 ÷ 3/8 was like finding how many 3 eighths are in 7 eighths or how many groups of 3 are in 7.

In this scenario, students had moved to working with mixed numbers. The problem being worked on was *You have 2 2/3 pounds of hamburger and you are making 2/3 pound patties. How many patties can you make?* A student presented a picture where three wholes were partitioned into thirds. Two and two-thirds was marked. The student then marked and counted out how many two-thirds were in 2 2/3. The number sentence they wrote was 2 2/3 ÷ 2/3 = 4.

T: Did anyone have a different number sentence then what she had written there? She had 2 2/3 ÷ 2/3 = 4 which is correct. But I think there is another number sentence that could help make the answer stand out even better.
Cody: 8/3 divided by 2/3 equals 4.
T: Can you write that number sentence up there? [pause] Look at that number sentence. We are purposefully putting these up there so you can look at those and start seeing if there is a faster way to do this then drawing a picture or making these [rate] tables that we are making. 8/3 divided by 2/3 is 4. I can see that really easily, but I had a hard time seeing it with 2 2/3 ÷ 2/3. So keep thinking about that.

Next, students worked work on the problem *You have 2 1/4 pounds of hamburger and you are making 3/8 pound patties. How many patties can you make?* In his diagram, a student partitioned each pound of hamburger into eighths and marked groups of 3/8. Along with a drawing to support an answer of 6, the student presenting his work wrote the number sentence 9/4 ÷ 3/8 = 6.

T: I am looking at his number sentence. I am having a hard time seeing that the answer is 6. Does any one have a way that we could write that number sentence that could help us see the answer better. I saw some other number sentences on peoples' work.
Chris: You could write 18/8 ÷ 3/8 equals 6. [This is recorded on the work being displayed.]
T: Why is the first sentence [9/4 ÷ 3/8 = 6] so hard to deal with?
Ali: We don't have common denominators.

The class continued to discuss why having common denominators were helpful. In these examples the teacher was drawing out the basis behind using the common denominator algorithm. The students' number sentences did not capture how they were using common-size parts in their drawings. Leveraging equivalence as a tool was one way to draw out a connection between students' diagrams, their symbolism and a potential algorithmic approach.

Discussion and Significance

The contribution of this work is an articulation of specific ways that teachers might leverage equivalence for a particular fraction-based operation without reducing the cognitive complexity of the students' work. In the bigger picture of supporting algorithm development, there were connections made between symbolism, visual models, and equivalence. The leveraging of equivalence as a tool supported students to make their implicit or informal ideas, found in their various representations, explicit for public discussion. While the data presented did not share the actual emergence and articulation of specific algorithms for each operation, it highlighted ways a teacher might use equivalence as a tool to support students to invent (or reinvent) for themselves algorithmic procedures for operating with fractions based on their informal work. This focus on leveraging equivalence as a tool is in contrast to presenting equivalence as a rote procedural step as is common when instruction presents algorithmic procedures as ready-made.

While it was not the direct focus of this paper, an important part of the work students were doing involved developing visual representations or models for scenarios that enacted the four fraction operations. Students then attached symbolism in the form of number sentences to their visual representations. The data shared revealed ways in which the visual representations and the symbolic representations were important in the algorithm-development process. While there was not enough space here to display full development from informal to formal, equivalence is presented as one important tool that teachers might leverage to help students engage in mathematical reasoning that supported the emergence of meaningful procedures and algorithms for fraction operations.

We interviewed 40 students in Grade 7 to investigate their integer reasoning. In one task, children were asked to write and interpret equations related to a story problem about borrowing money from a friend. Their responses reflect different perspectives concerning the relationship between this real-world situation and various numerical representations. We identify distinct ways in which integers were used and interpreted. All of the students solved the story problem correctly. Few thought about the story as involving negative numbers. When asked to interpret an equation involving negative numbers in relation to the story, about half related it to the story in an unconventional fashion, which contrasts with typical textbook approaches. These findings raise questions about the role of money and other contexts in integer instruction.

Keywords: Middle School Education

Introduction

The use of contexts is common in integer instruction. In a review of fifth and sixth grade textbooks adopted by the state of California, we found that 94% of these used the context of money in instruction concerning integers. Elevation (89%) and temperature (89%) were also popular contexts (Whitacre et al., 2011). There are conventional ways in which textbook authors relate these contexts to the integers and to integer arithmetic. These conventions may or may not jibe with children's intuitions. In interviews with 40 seventh graders, we investigated how children made sense of a story problem concerning borrowing money from a friend, and how the children saw this context as related (or not) to various equations. We report on children's ways of reasoning about the relationship between the context and the equations. These new findings concerning children's reasoning about integers suggest implications for integer instruction.

Theoretical Framework: A Children's Mathematical Thinking Perspective

We approach this study from a children's mathematical thinking perspective. In the tradition of Cognitively Guided Instruction (CGI), we value children's mathematics. We take seriously the nature of that mathematics, even if it is incorrect from an expert perspective. We endeavor to see the mathematics through children's eyes in order to better understand the sense that they make (Bishop et al., 2011; Lamb et al., in press). We do this because the ultimate goal of our research is to find ways to better support children's learning of mathematics (Carpenter, Fennema, Franke, Levi, & Empson, 1999; Carpenter, Franke, & Levi, 2003; Empson & Levi, 2011).

A Distinction Informed by the History of Mathematics

There is a somewhat subtle distinction that is relevant to the analysis presented in this paper. As a matter of background, the notion of a negative number was controversial historically. Many mathematicians resisted the idea of negative numbers because numbers were associated with magnitudes, and magnitudes less than zero seemed nonsensical. During the 13th through the 18th centuries, many Western mathematicians used negative numbers in algebra, although these remained hotly debated and were not generally regarded as legitimate numbers (Gallardo, 2002; Hefendehl-Hebeker, 1991; Henley, 1999).

Taking account of the history of negative numbers, it would be tempting to say the following: "Positive numbers existed before negatives. Furthermore, even after negatives came into use, it took a long time for them to become understood and accepted as legitimate numbers." We would take exception with one aspect of this account—the use of the word *positive*. Prior to the advent of negative numbers, there was no such thing as a positive number. Positive and negative are opposites. Their meaning derives from the contrast between the two. Before the notion of a negative arose, there were simply numbers. In keeping with the language that many children have used in our interviews, we refer to these as *regular numbers.*

Consider the integers. It is commonplace today to refer to the positive integers and the natural numbers as one in the same—at least among mathematicians or in mathematics classes at the middle school level and above. Historically, however, the natural numbers predate the integers. More importantly, there is a conceptual distinction between these sets. The positive numbers are signed numbers. The natural numbers are not. Put another way, signed numbers may be thought of as *directed magnitudes*. That is, they convey two distinct pieces of information, direction (sign) and magnitude (absolute value). The positive numbers have this property. The natural numbers, by contrast, have only magnitude.

This distinction is relevant to the experience of children learning mathematics today. For the first so many years of a child's life, numbers are not signed. Children learn to count with natural numbers. At some point, they learn about zero. Later, they encounter nonnegative rational numbers, which they come to know as fractions and decimals. Typically, a child's introduction to negatives (and positives) comes after all this. In fact, we have found that many elementary children who have some familiarity with negative numbers have never heard of positive numbers. When they learn about integer arithmetic, which typically occurs in middle school, children are told that the regular numbers are actually positive. However, there is a sense in which this distinction remains salient. The distinction between positive numbers and regular numbers plays a part in the analysis that we present.

Methods

We interviewed 40 children in Grade 7 during the spring of 2011. The interviews were conducted at public schools in an urban area in California. All Grades 5, 6, and 7 mathematics textbooks adopted by the California Department of Education contain material concerning integers and integer arithmetic. Thus, we expected that the students we interviewed all would have received substantial instruction on integers. Indeed, we know from the interviews that all 40 of the children were familiar with negative numbers and were able to solve (at least some) problems involving integer arithmetic.

The interviews consisted of a range of tasks, including open number sentences, number comparisons, and story problems. Interviews were conducted at the children's school sites, during the school day. Interviews were videotaped and typically lasted between 60 and 90 minutes.

Task: The Money Problem

In this report, we focus on the following story problem:

> *Yesterday, you borrowed $8 from a friend to buy a school t-shirt. Today, you borrowed another $5 from the same friend to buy lunch. What's the situation now?*

The interviewer would often clarify the question by asking, "Do you owe your friend money? Does your friend owe you money? How much money?" Students were asked to solve the problem and to explain their thinking. They were also asked to write a number sentence that would represent the problem, including its solution, and to explain how this equation related to the story. Students were then asked if they could write additional equations that would also represent the story. Next, they were presented with three equations, one by one. They were told that these had been written by other children to represent the same story. Students were asked to tell whether or not they thought each equation matched the story and to explain why. The equations shown to students were the following:

i. -8 + -5 = -13
ii. -8 – 5 = 13
iii. 8 + 5 = 13

Order of presentation varied. Typically, if one of equations i–iii matched an equation that the child had written, this one was shown first.

Analysis of Children's Responses

We first analyzed a subset of the data qualitatively, focusing on children's solution strategies and underlying ways of reasoning. We used principles of grounded theory (primarily the constant comparative method) to identify emergent, distinguishing themes in students' reasoning (Strauss & Corbin, 1998). Once a set of codes was generated that fit this subset of the data, these were used to code the remainder of the data. In particular, our analysis of children's responses to the story problem revealed an interesting theme, that of *perspective*. This is a category of codes. Within that category, we identify three ways of reasoning with regard to perspective: *conventional*, *unconventional*, and *perspectiveless*. These three ways of reasoning were used to code the responses of all 40 children. These apply to children's explanations of their own equations, as well as to their interpretations of equations i, ii, and iii.

As a reliability check, 25% of the data was double-coded. For 10 of the 40 children's responses, two researchers independently coded those responses using the perspective codes. Coders agreed on the ways of reasoning of 9 of the 10 children (90%). The one instance of a disagreement was a case of coder error, and it was corrected. We also coded children's responses to the story problem as correct or incorrect, and we recorded the equations that they wrote. We then tabulated the results.

We report here on the percentage of children who solved the story problem correctly, the percentages of children who wrote certain equations to represent the story problem, and the percentages of children who interpreted equations involving negatives from a conventional or an unconventional perspective.

Results

First, we describe the three different ways of reasoning. Then we provide specific examples of each way of reasoning. Finally, we report the results of our analysis of the responses of all 40 children who were interviewed.

Ways of Reasoning

We describe the ways of reasoning that were identified.

Perspectiveless. The child sees regular numbers as an appropriate representation of amounts of money. Thus, 8 + 5 = 13 would appropriately represent the situation because 8 represents $8, 5 represents $5, and 13 represents $13. The fact that this was money borrowed from a friend is relevant only in that the answer of 13 refers to a total amount of money borrowed/owed. However, the same equation could just as well represent the situation from the lender's side. In either case, $8 plus $5 is $13. The numbers are being used here only to communicate magnitude, not direction (of owing).

Unconventional perspective. The child views positive numbers as representing money that the *borrower* gained, even though the money was borrowed. From this perspective, 8 + 5 = 13 matches the story because 8 represents $8 given to me by a friend, 5 represents an additional $5 given to me by that friend, and 13 represents the total of $13 that I acquired. For children reasoning from this perspective, -8+ -5 = -13 does not match the story from the borrower's side, but it could match the story from the lender's side because the lender lost money by lending it.

Children whose responses were coded as reflecting an unconventional perspective were taking perspective into account. They reasoned about the appropriateness of using positive or negative numbers to represent the situation. Negative numbers had meaning for these students, albeit an unconventional meaning. We use the term *unconventional* because, in our review of textbook approaches to integer instruction, we did not find negatives used in this way. Furthermore, the unconventional perspective contrasts directly with the conventional perspective, which is typical of textbook treatments.

Conventional perspective. The child views negative numbers and subtraction as representing debt or net loss. For example, -8 + -5 = -13 is seen as matching the story about borrowing money from a friend because -8 represents a debt of $8, -5 represents an additional debt of $5, and -13 represents the total debt of $13. From this perspective, positive numbers would be used to represent the lender's situation. That is, 8 + 5 = 13 would not describe the situation from the borrower's side, but it would describe the situation from the lender's side.

Children's Responses

Below, we present examples of particular children's responses that illustrate these distinct ways of reasoning.

Perspectiveless. Elisa wrote 8 + 5 = 13 as her equation. Like the other children who wrote this equation, her explanation was perspectiveless:

Interviewer: Okay. And can you explain to me how this equation matches the story?
Elisa: Okay. So, yesterday I borrowed eight dollars from my friend to buy a school t-shirt. So, I have eight dollars from my friend [points at "8" in equation]. And then today I borrowed five from the same friend, and I bought a lunch. And then plus five that I borrowed from her [circles "+ 5" in equation] equals thirteen dollars that I borrowed from her [circles "13" in equation]. And what's the situation? I owe her thirteen dollars.

Elisa made sense of the story and was well aware of who owed money to whom. However, this directional information was not conveyed in her equation. It belonged to what she knew the equation represented—how much money she owed her friend. The equation itself simply conveyed magnitude information: the sum of $8 and $5 is $13.

Unconventional Perspective. Tommy also wrote 8 + 5 = 13 to represent the story. When he was shown -8 + –5 = 13, he said that it would not work to describe the borrower's situation. Tommy's explanation is an example of unconventional perspective:

Interviewer: Can you read that one for me? [Interviewer reveals -8 + -5 = -13 on paper]
Tommy: Negative eight plus negative five equals negative thirteen.
Interviewer: Okay, and what do you think about that? Do you think that that describes the situation, or the story?
Tommy: Um, no. Because it's like, it's basically like saying that they owe you because it's like, it's like you're not taking any money. It's like they're taking your money. Because it's negative, which means it's like, it's kind of lower; it's lower than zero. Like, so then it's like they're owing you money, instead of you owing them.

Tommy interpreted negative numbers as indicating someone "taking" money. He viewed the situation from his side (as the borrower), and so he said that the equation would not fit because the negatives would mean that money had been taken from him, rather than given to him.

Conventional Perspective. Jen initially wrote -8 – 5 = x as her equation. At the interviewer's request, she later rewrote her equation, replacing x with a known number (-13). Her explanation conveyed a conventional perspective:

Interviewer: Okay, so tell me about what you wrote.
Jen: I wrote negative eight minus five equals x [pause] because, um, because if I borrow money, it's like I'm, I'm like losing money. No, it's not I'm losing money. It's like I'm, I'm borrowing someone else's money. So, on my side, it would be a negative. And then on another day, I'm also borrowing money, so that's also like a negative.
Interviewer: Okay. And what would the x be here?

Jen: It'd be like how much money I borrowed in total.
Interviewer: Mm-kay. And could you rewrite this and replace x with the answer?
[Jen writes -8 – 5 = -13]
Interviewer: Okay. So, why did you write negative thirteen for the answer there?
Jen: Because negative eight minus five is negative thirteen.
Interviewer: And how does that relate to the story?
Jen: It relates to the story because, if I borrow eight and five, I owe them thirteen. So, it's like a negative thirteen dollars on my side.

Jen articulated a view of negatives as representing debt. For her, -8 represented $8 that she had borrowed, – 5 represented $5 that she had borrowed, and -13 represented the total amount that she owed to her friend.

Overall Results

All 40 of the 7th graders (100%) solved the story problem correctly. That is, they said something like, "I owe my friend $13." They were then asked to write one or more equations to represent the story. Of the 40 students, 33 (82.5%) wrote 8 + 5 = 13 as one of their equations. Usually, this was the first equation that they wrote. Often it was the only equation that they wrote. Rarely did students write equations involving negative numbers. Those who wrote multiple equations typically created variations that also involved natural numbers. The equation 5 + 8 = 13 was the most common second choice. In each case that a child wrote 8 + 5 = 13, the child's explanation for that equation was perspectiveless. The child talked about the numbers as representing amounts of money, and there was no evidence that he or she intended to convey information about the direction of borrowing/owing with the signs of the numbers. These children were using regular numbers.

Only 8 of the 40 students (20%) wrote an equation involving negative numbers. Six children wrote -8 + -5 = -13, and two children wrote -8 – 5 = -13. Children's explanations for these equations naturally addressed the issue of perspective since the children had made a choice to use negative numbers. Thus, only 20% of the children took perspective into account in writing an equation to represent the situation.

The children were then shown equations i, ii, and iii. We report here on the perspective reflected in their interpretations of equations i and ii (-8 + -5 = -13 and -8 – 5 = -13). Often children's responses explicitly addressed perspective for either i or ii but not both. In cases where perspective was explicitly addressed for both, the perspective was always consistent. For these reasons, we group children's responses to i and ii. Of the 40 children who were shown equations i and ii, 19 of them (47.5%) articulated a conventional perspective. They interpreted the negative numbers in the given equation as representing debt. For them, the given equation was appropriate for describing the borrower's situation. An additional 19 children (47.5%) expressed an unconventional perspective in interpreting one or both of equations i and ii. These children viewed negative numbers as representing money lost or taken away. For these children, the given equation described the lender's situation. Two of the children (5%) were not given any perspective code for i or ii. It was not clear that they had any way of interpreting negative numbers with respect to the context.

Discussion

We have identified three distinct ways in which children reason about equations like 8 + 5 = 13 and -8 + -5 = -13 in relation to a story about borrowing money. Our analysis has involved two key ideas that arose in children's mathematical thinking. The first is the distinction between regular numbers and positive numbers. When children wrote 8 + 5 = 13 to represent the situation, they were using regular numbers. They viewed this equation as related to the context in terms of the numbers and the operation involved. The children were aware that the number 13 represented $13 borrowed from a friend; however, information about the direction of borrowing/owing was not contained in the equation.

The second key idea involves another distinction, and it applies only to those children whose mathematical worlds include positive and negative numbers *and* who see these as related in some way to the context of borrowing/owing money. Our analysis of the responses of children like these revealed two distinct perspectives, conventional and unconventional. Of the 38 children who were able to interpret negative numbers in relation to the story, exactly half of them expressed a conventional perspective. They interpreted the negative numbers in the given equations as representing debt, or money owed by the borrower to the lender. The other half of the children expressed an unconventional perspective. They interpreted negative numbers in the opposite fashion, as expressing money lost by, or taken away from, the lender. Both groups of children consistently viewed the equations as making sense for describing the situation of one person in the story (either the borrower or the lender) and not the other. In this respect, the two perspectives are incompatible. Their interpretations disagree with one another.

Implications

Story problems in real-world contexts are widely used in integer instruction, and stories involving money are among the most common of these. The reason we have used the terms *conventional* and *unconventional* to describe students' reasoning in relation to these contexts is that the conventional perspective is typical of the way that positive and negative numbers are used to represent debt in mathematics textbooks. That is, the conventional perspective is the accepted perspective of the mathematical community. It is also reflected in the standard notation used in bank statements, utility bills, and so on. Negative numbers are used to denote a debt or debit; positive numbers are used to denote a deposit or credit. Thus, it is noteworthy that this convention is not consistent with the reasoning of many children. In particular, our review of textbook approaches to integer instruction suggests that the vast majority of 7th graders have encountered money contexts in their instruction concerning integers. Yet approximately half of the 7th graders that we interviewed interpreted the relationship between integers and money from the unconventional perspective, which contrasts with the interpretation reflected in the textbooks.

These findings raise questions concerning the roles of contexts such as money in integer instruction. Our group has begun to question what it means to make sense of integers and integer arithmetic. Often making sense in K–8 mathematics seems to be defined in terms or relating numbers and operations to quantities in the world. At least in the case of the integers, we believe that this notion may be in need of revision. Certainly, a mature understanding of integers includes the ability to relate them to quantities in the world. However, this does not entail that reasoning about real-world quantities like money should serve as a *source* for children's mathematical intuitions. On the contrary, we can imagine children developing a deep, purely mathematical understanding of the integers. This understanding could then be superimposed upon real-world situations, in the way that we do as mathematically literate adults.

We hope that the distinctions that we have discussed may be useful to both researchers and practitioners who are interested in the teaching and learning of integers and of integer arithmetic. In particular, sensitivity to the distinction between regular numbers and positive numbers can inform the language that we use with students and the care that we take in introducing them to the notion of signed numbers. Likewise, sensitivity to the issue of perspective can inform instructional decisions. It reminds us of the importance of eliciting the details of students' thinking and of having explicit discussions of different ways of reasoning.

Acknowledgments

These interviews were conducted as part of an NSF-funded research project entitled Mapping Developmental Trajectories of Students' Conceptions of Integers (grant number DRL-0918780). Any opinions, findings, conclusions, and recommendations expressed in this material are those of the authors and do not necessarily reflect the views of NSF.

We would like to thank the children for their participation, as well as the cooperating teachers and other school staff for their help arranging the interviews.

INTERPRETING AVERAGE RATE OF CHANGE IN CONTEXT

Jonas B. Arleback

This paper draws on a models and modeling perspective to investigate students' abilities to describe and interpret non-constant average rates of change in the context of exponential decay. The results show that about half of the students could describe the behavior of the function and its rate of change, with more than half of those also referring to the problem context. Two themes in the students' responses are discussed: describing the context as a way of describing the function, and difficulties related to the use of language in describing changing phenomena.

Keywords: Advanced Mathematical Thinking; Modeling

Students' difficulties when creating and interpreting functions as models of changing phenomena are well documented (Carlson et al., 2002; Thompson, 1994). Students must be able to simultaneously attend to both the changing values of the output of a function and the rate of that change as the input values vary over intervals in the domain (Oerhtman, Carlson & Thompson, 2008). The complexity of such reasoning has proven difficult even for high achieving undergraduate students (Carlson, 1998). Other researchers have emphasized the role of context in the development of students' reasoning about changing phenomena (Confrey & Smith, 1994; Michelsen, 2006; Shternberg & Yerushalmy, 2003). Michelsen (2006) argues that one source of difficulty in applying functions in context is that students fail to treat variables as related quantities that change and hence have difficulties in recognizing that functions are tools for describing, explaining and predicting the relationships among changing quantities.

In this paper, we examine how students interpreted and attended to function values, average rates of change and changing average rates of change in the context of a discharging capacitor.

Theoretical Background, Design, Methodology and Methods

Our research used a contextual modeling perspective on the teaching and learning of modeling (Kaiser & Sriraman, 2006) to design a model development sequence (Lesh et al., 2003) to motivate students to develop the mathematics needed to make sense of meaningful situations. Each task in such a sequence engages students in multiple cycles of descriptions, interpretations, conjectures and explanations that are iteratively refined while interacting with other students. The sequence formed the basis for a six-week summer course for students preparing to enter their university studies in 2010 and 2011. This paper analyzes the responses of 51 students (15 females and 36 males) on a task given to the students at the end of the sequence. All but one participant had completed four years of study of high school mathematics; 29 students had studied calculus in high school.

In the task, the students were given a data set of the voltage drop across a discharging capacitor for 50 seconds and were asked to: (a) find an equation of the form $y = a \cdot b^x$ that could be used to describe the data; (b) give an interpretation of the constants a and b in this equation; (c) find the point in time when the voltage across the capacitor was 0.05 V; (d) compute the average rate of change over three subintervals of time; and (e) write two or three sentences interpreting the average rate of change data in (d). In this paper, we report on the analysis of the students' responses to the last part of this question. Figure 1 shows a graph of the voltage data, modeled by an exponential decay function, decreasing with an increasing average rate of change across the sub-intervals of time. Since the function is decreasing the average rate of change is negative. However, the average rate of change is getting successively less negative and closer to zero. Hence the average rate of change is increasing. In terms of the context, this means that the voltage across the capacitor is decreasing at an increasing rate.

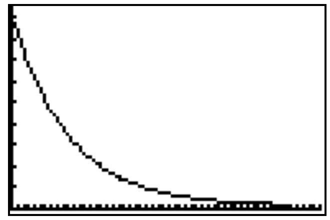

Figure 1: A plot of the voltage data provided to the students

The analysis of the students' written work was done in three phases. First, the written work of the 49 students who answered the question were read focusing on the extent to which the students made references to and distinctions among the behavior of the function, the average rate of change, and the context. This resulted in the identification of a preliminary set of categories and themes capturing the variations of the students' answers. In the second phase, each student's answer was re-read and coded with respect to which aspects of the changing phenomena the student described in terms of (1) the behavior of the function, (2) the average rate of change, and (3) the context. The student responses in each category were also coded correct, incorrect, or not addressed. Further, the answers were classified and grouped in the three categories listed in Table 1. This coding was carried out independently by two of the researchers and discrepancies were discussed and resolved. In the third phase of the analysis, the students' answers were revisited in the search of patterns, commonalities and differences.

Results

Table 1 summarizes how the students simultaneously attended to function values, average rates of change and changing average rates of change in the context of a discharging capacitor. Approximately 49% of the students could correctly describe both the behavior of the function and the average rate of change with more than half of those students (58% or 14 out of 24) also including a reference to the context of the voltage drop across the discharging capacitor.

Table 1: Students' Interpretations of Average Rate of Change

Category	# total students	# correct answers	# incorrect answers
(R+C+F) Students interpreting the average rate of change with reference to both the behavior of the function and the context.	19 (39%)	14 (29%)	5 (10%)
(R+F) Students interpreting the average rate of change with reference to the behavior of the function but without any reference to the context	15 (31%)	10 (20%)	5 (10%)
(R) Students interpreting the average rate of change without any references to context or to the behavior of the function	15 (31%)	5 (10%)	10 (20%)
Total	49 (100%)	29 (59%)	20 (40)

Note: All percentages are calculated relative the whole population and are rounded to the nearest whole percent.

An example of a correct answer in the **(R+C+F)** category is: "The function is decreasing at an increasing rate. You can come to this conclusion because the voltage (or *y* values on the table) is decreasing and the average rate of change values are becoming less negative, which means that it is increasing." This student provides a correct description of both the behavior of the function and the average rate of change, while making a reference to the context. A typical a correct answer in the **(R+F)** category is: "The average rate of change from the intervals above [referring to his calculations] show that as the time increases the function decreases at an increasing average rate of change." This student correctly distinguishes between the function values, which are decreasing, and the average rate of change, which is increasing. This is done with reference to prior numerical calculations, but without reference to the voltage change across the capacitor. An example in the **(R)** category is: "The average rate of change is increasing because it is becoming less negative." This student answers the question as it is posed, but does not go beyond the question to describe the function nor the context.

Describing the Context as a Way to Describe the Function

Using the context as a way to describe the function was a frequent characteristic found in the students' answers. One student used "the capacitor is discharging" to mean that the function is decreasing: "As time passes by, the capacitor is discharging at an increasing rate." Another student wrote: "Between the intervals 5 to 10, the charge of the capacitor dropped at a rate of .43 v/s. For every second, the charge went down by –.43 volts. Between 20 to 25, for every second, the charge of the capacitor went down by –.05 volts. Between 40 to 45 seconds, for every second, the charge of the capacitor went down by –.0004 volts. I can also say that the charge was decreasing at a decreasing rate because the numbers were getting more negative." Although this student exhibits conflated ideas about the behavior of the function and the average rate of change, the description of the behavior of the function is closely tied to the context: "the charge of the capacitor dropped" and "the charge went down." This example also points to students' difficulties related to the language of change when rates are negative. The student correctly states that "the charge of the capacitor dropped at a rate of .43 v/s." But then the student states that "the charge went down by –.43 volts," thus mixing everyday language (went down) and the rate of the change as a signed quantity. In the second statement, the use of the magnitude of the rate would have been more appropriate.

Difficulties Related to the Use of Language in Describing Changing Phenomena

The role of language became increasingly apparent in our analysis of students' answers. The ability to use notions and concepts in a mathematically meaningful way, while keeping these meanings distinguished from similar everyday language is crucial for being able to formulate precise descriptive statements. For example, some students described the magnitude at which the rate of change changed rather than describing this change as a signed quantity. This may have blurred the interpretation of the average rate of change since the magnitude (the absolute value) of the average rate of change is decreasing whereas the signed average rate of change is increasing. The following example shows how easy it is to shift between conflicting formulations: "In (d) the average rate of change is negative and thus we know that voltage is decreasing. However, the rate at which voltage is decreasing is less and less each seconds. This statement can be concluded because comparing the first, middle, and ending intervals shows that the average rate of change is becoming less negative. Thus we see that the average rate of change is decreasing at an increasing rate." In the first and third sentence of this student's answer, the average rate of change is seen and used as a signed quantity, enabling the student to correctly describe both the behavior of the function ("voltage is decreasing") and the average rate of change ("is becoming less negative"). In the second sentence, the average rate of change is seen and used in a magnitude sense, leading the student to incorrectly conclude that the rate of change of the voltage is decreasing. In the fourth sentence, the student's statement ("the average rate of change is decreasing") is true about the magnitude about the average rate of change, but not about the signed quantity.

Everyday language mixed with mathematical terminology sometimes obscured the clarity and precision of what the students were trying to convey. For example, one student wrote: "The average rate of change is constantly increasing. This means that voltage across the capacitor is still decreasing, but at a increasing rate." Here, the ambiguity is with the use of "constantly." From a mathematical point of view, the first statement about the average rate of change is incorrect; it is not increasing constantly (at a constant rate). However, in an everyday use of the word "constantly," it makes perfect sense, meaning that the average rate of change is increasing "all the time" over the intervals under consideration.

Discussion and Conclusions

Describing the behavior of the voltage drop of a discharging capacitor, modeled by an exponential function, revealed a number of conceptual and contextual challenges for the students. The conceptual challenges resides, in part, in attending simultaneously to the global features the behavior of the function and the average rate of change, and in coordinating one's understanding of the change in function values with the rate of that change over various subintervals, especially when the rates are negative but increasing. The contextual challenges arise from the difficulties in everyday language in describing magnitude of the voltage drop, since this magnitude decreases, while the signed average rate increases as it becomes less negative. Everyday language for describing the change in rate appears in conflict with formal mathematical language for describing that change.

Overall, half of the students were able to give meaningful interpretations of the data and descriptions of change in context. Students' difficulties in distinguishing the function values and changes in the average rate of change when the average rates of change were negative suggest the need for closer attention to developing the concept of a negative rate of change in context and using language to express that concept.

USING DISTANCE AS A DEFINITION FOR ABSOLUTE VALUE

Timothy C. Boester

Anna C. Talbert
Wright State University
talbert.10@wright.edu

Students tend to struggle with both the algebra and the logical reasoning required to solve absolute value equations (and inequalities) through the algebraic "reasoning by cases" technique. Recent research of the epistemology of absolute value has focused on how to make this technique more accessible. But what if there was a way to simply avoid the algebraic difficulties while simultaneously revealing the logic of having multiple solutions (or ranges of solutions)? Following the format of a design-based case study, we used a definition of absolute value based on distance to create and implement an instructional sequence in an eighth grade classroom. While having more conceptual parts to keep track of, students using this distance-based definition were more likely to solve absolute value equations successfully by avoiding the consistent algebraic errors found in the control group.

Keywords: Algebra and Algebraic Thinking; Design Experiments; Middle School Education

Theoretical Framework

The first attempts to study student conceptions of absolute value focused on simply illuminating the subject, either pedagogically or mathematically. For example, Brumfiel (1980) laid out a mathematical framework for how absolute value can be defined in equivalent ways. Two of the five definitions he listed are geometric, based on distances for $|x|$ and $|x-y|$, while the other three are arithmetic: $|x| = x$ if $x \geq 0$ or $|x| = -x$ if $x < 0$, $|x| = +\sqrt{x^2}$, or $|x| = \max\{x;-x\}$. Chiarugi, Fracassina, and Furinghetti (1990) found that instruction needs to include situations to motivate the algebraic approach most students had simply proceduralized.

Recent research on student conceptions of absolute value has been influenced by two pairs of significant journal articles. The first pair focus on the didactic effectiveness of instruction of arithmetic definitions. Wilhelmi, Godino, and Lacasta (2007) explored an epistemic network created by the three arithmetic definitions presented by Brumfiel (1980) plus a fourth piecewise functional definition related to solving absolute value equalities by splitting the domain into two pieces. Sierpinska, Bobos, and Pruncut (2011) created different approaches to teaching absolute value using the piecewise functional definition in a college setting. They found that a visual approach, using graphs to demonstrate the generation of cases, showed the greatest effectiveness. They concluded that the dual nature of the instruction, both graphical and algebraic, helped students to reason through problems instead of blindly following a procedural technique.

The second pair of articles present lessons based on Brumfiel's (1980) geometric definitions of absolute value that were mostly ignored in the previous pair of studies. Ponce (2008) recognized the difficulties students have with the arithmetic definitions and noticed a theme in previous research (Arcidiacono, 1983; Wallace, 1988; Horak, 1994; Wei, 2005) that students are more successful when using a number line than those who stick with algebraic strategies. His students solve absolute value equalities and inequalities centered at zero by translating them to story problems and number lines. Ellis and Bryson (2011) proposed an improvement to this distance-based definition by relocating the center to match the problem, instead of always being at the origin. Their method asks the students "to connect the symbolic expression $|x-b| = c$ to the verbal phrase '*x* is *c* units from *b* in either direction'" (p. 593). Like the Sierpinska et al. (2011) study, this process is meant to help students reason through problems instead of simply following an algebraic procedure. However, by grounding the problem through story problems and number lines, the algebra can be avoided completely.

Given the reported success of using a distance-based definition of absolute value in the second pair of studies, the lack of its inclusion in the didactic analysis in the first pair of studies opens an opportunity for further research, especially since studies up to this point have not formally investigated using a distance-based definition in a classroom. We wish to explore the epistemic, cognitive, and instructional implications of a choice of absolute value definition that avoids the algebra heretofore deemed necessary to solve such problems. We believe that this definition will have the benefits of the visual approach studied by Sierpinska et al. (2011) while moving beyond its success, because students will not need to rely on the reasoning by cases procedure either to generate or verify their answers.

Method

We used a design-based case study (Cobb, Confrey, diSessa, Lehrer, & Schauble, 2003) in two eighth grade teaching practicum math classes located at a mid-size, Midwestern public school to explore the implications of solving absolute value equality problems using either the $|x-y|$ distance definition (seven students in one class) versus the piecewise functional definition (14 students in the other class). Both groups of students had been introduced to absolute value of numbers three months before our instruction, using the $|x|$ distance definition to describe how to find the absolute value of positive and negative values. Students had also covered one-step and two-step algebraic solutions to linear equations, the role of the equal sign in equations, and identifying points on a number line.

Piecewise functional definition instruction began by motivating the need for two solutions to algebraic absolute value equality problems like $|x-A|=B$ with an arithmetic example: $|x|=3$. Note that we specifically chose to use the two solutions of $\pm(x-A)=B$, and not $(x-A)=\pm B$, because the former matches the operation of applying the absolute value when $x-A<0$ in the piecewise functional definition. Discussion of several examples of problems of this form were led by one of the researchers and the students before completing a homework assignment covering $|x-A|$ and $|x+A|$ problems with positive and negative solutions.

Distance definition instruction began for this class by motivating the need for two solutions to absolute value equality problems with a story problem: Jake and Sarah are in a tall building. Jake is waiting on the 10th floor for Sarah. If Sarah is 6 floors away, what floor is Sarah on? After it was established that there are two possible solutions to this problem through the use of a vertical number line, several more problem scenarios relating to distance were solved and discussed as a class using number lines. The following day, students continued the topic with a new story problem using temperature, a context chosen to enable a sensible negative solution. Then the task was reversed: starting with a number line picture, showing a center and a distance from the center, can you create a story problem that matches the number line? Finally, the symbolic notation of absolute value equalities, $|x-A|=B$, was connected to the idea of center and distance. After examples of translating number lines and story problems into the symbolic notation were discussed, students were given a fifteen question worksheet that asked them to translate from each of the three representations used (symbolic notation, number line, story problem) to the other two, then find the solutions.

Results

Both groups of students initially had difficulty understanding why there would be two solutions. One student in each class suggested that there could be two solutions, and this idea quickly caught on. From here, however, each class went on to have different sets of difficulties. In the piecewise functional definition instruction, using the dual solutions of $|x|=3$ to explain why we get two solutions to the problem $|x-A|=B$ confused the students. There were several questions concerning where the second (negative) case came from, and it took many examples completed as a class for some of the students to begin to catch on to the procedure. On the homework, two students completely forgot to include a negative equations. But the other 12 students who set up the cases correctly repeatedly made multiple types of algebraic and arithmetic errors. Thus, while most of the students eventually figured out the need for two solutions, and could set up the algebraic equations to obtain both solutions, only three students consistently (>95% of the time) found both correct solutions.

On the first day of distance definition instruction, the students rapidly became proficient in finding the solutions to story problems through the use of number lines. By the end of the second day, most students were independently translating the symbolic notation into story problems or number lines. From the problems assigned the second day, six of the seven students consistently solved the problems correctly, regardless of which representation was initially given. However, even though students were successful in finding the solutions to problems overall, generating different representations showed weaknesses in their comprehension of each representation.

When translating from story problems to symbolic equations, errors included one student putting a negative sign in front of the absolute value, one student writing an incomplete equation, and two students giving no equation at all. Students made fewer errors when translating from number lines to equations, with one student forgetting the absolute value symbols, and another writing equations of the form $|A+B| = x$ and $|A-B| = x$.

When translating from number lines or equations to story problems, students were roughly split between reusing cover stories that had already been established in class and creating new cover stories. Regardless, errors included inappropriate context for negative solutions, implied change in only one direction (instead of both), inconsistent starting points for change in both directions, situations that only promoted adding or subtracting values instead of using absolute value, simply repeating the absolute value notation using words, or no story problem given. Thus, students had difficulties in writing appropriate story problems, even when reusing contexts presented in class.

It was clear that students preferred to use number lines over the other two representations to solve absolute value equalities. During the second day, when students had a choice of translating symbolic notation into number lines or story problems, the researcher observed students consistently choosing to use number lines to solve the problems. In addition, while some students did not produce other representations when translating, every student always generated a number line when given a story problem or a symbolic representation. Amazingly, even though number lines were their favored representation, students had more difficulties with number lines than either of the other two representations. In translating from story problems and equations to number lines, the most frequent errors were labeling equally spaced distances on their number line as representing different values and creating inappropriate tick marks (such as using increments of five to count up to 23). Other errors included having one too many/few tick marks between the center and the edge and using the same number of unlabeled tick marks regardless of the numbers involved in the problem. Six of the seven students made at least one of these errors, and most students made multiple errors. However, errors in creating each representation did not affect students' ability to obtain correct solutions to the problems.

Conclusion

Students who learned the piecewise functional definition eventually were able to accept the idea that two solutions were necessary and set up the correct pair of equations, but algebraic difficulties consistently got in their way to finding the correct solutions. Students who learned the distance definition also had difficulties in generating story problems, symbolic notation, and number lines. However, these difficulties did not prevent them from successfully finding solutions. The researcher observed several of these students lifting the values out of the given representation and then solving the problems using arithmetic. In each representation, the students successfully established which number was the center and which number was the distance from the center, and then found center + distance and center – distance. Even though students had several misconceptions about number lines, the concept of a center and distance was clear enough. With the solution in hand, other representations were then created.

The value we discovered in presenting the distance definition to these students was thus twofold. It completely avoided the algebraic difficulties that prevent students from successfully finding solutions via the reasoning by cases procedure. These difficulties, seen in previously cited studies, were also seen in the piecewise functional definition group. More importantly, it appears that the distance definition promotes an understanding of the values involved in an absolute value equality that is basic enough to avoid common misconceptions surrounding number lines. By connecting symbolic notation to number lines and story problems, students were able to find and utilize the ideas of center and distance from the center in each representation.

STUDENTS' TRANSITION FROM PROTO-RATIO TO RATIO AND PROPORTIONAL REASONING THROUGH CO-SPLITTING AND EQUIPARTITIONING

Andrew Corley
North Carolina State University
akcorley@ncsu.edu

Jere Confrey
North Carolina State University
jconfre@ncsu.edu

This paper presents preliminary findings on the strategies used by third-grade students while working with the topic of co-splitting, a form of covariation, and how students develop an understanding of the concept based on prior learning experiences within equipartitioning. The range of these strategies are discussed as to how they pertain to a movement from proto-ratio reasoning to more fluent and sophisticated ratio and proportional reasoning, eliciting implications of equipartitioning as a strong foundation for a transformative move in thinking.

Keywords: Elementary School Education, Learning Trajectories, Rational Numbers

The purpose of this work is to address the transitional levels third grade students pass through in moving from early proto-ratio reasoning to more formal ratio reasoning. The following research question was formulated: *What are the different strategies of third-grade students working with co-splitting tasks based on their knowledge of equipartitioning?* A study of this nature is important because it recognizes equipartitioning and splitting as a foundation for multiplicative proto-ratio reasoning, which holds the potential to lead to ratio and proportional reasoning earlier and more directly than through additive compositions.

Literature and Framework

Ratio and proportion have been well-documented as difficult concepts for children to understand (e.g., see Behr, Harel, Post, & Lesh, 1992). Descriptions of protoquantitative ratio reasoning (Resnick & Greeno, 1990) and proto-ratio reasoning (Singer, Kohn, & Resnick, 1997) have been noted to only account for the development of additive properties of measure numbers (Singer & Resnick, 1992). Lamon (1993) found that some sixth grade students were capable of formal ratio reasoning, treating ratio as an invariable composite unit in solving proportion tasks. However, Streefland (1984, 1985) pushed for an earlier introduction of ratio reasoning, and Confrey (1994) too has argued that the concept of ratio can be accessed even at the early elementary grades with its cognitive underpinnings lying within an understanding of splitting and equipartitioning. She demonstrated that 3rd–5th graders could develop *ratio constructs* simultaneously as they worked with multiplication, division, slope and similarity. Nonetheless, there is a gap in the literature as to what the intermediary understandings are between these later and earlier treatments of the concept, what types of strategies are seen to coincide with those understandings, and what types of tasks may aid in eliciting those strategies.

Our research team has developed a learning trajectory for equipartitioning (Confrey, Rupp, Maloney, & Nguyen, in review), built on the context of fair sharing (Squire & Bryant, 2002; Confrey, Maloney, Nguyen, Mojica, & Myers, 2009) which relies on sharing collections (Pepper & Hunting, 1998) and partitioning a whole (Pothier & Swada, 1983). Co-splitting has been identified as a key construct at its upper levels where fair sharing is extended to multiple wholes among multiple people. Co-splitting is a specific, "primitive" form a covariation which establishes a ratio relationship between two quantities, such that any multiplicative change in one quantity is coordinated with the same multiplicative change in the other quantity. Moreover, these changes always occur in the same direction: increasing or decreasing. The term co-splitting was conceived to make explicit the nature of relationships in the tasks and problem-types utilized in equipartitioning that differ from many ways covariation is used in other places in the literature, which include coordination of changes that are additive or other (e.g., see Rizutti, 1991; Thompson, 1994; Confrey & Smith, 1995; Carlson, Jacobs, Coe, Larsen, & Hsu, 2002).

Methods

The site of the study was a small charter school in an urban setting in the southeastern United States. A sample of eight students was purposefully chosen based on those students presence during the equipartitioning portion of an earlier teaching experiment. For a sample with maximum variation, prior student work and observations by the classroom teacher and the researchers were considered, and for gender balance, four females and four males were selected.

Two, semi-structured clinical interviews were conducted by the same interviewer with each of the eight students. These were limited to 45 minutes each so as to keep the student's interest, and therefore two sessions were necessary to complete the tasks, but both interviews were video-recorded and occurred within the same week for every student. The collected data were first open coded, considering single statements, responses, and mathematical moves (physical actions relevant to solving a problem or explaining how a problem was solved) to be the units of data. In a second round of coding, specific codes were developed based on common themes across the students that were relevant to the research question.

For the clinical interviews, we adopted the notion of what Streefland (1991) called "distribution" problems, asking students to determine how a number of people and a number of pizzas could be fairly distributed across multiple tables so that all receive the same size share. His representation for the problem displayed a circle and number of pizzas over a number of people sharing (hereafter a Streefland diagram, Figure 1). Students were presented with three tasks: (1) 24 pizzas and 18 people, (2) 12 pizzas and 8 people, and (3) 25 pizzas and 15 people.

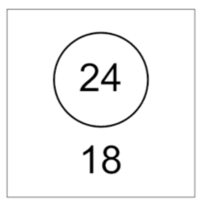

Figure 1: Streefland diagram for 24 pizzas and 18 people

Results

There were four types of strategies utilized by the third-graders working with co-splitting tasks. More than one level was observed for some strategy types, all eight of which have been ordered from lowest to highest sophistication and are shown in Table 1 below. There was also one dominant facilitating strategy that showed up across these main strategies, which was the use of manipulatives or drawing physical representations. In doing so, the students relied on experiences from equipartitioning collections of objects and equipartitioning single wholes, particularly dealing in rounds and establishing one-to-one correspondences. This often led them to the determination of the ratio unit (smallest whole number ratio within a set of proportions) and/or the unit ratio (quantity per 1)—which represented the fair share in these problems. Most all of the students used more than one of the strategies during the course of the interviews. No students initially attempted to create an arrangement that did not involve a splitting action on the people and pizzas. However, all but one student were able to justify presented arrangements that involved different numbers of people and pizzas at one or more tables, and more than half went on to later create at least one arrangement involving unequal quantities of people and pizzas across the tables. Therefore, almost every student reached a combining ratios level at some point.

Table 1: Observed and Hypothesized Strategies

Type	Strategy	**Brief Description:** Students determine the number of tables by …	Exemplar of Student Work
Guess	Guess	… random choice – do not specify mathematical reasoning (often an initial approach)	Adjustment	Incremental Adjustment	… adding/subtracting tables from previously attempted numbers		Factor-based Adjustment	… multiplying/dividing tables from previously attempted numbers	Splitting and Co-Splitting	Split and Check	… splitting (partitive) one quantity, and then checking the same split on the other quantity		Partitive Co-split	… splitting (partitive) both quantities		Inverse Co-split	... inverse splitting (doubling or *n* times) both quantities	Combining Ratios	Combining Like Ratio Units	… combining like unit ratios, ratio units, or compound ratio units, to form equivalent fair shares	
	Hypothesized: Combining Unlike Ratio Units	… combining unlike unit ratios, ratio units, or compound ratio units, to form equivalent fair shares	*From above – create two tables: one with 3 pizzas and 2 people and the other with 9 pizzas and 6 people*

Discussion and Conclusions

An understanding of what it means to preserve the fair share (unit ratio) was vital to students being able to properly justify their responses and work flexibly with different splits and strategies. However, finding the unit ratio corresponding to a fair share did not imply that students would use a more sophisticated strategy, such as combining ratio units. The students in this study were able to find a unit ratio readily, which appeared to be based on equipartitioning knowledge and skills, but only one student used the combining ratio units strategy fluently.

Proficiency in this upper-level equipartitioning construct of co-splitting clearly required knowledge of fairly sharing collections and single wholes, and an understanding of the principle of continuity, which states that fair sharing of a single whole is possible for any number of people. However, the construct is also further enhanced by understandings of compensation and reallocation. Therefore, mastery of *all* the lower levels in the equipartitioning learning trajectory provides a solid path along which the construct of co-splitting is understood and the strategy of co-splitting can be used to solve these types of sharing problems. Experiences with co-splitting tasks such as these will allow students reaching the combining ratios strategy to establish a multiplicative proto-ratio understanding, which can be later built upon and used in conjunction with ratio comparison tasks to create a more formal understanding of ratio.

A key transition for students is from arithmetical thinking to algebraic reasoning. Measuring the impact of materials and approaches intended to promote this transition requires assessment tools that address more than symbol manipulation skills and computational fluency. This paper provides a brief overview of our perspective of conceptual algebra readiness, our initial attempt to measure this construct, and a brief glimpse of how we are using the test results to develop activities to help students develop conceptual algebra readiness.

Keywords: Algebra and Algebraic Thinking; Learning Trajectories (or Progressions)

Introduction

This study is part of a larger project to prepare students to be conceptually ready for algebra, (conceptual algebra readiness). To accomplish this goal, we first attempted to gain a better understanding of conceptual algebra readiness. Second, we attempted to measure this construct. Finally, we are using these results to develop and refine activities that promote this construct. This paper will address our attempts to determine test items and constructs that measure conceptual algebra readiness and also its utility as a potential predictor of success in algebra.

Through a state Mathematics Science Partnership grant with a local school system, we are developing weekly problem solving activities for students in grades 4–7 to improve their conceptual algebra readiness. In the year prior to the implementation of the activities in classrooms, we conducted a study of eighth grade students in a different, but neighboring, school system to try to determine what problems and constructs were indicators of conceptual algebra readiness.

Our reasoning is that helping students understand certain underlying concepts will better prepare them for success in algebra. And if we can measure students' understanding of these underlying concepts or constructs we can (1) develop and refine activities which will help students gain the appropriate conceptual understandings, and (2) predict success in algebra. If we can measure algebra readiness and predict success in algebra then we will have a way to measure the success of our project.

Measuring the impact of materials and approaches intended to promote conceptual understanding of algebra requires an assessment tool that addresses more than symbol manipulation skills and computational fluency. There are a multitude of tests that purport to measure algebra readiness. A brief examination of some of these tests reveals that most are focused on the skills necessary to succeed in algebra (e.g., computational fluency, fractions, decimals, percent, inequalities, etc.). While these tests attempt to measure algebra readiness, they typically measure knowledge of students' arithmetic skills or pre-existing algebraic understandings and do not get at the conceptual nature of algebra—the real difference between algebra and arithmetic—the ability to generalize and work with generalizations. Other, existing tests are measures of symbolic manipulation. However, these tests fail to address the need to assess students' conceptual readiness for algebra.

Theories and Perspectives of Early Algebraic Learning

The field of research on early algebra—developing algebraic reasoning prior to formal algebra—is quite diverse with several different approaches and theories guiding these approaches (Blanton & Kaput, 2003; Carraher, Schliemann, & Brizuela, 2000; NCTM 2000; Schifter, 1999). Our project has attempted to translate (Lagemann, 2009) these theories and approaches into usable knowledge in order to determine "what works." Under further examination, we found that no one theory could effectively explain how children learn algebra and there was no consensus. Consequently we used multiple theories and approaches as a theoretical basis for the test we developed.

Methodology

Using the previously described theoretical perspectives and others which are too extensive to include in this paper, we developed a test for eighth grade students designed to measure conceptual algebra readiness. The test consisted of 15 items with sub-parts for a total of 23 responses. Items were either scored correct, "1" or incorrect, "0."

The study took place in two middle schools, grades 6–8, from a Midwestern city school system, population 6,344 with 49% of the students receiving free or reduced lunches. The state average is 48%. At the beginning of the school year, the test was given to all eighth grade students taking algebra and to eighth graders taking pre-algebra whose parents had completed a student permission form. At the end of the school year the students' grades were collected in algebra and pre-algebra and the algebra students' End of Course Assessment (ECA) on the state mandated test in algebra. Table 1 shows the number of students in each group who took the test at the beginning of the year. The number in parentheses is the number of students who we received their final grade and /or ECA score.

Table 1: Samples Sizes

School	#Pre-algebra	#Algebra
B	80 (64)	47 (45)
K	41 (36)	34 (29)
Total	121 (100)	81 (74)

Results and Discussion

As part of the analyses we computed the mean number of correct responses and standard deviation of each group on the test. In each school the algebra students scored higher than the pre-algebra students, as expected.

Table 2: Mean and Standard Deviation

School	Pre-algebra Mean (STD)	Algebra Mean (STD)
B	11.4125 (3.22)	17.213 (2.36)
K	10.8049 (3.06)	15.4706 (3.50)
Combined	11.16 (3.16) n = 100	16.58 (2.68) n = 74

We combined the pre-algebra students from both scores and the algebra students and conducted a two-tailed *t*-test of the means. The test was statistically significant at the $p = .01$ level.

On all items, the algebra students scored better than the pre-algebra students. How might this chart inform our test construction and design of student activities? Item #3 asks students to generalize:

> *A machine that puts kites together costs $12.00. The cost of materials to make one kite is $3.00 per kite.*
> *1c. What if you do not know the number of kites you need to make.*
> *How much will it cost to make 'n' kites?*

Here we expected differences between the groups; 46% and 74% respectively. We expected the Algebra students' ECA score would correlate with this item. We ran a basic Pearson correlation between the test item #3 and students ECA scores where we found a low correlation of 0.16. This item represents a key focus of our project and we will need to consider why there was not higher correlation.

Items #18–21 ask students to graph points on a coordinate plane.

Plot the following points on the graph provided: (-3,4), (0,-2), (2,3),(4, -1)

Both groups did well with small differences. This suggests that graphing ordered pairs on a coordinate plane need not be a major focus of our student activities. Our next test iteration may focus on the concept of slope instead.

A more modest correlation, 0.48, occurred between item #5 and students' ECA scores which dealt with general problem. In the algebra group, 64% of the students had this item correct and 36% of the pre-algebra students had the item correct.

A protractor and a compass cost $3.00. If the protractor costs $.80 more than the compass, how much does each cost?

Here there is a major difference between the two groups. We will keep this question on our next test iteration and develop more student activities similar to this problem. Consequently, to improve the conceptual algebra readiness of students in grades 4–7, we will focus more on problem solving. This reinforces one of our underlying premises of the project; a problem solving approach is a viable way of helping children develop algebra readiness.

Another modest correlation; 0.47 occurred between item #22 (a generalization problem where students were asked to choose the best deal) and students' ECA scores.

Raymond has some money His grandmother offers him two deals:
Deal 1: She will double his money
Deal 2: She will triple his money and then take away 7
Raymond wants to choose the best deal. What should he do?

We expected a difference between the pre-algebra and the algebra groups: 20% and 47 %. This suggests that these types of problems might be a focus of student activities we design for the project.

Conclusions

We are using these analyses to make revisions to a conceptual algebra readiness test we developed and to the classroom activities we are developing. Conceptual algebra readiness is a difficult concept to measure. However, our initial attempts to measure it have proven fruitful in helping us refine student activities and in developing the second iteration of a test.

Our study was limited in that we do not yet have the ECA scores from the students who were in pre-algebra. We also expected higher correlations on the item analysis.

Our next phase is to refine our activities for students based on our findings from this study. We would like to give the algebra readiness test to students who have used our activities, to assess how well our project is preparing students conceptually for algebra. Ideally, we would like to test students with multiple years of experience using our activities in grades 4–7. Our aim is to both measure conceptual algebra readiness and to better prepare students for algebra.

EXPLORING EQUIVALENCE OF EXPRESSIONS THROUGH SPREADSHEETS

Nicholas J. Gilbertson
Michigan State University
gilbe197@msu.edu

In this study, I investigated how two first year university students in an introductory algebra class developed ideas about equivalence by using spreadsheet-based tasks. Using a teaching experiment method I proposed a small-scale hypothetical learning trajectory focused on three topics; variable, explicit form, and methods for determining equivalence. Participants showed progress along these three landmarks as indicated by a pre-survey and post-interview data as well as discourse data from the three teaching sessions. Evidence from this study suggests that spreadsheet-based tasks may support some students with investigating, conjecturing, and reasoning about the equivalence of algebraic expressions.

Keywords: Algebra and Algebraic Thinking; Design Experiments; Technology

Purpose

Algebra has been called a *gatekeeper* for future opportunities in education and employment (e.g., Knuth, Alibali, Weinberg, & Stephens, 2005), and research indicates that students who successfully pass algebra requirements have more opportunities than students that do not (National Mathematics Advisory Panel, 2008). Equivalence of expressions sits at an important crossroads in the learning of algebra because it relies on an understanding of *variable* and a relational view of the equal sign, something with documented challenges for younger students (e.g., Knuth, Stephens, McNeil, & Alibali, 2006).

Learning Equivalence through Technology

Although research on equivalence of algebraic expressions is somewhat limited there are some studies that indicate technology could be a potentially useful instructional tool (e.g., Kieran & Saldanha, 2005). Interested in the affordances of technology in learning equivalence, I chose to focus on spreadsheets for three primary reasons; they are economically viable and widely available, there are similarities between algebra-syntax and cell-formula programming, and a main feature of spreadsheets is the capability to generate large tables of values to inspect and reason about equivalence. The research question for this study was, *What is the nature of learning of algebra students on equivalence of expressions by interacting with tasks in a spreadsheet environment?*

Theoretical Framework

To address the research question I conducted a teaching experiment. A core purpose of this method is to better understand student thinking by generating models of learning (Lesh & Kelly, 2000). A main feature of teaching experiments is the close interaction of the researcher with the instructor whether it is as a consultant or a dual role as in this study. The main rationale for conducting a teaching experiment in this study was two-fold. First, I was interested in studying a change in knowledge (i.e. learning) that took place over time. Second, although this was a small-scale introductory study, any notions of generalizability would hopefully be useful to practicing teachers. Thus, it was important to strike a productive balance between creating a research-friendly environment while maximizing the authenticity of classroom interactions.

Hypothetical Learning Trajectory on Equivalence

Underlying the teaching experiment method is an articulation of how participants' understanding of equivalence changed over the sessions called a *hypothetical learning trajectory* [HLT] (Simon, 1995). This trajectory is the researcher's hypothesis of how participants will progress through the teaching experiment, which includes certain landmarks of understanding. The trajectory and landmarks should be informed by research whenever possible. Because the research literature on equivalence is less developed compared to other mathematical topics, there is minimal elaboration of what an HLT on equivalence of expressions might look like. In the next few paragraphs I outline three important landmarks as one possible trajectory.

Landmark 1 – Variable. Researchers (e.g., Usiskin, 1988) have indicated many different ways that the term *variable* can be interpreted, ranging from a specific unknown value, to representing a set of values, to a "*temporally indeterminate number* whose fate is to become determinate at a certain point" (Bardini, Radford, & Sabena, 2005, p. 129). Others (e.g., Wagner, 1981) have pointed out how students misinterpret variables in particular situations. The general nature of variables is essential in seeing the corresponding generality in two equivalent expressions and so it was included as the initial landmark of the HLT.

Landmark 2 – Explicit form. The second landmark is writing a rule in explicit form. This landmark was chosen specifically because of the spreadsheet intervention. The ability to generate large tables of values using a spreadsheet might lend participants to reason recursively. Recursive equivalence is in some ways more complicated, and explicit form is in many cases simpler when talking about relationships of certain uncountable sets. Researchers (e.g., Lannin, 2004) have claimed that it is more natural for students to reason recursively and others such as Swafford and Langrall (2000) report findings indicating that some students' ability to represent situations symbolically is related to the likelihood they would symbolize a relationship explicitly.

Landmark 3 – Equivalence methods. The final landmark is creating a method to reason about equivalence. Kieran and Drijvers (2006) refer to one approach for determining equivalence as *numerical*. Using the method a student reasons two expressions are equivalent if the same input values correspond to the same output values for both expressions. In contrast, Kieran (2007) provides an alternative approach referred to as the *transformational* approach that uses algebraic properties (such as the distributive property) to reason if two expressions are equivalent. This final landmark is the end goal of the HLT, for a student to develop a rationale for determining whether two expressions are equivalent or not.

Method

Two college algebra students met with the teacher-researcher over three 60–90 minute teaching sessions in a three-week time period with an individual post-interview a few days after the final teaching session. The sessions consisted of two to three tasks per session designed to create opportunities to encounter equivalence in different ways such as geometric patterns and relationships between numbers. In between sessions a colleague played the role of consultant helping with planning and making any modifications to the planned tasks for the sessions.

Data Collection

Throughout the sessions participants' paper-and-pencil and electronic work was collected. Video was recorded and later transcribed both in large group and on the participants' computers by use of screen capture software. Participants' responses on a pre-survey and post-interview were also collected. The first part of the survey focused on comfort and frequency of spreadsheet use. The second part focused on equivalence of algebraic expressions. In the post-interview, participants were asked open-ended questions about their experiences, as well as five identical questions from the pre-survey on identifying equivalence. Analysis of these items was conducted comparing the answers provided on the pre-survey with post-interview responses.

Analysis of sessions. To analyze how participants progressed along the HLT a discourse analysis was conducted focusing on two types of talk; how they talked about the spreadsheet, and how they talked about equivalence of expressions. Along with coding on expressions and equivalence, Gibbons (2002) *mode continuum* was used as a framework to analyze participants' talk about spreadsheets. The mode continuum describes how explicitly or implicitly participants talk refers to objects with shared meaning. Table 1 below describes the three subcategories along the continuum that was coded.

Table 1: Example Coding of Participant Discourse

Modal Code	Description	Example
Situation embedded	Shared meaning of language, often using pronouns such as *this*, *that*, or *it*.	"It will give you what that equals"
Specific Language	Objects in the statement are referred to explicitly, the speaker reconstructs experience through their description	"In C2 I guess you'd do A1 plus B2"
Object-Generic	Speaker talks non-temporally, the statement is about an object not a specific event.	"Spreadsheets are amazing"

Results

In this section I provide results in the form of a case study. Due to space limitations, I only provide Xandra's results from the discourse analysis and movement along the HLT. Xandra's discourse analysis shows a gradual shift from situation embedded language (66% in session 1) to more specific language (64% in session 3). Xandra seemed to have a solid working definition of variable as evidenced by her ability to relate cell-formula names to their algebraic analogues. She was able to justify why the expression 3*(G1 + 2) was equivalent to 3*G1 + 6 via the distributive property. It was unclear however, when Xandra used the drag-fill feature whether she interpreted the copying and pasting to be a move from a single situation (i.e., B1 = 3*A1) to a more global situation (i.e., column B = 3 times column A) analogous to a students' movement from interpreting a literal symbol as an unknown to a variable.

For the final two landmarks on the HLT, Xandra demonstrated the ability to look for patterns and describe relationships both recursively and explicitly. She often articulated expressions multiplicatively instead of additively consistent with an explicit form approach for the tasks provided. From the beginning of the first session, Xandra used the spreadsheet to investigate equivalence. Across the sessions, Xandra was more likely to justify equivalence through the use of properties (34%) such as the distributive property, and she made over twice as many claims about why expressions were equivalent than Melissa. Overall, Xandra showed strengths in her understanding of variable, her ability to generate expressions in explicit form, and fluency in reasoning about equivalence. Her post-interview told a somewhat different story.

Xandra had only one correct answer on the pre-survey's five questions focused on determining whether two expressions were equivalent. Identical questions were given during the post-interview. Xandra confidently answered all five incorrectly. After providing her answers she was prompted, "is there a way you could use the spreadsheet to convince someone that…[these expressions are] equivalent or they're not equivalent?" One by one, she worked through the problems using the spreadsheet and convinced herself that her original conclusions were all incorrect.

Conclusions

The results of this study indicate that Xandra used spreadsheet based language with increasing specificity as the sessions progressed. This lends evidence to the claim that her ability to communicate in the technological discourse increased indicative of a change in knowledge. In Xandra's case she was able to re-convince herself of the equivalence or non-equivalence of two algebraic expressions by using the spreadsheet. Admittedly, it is unclear whether Xandra's move to use the spreadsheet was the reason for the change in her solutions, or whether a similar occurrence would have resulted by similar presses for justification by the instructor/researcher.

While generalizable claims are difficult to make given the small convenient sample size and participants' general interest in technology, both participants did show movement along the HLT. Variables were seen as generalized quantities, participants articulated the advantages of writing expressions in explicit form, and they applied different methods for determining equivalence. These landmarks provide a productive starting point for future work on unpacking students' notions of equivalence of algebraic expressions.

This ongoing study focuses on the algebra knowledge of 4th and 8th grade students as measured by the 1996 through 2011 NAEP mathematics assessments. Over that period, 149 items have been used allowing analysis of performance on topics such as understanding and use of algebraic expressions, understanding of numeric patterns, and ability to use equations and inequalities to solve problems. For example, performance on a grade 8 item assessing ability to write the equation of a line passing through a point increased significantly from 2007 to 2011, suggesting that there is improved coverage of this topic at the middle school level. In contrast, there has been little change on three items requiring equations to solve word problems. Knowledge of such patterns provides information about what areas of the mathematics curriculum are effective and what areas need to be strengthened.

Keywords: Algebra and Algebraic Thinking; Assessment and Evaluation

The National Assessment of Educational Progress (NAEP) has collected data on the performance of elementary, middle, and high school students in the United States since the late 1960s. Of the content areas that NAEP has assessed, there has been more growth in mathematics performance at the elementary and middle school levels than any other subject area (Kloosterman & Walcott, 2007). Growth in mathematics performance at the high school level has been modest, although major changes in the grade 12 assessment between the 2000 and 2005 administrations make patterns of growth after 2000 difficult to quantify.

In addition to reporting overall results, NAEP has reported results by content strand (number and operation; geometry; measurement; algebra; and data analysis, probability, and statistics) since 1990. Like the overall trends in mathematics performance, the trends in performance in the algebra strand for students in grade 8 showed substantial improvement between 1990 and 2011. In contrast, there was substantial improvement between 1990 and 2005 at grade 4 but there was only a 3-point gain between the 2005 and 2011 administrations and the algebra score did not change at all between 2007 and 2011 (NAEP Data Explorer, 2012). Given the importance of algebra and algebraic thinking (National Mathematics Advisory Panel, 2008), this study analyzes grade 4 and grade 8 NAEP algebra data from 1996 through 2011 with the intent of explaining what NAEP assesses with respect to algebra and the extent to which gains have varied across topics within algebra (patterns, graphing, linear equations, etc.).

Background

The National Center for Education Statistics (NCES) provides reports on overall findings of each NAEP assessment. The Main NAEP assessments, which are the basis for this study and a bit different from the Long-Term Trend Assessments (Kloosterman & Walcott, 2007), provide overall results for the nation as a whole, by state, and by demographic subgroup. The reports also provide technical information such as sampling procedures, item development and scoring procedures, and details of statistical analyses performed on the data. Because NAEP is based on a representative national sample of students at the grades where it is administered (4, 8, 12), results based on NAEP data are valid for the United States as a whole. Although any one student completes at most 25 NAEP items, different items are completed by different students so when results are pooled across students, there is information on a wide variety of skills. The 2003 Main NAEP assessment, for example, used 182 items at grade 4 and 189 items at grade 8. Of these, 26 of the grade 4 and 48 of the grade 8 items were in the algebra strand. After each administration, roughly one-fourth to one-third of the items are replaced so that there are enough items to track tends over time while allowing for updates to keep the assessment consistent with changes in curriculum. Most items that have been retired are released to the public (see http://nces.ed.gov/nationsreportcard/itmrlsx/). One of the reasons that items are retired is that they no longer represent what is being taught in schools and thus released items are not necessarily representative of the NAEP assessment as a whole.

Since the early years of NAEP, there have been interpretive reports based on the specific items used for the mathematics assessment. Some of these reports have focused specifically on NAEP algebra items. For example, Chazen et al. (2007) reported that gains in the algebra strand were greater than gains in any other content strand for grades 4 and 8 in recent years but that gaps in performance based on race/ethnicity persist. These researchers also found that performance on items used at both grades 4 and 8 was always higher at grade 8 although the amount of difference between grades varied substantially by item. Looking at performance of grade 8 students on NAEP, Sowder, Wearne, Martin, and Strutchens (2004) reported on 10 algebra items that were used in 1990, 1992, 1996, and 2000. Of those items, performance increased significantly from 1990 to 2000 on both pattern items, three of six items involving algebraic expressions or equations, and both items involving graphing. In contrast, performance increased significantly on only 1 of 8 algebra items administered from 1996 to 2000. In a similar analysis, Kloosterman et al. (2004) found significant gains on all 5 pattern and informal grade 4 algebra items used from 1990 to 2000 but just 2 of 5 items used only in 1996 and 2000. These types of analyses show that progress varies depending on time frame and also on the specific task assigned.

NAEP Conceptual Framework

The NAEP assessment has always been based on a conceptual framework outlining content and grade or age level assessed, sampling characteristics, item format, and additional issues such as use of calculators and complexity or difficulty of items (e.g., National Assessment Governing Board, 2010). This framework, which is updated periodically, affects both what and who is assessed. For example, the current framework includes provisions for accommodations for students with disabilities in the sample whereas the framework used 20 years ago included students with disabilities only when they could complete the assessment without accommodations. For the purposes of this study, it is assumed that the NAEP frameworks are adequate for item development along with collection and reporting of performance data. It is also assumed that NAEP items used in the study are appropriate measures of algebraic reasoning. In other words, this study defines student understanding of algebra as the responses given on the NAEP assessment.

Method

Because the sampling procedure for Main NAEP was the same from 1996 to 2011, this study focuses on all items that included algebraic concepts used during that period. Given that previous research, including the research described earlier in this report, has reported on some of the algebra items used between 1996 and 2003, there will be a special focus on performance between 2003 and 2011. Note that only items that have been released can be reported verbatim, but the content of non-released items can be described in general terms and thus non-released items are also included in the analyses.

All items were coded by two members of the research team into categories including (a) algebraic expressions; (b) patterns, relations, and functions; and (c) mathematical reasoning in algebra. Based on those codes and the need to have enough items in any one sub-category to make generalizations, the research team is currently building tables of results for the items on topics where there are four or more items. Tables showing items and results for all categories for grades 4 and 8 will be available on the project website (ceep.indiana.edu/ImplicationsFromNAEP/) in time for discussion of those tables at PME.

Results

Table 1, provided as an example of the tables that are being developed, shows the percentage of students correctly answering items related to understanding and use of algebraic expressions at grade 8. The table includes 5 released items, which are reported verbatim, and one non-released item, which is only described. As was the case in previous reports of item-level performance on NAEP, results reported in Table 1 show that performance on some of the individual items has been relatively stable but performance on others has changed. Item 2, in which students were told that N equals a specific perfect square and then asked to identify the square root of N, had the greatest gain with a 6% increase in performance over a 4-year period. Item 6, where students had to identify the equation of a line passing through a given point, had a 5% increase in performance over 4 years. These results suggest that seeing square roots in symbolic format and seeing the connection between equations and graphs are topics that are getting more attention at the middle school level. The relatively low performance on item 1 shows that while students have experience at using common formulas in middle school, they have difficulty when formulas are described rather than explicitly stated. Item 3 shows that almost ¾ of students can write a simple algebraic expression while items 4 and 5 show that when expressions get a bit more complex, performance drops significantly.

Discussion

Although NAEP provides overall results by content strand, those results are too general to give a good sense of exactly how performance changes over time on specific types of mathematics tasks. Item-level analyses help to alleviate this problem. Between 1996 and 2011, there were 55 grade 4 and 94 grade 8 items that involved some sort of algebraic reasoning and most were used for more than one year. With an item pool this large, there are enough items on relatively specific algebra-related topics to get a sense of the algebra knowledge of 4th and 8th graders as well as a sense of how knowledge in each of those areas is changing over time.

Table 1: Performance on Grade 8 Items Involving Understanding and Use of Algebraic Expressions

	Percent Correct				
Item Description	2011	2009	2007	2005	2003
1. The temperature in degrees Celsius can be found by subtracting 32 from the temperature in degrees Fahrenheit and multiplying the result by 5/9. If the temperature of a furnace is 393 degrees in Fahrenheit, what is it in degrees in Celsius, to the nearest degree? (calculator available)			37	35	35
2. Find a number given its square root. (secure item)			64	61	58
3. If *m* represents the total number of months that Jill worked and *p* represents Jill's average monthly pay, which of the following expressions represents Jill's total pay for the months she worked?			73	72	73
4. At the school carnival, Carmen sold 3 times as many hot dogs as Shawn. The two of them sold 152 hot dogs altogether. How many hot dogs did Carmen sell?			47	47	47
5. Robert has x books. Marie has twice as many books as Robert has. Together they have 18 books. Which of the following equations can be used to find the number of books that Robert has?	53	52	52		
6. Which of the following is an equation of a line that passes through the point (0, 5) and has a negative slope?	31	29	26

LEARNING TRAJECTORIES: THE DEVELOPMENT OF EARLY FUNCTIONAL THINKING WITH GEOMETRIC GROWING PATTERNS

Kimberly A. Markworth
Western Washington University
Kimberly.Markworth@wwu.edu

Learning trajectories have gained recent attention and prominence in mathematics education. This research investigated the development of a tentative learning trajectory in relation to students' algebraic reasoning with geometric growing patterns. Design research was used to develop a local instruction theory, to which figural reasoning was central. A hypothetical learning trajectory was developed, including a learning goal, instructional activities, and a learning progression. Four teaching experiments were conducted in sixth grade classrooms. Based on the analysis of several sources of data, changes were warranted for the hypothetical learning trajectory, and a revised learning progression is outlined and discussed.

Keywords: Algebra and Algebraic Thinking; Design Experiments; Learning Trajectories (or Progressions)

Learning trajectories have gained recent attention and prominence in mathematics education. They played a major role in the development of the Common Core State Standards in Mathematics (Common Core State Standards Initiative, 2010); when possible, the research around students' learning of mathematical concepts was used to design appropriate mathematical standards for the grade levels (Daro, Mosher, & Corcoran, 2011). Empirically-based learning trajectories, however, are not available in all domains of mathematics. In a 2011 report (Daro et al., 2011), the status of learning trajectory research in mathematics was summarized, citing rigorous research in several domains. Although quality research exists and is ongoing, algebra was identified as an area lacking research on learning trajectories.

In this paper, I summarize one aspect of my dissertation research in the development of a learning trajectory in relation to students' algebraic reasoning with geometric growing patterns. Growing patterns have characteristics which make them unique and ideal for supporting students' development of functional thinking. Shapes comprise geometric growing patterns; these shapes and their configurations can range from very simple to exceedingly complex.

This study used design research to develop a local instruction theory: "a theory about the process by which students learn a given topic in mathematics and theories about the means of support for that learning process" (Gravemeijer & van Eerde, 2009, p. 510). One aspect of a local instruction theory is a hypothetical learning trajectory. As defined by Simon (1995), a hypothetical learning trajectory consists of three components: (1) a learning goal, (2) learning activities, and (3) the hypothetical learning progression by which students' thinking might evolve.

Hypothetical Learning Trajectory

The learning goal for this learning trajectory was the development of students' functional thinking. Smith (2008) defines functional thinking as "representational thinking that focuses on the relationship between two (or more) varying quantities, specifically the kinds of thinking that lead from specific relationships (individual incidences) to generalizations of that relationship across instances" (p. 143). The functional relationship is the relationship that is identified between the stage number and some aspect of the geometric growing pattern. Figural reasoning is central to this conjectured local instruction theory and "relies on relationships that could be drawn visually from a given set of particular instances" (Rivera & Becker, 2005, p. 199).

Four mathematical practices along a learning progression were proposed: (1) identifying and articulating the growth in a geometric growing pattern using figural reasoning, (2) translating figural reasoning to numerical reasoning, (3) identifying and articulating a relationship between the stage number and a quantifiable aspect of the geometric growing pattern, and (4) using variables as varying quantities for generalization of the linear function. Figural reasoning is foundational to the first three mathematical practices; the relationship that is articulated should be based on figural reasoning. It was anticipated that students would first articulate a relationship using words. Variables would be used as a more succinct expression of the functional relationship in the fourth mathematical practice. Six lessons were designed for use in sixth grade classrooms to support students' progression through these four mathematical practices.

Methods

This study consisted of four teaching experiments, with two teaching experiments conducted simultaneously in two macrocycles. Each macrocycle consisted of the three phases of the design research process: design of instructional materials, classroom-based teaching experiments, and retrospective analyses (Gravemeijer & Cobb, 2006). A revised version of the instructional materials was implemented in the second macrocycle.

Participants

Teaching experiments were carried out with classes of sixth grade students. Four teachers (two pairs of teachers from two schools) participated in the study. One class was selected from each teacher's schedule. All students in the classes selected received instruction by the researcher and were recruited for participation in data collection procedures (Table 1).

Table 1: Student Participants in Teaching Experiments

Teaching Experiment	Total Students in Class	Number of Student Participants	Number of Participants Allowing:		
			Video-Recording	Collection of Student Work	Interviewing
TE1	23	12 (52.2%)	10	12	8
TE2	23	16 (69.6%)	16	16	13
TE3	28	13 (46.4%)	12	13	9
TE4	24	13 (54.2%)	12	13	9

Data Collection and Analysis

Several sources of data were used in this study: a pretest and posttest, co-researcher and witness classroom observations, whole-class and small group video-recording, daily reflection audio-recording with research team, student interviews, and artifact collection of student classwork and SMART board files. At the conclusion of the first macrocycle, all data from the teaching episodes were compiled for retrospective analysis. Retrospective analysis at the conclusion of the study included a thorough organization of the data, rescoring of all pretests and posttests, field notes on several forms of data collection, some statistical analysis, and extensive coding of both *a priori* and emergent themes.

Findings

Overall, figural reasoning strategies increased and numeric reasoning strategies decreased throughout the course of the instructional sequence. Whole-class discussions established the expectation that students base calculations on a way of seeing identified through engagement in the first mathematical practice. Although the result of the second mathematical practice was a numerical expression, it was consistently conveyed that this expression must be grounded in the pattern's physical structure. This allowed students to identify a generalizable calculation method.

Although other aspects of the instructional design brought out and supported students' functional thinking, the three-column table was a particularly effective tool. Typically, the first three stages of the growing pattern were articulated in the three-column table. The numerical calculations (based on figural reasoning) were then extended to other stage numbers. Students successfully used the thinking from the middle column of the three-column table to extend and generalize a calculation involving the stage number that generated the total number of pattern blocks, chairs, etc. Thus, the three-column table supported students' functional thinking.

Students' representations of the functional relationships were supported by the extended use of the three-column table. In the first macrocycle, students' representations progressed from rules with words to semi-symbolic rules, to full symbolic rules incorporating variables. Very few rules progressed to this full symbolic representation, in part because of the extensive time needed to guide students through this process. In the second macrocycle, this process was facilitated by the use of the three-column table; the numerical reasoning was extended and generalized in the three-column table by substituting a variable for the stage number.

Revised Hypothetical Learning Trajectory

The findings of this research warranted changes to the hypothetical learning trajectory. Functional thinking remains the goal, but increasingly sophisticated representations of this thinking can be considered an extension. The results of this study suggest that the learning progression of the hypothetical learning trajectory can be refined (Figure 1). The first three practices illustrate students' learning progression with figural reasoning, translating figural reasoning to numerical reasoning, and identifying the functional relationship. The bottom section of the diagram illustrates potential progressions in students' representation of the functional relationships.

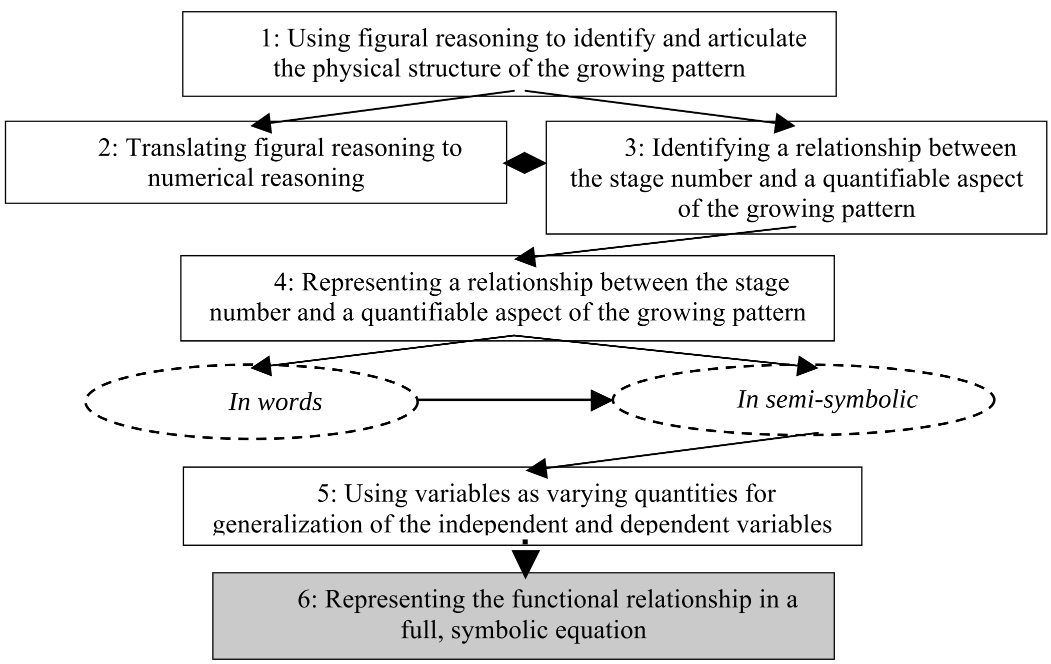

Figure 1: Revised learning progression

Students' responses in this study indicated that a focus on growth elicits recursive descriptions of the patterns. Rephrasing the first mathematical practice focuses on the physical structure of the pattern, rather than the growth that occurs as a change from stage to stage. The second mathematical practice remains the same, but the third mathematical practice has been broken into two different mathematical practices, first focusing on identifying a functional relationship and second focusing on representing the functional relationship. Two avenues of representation are suggested. The first path (left first) is suggested when the ways of seeing the growing patterns are not too complex to be represented in words. The second path (right first) is suggested with more complex patterns, for which the representations in words can be unwieldy.

The introduction to variables as varying quantities can effectively build upon the representations that students generate using familiar mathematical symbols, i.e., numerals and symbols for operations (the fifth mathematical practice). Representation of the independent variable was successful in this study, but further work is necessary around using two variables to represent functional relationships. A sixth mathematical practice has been added to the learning progression. This practice was achieved on two occasions in this study, and these occurred in whole-class discussions in the first macrocycle. More effective progression to this mathematical practice likely requires more time and exploration with geometric growing patterns. This worthy extension of the goal should be considered with further research.

Conclusion

This instructional sequence was intended to be an introduction to functions and the use of variables in representing functional relationships. Neither the mathematical context of geometric growing patterns nor the duration of the experience is sufficient for bringing students to a thorough understanding of functional relationships or how to express these relationships in full, symbolic form. However, this research provides an empirically-based, tentative learning trajectory for students' development of functional thinking in algebra. It is a place to begin with additional research to determine if this sequence of mathematical practices is valid, and how tasks might be improved to support students' development of functional thinking at other ages.

This systematic review of mathematics education literature identified over 800 manuscripts that addressed students' algebraic thinking. Initial analysis of articles led to a framework examining the math involved in a misconception or way of thinking, assessment problems, interviews with students describing their thinking, and suggested instructional strategies to develop understanding. The articles were divided into five domains of algebraic thinking based on the Common Core State Standards: Variables & Expressions, Algebraic Relations, Analysis of Change, Patterns & Functions, and Modeling & Word Problems. This report summarizes what we know from research in each domain that may be useful for teachers.

Keywords: Algebra and Algebraic Thinking; Mathematical Knowledge for Teaching; Teacher Knowledge

Algebra is the "gatekeeper" to higher education and employment because, rather than helping students develop mathematical competence and gain access to higher education, it screens out many students. For instance, in the Los Angeles School District, "48,000 ninth-graders took beginning Algebra; 44% flunked, nearly twice the failure rate as in English… It triggers dropouts more than any single subject" (Helfand, 2006, p. 1). The literature indicates students' comprehension of algebraic ideas is often not what it seems. Errors can result from simple carelessness or forgotten rules, but studies indicate common struggles with more complex sources. Some "errors are widespread among students of different ages, independent of the course of their previous learning of algebra" (Demby, 1997, p. 48). Students' have significant mental hurdles in making the transition from arithmetic to algebra (Booth, 1984; MacGregor & Stacey, 1997; Moseley & Brenner, 2009). This project captured research on students' algebraic thinking that might be useful for preservice and early career teachers, created resources based on findings, and is now helping teachers make use of that resource. We are currently in the second year of a three-year Fund for the Improvement of Secondary Education (FIPSE) grant, developing the *Center for Algebraic Thinking.*

Theoretical Framework and Background

This systematic review of the mathematics education literature identified 858 manuscripts that addressed students' algebraic thinking. Articles typically included a discussion of the math involved in a misconception or way of thinking about algebra, assessment problems, transcripts of interviews with students describing their thinking with problems, and suggested instructional strategies to address misconceptions or ways to develop understanding. Accordingly, five questions served as the framework for the synthesis of research:

1. What Common Core State Standard(s) does this research address?
2. What is the symbolic representation of thinking with the idea? (What does it look like?)
3. How do students think about the algebraic idea? (What does it sound like?)
4. What are the underlying mathematical issues involved?
5. What research-based strategies/tools could a teacher use to help students understand?

Findings from the readings contributed to three resources: a wiki-based Encyclopedia of Algebraic Thinking (www.algebraicthinking.org), a Formative Assessment Database, and Instructional Modules for Mathematics Methods courses. The above questions defined the framework for the encyclopedia entries. In addition, most manuscripts included a problem or problems that were designed to elicit a range of students' thinking around a particular algebraic concept that we collected into the Formative Assessment Database. Besides project resources, videotape of students' describing their thinking as they solve algebra problems are incorporated into the Instructional Modules.

Method

We divided articles into five domains based on the Common Core State Standards (CCSS): Variables & Expressions, Algebraic Relations, Analyzing Change, Patterns & Functions, and Modeling & Word Problems. Articles were read by a Domain Team, consisting of three to four readers who were mathematics faculty, teacher education faculty, or public school mathematics teachers from institutions in Oregon and Colorado. The director of the project identified potential worthwhile articles, categorized them by domain, and sent them to the appropriate team. Each team member read approximately 35–50 pages of articles each month for eight months. Each reading did not necessarily provide clear responses to each question, so, in some cases, the distillation of the reading into the framework was incomplete. In cases in which an article applied to more than one domain, each relevant Domain Team would read the article. Each Domain Team took responsibility for reading and discussing the articles and populating a single document with responses to each of the framework questions, with an emphasis on what would be useful to algebra teachers in middle and high school.

Each Domain Team coded the findings from the readings into themes, determining the nature of each theme as they progressed with the reading of the manuscripts. Themes were fluid throughout the process, breaking into smaller themes or combining into one theme as insights were gained from the readings. Each theme was translated into a single document with references to one or more readings. Each document addressed each of the five framework questions, where possible. Of the original 858 articles read, 680 articles were ultimately distilled into the resources. After one month of reading, teams convened to discuss their findings and suitability of the framework and made adjustments to the process. At the end of eight months, teams convened to compare findings, discover connections across domains, and refine entries. Finally, theme documents were loaded as entries into the Encyclopedia of Algebraic Thinking. The following are highlights of the research across the five domains.

Results

Two hundred twenty-eight (228) articles were identified that discussed **Variables and Expressions**. Of those, 137 were potentially relevant for teachers The majority of research fit into themes identified by Kuchemann (1981): *Letter evaluated, Letter not used, Letter used as an object, Letter as a specific unknown, Letter used a generalized number,* and *Letter used as a variable*. Four other themes also arose from examination of the literature: *Representation, Acceptance of Lack of Closure, the Process-Product Dilemma,* and *Conservation of Variable*. An example of the research findings is that students struggle to understand the stability and *Conservation of Variables*: when a letter can represent a specific unknown *or* a range of values as well as if the value of letters can change within or across problems. For instance, students were asked when the statement L+M+N=L+P+N was true (always, never or sometimes). A high proportion of students, in multiple studies, chose *never* (Steinle et al., 2009), believing M and P would never be the same amount because they are different letters. In an equation such as $x + x + x = 12$, some students believe that the same letter in an expression does not necessarily stand for the same number. A student who believes that 10 + 1 + 1 is an acceptable answer, is unlikely to make sense of the explanation that $x + x + x = 12$ is equivalent to $3x = 12$ and then $x = 4$ (Fujii, 2003). In another study, a student given the equation $x + 5 = x + x$ responded that the second x on the right side had to be 5, but the other x's could be anything (Wagner & Parker, 1993). Hearing that "x can be any number" repeatedly in class, students may logically take that principle to the extreme.

One hundred seventy-nine (179) articles were identified that discussed **Algebraic Relations**, including equations and inequalities. Of those, 135 were potentially relevant for teachers. Some related to pre-requisite knowledge: Negative Numbers and Rational Numbers. Other themes related to the structure of problems: One and Two Step Equations (x on One Side), Solving Equations with Variables on Both Sides, Solutions Involving Zero, and Inequalities. Finally, themes related to students' conceptual understanding: Flexible Use of Solution Strategies, Student Intuition and Informal Procedures, and Translating Word Problems into Equations. An example of the findings is that mathematical structure of a problem can present difficulties for students. When students approach a problem, they rely on procedures demonstrated in that day's lesson. Successful students rely on relational thinking—rewriting the problem into a form more easily understood (Demby, 1997). Once developed, students can be more successful when approaching problems that involve special characteristics such as trivial equations (x=2), equations with no solution (0x=7), equations with a solution of zero (3x=0), and with infinite solutions (2x+4=2x+4).

One hundred sixty-three (163) articles were identified that related to students' understanding of **Analysis of Change** (Graphing). Of those, 120 were potentially relevant for teachers. Three themes emerged: Creating Graphs (connecting graphs to real world data and problems with scaling), Interpreting Graphs (connecting graphs to algebraic relationships and viewing graphical representations as literal pictures), and Describing Analysis of Change (understanding slope and rate of change).

For instance, in regard to Creating Graphs, students often learn mechanical steps of graphing a set of points without understanding the real world situation they represent or understanding the relationship between the variables they are plotting. Widespread use of graphing calculators to teach graphing can complicate matters, as unequal scaling of the axes can distort the shape of the graph, further impairing student understanding of the situation being graphed (Mitchelmore & Cavanagh, 2000). Students should be involved in gathering data, creating a graph, and analyzing variables, starting as early as the elementary grades, before students study negative numbers. There is some research (i.e., Mevarech & Kramarski, 1997) that claims traditional approaches to teaching graphing that begin by first breaking the process of producing a graph into step-by-step items in a procedure may in fact perpetuate the perceived problem that graphing is a difficult topic. A preferred approach is to present students with a purposeful task in a familiar context, and students will be able to act intuitively to use line graphs.

One hundred forty-six (146) articles were identified that related to students' understanding of **Patterns and Functions**. Of those, 104 were potentially relevant for teachers. The domain team found the following themes: Reasoning and Interpreting; Translating Across Representations; Developing the Concept of Function; and Building, Transforming, and Generalizing. An example of findings from the research is that students need to see a wide variety of functions (Even, 1998). Students who only see continuous functions come to believe that functions must be continuous; students who see only smooth functions (e.g., no cusps) believe that functions must be smooth. Students should work with discontinuous functions, piecewise-defined functions, functions with holes in the domain, functions with discrete domains, with non-numeric domain and/or range, etc.

One hundred forty-two (142) articles were identified that related to students' understanding of **Modeling and Word Problems**. Of those, 108 were potentially relevant for teachers. The modeling domain team found that articles fell into several broad categories: Syntactic Issues in Problem Solving, Choosing Strategies that Result in Meaningful Solutions, Drawing Models as an Intermediate Solution Step, and Issues with English Language Learners (ELL). An example of findings from the research include that students may be overly focused on the structure of the narrative, losing the connection between the context and mathematical expression. The problem, "There are six times as many students as professors" is frequently translated as 6S = P, where S=students and P=professors (Fisher, 1988). In order to help children understand word problems, teachers often focus on key words such as "more" and "times." This strategy is useful but limited because key words don't help students understand the problem situation. Key words can also be misleading because the same word may mean different things in different situations.

Conclusion

The project has transformed the research on students' algebraic thinking into entries of an *Encyclopedia of Algebraic Thinking*, a *Formative Assessment Database*, and Instructional Modules that will are currently being incorporated into Math Methods courses at our four institutions. These resources are the heart of our current preparation of preservice teachers.

Many children have a limited understanding of the equal sign ("="), interpreting it as an *operator* (i.e., as a symbol to "do" something; Carpenter et al., 2003) without understanding that the left and right sides of an equation need to represent the same amount (i.e., a *relational* view). This is worth exploring because conceptual understanding of the equal sign is at the basis of algebraic thinking (Franke et al., 2008). Instructional interventions on the equal sign are not uniformly successful and investigating the sources of students' individual differences solving non-canonical equivalence problems (e.g., 4 + 3 + 7 = 6 + __) may shed light on this phenomenon. In the present study, we investigated the domain-general and domain-specific factors that account for differences in children's performance on non-canonical equivalence problems.

Fifty-six third- and fourth-grade students from a suburban school district in Canada were asked to solve a series of non-canonical equivalence problems before and after receiving explicit instruction on the equal sign. As a group, the students showed significantly higher scores after instruction, but a full 30% were unsuccessful on more than half of the items on the posttest. We conducted individual interviews to determine the source of the variability, and measured (a) general cognitive ability, (b) working memory, (c) mathematical fluency, (d) conceptual understanding of equivalence, and (e) ability to rate and generate definitions of the equal sign.

Regression analyses indicated that of all the variables, only general ability and mathematical fluency were significant predictors of performance on the posttest. Furthermore, qualitative analyses of the interview data revealed that 39% of the students generated an operational definition of the equal sign (Operational group), 38% of them generated a definition that included both operational and relational features (Combined group), and 23% generated a relational definition (Relational group). We found a significant effect of definition type on posttest performance, $F(2, 53) = 6.93$, $p < .01$. Post-hoc tests revealed no significant difference between the Combined and Relational groups, but each outperformed the Operational group, ($p < .0167$ in both cases).

These findings suggest that performance on problems that assess the understanding and use of the equivalence concept is related to content-specific skills, namely the ability to generate an accurate definition of the equal sign. More specifically, holding an operational definition does not hinder successful problem solving as long as it is accompanied by some element of relational understanding. This finding suggests that learning the meaning of the equal sign is not straightforward; rather, it appears to be initially context-bound and fragmented (Lawler, 1981).

CHALLENGES IN ASSESSING COLLEGE STUDENTS' CONCEPTION OF DUALITY: CASE OF INFINITY

Grace Babarinsa
University of Texas at El Paso

brmcdermott@miners.utep.edu

The paradoxical nature of infinity makes it challenging for students to conceptualize. Understanding the process-object duality of infinity is essential for having a formed conception of infinity, which is crucial for students to be successful in advanced mathematics courses. The purpose of this study was to examine college students' conception of duality and determine whether or not they possessed a dual process-object view of infinity. More importantly, (1) how is the duality conception externalized and expressed by college students, and (2) how could students' conception of duality be assessed?

Theoretical Framework

The study is supported by APOS theory to model the development of the duality conception (Dubinsky, Weller, McDonald, & Brown, 2005) via *actions*, *processes*, *objects*, and *schema*. The schema represents the "process-object duality" (Monaghan, 2001), and this dual nature of mathematical constructs can be observed through students' representations (Sfard, 1991, Gray & Tall, 1994). At the same time, scholars warn about the danger of assumption that comes with process-object duality and emphasize dynamic nature of the duality conception (Falk, 2010; Bingolbali & Monaghan, 2008) arguing that care needs to be taken in interpreting students' representation of infinity. The proposed study examines challenges in coding and assessing students' conception of duality as well as addresses diversity and variations among students' conception of duality (e.g., cases where the student's process view is dominant and the object view is recessive, cases where students' object view is dominant and process view is recessive).

Method of Inquiry and Preliminary Results

The research sample included N = 192 college students taking Calculus sequence courses at one of the U.S. southwestern universities. Multiple measures to assess students' externalization of their conception of infinity were used in the study. The first measure was a survey addressing students' concept-definition of infinity with the following statement: "When you think of infinity what comes to your mind?" The second construct was a survey assessing students' concept image of infinity in the form of "draw infinity" task with a direct statement: "Draw infinity in the space provided." The third measure was a task that includes a contextualized problem. Rating scale "duality-abstractness" was used to determine students' positioning toward duality of infinity concept. The study found that the coding and assessing college students' conception of duality is a challenging and complex process due to the dynamic nature of the conception that is (1) task-dependent and (2) context-dependent. The results of this study could be used as a springboard to further analyze cognitive obstacles in college students' understanding of infinity concept.

RELATIONSHIPS BETWEEN REPRESENTATIONAL FLEXIBILITY AND NUMBER CONCEPTS: DRAWING ARRAYS AND (MIS)UNDERSTANDING SQUARE NUMBER PROPERTIES

Reality S. Canty
University of Illinois at Chicago
rcanty1@uic.edu

Daniel Pak
University of Illinois at Chicago
danpak15@gmail.com

Keywords: Cognition; Number Concepts and Operations; Elementary School Education

A useful factor in navigating the transition from misunderstanding to understanding in math may be *representational flexibility* (RF: Nistal et al., 2009), a complex of representation abilities. One such ability is the capacity to see numbers as objects with spatial and numerical properties. Considering that number concepts (e.g., squares, primes, and composites) are central to math and understanding them may be required to use higher-order operations and reasoning (e.g., functions and integration), more work is needed to explain how they are acquired through representational experiences. A positive relationship was predicted such that students able to represent square number spatially and numerically should demonstrate greater conceptual knowledge of square number whereas those not able should reflect greater misunderstanding.

Method

Thirty fifth-graders were interviewed on two items to examine the relationship between RF (i.e., constructing spatial and numerical representations of a square number) and conceptual knowledge (i.e., explain square number in terms of its properties). Square arrays were first defined; *A **square array** is a special rectangular array that has the same number of rows as it has columns. A square array represents a whole number, called a **square number***. A spatial-numeric pattern of the first four square numbers (see Figure 1) was described; *The first four square numbers and their arrays are shown below*. The Item 1 instruction was, *Draw a square array for the next square number after 16*; a dot matrix on which to draw the array and a place to write the the square number were presented. Item 2 asked, *Can a square number be a prime number? Why or why not?* Item 1 was analysed for patterns of accuracy in students' drawn arrays and written square numbers. Explanations observed in students' responses to Item 2 were analyzed for features of an underlying conceptual model of square number.

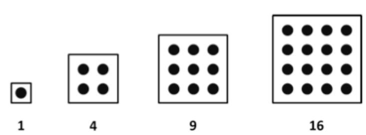

Figure 1: Visual pattern of first four arrays

Results and Discussion

RF and conceptual understanding of square number were found to be positively related and several interesting misunderstandings emerged from students' explanations. Only students who constructed equivalent array and numerical representations ever demonstrated understandings of square number properties whereas those who constructed nonequivalent representations always reflected misunderstandings about those properties. The results suggest that number concepts should be promoted by helping students represent key properties of concepts. The implications for navigating transitions from misunderstanding to understanding will be discussed.

NOTICING RELEVANT PROBLEM FEATURES: EXPERIENCE AFFECTS STUDENTS' RECONSTRUCTION AND SOLVING OF EQUIVALENCE PROBLEMS

Noelle M. Crooks
University of Wisconsin–Madison
nmcrooks@wisc.edu

Martha W. Alibali
University of Wisconsin–Madison
mwalibali@wisc.edu

Keywords: Elementary School Education; Algebra and Algebraic Thinking; Number Concepts and Operations; Instructional Activities and Practices

Elementary and middle school students often fail to correctly solve mathematical equivalence problems, which are problems that have operations on both sides of the equal sign (e.g., 3 + 4 + 5 = 3 + __) (e.g., Perry, Church, & Goldin-Meadow, 1988). These difficulties with mathematical equivalence have far-reaching effects, as understanding of the equal sign is associated with students' abilities to solve algebraic equations—a skill considered essential for long-term success in mathematics (Knuth, Stephens, McNeil, & Alibali, 2006).

This study investigated a possible causal mechanism for these difficulties, namely that the way we teach math during elementary school creates fundamental misconceptions about equations. Specifically, students' experience appears to follow three operational patterns that hinder performance on equivalence problems (McNeil & Alibali, 2005). First, students learn the perceptual pattern that equations always follow an "operations = answer" format. Second, students learn the conceptual pattern that the equal sign means to "calculate the total" or "put the answer." Finally, they learn the procedural pattern that the correct way to solve an equation is to "perform all the given operations on all the given numbers." These operational patterns may hinder students' performance is by affecting what they *notice*, or encode, about problems.

It would be inappropriate to investigate the causal basis of young students' performance by strengthening their misconceptions. However, some information about the mechanisms can be obtained through research with adults. Previous research has shown that activating adults' knowledge of the operational patterns with a priming task disrupts their ability to solve equivalence problems (McNeil & Alibali, 2005). One remaining question is how exactly these experiences affect students—does activating knowledge of the three patterns affect not only the way they solve the problems, but also what they notice about the equations? In the current experiment, adults (N = 138) were primed with either the operational patterns or with neutral stimuli. Knowledge activation condition affected the problem features that participants noticed. Specifically, participants who were primed with operational patterns both encoded and solved the equations as if they were traditional arithmetic problems, leading to less accurate performance than participants primed with neutral stimuli $t(134) = -3.09$, $p = .002$ for encoding, $t(120) = -2.56$, $p = .012$ for solving). These findings suggest that one way in which traditional mathematics education might hinder children's ability to solve equivalence problems is by leading them to misencode relevant problem features.

Keywords: Algebra and Algebraic Thinking; Learning Trajectories; Instructional Activities and Practices

The concept of a *Learning Trajectory* has recently acquired new importance as the organizing principle for the new Common Core State Standards in Mathematics (CPRE, 2011). There are several definitions of a learning trajectory within the research profession; for the purpose of this work we take the definition of Clements and Sarama (2009): A ***Learning Trajectory*** (LT) of a particular mathematical concept consists of three components:

- a specific mathematical goal,
- a developmental path along which students' thinking and comprehension develops and
- a set of instructional activities that help students move along that path.

The effectiveness (efficacy) of the LT/CCSS in Mathematics approach depends on the classroom on the teachers' ability to incorporate the developmental information contained therein into the classroom instruction.

> For that to happen, teachers are going to have to find ways to attend more closely and regularly to each of their students during instruction to determine where they are in their progress toward meeting the standards, and the kinds of problems they might be having along the way. Then teachers must use that information to decide what to do to help each student continue to progress, to provide students with feedback, and help them overcome their particular problems to get back on a path toward success. This is what is known as *adaptive instruction* and it is what practice must look like in a standards-based system. (Consortium for Policy Research in Education Report [CPRE], 2011)

How to assure the required level of teachers' involvement, how to prepare them professionally for the new challenges of the job—are questions which are preoccupying American educators at present (*Education Week*, February 1 through April 3, 2012).

Two Learning Trajectories from Arithmetic/Algebra divide, "Number Sense as the Gateway to Algebra" and "Linear Equations," will be presented on the background of the Arithmetic/Algebra concept map. Both trajectories had been obtained with the help of several cycles of *Teaching Research* (TR) NYCity Model, each developing a new iteration. The TR NYCity underlying their development involves the teacher in every component of adaptive instruction specified above. The choice of LT's developed by the TR methodology responds to the local educational needs; the most critical area along the mathematics education spectrum (middle school, high school, remedial college) is the transition from arithmetic to algebra. The aim of both trajectories is to guide the teacher in the design of adaptive instruction along that transition.

"SOME STUDENTS ARE ADVANCED AND CAN JUST FACTOR": ALGEBRAIC PROCEDURES AND STUDENTS' INSTRUCTIONAL IDENTITIES

Anna DeJarnette
University of Illinois at Urbana–Champaign
fricano1@illinois.edu

Gloriana González
University of Illinois at Urbana–Champaign
ggonzlz@illinois.edu

Keywords: Affect, Emotion, Beliefs, and Attitudes; Algebra and Algebraic Thinking; High School Education

In mathematics learning, students' identities impact whether and how students choose to engage in mathematical activities, as well as their attitudes and dispositions towards mathematics (Bishop, 2012; Boaler, 1999; Cobb, Gresalfi, & Hodge, 2009). With this poster we consider the instructional identities (Aaron, 2011; Aaron & Herbst, 2010) that students may enact in an Algebra I class. The construct of instructional identities is helpful to highlight the interaction between students' dispositions towards certain actions and the instructional context in which they are acting. In this study we focused on three questions: *What value did students ascribe to each of three strategies for finding the zeroes of a polynomial—factoring, using the quadratic formula, and using a calculator? What were the justifications for each of these evaluations? What instructional identities could be distilled from the students' values of each of the strategies?* Taken together, these questions inquire into students' instructional identities as they are played out in the everyday work that students do in an Algebra I class.

To explore these questions, we interviewed 11 students from two high schools about their perspectives about the three strategies for finding the zeroes of a polynomial. We used Toulmin's (1958) model of argumentation to decompose students' arguments into six components: *data*, *claim, warrant*, *backing*, *qualifier*, and *rebuttal*. We have found that students often base their evaluations of different algebraic procedures on either the abilities of a student (e.g., factoring is good for students who are advanced enough to use it) or on the appropriateness of the procedure for a particular task (e.g., factoring is more efficient for simple polynomials). Moreover, students are slightly more likely to determine the appropriateness of a particular procedure based on their perceived ability of the student using that procedure. This indicates that students' may place greater emphasis on how they perceive themselves as learners than what a particular task calls for when approaching problems in Algebra. Understanding how these factors influence students' instructional identities can help to explain whether and how students choose to engage in particular algebraic activities.

FROM CONFUSION TO CLARITY: HOW COMPLEX INSTRUCTION SUPPORTS UNDERSTANDING OF LINEAR FUNCTIONS THROUGH NON-LINEAR PATTERNS

Frances K. Harper
Michigan State University
franceskharper@gmail.com

Keywords: Algebra and Algebraic Thinking; Equity and Diversity; Instructional Activities and Practices; Teacher Beliefs

The standards published by the National Council of Teachers of Mathematics emphasized that all students are capable of learning mathematics and should be given access to developing high-level mathematical proficiency (Tate, 1997). However, the perception of mathematical understanding as only accessible to a select few still lingers (Boaler, 2008). Gaps in levels of proficiency persist because students view themselves as either capable or incapable of success in mathematics (Cobb et al., 2009).

Research suggests that Complex Instruction (CI) provides teachers with a powerful tool for promoting rigorous and equitable learning (Cohen et al., 1999). However, even among teachers with the same training, implementation of CI varies significantly (Lotan, 1989). This study focuses on the critical case in which all the conditions of CI are met, as closely as possible (Yin, 2009). In one specific task within a broader curricular effort, students explore patterns of non-linear functions, as an introduction to the upcoming unit on linear functions. The teacher admits that many of his colleagues feel this design is backwards, and they worry that such a challenging task may block access to learning. He responded, “Watching kids wrestle with this task affirms for me that it is the right sequence. Asking them to do something, much, much harder makes the subsequent stuff more obvious to them” (personal communication, March 9, 2012). This case provides an example of how introducing student to complex mathematical ideas first can encourage deeper understanding and proficiency, with proper instructional support provided by CI. Students gain access to this proficiency through peer collaboration, which is supported by multiple ability tasks, appropriate classroom norms and the teacher’s efforts to assign competence to low-achieving students. The teacher’s effective use of these aspects of CI facilitates each student’s transition from exploring challenging concepts with non-linear functions to developing more precise proficiency with linear functions.

ROBUSTNESS CRITERIA AS A FRAMEWORK TO CAPTURE STUDENTS' ALGEBRAIC UNDERSTANDING THROUGH CONTEXTUAL ALGEBRAIC TASKS

Sihua Hu

Jamie Wernet
Michigan State University
wernet@msu.edu

Our project aims to develop research tools to provide empirical evidence for links between teaching practices and students' understanding of algebra. Each year, students were pre- and post-tested using an assortment of Contextual Algebraic Tasks (CATs)—rich word problems adapted from tasks developed by the Mathematics Assessment Resource Service ([MARS], available at http://www.noycefdn.org/resources.php). By focusing on these tasks, we are able to examine a range of student skills using a set of criteria we developed, Robustness Criteria (RCs), which includes sense making, modeling, representational, and procedural skills.

We use the RCs in part as a framework to capture students' understanding. The five RCs are: (1) interpreting text and context in problem statements; (2) identifying and relating salient quantities; (3) generating, interpreting, and making connections between representations to solve problems; (4) executing algebraic procedures and calculations and checking plausibility of results; and (5) providing explanations that give insight into the depth of students' algebraic thinking. The criteria were developed based on literature on problem solving and algebra, particularly functions (e.g., Chazan, 2000; Schoenfeld, 2004). With this poster, we address how our scoring rubrics have evolved to provide information on students' understanding according to the RCs.

Our early rubrics were based on existing, well-tested MARS rubrics, which provide an overall score for each task based on correctness of student responses. We decided, however, that it was important to capture student understanding at the fine-grained level of individual RCs to answer our overall research questions. As a result, in Year 2 we developed new rubrics that not only provide an overall correctness score, but also scores for each RC. RCs can be assessed by looking at both students' answers to specific parts of the task and their use of particular strategies. The overall scores using these new rubrics were highly correlated with the MARS scores. Moreover, among the eight scorers across our research sites, the correlation of the scores for each RC and the overall score was above 0.700.

MULTIPLICATIVE THINKING AND STRATEGY USE OF A STUDENT WITH MATHEMATICS LEARNING DISABILITIES AFTER STANDARDIZED INTERVENTION

Jessica H. Hunt
Utah State University
Hunt.jessica.h@gmail.com

Fraction equivalency is one of the most relentless areas of difficulty in mathematics performance and understanding for all students (National Center for Educational Statistics, 2009; Siegler, Carpenter, Fennell, Geary, Lewis, Okamoto, et al., 2010). Unfortunately, students with mathematics learning disabilities (MLD) perform far worse on tests of fraction concepts compared to typical students and even students who struggle with mathematics but do not have disabilities (Hecht, Vagi, & Torgesen, 2007; Mazzocco & Devlin, 2008). The researcher designed an intervention for equivalency concepts based in the ratio interpretation (Lamon, 1993; Streefland, 1993). The researcher delivered the intervention to several students with MLD through research-based, systematic instructional methods led by teaching scripts (Fuchs & Fuchs, 2006).

Methods

One student in the third grade ("Bill") is the focus of this report. The researcher chose third graders to receive supplemental intervention in fraction equivalency due to grade level content specifications. The focal student had a label of "learning disability" from the school district and failed a curriculum-based pretest of fraction equivalency. Data sources were curriculum-based measures (CBM) and two clinical interviews given before and after 20 one-half hour supplemental teaching sessions. The intervention provided instruction on relationships found within a fractional unit (Lamon, 1993) and how to use representations and mathematical operations to generate equivalent fractional units (Streefland, 1993). Analyses of interview data involved several stages of identifying, sorting, and analyzing involved in thematic analyses as described by Grbich (2007).

Findings

Bill's performance on the CBMs and post interviews did not improve significantly after intervention. His inability to understand or iterate the fraction unit continued. Despite the ratio-based instruction, Bill viewed each equivalency problem as a sharing or partitioning situation. Although Bill's notions of fractions through partitioning were at a level of pre-coordination with potential for further development (Empson, Junk, Dominquez, & Turner, 2005), the scripted intervention was too static and did not allow for development of Bill's informal notions of fractions and fraction equivalency. Instructional experiences for students with MLD must change from static teacher driven approaches to iterative processes of student activity and teacher support based in what a student currently conceives of a mathematics concept.

Our study focuses on developing a classroom observation scheme for capturing and analyzing teaching practices hypothesized to foster students' development of robust understanding of algebra. We aim to provide a tool to address questions such as: "What are the critical aspects of Algebra classrooms?" by capturing critical aspects of classroom interaction through real-time classroom observations. Our coding scheme, Dimensions of Teaching for Robust Understanding in Mathematics (TRU MATH), builds on the work of existing classroom observation tools, such as IQA (Junker et al., 2005), but includes an algebra-specific focus. In this poster, we will share the rationale for TRU MATH, and report on the results of the use of this scheme in twelve Algebra 1 classrooms.

TRU MATH focuses on 6 dimensions of classroom practice: (1) Important Mathematics; (2) Cognitive Demand; (3) Access; (4) Agency, Authority, and Accountability; (5) Uses of Assessment; and (6) Algebra Content-Specifics addressing the following "essential" questions about mathematics classrooms: (1) Did the lesson engage the students and teacher in working on mathematics consistent with the Common Core Standards? (Common Core State Standard Initiative, 2010); (2) Did students engage in "productive struggle" with the mathematics? (Henningsen & Stein, 1997); (3) Did all students have the opportunity to engage with the learning? (Cohen & Lotan, 1997); (4) Who had a voice in the classroom discussion and ownership over the mathematical ideas? (Engle & Conent, 2002); (5) Did instruction seek to reveal what students know and build on it? (Black, Harrison, Lee, Marshall, & Wiliam, 2003); (6) Did students engage in practices that support solving algebra word problems? These dimensions are scored on rubrics specific to particular facets of classroom interaction, such as: the launch of a task, whole class discussion of mathematical ideas, or the connecting of ideas to prior knowledge. Using these scores, we can create profiles of Algebra teaching across these dimensions which can be correlated with student performance on contextual algebraic tasks (described in another proposal) to provide insight that supports and improves the teaching of Algebra.

BEYOND LOW ACHIEVEMENT: IDENTIFYING MATHEMATICAL LEARNING DISABILITIES THROUGH ATYPICAL UNDERSTANDINGS

Katherine E. Lewis
University of California, Berkeley
kelewis@berkeley.edu

It is estimated that approximately 6% of school-aged children have mathematical learning disabilities (MLDs; Shalev, 2007), which are cognitively-based differences in numerical processing that result in persistent and significant problems learning even the most basic mathematics. Subject identification remains *the* central issue in studies of MLDs, because there is no assessment to accurately identify students with MLDs (Mazzocco, 2007). I present two related studies that attempt to gain traction on differentiating general low math achievement from MLDs, by identifying the atypical understandings displayed by students with MLDs.

Study 1 involves a detailed analysis of two college students with MLDs engaged in weekly videotaped tutoring sessions on the topic of basic fraction concepts (Lewis, 2011). In addition to having low math achievement, these students met rigorous response-to-intervention learning disabilities criteria (Fletcher, Lyons, Fuchs, & Barnes, 2007). Microgenetic analysis revealed that the students with MLDs relied upon a small number of atypical understandings. For example, these students tended to focus on the fractional complement (rather than the fractional quantity), and represented 1/2 as the act of halving rather than the quantity 1/2. These atypical understandings accounted for nearly all the student's incorrect answers, resisted standard instruction, and were detrimental to the student's ability to learn more complex fraction concepts.

In Study 2, to determine the prevalence of these atypical understandings, a 16 question paper-and-pencil assessment was designed and was administered to 384 seventh and eighth grade students. The assessment was scored for evidence of these atypical understandings (1 point for each answer that was consistent with an identified atypical understanding). Most students (61%) demonstrated no atypical understandings, and only 11% of the students were classified as having high levels of atypical understandings (3 or more atypical understanding points).

Study 1 identified that students with MLDs demonstrated atypical understandings of fractional quantity and Study 2 indicated that the prevalence of these atypical understandings were not common in a larger sample of younger students. This suggests that identifying atypical understandings may be a way to begin to differentiate low achievement from MLDs. Accurately identifying students with MLDs is a necessary first step toward better understanding the very nature of MLDs. Only then can we understand the unique difficulties students with MLDs face and provide tailored instruction to help these students navigate the mathematical transitions.

VIEWS OF LESS PREPARED STUDENTS ON INSTRUCTION INCORPORATING THE COMPARISON OF MULTIPLE STRATEGIES IN ALGEBRA I

Kathleen Lynch
Harvard University
Kathleen_Lynch@gse.harvard.edu

Jon Star
Harvard University
Jon_Star@harvard.edu

Keywords: Algebra and Algebraic Thinking; High School Education; Middle School Education

Increasing evidence suggests that the practice of comparing and discussing multiple solution strategies to mathematics problems is beneficial for students' learning (e.g., Carpenter, Franke, Jacobs, Fennema, & Empson, 1998; Star & Rittle-Johnson, 2008). Yet considerable doubt remains among practitioners as to whether multiple strategies instruction is beneficial to *all* students or only to high-achievers.

In the current study, we ask: How did nine less prepared students view the practice of learning multiple strategies for solving math problems, after participating in full, year-long algebra courses "infused" with multiple strategies that were taught by regular classroom teachers? The nine students interviewed attended five different middle and high schools in four different parts of a single large metropolitan area, yet were similar in that they were all under-prepared for algebra as evidenced by their September algebra readiness exam scores.

When students were asked whether they had ever had teachers emphasize more than one way to solve a math problem *prior* to the intervention year, seven of the nine students responded that they had never or rarely had teachers emphasize multiple strategies.

When asked about advantages of the approach, students stated that learning more than one way to solve a problem helped them to *find a method that "worked for them"* (6); improved their *understanding of methods and concepts* (6); improved their *understanding of specific mathematical methods* (5); improved their *efficiency and speed* (4); improved their *accuracy in finding correct answers* (2); and *reduced their anxiety about mathematics* (2).

Students also described several curriculum features as advantageous, particularly the guiding *structured comparison questions* and the *clarity* of the step-by-step examples presentation.

Responding to the question, "What are the disadvantages of learning more than one way to solve a problem?" five students stated that there were *no disadvantages*. Four cited possible *confusion*, such as learning too many methods and forgetting one, as a disadvantage. All nine students stated that there were more advantages than disadvantages to multiple strategies.

Concerns about overwhelming low-achieving students were largely not substantiated among the students that we interviewed. In fact, students cited the advantage of *improved* understanding repeatedly throughout the interviews, and felt that the risk of confusion was minor. When developing instructional plans for struggling learners, we suggest that teachers and researchers should take struggling students' own views about multiple strategies into account.

RELATING CHILDREN'S TOPOLOGICAL UNDERSTANDINGS WITH NUMBER UNDERSTANDING THROUGH SUBITIZING

<u>Beth L. MacDonald</u>	**Cong Ze Xu**	**Jesse L. M. Wilkins**
Virginia Tech	Virginia Tech	Virginia Tech
bmacdona@vt.edu	jmf@vt.edu	wilkins@vt.edu

Keywords: Cognition; Number Concepts and Operations; Geometry and Geometrical and Spatial Thinking

Theoretical Framework

Piaget (1941/1964) explains that for number to be understood and expressed by an individual, a simultaneous coordination of the serial (sequential) and algebraic (classification) thinking structures must occur. This study focuses on how three developmental characteristics related to topology (separation, proximity, and enclosure) relate to children's coordination of serial and algebraic thinking structures. Both separation and proximity are defined by Piaget and Inhelder (1948/1956) as the perceptual joining or separating of objects due to a particular orientation of a set of objects. Enclosure is defined as a type of "between separate elements" (Piaget & Inhelder, 1948/1956, p. 80) and is dependent upon the dimension an individual perceives an object as being enclosed within. The purpose of this study was to investigate the relationship between children's topological and number understandings as it relates to conceptual subitizing.

Methods

Two 4-year-old children, Mary and Neil, from a rural area in the southeastern United States were chosen as participants due to their inability to conserve number consistently, yet ability to exhibit 1:1 correspondence and keep track of items perceptually. A teaching experiment was used to better witness the "essential mistakes" (Steffe & Thompson, 1991, p. 20) children make, informing researchers' of children's models of learning. The six teaching experiment sessions included tasks to assess children's notion of number and topological thinking structures, while focusing on children's ability to conceptually subitize and draw what they "saw."

Results and Conclusions

The children each drew upon both topological perceptions as well as their understanding of number when expressing and drawing what they "saw" when subitizing numbers four or fewer. However, children did not consistently coordinate these thinking structures. As Neil and Mary looked at dots, they seemed to attend to location of objects and then quantity of objects; quantity of objects and then location of objects; or both location and quantity simultaneously. When quantity was attended to before space, the dots drawn by the children were represented as one line or two equal lines. When space was attended to before quantity "action" was described, preventing a re-visitation of the space. The one time space and quantity were attended to simultaneously a group of four objects were decomposed into two groups of two objects, respectively. Separation and proximity seemed to relate to participants' ability to coordinate both serial and algebraic thinking structures.

A COMPARISON OF COLLEGE INSTRUCTORS' AND STUDENTS' CONCEPTUALIZATIONS OF SLOPE

Courtney Nagle
Pennsylvania State University,
The Behrend College
crt12@psu.edu

Deborah Moore-Russo
University at Buffalo,
State University of New York
dam29@buffalo.edu

This study investigates university calculus students' and instructors' understandings of slope using eleven conceptualizations proposed by Moore-Russo and colleagues (Moore-Russo, Conner, & Rugg, 2011; Stanton & Moore-Russo, 2012) and based on the earlier work of Stump (1999, 2001a, 2001b). Data were collected from 65 university students enrolled in two sections of an introductory calculus course and 26 mathematics professors attending a regional conference of postsecondary mathematics instructors in the same geographic area as the university. The students and instructors responded to the same five items related to slope, and each response was coded to indicate which conceptualizations were demonstrated.

Based on all responses to the five items, students most commonly conceptualized slope as a *parametric coefficient* (m), a *behavior indicator* (increasing or decreasing line), and as an *algebraic ratio* (y_2-y_1/x_2-x_1). The conceptualizations most frequently used by instructors were *functional property* (rate of change), *calculus conception* (derivative or slope of tangent line), and *geometric ratio* (rise over run). When considering whether the participants used one of the conceptualizations on any of the five items, *behavior indicator*, *parametric coefficient*, and *algebraic ratio* were still the most common among students, but *real world situation* moved ahead of *calculus conception* for instructors.

Students' responses demonstrated a limited diversity in conceptualizations of slope, most often interpreting slope as a coefficient or ratio that describes a line's behavior. Students demonstrated a procedural emphasis with little indication of the meaning for the covarying quantities involved or the physical and real world applications. Instructors' responses provided evidence of relatively diverse conceptualizations of slope, viewing slope as a ratio of covarying quantities with utility in a variety of applied contexts. Despite this diversity, instructors rarely used the *behavior indicator* conceptualization of slope prominent in students' responses. While these results may suggest that college instructors do not utilize students' prior knowledge as a foundation for more advanced notions of slope, further investigation of instructional emphasis and the possibility of a hierarchical relationship among the various slope conceptualizations is needed to better understand this discrepancy.

LEARNING TO REPRESENT, REPRESENTING TO LEARN

Sarah Kate Selling
Stanford University
sselling@stanford.edu

Keywords: Problem Solving; Algebra and Algebraic Thinking; Reasoning and Proof

Representation is central to learning and doing mathematics. As a mathematical practice, it involves more than simply learning to use and interpret canonical representations (e.g., Cartesian graphs). Representational practice also involves learning to invent, communicate, and reason with representations as tools for problem-solving (Greeno & Hall, 1997). Engaging in representational practice in these ways can support the development of complex reasoning and justification skills (Maher, Powell, & Uptegrove, 2009). But students may need explicit opportunities to learn how to engage in representation practice in these ways. This study explored how students' engagement in representational practice changed through participating in a five-week summer school exploratory algebra class for middle school students. The teaching intervention was explicitly designed to foster mathematical practices, including representation (Boaler et al., in preparation). The study focused on a heterogeneous group of boys, who had no prior access to this type of math instruction. Analyses of the boys' math journals showed that their written representations became more sophisticated over the five weeks as evidenced by (1) greater variety of representational forms, (2) use of multiple representations for a single problem, and (3) making connections between representations. Analysis of their small group interactions around a quadratic growth pattern task provided evidence of how they learned to create, invent, communicate, and reason with representations while problem-solving. Representation emerged as a tool for the boys to act upon the mathematics, supporting both their engagement with content (quadratics, first and second differences, and Gauss's pairing method) and other mathematical practices (justification, generalization, and making use of structure). The boys' interactions also suggested that representation supported their persistence and collaboration. Changes in their discourse revealed how negotiating multiple representations positioned them to act with agency. These findings imply that representation may be generative for students. Through learning to represent, students gained tools to support further learning of mathematics. While this study focused on a small group of students in a university-led intervention, it provides a compelling "image of the possible" (Shulman, 1983). When given access to experiences designed to explicitly foster representational practice, the boys showed substantial changes in both their engagement in representation and mathematics more broadly. With the transition to the Common Core Standards fast approaching, this study suggests that students may need access to explicit opportunities to learn mathematical practices such as representation.

SUPPORTING CONCEPTUAL REPRESENTATIONS OF FRACTION DIVISION BY ACTIVATING PRIOR KNOWLEDGE DOMAINS

Pooja G. Sidney
University of Wisconsin–Madison
pgupta6@wisc.edu

Martha W. Alibali
University of Wisconsin–Madison
mwalibali@wisc.edu

Keywords: Number Concepts and Operations; Rational Numbers; Problem Solving

Fluency with fraction operations is foundational for algebra, but often a source of difficulty (NMAP, 2008). Both young students and adults struggle to understand fraction division, and many of their errors suggest that they spontaneously attempt to transfer other operations with fractions concepts to make sense of fraction division (Ma, 1999; Siegler, Thompson, & Schneider, 2011). A structure-mapping framework (Gentner, 1983) predicts this negative transfer, since fraction division and other operations on fractions share surface similarities that encourage students to draw on this prior knowledge. This framework further predicts that students should benefit more from a structurally similar analogue, such as whole number division, which shares the abstract division structure with fraction division. Therefore, we hypothesized that students would have stronger conceptual representations of fraction division after studying whole number division than after studying fraction subtraction. To test this hypothesis, 47 undergraduates were randomly assigned to compare fraction division problems to either whole number division or fraction subtraction problems. Each participant completed a fraction division pretest, 3 comparison-to-an-analogue problems, a picture generation task, and a fraction division posttest.

The data indicated that participants transferred and adapted conceptual representations of their given analogue to fraction division. Overall, participants who compared fraction division to whole number division were more likely to demonstrate conceptual representations that included the grouping structure common to fraction division (68.2%) than those who compared fraction division to fraction subtraction (40.0%; Fisher's exact test, $p = .05$). In contrast, students who compared to fraction subtraction were more likely to draw pictures that included features of fraction subtraction. Furthermore, students who drew correct pictures gained more from pretest to posttest than did students who drew incorrect pictures on an item that required them to generate a story to correspond with a given fraction division equation, $t(45) = 2.07$, $p = .04$.

Though this study was carried out with adults, for whom fraction division is not a novel concept, we still found that activating different types of related knowledge shaped their immediate conceptualization of the problems. This work has implications for curricular sequencing, as students often learn fraction division along with other fraction operations. This proximity may contribute to negative transfer from domains with similar surface features. Instead, students may be better served by instruction that highlights whole number division as a structural analogue.

EXPLORING THE IMPACT OF KNOWLEDGE OF MULTIPLE STRATEGIES ON STUDENTS' LEARNING ABOUT PROPORTIONS

Jon R. Star
Harvard University
jon_star@harvard.edu

Claire Gogolen
Harvard University
claire_gogolen@harvard.edu

Keywords: Problem Solving; Middle School Education; Learning Progressions; Rational Numbers

Proportional reasoning is widely considered to be a major goal of mathematics education in the middle grades. The literature identifies three strategies that are commonly used by students in solving simple proportion problems: cross multiplication, equivalent fractions, and unit rate. In past research, scholars have expressed concern that students rely too heavily on cross multiplication when solving these types of problems and have advocated delaying instruction on cross multiplication in favor of both unit rate and equivalent fractions (Cramer & Post, 1993; Stanley, McGowan, et al., 2003). In fact, there is evidence that, when instruction is delayed on cross multiplication, students tend to use the unit rate strategy most frequently (Cramer & Post, 1993; Post, Behr, & Lesh, 1988). As part of a larger project investigating the effectiveness of an intervention on ratio and proportion problem solving, we assessed students' strategy repertoire for solving proportion problems and to what extent students' prior knowledge of one or more strategies impacted their learning from the curricular intervention. A sample of 430 seventh grade students completed a pretest (that took 45 minutes) and then participated in a six-week scripted intervention that focused on ratio and proportion concepts (including percent) and solving ratio and proportion word problem solving.

Contrary to our expectations, the participants in the present study relied most heavily on equivalent fractions when solving proportions at pretest, rather than either cross multiplication or unit rate. This suggests that perhaps some of the past claims about student reliance on cross multiplication may now be outdated. Consistent with the literature on cross multiplication, we found that exclusive reliance of cross multiplication at pretest had a negative impact on learning from our instructional intervention. Prior knowledge of equivalent fractions, unit rate, or multiple strategies, however, had a positive impact on students' abilities to learn from our intervention. The students who were able to benefit the most from the intervention were students who demonstrated procedural flexibility, defined as the ability to select the most appropriate strategy for a given problem (Star & Rittle-Johnson, 2009), at pretest. This finding provides further support for the growing body of literature that suggests that students' learning is enhanced when they have the opportunity to learn multiple methods and compare and contrast them.

STUDENTS WITH MATHEMATICAL LEARNING DISABILITIES RESPONSES TO WORD PROBLEMS

Helen Thouless
University of Washington
hthoules@uw.edu

This poster presents findings from a project that combines two disparate perspectives that generally do not intersect in academe: special education and mathematics education. Although the two perspectives are usually separate at the research level, they do interact in the field. Shalev (2007) estimates that approximately 6% of the population has a mathematical learning disability (MLD), a disorder that leads to problems with many aspects of number sense, including counting, magnitude estimations, word problems, and retrieval of basic facts (Jordan, 2007).

Mathematics education research has long focused on how children understand mathematics. In particular, there has been considerable research using the framework of Cognitively Guided Instruction (CGI) to explicate how typically developing children understand addition and subtraction (Carpenter et al., 1999). This framework has helped mathematics educators understand the typical developmental trajectory of these skills. However, there has been limited research using the CGI framework with students who have MLD. Most of the research on mathematics for students with MLD has focused on the students' mathematical deficits, but there has been limited research into what they do understand about mathematics. This means that most intervention studies for this population have been designed from this deficit perspective and may be built on faulty assumptions because they do not take into account what the student does understand. This current study examines what students with MLD already understand about addition and subtraction, and how this compares with students without MLD. This is important preliminary information in order to be able to later design effective interventions.

This poster presents findings from a comparative study of students with and without MLD. This study examines the following research questions: (1) How do the types of word problems solved accurately by students with and without MLD compare? (2) How do the patterns of strategy use among students with and without MLD compare? The study involves individual clinical interviews of ten third grade students with MLD and ten without MLD, using the CGI framework on a variety of tasks involving counting tasks, and addition and subtraction word problems. This poster presentation will present the preliminary analysis of the study. Implications for designing future interventions will also be shared.

STUDENT REASONING ABOUT THE INVERTIBLE MATRIX THEOREM IN LINEAR ALGEBRA

Megan Wawro
Virginia Tech
mwawro@vt.edu

I report on how a community of learners in a linear algebra classroom reasoned about the Invertible Matrix Theorem (IMT) over time. The IMT is a core theorem in linear algebra in that it connects many fundamental concepts together through the notion of equivalency. As the semester progressed, the class developed the IMT in an emergent fashion, adding equivalent statements to the theorem as the students explored related concepts. As such, the various equivalencies took form and developed meaning as students came to reason about the ways in which key ideas involved were connected.

Data for this study came from the third iteration of a semester-long classroom teaching experiment (Cobb, 2000) in an inquiry-oriented introductory linear algebra course in the southwestern United States. There were 30 students in the course, and the text *Linear Algebra and its Applications* (Lay, 2003) was used. Data sources included video and transcript of whole class discussion relevant to the development of and reasoning about the IMT, and these occurred on 10 of the 31 days of the semester. From this, 109 relevant arguments were identified, where *argument* is defined as "an act of communication intended to lend support to a claim" (Aberdein, 2009, p. 1). Through grounded analysis, these arguments were broken down into clauses of separate ideas and coded as either concept statements from the IMT or interpretations of those concept statements. Adjacency matrices were then used to organize and analyze this information.

An adjacency matrix depicts how the vertices of a particular directed graph are connected. For a given directed graph, an adjacency matrix is an $n \times n$ matrix $[a_{ij}]$ with one row and one column for each of the n vertices in the digraph, and entry $a_{ij} = k$ indicated k edges from the i^{th} vertex to the j^{th} vertex (Chartrand & Lesniak, 2005). The adjacency matrices analyzed in this study correspond to directed graphs in which the vertices are the aforementioned coded clauses from arguments regarding the IMT, and the edges are directed in such a way as to match the implication offered by the speaker(s). Adjacency matrix analysis revealed not only what mathematics developed in the class, but also the various structures of argumentation and what concepts were included within particular arguments. Results will include centrality of concept statements, density and continuity of ideas (Tiberghien & Malkoun, 2009), and an analysis of argumentation patterns over the semester that provides a summary of the emergence and shift of the collective's mathematical ways of reasoning about the IMT.

A RETROSPECTIVE ANALYSIS OF STUDENTS' THINKING ABOUT VOLUME MEASUREMENT ACROSS GRADES 2–5

Melike Kara
Illinois State University
mkara@ilstu.edu

Amanda L. Miller
Illinois State University

Craig J. Cullen
Illinois State University

Jeffrey E. Barrett
Illinois State University

Julie Sarama
University at Buffalo,
State University of New York

Douglas H. Clements
University at Buffalo,
State University of New York

This paper describes a retrospective analysis of data collected during a 4-year longitudinal study on children's thinking about measurement through a teaching experiment methodology. It focuses on results from individual interviews with two students on volume measurement. Data analysis was guided by Sarama and Clements' (2009) learning trajectory on volume measurement. Results indicate that (1) both students progressed through levels of the learning trajectory during the study, (2) different representations of 3-D objects (e.g., physical objects, cubes, pictorial representations) influenced their strategies, and (3) their individually constructed definitions for the term "volume" affected their decisions in volume comparisons.

Keywords: Measurement; Learning Trajectories; Geometry and Geometrical and Spatial Thinking; Elementary School Education

Background and Rationale

Measurement can bridge two critical domains of mathematics, geometry and number, as well as provide conceptual support to those domains (Clements & Sarama, 2007). Research has shown that children have difficulty in fully grasping the concept of volume measurement (Battista & Clements, 1996; Ben-Haim, Lappan, & Houang, 1985; Enochs & Gabel, 1984). In measurement contexts, including volume, many children apply formulas to get the answers without understanding the meaning of these formulas (Clements & Battista, 1992). Nation-wide assessments also revealed student difficulties in solving volume measurement problems. The 1977–1978 results from the National Assessment of Educational Progress (NAEP) showed that less than 50 percent of the students at grade 5 through 8 were able to answer questions correctly about the volume measurement of three dimensional (cube) arrays (Ben-Haim et al., 1985). Students' errors stemmed mostly from counting the number of visible faces of cubes shown, counting the number of visible cubes in the diagram, estimating the number of faces of cubes shown in a given diagram, and double counting cubes (Battista & Clements, 1996; Ben-Haim et al., 1985). The researchers stressed that many students were unable to enumerate the cubes correctly in such an array. Overall, these studies showed that students could not correctly solve volume measurement tasks because they were (a) not correctly applying the volume formula, (b) not correctly counting the number of cubes in 3-D arrays, or (c) confounding volume and surface area measurement. Although the current research tells us much about children's thinking in volume measurement, missing is longitudinal work showing how students' thinking about volume measurement grows throughout their development and with the instruction they receive.

Theoretical Framework

The theoretical perspective guiding this study is described by the framework of *hierarchic interactionalism,* which indicates "the influence and interaction of global and local [domain specific] cognitive levels and the interactions of innate competencies, internal resources and experience" (Clements & Sarama, 2007, p. 464). Of the 12 tenets of *hierarchic interactionalism*, the learning trajectories tenet (Sarama & Clements, 2009) is the most germane to this report. It guided the design of the longitudinal study and informed the development of instructional tasks. A hypothetical learning trajectory consists of three components: a learning goal, a likely path for learning as students progress through levels of thinking, and the instruction that guides students along the path (Sarama & Clements, 2009). Furthermore, the learning trajectory for volume measurement was utilized as the data analysis tool for this study.

Sarama and Clements (2009) asserted that students' understanding of volume measurement gradually improves with the instruction they receive in addition to their natural development. They defined the volume measurement trajectory through eight levels. According to the trajectory, children initially focus on external aspects of arrays as sets of faces. Later, students develop an appreciation of the internal structure of 3-D arrays. They gradually become capable of counting the number of cubes contained in objects, one by one or in a pattern of rows and columns and layers. This level is called Primitive 3-D Array Counter (PAC). The next level, Capacity Relater and Repeater (CRR), focuses more on volume as capacity. At the CRR level, a student "fills a container repeatedly with a unit and counting how many. With teaching, [a student] understands that fewer larger than smaller objects or units will be needed to fill a given container" (Sarama & Clements, p. 307). The next level, Partial 3-D Structurer (PS), describes student counting in terms of rows or columns (or units of units) of a solid built with unit cubes. The next more complex level of volume involves thinking in terms of layers of unit cubes and is called 3-D Row and Column Structurer (VRCS). The highest level described in the volume measurement learning trajectory is 3-D Array Structurer (AR). At this level, students can mentally de/compose 3-D arrays into layers. These levels are used to describe student's thinking for a particular task or teaching episode rather than to define the student's overall thinking about volume measurement.

Purpose

The aim of this study was to investigate students' thinking in volume measurement over a four-year period within the context of a teaching experiment.

Research Question 1: How do students develop coherent knowledge and integrated strategies for volume measurement across Grade 2 through Grade 5?

Research Question 2: How are students' abilities for spatial thinking, algebraic reasoning, or proportional reasoning related to their measurement knowledge and strategies?

Method

The sample for this report consisted of two children (Ryan and Owen) from a Midwestern public school. Each student represents just one of seven case studies within a four-year longitudinal study investigating children's thinking and learning across length, area, and volume for Grades 2–5. Instructional tasks were developed within the context of a teaching experiment (Steffe & Thompson, 2000). The teaching experiment consisted of a series of teaching episodes for which the research team generated a set of tasks and predictions for student responses and then later checked student responses against these predictions. Each teaching episode was an individual, semi-structured interview, which lasted 15 to 40 minutes. The interview tasks were informed by the learning trajectory for volume measurement (Sarama & Clements, 2009). Before the first teaching episode, an initial assessment was administered in the form of a clinical interview in which the interview tasks were posed without feedback or instruction. All interviews, including the initial assessments and teaching episodes, were videotaped, transcribed, and analyzed by a group of researchers, the authors.

During the four-year teaching experiment, Owen encountered 30 volume measurement tasks within 12 interviews, and Ryan encountered 30 volume measurement tasks within 11 interviews when they were in third, fourth and fifth grades in addition to their initial assessment interview during second grade. The teaching episode tasks represented volume with a variety of objects (e.g., physical objects, cubes, pictorial representations). Additionally, the tasks required a variety of actions: filling a container with water, packing a box with the unit cubes, building a prism with unit cubes, and finding the volume given only linear measurements. Some of the tasks required students to draw 3-D objects.

Results and Discussion

Five themes emerged from the analysis of the data for both students: (a) finding volume of rectangular prisms, (b) relating the size and the number of units, (c) visualizing representations of the 3-D objects, (d) flexible unit sense, and (e) fractions and volume measurement. Due to space limitations, only the first three themes will be presented in this paper.

Owen's Thinking on Volume Measurement

a) Finding volume of rectangular prisms. In the second grade spring semester—during his initial assessment, Owen was asked to determine the number of cubes needed to make a 3 in × 2 in × 2 in prism presented as a physical object with the individual cubes displayed. While holding the prism and showing the interviewer what he counted, Owen said, "12…because there is 3 here [showing one whole surface of one face] …and 3 here [showing another whole surface of one face]." Later, he changed his answer to 6 (correct). While determining the number of cubes, Owen mentally constructed and counted layers (composite units) of 6 in the figure. However, when asked how many cubes altogether would be needed to fill the partially filled box of 3 units × 3 units × 4 units (Figure 1), he looked at the figure and said "about 35" without any apparent strategy.

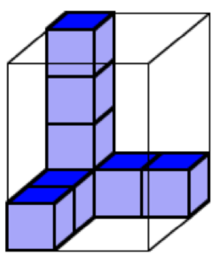

Figure 1

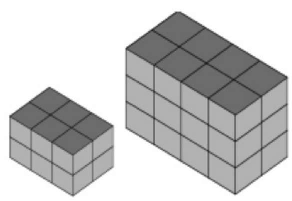

Figure 2

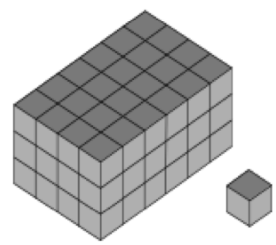

Figure 3

Approximately 12 months later, in the third grade spring semester, Owen was asked to compare the volume of the two prisms in Figure 2. Although he reported a correct additive comparison of 12 more cubes would be needed to build the larger prism, to determine how many blocks would be needed to make the smaller prism (3 units × 2 units × 2 units), he incorrectly answered 16. When asked to build the first figure with the actual cubes, Owen built the figure by using an appropriate row structuring strategy, with 12 cubes. He made two separate rows of 3, placed them next to each other, then explained that there were two layers of 6 in the figure, and changed his answer from 16 to 12. In response to an extension of the same task, Owen said that he would need 36 cubes to build the second figure (4 units × 2 units × 3 units) shown on the paper. Pointing to one of the lateral faces of the figure, he explained 6 plus 6 is 12 and then pointed to the front face and lateral face respectively and said "another 12." Owen appeared to have attended to the surface area of the vertical faces only. When asked to build the figure with cubes to check his answer, he constructed rows and layers correctly and changed his answer to 24.

Throughout the interview, Owen did not initially determine the number of cubes correctly. Instead he first attended to the surface area or counted the squares on the lateral faces. These actions are consistent with the PAC level. On the other hand, when asked to build, Owen correctly resolved the tasks at the PS level by skip-counting and thinking about volume in an organized way; he was adding the number of units in rows.

Approximately eleven months later, in the spring semester of fourth grade, Owen was asked to compare the volume of a rectangular prism to a unit cube (Figure 3). Owen stated that one cube on the side was one of the cubes in the rectangular prism and counted the number of cubes on the bottom. He said that 5 times 4 was 20 and 20 times 3 was 60. In this task, he saw that there were 3 horizontal layers in the solid. However, he calculated the number of cubes in each layer incorrectly; he counted the length as 5 instead of 6, likely in an attempt to avoid double counting a row. Nevertheless, this showed that he could think at the

VRCS level by counting layers of units multiplicatively. Later, in the same interview, Owen was given the same task again (see Fig. 1) and asked how many cubes would be needed to fill the outlined box. By attempting to count the cubes individually Owen gave an incorrect answer of 27. He did not use layers or multiplicative thinking although he used the strategy of structuring in terms of layers for the previous tasks of the same interview. Owen may have failed to resolve this task successfully because of the high visualization demand of the task.

Approximately eight months later, in the first interview of fifth grade, Owen was given a solid box (4 in × 3 in × 3 in), which did not have any unit indication on it and a collection of 1-inch cubes and was asked how many small boxes it would take to fill the big box (Figure 4). Owen struggled in the beginning and gave an incorrect answer of 12. After building one vertical layer of 4 in × 3 in × 1 in, which aligned to one face of the box, he changed his answer. He found the number of cubes in one layer, 12, and thought there were "3 rows [layers]" so 36. In this instance, Owen showed the VRCS level of thinking as evidenced by his tendency to think about prisms in terms of layers built from cubes.

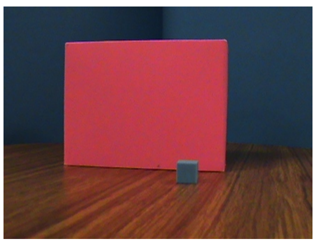

Figure 4

Figure 5

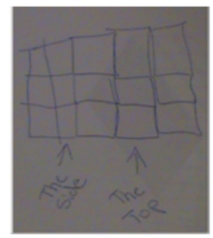

Figure 6

One of the tasks for the second interview of the semester was about finding the volume of the room compared to a cubic meter and a cubic decimeter (Figure 5). After iterating a meter stick across the floor of the room, 6 times for the length and 3 times for the width of the base of the room, Owen reasoned correctly that 18 cubic meters would fit in the bottom layer of the room. He said that there would be "3 of those [layers] going high…so 18 times 3." He concluded that therefore, 54 cubic meters would fit into the room. He also measured all three dimensions of the cubic meter and one dimension of the cubic decimeter block with a meter stick and found that 10 cubic decimeters would fit along each edge of the cubic meter. Thus, he multiplied 10 times 10 times 10 and found a product of 1000 to represent the number of cubic decimeters in one cubic meter. In order to determine the number of cubic decimeters that would fit into the room, he multiplied 54 by 1000. Owen found approximate values for the measurement of the dimensions of the room (actual room size: 7 m × 4 m × 3 m). The student applied multiplication and applied AR level strategies to resolve this task by using only the linear measurement of the 3-D prisms, by building and manipulating composite units of cubic decimeters as well as cubic meters, and by mentally decomposing arrays into layers, rows, and columns.

b) Relating size and number of units. Owen encountered a number of tasks requiring him to relate the size and number of units. Starting in third grade, as suggested in the volume measurement trajectory CRR level, he was aware that different units would give a different volume measurement and he recognized an inverse relationship between the size and number of units.

c) Visualizing representations of the 3-D objects. In the spring semester of fourth grade, Owen was asked to draw something that was 3 times as big as a 1-unit cube. Owen drew three squares in a 3×1 form. Next, he was asked to draw a picture of a solid three times the volume of a 3×2×1 solid. He created the drawing shown in Figure 6. With an aerial perspective, he could visualize the new solid from a top view. In the follow up interview, while looking at his old drawing, Owen explained that there would be 2 layers of 9 so that there would be 18 cubes. The figures Owen drew did not have 3-D perspective; however, he could use his own representations to determine the number of cubes in the figures.

Ryan's Thinking on Volume Measurement

a) Finding volume of rectangular prisms. In the second grade spring semester initial assessment, Ryan was asked how many cubes altogether would be needed to fill the partially filled box of dimensions 3 units × 3 units × 4 units (Figure 1). Ryan drew line segments extending the edge lines of the cubes and gave an incorrect answer of "18."

In the third grade spring semester, when asked how many of these cubes were necessary to make the smaller shape in Figure 2, Ryan gave the answer 25 (incorrect) and explained that he counted 4 for each lateral side, 6 for the front side, and 6 for the ceiling. He did not count the cubes on the base and also added the numbers incorrectly. Ryan was asked to build the physical representation of the shape with actual unit cubes. After building he noticed his mistake and said, "I was counting them wrong…I was counting the sides…I should have been counting cubes." He also took the cube in the top corner and said that he was counting that cube as two although he should have counted it as one. His final answer of 12 was correct after being allowed to build the structure with unit cubes. Ryan's realization of his incorrect strategy might have influenced his volume definition throughout the task, which changed to "how many cubes there are." In the next task of the same interview, while finding the number of cubes in the second figure of dimensions 4 units × 3 units × 2 units (Figure 2), Ryan curtailed his previous strategy of counting the faces of cubes. However, he still answered incorrectly (28 cubes) because he only counted the visible faces of some cubes. When he was asked to build the physical representation of the figure, he built the actual figure row by row and reached the correct answer. Ryan's responses and strategies, while resolving these tasks, were consistent with the PAC level. Specifically, he initially counted the outer faces of cubes. On the other hand, while building the shape with the actual cubes, Ryan could think more systematically in terms of columns as exemplified in the PS level. Ryan used a higher level of strategy while using 3-D physical objects than when resolving the task with the figural representations on the paper.

Seven months later, in the fall semester of fourth grade, Ryan was shown the actual cubes and container in Figure 7 and asked how many blocks would be needed to fill the container. Ryan counted by fives up to 20 by showing the bottom rows of 5 and said that there would be about 20 blocks. Then he counted by 20s up to 100 reporting a correct answer. When the same type of question was asked for a larger container (8 in × 10 in × 5 in) and with missing cubes in the first layer (Figure 8), Ryan failed to give a correct answer for the number of blocks needed to fill the whole container. In order to prompt the student, the interviewer took the extended rows and columns so the shape was changed back to its original version, and reminded Ryan that he said 100 blocks would fill the previous container. Next, the interviewer added 4 more cubes to the side of 4 and repeated the question. Ryan explained that the complete part had 4, the missing part also had 4 and explained that if they filled the missing part, 40 would go in the first layer, 80 in two layers, and so forth; he added composite units of 40s until he reached a correct response of 200. In the first task of the interview, Ryan counted first row by row and after finding the number of cubes for one layer, iterated the numbers by adding for each layer. However, he could not implement the same strategy properly when both rows and columns were missing on the bottom layer or when the numbers got bigger than 5 or 6 in a row.

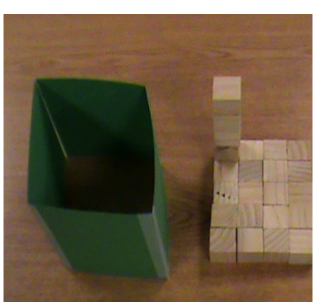

Figure 7

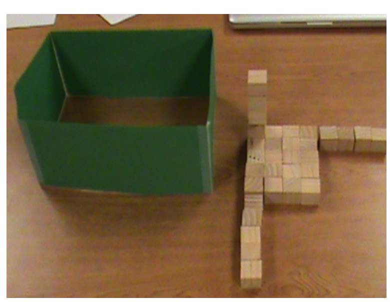

Figure 8

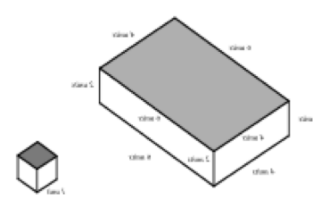

Figure 9

Although Ryan showed VRCS level strategy of counting composite units and then counting layers by skip counting in the first task, he did not use this strategy when the mental structuring demand increased as in the later task. Once he knew how many cubes were in one layer, he used repeated addition to add up the blocks in all the layers. This strategy is a typical VRCS strategy in the learning trajectory.

Eight months later, in the spring semester of fourth grade, Ryan was shown the task represented in Figure 9 and was asked, "If this cube has a volume of one, what is the volume of this solid? How many cubes would it take to fill the box?" Ryan found the volume by adding all of the number labels given for the edges. This task representation did not elicit his thinking clearly whereas the previous task was useful to probe his thinking about structuring in volume measurement.

Approximately five months later, in the first interview of fifth grade, Ryan was given a rectangular prism (4 in × 3 in × 3 in), which was wrapped with paper, and a 1-inch cube (Figure 4). He was asked how many of the cubes it would take to fill the box. By iterating the cube along one side of the prism, Ryan said "it is about 36….1,2,3,4." He pointed to a row of 4 on the bottom of the lateral face by iterating the cube and continued to iterate vertically by counting "4, 8, 12." Then he continued to count by pointing with his finger on the upper edge of the box vocalizing 12, 24, 36. Later, when given a centimeter cube and asked how many of those cubes would fit into prism, Ryan made a composite unit of 8-centimeter cubes to represent each 1-inch cube. Next, he reasoned correctly and multiplied 36 by 8 and gave an answer of 288. Ryan showed VRCS level of thinking by mentally decomposing a 3-D array into layers. Additionally, his strategy of building a composite unit of 8-centimeter cubes was consistent with AR level.

b) Relating size and number of units. In the spring semester of third grade, Ryan's volume definition was, "the number of cubes in a shape." In order to determine whether he was able to relate the unit size and volume, he was posed a task requiring him to compare the volume of a 4 in × 2 in × 2 in rectangular wooden prism with a 4 cm × 3 cm × 2 cm rectangular yellow plastic prism. He was told, "Another person compared the figures and thought that since the yellow prism has 24 cubes and the wooden one has 16, the yellow figure has a larger volume. Do you agree?" Ryan thought, by his definition of volume, that the volume of the block made of centimeter cubes was greater even though he articulated that two wooden cubes are just like 24-centimeter cubes. Similarly, in the spring semester of the fifth grade, he was given a task relating different unit sizes and the number of units in volume measurement. When asked which objects would melt into more water, Ryan thought that the collection of smaller cubes would melt into more water because there were more of them even though he noticed the difference in the unit size. He stated that they would need four of the larger cubes to "make" the six of the smaller cubes. We suggest that Ryan's volume definition had not substantially changed through third and fourth grade, nor had he conceptualized volume as the amount of space an object would take up.

c) Visualizing representations of the 3-D objects. In the spring semester of fifth grade, Ryan was asked to make a drawing on paper of a 1-inch cube that he was handed, and second to draw a picture of 3 in × 2 in × 2 in figure shown in a two-point perspective drawing with shading. He drew a square and called it a cube. He struggled to copy the 2-D drawing of the 3-D image.

Conclusions and Implications

According to the results, when finding the volume of rectangular prisms, both Owen and Ryan demonstrated abilities in each of the levels of PAC, PS, VRCS, and finally AR. However, both students also employed lower level strategies for some tasks.

Consistent with prior research, (e.g., Battista & Clements, 1996; Ben-Haim et al., 1985), initially, both students had the tendency to count the outer faces of the cubes instead of the number of cubes, demonstrating PAC level strategies. After one or two semesters, they could see the row, column, and layer structures in the rectangular prisms and count the number of cubes by creating composite units (row, column, layers). In later semesters, both students used multiplication as repeated addition while thinking in terms of rows, columns, and layers made of unit cubes.

Ryan mostly used multiplication when the figures were represented physically but not pictorially. These findings suggest that it is important to provide a variety of representational forms of 3-D objects in volume measurement tasks in order to help students solidify the meaning of multiplication in volume measurement. In addition, the formula for the volume of a rectangular prism may not make sense to students without understanding why they need to multiply the linear dimensions (Clements & Battista 1992).

In spring semester of fourth grade, although Ryan and Owen struggled to determine the volume of rectangular prisms without any grid on them, they were able to resolve some of the tasks when prompted to use a 3-D unit. For example, both students could resolve the task represented in Figure 4 by using the unit cube given. Ryan iterated one unit cube along the edges of the cube to find the number of unit cubes in each row, column, and layer. Owen was prompted with multiple cubes aligned as a vertical layer of the prism. Therefore, giving a 3-D solid unit was helpful for both students.

Students' thinking differed according to the physical versus pictorial representations provided in the tasks. When both students were posed tasks requiring them to imagine rows, columns, and layers, and some aspects of the figure were obscured, the students sometimes gave incorrect answers and used incorrect strategies. For the task represented in Figure 1, Owen struggled to visualize the complete rows, columns and layers if the box was full of cubes. Similarly, Ryan could not resolve the task (Figure 8) when there were hidden rows and columns on the bottom layer, as the visualization demand was higher.

Based on students' responses, it can be claimed that students' strategies about relating the unit size and the total number of units in the objects were influenced by their volume definition. For Ryan, who defined volume as, "the number of cubes in a shape," the volume of the block made of more (centimeter) cubes was greater than the one made of fewer inch cubes even though he noticed the difference in the unit size. Therefore, while preparing the instructional materials for students, using different size units and comparing the volume of objects with those units should be considered, especially for the students who have a misconception that the volume is the number of units instead of the amount of 3-D space an object takes up.

Moreover, both students had difficulties in drawing or copying 3-D figures made of cubes on paper. Although they could calculate the volume of those objects, their drawings did not correctly represent the actual figures. We claim that Owen could interpret his own drawing and that he could hold a correct mental representation in his mind for the object. This showed that the students' representations might be identified as incorrect, even though they have correct mental representations for the figures in their minds. Students should be given opportunities to draw representations and at the same time given opportunities to articulate what they are seeing from the pictures. This might let teachers understand how students think and visualize the 3-D objects.

Lastly, on most of the tasks requiring students to interpret 2-D drawings or pictures of 3-D figures, students resolved the task if they were allowed to build the figures with the actual unit cubes. Building the figures with cubes apparently helped students identify their mistakes and change their strategy to count in terms of rows, columns, and layers. Therefore, students should be given opportunities to build the shapes, which are shown on paper.

This report describes navigating transitions along continuums of professional learning. We discuss current approaches and introduce a discourse-centered educational model to introduce secondary mathematics teachers to dynamic geometry environments (DGEs). We present how our course will engage teachers in a collaborative online environment, known as Virtual Math Teams with GeoGebra (VMTwG), focusing on significant mathematical discourse.

Keywords: Classroom Discourse; Geometry and Geometrical and Spatial Thinking; Teacher Education–Inservice/Professional Development; Technology

To effectively improve mathematics education to be aligned with Common Core State Standards for Mathematics (CCSSM), teachers need to understand and learn to use innovative technologies and pedagogies. For instance, the CCSSM recommends, "students consider the available tools [such as] dynamic geometry software…to explore and deepen their understanding of concepts." To accomplish this recommendation, middle and high school teachers first need to be equipped to engage students meaningfully in lessons that incorporate dynamic geometry software and other technologies. However, the research literature in mathematics education contains few investigations on teacher professional learning in the use of dynamic geometry software. To address this scarcity, this report has two aims. First, it discusses what the research literature in secondary mathematics education offers about how to support practicing teachers' use of dynamic geometry. Second, it presents a model for professional learning that seeks to empower and support mathematics teachers to appreciate and engage in new approaches using dynamic geometry and, particularly, within a cyber-learning environment.

This work is important because it is a key component of our collaborative research project between investigators at Drexel and Rutgers Universities,[1] that integrates a dynamic geometry environment (DGE) with collaborative tools for mathematics exploration to provide a range of opportunities for students to engage in significant mathematical discourse, and develops supporting professional learning opportunities for practicing teachers. This project incorporates the use of GeoGebra, which currently only exists in single user mode, and an application of computer supported collaborative learning, known as Virtual Math Teams (VMT), which the project is extending to include the first multi-user, dynamic DGE, known as Virtual Math Teams with GeoGebra (VMTwG).

Professional learning of DGEs and use of online collaborative environments each includes navigating transitions through several stages. We offer theoretical considerations and examine challenges that occur when teachers move along a novice-expert continuum, using similar environments, as reported in the literature. We are in the first year of a four-year project; therefore, we present preliminary results from our design-based research (Brown, 1992; Cobb, Confrey, diSessa, Lehrer, & Schauble, 2003). We offer approaches to the challenges through our design for professional learning courses that intend to support teachers through their transitions. Finally, we identify issues we anticipate emerging from this work that will be important to examine carefully, and we make suggestions for future research.

Theoretical Framework

The theoretical framework for the discourse focus in VMTwG is situated in theories of knowledge and meaning making in mathematics. Using Vygotsky's theory of social mediation, we believe that higher functions of human thought are first learned socially, as part of interactions among people, and that knowledge is an evolving achievement of interpersonal meaning making. We view mathematics as discourse, using a participation metaphor (Sfard, 2001, 2008) and believe that norms can be established to engender productive mathematical discourse (Michaels, O'Connor, & Resnick, 2008). In line with this and adding to the Vygotskian notion of the zone of proximal development, a group of peers has the ability, though its discourse within a computer supported collaborative learning environment, to develop new knowledge that exceeds the capabilities of any one member of the group (Stahl, 2009).

Collaborative problem solving among learners working as small teams is an interactive, layered building of meaning. Through their discursive interaction teams create objects and, in turn, these objects shape and advance the discourse. Further, the team's discursive interactions occasion their reflections on relations among objects and dynamics among relations, as well as reasoning and problem-solving heuristics. The interactive work leaves the team with tools for future collaboration (Powell & Lai, 2009). The public and permanent nature of online mathematical collaboration allows classmates to follow their own and other groups' mathematical accomplishments, observing and reflecting on their colleagues' developing knowledge, successful mathematical collaboration, and shifts in discourse (Silverman, 2011).

The research literature describes gradual transitions learning DGEs: as teachers are introduced to DGEs, they use the environment first to produce static handouts, and then for presentation of dynamic visualizations. Once teachers feel comfortable and self-confident, they allow their students to actively discover mathematical concepts through discovery learning and lesson enrichment. Some teachers do not move past the presentation stage, and many take several years to transition to discovery learning (Laborde, 2007; Lu, 2008a; Preiner, 2008).

The mathematics education literature reports teachers rarely find time to engage in learning processes capable of transforming their teaching practice or significantly modifying their highly constrained curricula (Assude, 2005; Cuban, Kirkpatrick, & Peck, 2001; Laborde, 2007).

Methods

Using time they have scheduled for masters-level courses, we invite practicing teachers to identify their least favorite topic to teach, or a topic their students have difficulty learning, as one VMTwG lesson to incorporate into their practice. To help in-service teachers navigate the transitions reported in the literature, we are developing an online course in VMTwG that will catapult teachers' learning beyond the initial phases directly to preparing teachers to engage their students in learning mathematics through significant mathematical discourse. We propose to accomplish this through a series of synchronous and asynchronous activities in which teachers function in collaborative teams. Customized activities are being adapted from existing curricula, aligned with the Common Core State Standards, and through reflections on course readings, which include learning VMT and GeoGebra. Teachers will also learn to help students develop discourse strategies that lead to productive and accountable collaboration.

Within their team's "chat room," teachers first become familiar with the VMTwG environment, which includes a chat panel, a whiteboard tab, a wiki page tab for summaries and reflections, and a multi-user, dynamic version of GeoGebra, where users can define dynamic objects and where diagrams can be dragged around the screen. Each team has a common GeoGebra tab, and each team member has a GeoGebra tab for individual work.

For each course module, team members are prompted do some mathematics asynchronously in their GeoGebra tab, and post their noticings and wonderings to a group wiki page. The team then meets synchronously at its scheduled time, and chats about interesting noticings and wonderings. In the same synchronous session, the team collaborates to solve open-ended mathematics problems on the common GeoGebra tab, guided by prompts to engage in mathematical discourse surrounding discovery learning, with team members taking turns to accomplish the activity and to explain reasons for their actions.

Constructions are validated by showing that the properties and relations of their diagram remain intact when they drag any basic object that they used to construct it (Powell & Dicker, 2011). Each member of the team will be accountable to the whole team, ensuring that every member is capable of accomplishing each task. To help teachers become better prepared to orchestrate significant mathematics discourse with their students, they reflect on their experience and how they will structure a similar activity for their students, empowering them as they develop their discourse pedagogy.

Finally, team members will reflect on the logs of their discourse and the discourse of the other teams, which will be captured in VMTwG, to identify successful discourse moves and discourse moves that may have hindered progress, moving them along the continuum of first learning and then learning how to support significant mathematics discourse among their students, posting their reflections on the team's wiki page. There will be a final synchronous session in which the team discusses the most interesting discourse reflections.

Throughout this course, cycles of problem solving followed by analysis, discussion, and reflection on the solutions in small groups move teachers towards the goal of facilitating the transition from doing math and supporting each other's mathematical development to synthesis and reflection on the significant mathematical ideas that transcend particular solutions or solution method (Silverman, 2011). This is the first of two professional learning courses. In the second course, teachers will implement what they have learned in their classrooms, within the context of their current curriculum; with mentoring and resources to support this effort.

Preliminary Results

Engaged in design-based research, we are seeing what an emerging educational model using GeoGebra might look like in a collaborative synchronous environment. We have just begun to collect data from our research team and from groups of teachers participating in our formative evaluation, in the form of whiteboard summaries, logs of chat and of GeoGebra moves. From the data collected, we are developing codes to analyze the mathematics discourse. This data has led to the following two preliminary results:

First, we see that systematic turn taking in GeoGebra, is necessary for both technical and collaborative reasons, with clarification of who is doing what.

Second, in an online environment, we have found it necessary to simulate classroom procedures of periodically calling the class together to make meaning of an activity. To do this, we have refined the model to have multiple stages: asynchronous (noticing and wondering, getting everyone on the same page), synchronous (talk about the activity, and then doing it), asynchronous (reflections on the math, the discourse, and the VMTwG system), and for some modules, synchronous (reflection on discourse moves).

Discussion and Implications

Some of the issues we anticipate emerging that will be useful to investigate are as follows: How do we assess teachers' transition along the novice-expert continuum? How can we provide optimal scaffolding so that the teachers emerge from a one semester course with sufficient skill and confidence to implement what they have learned with their students, and mentor other teachers, the following semester? As the original cohort of teachers transition along the novice-expert continuum with VMTwG, how will their transition correlate with students' performance?

DOES BLOCK PLAY SUPPORT CHILDREN'S NUMERACY DEVELOPMENT?

Block play engaged by young children has been found to predict their subsequent mathematical and literacy competence in formal schooling (Clements & Sarama, 2007; Wolfgang et al., 2001). Moreover, studies have shown that adult number talk has been found to relate to children's emergent numeracy skills (e.g., Levine et al., 2010). However, little is known whether parents' engagement in block play also supports preschoolers' early acquisition of numeracy skills. Thus, the current research investigated whether the complexity of block play engaged by the parents is related to their children's numeracy abilities a year later. Twenty-seven children (14 girls, 13 boys) between the ages of 31–41 months old and their parents participated in a 30-minute play session at their home. Our findings reveal that the preschoolers' numeracy competence is positively related to the complexity of block play engaged by their parents.

Keywords: Early Childhood Education; Geometry and Geometrical and Spatial Thinking; Number Concepts and Operation

Introduction

The acquisition of mathematical knowledge at a young age is important as research has shown that children already exhibit individual mathematical differences before the age of four (Klibanoff, Levine, Huttenlocher, Vasilyeva, & Hedges, 2006); and these differences are predictive of children's later mathematical knowledge throughout elementary school (Duncan et al., 2007). For example, the amount of parental number talk children received between 14 and 30 months old is predictive of their acquisition of cardinality of number words when they are 46 months old (Levine et al., 2010). These findings reveal that there are already children who are at an academic disadvantage before entering formal school. Furthermore, they underscore the fact that it is important to support early mathematical learning and development via a mathematically-enriched home and/or preschool environment to facilitate young children's subsequent mathematical competence.

One type of mathematically-enriched activity that has been found to benefit children's subsequent mathematical competence is block play (e.g., Clements & Sarama, 2007; Wolfgang, Stannard, & Jones, 2001). For example, block play has been found to predict five- to seven- year-old children's spatial skills and geometric knowledge (Casey et al., 2008). Furthermore, engaging in block play has been reported to facilitate the development of a number of mathematical concepts and skills (MacDonald, 2001). Specifically, higher levels of block building by preschoolers are predictive of: subsequent mathematics scores on standardized tests in the 7th grade, the number of mathematics classes and honours classes taken in high school, average mathematics grades in secondary school, greater reading ability in elementary school, and a faster rate of growth in reading skills (Hanline, Milton, & Phelps, 2010; Wolfgang et al., 2001).

Despite these findings on the benefits of block play in supporting academic skills, the National Research Council committee on Early Childhood Mathematics (Cross, Woods, & Schweingruber, 2009) has strongly recommended that children between three and six years old learn geometry (along with numeracy) as they are not currently provided with adequate opportunities to engage in developmentally appropriate early childhood math activities. This sentiment is supported by a survey with preschool teachers revealing that engaging in geometry is their least favorite topic compared to counting (Sarama, 2002). Additionally, there is a dearth of research on the role of adult geometric talk and play on children's mathematics competence. Hence, there is a pressing need to (1) examine the relationship between engaging in block play and numeracy development and (2) understand how adults—parents and early childhood educators—scaffold the development of numeracy through their geometric input using blocks prior to kindergarten and formal schooling.

Thus, the present research investigated the relationship between the level of complexity of block play engaged by parents with their children during play and children's subsequent numeracy competence a year later. Competencies in geometry and numeracy have been reported to being closely related to each other. For example, young children with visual-spatial deficits also experience difficulties performing numerical tasks (e.g., Semrud-Clikeman & Hynd, 1990). Previous studies have determined a child's level of block play by taking a snapshot of each child's final construction and then determining which level this final creation most resembled (Hanline et al., 2010; Wolfgang et al., 2001). A limitation of this approach is that the final construction may not accurately reflect a child's grasp of spatial and geometric knowledge, especially for young children with incomplete mastery of motor and coordination skills. An example is a child building a castle/tower who was unable to put a roof properly on the castle/tower due to limited motor skills. Based on the final creation, one would determine the child's block play to be at the level of block stacking, instead of at the level of block bridging which is considered more advanced according to Johnson's (1966) developmental stages of block play. The current study sought to capture more accurately the level of block play in preschool children (and their parents) by observing the entire block manipulation process.

Method

Participants, Materials and Procedure

Twenty-seven native English-speaking children (14 girls; 13 boys) aged 31 to 41 months old (*M age* = 35.55, *SD* = 2.65) and their primary caregiver (the mother was the primary caregiver in 24 observations) participated in a 30-minute play session at home. The participants were part of a longitudinal study that examined young children's mathematics development. The family socio-economic status (SES) was measured by the mother's education level, a reliable proxy for SES (Catts et al., 2001). The highest education level attained by mothers was as follows: 8% of mothers with high school or lower, 30% with college/trade, and 62% with university, graduate or professional education. All families were two-parent households.

A standard set of toys such as puppets, shapes, and foam blocks were provided in order to minimize differences in the immediate environment. The parent-child dyad play sessions were recorded, transcribed and the parent's levels of block play were coded using the Observer XT 8.0 system and software program (Noldus Information Technology, 2008). A weighted average was used to compute the average level of block play complexity for each parent. Twenty-two percent of the visits were secondary coded by a trained research assistant. The levels of block play were coded based on Johnson's (1966) developmental stages of block play (see Table 1).

One year after the home-visit, the children were individually administered the Test of Early Mathematical Abilities version 3 (TEMA-3) (Ginsburg & Baroody, 2003) to assess their numeracy competence. The TEMA-3 is a standardized early mathematics test that is administered orally and assesses both informal (e.g., numbering) and formal (e.g., written representation of numbers) mathematical concepts. The test has a total of 72 questions; however, the testing stopped once the children answered five consecutive questions incorrectly. The raw TEMA-3 score for each child was computed and used in the analysis.

Results

Our results indicate that caregivers produced 348 instances of block play during the 30-minute play session. About 20.4% of the play session was spent in block play. Most children had some exposure to mathematical-oriented games in their homes; about 62% of the children played frequently with blocks. As shown in Table 1, out of the eight levels of block play, the most frequent levels modeled by parents were in the lower levels, specifically, levels 1 (40%), and levels 2 (40%), followed by levels 4 (7%), and levels 8 (5%). Examples of Level 7 and 8 block play engaged by two parents are presented in Table 2. The inter-coder reliability based on 22% of the play sessions was as follows: Cohen's Kappa at 92% and the population coefficient (Rho) at 97%.

Furthermore, our findings reveal that the average level of block play engaged by parents (M = 2.15, SD = .77) were positively and significantly correlated with the children's TEMA-3 raw score (M = 12.44, SD = 7.16), [$r(25) = .40$, $p = .037$], indicating that parents who engaged in higher levels of block play had children who received higher scores on the numeracy task one year later.

Table 1: Frequency/Instances of Block Play Levels

Block Play Level	Total instances across families Parent(s)	Proportion of total types Parent(s)	Number of families using the type Parent(s)
1: Carrying involves carrying, grouping, and exploring the properties of the blocks but not using them to build	140	0.40	25
2: Simple Building involves horizontal and vertical rows being stacked	142	0.40	27
3: Bidimensional Building involves superimposing two or more horizontal or vertical rows to make a longer or higher row	6	0.02	5
4: Bridging involves connecting two blocks by a third block to form a roof/bridge over the space between them	23	0.07	12
5: Enclosing involves placing blocks in such a way that they enclose a space	9	0.03	10
6: Tridimensional Enclosing involves superimposing two or more enclosures to make additional layers	3	0.01	3
7: Making Decorative Patterns involves any pattern that follows an AB, ABA, or AABB pattern with the shape or colour of the blocks	6	0.02	2
8: Representational Play involves using the block constructions to represent things	19	0.05	8

Table 2: Examples of Levels of Block Play

Level 7:

Mother: Make this side of the castle the same as that side! See how we used the red rectangle on that side with the blue cylinder on top and then another red rectangle on top of that. Why don't you try to make this side the exact same as that?

Level 8:

There were many parents who would direct their children to try and do representational play and pretend that their block construction was something else.

Mother: Let's pretend that this is a fire station. This block could be the door, this space here could be where all of the fire trucks are kept, and on this block is where the firefighters wait to get called.

Discussion

The results reveal that children's emergent numeracy skills are positively related to the levels of complexity in block play by their parents. However, our findings also indicate that the parents spent more time engaging at the lower levels of block play with their children. This set of findings is consistent with the findings that most parents are unsure of how to engage in mathematics activities with their children (Cannon & Ginsburg, 2008).

Ideally, children between three and six years old should be engaged in developmentally appropriate early childhood math activities such as blocks to learn geometry and numeracy (Cross, Woods, & Schweingruber, 2009). Levels of block play are indicative of having advanced understanding of geometry and spatial skills, therefore, parents should be encouraged to move beyond carrying blocks around and simple building to enrich children's understanding of early mathematical development.

EVOLUTION OF NUMBER AND PERMUTATION ACTIVITIES WITHIN AN ELEMENTARY 3D VISUALIZATION TEACHING-LEARNING TRAJECTORY

Jacqueline Sack
University of Houston Downtown
sackj@uhd.edu

Irma Vazquez
Houston Independent School District
irmavazquez@sbcglobal.net

This research team is developing a teaching-learning trajectory on 3D visualization for elementary children. This paper focuses on how specific teaching activities that connect to number and permutation concepts have evolved since the project began four years ago. Implications for mathematics learning at the elementary level are discussed.

Keywords: Geometry and Geometrical and Spatial Thinking; Learning Trajectories (or Progressions); Elementary School Education; Instructional Activities and Practices

Theoretical Frameworks, Context and Methods

We define the 3D visualization construct as the capacity to move among various representations of solid geometric figures. This design research project responds to the need to develop coherent classroom activities around 3D visualization that will impact learners' capacities to engage in higher-level mathematics and science at a later stage.

The *spatial operation capacity* (SOC) framework (van Niekerk, 1997; Sack & van Niekerk, 2009) that guides this study exposes children to activities that require them to act on a variety of figures made from wooden cubes or their 2D images including physical and mental use of transformations, to develop skills necessary for solving spatial problems.

The SOC framework (see Figure 1) uses: full-scale figures, that, in this study, are created from loose cubes or Soma figures, made from glued unit cubes (see Figure 2); conventional 2D pictures; abstract representations such as front, top and side views or numeric top-views that do not obviously resemble the 3D figures; and, verbal descriptions using appropriate mathematical language that may be accompanied by gestures (Sack & Vazquez, 2008). When designing tasks the research team selects one of the SOC representations to be the stimulus object that learners must act upon in specific ways. The product may be among any of the SOC representations.

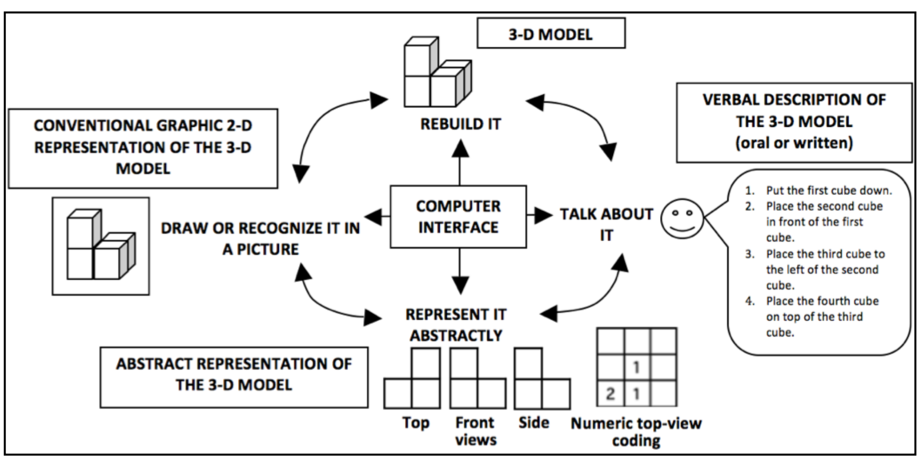

Figure 1: Multiple representations within 3-D visualization

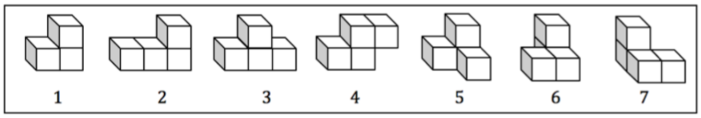

Figure 2: The seven Soma figures

In addition, the project utilizes a dynamic computer interface, Geocadabra (Lecluse, 2005). Through its Construction Box module, complex, multi-cube structures can be viewed as 2-D conventional representations or as abstract top, side and front views or numeric top-view codings. These options can be (de)selected according to instructional goals. The interface integrates the SOC representations in the form of a dynamic image that can be moved with the mouse to provide the same views as if moving about the 3-D object. These images replicate the attributes of the physical 3D objects by behaving as such in learners' minds. This becomes the basis upon which later mathematical thinking occurs. The model extends as the child develops his or her own problems based upon the objects that were recently defined (Connell, 2001).

The study is conducted in an urban elementary school within a large southwestern US public school district. More than 50% of its students are designated "At Risk" and as English Language Learners. The study occurs weekly for one hour in teacher-researcher, Vazquez' 3rd-grade classroom within the school's existing after-school program. The research team uses socially mediated instructional approaches to support a problem-solving environment that fosters children's creativity according to readiness and interest.

Based on design-research principles (e.g., Cobb, et al, 2003) this research team has developed a teaching and learning trajectory to develop children's 3D visualization capacity. In this particular context, the teaching and learning trajectory refers to several knowledge-development pathways, including: sequencing of learning tasks and/or their delivery; interpretation of children's learning and development of 3D constructs as tasks are enacted; and trials of modified or new tasks to further enhance learning about 3D constructs.

Each experimental lesson is followed by a retrospective analysis in which the research team determines the actual outcomes and then plans the next lesson. This may be an iteration of the last lesson to improve the outcomes, a rejection of the last lesson if it failed to produce adequate progress toward the desired outcomes, or a change in direction if unexpected, but interesting, outcomes arose that are worthy of more attention. Data corpus consists of formal and informal interviews, video-recordings and transcriptions, field notes, student products and lesson notes.

Results and Discussion

Initial Trajectory Summary

At first, children solve problems with 3D models and 2D task cards using loose cubes and then the Soma figures. The task cards show assemblies of two Soma combinations in different orientations requiring figure identification and classification. Thus, learners become familiar with the SOC 3D and 2D conventional graphic representations. Then, children begin to digitally reproduce figures printed in a customized manual (e.g., see Figure 3). Through these tasks the children begin to coordinate numeric top-view codings with 2D pictures. They assemble various combinations of two Soma figures and produce their own printable task cards using the Construction Box. They draw the top-view numeric codings for others to identify which two Soma figures correspond to their coding diagrams. This sequence within the project's original trajectory has been retained with few changes for subsequent cohorts.

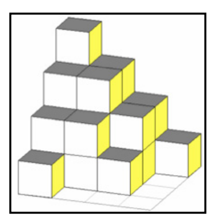

Figure 3: Task 1*f*

Permutations: Fixed Volume Rectangular Prisms

Through pre-program interviews, the research team has confirmed that many children find rectangular prisms made of unit cubes more difficult to visualize and enumerate than irregular structures such as those in Figure 3 (Sack & Vazquez, 2010). The research team developed a problem: *Ms. Moral must ship 24* *cube-shaped shoeboxes to a nearby city. How can the boxes be arranged if they must be shipped in a rectangular prism container?* Twenty-four has a relatively large number of factors leading to a variety of permutations across all factor sets. The research team hypothesized that the children would use the $l \times w \times h$ volume formula from their regular classroom. However, they surprisingly recorded each prism using the top-view numeric notation learned in our program.

The children's development of multiplication constructs during their academic day centers on visual representations, such as, area models, number-line jumps and various pictorial grouping models. Rectangular volume follows much later in the curriculum. Children begin to recognize the area model within the top-view numeric coding of rectangular prisms. Several different 24-cube prisms are constructed. The discussion about the numbers of rows, number in each row, and number of stacks is enacted many times and allows the children to conceptualize volume deeply through the top-view numeric representation. They discover that by rotating one prism onto a different face a permutation of its representation can be created and recorded (e.g., Figure 4.)

Figure 4: Children's top-view numeric grids and volume calculations

At the end of the year, the children are challenged to create a rectangular cake pattern with all seven Soma figures laying flat except for #5, #6 and #7, which have one cube sticking up from the base rectangle, forming three candles. They draw the top-view coding for each design. One will be selected as a template for the end-of-year party cake. See Figure 5 for an example.

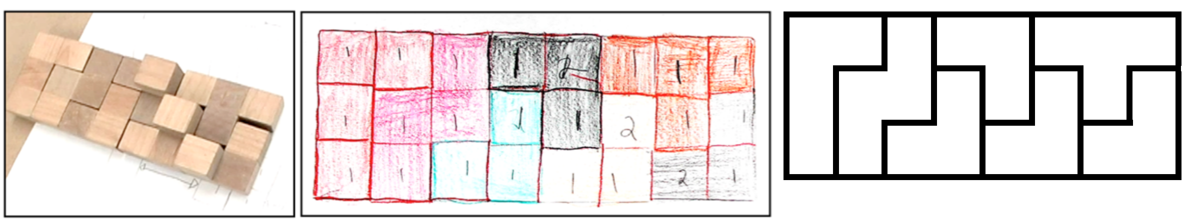

Figure 5: A cake pattern made from the 7 Soma figures and its top-view numeric coding

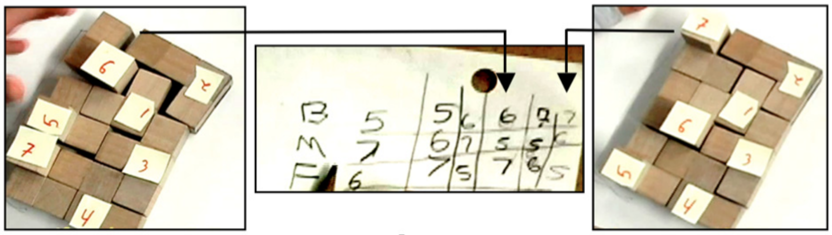
During the first cohort, Sara (pseudonym), noticed that the bases of Somas #5, #6 and #7 all formed the same L-shape and these could be interchanged providing a hands-on permutation experience. During the academic day, Sara struggled with analytical skills in which she was deficient relative to the 3rd grade norms. However, this program provided an opportunity for her to engage her relatively strong visual skills to solve quite difficult spatial problems. Figure 6 shows a tabulation that Sara created spontaneously during her explanation to the whole group. In Sara's chart, F represents the L-shape in the front of the figure, closest to her; B represents the L-shape at the back; M represents the L-shape in the middle of the figure, where Soma figures #5, #6 and #7 are positioned in Figure 6a to the left and Figure 6c to the right. Teacher Vazquez had asked Sara to label her Soma figures to keep the focus on their positions rather than on their identification each time they were moved about within the base pattern.



a. b. c.

Figure 6: Sara's cake permutations

Connections were made to academic day class work in which children determined how many different words, real or not, could be made from 3 random letters, such as T, E, and A; or, how many different 3-digit numbers could be made from 3 random digits. Sara compared the Soma figures, #5, #6, and #7, with her letters for the cake positions, F, M, and B. Sara was now able to explain how many words or numbers can be made much in the way different candle positions could be determined on her cake pattern. This was a significant connection for this child.

The ability to create multiple patterns by interchanging these figures (including Soma #1) has emerged with each cohort and is a key group discussion to connect permutations within the SOC framework.

Conclusions

This program focuses on 3D visualization in the geometry strand of the elementary mathematics curriculum. The specific teaching activities that connect to number and permutation concepts integrate all of the SOC representations. These exemplars show how children make meaningful connections through worthwhile problems across the SOC framework in ways that help them build the capacity to abstract and generalize. This is largely due to this research team's deliberate efforts to honor and encourage children to share their thinking publicly and safely in the classroom. The research team believes that these experiences will provide learners a solid foundation for extending their spatial processing knowledge to other STEM domains.

USING THE GSP AS A PSYCHOLOGICAL "TOOL" TO RECONCEPTUALIZE SOME PROPERTIES OF ISOSCELES TRAPEZOIDS

Adalira Sáenz-Ludlow
University of North Carolina at Charlotte
sae@uncc.edu

Anna Athanasopoulou
University of North Carolina at Charlotte
aathanas@uncc.edu

A semester-long pilot teaching-experiment on the teaching-learning of geometry was conducted with four sophomore pre-service teachers. They had taken no geometry courses in college and their knowledge was rooted only in their high-school experiences. The main goal was to use the Geometer's Sketchpad (GSP) as a mediating "tool" to develop their understanding of triangles and quadrilaterals. Here, we analyze a task about trapezoids posed to one of the pre-service teachers, with the pseudonym of Michael, who advanced his understanding of congruence and similarity of triangles at a faster rate than the other teachers.

Keywords: Geometry; Technology; Teacher Education–Preservice

Rationale

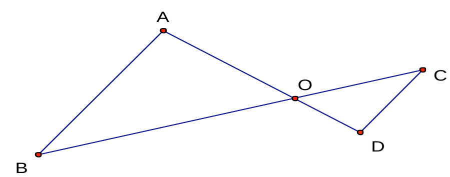
The study was framed within the Vygotskian theory of conceptual development. This theory considers that *material tools*, *psychological tools*, and *social interaction* mediate cognitive development. Prominent examples of psychological tools in mathematics are place-value systems, number line, *x-y* coordinate plane, equations, and the language of mathematics. These devices are, more often than not, perceived as pieces of information rather than "tools" to be used to organize and construct mathematical knowledge and understanding (Kinard & Kozulin, 2008). Likewise, the GSP can be used as a *technical tool* to make constructions rather than as a *psychological tool* to explore and better understand definitions and properties of two-dimensional geometric figures. We concur with Laborde (1993) and Hoyles (1996) who argue that dynamic environments, like GSP, lead us to change the way we think about solutions of geometric tasks. Mariotti (2001), Jiang (2002), Christou, Mousoulides, Pittalis, and Pitta-Pantazi (2004), De Villiers (2004), Mariotti (2006), and Laborde, Kynigos, Hollebrands, and Strässer (2006) also argue about the appropriateness of geometric tasks for dynamic environments as well as the guiding role of the instructor to facilitate argumentations, explanations, justifications, and proofs.

Methodology

A semester-long, pilot teaching-experiment on the teaching-learning of triangles and quadrilaterals was conducted with four sophomore pre-service teachers who had taken no geometry courses in college. The pilot study had two goals. The first was to use the GSP in such a way that it would be not only perceived as a *technical tool* but also used as a *psychological tool*. The second was to pilot the tasks designed for a research study to be conducted with pre-service high-school teachers. The purpose of each task was to allow freedom to explore, to make conjectures, and to prove it. Each pre-service teacher participated in nineteen, 90-minute, one-to-one weekly interviews. The guiding principle of the teaching-experiment was to use semi-structured tasks to mediate the three-way interaction between the pre-service teachers, the GSP, and the interviewer. Two researchers participated in the study. The interviewer was one of the researchers and the other was the participant observer. The tasks for the first thirteen interviews were designed to re-conceptualize the notions of congruence and similarity of triangles as well as some properties of parallelograms, rectangles, and squares. In the fourteenth interview, Michael was given the task to *transform* a drawing of a trapezoid into a drawing of an isosceles one. Here we analyze Michael's case for two reasons: (1) he was able to re-conceptualize congruence and similarity of triangles faster than the other participants, and (2) we hypothesized that congruence and similarity of triangles would help him to re-conceptualize quadrilaterals in a systematic way. Given the space constraints, we only present short excerpts of this interview and mainly describe it in order to analyze (a) Michael's strategies, and (b) the efforts of the interviewer to indirectly guide his geometric activity.

The Semi-structured Task Posed to Michael

A GSP *drawing* of a geometric figure is called *robust* when the dragging-function preserves the Euclidean definitions and properties of that figure. In contrast, a GSP *drawing* is called *non-robust* when the dragging-function continually gives us a drawing of a different geometric figure. We view a geometric task as *structured* when the questions are related to a *robust drawing* and as *semi-structured* when the questions are related to a *non-robust drawing*. The task given to Michael, in this interview, is an illustration of a semi-structured task. In Drawing 1 the side AB is parallel to the side CD. Michael was asked first to *drag* points and segments and to observe *what* kinds of quadrilaterals would result. Second, he was asked to transform the trapezoid ACDB into an isosceles one.



Drawing 1

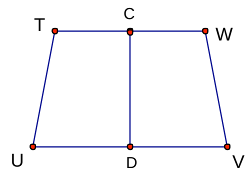
With respect to the first question, Michael dragged points and segments and formed parallelograms, rectangles, squares, and trapezoids using the property of opposite parallel sides and the lengths of the diagonals. In prior interviews, he had investigated and proved some properties of parallelograms, rectangles, and squares using congruent triangles. With respect to the second question, Michael initially explored the drawing, at random, without taking into consideration any specific properties of isosceles trapezoids.

Unsuccessful Transformation of Drawing 1 into an Isosceles Trapezoid

The researcher asked Michael to observe and explore Drawing 1. He observed that triangles AOB and DCO are similar and tried to transform Drawing 1 into an isosceles trapezoid by dragging sides and vertices, but he was not sure what to do. Then, the researcher intervened asking him to explain *how* he was trying to do this transformation. Michael said he was trying to make *the base angles congruent,* but he continued dragging the vertices at random. Therefore, the researcher decided to facilitate Michael's activity and advised him to construct, on a new screen, an isosceles trapezoid. He constructed an angle and his goal was to mirror the constructed angle and get an equal angle at the other endpoint of the horizontal line segment using the GSP as a *technical* tool. However, Michael did not know *what* line should be the mirror. Then, he constructed an angle at the other endpoint of the horizontal line segment and measured both angles. He moved the non-common side of one of the angles until the two measurements were roughly the same. Finally, he constructed a line segment parallel to the initial horizontal line segment forming a *non-robust* isosceles trapezoid. Then, by indirect questions, the researcher helped Michael to establish an association between *isosceles triangles* and *isosceles trapezoids*. Although Michael made the connection that the non-parallel sides are congruent in isosceles trapezoids, he was unable to use this fact to construct a *robust* isosceles trapezoid. The construction of *robust drawings* requires a purposeful use of the GSP. This is to say that Michael also needed to use the GSP as a tool to organize and guide his thinking rather than just as a measuring tool. This is what we have called the *transformation* of the GSP into a psychological tool (Sáenz-Ludlow & Athanasopoulou, 2008).

Inferring and Proving a Property of Isosceles Trapezoids

The researcher continued asking Michael if he knew other properties of isosceles trapezoids. He gave no answer, so the researcher suggested to Michael to join the midpoints of the parallel sides of the isosceles trapezoid he had constructed (Drawing 2).



Drawing 2

Michael measured the angles formed between CD and the bases UV and TW and then he said, “The line CD is perpendicular to the bases.” The researcher asked him if he could prove this statement. He constructed line segments CU and CV. He proved the congruence of triangles ΔCTU and ΔCVW by SAS as well as the congruence of triangles ΔCUD and ΔCVD by SSS. Using the implication of the later congruence ∠UDC=∠CDV and the property that these angles are supplementary, he concluded that CD is perpendicular to the base UV. He also added that by a similar argument CD is perpendicular to the base TW. Then, the researcher asked Michael if CD is a line of reflection. He said,

> 265 I think it is. Let’s see….[He uses the GSP as a *technical tool* to mark CD, to highlight points T and U, and to reflect them with respect to CD. Points T and U fall over the points W and V]. Yes, CD is a line of symmetry; it is a *mirror*. It is symmetric.

Michael used the reflecting function of the GSP to verify the symmetry of the drawing with respect to the line CD. That is, he used the GSP to verify his implicit idea of some type of symmetry in isosceles trapezoids. He was looking for the mirror! Now the GSP was not only a technical tool, it was also a tool to guide his thinking—a *psychological tool*. With some hints on the part of the researcher, he was able to set in motion the proof of his statement using his consolidated knowledge of congruence of triangles.

Inferring and Proving one More Property of Isosceles Trapezoids

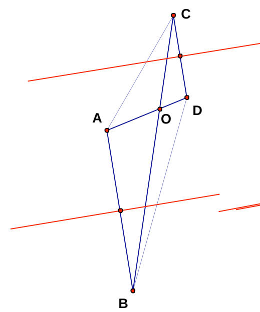
The researcher guided Michael to infer another property of isosceles trapezoids. The researcher asked Michael to copy Drawing 2, to hide the line segment CD, and to construct the diagonals TV and WU. Michael explored the drawing by *measuring* the diagonals and the sub-segments created by the intersection of the diagonals and tabulated these measurements. He observed that the diagonals did not bisect each other and he added that “if they bisected each other, the quadrilateral could be a parallelogram, or a rectangle, or a rhombus, or a square.” Then, he conjectured that the diagonals were congruent. The researcher asked Michael if he could prove it. He proved that ΔTUV and ΔWVU were congruent by SAS and inferred the congruence of the diagonals.

The above episode indicates that Michael was learning to guide his own geometric activity. He used the GSP as a *technical* and *psychological tool* when he measured the diagonals and the sub-segments determined by the intersection, tabulated all the measurements, and conjectured that in isosceles trapezoids the diagonals were congruent. The fact that he was able to conjecture and prove a new statement about isosceles trapezoids indicates a progress in his geometric activity. This episode also indicates that Michael is starting to gain control on his geometric thinking aided by the GSP and his interactions with the researcher.

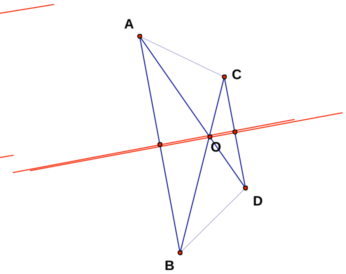
Back to the Initial Question

The researcher suggested to Michael to go back to Drawing 1 and to try to transform the trapezoid ABDC into an isosceles one. He measured the diagonals and then dragged a vertex in an effort to make them congruent. This strategy created a non-robust geometric drawing, so the researcher asked Michael to do the transformation without measuring but by using either of the two properties of isosceles trapezoids he had proved.

After several failed attempts to construct equal diagonals without measuring, Michael came up with the idea to construct perpendicular lines through the midpoints of the bases AB and CD. Then, by dragging different vertices, he saw that when the two perpendicular bisectors of the bases became one and the same, the intersection of the diagonals fell over the perpendicular bisector (Drawings 3 and 4) making the trapezoid ABDC, at that moment, an isosceles trapezoid. In other words, Michael had used the GSP as a *technical* and *psychological tool* to generate a strategy that involved one of the properties he had proved before in isosceles trapezoids.



Drawing 3



Drawing 4

Concluding Remarks

The analysis indicates that Michael, with the indirect guidance of the researcher and with the mediation of the GSP, was able to conjecture and prove two properties of isosceles trapezoids. One was that the segment joining the midpoints of the bases is also perpendicular to them. The other was that the diagonals are congruent. He used his consolidated knowledge about congruence of triangles to prove the statements. Further, Michael was able to use the GSP as a *psychological tool* to *transform* a drawing of a trapezoid into a drawing of an isosceles one by applying the first property.

The analysis also indicates that Michael transcended the *technical* aspects of the GSP and started to use it as a *psychological tool* not only to conjecture and prove properties of isosceles trapezoids but also to *transform* a trapezoid into an isosceles one. In sum, the semi-structured task for the GSP mediated the three-way interaction between the Michael, the GSP, and the researcher. In addition, the semi-structured task, the GSP, and the indirect guidance of the researcher contributed to improve the development of Michael's geometric activity and initiated *self-regulation* of his geometric activity.

Mental rotation is the ability to look at an object and visualize its rotation in three-dimensional space. Males, in general, have stronger spatial reasoning skills, and typically outperform their female counterparts on mental rotation tasks (Linn & Petersen, 1985). The purpose of this study was to examine differences between two groups of sixth grade students' spatial reasoning skills. Specifically, How do high and low performing students spatially reason, and what gender differences exist between high and low performing students as they spatially reason? Using a mixed methods approach, we investigated students' spatial development by gender within and between control and experimental groups. Both student groups (two experimental and one control) studied Earth/Space concepts related to the Solar System, which integrated various mathematical concepts. Students' understanding was documented before, during, and after project implementation. The quantitative data source used to assess students' pre and post understandings was the Lunar Phases Concept Inventory (LPCI, Lindell & Olsen, 2002), which is a 20-item multiple-choice instrument that assesses eight science domains and four mathematics spatial domains. To examine students' spatial reasoning skills, twenty-four students participated in video-recorded clinical interviews. Students were selected based on their highest and lowest change scores on the LPCI from pre to post. Eight students (2 low female, 2 high female, 2 low male, 2 high male) per teacher were interviewed. Overall, the high performing students (males and females) made positive gains from pre to post on every LPCI mathematics domain. The low experimental females made slight gains on both spatial projection and periodic patterns, whereas the low control males only made slight gains on periodic patterns. The low control females made slight gains on geometric spatial visualization, and both the low control and low experimental males did not have any positive gains on cardinal directions. All the male subgroups, except the low experimental males, had higher post scores on spatial projection. Students were then asked to sketch the top and bottom view of Figure 1. Students who sketched the top and bottom view holistically (viewed the object as a whole and first sketched the outline of the shape) were more successful mentally manipulating figures. However, students (mostly low males and low females) who sketched the top and bottom view discretely (sketched each individual block separately) were not as successful mentally manipulating objects. Additionally, students who approached the task holistically, scored higher on the post assessment for the mathematics domains of the LPCI. Understanding how males and females (low and high) reason spatially may lead to more focused interventions that better promote spatial skills for *all* students.

A COMPARISON OF THREE STUDENTS' RESPONSES TO AREA INVARIANCE TASKS ACROSS GRADES 2–5

The theme of area invariance is one of the most difficult concepts related to area measurement. Students struggle to conceptually understand how two regions may look different but have equivalent areas (Lehrer, 2003). The authors of this report define area conservation to be a subset of area invariance. With area conservation, the child observes a region being decomposed into parts, as well as how those parts are recomposed to form a new region that has the same area as the initial region; whereas, with area invariance, the child does not observe the transformation directly. Historically, research has been conducted related to area conservation, but more research needs to be conducted on students reasoning about area invariance.

The data discussed in this report come from a longitudinal teaching experiment (Steffe & Thompson, 2000) with 16 students from a Midwestern public school. The study was designed to investigate children's thinking and learning about length, area, and volume measurement across grades 2-5. In this report, we consider a subset of that data. Although area invariance was not a focus of the longitudinal study, area invariance is related to area measurement. Hence, results were re-analyzed retrospectively with respect to the development of area invariance.

Our results suggest that some students can reason qualitatively about area invariance, some can reason quantitatively about area invariance, and others can reason flexibly about area invariance, integrating qualitative and quantitative arguments. Abby, Anselm, and Owen followed consistent and steady paths for developing area conservation competencies but in different ways. Throughout seven semesters, Anselm never made an error related to area invariance. Anselm demonstrated an ability to reason qualitatively and quantitatively about two-dimensional space throughout the entire study, from grade 2 through grade 5. Owen illustrated steady progress in his reasoning about area invariance. Initially, he conserved shape and area qualitatively by mentally decomposing and recomposing, but he could not reason quantitatively. However, he demonstrated an ability to reason qualitatively and quantitatively about two-dimensional space by the end of fifth grade. In contrast to Anselm and Owen, Abby was inconsistent in her responses to area invariance tasks. She initially recognized that different shapes could have the same amount of area. However, in later grades, she did not reason about area invariance of two shapes either qualitatively or quantitatively.

These results indicate that young children may not be able to attend to two dimensions simultaneously when attempting to reason about area invariance. Furthermore, reasoning about shape, reasoning about area, and reasoning about space seem to be intertwined concepts. These results also suggest that reasoning about area invariance qualitatively is disconnected from reasoning about area invariance quantitatively. Thus, reasoning flexibly both qualitatively and quantitatively about area invariance is non-trivial.

BODIES IN MOTION: LEARNING MATHEMATICS AND SHI-DO-KAN KARATE

Joy Oslund
University of Michigan
joyaoslund@gmail.com

> There is no such thing as a computational person, whose mind is like computer software… Real people have embodied minds whose conceptual systems arise from, are shaped by, and are given meaning through *living human bodies*. The neural structures of our brains produce conceptual systems and linguistic structures that cannot be adequately accounted for by formal systems that only manipulate symbols (Lakoff & Johnson, 1999, 6, emphasis mine).

Mathematics educators rarely acknowledge the role of the human body in producing mathematical knowledge. Gesture research describes the communicative function of spontaneous movements (Sfard, 2008) but less on deliberate movements and their meaning-making function. Work on embodied cognition reports the interaction between physical objects and mathematical knowing (Lakoff & Núñez, 2000; McGarvey & Thom, 2010), but focuses more on the objects as representations of mathematical concepts and less on students' bodies. Human bodies have implications for mathematical knowing—they balance, move through space, and reach out to grasp objects, all of which require spatial reasoning, transformations, etc. Understanding the tacit knowledge required for these deliberate movements pushes the boundaries of mathematical knowing, broadening conceptions of how students make meaning of three-dimensional space.

On this poster, I theorize data from an ethnography of a karate dojo. I mathematize the bodily movements of karate students to understand their opportunities to develop tacit and explicit knowledge of mathematics as they learn *kata*. Kata are choreographed series of movements that are scaffolded over time to increase in complexity of directions, angles, and distances of movement. Students are expected to verbally describe the movements, developing both informal and formal mathematical language for them (e.g., using terms like higher, forward, 65%, 45 degrees). Using pictures and other representations of the kata alongside transcripts of student and teacher discourse, I depict students' opportunities to embody (and in some cases, talk about), spatial relationships, transformations, and spatial reasoning (NCTM, 1999). I discuss the human body in motion as a source of funds of mathematical knowledge (González, Andrade, Civil, & Moll, 2001) and a resource for modeling and model-eliciting activities (Lesh & Doerr, 2000).

CONCEPTUAL UNDERSTANDING OF DIMENSIONAL CHANGE

Elizabeth T. Walker
University at Buffalo
etwalker@buffalo.edu

Deborah Moore-Russo
University at Buffalo
dam29@buffalo.edu

Keywords: Spatial Thinking; Teacher Knowledge; Mathematical Knowledge for Teaching; Teacher Education

Dimensional reasoning includes the ability to predict changes in measures across dimensions, such as predicting changes in area or volume given variations in edge length. This study examined methods of determining dimensional change for pre and in-service teachers (n = 90). Data were collected from problem situations where information for a computational solution was readily available and in problem situations where it was necessary to generalize the effects of dimensional change to obtain a solution. Results suggest that teachers in this sample do not exhibit flexible and generalized knowledge of geometry and dimensional change. This is a concern as teachers who emphasize computational solutions more heavily than conceptual understanding in their own mathematical solutions may neglect to emphasize conceptual understanding in geometry instruction. The results from this study suggest a more balanced geometry instructional focus that includes formulas, computation and memorized characteristics as well as exploration, generalization, and flexibility concerning relationships between shapes, measures and dimensions.

The teachers in this study relied heavily on computation strategies using familiar formulas to determine resultant change from changes in dimensional measures. One example of using formulas and computation is for the question: If a box has a volume of 10, what would its volume be if all its sides were doubled? Participants were able to identify the length, width, and height for a box with a volume of 10, double all of the sides, compute the new volume, and then compare old and new volumes. When figures became too complex for computation, or formulas could not be recalled, teachers were less successful in obtaining correct answers. This difficulty may indicate a lack of a generalized concept of dimensional change.

Several possible rationales for the exhibited lack of dimensional reasoning exist. Participants may lack conceptual knowledge about what is meant by the word “dimension.” Arcavi (2003) recognized that visualization is a “key component of reasoning” (p. 235). Participants may not be able to visualize the dimensional change occurring in each problem. Because many participants did not utilize dimensional change from one to two dimensions to predict change from two to three dimensions, nor did they utilize changes in simple figures to predict changes in more difficult figures, it appears that participants may not recognize that a pattern or generalization exists for dimensional change. More research is needed to identify why specific dimensional reasoning deficits exist and determine ways to mediate them.

WHY ORDER DOES NOT MATTER: AN APPEAL TO IGNORANCE

Egan J. Chernoff
University of Saskatchewan
egan.chernoff@usask.ca

Gale L. Russell
University of Saskatchewan
gale.russell@usask.ca

Within the limited field of research on teachers' probabilistic knowledge, incorrect, inconsistent and even inexplicable responses to probabilistic tasks are most often accounted for by utilizing theories, frameworks and models, which are based upon heuristic and informal reasoning. More recently, the emergence of new research based upon informal logical fallacies has been proving effective in accounting for certain normatively incorrect responses to probabilistic tasks. This article contributes to this emerging area of research by demonstrating how a particular informal logical fallacy, known as "an appeal to ignorance," can be used to account for a specific set of normatively incorrect responses to a novel probabilistic task, which were provided by prospective elementary and secondary mathematics teachers.

Keywords: Cognition; Probability; Teacher Education–Preservice; Teacher Knowledge

The objective of this article, in general, is to contribute to the limited amount of research on (prospective) "teachers' probabilistic knowledge" (Jones, Langrall, & Mooney, 2007, p. 933; Stohl, 2005). In specific, the objective of this article is to contribute to the well-established domain of research, which accounts for (through various theories, models and frameworks) incorrect, inconsistent, sometimes inexplicable responses to a range of probabilistic tasks (Abrahamson, 2009; Chernoff, 2009; Kahneman & Tversky, 1972; Konold, 1989; Konold, Pollatsek, Well, Lohmeier, & Lipson, 1993; LeCoutre, 1992; Tversky & Kahneman, 1974).

To meet the general and specific objectives stated, prospective teachers were asked to determine and justify which of two student responses provided the correct answer and explanation to a question, which involved determining the probability that a three-child family has two daughters and one son. In addition to contributing a twist to a task recently introduced to the research literature, we also utilize a novel lens to account for certain responses to that task. In our analysis, we demonstrate that logically fallacious reasoning, more specifically, in this instance, an appeal to ignorance (i.e., there is no evidence for *p*; therefore, *not-p*) accounts for certain prospective teachers' normatively incorrect responses to the task. By meeting the general and specific objectives presented, this article will correspond and contribute to a continuation or, stated in terms associated with the theme of PMENA 2012, a *transition*—from heuristic reasoning (e.g., Kahneman & Tversky, 1972) and informal reasoning (e.g., Konold, 1989) to logically fallacious reasoning (e.g., Chernoff & Russell, 2011a, 2011b, in press)—in how researchers account for particular prospective teachers' responses to probabilistic tasks.

A Brief Summary of Prior Research

Research into probabilistic thinking and the teaching and learning of probability has, in the past, seen a focus on normatively incorrect responses. Worthy of note, the focus on normatively incorrect responses does not, in any way, suggest a negative view of the mind (Kahneman, 2011). The theories, models and frameworks associated with heuristic and informal reasoning—rooted in the notions of conceptual analysis (Thompson, 2008, Von Glaserveld, 1995), grounded theory (Strauss & Corbin, 1998) and abduction (Peirce, 1931)—have, traditionally, accounted for normatively incorrect responses to probabilistic tasks within the field of mathematics education. Chernoff (2009a, 2009b, 2009c, 2011, in press) and Chernoff and Russell (2011a, 2011b, in press) have provided detailed accounts of the theories, models and frameworks associated with heuristic and informal reasoning in the field of mathematics education and are recommended—given the 8-page limitation associated with the present venue—to the reader.

More recently, a burgeoning area of research suggests that fallacious reasoning, more specifically, the use of informal logical fallacies, can account for certain normatively incorrect responses to probabilistic tasks. For example, Chernoff and Russell (2011a) demonstrated that certain prospective mathematics teachers—when asked to identify which event (i.e., outcome or subset of the sample space) from five flips of a fair coin was least likely to occur—did not use the representativeness heuristic (Kahneman & Tversky, 1972), the outcome approach (Konold, 1989) or the equiprobability bias (Lecoutre, 1992), but, instead, utilized a particular informal logical fallacy, the fallacy of composition: when an individual infers something to be true about the *whole* based upon truths associated with *parts* of the *whole* (e.g., coins (the parts) are equiprobable; events (the whole) are comprised of coins; therefore, events are equiprobable, which is not necessarily true). Worthy of note, the fallacy of composition accounted for both normatively correct and incorrect responses to the new relative likelihood comparison task.

In subsequent research, Chernoff and Russell (2011b, in press) applied the fallacy of composition to a more traditional relative likelihood comparison. Prospective mathematics teachers were asked to determine which of five possible coin flip sequences—not events—were least likely to occur. As was the case in their prior research (e.g., Chernoff & Russell, 2011a), the fallacy of composition accounted for normatively incorrect responses to the task. More specifically, the researchers demonstrated that participants reference the equiprobability of the coin, note that the sequence is comprised of flips of a fair coin and, as such, fallaciously determine that the sequence of coin flips should also have a heads to tails ratio of one to one. In other words, the properties associated with the fair coin (the parts), which make up the sequence (the whole), are expected in the sequence. Once again, the fallacy of composition, not the traditional theories, models and frameworks associated with heuristic and informal reasoning, accounted for certain normatively incorrect responses to a probabilistic task.

Chernoff and Russell (2011a, 2011b, in press) contend, based on their research utilizing the fallacy of composition, that they have (re)opened a new area of investigation for those researching probabilistic thinking and the teaching and learning of probability. However, they also contend that more research will allow individuals to determine to what extent informal logical fallacies and fallacious reasoning can account for normatively incorrect responses to a variety of probabilistic tasks. The former and latter contentions have provided the motivation for us to determine whether or not another informal logical fallacy, an appeal to ignorance, can account for normatively incorrect responses to a probabilistic task that has recently been introduced to the research literature.

Theoretical Framework

Of the numerous informal fallacies that could, potentially, be utilized as a theoretical framework (e.g., equivocation, begging the question, the fallacy of composition, the fallacy of division and others), our analysis of results will rely, specifically, on one particular informal logical fallacy: *an appeal to ignorance*, which, essentially, "is an argument for or against a proposition [*p*] on the basis of a lack of evidence against or for it" (Curtis, 2011, para. 3). However, and worthy of note, an appeal to ignorance can come in one of two forms: (1) there is no evidence against *p*. therefore, *p* and (2) there is no evidence for *p*. therefore, *not-p*. To be more specific, our analysis of results will rely on the second form of an appeal to ignorance: there is no evidence for *p*. therefore *not-p*. Stated in more colloquial terms, the reader may be familiar with the following phrase: "the absence of evidence is not evidence of absence." For example, consider the following question: Is there a lawn mower in my garage? If one does not look inside my garage, the absence of evidence does not amount to evidence of an absence of a lawn mower because there may, in fact, be a lawn mover in my garage. Thus, and stated once again in colloquial terms, an individual who declares the absence of evidence as evidence of absence is employing (the second form of) an appeal to ignorance. Our attention, in the analysis of results, will focus on a set of individuals utilizing the absence of evidence as evidence of absence. Stated, in the terms of our example, our analysis of the results will focus on those individuals who do not look inside my garage and use their lack of evidence of a lawn mower in my garage to declare that there is no lawn mower in my garage. However, our research does not focus on garages and lawn mowers; instead, our research focuses on whether order matters or order does not matter for a particular probabilistic task.

The Jane or Dianne Task

The Jane or Dianne task, presented below in Figure 1, represents an alteration to the original "two boys and a girl task" (Chernoff & Zazkis, 2011, p. 21), which was utilized in previous research (Chernoff & Zazkis, 2011) and introduced by Chernoff and Zazkis (2010).

> What is the probability that a three-child family has two daughters and one son?
>
> **Jane's explanation:** Out of the four possible outcomes (3 daughters, 0 sons; 2 daughters, 1 son; 1 daughter, 2 sons; and 0 daughters, 3 sons) only one outcome (2 daughters, 1 son) is favourable, so the probability is one-fourth.
>
> **Dianne's explanation:** Out of the eight possible outcomes (daughter, daughter, daughter; daughter, daughter, son; daughter, son, daughter; son, daughter, daughter; daughter, son, son; son, daughter, son; son, son, daughter; son, son, son) only three outcomes (daughter, daughter, son; daughter, son, daughter; son, daughter, daughter) are favourable, so the probability is three-eighths
>
> ________________________ 's explanation is correct because.....

Figure 1: The Jane or Dianne task

Fundamentally, the two boys and a girl task is the same as the Jane or Dianne task. In other words, the core of the task, the probability question, that is, what is the probability that a three-child family has two daughters and one son, is the same in both tasks. Previously, the task was utilized in order to elicit insight into prospective secondary school mathematics teachers' pedagogical approaches. In this new version of the task, however, the focus is not pedagogical, but, rather, on which response prospective mathematics teachers deem mathematically correct and, relatedly, which explanation is deemed appropriate. Stated in more general terms, the task has been altered in order to contribute to the limited amount of research on what Jones, Langrall, and Mooney (2007) called "teachers' probabilistic knowledge" (p. 933).

Participants

The (*n* =) 130 participants in our research were comprised of 52 (40%) prospective elementary school teachers (PESTs) and 78 (60%) prospective secondary school teachers (PSSTs). The PESTs were enrolled in a methodology course designed for teaching elementary school mathematics and the PSSTs were enrolled in a methodology course designed for teaching secondary school mathematics. The 52 PESTs were from two different classes (each containing approximately 25 students) and, similarly, the 78 PSSTs were from three different classes (each containing approximately 25 students). For both the PEST's and the PSSTs, the topic of probability had not yet been addressed in their methodology courses. Instead, content, strategies and approaches garnered from research and practice related to the teaching and learning of probability were addressed after the data for this research was collected. To collect the data, participants were asked and given as much time as required to determine, via written response, which of the two explanations, Jane's or Dianne's, was correct and, further, to justify their choice also via written response.

Results

As seen in Table 1 below, there was, roughly, an even split between those individuals who declared and explained why Jane and Dianne's response was correct. Roughly half (51%) of the participants declared that Dianne's explanation was correct. More specifically, 40 of the 78 PSSTs (51%) and 26 of the 52 (50%) of the PESTS chose Dianne and her explanation. Thus, there was little difference between the percentage of PESTs and PSSTs that chose Dianne and her explanation. Worthy of note, not all 66 of the 130 participants provided an appropriate justification for why Dianne's explanation was correct. Interestingly, 9 of the participants (7%) chose an option that was not presented to them. These individuals may have indicated that neither choice and explanation was correct or that both of the choices and explanations were correct. These individuals have been placed in the ‘Other’ column in Table 1. As mentioned, there are certain pagination limitations associated with the current venue and, as such, the responses from those individuals who chose Dianne or who fell into the ‘Other’ category will not be part of this analysis of the results.

Table 1: Numerical Results

Participants	Jane	Dianne	Other
PESTs (52)	23	26	3
PSSTs (78)	32	40	6
Total (130)	55 (42%)	66 (51%)	9 (7%)

Instead, our analysis of the results will focus on the 55 participants (42%) that chose Jane and her explanation. More specifically, 23 of the 52 PESTs (44%) and 32 of the 78 (41%) of the PSSTs chose Jane and her explanation, which, as was the case with Dianne, shows little difference between the percentages associated with the PESTs and PSSTs. The 55 participants who chose Jane and her explanation did not have similar justifications for why Jane’s response and explanation was considered correct. As such, the 55 responses from those individuals who chose Jane have been further categorized in Table 2 below.

Table 2: Numerical Results within Jane Responses

Reference	order	no order	order & question
PESTs (23)	15	8	8
PSSTs (32)	30	2	13
Total (55)	45	10	21

Jane responses were organized into two distinct categories: those responses that referenced order and those responses that did not reference order. Of the 55 participants that chose Jane’s response, 45 (82%) referenced order in their justification and 10 (18%) did not reference order in their response justifications. More specifically, of the 23 PESTs that chose Jane’s response, 15 (65%) referenced order and 8 (35%) did not make reference to order and, of the 32 PSSTs that chose Jane’s response, 30 (94%) referenced order in the justifications and 2 (6%) did not reference order in their justifications, which represents a departure from the previous even split seen between PESTs and PSSTs.

Refining “Jane” responses a step further, of the 45 people that referenced order in their response justifications, 21 individuals (47%) also made reference to the question, that is, what is the probability that a three-child family has two daughters and one son, in their response justifications. More specifically, 8 of the 15 PESTs (53%) and 13 of the 30 PSSTs (43%) specifically referenced order and the question. The 21 responses referencing both order and the question, which represent, concurrently, 16% (21/130) of all participants, 38% (21/55) of those who chose Jane’s response and 47% (21/45) of those who chose Jane’s response and referenced order in their justifications, are featured in the analysis of results.

Analysis of Results

Given the consistency associated with all 21 of the responses that referenced both order and the question, 5 of the 8 responses from the PESTs and 5 of the 13 responses from the PSSTs, that is, 10 in total, are presented for analysis.

PESTs Response Justifications

In what follows, we analyse five exemplary responses, from Sam, Rebecca, Carla, Ernie and Woody, which all evidence an appeal to ignorance. We begin by considering the responses of Carla and Woody.

Carla: Dianne's explanation gives possibilities of 2 girls and one boy *plus birth order possibilities – this is not what the question asked.*

Woody: Dianne reuses some of the possibilities multiple times. *GGB is the same as GBG*. *The question is not asking anything about the order in which they were born*.

As italicized in the responses from Carla and Woody above, both individuals reference that birth order should not be taken into consideration. On the one hand, Woody, declaring that "GGB is the same as GBG," is implicitly declaring that order does not matter. Carla, on the other hand, is more explicit in declaring that Dianne's explanation calculates the possibilities "plus" the birth order, which can be interpreted to mean that the order is in addition to what the question is asking. Both Woody and Carla, however, are quite clear in declaring why they have concluded that birth order does not matter. Essentially, both individuals make it clear that the question does not "ask" about the order. As seen in the responses from Sam, Rebecca and Ernie, which are presented below and similarly italicized as above, they, too, reference that the question does not "say anything" or "mention" or "never asked" (respectively) about birth order.

Sam: This explanation is better because *the question doesn't say anything about birth order*. It just wants to know the probability of 2 daughters and 1 son; *whether or not this occurs as DDS, DSD, or SDD does not matter*. I think they have a 1/4 chance of the 2 daughters and 1 son outcome.

Rebecca: There are no repetitions of the number of each sex of child in Jane's. *The question doesn't mention birth order and therefore there is no need to consider that GGB and BGG is the same thing* in answering this particular question.

Ernie: *The question never asked about order* so the only total is assumed and therefore needed ~ *disregard order patterns* so 4 possible outcomes.

Further, the responses from Sam, Rebecca and Ernie indicate that there is no need to consider birth order or one can, as stated by Ernie, "disregard the order patterns." Alternatively stated, for all three responses, the question does not make reference to order mattering and, as such, order does not matter, which, ultimately, leads to choosing Dianne and her explanation as correct.

Considered from within an appeal to ignorance framework, the responses from Sam, Rebecca and Ernie and, further, from Carla and Woody (and the other 3 PESTs who referenced both order and the question in their responses), all note that the question does not provide evidence that order matters (i.e., there is no evidence for *p*) and, as a result, order does not matter (i.e., therefore *not-p*), which, ultimately, predicates a justification for why Dianne's response and her explanation are correct. Similar results are found within the responses from the PSSTs.

PSSTs Response Justifications

In what follows, we analyse five exemplary responses, from Frasier, Eddie, Robin, Paul and Glen, which also all evidence an appeal to ignorance. We first consider the responses of Paul and Eddie.

Paul: There are four different combinations that are possible *because it didn't specifically say that order mattered*. So generally, you can have 2 sons, 1 daughter; 2 daughters, 1 son; 3 sons; 3 daughters *in any order*.

Eddie: *There is no specification as to what order the daughters & sons have to be born in. Therefore, there is only four possible outcomes* causing a one in four chance.

As seen in the responses from Paul and Eddie, they make reference to the question not specifying that order mattered. Worthy of note, we are inferring in these particular responses that "it" for Paul and "there is no specifications" for Eddie are implicit references to the question. Working from this inference, for both Paul and Eddie, the reason that there are only four possible outcomes or that the different events can happen in any order are predicated on the question not providing evidence that order mattered. The responses from Frasier, Robin and Glen, presented below, are more explicit in their reference to the question.

Frasier: *The question does not state the order of the siblings matters* → they simply want a 2 girl + 1 boy family. *Dianne has multiples of the same outcome* such as DDS, and DSD.
Robin: *The question did not ask* what the probability is that the family has 2 daughters and one son *in that order, so there are only 4 possible outcomes*.
Glen: *The question does not specify that the order of the children matters*, they just want 2 daughters and a son. It shouldn't matter what order they come out in. *As far as the question is concerned, the DDS, DSD, SDD are all the same outcome*.

In fact, the above three responses are quite explicit in declaring that the questions does not "state", "ask" or "specify" that the order of the children matters. Further, and working from the notion that the question does not specify that the order matters, all three participants conclude that the order does not matter, albeit in different ways (e.g., "multiples of the same outcome"; "there are only four possible outcomes"; "DDS, DSD, SDD are all the same outcome"). Alternatively stated, for the responses of Frasier, Robin and Glen, the question does not specify that order of the children matters and, as such, order does not matter, which, ultimately, leads to choosing Dianne and her explanation as correct.

Considered from within an appeal to ignorance framework, the responses from Paul, Eddie, Frasier, Robin and Glen (and the other 8 PSSTs who referenced both order and the question in their responses) all note that the question does not provide evidence that order matters (i.e., there is no evidence for *p*) and, as a result, order does not matter (i.e., therefore *not*-*p*), which, ultimately, acts as a justification for why Dianne's response and her explanation are correct.

Concluding Remarks

As demonstrated in the analysis of results, all 10 responses that were analyzed can be framed within the informal logical fallacy know as an appeal to ignorance. More specifically, all 10 responses made reference, whether implicit or explicit, to the question not "stating", "asking", "indicating" or "declaring" that order mattered (i.e., there is no evidence for *p*) and, as such, the responses further concluded that the order (of the outcomes) does not matter (i.e., therefore *not*-*p*), which was represented differently by different individuals and which led, ultimately, to their decision to choose Dianne's response and explanation. Although only 10 responses were presented in the analysis of results, we further note, based upon the striking similarities between the 10 responses presented and the 11 responses not presented, that the informal logical fallacy, known as an appeal to ignorance, accounts for 100% (21/21) of the participants whose responses referenced both order and the question, which also represents, concurrently, 47% (21/45) of the responses who chose Jane's response and referenced order in their justifications, 38% (21/55) of those responses who chose Jane's response and 16% (21/130) of all the participants involved in the current research.

Discussion

Research into the teaching and learning of probability and probabilistic thinking has focused on accounting for normatively incorrect, sometimes inexplicable responses to a variety of probabilistic tasks. Stemming from these investigations, a number of theories, models and frameworks have been developed to account for and to make sense of particular responses. Traditionally, this particular domain of research has been focused heuristic and informal reasoning. More recently, a emerging thread of research has (re)opened informal logical fallacies as a fresh perspective to account for certain response justifications. While it has been established that the fallacy of composition is able to account for incorrect responses to comparisons of relative likelihood (Chernoff & Russell, 2011a, 2011b, in press), it had not been determined to what extent informal logical fallacies can describe response justifications to other probabilistic tasks other than relative likelihood comparisons and which other fallacies could be utilized. Building upon this emerging thread of research, this article has demonstrated that another informal logical fallacy, other than the fallacy of composition, is able to account for particular responses to probabilistic tasks. More specifically, in this case, an appeal to ignorance can be added to the fallacy of composition as another particular informal logical fallacy that is able to account for certain responses to probabilistic tasks. In other words, it can be argued that this article further strengthens the use of logical fallacies as a new area of investigation for future research on probabilistic thinking, the teaching and learning of probability and teachers' probabilistic knowledge. Despite what can be considered as early "success" with the use of particular informal logical fallacies, for example, the fallacy of composition and an appeal to ignorance, more research will determine to what extent logical fallacies play a part of teachers' and students' knowledge of probability. Speaking inductively for a moment, it appears that we are off to a good start.

STRATEGIES AND DIFFICULTIES THAT UNIVERSITY STUDENTS DEVELOP THROUGH THE MODELING OF RANDOM PHENOMENA BY SIMULATION

Santiago Inzunsa
Universidad Autónoma de Sinaloa
sinzunza@uas.uasnet.mx

Mario Romero
Universidad Autónoma de Sinaloa
mario.romero@info.uas.edu.mx

This paper reports the results of a research about the strategies and difficulties developed by university students in the process of modeling and simulating of random phenomena in an environment of a spreadsheet. The results indicate that students had difficulties to identify key components of the problems, which are crucial to formulate a simulation model. We have identified three different schemes to generate the results of the key components, which only one of them is correct; this scheme is based in the generation of random numbers. In consequence during this investigation it was observed that the process of the instrumentation of the spreadsheet to simulate random phenomena it is complex.

Keywords: Spreadsheet; Modeling; Probability

Purposes of the Study

The computer simulation has been suggested for many researchers and organizations as a pedagogical tool for the probability and statistics teaching, but above all, the statistics software, spreadsheets and computer technology have been penetrating even more inside laboratories and schools (Biehler, 1991; NCTM, 2000). In this way, the modeling of random phenomena by simulation has been constituted as an important part of research in statistics education during the last years. As a consequence of this, some studies were undertaken in order to know their effectiveness in probability and statistics teaching and learning (Maxara & Biehler, 2006; Lee & Mojica, 2008; Chaput, Girard & Henry, 2011).

The computer simulation integrates different aspects that are important in mathematics teaching, and particularly, in probability teaching:

1. It requires an activity of mathematical modeling in which students develop some skills, such as making assumptions to simplify the problem, identify and symbolize variables and parameters, as well as formulate the model by taking into account the assumptions and conditions, to finally, solve them and interpret the results.
2. When it is possible an analytic solution of the problem, the experimental results that are generated by the simulation can be contrasted with theoretical results. In some cases, in which the analytic solution is not possible or complex, the simulation is an important and fundamental tool.
3. It allows to work with abstract issues in concrete words, and above all, when the simulation is performed in computer environments that are equipped with representations (graphics, symbols, numbers) bound together, which make possible a visualization and feedback of the different parts of the model.

Among the advantages of using simulation as a method to solve problems of probability and statistics, Biehler (1991) mentions:

1. The possibility of formulating models in concrete terms instead of expressing the ideas by means of symbolic models (representational aspect).
2. Students can process the data generated more easily than data generated using analytical and combinatory methods (computational aspect).
3. It is possible to begin with the design of the experimental environment instead of starting with the calculations (concept-model aspect).

There are different proposals to formulate a simulation model in a computer environment. Some examples are Gnanadesikan, Scheaffer, and Swift (1987) that propose a complete and detailed a process:

1. State the problem clearly.
2. Define the key components.
3. State the underlying assumptions.
4. Select a model to generate the outcomes for a key component.
5. Define and conduct a trial.
6. Record of observation of interest.
7. Repeat steps 5 and 6 a large number of times.
8. Summarize the information and draw conclusions.

On the other side, Albright (2010) proposes a three step process:

1. Construct a model that uses random numbers.
2. Evaluate the model many times using different random numbers each time.
3. Analyze the results statistically.

The implementation of the simulation in probability and statistics teaching could be given in different ways. NCTM (2000) recommends that the probability's problems could be first investigated through simulations in order to get an estimated result, and after that, to use a theoretical model in order to find the exact result.

One of the most important aspects in the implementation of simulation as a pedagogical tool is the computer tool utilized, because its design determinate some potentialities and constraints to the mathematical activity that students develop through the interaction with it. A special kind of tool in which it's easy to simulate different random phenomena is the spreadsheet. However, its use in mathematics education remains still relegated, despite its potential to handled quantitative information (Haspekian, 2005).

Although, the advantages that simulation offers, it is necessary to do a deep analysis about its didactic potentially. Our interest in this work has been the research of the potential that a spreadsheet can have in order to modeling random phenomena in a basic probability university course, and the difficulties that the students present in the different stages of the process of modeling. Particularly, we ask the following questions: (a) what are the potentialities and constraints that the spreadsheets have to the simulation of random phenomena? (b) what are the strategies that students can develop? and (c) what are the difficulties that students can find in the process of modeling?

Theoretical Framework

In the development of this work, we have adopted an instrumental approach of the mathematical cognition (Artigue, 2002). The most basic notions of this approach consist in the meanings of *instrument* and *artifact*. The artifact is a material or abstract object that is available for certain activities. Examples of this are the language, the calculator and the spreadsheet. On the other hand, the instrument is a personal construct that can be developed by handling an artifact in a progressive way.

An artifact becomes a instrument when the subject achieves to appropriate of the artifact and establishes meaningful relationships for doing a specific kind of work (a mathematical one, in this case), this means that the subject can use and control this artifact to achieve their goals, and to integrate it to their activities (Verillón & Rabardel, 2005). The process of the transformation of the artifact into an instrument is called *instrumental genesis.*

The process of instrumental genesis evolves in two interrelated directions. The first one is directed to the artifact, loading it progressively with potentialities, and eventually transforming it for specific uses; this is called the *instrumentalization* of the artifact. Secondly, instrumental genesis is directed towards the subject, leading to the development or appropriation of schemes of instrumented action, which progressively take shape as techniques that permit an effective response to given tasks. The latter direction is properly called *instrumentation*. In order to understand and promote instrumental genesis for learners, it is necessary to identify the constraints induced by the instrument (Artigue, 2002). The restrictions are the result of the tool's design. In this way, the use of a tool is not a unidirectional process, but a dialectic process between the subject that acts over the instrument, and the instrument, which acts over the thinking of the subject.

In the process of instrumental genesis, the user develops mental schemes for specific tasks. In these schemes, the technical knowledge or in other words, the skills to use the artifact and the knowledge of the specific domain of the mathematical content, are intertwined or complimented (Drijvers & Trouche, 2008). An instrument is a mixed entity constituted by one piece of artifact and other part with the personal schemes that the users develop through doing specific tasks. In the case of a mathematical task, a mental scheme involves the global strategy of solution, as well as the technical resources that the artifact offers, and the mathematical concepts in which underpin the strategy.

Potentialities and Constraints of the Spreadsheet to Random Phenomena Simulation

Excel spreadsheet possesses diverse potentialities and a framework of representational aspects of calculation and communication. In the communication aspect, a spreadsheet requires that the students work with an interactive algebra-like language, which focuses their attention on a rigorous syntax. This is why it is said that spreadsheets help to translate a problem by means and algebraic code (Haspekian, 2005). Into the representational aspect, the spreadsheet has multiple representations that allows several semiotic registers that can be presented in simultaneous ways on screen, such as the case of the formulas register to express relations between cells, numerical register to represent data or results of calculations, graphics register that allows user several types of graphical representations dynamically linked to the numerical data. And finally, for the aspect of calculation, Excel has an extended range of formulas that make possible formulating models, generating data and making calculations. Other important element is the numerical feedback obtained when working with a formula, which allows students to experiment, speculate, and help them to find mistakes. On the specific case of simulation of random phenomena, Excel spreadsheet has several commands to generate pseudorandom numbers. Under the case of discrete random phenomena which are simulated through models of urns (as it is in our case), Excel has two commands that generates numbers provided from a uniform distribution: *rand() and randbetween(bottom,top).* The function *rand()* returns a random number between 0 and 1, meanwhile the function *randbetween(bottom,top)* returns an entire random number between the limits specified. The figure 1 and 2, show those formulas and the resulted generates are shown:

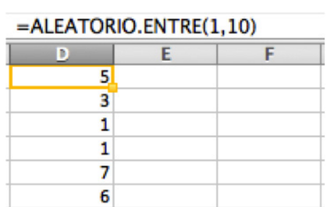

Figure 1: randbetween(1,10)

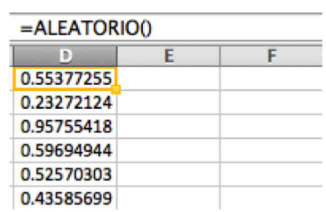

Figure 2: rand()

The pseudorandom numbers generated by *rand()* or *randbetween(inf,sup)* have two properties that make them comparable to in fact random numbers:

1. Any number between 0 and 1 has the same probability to be generated.
2. The numbers generated are independent between each other.

Excel spreadsheet, also as we know, works with arithmetic formulas, conditionals and statistics that make possible the conditions of a problem and realize the analysis of the results. The copy/paste option and F9 permits to evaluate the model as many times doable and therefore a quick feedback.

Methodology

This study was done with 22 students between 19–20 years old of the undergraduate program of Information Systems. The students were enrolled in a basic course of probability and statistics in the first semester of the school year 2011–2012. This course emphasized the simulation as complement of the probability theoretical approach in some themes. Students weren't trained in a previous course about use of Excel to simulation and the study started with the their basic knowledge of Excel spreadsheet. Simple examples of simulation were raised in the class and some assignments to be complement it took place, therefore contrast results of the simulation with the theory achievement. The present work shows the results from the following three activities:

Activity 1: Simulate the rolling of two dices:

a) *Add of points resulting of faces up and determine the probability that the result is 7.*
b) *Subtract points resulting of faces up and determine the probability that the difference of points is 3.*
c) *Multiplicate the points of the faces up and calculate the probability that the product of points is bigger than 10.*

The purpose of this activity was to introduce students to simulation environment in the Excel´s spreadsheet, to observe with what formulas they will be working for and what difficulties they will be confronted with to finally formulate the model. According with the instrumental theory, this activity represents the starting point for the analysis of the instrumentation developed by the students in the spreadsheet.

Activity 2: If a friend of yours thinks in a number between 1 and 100 ¿what is the probability of making it divisible by 6 or 10?

This activity require the application of the rule of the addition of the probabilities; this is it, $\mathrm{P(AUB)} = \mathrm{P(A)} + \mathrm{P(B)} - \mathrm{P(A \cap B)}$, where A is an event that represents divisible numbers by 6, B is an event that represents divisible numbers by 10 and $\mathrm{P(A \cap B)}$ is event that represents divisible numbers by 6 and by 10.

Activity 3: There are 3 urns with black and white balls (Urn 1: 3 white and 2 black. Urn 2: 1 white and 3 black. Urn 3: 6 white and 2 black). There is selected one ball from one urn. What is the probability that a ball color white shows up? There is an assumption of equal probabilities to select any of the urns.

The purpose of this activity was to formulate a model of simulation to the calculus of the total probability of a event; this is it, $P(B) = P(U1)P(B/U1) + P(U2)P(B/U2) + P(U3)/P(BU3)$, where U1, U2 and U3 are events Urn 1, Urn 2, Urn 3 respectively, and B is the event that represents to which white ball is selected. Formulate the model requires identify 2 stages; the first one consist in decide the urn in a random way, and second stage; select the ball from that urn.

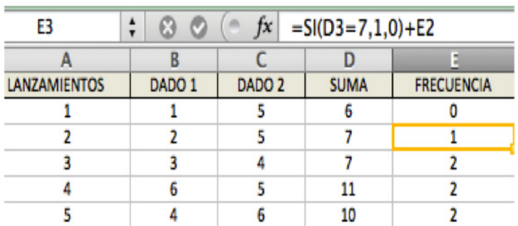
In the analysis of the information we have present the strategies and the elements of the spreadsheet that were used by students in each phase of the process of the modeling described by Gnanadesikan, Scheaffer, and Swift (1987) and Albright (2010).

Results

Formulation of the Models through Random Nnumbers

The formulation of a simulation's model of random phenomena contemplates the comprehension of the problem, identify the key components, make assumptions and build a symbolic expression through one or more commands to obtaining results.

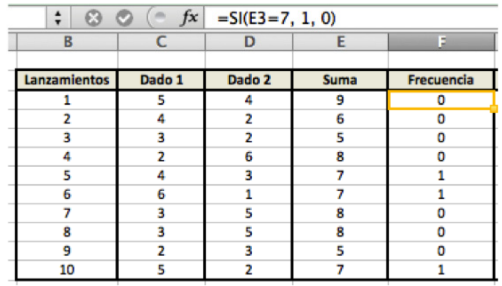
In the context of the activity 1, the key components are the results of the dices. The assumption is that the dices are symmetrical, because each face of them is equally possible. One result is obtained adding, subtracting or multiplying the points of two dices -referring that case-. In this activity the students didn't show difficulties in identify the key components, which are essential part to make the simulation correctly. Figures 3 and 4 show the model made it by two students on the case by adding points:



E3 =SI(D3=7,1,0)+E2

LANZAMIENTOS	DADO 1	DADO 2	SUMA	FRECUENCIA
1	1	5	6	0
2	2	5	7	1
3	3	4	7	2
4	6	5	11	2
5	4	6	10	2

Figure 3: Model constructed by Luis



=SI(E3=7, 1, 0)

Lanzamientos	Dado 1	Dado 2	Suma	Frecuencia
1	5	4	9	0
2	4	2	6	0
3	3	2	5	0
4	2	6	8	0
5	4	3	7	1
6	6	1	7	1
7	3	5	8	0
8	3	5	8	0
9	2	3	5	0
10	5	2	7	1

Figure 4: Model constructed by Silvia

In the case of the activity 2, the key component is the number that is thought. There is the assumption of any number between 1 and 100 are equally probable to happen, therefore the result from the key component is obtained generating random numbers between 1 and 100. In this case, students had difficulties to identify the key component and most of them started with favorable results (divisible by 6 or by 10 or both), when the correct one was to generate firstly the key component and lately to identify favorable results.

In other hand, in the activity 3, the key components are the selection of the urn (urn1, urn2 or urn3) and the selection of one of the balls (black or white). The assumptions are that each urn has the same probability to be selected and for the balls option is that each ball has the same assumption of equal probability. As the same way that it was in the other activities, here was observed that students do showed difficulties to identify the key components, however some of them identified the balls selection (second part) but omitted the urn selection (first part).

In conclusion, we have identified three schemes for the formulation of the model:

1. Students, who use the space of the spreadsheet like a notebook, make calculus in manual manner and write it down the results. They don't use the potential of the spreadsheet.
2. Students, who use formulas to calculate probabilities, but do not request to generate random number how it is supposed to be in a model of simulation.
3. Students, who use formulas with random numbers to simulate the key components.

In the following figures of one the students who participated in the activity 2 which results generated from a random command (Figure 5) and another one where no random formula results to accomplish the divisibility condition (Figure 6).

Figure 6: Model constructed by Ana

For his part in Figure 7, the student Angel shows his work in activity 3. Where, first at all, he made calculations in manual method using formula of total probability, then simulates extraction of balls and calculates frequencies to 10,000 cases. Results of both approaches match up given certainty to precision of his problem.

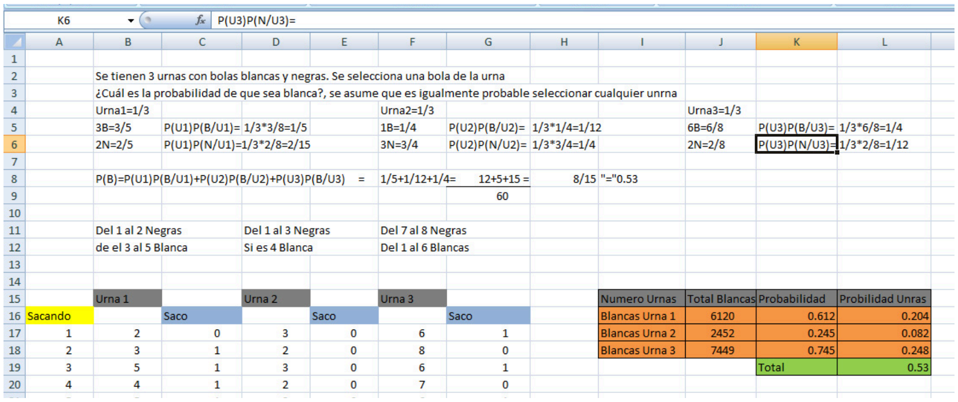

Figure 7: Work developed by Angel in activity 3

The Table 1, show the results of the different schemes developed by the students and the commands utilized to formulate the model of simulation.

Table 1: Classification of Students by Schemas and Commands Utilized

Activity	*Frequency of students by schema*			*Commands used to generate the model*
	1	*2*	*3*	
1	8	0	14	Randbetween(1,6) A1+A2, Sum(A1,A2), A1-A2, A1*A2
2	7	9	6	Randbetween (1,100)
3	3	14	5	To the selection of the urn: Randbetween(1,3) To the selection of the balls: Randbetween (1,5), Randbetween (1,4), Randbetween (1,8).

Evaluation of the Model

The evaluation of the model consist in generate a case and record the outcome of interest, and then repeat it many times and see if the results satisfy the conditions of the problem. In the first activity, the analysis reveals that the students who generated the results of the key components though a random function (scheme 3), use the function “copy of formulas” to generate many cases (hundreds or thousands) as it is shown in figures 1 and 2. Other students used F9 in order to repeat the case in the same cell, and afterwards, they copied again. The students who used scheme 1 (data direct introduction) had the difficulty to generate many cases. It is also important to highlight that some students found out some mistakes in their model when the result obtained was not what they were waiting for. This important function of the spreadsheet allows students to monitor a problem solution process.

In activity 2 the students who did not use a random formula to generate the results of the key components (thought number), could not evaluate their model as a case of simulation, however, they got correct results through probability's classic formula. In the case of the students, who generated randomly the results (e.g., José, Figure 5), identified the favorable cases through the formula *residue(number,number_divisor),* combined with the conditional formula *if(logical test,value_if_true_value_if_false).* Afterwards, when students observed that some correct results were produced, they copied the formula to solve many cases (see Figure 5).

On the other side, in activity 3, only 5 students used random numbers in order to build a model and as mentioned before, the simulation was partial (the extraction of the ball in the urn selected), and this is the reason why the evaluation of the model consisted in identifying if the random generated number corresponded to the white or black ball, for which they used the conditional formula *if(logical test, value_if_true_value_if_false).*

Table 2: Commands Utilized to Obtain Conditions and to Evaluate the Model

Activity	*Commands used to identify favorable results*
1	To additions=7: IF(D6=7,1,0 To substractions=3: IF(G6=3,1,0) To products > 10: IF(J6>10,1,0)
2	To divisors of 6: IF(RESIDUE(B1,6)=0,1,0) To divisors of 10: IF(RESIDUE(B1,10)=0,1,0) To divisors 6 or 10: =COUNTIF(C2:C1000,1,E2:E1000,1),

3	IF(B17=1,0,IF(B17=2,0,1))
	IF(D17=4,1,0)
	IF(F17=7,0,IF(F17=8,0,1))

Statistic Analysis of the Results

In this phase, we focus on summarize the information obtained by the model and draw conclusions. In specific, it means register observations of interest (favorable events), and calculation of the relative frequencies.

In activity 1, most of the students who generated the model through of a random command followed a schema of identify and accumulate the favorable cases in the same column, what means introduce a recursive formula starting at the second line, how is showed in case Luis (Figure 1). This part was cause of difficulties for some students, who only can identify the favorable cases but no one accumulated the results as is showed in Silvia's work. A schema more simple was identified the favorable cases and make additions in determined cells, nevertheless, any student didn't show that kind of schema.

In the activity 2, the register of the favorable results and calculation of the frequencies did it by the students using a random phenomena through formulas like *countif(range,criteria)* and *countif(range,criteria1,range,criteria2,).* In other hand, activity 3, using 0 and 1 as variable indicator to identify favorable results, it helped to calculate the frequency through the formula *countif(range,criteria)* or *sum(number1,number2)*

Table 3: Commands Used for the Register Favorable Results and Calculation of Frequencies

Activity	*Commands used to count favorable results*
1	=IF(D5=7,1,0)+E4
2	=COUNTIF(E2:E1000,1)
3	=COUNTIF(C17:C10016,1)

Conclusions

The results obtained in this research have showed that the process of the instrumentation of the spreadsheet in the modeling of random phenomena it is not an easy process, even for the students with a previous programming knowledge, as it was the case of the subjects involved in our study. The process of simulation works with a methodology that demands from students the use of intertwined strategies between the knowledge they already have of the topic and the technical knowledge of the resources that the spreadsheet has.

As it was observed the empty knowledge of the functions of the spreadsheet (potentialities) and constraints, from where depends the level of instrumentation, by taking in consideration spreadsheet wasn´t conceived as an educational tool. In other hand, the theoretical approach that the students are used in probability courses since secondary school is part of the influence that relegate the use of the Excel potentialities to the typical calculus functions, because for them results more simple and easy use it in that way.

The incorrect schemas developed for the formulation of the model show the difficulties that the students had in identify the key components of the problems, therefore they opted to use other strategies as to introduce in a direct way the data or generating through no random formulas to accomplish the problem. According with this our conclusion states that the competences to develop models of simulation in a spreadsheet, requires a planned process to show to the students the methodology of simulation, as well it is needed a better knowledge of the potentialities and constraints of the tool.

NAVIGATING THE TRANSITION FROM DESCRIPTIVE TO INFERENTIAL STATISTICS THROUGH INFORMAL STATISTICAL INFERENCE

Bridgette L. Jacob

hmdoerr@syr.edu

Keywords: Data Analysis and Statistics; Probability; High School Education

Students' difficulties in understanding formal statistical inference in introductory statistics courses are well known in the field of statistics education. Recent research efforts have focused on "informal" statistical inference to understand how students begin to reason about data as they transition from descriptive statistics to formal statistical inference (Pfannkuch, 2011). In "informal" statistical inference, students generalize about populations based on sample data without the formalities of constructing a confidence interval or conducting a hypothesis test. This qualitative study investigates: (a) How does students' informal inferential reasoning develop over a series of three informal statistical inference tasks? and (b) What are the characteristics of students' informal inferential reasoning as they make informal generalizations?

Influenced by the task design framework proposed by Zieffler et al. (2008) and research on students' difficulties and misconceptions in introductory statistics, this study used a framework that focused on three tasks explicitly linked to the concepts of descriptive statistics, probability, and the sampling distribution. Task-based interviews (Goldin, 2000) were conducted with three pairs of high school students taking statistics for college credit. We used Makar and Rubin's (2009) principles for informal statistical inference to document the development of students' informal inferential reasoning as evidenced by the extent to which they: (a) made generalizations that extended beyond the data at hand, (b) used the data as evidence for their generalizations, and (c) indicated a level of certainty in their generalizations.

As the student pairs worked through the three tasks, we found evidence of how their informal inferential reasoning developed. As the complexity in comparing the distributions increased from a focus on mean and skewness to include variation and proportional reasoning, students focused on individual elements rather than the overall distribution in making generalizations. In the second task, students' generalizations progressed to extending beyond the data as they estimated population probabilities and proportions based on the data they had collected. Another characteristic of students' inferential reasoning occurred during the third task when the normality of the sampling distribution was not accessed by students as they decided on the validity of a claim about a population.

UNDERSTANDING RISK THROUGH THE COORDINATION BETWEEN LIKELIHOOD AND IMPACT

Nenad Radakovic
University of Toronto
nenad.radakovic@utoronto.ca

Keywords: Data Analysis and Statistics; Probability; Design Experiments; High School Education

The purpose of the study is to investigate secondary students' understanding of risk with respect to the coordination between likelihood and impact. There are two objectives: (1) to investigate students' informal knowledge of risk and their informal coordination between likelihood and impact; (2) to explore ways in which the formal instruction can foster the coordination between likelihood and impact. In this study, risk of an event is defined as the measure of both likelihood and impact (Pratt et al., 2011). The study uses the design experiment approach (Cobb & Gravemeijer, 2008) to explore risk literacy education within the context of secondary school mathematics. In the research, there were two cycles of the design experiment. The first cycle took place in a grade eleven classroom at a secondary school in Ontario during the probability and statistics unit (23 participants, all boys). The second design experiment was conducted in a different educational setting, i.e., a different independent school in Ontario in a grade eleven enriched classroom during the probability and statistics unit (23 participants, 19 girls and 4 boys).

During the initial written assessment, students were given a question concerning safety of nuclear power plants. Out of 19 students who completed the initial assessment, eight out of 19 students made arguments based on impact. Based on the initial assessment, students were divided in five groups and given an activity in which they had to assess the safety of nuclear power plants using data including likelihood and impact. In all five groups students estimated that the probability was small. In the second part of the activity, students were asked to estimate an impact of an accident based on empirical data provided. The students were then asked to assess the risk of both nuclear and coal accident by combining the data on probability and impact. Most of the students, decided to multiply the two values which is a sound mathematical technique. However, when asked to provide reasons for the operation, the students were not able to provide adequate explanations. This suggests that the coordination between likelihood and impact needs to be presented in a more meaningful way.

For the second cycle, the results of the initial assessment were very similar to the first group. However, for the group activity, instead of the introduction of the product, the students were provided the set of coordinates with the probability on the vertical axis and the impact on the horizontal axis. The students were then asked to plot the values for the probability and impact for both nuclear power plants and coal power plants. Based on the results, there is evidence that students already possess the idea that the assessment of risk requires combination of likelihood and impact. Out of the two mathematical ways of coordinating the two, the graphical representation yielded a more of conceptual understanding of the nature of risk.

While computing technologies are widely available in secondary schools, these technologies have had only limited impact on changing classroom practices. Partly, this can be attributed to an underdeveloped understanding of the role of the teacher in engaging in classroom practices that can support student learning with technology. In this study, we analyzed the teaching practices that supported students' learning of a conceptually rich and deep topic (the average rate of change) when using an exploratory computer simulation environment. The results illustrate the demands placed on teachers when faced with the multiplicity of student ideas generated by their interactions with the simulation and three aspects of a teaching practice in response to those demands. These findings contribute to evolving frameworks for understanding meaningful and productive technology use in teaching secondary mathematics.

Keywords: Teacher Knowledge; Technology; Modeling; Advanced Mathematical Thinking

Over the past three decades, much research has focused on the potential for computing technology to impact K–16 mathematics education. Graphing calculators, internet access, and (most recently) interactive whiteboards are now widely available in secondary schools and colleges. But the widespread availability of computing technology has had only limited impact in making the kinds of changes to classroom practices envisioned by research. While many factors contribute to the successful adoption of any technology, one crucial factor in any kind of change to classroom practices is the teacher (Godwin & Sutherland, 2004; Ruthven, Deaney, & Hennessy, 2009). An underlying assumption of this study is that our understanding of the role of the teacher in supporting learning with computing technologies is underdeveloped.

The need to understand the relationship between pedagogy and student learning with technology was identified in the early 1990s by Hoyles and Noss (1992) as they observed "the inescapable and perhaps unpalatable fact that simply by interacting with an environment, children are unlikely to come to appreciate the mathematics which lies behind its pedagogical intent" (p. 31); they also noted the sparseness of research that addresses the nature of pedagogies that can support student learning with computer environments. More recently, Ruthven and colleagues have noted that the teaching practices associated with the widespread use of graphing technology have received relatively little attention from researchers (Ruthven et al., 2009). Ruthven et al. argue for the development of teachers' craft knowledge to support their classroom use of technology. This perspective is in contrast to a less situated approach to teachers' knowledge that is characterized by the TPACK (technological pedagogical content knowledge) construct (Mishra & Koehler, 2006; Neiss, 2005).

The larger goal of this study is to contribute to the development of a model of teaching practices that support student learning with exploratory computer simulations. To that end, we investigated the teaching in a pre-college classroom setting where the students used a computer simulation to study of the average rate of change, a traditionally difficult, yet conceptually rich and foundational topic in mathematics. Our study was guided by the following question: what was the nature of the teaching practices that supported students' learning of average rate of change when using an exploratory computer simulation?

Theoretical Background

Much recent work on the relationship between teaching practices and technology has drawn on the TPACK model, often examining the preparation of teachers or the professional development of in-service teachers (e.g., Bowers & Stephen, 2011; Neiss, 2005). However, Graham (2011) and others have criticized the TPACK model for lacking clear theoretical distinctions between the elements of the model, a lack of precision in definitions, and difficulties in discriminating between the proposed constructs of "technological content knowledge" and "technological knowledge." The fuzziness at the boundaries of the TPACK model may call into question the existence of the proposed constructs or it may simply point to the need for empirical work on teaching practices that can inform revisions and clarity within the model. Our purpose in this paper is not to critique the TPACK model, but rather to study teaching practices to better understand the role of the teacher when using computer technology, in particular an exploratory computer simulation. As Hoyles and Noss suggested in 1992, such a pedagogy would include introducing a mathematical agenda, a progressive sequence of computer tasks, related paper-and-pencil work and class discussions of computer-based work, and small group activities to bring together computer and non-computer work. Ruthven and colleagues (2009) argue that, when using graphing software, the teacher plays a fundamental role in making the mathematical relationships meaningful for students by supporting the mathematical interpretation of the technology-based representations. Our goal in this study is to contribute to a clearer understanding of the nature of teaching practices with computer technology, particularly as students come to understand the concept of average rate of change.

Over the last twenty years, researchers have documented the difficulties that students encounter in learning to interpret models of changing phenomena (Carlson et al., 2002; Thompson, 1994). In this paper, we draw on a modeling approach to student learning that Kaiser and Sriraman (2006) identify as a "contextual modelling" perspective. This perspective emphasizes the design of activities that motivate students to develop the mathematics needed to make sense of meaningful situations. Much work done within this perspective draws on model eliciting activities developed by Lesh and colleagues (e.g., Lesh & Zawojewski, 2007). Such activities confront the student with the need to develop a model that can be used to describe, explain or predict the behavior of familiar or meaningful situations. Considerably less research has focused on model exploration activities, where students explore the mathematical characteristics of the model. In this paper, we focus on a set of model exploration activities using a computer simulation environment, accompanied by student presentations and teacher-led discussions that focused on the underlying structure of the model, on the strengths of various representations, and on ways of using representations productively. Thus, for this study, we designed an instructional sequence that began with a modeling activity to elicit the construct of average rate of change, followed by model exploration tasks that examined the underlying mathematical structure and its representations. The focus of this study is on the role of the teacher in facilitating student presentations and leading class discussions that support students' understandings of how to represent the average rate of change.

Research Design and Methodology

This study used design-based research as an approach to studying teaching and learning as it occurs within the complexity of a naturalistic classroom setting (Cobb et al., 2003). This approach is intended to generate principles of practice, in this case related to teaching with computer simulations. We draw on the multi-tiered design experiment (Lesh & Kelly, 2000), which provides a framework for collecting and interpreting data at the researcher level, the teacher level and the student level. Central to our analytic approach is the notion that, as researchers, we examine the teacher's actions in the classroom and her interpretations of those actions, which are in turn influenced by the students' interactions with the tasks in the simulation environment. The researchers and the teacher (the third author) collaboratively developed the tasks that were designed to support students in understanding the concept of average rate of change.

Simulation Environment and Task Design

We began the instructional sequence with a model-eliciting activity, using the physical situation of motion along a straight line. Students created graphs using their own bodily motion and a motion detector and wrote verbal descriptions of that motion. This included comparative situations of faster and slower constant speed, changing speed and changing direction. Following the model-eliciting activity, the students engaged in a sequence of model exploration tasks. These tasks were designed to help students to think about the underlying structure of the model of constant and non-constant motion. An important goal of these tasks was to engage students in using informal and formal language to describe the average rate of change and to develop their understanding of the representational systems for describing change. As argued earlier, this brings with it a concomitant role for the teacher in using instructional strategies that will support students in interpreting the mathematical relationships intended in the tasks and instantiated in the computer environment.

The model exploration tasks used SimCalc Mathworlds (Kaput & Roschelle, 1996). This computer simulation environment was designed around the context of one-dimensional motion to explore the relationship among position, velocity and acceleration, the connections between variable rates and accumulation, and an understanding of mean values. The drag-and-drop environment makes use of piecewise linear functions to create position or velocity graphs; these graphs drive the one-dimensional motion of cartoon-like characters in the linked WalkingWorld. The MathWorlds environment reversed and extended the representational space of the model-eliciting activity with the motion detector where bodily motion created a position graph; in the simulation environment, the students created velocity graphs that generated the cybernetic motion of a character. From the simulated motion, the students created position graphs, thus developing an understanding of how the position graph could be constructed by calculating the area between the velocity graph and the *x*-axis. In exploring this linked relationship among the characters' motion, the velocity graph and the position graph, students began to reason about the position of characters solely from information about the velocity of the characters. This model exploration task provided an opportunity for students to develop their abilities to interpret position information from a velocity graph and velocity information from a position graph. Subsequent model exploration tasks introduced the concepts of average velocity, negative velocities, linearly increasing and decreasing velocities and their associated position graphs.

Context and Participants

The sequence of model exploration tasks was part of a larger set of modeling tasks that formed the basis for a six-week course for students who were preparing to enter their university studies. The teacher and the first author collaborated in the development of the entire set of tasks for the course. The teacher had three years of experience teaching secondary and college students; this was her second year teaching the summer course. There were 17 students in the course all of whom volunteered to participate in the study. Three of the participants were female and 14 were male. All participants had completed four years of study of high school mathematics; 11 students had studied calculus in high school and six had not studied any calculus. The model exploration tasks were done individually at a computer; however, the participants were encouraged to discuss their work with each other. Following each task in the sequence, there was a whole-class discussion that usually involved students in presenting the results of the work produced during the model exploration tasks. The class discussion following these tasks focused on the mathematical structure of the model and on the relationships among different representational systems.

Data Collection and Analysis

Consistent with the methodology of multi-tiered design experiments, data for this study were collected at two levels: the level of the teacher and the level of the students. The data sources at the teacher level included videotapes of all class sessions, written field notes and memos, class materials such as worksheets and a record of board work, the teacher's lesson plans and annotations made by the teacher during the lesson. Following each lesson, there was a debriefing session with the teacher, which captured the teacher's reflections on the lesson and any changes to the plans for subsequent lessons. These debriefing sessions were audio-taped and transcribed. The model exploration activities with the simulation world took place over a total of six lessons; each lesson lasted one hour and 50 minutes. Central to our analytic approach is the notion that as researchers we examine the teacher's descriptions, interpretations, and analyses of artifacts of practice that were developed, examined and refined during our collaborative work on the design and teaching of these six lessons. In this paper, we only report on the analysis of the teacher level data, although we acknowledge that this analysis was influenced by the data at the student level.

The analysis of the data took place in three phases. Consistent with the iterative approach of design-based research, the first phase of analysis took place during the six weeks of teaching. In this phase, the research team met with the teacher and regularly engaged in discussion about the model exploration tasks, the progress of the class as a whole, and our observations about students' thinking about average rate of change and their language for expressing their ideas. Analytic memos were written by members of the research team to document their emerging understandings of the teaching practices and observations about student learning.

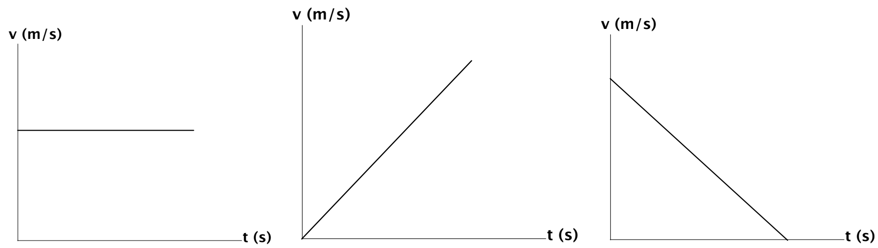
In the second phase of the analysis, the research team viewed the videotapes and wrote a detailed script of each lesson, identifying the nature of the teacher's activity in each segment of the lesson and its time-stamp and duration. Following the principles of grounded theory (Strauss & Corbin, 1998), preliminary codes were developed to categorize what the teacher did in the classroom. Drawing on this analysis, the research team identified a set of approximately six to eight video segments within each lesson that captured recurrent themes and for which we wanted the teacher's retrospective perspectives and interpretations. These video segments were the basis for video stimulated recall with the teacher and gave further insights into the teaching practices from the perspective of the teacher. This in turn led to further refinement of the coding scheme. In the third phase of the analysis, we coded the videotapes of the six lessons using the revised coding scheme. As we analyzed the teaching practices, we sought confirming and disconfirming evidence in the teacher's lesson plans and annotations during the lesson, and with the teacher's perspective on the lesson from the de-briefing interviews and the post lesson video stimulated recall. This led to the formulation of the results in three broad categories: (1) pressing students for representations; (2) harvesting student ideas; and (3) sorting out and refining student ideas. In this paper, we report on the results in the first category: pressing students for representations.

Results

A representational press occurs when the teacher applies pressure on students for the purpose of furthering the students' emerging understandings of the representations of average rate of change, which in this case occurred within the computer simulation environment and in students' related work. This related work could be any one of the forms of the following representations: language (both written and spoken); table; symbolic (such as function notation and algebraic expressions); iconic or graphical; and enactments (either cybernetically in the simulation world or bodily in the real physical world). We found three categories of representational presses that the teacher engaged in: (1) explicitly inserting a representation into the discussion to support connections to other representations; (2) pressing the students to give interpretations of their representations in terms of the context of the task, while articulating arguments that justify their interpretations; and (3) pressing students to use representations to clarify a situation or question. Due to space limitations, we report here only on the second and third categories.

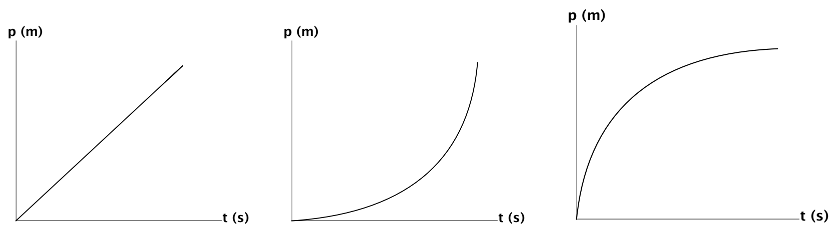
Interpreting Representations

In this episode, we illustrate how the teacher pressed the students to give interpretations of their graphs in terms of the context of the task while articulating arguments that would justify their interpretations. This episode occurred in the fourth day in the sequence of the six lessons. The teacher led a whole class discussion about the characteristics of three different linear velocity graphs and their corresponding position graphs, which had been the focus of the tasks with the simulation environment. The three velocity graphs are shown in Figure 1 and their corresponding position graphs are shown in Figure 2.



(a) (b) (c)

Figure 1: Comparing three velocity graphs from the simulation environment



(a) (b) (c)

Figure 2: Comparing the corresponding position graphs

During the whole class discussion, the teacher labeled the graphs on the blackboard with the students' verbal interpretations of the graphs. Graph (a) was described as constant velocity and constant speed; graph (b) was described as increasing velocity, increasing speed, and acceleration; and graph (c) was described as decreasing velocity, decreasing speed, and acceleration. The position graphs shown in Figure 2 were interpreted as: (a) linear, increasing position; (b) curved, accelerating, increasing position, "walk slow then fast"; and (c) accelerating, increasing position, "walk fast then slow." In the following excerpt from the class discussion, the teacher focused students' attention on the velocity graph (c) in Figure 1. In this exchange, we see the teacher pressing students (1) for the use of appropriate language to describe the graph, (2) for making connections between cybernetic and physical enactments, and (3) for understanding the meaning of the relationship between a constant or linearly changing velocity graph and its associated position graph.

1 *Tchr:* How would you describe this motion here [graph (c) in Figure 1]?
2 *Chris:* Uhmm, it's deceleration [inaudible]
3 *Tchr:* Okay, so we also have acceleration here, okay, uhmm, because why?
4 [Several students talking]
5 *Tchr:* Because why?
6 *Chris*: Umm, as the…because the velocity is changing
7 *Tchr:* Um, how would you have to walk? If you were trying to match that graph from the third day we did *Hiker* [an earlier activity]? You're holding the motion detector. How would you tell the person to walk?
8 *Quent:* For which one? [Teacher points to graph (c) in Figure 1]
9 *Vic:* You tell him to walk away from the censor;
10 *Quent:* Real fast
11 *Tchr:* Real fast
12 *Vic:* And then slowing down
13 *Tchr:* And then slow… Okay.

This episode began with the teacher pressing the students to interpret the decreasing velocity graph from the simulation environment and to verbalize deceleration as changing velocity. In turn 7, the teacher pressed for a description of this changing velocity in terms of enacted physical motion. She invited the students to describe an enactment of the motion in terms of a device (the motion detector) that could measure and record the physical motion of a person walking. In this way, the teacher engaged the students in generating verbal descriptions of simulated motion that were explicitly connected to physical motions that the students had experienced earlier.

Using Representations to Clarify Situations

In this episode, we illustrate how the teacher pressed a student to insert a representation into an argument so as to support and clarify his reasoning about a specific situation. The teacher had posed the following question to the class for homework: "If two people take a walk and end together, have the same velocity throughout the walk, then both must have walked for the same amount of time. True or false?" This task was designed with some intentional ambiguity around what it means to "have the same velocity" that the students would need to resolve in answering the question. In the class discussion the next day, the teacher polled the students and made public the result of the poll: all of the students, except one, thought that the claim in the posed question was true. The teacher decided to hear about the false argument:

1 *Vic:* It says take a walk. It doesn't say that they started the same time, so one [person] can have already been going at… that for a while so… they could have…. at the same time so… Let's say [inaudible] one's going somewhat faster and the other one could be going somewhat slower, but the slower one started earlier… so they end together, at the same place at the same time… but… this does not seem, I mean… they had their own velocities, uh for the walk… that is to say that, they both had the exact same velocities.
2 *Tchr:* Is this bouncing off of Vic or new idea? [to Jorge who is holding up his hand]
3 *Jorge:* I have a new idea. Uh, it says that they "have the same velocity". If they didn't have the same velocity and one person was already ahead of the other then they would never end up at the same time.
4 *Tchr:* Uh huh
5 *Jorge:* Like if two people are walking at 4 meters per second – how are they gonna end up at the same place in the same amount of time if one already started walking.
6 *Tchr:* So what do you take "same" to mean?
7 *Jorge:* That… basically two people are walking at the same time, and one walks for a longer dist[ance], for a longer amount of time, then he'll walk more distance.
8 *Tchr:* Okay.
9 *Vic:* Um
10 *Tchr:* [To *Vic*] Do you have a rebuttle to that?
11 *Vic:* Uh huh
12 *Tchr:* You want to argue with that?
13 *Vic:* Yes, um, that's still not taking into account that someone could have already been ahead of the other [person]. But going into, the velocity, um, but it's still, making the velocity constant. It isn't saying that it has, that is, that it has to have the exact same velocity. It says "have the same velocity throughout the walk." That could mean anything. That could even just mean constant velocity.

In the first turn, Vic offers the argument that the "same" velocity means that the walkers each had their own "same" constant velocity throughout the walk. But, in turn 5, Jorge makes clear that he has interpreted "same" velocity to mean the same as each other: both are walking at a constant velocity of "4 meters per second." In turn 6, the teacher acknowledges the ambiguity of the meaning of the "same" and in turn 10 invites Vic to further his argument.

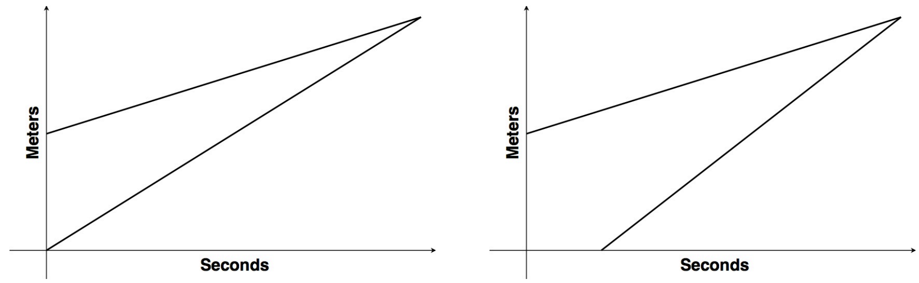


Figure 3: Representing the "same velocity" with different times

After checking with the students in the class for their understanding of Vic's argument the teacher asked Vic: "Do you think that you can demonstrate what you are talking about?," a suggestion Vic quickly takes up; he goes to the blackboard and draws the graph shown on the left in Figure 3. This graph shows "the slower one" (as Vic expressed in turn 1) starting behind the other walker in terms of position (as expressed in turn 13), but both walkers walk the same amount of time and hence this is not a counterargument to the original claim. As Vic elaborates his thinking, he correctly revises his graph to the one shown on the right in Figure 3, which shows the slow walker being ahead of the fast walker, but the walkers walk for different amounts of time, an argument that convinces many students that the original claim is false. The teacher had not (and could not) fully anticipate all of the students' arguments and pressing for representations was helpful to her in understanding the complexity of the students' arguments.

Discussion and Conclusions

Students' difficulties in learning to interpret rates of change, particularly in the context of one-dimensional motion, are well known in the research literature. Computing technology would seem to hold great potential for helping students to understand this rich and yet challenging concept. However, the relationship between pedagogy and student learning with technology is still an area in need of research (Hoyles & Noss, 1992; Ruthven et al., 2009). The computer technology provided a flexible way for students to represent their ideas and to manipulate them. As students engaged with the tasks in the environment, and the related non-computer tasks where they had to interpret the meaning of graphs and give verbal descriptions or arguments justifying their representation, more student ideas were generated and conflicts among interpretations arose that needed to be resolved by mathematical reasoning. The technology also provided a common frame of reference for small group conversations and whole class discussions. However, as Hoyles and Noss (1992) warned, one cannot assume that the students fully understand the representations in the computing environment. The generation of student ideas and the need for students to interpret and give meaning to the representations in the computer environment place new demands on the craft knowledge of the teacher. In this study, we found the emergence of a teaching practice that responded to these new demands, namely pressing for representations. Through this practice, the teacher pressed the students to articulate the connections among representations, to make interpretations of their representations while giving arguments to justify their interpretations, and to use representations to clarify situations and resolve questions.

DEVELOPING TPACK ALONGSIDE PROFESSIONAL VISION OF TEACHING MATHEMATICS WITH TECHNOLOGY

Suzanne R. Harper
Miami University
harpersr@muohio.edu

Dana C. Cox
Miami University
coxdc4@muohio.edu

This study questions the extent to which a course in Mathematical Problem Solving with Technology was developing TPACK in mathematics preservice teachers. In order to measure the development of TPACK, both quantitative and qualitative data were collected. Preliminary findings are promising. Preservice teachers developed a vision of technology use in the classroom that better aligned with the vision outlined in the NCTM Technology Principle. Students reported they had sufficient opportunities to work with different technologies throughout the course. Moreover, students reported they could choose technologies that enhance the mathematics for a lesson.

Keywords: Teacher Education–Preservice; Technology; Problem Solving

Introduction

In seminal works (Niess, 2005, 2008; Mishra & Koehler, 2006) that have culminated in the description of a framework by which to study the development of Technology, Pedagogy And Content Knowledge (TPACK), mathematics teacher educators have envisioned teacher education programs that integrate technology instruction with content and pedagogy. These programs would provide preservice teachers with learning opportunities that might help them amend personal philosophies of teaching to reflect a deep understanding of teaching with technology. A picture of how to accomplish this integration is emerging in the field, including Zbiek and Hollebrands' (2008) position that the ways in which technology is integrated into teachers' classrooms is influenced by their conceptions of technology, mathematics, learning and teaching. Furthermore, Zbiek and Hollebrands (2008) recommend that preservice teachers be given opportunities to use technology as a mathematics learner and then reflect on those experiences from a pedagogical perspective.

We have begun to develop our own vision of what it means to enact these principles in the development of preservice secondary mathematics teachers (PSMTs) and to honor the rich connections between technology, mathematics, and teaching. This paper reports on a study of 39 PSMTs enrolled in two sections of a course, *Mathematical Problem Solving with Technology*. In this course, PSMTs are expected to revisit their own learning of secondary mathematics and investigate mathematical concepts by way of problem solving with various technological tools. Taught with an eye toward immersion learning, the PMSTs in our course are engaged almost entirely in lab-based activities and discussion of the mathematical, pedagogical and technological principles they encounter along the way.

Methodology

As a means to inform our own practice, we engaged in research to uncover the extent to which our course was supporting the development of TPACK in our preservice teachers. We set about to explore two research questions: (1) What is the vision of teaching mathematics with technology held by PSMTs prior to and at the conclusion of a semester of concentrated experiences utilizing technology for mathematical problem solving? (2) To what extent does our course influence TPACK of our PSMTs?

Participants and Setting

The participants of this study were enrolled in a semester-long course, *Mathematical Problem Solving with Technology*, during the 2010-11 academic year. PSMTs pursuing licensure to teach secondary mathematics typically take this course during their sophomore year. As our PSMTs enroll in the majority of their education courses in the junior year, those enrolled in this course have not yet taken any methods courses or completed any field placements in a K–12 setting. Of the 39 participants, three had graduate student standing but had not taught secondary mathematics at the beginning this course. During the fall semester, 18 participants were recruited and during the spring semester, 21 students were recruited.

Data Collection

Data were collected with the purpose of measuring the development of TPACK as well as linking that development to practice. In order to accomplish this goal, two distinct perspectives were taken. First, we wanted a quantitative tool by which to capture growth in TPACK over time. We selected a survey intended to measure TPACK (Zelkowski et al, under review) and administered it as a pre/post measure during the first and last weeks of the course. The survey is divided into multiple sections with items assessing each of the domains within the TPACK framework, but we chose to focus our analysis on six items shown to be reliable and valid in measuring perceptions of TPACK (Zelkowski et al, under review).

Table 1: Summary of Selected TPACK Survey Items

Item	Prompt
Item 1	I can use strategies that combine mathematics, technologies, and teaching approaches that I learned about in my coursework in my classroom.
Item 2	I can choose technologies that enhance the mathematics for a lesson.
Item 3	I can select technologies to use in my classroom that enhance what I teach, how I teach, and what students learn.
Item 4	I can teach lessons that appropriately combine mathematics, technologies, and teaching approaches.
Item 5	I can teach lessons that appropriately combine algebra, technologies, and teaching approaches.
Item 6	I can teach lessons that appropriately combine geometry, technologies, and teaching approaches.

It was also important for us to take a deeper look at individual development throughout the course in order to index any global shifts in TPACK to specific facets of the course. In order to examine the opportunities we were providing our students to develop TPACK and to more closely examine any shifts in TPACK that were captured by the survey, samples of student reflective writing were collected of which two samples were used in the current analysis.

Principles of Mathematical Problem Solving with Technology. Within the first month of the course, students were asked to read three items and write a reflection paper. The three items were selected to convey to our students the underlying principles of the course. First, we selected the NCTM Technology Principle (NCTM, 2000). Second, we selected two chapters from *Teaching Mathematics through Problem Solving K–12* (Schoen & Charles, 2003). The chapter written by Hiebert and Wearne (2003) was selected for its overview of problem solving and the vision it provided of teaching and learning. The chapter written by Zbiek (2003) was selected for its attention to the role of technology in a classroom where problem solving is valued. Students were asked to respond to three prompts:

1. *How is the perspective taken in the readings similar or different from your own experiences learning mathematics?*
2. *How does it compare to your own beliefs about teaching?*
3. *What ideas did you find yourself (dis)agreeing with?*

Final Examination. A final examination prompt was provided asking students to describe their vision of responsible use of technology in the classroom.

> *Many of you have reflected on the use of technology in mathematics education and used a statement similar to, "technology is a benefit to the mathematics classroom as long as it is used responsibly." Reflect on this statement and explain to me what "responsible use of technology" looks like in the mathematics classroom. Do not define it in terms of what it is NOT—I am not interested in hearing about examples of irresponsible uses of technology and these will detract from your answer. Instead, use your experiences and any readings you have completed for this class to craft a reasonable*

definition or standard by which I could determine if technology were being used to support teaching and learning of mathematics in your classroom.

This prompt was devised in response to themes identified in classroom discussions throughout the semester. It is not uncommon for PSMTs to begin to categorize their experiences, both past and current, as appropriate/inappropriate. In both semesters, PSMTs invoked the phrase “responsible use” to differentiate between technology practices that they endorsed (“responsible”) and those they did not (“irresponsible”). This prompt was aimed at assessing PSMTs’ outgoing vision of “responsible use.”

Data Analysis

Analysis of written reflection. The two reflections described in the previous section were chosen because of their timing, one in the fifth week of the semester and the other at the completion of the course. Furthermore, the nature of the assignments has the potential to illustrate changes in our PSMTs’ visions of teaching mathematics with technology.

Both top-down methods (Miles & Huberman, 1994) and grounded theory (Strauss & Corbin, 1990) were used to develop and apply a coding instrument. Within NCTM’s Technology Principle (2000) and also Zbiek (2003), there are many smaller statements about the envisioned role of technology in the mathematics classroom. From these sources, we created a framework by which to analyze the vision our PSMTs held of teaching mathematics with technology. From each statement indicating a potential role for technology, a code was developed. For example, the statement “With calculators and computers students can examine more examples or representational forms” (NCTM, 2000, p. 23) yielded two initial codes, “Examples” and “Representational Forms.” While Doerr and Zangor (2000) classified calculator use into five broad categories: Computational, Transformational (changing the nature of the task), Data Collection and Analysis, Visualizing, and Checking (confirming conjectures, understanding multiple symbolic forms), we initially identified 25 specific roles technology plays in the classroom. We later refined this list to 17 as coding progressed, including combining “Representational Forms” with “Visualization,” as it was difficult to parse out differences such as this in our PSMTs’ writing. The final list of codes is listed in alphabetical order in Table 2.

Table 2: Framework for Examining *Vision of Technology for Teaching*

Perceived Roles of Technology in the Mathematics Classroom		
Assessment	Exploring Conjectures	Problem posing
Communication	Extends Range of Problems	Problem Solving/Reasoning
Differentiated Learning	Mathematical Change	Reflection
Efficiency/Accuracy	Mathematical Connections	Supplementation
Engagement	Organize/Analyze Data	Visualization/Representational Forms
Examples	Present/document	

TPACK surveys. Pre- and post-survey data were collected and analyzed to determine overall shifts in perceived TPACK amongst PSMTs taking a semester-long course in problem solving with technology. In order to compare the results of the administrations of the TPACK survey, individual scores were tabulated by summing the responses given by an individual to each of the six items in terms of the 5-point Likert scale values (1 = Strongly Disagree, 5 = Strongly Agree). Quartile scores for each administration were calculated and compared using a box-and-whisker plot. In order to delve deeper and assess growth with individual items, a novel data visualization was constructed utilizing color as a means to assess the extremity of individual responses as well as the overall change in PSMT responses between administrations. A detailed description of this data visualization is provided along with the results of the analysis.

Results

In response to the research questions outlined above, the results will be organized in three distinct sections. First, we will present the results of the qualitative analysis of the two collected samples of reflective writing. Then, we will present the results of a quantitative analysis of the TPACK survey data.

Incoming Vision of Teaching with Technology

Utilizing the framework in Table 2, we coded each of PSMT's reflections on the role of technology in the teaching and learning of mathematics. While we could recognize at least one of the roles in most of the reflection papers, there were two reflection papers that received zero codes. These two PSMTs did not share a vision with regard to the inclusion of technology in the classroom. One stayed close to a positive, yet non-specific message, that technology should be used to enrich the students' experience, while the other challenged the essentiality of technology in the classroom altogether, stating:

> *Why is it so essential, as described in the Technology Principle, that technology be used in the application and problem solving of math (NCTM, 2000)? My thought is that shouldn't anything in math class be able to be solved without the aid of technology?*

In the remaining 37 reflections, we were able to recognize anywhere between one and nine of the roles (and on average 3.35), whether the PSMT agreed, disagreed or simply summarized the author's position. The most-agreed-with roles include Supplementation (49%), Efficiency/Accuracy (36%), Problem Solving/Reasoning (28%), and Visualization and Representational Forms (41%) (see Figure 1 [red columns]). Of the 17 roles, some seemed to garner more argument than others. Engagement (33%), Visualization/Representations Forms (41%), and Mathematical Change (13%) were mentioned more than most of the other roles both positively and negatively. While 33% of our students agreed that technology engages students, 10% disagreed, claiming technology was a distraction. Walter calls some of the statements made in the Technology Principle "too sweeping" and explains,

> *I submit that if a student is not motivated by the task at hand, then a computer provides many more distractions for them. This is not to suggest that one should not use a computer, only that I disagree with the implication that utilizing a computer task is a cure for those that are easily distracted.*

While this provides a snapshot of the specified vision our PSMTs had at the start of the semester, there was also an undercurrent of concern about the use of technology in the classroom in general. The most common concern was that technology would prevent students from achieving mastery of mathematics. More than 25% of our students specifically mentioned their concern that students will either miss out on learning basic skills (generally arithmetic) or that this knowledge initially gained will atrophy once technology is in hand. Even more expressed concern that technology would replace a student's basic understandings of mathematics, with 49% choosing to quote, paraphrase or reinterpret the statement, "technology should not be used as a replacement for basic understandings and intuitions; rather it should be used to foster the understanding and intuitions," (NCTM, 2000, p. 24). This was, by far, the most cited passage in all three readings. In addition to these concerns, some PSMTs expressed a sense of nostalgia and favored tradition over technology. Mary says, *"I got through all of those high school courses with just a graphing calculator and passed with flying colors, so why do we need all this technology in our classrooms now?"* This narrow view of education based on personal success or failure permeates the initial reflection papers and causes many to question NCTM's assessment of technology as *essential* in the classroom. A student who feels that they have achieved success in school mathematics potentially sees himself or herself as a counterexample to the essentiality of technology. There is a general reluctance to consider what experiences they may have missed and to judge their own stories as complete and representative of mainstream.

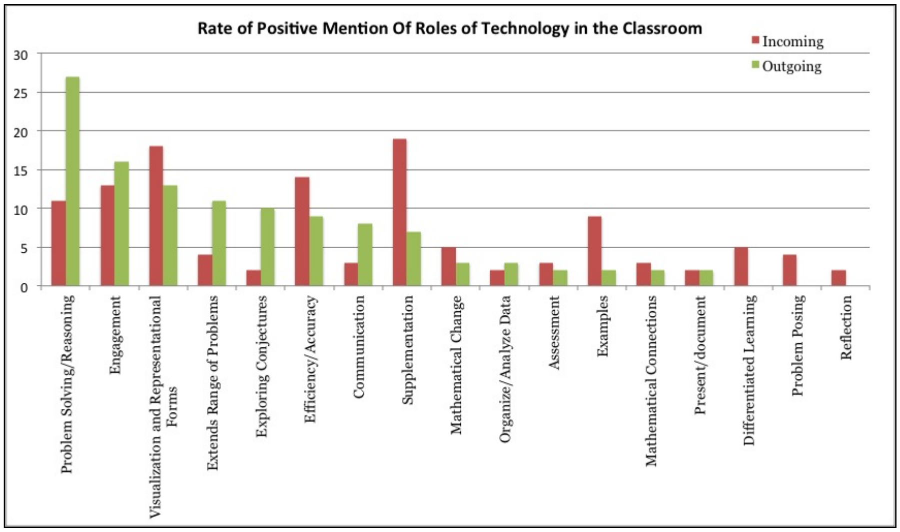

Figure 1: Incoming vision (red) and outgoing vision (green) of teaching with technology

Outgoing Vision of Teaching with Technology

In order to gauge the vision of teaching with technology that our PSMTs had when they exited our course, we conducted a similar analysis of their responses to the Final Examination Prompt. In this assignment, our PSMTs were explicitly asked to share their vision of "responsible use of technology in the classroom." In this sense, the assignment was different from the first reflection in that the PSMTs were not asked for their reactions to an expressed vision, but rather to create their own.

Unlike their initial reflections, every PSMT identified at least one specific role that technology plays in the mathematics classroom. On average, students identified three roles with the maximum being eight. Figure 1 (green columns) is a depiction of the overall vision. Again, if we take a look at the most identified roles, we get an indication of the vision of the group. Almost 70% of our PSMTs made mention of the role technology plays in problem solving and reasoning in the classroom. Engagement, Visualization and Representational Forms, Efficiency/ Accuracy and Supplementation are still among the most cited. However almost three times as many PSMTs as did initially indicated technology extends the range of problems that can be used in the classroom and aided in Communication, and five times as many noted technology could be used to Explore Conjectures. The number of students who indicated technology should be used to supplement pencil-and-paper instruction dropped by a factor of three.

TPACK Survey Data

In order to compare the results of the administrations of the TPACK survey, individual scores were tabulated by summing the responses given by an individual to each of the six items in terms of the 5-point Likert scale values (1 = Strongly Disagree, 5 = Strongly Agree).

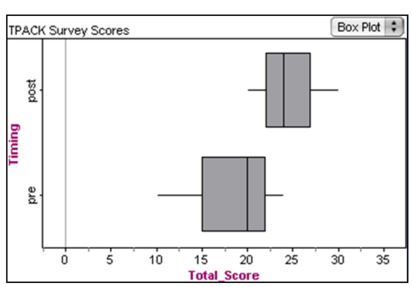

Figure 2: Box plot with whiskers comparing TPACK scores for two administrations

These ordinal data are displayed in a box and whiskers plot in Figure 2. The median score increased from 20 on the pre-survey to a 24 on the post-survey. Furthermore, the first quartile of the post-survey and third quartile of the pre-survey are equal, implying that 75% of the post-survey scores were higher than 75% of the pre-survey scores.

To get a deeper sense of these shifts, we composed a color-coordinated image of the data set. The individual responses to each item given on the pre- and post-survey are shown in Table 3. Each row pertains to an individual PSMT and the rows have been sorted in decreasing value according to the sum of the Pre-test scores. The left table contains data collected by the pre-survey. The middle table contains data collected by the post-survey, and the right table contains calculated differences indicating shifts in responses. These were calculated by subtracting pre-survey responses from post-survey responses. Due to page limitations, we have provided only a portion of the table to give the reader a sense of the trends in the data.

Table 3: Color-Coded TPACK Survey Where Individual Responses Have Been Highlighted

Student	Item 1	Item 2	Item 3	Item 4	Item 5	Item 6	Total (Pre)

In each table, color has been used to visually differentiate the responses with the more saturated colors indicating more extreme views. In the first two tables, green (responses 4 & 5) indicates that the student has agreed with the prompt and red (responses 1 & 2) indicates that the student has disagreed with the prompt. White (response 3) would indicate a Neutral response. In the final table, green (positive integers) indicates a positive shift while red (negative integers) indicates a negative shift.

Interpreting the tables means looking at how the color patterns change. If we compare the pre-survey and post-survey scores from all 29 participants, we find dramatic color shifts. The cloud of red at the bottom of the pre-survey data disappears in the post-survey data and is replaced by light green and even some dark green cells. At the top of the tables, we see a dark green cloud emerge in the post-survey data replacing the light green and white that was present in the pre-survey data. Red and pink have virtually disappeared from the post-survey data, demonstrating that PSMTs disagreed with very few prompts after the course had completed.

This is also reflected in the overall color tone of the difference table, which is almost entirely composed of white and shades of green. Very few items showed a negative shift from pre-survey to post-survey, and these are indicated by the pink cells.

Findings and Implications

This study seeks to further the research in the field of TPACK by testing the hypothesis set forward by Zbiek and Hollebrands (2008) that a key experience for PSMT should be to use technology as a mathematics learner and then reflect on those experiences from a pedagogical perspective. Our results show that a course in Problem Solving with Technology that provides opportunities for PSMTs to reengage with school mathematics using a problem-based curriculum in a technology-rich environment has a positive impact on PSMT TPACK development as well as on PSMTs vision of teaching with technology. This vision was communicated in part by examining specific experiences and readings encountered during the course and presenting them as illustrating examples of what the 'responsible use' of technology looks like in the classroom. We find that we can draw two conclusions.

Finding 1: Our students developed a vision of technology use in the classroom that better aligned with the vision outlined in the NCTM Technology Principle. If we take a closer look at the nature of the roles that we were able to identify in the incoming visions of PSMTs, Supplementation (49%), Efficiency/Accuracy (36%), and Examples (23%) are roles that suggest our PSMTs are envisioning technology as "computational" tools rather than "transformational" or "visualizing" tools (Doerr & Zangor, 2000). In contrast, we find the roles of Visualization and Representational Forms (41%) as well as Problem Solving/Reasoning (28%). This may be due to the brief exposure our PSMTs had to problem solving using dynamic geometry software in the five weeks prior to the submission of this reflection. It was clear that many were enamored with the ability to generate dynamic geometric objects for study and had begun to envision their personal independence in mathematical problem solving. It is likely that even this brief exposure had an impact on the PSMTs' vision. It is unclear whether that vision was truly aligned with that of NCTM, but many referenced these roles positively. Whereas their initial vision favored using technology to "do mathematics", the outgoing vision seems to favor technology for learning mathematics. PSMTs more readily identified roles that were "transformational" or "visualizing" (Doerr & Zangor, 2000). Furthermore, PSMTs readily accepted the role technology plays in generating and sustatining classroom discussion of mathematics and collaborative work habits, something that was missing from their initial vision.

Finding 2: A course in problem solving with technology can have an impact on the TPACK development of PSMTs. The results of our analysis of pre- and post-survey data show a clear increase in the TPACK of our PSMTs. The items that saw the greatest gains were, "*I can choose technologies that enhance the mathematics for a lesson," "I can select technologies to use in my classroom that enhance what I teach, how I teach, and what students learn,"* and, *"I can teach lessons that appropriately combine geometry, technologies, and teaching approaches."* Comments made in their final exam reflections would support this finding as well. It is clear that PSMTs are thinking more about what it would take to enact their vision of teaching with technology and the complexity of that practice.

Conclusion

Many factors affect the development of PSMTs' use of appropriate technology tools. Olive and Leatham (2000) have documented that using technology as a tool for learning mathematics is not enough to ensure PSMTs will use technology as a teaching and learning tool in their own classrooms. Many PSMTs need sustained interactions with technology throughout their teacher education programs, especially in the context of content and pedagogy courses, combined with positive experiences that would challenge their deeply rooted beliefs. However, unless students are given opportunities to reflect on their beliefs and come face-to-face with them, it will be difficult for them to relinquish their fears and mistrust (Fleener, 1995).

YOUNG CHILDREN'S UNDERSTANDING OF ANGLE IN A DYNAMIC GEOMETRY ENVIRONMENT

Harpreet Kaur

Nathalie Sinclair
Simon Fraser University
nathsinc@sfu.ca

This paper examines the effect of the use of dynamic geometry environments on children's thinking about angle. Using a driving angle model in Sketchpad, kindergarten children were able to develop an understanding of angle as "turn," that is, of angle as describing an amount of turn. Gestures and motion played an important role in their developing conceptions.

Keywords: Geometry and Geometrical and Spatial Thinking; Elementary School Education; Angle; Gestures

Introduction

The concept of angle is multifaceted and can pose challenges to learners, even into secondary school (Close, 1982, Mitchelmore & White, 1995). Despite these difficulties, children show sensitivity to the concept of angle from very early years (Spelke, Gilmore, & McCarthy, 2011). Angles are normally introduced to children quite late in formal school settings. For example, in British Columbia, they are introduced in grade 6 (12 years old), even though students are expected to describe, compare, and construct 2-D shapes, including triangles, squares, rectangles and circles in grade 2. The strong capacity of young children to attend to and identify angles in various physical contexts motivated us to see whether a more dynamic conception of angle—namely, angle-as-turn—might support their developing understanding at an earlier age.

We have been investigating other geometry-related concepts at this age too, using DGEs, including shape identification, symmetry and parallel lines (Sinclair, Moss, & Jones, 2010; Sinclair & Kaur, 2011). Previous research reports on the effectiveness of Turtle Geometry (Logo) for teaching the concept of angle (Clements, Battista, Sarama, & Swaminathan, 1996; Simmons & Cope, 1990). However, we believe that DGE might be helpful in thinking of angles as turns and rotation more effectively. In this paper, we report on an exploratory study conducted with a split class of kindergarten/grade 1 children (ages 5—6) working with angle using *The Geometer's Sketchpad*. We focus on the emergence of the concept of angle-as-turn and discuss the specific mediating role of the use of the software on this thinking.

Children's Understanding of Angle

In the research literature, the concept of angle is shown to have different perspectives, namely: angle as a geometric shape, union of two rays with a common end point (static); angle as movement; angle as rotation (dynamic); angle as measure; and, amount of turning (Close, 1982; Henderson & Taimina, 2005). Due to different prevalent definitions of the term angle, teachers often face difficulty in knowing what definition of angle to use (Close, 1982). Mitchelmore (and colleagues) and Clements (and colleagues) have done abundant research in the area of angle concept over the past twenty years. Much research has been conducted on the development of the concept of angles, focusing at the grades 3, 4 and higher levels. Mitchelmore and White (1995) suggest that angles occur in a wide variety of physical situations that are not easily correlated. Despite the excellent knowledge of all situations, specific features of each situation strongly hinder recognition of the common features required for defining the angle concept (Mitchelmore, 1998). Mitchelmore and White (1995) proposed that children initially acquire a body of disconnected angle knowledge situated in a large number of everyday experiences; they then group situations to form angle contexts such as turns and corners; and finally they form an abstract angle concept by recognizing similarities across several angle contexts.

Later works of Mitchelmore involved teaching experiments (White & Mitchelmore, 2003) in which they divided angle situations into three clusters—2 line angles (corners of room, intersecting roads, pairs of scissors), 1-line angles (doors, windshield wipers), and 0-line angles (the turning of a doorknob or a wheel). The situation is more problematic for students where the two arms (of angle) are not clearly visible. Research using *Logo* shows that students tend to visualize the turn of turtle as turn of their body but making these turns involves writing numerical commands (Clements, Battista, Sarama, & Swaminathan, 1996). The DGE does not involve the writing of the commands and can thus be used at an earlier age to develop more qualitative understanding of angle. We believed that the DGE approach would be helpful in developing the dynamic as well as static concept of angle.

Theoretical Perspective

In previous research, we have found Sfard's (2008) "commognition" approach is suitable for analysing the geometric learning of students interacting with DGEs (see Sinclair, Moss, & Jones, 2010; Sinclair & Kaur, 2011). For Sfard, thinking is a type of discursive activity. Sfard's approach is based on a participationist vision of learning, in which learning mathematics involves initiation into the well-defined discourse of the mathematical community. The mathematical discourse has four characteristic features: word use (vocabulary), visual mediators (the visual means with which the communication is mediated), routines (the *meta-discursive rules* that navigate the flow of communication) and narratives (any text that can be accepted as true such as axioms, definitions and theorems in mathematics). Learning geometry can thus be defined as the process through which a learner changes her ways of communicating through these four characteristic features. We have previously presented a developmental trajectory related to identifying shapes in terms of different levels of discourse and now we are trying to do the same thing with angles, but we will look first at how the different components of the discourse change as the students work within the DGE. We are particularly interested in investigating how the students might move between different word uses and to examine the informal language they use to talk about angles.

Similarly, given the importance of gestures in communication of abstract ideas (Cook & Goldin-Meadow, 2006), and their potential to communicate temporal conceptions of mathematics (Núñez, 2003; Sinclair & Gol Tabaghi, 2010), we chose to extend Sfard's approach to incorporate gestural forms of visual mediators. Given the fact that we are working with very young children who have had little exposure to a mathematical discourse around angle, we will be interested in seeing whether they make use of kind of "mismatch" gestures that Goldin-Meadow (2004) describes as indicating a readiness-to-learn. Kita (2000) focuses on the cognitive functions of gestures, which play an important role in communication. He points out that the production of a gesture helps speakers organize rich spatio-motoric information, where spatio-motoric thinking organizes information differently than analytic thinking (which is used for speech). We thus expect that children will use gestures to convey spatio-motoric information, even though they might not be able to convey the analytic thinking used in speech. Moreover, children's gesture might be non-redundant with their speech. Our goal in looking at the gestures will be to see how they communicate different ideas about angles; particularly the mobile ones associate with angle-as-turn. We are less interested in classifying the students' gestures in terms of McNeill's (1992) categories than in understanding the embodied, conceptual basis of the gestures.

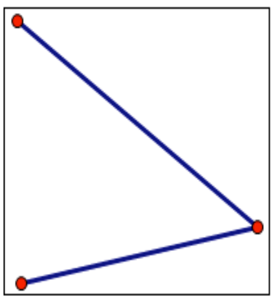
Exploring the Concept of Angle

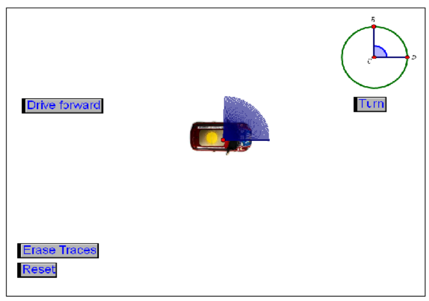
Participants and Tasks

We worked with kindergarten/grade1 children (aged 5—6) from a school in a rural low SES town in the northern part of British Columbia. There are 20 children with diverse ethnic backgrounds and with a wide range of academic abilities. We designed lessons related to angle along with the classroom teacher, who has a Master's degree in mathematics education and has been developing her practice of using DGEs for a couple of years. The teacher and students worked with angles in different ways using Sketchpad for six lessons in a whole class setting with an IWB (Interactive Whiteboard). Each lesson lasted approximately 30 minutes and was conducted in a group with the children seated on a carpet in front of a screen. Lessons were videotaped and transcribed.

Dynamic Angle Sketches

In this study, we used two different sketches to explore the concept of angle with the children. We began with a simple angle diagram (Fig.1). In the sketch, dragging the vertex of an arm of the angle changes the angle. The purpose of using this sketch was to enable children to focus on the standard form of angle as a geometric shape and to build an understanding of angle through its behavioural properties. The research suggests that children have difficulty seeing a static angle as a turn. The situation is more problematic when the two arms of the angle are not clearly visible. The second sketch used is a "driving angle model," which shows both a static as well as dynamic sense of angle (Fig.2a, 2b). It includes a car that can move forward as well as turn around a point. The turning is controlled by a little dial (which has two arms and a centre). No numbers are used. There are four action buttons (Turn, Drive Forward, Erase Traces and Reset) that control the movement of the car. Students can regulate motion and turns to create different shapes like random paths, squares, rectangles, and so on.





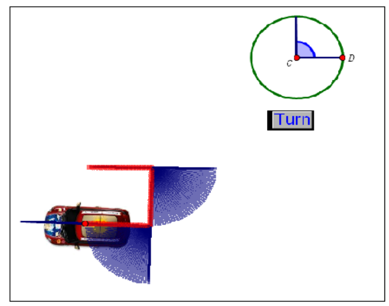


Figure 1: Angle as a Shape **Figures 2a and 2b: Driving Angle Model**

The traces offer a visible, geometric record of the amount of turn. The purpose of this sketch was to move to a more dynamic presentation of angle related to a real life context, where the focus of the children would be more on the continuous behaviour of the turning wheels and would enable them to see the process of turning along with the final product (position after a specific angle turn).

Classroom Discussion

The classroom teacher tried to support the discourse of angle-as-turn as she worked with the sketches. In what follows, we report on the children's work with the first sketch and then their developing sense of angle as they worked with the second one.

Introducing the angle as a geometric shape. The teacher began by showing the children the sketch in Figure 1 and asking them what they saw. Initially, the students attended to the features of the figure like points, circle etc. One student uttered the word "angle," although, when prompted, didn't elaborate. Two students, Colin and Jasmine, compared the sketch with triangle. Kristian was the first to impose motion on the diagram:

Teacher: Kristian, what do you see? (*Pointing towards figure1 on the screen*)
Kristian: I see the point is going back and that point is going up…*Inaudible*…

Kristian focussed here on the two arms of the angle, not mentioning explicitly the point at which they meet. The teacher asked about other similar examples and the children described what they saw in terms of concrete objects like a swing, slide, the letter "w," a house, the bottom of a hill, and a nose in their responses. Thus, initially their discourse was dominated by everyday language and they made little or no use of mathematical words—and their comparisons involved very loose visual resemblance. Following initial discussion, the teacher dragged the vertex of one arm of the angle.

Teacher: What happens if I do this? (*dragging one vertex of one arm of the angle*)
Will: It turns wider

Van Zoest, L. R., Lo, J.-J., & Kratky, J. L. (Eds.). (2012). *Proceedings of the 34th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Kalamazoo, MI: Western Michigan University.

Teacher: It does turn wider. What about if I do this? (*dragging the vertex further*)
Morris: It widens even more now.
Teacher: It widens even more. What am I doing if I am moving this line? What kind of movement is that?
Jasmine, Will, Kristian: Square, it's a clock
Teacher: It's a clock movement?
Students: Yeah
Teacher: What am I doing to the line?
Students: Moving, clock.

When the teacher drags the vertex of one arm of the angle to make it wider, Will and Morris describe the change in terms of widening; Will also uses the word "turn" to describe the motion. Several students describe the movement of the arm of the angle as the movement of the clock. This is the first instantiation of angle-as-turn, which the students associated with a clock. Note that they do not explicitly use the word "angle," but they talk about the same diagram they saw before, now using an entirely new comparison, which becomes shared widely. The teacher finishes the lesson by talking about the space between the two arms and showing them how to mark an angle between two arms in *Sketchpad*, which can be done using the Marker tool.

Introducing driving angle model. In the subsequent lesson, the teacher presented the driving angle model to the students and asked them what they saw. Initially children focused more on features like color of lines, circle and points. The teacher prompted them to find the similarity between the two sketches (Figures 1 and 2a). Most of the students focused on describing the absence of the car in first sketch (Fig.1) and the presence of the circle in the second sketch (Fig. 2a). During comparison, only the second sketch was displayed on the IWB.

Will: And there is a blue one on this one
Teacher: There is a blue one on this one. That's the same?
Will: Yeah, Surrounded by a circle (*draws circle in the air to show the surroundedness. Repeats gestures a few times*)

Will recalled the angle diagram of first sketch and noticed its presence in both the sketches, but his description "blue one on this one" showed a dominance of everyday language. Despite the use of word "angle" by the teacher (while marking the angles) at the end of previous lesson, none of the students used the word in their comparison of the two sketches. During the classroom discussion, the children asserted that in order to drive the car, the wheels should be turned.

Teacher: Okay, I have another question for you guys. What does the car do?
Will: It drives on the ground. (*gesturing with both arms, turning both his arms together from left to right*)
Teacher: It does drive on the ground. So we're going to pretend our screen is the ground. How is it going to drive on the ground? What ways can it drive? Jasmine?
Jasmine: You have to turn the wheel. (*With both arms turning as if turning a steering wheel*)

Will and Jasmine both used gestures to describe the turning of the car. Many children in the class imitated their gestures. Jasmine used the gesture of turning the steering wheel as a visual mediator while associating the motion of car with the turning of wheels. The teacher then pressed the Turn button and the car turned by the same amount indicated by the angle dial, also leaving a trace of the turn behind.

Teacher: Okay…I am going to move something for you, here. Okay… If I tell you that this is kind of like the car's steering wheel, what do you think that car is going to turn like now? What do you think is going to happen? Think about it. (*Making the turning angle smaller in the size*), What is it going to do now?
Students: Turn, turn
Teacher: Turn…is it going to turn the same?

Students: Yeah.

The teacher told the students that the angle dial was like the car's steering wheel and she changed the size of the angle in the dial. Then she prompted the students to predict the outcome on pressing the Turn button; several students predicted that car would turn although they could not predict the amount of turn. This shows that students did not associate the turn of the car with the angle in the dial: they had no routine for assessing the magnitude of the turn. The teacher invited the children to compare the size of the angular turns. She changed the size of the angle and asked the children to decide whether this turn was smaller or larger than the previous amount of turn.

Teacher: The car is stopped…but if you look, that's like right here. The car is turned … turnn ... and stops here. And then I moved this steering wheel up here with the angle (Fig. 3a) and we press turn again and it only went from here to here (Fig.3b). Are these the same?

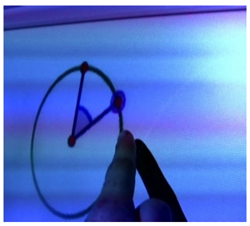

Figure 3a

Figure 3b

Figure 3c: Morris's gestures

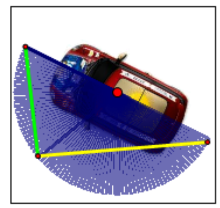

Figure 3d

Students: No, no, no…that one is too bigger (*pointing towards the screen*)
Teacher: Which one is bigger?
Morris: They don't match. There is no match. One is bigger (*Lying on the carpet, gesturing with his fingers as if he is comparing the sizes (Fig. 3c). And then shaking his head no*).

Morris compared the two different amounts of angle turns by comparing the size of the traces. Morris linked the difference in the size of two fingers (Fig. 3c and 3d) with the difference in two amounts of turn (sizes of traces). He used the gestures with two index fingers to explain his reasoning. These are new visual mediators that are used to express the idea of angle. They also point to a new routine for comparing "turn." His gesture here is non-redundant (see Kita, 2000) with his speech since he expresses meanings for angle/turn that are not evident in the speech. Indeed, the children use very few verbal expressions in these lessons. We note that the initial use of concrete visual mediators in first lesson was replaced by the use of embodied mediators in the form of gestures.

Understanding of benchmark angles. The teacher introduced some benchmark angles in the next lesson by using the first sketch with words like "right turn." She showed the 90° angle in the sketch (Fig.4a). The children compared the right angle with the side of a house and corner of a box. The teacher showed a whole movement of the one arms of angle from 0° to 180° by dragging the vertex of one arm (Fig. 4b).

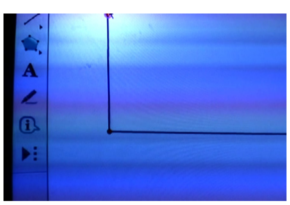

Figure 4a: Sketch showing 90^0

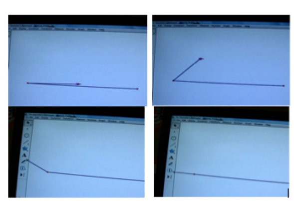

Figure 4b: Movement of one arm from 0^0 to 180^0

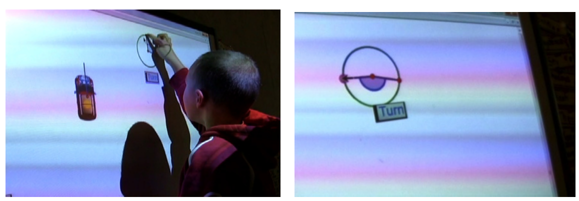
The children compared 180° to a line and a road. Morris made a gesture with his hand moving along a straight path, while describing a car moving along a straight road (Figure 5a)—thus picking up the context of the previous day's work. The teacher asked the students how they could make the car turn by 180^0.

Teacher: How can you make that car go that far…go in a straight line…Remember we did the 180 that was a straight line on the board. You said that it looked like a road. What can you do to the steering wheel?
Students: Press it
Teacher: No
Will: Move it
Teacher: How can you move it, Will? Show us. Could you show us that up there, Will? Give it a try. Can you show how to make it go 180? Show us how to go halfway around? (*Will comes on the board and try to move the vertex (point) on angle dial to adjust angle, but fails to move the point* (Fig.5b)). You have to hold it. Tell me when to stop? (*Will hold the vertex while dragging and adjusts angle to approx. 180^0* (Fig.5c))

None of the children, other than Will, were able to recognize that they needed to change the angle in the dial in order to make the car to turn by 180°. Will showed an understanding of the association of the turn of car with the angle in the dial. This shift in the Will's understanding might be the result of seeing the teacher repeatedly changing the angle in the dial during the lesson and of seeing her systematic dragging shown in Fig. 4b.

At the teachers' request, Jasmine made the car turn halfway by pressing the Turn button (Fig. 5d). When the teacher asked about the direction of the car after pressing the Turn button again, both Chloe and Jasmine predicted that the car would complete the full turn.



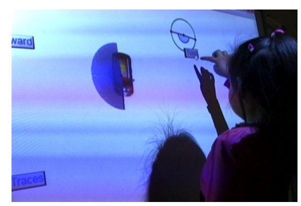


Figure 5a **Figure 5b & 5c: Will adjusting dial to 180^0** **Figure 5d**

Teacher: Why do you think it is going to go all the way around?
Chloe: Because when you press it, it will go…and stop
Teacher: Okay, can you think why it is going to do that?
Chloe: Because it goes that way and stops right there. (*Pointing towards the screen and reflecting, as if imagining the turn* (Fig. 6a))

Figure 6a: Chloe while responding **Figures 6b & 6c: Jasmine gesturing half and full turn**

From Chloe's explanation (including her gestures), it seems that she imagines the car turning and explains her reasoning in terms of the stopping point of the wheel.

Teacher: It is going to close. Why do you think it is going to close?
Jasmine: Because it is like this [*gestures shown in Fig. (6b, 6c)]*
Teacher: Yeah, because it is half way now…oh…that's interesting

While Chloe and Jasmine both visualised the final position of the car successfully, Chloe used words to describe the turn of the car, whereas Jasmine used the gestures to explain the reasoning in terms of half turning and full turning position. Both seemed to understand that two half turns result in a full turn. Once again, their understandings were communicated by the non-redundant gestures, in which arms are used as sides of angle, which provided new visual mediators for their reasoning.

Discussion and Conclusion

At the beginning of the episodes, the children had virtually no mathematical discourse around angle. By working on situations involving turn, which we thought would provide a strong embodied connection for the children, the goal of these lessons was to see whether students could develop a more sophisticated discourse around angle-as-turn—and not necessarily involving any numerical quantification of angle.

The dragging of the one arm of the angle focused the children's attention on the turning behavior of the segment in the diagram. This seemed to act as a visual mediator to which the children associated the movement of a clock. The clock movement metaphor enabled the children to see the angle diagram as turning of arms, and hence, initiated the discourse angle-as-turn. When the children were asked to work with the Drive model, they initially used informal ways to describe the turning of the car by gesturing the turning of a steering wheel. This steering wheel metaphor differs in important ways from the clock metaphor. While the latter focuses on the changing position of the arms (and thus on the changing "size" of the angle between the arms), the former focuses on the angle as a movement from one arm to another (and thus, on the "size" of a given angle).

Only one student was able to associate the turn of car with the angle dial explicitly. Will's recognition of the need to adjust of angle dial to 180^0, in order to move the car halfway, shows that the difficulty in visualizing the 0-arm angle—as reported by White and Mitchelmore (2003)—could be eased by the trace feature of *Sketchpad*, enabling students to see the process of turning as well as the product. Some children were successful in comparing two different amounts of turns. Also, some children were able to reason about half and full turns—in fact, they could explain that a full turn would require the repetition of two half turns. They could not talk about angle and turns using mathematical vocabulary.

At the beginning, the students described the angle diagram in terms of its parts, using concrete, everyday language; they eventually came to associate the notion of "angle" and "turn" to both a clock and a steering wheel—both of which capture something about the idea of angle-as-turn. Several students also used gestures to express the notion of angle, as can be seen in Figures 3 and 6. Finally, the students could also talk about angle in terms of various sizes (especially, the half angle). We argue that the gestures used by the students became part of their visual mediators for the concept of "angle." These gestures were at least in part evoked by the diagrams in *Sketchpad*. For example, the two index fingers shown in Figure 3 arise from the angle dial used by the teacher. The children's use of "turning" gestures in their responses to the car sketch shows that they created gestures as mediators for the purpose of communication. Also, Jasmine's gesture (Figure 6) relating half turn to full turn is a clear example of the effect to dynamic visualization offered by Sketchpad. The traces of half turn in *Sketchpad* acted as a visual mediator and then Jasmine used her gestures of half turn (straight opened arms) to make a full turn (covering the whole movement of arms to close hands) as a means of communication. This interplay between gesture and diagram resonates with Châtelet's (1993) theory of mathematical inventiveness, which de Freitas and Sinclair (2012) discuss in the context of mathematics education; in this case, the dynamism of the diagram seems to evoke quite directly the moving of the children's fingers and hands.

At this early stage, we have focused on word use and visual mediators. There was little sense of any routines used for identifying angles or evaluating their size. Further, given the emergent sense of angle and turn, there weren't any endorsed narratives. However, the frequent use of non-redundant gestures by Morris, Will, Chloe and Jasmine during the lessons indicates, as well as the relatively infrequent use of verbal expression, suggests that the children had a certain "readiness to learn" (Goldin-Meadow, 2004) about angle-as-turn. The next phase of our research, for which we are now in the process of gathering data, involves exploring the way in which the children's emergent sense of angle can be developed into routines for identifying angles and talking about their size. We have some initial evidence that the children are able to identify two angles as being the same even when their arms have different lengths because they use a routine of comparing turn. This would be a very important result given the existing research that shows that children often confuse the size of an angle with the length of its arms (Stavy & Tirosh, 2000).

Acknowledgments

We wish to thank Eileen Bennison for her participation in this project, both practically and conceptually. We'd also like to thank Shiva Gol Tabaghi for valuable comments on previous drafts.

In this paper we analyze and discuss students' performance in a CAS environment related to the simplification of rational expressions. Results indicate that if students have more initial paper-and-pencil techniques, the CAS environment spurs them to deeper theoretical reflections than for students who have fewer techniques.

Keywords: Task-Technique-Theory; CAS; Rational Expression

Background

In the last few years, an area of research interest in mathematics education has developed that deals with the influence of CAS technology in students' algebraic thinking. Thomas, Monaghan, and Pierce (2004), for example, have identified some crucial questions when considering the use of CAS in the learning of algebra: "How does the use of CAS influence student conceptualization? How does the way students work on tasks by hand inform their work in a CAS environment and vice versa?" (p. 166). These paramount questions and those arising from other recent studies (e.g., Kieran & Drijvers, 2006; Hitt & Kieran, 2009; Guzmán, Kieran, & Martínez, 2010, 2011) have driven our interest in this area. In particular, these studies and others have suggested the importance of the technical aspect in algebra learning in CAS environments.

Researchers such as Kieran and Drijvers (2006) have indicated that the use of CAS promotes conceptual understanding if the technical aspect of algebra is taken into account; these researchers have shown specifically that technical and theoretical aspects of algebra co-emerge in students' thinking. In this sense, and related with the simplification of rational expressions, Guzmán, Kieran, and Martínez (2010, 2011) have shown the epistemic role of the use of CAS when students confront their CAS work with their paper-and-pencil work. These studies are related to the transformational activity of algebra (Kieran, 2004)—a characterization of algebra in which the importance of technique acquires relevance in the sense that, within transformational activity, conceptual understanding can come with technique.

Guzmán, Kieran, and Martínez (2010, 2011) have shown that the use of CAS provoked spontaneous theoretical reflections in students, which allowed them to think of new techniques to simplify rational expressions. The use of CAS promoted a change in the students' technique for simplifying rational expressions whose denominator is a binomial (from canceling "literal components" that were repeated in both numerator and denominator to using the polynomial division algorithm). This epistemic role played by the CAS occurred in students whose initial technique was "cancelling literal components," but for whom the notion of cancelling "common factors" and dividing polynomials was absent. Based on our previous studies (Guzmán, Kieran, & Martínez, 2010, 2011), one can therefore ask the following question: What is the role of CAS in students' algebraic thinking if they already have as initial techniques "canceling literal components" and the "long division of polynomials" for simplifying rational algebraic expressions? Does CAS promote other techniques and theories? This paper will deal with this issue.

Theoretical Framework

The Task-Technique-Theory perspective, which is part of the instrumental approach to tool use, has been proposed as a framework for analyzing the processes of teaching and learning in a CAS context (e.g., Artigue, 2002; Lagrange, 2003). This approach encompasses elements from both cognitive ergonomics (Vérillon & Rabardel, 1995) and the anthropological theory of didactics (Chevallard, 1999). There are two directions within the instrumental approach: one in line with the cognitive ergonomics framework, and the other in line with the anthropological theory of didactics. In the former, the focus, according to Drijvers and Trouche (2008), is the development of mental schemes within the process of instrumental genesis. Within this direction, an essential point is the distinction between artifact and instrument.

In line with the anthropological direction, researchers such as Artigue (2002) and Lagrange (2003, 2005) focus on the techniques that students develop while using technology. According to Chevallard (1999), mathematical objects emerge in a system of practices (*praxeologies*) that are characterized by four components: *task*, in which the object is embedded (and expressed in terms of verbs); *technique*, used to solve the task; *technology*, the discourse that explains and justifies the technique; and *theory*, the discourse that provides the structural basis for the technology.

Artigue (2002) and her colleagues have reduced Chevallard's four components to three: *Task, Technique,* and *Theory*, where the term *Theory* combines Chevallard's *technology* and *theory* components. Within this (Task-Technique-Theory) theoretical framework a *technique* is a complex assembly of reasoning and routine work and has both pragmatic and epistemic values (Artigue, 2002). According to Lagrange (2003), technique is a way of doing a task and it plays a pragmatic role (in the sense of accomplishing the task) and an epistemic role. With regard to the epistemic value of technique, Lagrange (2003) has argued that technique plays an epistemic role in that it contributes to an understanding of the mathematical object [in this case the rational expression and its simplified form] that it handles, during its elaboration. Technique also promotes conceptual reflection when the technique is compared with other techniques and when discussed with regard to consistency (p. 271).

According to Lagrange (2005), the consistency and effectiveness of the technique are discussed in the theoretical level; mathematical concepts and properties and a specific language appear. This epistemic value of technique is crucial in studying students' conceptual reflections within a CAS environment. We took into account this Task-Technique-Theory (T-T-T) framework in the designing of the Activity related to the task "simplifying rational expressions," in the conducting of the interview interventions, and in the analysis of the data that were collected.

Unfolding of the Study

In this paper we report and discuss the data of the first two of four Activities designed for a wider research study on a Technical-Theoretical approach in the construction of algebraic knowledge in a CAS environment.

The Design of the Activity

Hitt and Kieran (2009) have pointed out that when taking into account the transformational activity of algebra it is important that the design of the Activity promote the articulation between techniques and theory construction. Since we adopted the T-T-T framework for carrying out the study, the Activities were designed so that technical and theoretical questions were central. We wanted students to have the opportunity to reflect on both technical and theoretical aspects throughout the Activity that was embedded in a CAS environment. It is important to mention here that both paper-and-pencil work and CAS work were intertwined within the Activity. In addition, in this study we use the term task as is defined in the T-T-T framework. As Kieran and Saldanha (2008) state, the Activity is a set of questions related to a central task, in this case the "simplification of rational expressions." In the study, we developed four Activities, each one related to different aspects of the simplification of rational expressions. In this paper we report only the results of the first two Activities, which both involved paper-and-pencil work and CAS work, both with technical and theoretical questions.

Population

This report focuses in the work of one team (two students); the full study included seven teams (two students each team). The participants were 10th grade students (15 years old) in a Mexican public school. The selection of the students was made by their mathematics teacher. None of the students were accustomed to using CAS calculators; consequently, at the outset of the study, all the students received some basic training from the interviewer-researcher on how to use the TI-Voyage 200 calculator for basic symbol manipulation (how to introduce algebraic expressions, the use of the *Solve*, *Expand* and *Factor* commands, the use of the *Enter key* and the use of the "*equal sign*").

Implementation of the Study

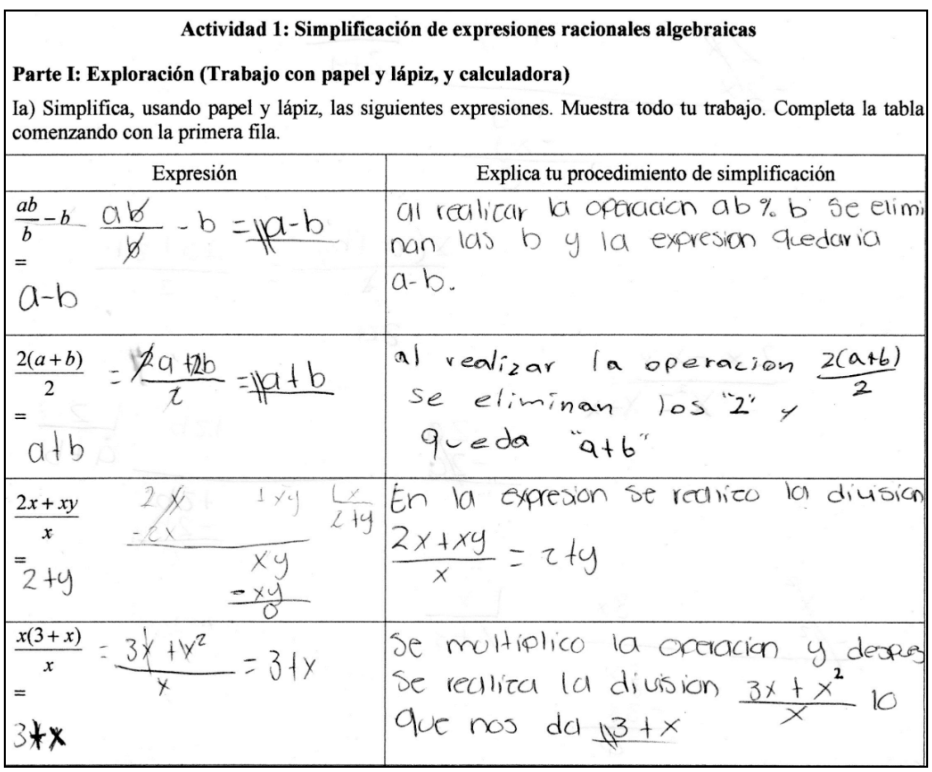
The data collection was carried out by means of interviews conducted by the researcher. Students worked in pairs; each work session lasted between two and three hours (for each Activity). Each team of two students had a set of printed Activity sheets as well as a TI-Voyage 200 calculator. Every interview was audio and video-recorded so as to register the students' performance during the sessions. So, our data sources included the audio and video recordings, the written Activity sheets, and the researcher's field notes.

Analysis and Discussion of Data

In this paper we analyse and discuss the work of one team. The team was chosen for this report because these students (we will call each of them Student A and Student B) used two techniques to carry out the task in the first Activity: Cancelling numbers or literal symbols that are repeated in the numerator and denominator of the rational expression, and at other times applying the long division technique. So the performance of these students fits the question that we try to respond to in this paper. The following analysis and discussion is restricted only to the first two of the designed Activities.

The Paper-and-Pencil Technique and Theory

As was mentioned before, in Activity 1, for those expressions that involved a monomial in the denominator, these students "simplified" the given rational expressions by using two techniques. One technique was cancelling the numbers or literals symbols that were repeated or common to the numerator and denominator. The following Figure 1 illustrates their paper-and-pencil work.



Actividad 1: Simplificación de expresiones racionales algebraicas

Parte I: Exploración (Trabajo con papel y lápiz, y calculadora)

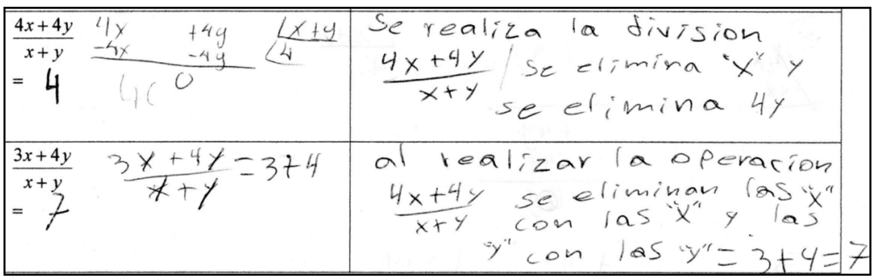
Ia) Simplifica, usando papel y lápiz, las siguientes expresiones. Muestra todo tu trabajo. Completa la tabla comenzando con la primera fila.

Expresión	Explica tu procedimiento de simplificación
$\frac{ab}{b}-b$ $\frac{a\cancel{b}}{\cancel{b}}-b = a-b$ = a-b	al realizar la operacion ab % b se eliminan las b y la expresion quedaria a-b.
$\frac{2(a+b)}{2}$ $=\frac{\cancel{2}a+2b}{2} = a+b$ = a+b	al realizar la operacion $\frac{2(a+b)}{2}$ se eliminan los "2" y queda "a+b"
$\frac{2x+xy}{x}$ = 2+y	En la expresion se realizo la division $\frac{2x+xy}{x} = 2+y$
$\frac{x(3+x)}{x}$ $=\frac{3x+x^2}{x} = 3+x$ = 3+x	Se multiplico la operacion y despues se realiza la division $\frac{3x+x^2}{x}$ lo que nos da 3+x

Figure 1: Students' paper-and-pencil work

In a first moment, the performance of these students was similar to that of others reported in an earlier pilot study in Guzmán, Kieran, and Martínez (2011). Students first expanded the expressions, and after that, they cancelled out the repeated elements in both the numerator and denominator. This technique works if the numerator is a binomial and the denominator is a monomial that is common to both terms of the binomial. The other paper-and-pencil technique that one can see in Figure 1 is the long division algorithm for polynomials. The explanations given by the students of these two techniques were more a description of what they did rather than a theoretical discourse. For instance, for the second expression (see Figure 1) they wrote: "When carrying out the operation… the 2's are cancelled and you are only left with *a*+*b*." For the third expression in Figure 1, their explanation included the terminology of *dividing*.

When the students were faced with expressions whose numerators and denominators were both binomials, they again used the techniques described above. Sometimes they used the long division technique and other times the "cancelling technique." As a result of using this latter technique applied to these kinds of expressions, they made well-known errors (Matz, 1980), that is, they applied the "cancelling technique" no matter whether the number or literal symbol they cancelled out was a common factor of both numerator and denominator or not (see Figure 2).

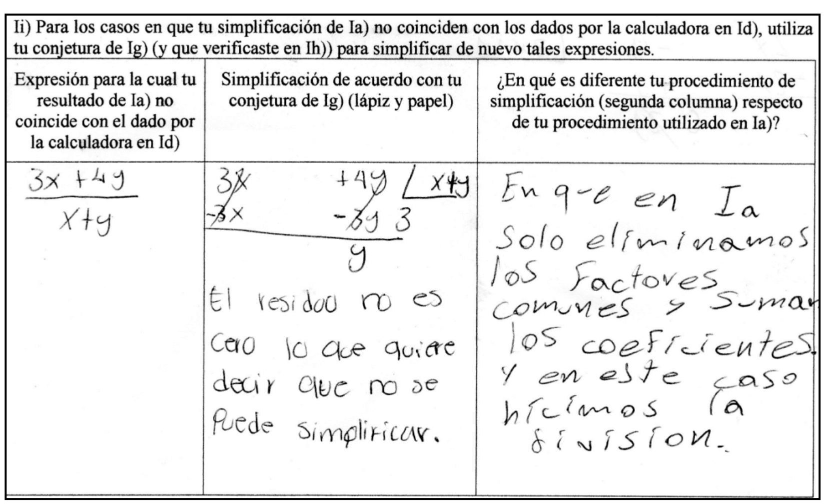


$\frac{4x+4y}{x+y}$ = 4	4x +4y ⌊x+y -4x -4y 4 0 0	Se realiza la division $\frac{4x+4y}{x+y}$ Se elimina "x" y se elimina 4y
$\frac{3x+4y}{x+y}$ = 7	$\frac{3\cancel{x}+4\cancel{y}}{\cancel{x}+\cancel{y}} = 3+4$	al realizar la operacion $\frac{4x+4y}{x+y}$ se eliminan las "x" con las "x" y las "y" con las "y" = 3+4=7

Figure 2: Students' paper-and-pencil work on binomial over binomial expressions

The CAS Work (a First Theoretical Reflection)

Once students confronted their paper-and-pencil results with the CAS results, a theoretical reflection based on their long polynomial division technique emerged. At this point we can see that using a technique is not just a routine work, just as Artigue (2002) has mentioned. The performance of these students fits the results obtained in a previous phase (the pilot study) of the research (see Guzmán, Kieran, & Martínez, 2011). In this main study, the same kind of theoretical reflection was provoked by the use of CAS (see Figure 3).



Ii) Para los casos en que tu simplificación de Ia) no coinciden con los dados por la calculadora en Id), utiliza tu conjetura de Ig) (y que verificaste en Ih)) para simplificar de nuevo tales expresiones.

Expresión para la cual tu resultado de Ia) no coincide con el dado por la calculadora en Id)	Simplificación de acuerdo con tu conjetura de Ig) (lápiz y papel)	¿En qué es diferente tu procedimiento de simplificación (segunda columna) respecto de tu procedimiento utilizado en Ia)?
$\frac{3x+4y}{x+y}$	3x +4y ⌊x+y -3x -3y 3 y El residuo no es cero lo que quiere decir que no se puede simplificar.	En que en Ia solo eliminamos los factores comunes y sumar los coeficientes y en este caso hicimos la division.

Figure 3: Students' reflection based on their CAS work

In this part of the Activity they wrote (see the second column of Figure 3): “the remainder is not zero; that means that the expression cannot be simplified.” As reported in Guzmán, Kieran, and Martínez (2011), we consider this kind of discourse to be a spontaneous theoretical reflection. In the third column of Figure 3, they included terminology of *common factors*. However, because of their previous work, we can say that they did not really understand this aspect (common factors); for them, all numbers or literals repeated in the numerator and denominator are *common factors*. In Activity 2, when these students had the opportunity to explore other cases, the use of CAS played an important role regarding the idea of *common factors* and making this idea more mathematically clear.

Second Theoretical Reflection Based on the CAS Technique

After the first theoretical reflection emerged, the students used their long division technique in order to explain the CAS results each time they found discrepancies between their paper-and-pencil work and their CAS work. Figure 4 illustrates this.

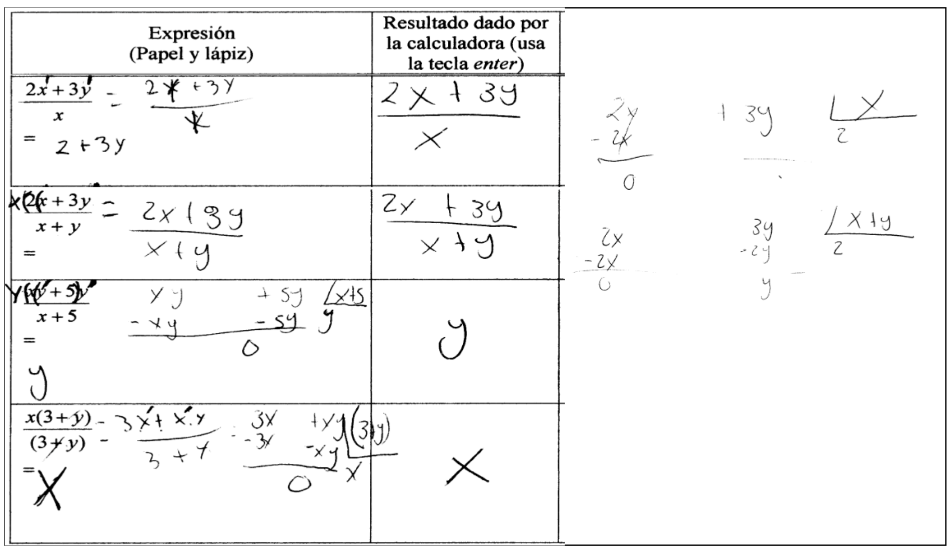


Figure 4: Use of long division technique in order to explain some CAS results

After the students had used CAS, their explanations (based on their theory of the remainder of the long division of polynomials algorithm) for simplifying expressions whose denominator is a monomial went a little bit further; in their discourse they included the words numerator and denominator. In the third column of Figure 5, they wrote: “before, we just eliminated the like terms from N/D [numerator over denominator] and now we know that if the numerator doesn’t have like terms then the expression cannot be simplified.” Compared to their written discourse shown in Figure 3, they had now begun to talk explicitly about the numerator and denominator and to speak about “like terms” instead of their very loose, and poorly understood, formulation involving “common factors.”

Expresión para la cual tu resultado con papel y lápiz no coincide con el dado por la calculadora en IIa)	Explica si es posible o no simplificar tales expresiones. Rehaz los cálculos, si es el caso.	En qué forma es diferente tu simplificación (segunda columna, si es el caso) respecto del procedimiento utilizado en IIa)
$\frac{2x+3y}{x}$ =	no se puede simplifica $2x \quad + 3y \quad \lvert \underline{x}$ $\underline{-2x} \qquad\qquad 2$ $0 \qquad 5y$ que antes solo eliminabamos los	rque antes solo eliminabamos los terminos comunes del $\frac{N}{D}$ y ahora sabemos que si el numerador no tiene terminos comunes no se puede simplificar la expresion.

Figure 5: Explanation as to why the given expression cannot be simplified

However, for the expressions of the form “binomial over binomial” (see the last three expressions of Figure 4), their explanations were (at this moment of the activity) still evolving. The next verbatim extract illustrates this.

Researcher: I heard that you said that in this case it is possible to cancel out elements of the expression [*Referring to the last expression of Figure 4; immediately after they finished the long polynomial division*].

Student A: Yes.

Student B: Because there is a monomial in the bottom …

Student A: It is a binomial, isn’t it?...

Researcher: So, why in the previous one [*Third expression of Figure 4*] is it that, that technique doesn’t work?

Student A: Because there are not the same terms above and below [*Referring to the numerator and denominator*]

Researcher: And in the last [*Expression*] they are?

Student A: [*Nods his head in agreement*]

Researcher: Which ones are those terms you are referring to?

Student A: *3* plus *y* divided by *3* plus *y*.

Researcher: So, there [*Referring to the last expression for the Figure 4*] you identify that both techniques work, dividing or cancelling?

Student A: Yes, but here as well [*Signalling the second expression of Figure 4, and he tries to factor the expression*]… For which one you asked?…

Researcher: For the third one [*Referring to the third expression of Figure 4*]

Student A: Let’s see… [*And he factors the expression, see Figure 4*]… Yes, you need to change the form [*of the expression*]

Student B: You factored the expression

After this, for expressions of the form “binomial over binomial” they explained their techniques in terms of factoring the expressions, even if for some cases there were still some inconsistencies in their explanations—that is, until they used the CAS for another case (see Figure 6).

Introduce en la calculadora	Resultado dado por la calculadora	Describe cómo harías para obtener el mismo resultado que el dado por la calculadora
$\frac{a+a\,x}{x}$	$\frac{a(x+1)}{x}$	Factorizando la expresion

Figure 6: CAS work

Once they used the CAS for simplifying the expression shown in Figure 6 and the CAS gave the result in factored form, this decisively changed their point of view regarding the technique for simplifying rational expressions. From then on, their explanations included the idea of factoring (as seen in the third column of Figure 6).

Conclusions

In this paper we have shown that the CAS environment led students to think in terms of factoring when simplifying rational expressions—something that they had not previously considered in their initial techniques of “cancelling” or using the “long division algorithm for polynomials.” This is in contrast to the findings from our earlier pilot study (Guzmán, Kieran, & Martínez, 2011) where students did not possess both initial simplifying techniques and where their CAS work did not lead to the emergence of the idea of factoring and its role in simplifying rational expressions. While both studies provided evidence for the power of CAS to stimulate theoretical reflection, the findings of this study suggest that if students have more initial paper-and-pencil techniques (even if not completely understood), the CAS work can spur them to deeper theoretical reflections than for students who have fewer techniques.

Acknowledgments

The authors express their appreciation to the students who participated in this research, their teacher, and the school authorities who offered us their facilities for data collection. We also acknowledge the support of the Social Sciences and Humanities Research Council of Canada (Grant #410-2007-1485).

DIGITAL TECHNOLOGIES IN MEXICAN HIGH-SCHOOLS

Ma. de Lourdes Miranda
Center for Research and Advanced Studies (Cinvestav), Mexico
mmiranda2002@hotmail.com

Ana Isabel Sacristán
Center for Research and Advanced Studies (Cinvestav), Mexico
asacrist@cinvestav.mx

In this paper we present some of the issues in Mexican public high-schools related to the incorporation of digital technologies in mathematics classrooms; noting that the inclusion of technologies is very isolated, and that schools still lack proper facilities. We also present some of the didactical approaches of teachers in using digital technologies during their lessons; we observe lack of preparation of these lessons and conflictive situations for the learning processes arising from difficulties in the implementation of technologies and generated by deficient technical content and pedagogical knowledge.

Keywords: Technology; Didactical Approaches; High School Education; Educational Changes

Introduction

The use of digital technologies (DT) in schools has become increasingly important in today's societies, due to its inherence in all areas of daily life. But in education, changes have been slow. In fact, research on the impact of computers in classrooms on students' academic performance has shown that the effect has been moderate if any at all (e.g., Papert, 1993; Kilpatrick & Cuban, 1998; Chadwick, 2001; Battista, 2007). The incorporation of DT in classrooms, is a particular challenge for teachers. The importance of teachers' professional development, that strengthen their competencies and knowledge for helping students address the needs of the 21st century, has been a theme of several international educational conferences (e.g., at the International Conference on Education—ICE, and the International Congress on Mathematical Education—ICME), in particular with regard to the need of incorporation of digital technologies. Over a decade ago, the National Council of Teachers of Mathematics (NCTM, 2000) stated that technologies had to be used widely and responsibly in order to achieve a complete mathematical training, and to facilitate visualization of mathematical ideas. However, as Chadwick (2001) cautions, when teachers use technology they should ensure that the means do not cause straying from the educational aims. Technology can be a didactical tool only insofar as it helps in the construction of meanings of the objects of study; we also believe that a responsible use of DT should be supported in results from educational research in order to be successfully implemented. Sacristán, Sandoval and Gil (2009) concluded, from a research conducted on Mexican primary and middle-school teachers, that if teachers are to successfully incorporate DT in their practice, they need to understand how to use these tools in order to create meaningful learning in students.

Research Objectives and Theoretical Framework

Our general research aims to analyze elements of teachers' didactical practices in Mexico, and their relationship with curricular contents and recommendations; one particular aspect that is the focus of this paper, is teachers' didactical practices related to the use of digital technologies in mathematics classrooms.

In our study, we use as framework the categories proposed by Shulman (2001) related to the knowledge base that teachers should have in their professional development; thus we consider pedagogical content knowledge (PCK), curricular knowledge, technological pedagogical and content knowledge (TPACK, that provides understanding on the technological tools that the teacher uses in her/his practice) (Mishra & Koehler, 2006), among others. Llinares (2000) recognizes that a fundamental part of a teacher's practice lies in the choice of the instruments s/he uses (spoken language, modes of symbolic representation, didactical materials, use of technologies in daily practice, etc.) and he emphasizes the importance of her/his understanding of which and how they will be used, and for which aims. On their part, Ponte and Chapman (2006) state that a teacher's knowledge and her/his didactical approach, are mutually dependent in the teacher's activity; this relationship is representative of the organization of the elements for teaching. We have used the above ideas to design our survey questions and to observe characteristics in teachers' development of knowledge, not only taking into account what they know (content knowledge), but what they *do* with what they know (knowledge use), in a twofold way: their mathematical content knowledge (Ball, 1988) and the technology use during their classroom practice. In this way we attempt to assess how meaningful is a teacher's use of DT in her/his classroom.

Methodology and Data Collection

In studying teachers' didactical approaches, we also consider their knowledge in terms of the educational changes and curricular reforms that have occurred in the last decades both at international and at national levels; in particular we consider those related to teaching methodologies (recommended classrooms strategies and dynamics, didactic materials, etc., often based on specific epistemological theories—e.g., constructivism) and the use of DT in the classroom (computers, videos, Internet, specialized software for mathematics, etc.).

In a first research phase, we carried out a documental type of research where we reviewed the diverse programs of study and curricular recommendations for high-school mathematics in Mexico, in order to establish what is considered essential for the teachers' practice. In a second research phase, we carried out a survey of 159 high-school mathematics teachers in different regions of Mexico; through this survey we had some panoramic insights of the ways in which high-school teachers have perceived the educational changes and needs in the 21st century world. In a third research phase, we carried in-classroom observations, as well as pre- and post- interviews, of a subset of the surveyed teachers: 13 teachers in Mexico City, who claimed in the survey to have changed, in the past decade, the way they teach and incorporated DT to their practice, and 3 other teachers, not originally surveyed, who where reputed in their schools to use DT in their lessons. Thus, we observed (and interviewed) a total of 16 teachers, in 5 different public high-schools in Mexico City, for up to two classroom sessions of 60 to 120 minutes, in which they were meant to use DT. It is worth noting that the 5 schools we visited are considered amongst the best public high-schools in the country.

For the analysis of the results, we carried out a correlation of the results, through a methodological triangulation to structurally relate the cualitative, quantitative and documental data (Denzin, 1990; Bryman, 2007). In this way we could analyze the relationships between a teacher's didactical beliefs (including her/his beliefs on educational needs and changes, and on DT tools as didactical instruments; teaching methodologies used in her/his practice; her/his changes in the last decades), what s/he claims to have changed due to educational reforms in Mexico, and her/his actual didactical approaches in the classroom.

Some Results and Sample Data

In this section we present some results derived mainly from the second and third phase, related to the use that the teachers in our study make of DT in their practice. Other results are beyond the scope of this paper.

Some General Results on the Use of DT by the Study's Teachers

The great majority of the 159 teachers surveyed, 91%, agreed that there have been significant educational changes in the last two decades in the world; however only 38% mentioned the use of technology as one of the most significant changes. Nevertheless, the surveyed teachers coincided in that the use of DT has become an essential part of students' development and that it is important to include them in teaching for didactic support. A large majority of them, 73.8%, claimed to use DT to support their mathematics teaching practice. And 65% said they used Internet to search for theoretical information related to the topics studied in their classes, to search for formulae, or to send homework to their students.

In terms of the observed and interviewed teachers, all 16 of them mentioned that they had taken professional development workshops on the use of digital tools, mainly on the use of graphing tools, such as Winplot—which was also the most common use mentioned; and on the use of information and communication tools (i.e., Internet) or office suites; and ten of them had had a short course on some dynamic geometry software (i.e., Cabri, SketchPad or Geogebra).

However, from the interviews, we realized that the way in which these third-phase teachers used DT, was mostly as checking and comparison tools, or to save time by using tools (e.g., Winplot) that would facilitate the construction of graphics. A surprising response was that of a teacher who said he only used DT because it was a requirement of his school.

Furthermore, although, when we interviewed them, all 16 teachers claimed to use DT for their lessons, at the time we visited them only four of them actually used them with their students in our observation sessions. Some of explanations that were given for the lack of use of DT when we observed, were the following:

- they only used DT in class once per school term (e.g., to show students how to use a graphing software) and afterwards students are supposed to use it for homework;
- they use Internet (e.g., email) for sending and receiving students' homework;
- they ask students to research how to use a graphing software at home and turn in computer-plotted graphs as homework;
- the school doesn't have the necessary equipment;
- they don't have access to the school's computer room;
- they only use DT for class preparation.

Therefore, though all these teachers claimed to use DT in their practice, it was clearly a very limited use, if any at all.

Sample Data from the Four Teachers Observed Using Technology

Here we summarize the way in which the four teachers used DT when we first visited them:

Three teachers, whom we will name teachers A, B and C took their own laptops and beamers to their respective classrooms. However, teacher A could only connect his equipment to the ceiling lamp, due to the lack of electrical outlets in his classroom.

Teacher A showed his students a video downloaded from the Internet on the theme of geometrical congruence and similitude that was the theme under study; however the video had no sound, had Portuguese subtitles and was blurry, so that it was difficult to follow and see.

Teacher B had no problems in connecting his equipment. He used a plotting software (Graphmatica) to show his students the domain and range of polynomial functions. Though he did allow a couple of students to play with the software, the DT tool was used only for visualization and the main activity was carried out in paper-and-pencil.

Teacher C also used Graphmatica, but she faced many problems in projecting the images (taking over 20 minutes of a two-hour session). She was teaching the theme of irrational functions and asked the students to type a function in Graphmatica. She began with $y=\sqrt{x}$ typing it on the whiteboard (Figure 1) and asking a student to do it with Graphmatica (Figure 2).

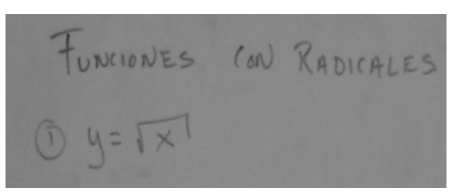

Figure 1: Teacher C writes function on board

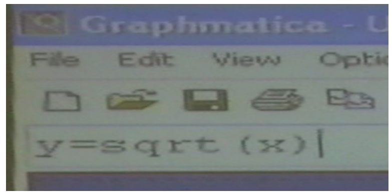

Figure 2: Graphmatica input

She wrote other functions on the board, that students took turns graphing in Graphmatica: $y=-\sqrt{x}$, $y=\sqrt{-x}$, $y=\sqrt{x}+3$, $y=\sqrt{x}-3$. But when she moved on to more complicated functions: $a)\ y=\sqrt{x^2+9}$, $b)\ y=\sqrt{x^2-9}$, $c)\ y=\sqrt{-x^2+9}$, $d)\ y=\sqrt{-x^2-9}$, the way of inputting these functions became more complicated: whereas before they had been using the SQRT command, they now had problems and the teacher changed to using the ½ power instead. But this created further problems; such was the case of function c) which was incorrectly inputted (Figure 3) and produced an incorrect graph (Figure 4).

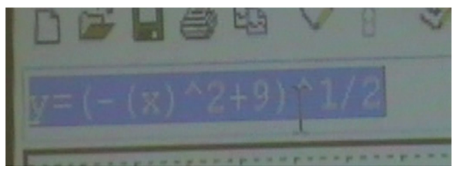

Figure 3: Input in Graphmatica for function c)

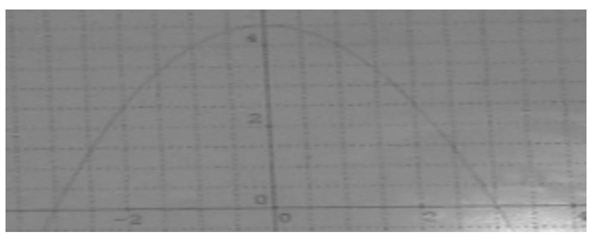

Figure 4: Graph produced by Graphmatica to an incorrect input

The problem with the input of this function was that the ½ power was not placed between parentheses. Therefore the plotted function was actually $y=\frac{(-x^2+9)^1}{2}$, which for x=0, gives y=9/2=4.5. However, the teacher did not notice this; even when a student pointed out that the graph was wrong, that the curve should have cut the y-axis in 3, she replied by saying that the root of the function, where the graph cut the x-axis, was 3, so the student's comment was not correctly taken into account. All the other functions were also incorrectly inputted and thus incorrectly graphed; the teacher, however, did not acknowledge that there was any problem. Another four students also doubted the accuracy of the graphs, but the teacher just said that those were the behaviors of the functions, never correcting the situation.

Teacher D took her students to the school's co mputer room, where each student could use Graphmatica. The topic was the same as Teacher C's, but in this case there were no problems.

Discussion and Concluding Remarks

Though curricular reforms and society's changes are pushing for the inclusion of digital technologies in schools, our results show that is not straightforward. Though the majority of the surveyed teachers are conscious of the changes brought about by digital technologies in the world and how these have permeated daily life, and 73.8% claimed to use computers as teaching aids, when we went to visit the schools we observed a different reality. In our study we observed that the incorporation of DT in Mexican public high-schools is extremely limited, if not nil.

One of the categories that were established in our study, derived from the work of Shulman (2001) and others (as discussed in the theoretical framework section above), is that related to curriculum knowledge: in our study, we wanted to see if and how teachers took into account and used the methodologies, strategies and other recommendations stated in the official programs and curricula, in their practice. But in our study, most teachers observed and interviewed were unable to explain what those recommendations from the curriculum were (let alone put them into practice), even though they had previously claimed explicitly to be using them, including the use of technology.

Another observation is the lack of equipment and facilities for using DT that is seen even at some of the best public high-schools in the country (which were the ones we visited). Most public high-schools are not equipped with computer rooms, and in those that do have them, teachers tend to not use them (in fact, we were able to observe only one teacher using it), arguing problems in accessing those rooms, or lack of training in their use.

When teachers do use DT, the use that is done, tends to be limited to presentation (as in the case of Teacher A), visualization or computing uses (e.g., using graphing software), for checking results produced in paper-and-pencil, or simply for communication (e.g. using email or Internet for sending homework's). It is thus more of a mechanical use (or, simply, for accuracy and saving time, as in the case of the use of plotters) rather than having educational aims, and much less a meaningful harnessing of the potential of DT for enhancing learning. Furthermore, we observed that teachers did not design any activities using DT (other than plotting a graph, or checking a result with the use of DT)

Those few teachers who mentioned to be up-to-date in the use of DT, underestimate their potential as educational aids and lack technical pedagogical and content knowledge (TPACK). They are not conscious of the difficulties that may arise during the implementation of DT in the classroom (such as in the cases of Teachers A and C), and lack the technical knowledge and mathematical content knowledge to deal responsibility with situations such as the one observed with Teacher C. Another deficiency noted, is that two of them had not prepared their lessons, which is an important aspect mentioned by Llinares (2000) that should be part of the professional teaching practice.

It is important to note that although some teachers have tried to adapt to the changes in education, attempting to change their teaching methodologies and attempting to incorporate DT into their practice, the lack of training and support can lead to confusions, misinformation, or even loss of interest or commitment. In fact, during the interviews, some of the high-school teachers complained that the only type of training they had received were on the basic use of office software suite packages, and not in more specific tools for mathematics education (such as dynamic geometry or CAS).

The above results coincide with those reported by Julie et al. (2010) from a survey conducted in Latin America in 2006. We would have expected changes since 2006, but as was noted ten years ago by Cuban, Kilpatrick, and Peck (2001) the incorporation of technology into classrooms has been a very slow process, and this seems to be particularly true in developing countries like Mexico, where the incorporation of technologies in teaching practices is limited. In Sacristán, Parada, and Miranda (2011) we discussed this problem, observing two types of limitations and obstacles: one related to digital divides (illustrated here by the lack of equipment and facilities); the second related to professional development of teachers and the educational system itself.

Hennessy, Ruthven, and Brindley (2005) point to the importance of teacher involvement (rather than a technologically-driven model of technology integration) in effecting classroom change; but they also point that this involvement is undoubtedly influenced by the teachers' working contexts. The little use of technologies we observed in our study, is partly due to lack of proper conditions, but also because teachers have not experienced other uses. Hitt (1998) pointed out that teachers will only feel the need to incorporate technologies to their practice when they experience the effectiveness of a tool or resource in dealing with a problem. Thus, rather than focus on the delivery of technical skills (which are the type of courses the teachers in our study had received), it might be helpful if teachers can participate in professional development models that immerse them—and support them—in the experience of dealing with mathematical situations through technology. However, taking into account the reality of countries such as ours, this may not be so easy.

THE ROLE OF TECHNOLOGICAL TOOLS IN RELATION TO STUDENTS' MATHEMATICAL THINKING DURING CLASSROOM TASKS

Milan Sherman
Portland State University
milan.sherman@pdx.edu

This study uses the Mathematical Tasks Framework (Stein & Smith, 1998) to assess the cognitive demand of mathematical tasks implemented in four mathematics classrooms, and to investigate the role of technology in both low- and high-level cognitive demand tasks. The metaphor of using technology as an amplifier or reorganizer (Pea, 1987) is used to characterize technology use. Results indicate that when technology is used as an amplifier, it has no influence on the thinking demands of a mathematical task, but when used as a reorganizer it is intimately related to the supporting students' high-level mathematical thinking. Furthermore, this distinction can be an important part of mathematics teachers' technological pedagogical content knowledge (TPACK) (Mishra & Koehler, 2006; Niess et al., 2009) by providing ways to distinguish uses of technology along dimensions that matter for students' mathematical thinking and learning.

Research on the use of instructional technology in secondary mathematics education has proliferated over the last 20 years (e.g., Heid & Blume, 2008; Zbiek, Heid, Blume, & Dick, 2007). There has also been an increased awareness of and interest in students' mathematical thinking and reasoning (Common Core State Standards Initiative, 2010; National Council of Teachers of Mathematics, 2009), However, little research has focused on how the use of technology can support students' mathematical thinking and reasoning more generally.

Theoretical Framework

As the purpose of the this paper is to characterize the use of common classroom technologies in relation to students' mathematical thinking, an array of classroom technologies are considered. The interest in the present study is with digital technologies used specifically as cognitive technologies (Pea, 1987). Pea defines cognitive technologies as those that "help transcend the limitations of the mind (e.g., attention to goals, short-term memory span) in thinking, learning, and problem-solving activities" (Pea, 1987, p. 91). By mediating human thought, cognitive technologies both assist and influence thought and learning. The focus of the present study is on *digital* cognitive technologies that may support students' mathematical activity. A distinction that Pea makes within cognitive technologies is between its use as an *amplifier* or a *reorganizer* of mental activity (1987). That is the focus of the next section.

Amplifier and Reorganizer Metaphors

When technology is used as an amplifier, it performs more accurately or efficiently tedious or time consuming processes that might be done by hand, like arithmetic computations or the generation of standard mathematical representations. In this use of technology, what students do or think about is not changed, but can be done with significantly less time and effort, and more accurately. The use of a scientific calculator for computations while students set up and solve proportions can make their work more efficient and help to avoid basic arithmetic errors in their solutions. However, what students are doing is not changed by the use of the calculator; their cognitive focus is still on setting up and solving proportions whether the calculator is used or not.

As a reorganizer, technology has the potential to support a shift in the focus of students' mathematical thinking and behavior, by producing novel representations which make salient some aspect of a concept which is difficult to make explicit without it, or by providing feedback to students that they would otherwise not have access to. For example, students might use dynamic geometry software (DGS) to construct a triangle and manipulate it in order to look for and make conjectures about the relationship between the lengths of the sides, with the goal of discovering the Triangle Inequality Theorem. By using

Van Zoest, L. R., Lo, J.-J., & Kratky, J. L. (Eds.). (2012). *Proceedings of the 34th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Kalamazoo, MI: Western Michigan University.

technological tools to generate dynamic and interactive representation, students are able to focus on looking for patterns and making and testing conjectures, rather than on drawing and measuring triangles. This use of technology supports a shift in the focus of students' mathematical activity and thinking.

An important aspect of the type of thinking afforded by the use of technology is the kind of problem or task that calls for its use. Whether technology is used or not, one way that teachers shape students' learning and view of the discipline of mathematics is by the choice of mathematical tasks for instruction (National Council of Teachers of Mathematics, 1991). However, with the introduction of technology comes the need to understand what kinds of tasks utilize the resources provided by the technology to support students' high-level thinking (Hollebrands, Laborde, & StraBer, 2008). A framework for understanding the influence of tasks on students' mathematical thinking is described in the next section.

The Mathematical Tasks Framework

The *Mathematical Tasks Framework* (Stein & Smith, 1998) has been used to describe and differentiate the type of thinking that is called for by a given mathematical task, defined as "a classroom activity, the purpose of which is to focus students' attention on a particular mathematical idea" (Stein, Grover, & Henningsen, 1996, p. 460). This framework distinguishes between low-level cognitive demand, including *memorization* and the use of *procedures without connections* to meaning or concepts, and high-level cognitive demand, including the use *of procedures with connections* to meaning or concepts, and *doing mathematics*, of which non-algorithmic thinking is characteristic. An important characteristic of this taxonomy is that it is not related to specific mathematical content, but rather characterizes different types of thinking that students may engage in while working on a mathematical task.

An important contribution of the *Mathematical Tasks Framework* is the recognition that the thinking requirements of a task may change during its enactment. The task as it appears in curricular materials does not directly influence students' learning by the type of thinking it requires, as those demands may be altered by the teacher when announcing the task to students during instruction, known as the *set up* phase, and again while students are working on the task, referred to as the *implementation* phase. This element of the *Mathematical Tasks Framework* makes it especially suitable for describing the impact of using technology on students' thinking in a classroom context. The research question investigated by this study is: what is the role of technology in relation to the cognitive demand of mathematical tasks?

Research Methods

This study uses a qualitative, observational research design with the goal of understanding the role of technology in supporting the mathematical thinking of students. Four teachers were recruited primarily based on their use of technology for mathematics instruction. One or two units of instruction, as designated by the teacher, were observed in each classroom. Each of the teachers had three years of teaching experience, and had taught the observed unit at least once previously. An overview of the data collection classrooms is given in Table 1.

Data collected at each site included lesson observation field notes, task artifacts and student work on the task, and audio recorded post-lesson interviews with the teacher. Hand-written jottings taken during the observation were developed into a detailed narrative of the lesson immediately following the observation (Emerson, Fretz, & Shaw, 1995), and all post-lesson interviews were transcribed. Using the *Task Analysis Guide* (Stein & Smith, 1998), each task was coded with respect to the cognitive demand of the task as stated in the curriculum, as introduced to the class (set-up), and implementation. In addition, for those tasks which utilized technology, the use of technology was coded as amplifier, reorganizer, both, or neither during the set up and implementation phases. Approximately one-fourth (24%) of the observed tasks were double coded for reliability, with 89% agreement on the cognitive demand, and 86% with regard to the use of technology. All discrepancies were resolved and the consensus code was assigned to the task.

Table 1: Summary of Data Collection Classrooms

	Tasks Observed	Grade/Class Level	Topics	Technologies
Ms. Jones[1]	12	9th grade Integrated Math	• Angle relations • Triangle Inequality • Similarity	• DGS • Scientific Calculators
Ms. Young	17	11th grade Inclusion	• Angle relations • Triangle Inequality	• DGS • Interactive Whiteboard • Scientific Calculators
Mr. Mack	17	6th grade Regular	• Order of operations • Fractions	• Interactive Whiteboard • Scientific Calculators
Ms. Lowe	17	10th grade Advanced	• Points of concurrency in a triangle	• DGS • Interactive Whiteboard • Graphing Calculators

Following data collection and coding, the coding results were summarized in order to observe patterns in the data that could guide qualitative analysis. For example, it had been hypothesized that the use of technology as an amplifier would be associated with low-level cognitive demand tasks. However, the summary of the coding results revealed that technology was used as an amplifier in both low- and high-level cognitive demand tasks across sites. These tasks were analyzed qualitatively in order to understand the role that technology played in these tasks, and how it was related to the thinking demands of the task. The constant comparative method (Glaser, 1965) was used in analyzing different tasks in the same classroom, as well as across classrooms, in order to make generalizations about the relationship between the role of technology and students' mathematical thinking.

Results

A primary concern in this study is how the use of technology might be correlated with the cognitive demand of the mathematical tasks within which that use is situated, and the meaning of those correlations. The hypotheses for this study were that technology is used as an amplifier in low-level tasks, and substantial evidence for the hypothesis that technology is used as a reorganizer (or both) in high-level tasks. The reasoning behind these hypotheses was that teachers would use technology to support a change in students' focus to high-level thinking by offloading computations or the generation of representations to the technological tools, or by providing novel representations capable of supporting conceptual connections that would be difficult or impossible to produce by hand. According to this logic, a teacher that did not utilize technology as a reorganizer would not be attempting to support such a shift, and thus the task would remain at a low-level. Results of the study provide partial evidence for the hypothesis that technology is used as an amplifier in low-level tasks, and substantial evidence for the hypothesis that technology is used as a reorganizer (or both) in high-level tasks.

The results of the coding of tasks in terms of the cognitive demand and the use of technology are reported in Tables 2 and 3. Table 2 shows the distribution of tasks using technology as an amplifier during set up at a low- or high-level, and during the implementation at a low- or high-level, while Table 3 depicts the same for the use of technology as both an amplifier and reorganizer.[2] Technology use during the set up phase refers to the way in which technology was designed to be used in the task as set up by the teacher, but prior to students actually engaging with the task. For example, if the teacher introduced as task in which students were to use DGS to investigate the properties of medians of a triangle, the use of technology was coded as an amplifier and reorganizer during set up.

Table 2: Amplifier Technology Use in Relation to Cognitive Demand[3]

Amplifier Use of Technology	Low-level	High-level
Set up	24	7
Implementation	46	2

Table 3. Reorganizer Technology Use in Relation to Cognitive Demand

Technology Use as Reorganizer	Low-level	High-level
Set up	0	16
Implementation	2	6

Amplifier Use of Technology

As Table 2 indicates, within the sample of tasks set up at a low-level, the use of technology was always intended as an amplifier. Although there exists an association of low-level tasks with amplifier use during set up and implementation, qualitative analysis of these tasks revealed that the way the technology was used was not directly related to the low-level demands of the task. Indeed, technology was also used as an amplifier in high-level tasks, and likewise qualitative analysis revealed no relationship with the cognitive demand of these tasks; it was merely used for displaying the statement or description of a task that would have been high-level without it.

A primary way in which technology was used as an amplifier was in tasks in which the interactive whiteboard (IWB) was used to display lecture notes or practice problems, to project a worksheet while discussing problems or solutions, and in a few cases, it was used in conjunction with DGS in order to provide a dynamic demonstration or example. Another common amplifier use of technology included the use of a calculator for computations while practicing a procedure. For example, students used scientific calculators for arithmetic computations while solving for missing angles in a diagram of parallel lines cut by a transversal.

What all of these tasks had in common is that the cognitive demand of the tasks in which they appeared would not have changed if technology had been used in the way that it was, i.e., as an amplifier. Given the way that the amplifier use of technology is defined, i.e., making some process more accurate or efficient that could be accomplished without it, it makes sense that such a use of technology is not directly related to the cognitive demand. Rather, the association revealed in these data seems to be mediated through the teachers, and the affordances they perceive of the technology available to them in relation to low-level tasks. Thus, the selection of the task may be the primary factor in the cognitive demand when technology is used as an amplifier.

Reorganizer Use of Technology

The use of technology as a reorganizer was strongly associated with the set up and implementation of high-level tasks. As hypothesized, its use as a reorganizer was in all cases related to its use as an amplifier, in the sense that by offloading the construction, labeling, and measuring of mathematical objects to the technological tools there existed the potential for students to shift the focus of their mental activity to such behaviors such as dragging, observing, generalizing, and making and testing conjectures. In general, teachers used a dynamic geometry software package such as GeoGebra or Geometer's Sketchpad to have students investigate and explore the properties of geometric objects such as triangles.

Three of the four teachers this study used technology as both an amplifier and reorganizer to set up tasks at a high-level using DGS within a student-centered exploration. In general, the purpose of using technology in these tasks was to support students in constructing meaning for a mathematical concept or procedure, or to engage in mathematical behavior, such as observing, reasoning, generalizing, and conjecturing.

An example of a task that was set up and implemented at a high level using technology as a reorganizer is taken from Ms. Lowe's classroom. Ms. Lowe created a worksheet to guide students in using

GeoGebra individually at their own computer for most of the period in order to investigate the properties of the centroid of a triangle, i.e., the intersection of the medians[4] of a triangle. She guided students to construct a triangle and the medians of the triangle, to construct the centroid, to measure the segments from the vertex to the centroid, and from the centroid to the midpoint of the opposite side, and then to record these measurements in a table in order to look for a relationship[5] and make and test conjectures. In this case, the opportunity to drag and explore the properties of the medians individually was directly connected to the cognitive demand of the task.

As an example of the type of thinking that students engaged in while working on the task, the following conversation between two students was observed while working on the task:

> *Nick and Brian are dragging their figures and discussing what it is that they're supposed to be noticing.*
> **Nick:** I'm going to make it a right triangle. What would that do? It would stay at the center of the triangle, right?
> **Brian:** look at this.
> *Brian shows Nick his table, pointing out the 6.17 and the 3.08.*
> **Brian:** this one is almost exactly double that one.
> **Nick:** you can't make assumptions from one triangle
> *Both start dragging their triangles.*
> **Nick:** I see something like that, but if you stretch it far enough…
> *They continue dragging their triangles and looking at the measurements.*
> **Nick:** one is always half of the other
> **Brian:** the distance from the vertex is always double the distance to the midpoint.
> **Ms. Lowe:** change it, see if you can disprove it.
> *Starting over with a new triangle, Brian begins to measure the distances from the centroid to the vertex and from the centroid to the midpoint for each median.*
> **Brian:** (as he measures each segment) that is double that, and that is double that, and that is double that.
> *Nick drags his figure.*
> **Nick:** yes, it does stand true. (Field note, 2/7/11)

This excerpt demonstrates how technology can be used as both an amplifier and reorganizer. As an amplifier, students constructed a triangle, the medians of the triangle, and the centroid quickly and precisely, and measured and labeled the angles, the lengths of the medians, and the lengths of the segments. Most students had completed this part of the task within 10 minutes. While students might be able to construct the centroid of a triangle and use a protractor and ruler to make the same measurements, this could be difficult for most students to do accurately in 10 minutes. Furthermore, by dragging the triangle, students are essentially creating many triangles, medians, and centroids. As a reorganizer, dragging does more than just create multiple examples quickly and accurately. One can observe, for example, how the centroid moves in response to a vertex being dragged, or how the location of the centroid is changed as the triangle is changed from an acute triangle, to a right triangle, to an obtuse triangle, and back again. This sort of "real-time" motion of one object in relation to another is simply not possible in a pencil-and-paper environment.

Further evidence of the reorganizer use of technology is that students are not focused on making the measurements, but on using them to discern regularities in the behavior of the segments and on understanding what they mean. Nick's statement, "I'm going to make it a right triangle. What would that do? It would stay at the center of the triangle, right?" indicates the open-ended nature of having students directly manipulating the object created within a DGS, that there are many possibilities to choose from in terms of how to drag the object. It also reveals the making and testing of conjectures that is inherent in the development of a more strategic investigation of an object using dragging. Students must consider the purpose of dragging in terms of an overarching goal, what information would be helpful in achieving that goal, and what sort of dragging might provide that information. Once that move is made, students must assess if the object behaved in the anticipated manner, and if not, why, and what the next move should be in light of this information. The technology acts as a reorganizer by supporting these students' focus on looking for relationships, and making and testing conjectures, which constitute the high-level thinking demands of the task.

The Role of Technology in the Decline of Cognitive Demand

One explanation for the correlation of amplifier use of technology with low-level tasks during implementation is that many tasks that intended to use technology as both an amplifier and reorganizer in a high-level task during set up were implemented at a low-level when students used technology as an amplifier only. In these tasks it was the use of technology as a reorganizer that was intimately connected with the high cognitive demand of these tasks as set up. Thus, when technology failed to act as a reorganizer of students' thinking, the cognitive demand declined during implementation.

In these tasks, students constructed, measured, and manipulated figures, but did not engage in making mathematically meaningful observations, generalizations, or conjectures. For example, in Ms. Jones class, students created triangles and measured side lengths in order to explore the Triangle Inequality Theorem.[6] However, when asked if it were possible to create a triangle in which the sum of two side lengths could be less than the third, some students replied "yes," and very few students wrote a conjecture about the relationship between the lengths of the sides.

In general, these teachers seemed to underestimate the support that students would need in connecting their work with DGS to the mathematical thinking and behavior required by the task. While the affordances of DGS can support high-level thinking, there is nothing about the use of a DGS for an exploratory task that *causes* students to engage in high-level thinking. For example, if students have never been asked to make a conjecture before, providing them with technological tools will not necessarily result in their ability to do so. DGS can support students' ability to make conjectures by providing the opportunity to examine numerous examples to analyze as the basis for a conjecture, and strategically manipulate objects in order to test a conjecture. However, it does not inherently support students' understanding of the importance of examining a variety of examples, what is mathematically meaningful to look for across those examples, how to make a mathematically precise statement as a conjecture, the importance of testing a conjecture or looking for counterexamples, or the difference between a conjecture and a proof. Ultimately, when technology is used as both an amplifier and a reorganizer, teachers must support the shift entailed by its use as a reorganizer. What that support may consist of has been discussed elsewhere (Sherman, in press).

Discussion

The present analysis builds on previous work that makes use of the amplifier and reorganizer distinction (Ben-Zvi, 2000; Laborde, 2002), but extends the distinction by considering how technology might act as an amplifier or reorganizer during the implementation of classroom tasks. The use of technology as an amplifier was generally associated with the interactive whiteboard and calculator, while its use as a reorganizer was almost always in the context of using DGS. It is tempting to explain the difference in technology to the differences in the affordances of these classroom technologies. Research points to the potential of calculators to be used in ways that can support and influence students' thinking (Burrill et al., 2002). Thus, the real issue may be how the affordances of these technologies are perceived by teachers.

A way in which the results of the present study may contribute to research in mathematics education is by characterizing the use of technology in relation to students' thinking in a way that can differentiate superficial from meaningful use of technology for mathematical instruction and learning. These results provide empirical evidence that the mere inclusion of technology does not have any inherent implications for students' opportunity for high-level thinking, but how it is used does.

An understanding of this distinction may be an important element of mathematics teachers' TPACK (Mishra & Koehler, 2006; Niess et al., 2009), by providing a way to critically examine the role of technology in the tasks they enact with their students. Anecdotal evidence indicates that preservice teachers in a secondary methods course were able to learn and use this distinction in evaluating and selecting tasks. Research is needed to examine this claim more carefully, and to determine how it may influence in-service mathematics teachers' selection and design of classroom tasks.

Endnotes

[1] Pseudonyms

[2] For the sake of simplicity, "both amplifier and reorganizer" is used interchangeably with "reorganizer" for the remainder, since no cases of using technology were coded as reorganizer only.

[3] The discrepancy in the number of tasks set up and implemented using technology as an amplifier has two sources. Some tasks were set up by the teacher without any explicit mention of technology as part of the set up of the task, but students initiated its use during while working on the task. In other cases, the task was set up to use technology as both an amplifier and a reorganizer, but utilized technology as only an amplifier during implementation. This also explains why more tasks were set up than implemented using technology as a reorganizer, as shown in Table 3.

[4] A segment connecting the midpoint of a side of a triangle to the opposite vertex.

[5] The relationship that students were intended to discover is that the segment from the midpoint to the centroid is 1/3 the length of the median, and the segment from the centroid to the opposite vertex is 2/3 the length of the median.

[6] The sum of the lengths of any two sides of a triangle is always greater than the length of the third side.

EXAMINING THE TRANSITION FROM A PART-WHOLE TO PARTITIVE UNDERSTANDING OF FRACTIONS

Steven Boyce
Virginia Tech
sboyce@vt.edu

Anderson Norton
Virginia Tech
norton3@vt.edu

Sixth grade students' transitions from part-whole understandings of fractions to more powerful ways of operating were explored as part of a pilot study of student interaction with Candy Factory, an iPad app designed to support the construction of partitive fraction schemes. Students demonstrated a novel strategy for creating fractions of the form (n–1)/n. We will discuss this strategy and consider its potential for supporting students' development of an understanding of composite fractions as measures.

Keywords: Number Concepts and Operations; Learning Trajectories; Middle School Education

As part of a pilot study for the NSF-funded GAMES grant (award #1118571), we observed student engagement with the *Candy Factory* fractions iPad app (see http://ltrg.centers.vt.edu/). The study included observation of two sixth-grade classes using the app in the classroom, during which we noticed several students' use of a "complement" strategy for constructing proper fractions. The purpose of this paper is to consider how and why one student's use of the strategy might have supported the integration of his part-whole and measure conceptions of fractions.

Theoretical Framework

Researchers commonly consider knowledge about fractions in terms of the model proposed by Kieren (1980), in which facets of fractions understanding are described via relationships amongst five identified sub-constructs: part-whole, measure, ratio, quotient, and operator. A part-whole sub-construct includes understanding a fraction as a relation between a whole and a subset of that whole, whereas in the measure sub-construct, fractions are treated as measureable units, such as length. Via a longitudinal classroom teaching experiment, Lamon (2007) found that teaching with intent to encourage students' development of fractions as measures is the most powerful for the emergence of the other sub-constructs. The aforementioned model categorizes fractions knowledge of *adults*, and thus the relationships between the sub-constructs might not be part of *children's* understanding as they construct their knowledge (Thompson & Saldanha, 2003). Steffe and colleagues have identified and continue to refine a hierarchy of students' *fractional schemes* and associated operations such as *partitioning, splitting,* and levels of *unit-coordination* that are necessary and/or sufficient for the schemes' construction (see Steffe & Olive, 2010). The focus of this paper is on the development of a *partitive fraction scheme* (PFS), which is closely related to the measure sub-construct (Norton & Wilkins, 2010).

Methods

We observed two sixth-grade classes, once per week, for about thirty minutes, over a period of seven weeks, as students worked in pairs using the *Candy Factory* app. Our focus was to document students' verbalizations and observable actions within the game that were indicative of their ways of operating with fractions. For more fine-grained analysis of students' ways of operating, we also conducted a paired-student teaching experiment (cf. Steffe & Thompson, 2000) with nine weekly after-school sessions, each lasting approximately thirty minutes, using the app and other manipulatives such as Cuisenaire rods. We chose a participant from each of the two sixth-grade classes, Austin and Jane, because clinical interviews from another study revealed that they each had constructed only a part-whole scheme but not a partitive unit fraction scheme (see Wilkins, Norton, & Boyce, in review). Our focus in this paper is Austin, because he was the more demonstrative and verbal of the pair.

Results

Austin's Initial Ways of Operating with Fractions

While we were able to attribute only a *part-whole scheme* (PWS) to Austin based on our initial interview, our observations from the first few weeks of the teaching experiment led us to believe that Austin constructed a *partitive unit fraction scheme* (PUFS). He consistently arrived at the name for a unit fraction bar by iterating its length from left to right across a non-partitioned whole, both within and outside of the context of the app. When Austin was given the task of finding the length of a "whole" given a fraction rod that he was told was "three-sevenths," he iterated the given piece three times to form the whole and said that he "counted up three-sevenths." Thus, Austin did not appear to have constructed a PFS, for he did not conceive of a proper composite fraction such as three-sevenths as a unit consisting of three one-sevenths units, each of which could be iterated seven times to make the whole unit (Steffe & Olive, 2010).

Austin's Use of a Complement Strategy

In *Candy Factory*, a user "manufactures" a customer order by choosing the number of partitions of a whole "candy bar" and subsequently choosing a number of iterations of a resulting part. In the second week of classroom observations, we noted a pair of students using a "complement" strategy for customer orders that were proper fractions of the whole (see Table 1). We noticed several students using various forms of the strategy in subsequent weeks, including students with less-developed fractions schemes such as Austin. We retrospectively analyzed the teaching experiment data in order to incorporate his use of the strategy, both within and outside the context of the app, in our model of his understanding of fractions.

Table 1: A Complement Strategy

If customer order is perceived as:	"Close" to 1/2	Less than 1/2	Greater than 1/2
Student chooses partitioning to make:	1/2	1/n, for n > 2	1/n, for n > 2
Student chooses iteration to make:	1/2	1/n	(n–1)/n

In the segment below, Jane and Austin were playing a game with fraction rods, which were ostensibly distinguished in size only by color, although we also refer to them as multiples of the unit rod in this article. Concealing his or her actions from his or her partner, one student would choose a whole and create a proper fraction of that whole. The task for the other student was to make the whole, given the fractional part and its name. In the following segment, Jane has just chosen the brown 8-rod as the whole and named the purple 4-rod as two-fourths. [A: Austin; J: Jane; R: Teacher-researcher.]

Protocol 1: October 19, 2011

J: [Handing Austin the purple rod] Two fourths.
A: [Immediately picks up the black 7-rod and lines two purple 4-rods beneath it. He then tosses the black back into the box and pulls out the brown 8-rod. He lines two purples beneath the brown, and then puts it back as well. He pauses for two seconds, clenching his teeth and looking up, as if confused] Two-fourths?
R: Yeah, she said that the purple one was two-fourths.
A: [Gasps. Picks out the orange 10-rod and lines up two purple 4-rods beneath it from left to right, leaving a small gap on the right hand side] Nope. [He then lines up two purples beneath the blue 9-rod] Uh, no, wait. [He then gets the brown 8-rod back out it in his left hand and the blue in his right hand and moves them up in down as if deciding between the two. He then indicates that the brown 8-rod is his answer.]
J: [Three second pause] Are you sure?
A: [Slowly grabs the piece back] I'm not sure [Everyone laughs].

R: Why are you confused, can you explain why you're confused between those [the blue 9-rod and the brown 8-rod held in Austin's hands.]
A: She said two-fourths, and that's equal [lines up the two purples beneath the brown] and that's two and two.

The brown 8-rod was a whole for which the purple 4-rod was a unit fraction, but the purple was not a fourth of that whole. Thus for Austin, choosing the brown 8-rod as the whole required overlooking that there had been only two iterations despite the purple rod's name as two-*fourths*. It is unclear why Austin thought the blue 9-rod might be the whole, but one possibility could involve his use of a PUFS within a complement strategy: the blue is the length of two purple rods, with one-fourth of a purple rod remaining. The following week, there was additional evidence of his use of a complement strategy while solving a similar task. The researcher proposed the task to both students, who worked independently before sharing their results.

Protocol 2: October 26, 2011

R: This [teal 6-rod] is three-fourths of a whole I have in my pocket. Show me what the whole stick looks like.
A: You say three-fourths?
R: Yeah, show me what the whole stick looks like. [Puts a teal piece in front of Jane as well, so that she can concurrently but independently perform the task.]
A: She has more teal than me [in her box of fraction rods].
R: I'll even it out [puts two more teal 6-rods in Austin's box of fraction rods].
A: [Takes out all three teal 6-rods and lines them up end to end. Simultaneously puts his hands at either end of the long result as if to measure the total length. Puts two teal 6-rods back. Gets out a black 7-rod and lines it up beneath the teal rod so that the left sides are aligned. He holds them up together in a single hand, aligning first the left side, and then the right side of the two bars together. He then puts them down and gets out a brown 8-rod and lines it up above the teal 6-rod, so that the left sides are aligned. After looking at the rods for one second, he indicates the brown rod is his response.]

Austin's initial reaction to the task was to treat the composite fraction as if it were a unit fraction; he abandoned this after the result was much longer than any of the available fraction rods. The researcher asks Austin to prepare to present his solution while Jane continues to find a solution. Austin pulls out a blue 9-rod and a black 7-rod again and compares them with the teal 6-rod. He lines up a single tan 1-rod next to the teal rod as if to see what is missing to make the black rod from the teal rod. He then lines up two tan rods next to the teal as if to see what is missing to make the brown 8-rod from the teal. The fact that he immediately found the amount to append onto the teal rod to make the black rod and the amount to append onto the teal rod to make the brown rod indicate that these may have been the actions he was doing mentally beforehand. Thus, Austin chose the brown rod as his response because the complement of the brown rod and the teal rod was one-fourth of the brown rod.

Austin then watches as Jane lines up three red 2-rods beneath the teal and four reds beneath the brown. He appears to be concerned that he might have made a mistake because he hadn't used the red 2-rod—he gets out three reds and compares them to the size of the teal 6-rod before the exchange below.

A: My presentation is, this [the brown 8-rod] is not the right piece.
R: Ok, remind me what the question is.
A: What is three-fourths of this [teal 6-rod]?
R: I said that's three-fourths of the whole.
A: Oh, the whole thing [emphasis on the word whole]. [He then gets out a blue 9-rod, appends three tan 1-rods to the teal 6-rod to make the blue, which he holds up as the answer.] I changed it.

When Austin changed his answer from the brown rod to the blue rod, it was immediately after he noticed that the red rod fit into the teal rod three times. It appears that although he had created the correct whole with a complement strategy, he had not previously conceived of the teal rod as three iterations of the complement of the brown rod and the teal rod.

Discussion

We have described how the cognitive conflict Austin faced when constructing composite fractions reflects the incompatibility of his PWS with his newly formed PUFS. Using a PUFS, students can conceive of the whole as a unit and of a unit fraction such as $1/n$ as a unit measure. Thus, the complement strategy allows such students to conceive of a fraction such as $(n–1)/n$ as the result of action between two units. However, as seen with Austin, the structure of the result of the strategy does not necessarily retain the multiplicative relationship with the unit fraction. That is, although 1 and $1/n$ might be understood via the relation that n iterations of $1/n$ make the whole, and $(n–1)/n$ might be understood as the amount resulting from taking away $1/n$ from the whole, $(n–1)/n$ might not retain the structure of $n–1$ iterations of $1/n$. From our field notes, it appeared that, for students who had already developed a PFS, the result from the use of a complement strategy *did* retain this structure and it was simply a shortcut. However, is unclear whether the use of the complement strategy might interfere with the construction of more advanced schemes, such as an iterative fraction scheme, which is necessary for an understanding of improper fractions (Steffe & Olive, 2010). Future teaching experiments might address limitations of our study, which include the short time frame, close examination of only a single student who utilized the strategy, and exclusive use of a linear representation of fractions.

THE AFFORDANCES AND CONSTRAINTS IN IMPLEMENTING TECHNOLOGY-ENHANCED LESSONS IN ELEMENTARY MATHEMATICS CLASSES

Amber Candela
University of Georgia
agc2436@uga.edu

John Olive
University of Georgia
jolive@uga.edu

This study evaluates the affordances and constraints that elementary teachers in grades 3-5 experience when attempting to implement technology-enhanced activities designed to help students learn elementary number and early algebra concepts. We make use of a new theoretical model of didactic interactions in the presence of technology: the Didactic Tetrahedron, and the notion of teachers' Zone of Free Movement (ZFM) with respect to the implementation of technology. Video records of sequences of three lessons in each of three classrooms implementing Dynamic Number (DN) activities using DN fraction tools, interviews with the teachers and interviews with pairs of students from each classroom working with the DN tools provide the data for establishing the teachers' ZFM and the nature of the interactions among teacher, student, task and technology (the vertices of the didactic tetrahedron).

Keywords: Elementary School Education; Instructional Activities and Practices; Number Concepts and Operations; Technology

Objectives and Purposes of the Study

Key Technologies (developers of *Dynamic Geometry* and *Dynamic Statistics* software) have been awarded a research and development grant from the National Science Foundation to develop *Dynamic Number* (DN) tools for students and teachers in elementary and middle school (Scher & Rasmussen, 2009). Our role in the project is to evaluate the use of the DN tools and curricula activities by both teachers and students, and assess their potential for helping students learn elementary number and early algebra concepts. In working with the Dynamic Number project, the main focus, so far, has been on the mathematical knowledge of the students involved in the project and how Dynamic Number has promoted their mathematical thinking with number concepts (Olive, 2011). While the project is in its third year, it has come to our attention that another component, relating to the teachers, is contributing to both the successes and difficulties with the software. This realization has led us to focus on the teachers and to collect data that will allow us to understand the teachers' point of view in implementing DN lessons in the classroom.

We are focusing on both the affordances and constraints the teachers' experience when using the technology-based activities in their elementary classrooms. The site for this study is a small rural elementary school (grades 3–5) in Southeast United States. It has a student body that is about 80% white with over 50% on free or reduced lunch. The teachers have little access to technology with only one computer lab for the entire school. Although each classroom has some technology, they vary with both the amount and the availability of technology such as interactive white boards and tablets, which creates a unique situation for each teacher as far as planning and implementing technology-enhanced lessons. This diversity has allowed the researchers to evaluate the software-based activities from multiple levels and gives a more comprehensive overview of how both the teachers and the students interact with the software tools in their classrooms and how the tools impact the mathematical understanding of the students as well as alter the instructional methods of the teachers as they use Dynamic Number activities in their classrooms.

Theoretical Framework

The theoretical framework for this study needs to take into account the role of the teacher (or more experienced other) in the didactical situations made possible by the integration of technology. Olive and Makar (2009) put forward a new tetrahedral model derived from Steinbring's (2005) didactic triangle (see

Figure 1) that integrates aspects of instrumentation theory (Verillon & Rabardel, 1995) and the notion of semiotic mediation (Vygotsky, 1978; Saenz-Ludlow & Presmeg, 2006). Olive's and Makar's new tetrahedral model illustrates how interactions among the didactical variables: student, teacher, task and technology (that form the vertices of the tetrahedron) create a space within which new mathematical knowledge and practices may emerge. Olive and Makar state "we place the student at the top of this tetrahedron as, from a constructivist point of view, the student is the one who has to construct the new knowledge and develop the new practices, supported by teacher, task and technology" (p. 168). In this study, however, our main focus will be on the vertex representing the *teacher* and the interactions represented by the edges connecting the teacher to *student, task* and *technology*.

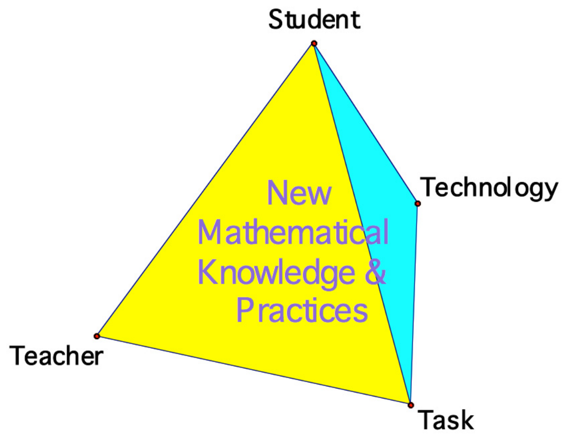

Figure 1: The didactical tetrahedron (from Olive & Makar, 2009, p. 169)

In analyzing these interactions represented by the three edges connected to the *Teacher* vertex, we make use of Valsiner's (1987) Zone of Free Movement (ZFM) which includes access to hardware, software and laboratories, access to teaching materials, support from colleagues, curriculum and assessment requirements, and students' attitudes and abilities.

Modes of Inquiry

The participants in the study are four teachers at a rural elementary school in the southeast, representing grades three through five. Three of the teachers are classroom teachers while one is a support teacher who both works with students needing extra help within the math classroom, as well as pulling out students for small group mathematics instruction. The majority of our data for this paper was collected during the implementation of the lessons involving the Dynamic Number fraction activities, along with semi-structured (Roulston, 2010) interviews of the teachers and interviews with pairs of students interacting with the software. We have been working with the teachers to choose a sequence of lessons to support their instruction on fractions. Working as a group, we chose specific Dynamic Number curriculum activities and then tailored those activities to the teacher's specified grade level to employ in the classroom. The lessons were taught in consecutive weeks so as to be able to capture the arc of the students' understanding of fractions and how the sequence of activities might promote the learning of fractions as well as being able to follow the teacher in their planning and implementation of the lessons with the use of Dynamic Number.

All lessons involving this sequence of activities were videotaped. Evaluation of the implementation of the tasks is ongoing, to ensure that the critical issues from the research perspective are being addressed. This evaluation component utilizes artifacts from the implementation including, but not limited to, videotaped segments and student work, as well as on-site observations and interviews with students and teachers. Audio-recorded interviews have been completed with each of the four teachers using a semi-structured interview guide in order to assess the Dynamic Number project from their perspective. We have also interviewed pairs of students from each class in order to gain the students' perspective. The student interviews were videotaped using the *Screenflow*® application to capture all of their work with the DN tools as the pair worked on related fractions tasks using a laptop computer. The students' interactions with one another and with the interviewer/researcher were captured using a video camera that feeds into the *Screenflow* recording using a picture-in-picture format.

Results

Currently the project is in its final stages with both the videotaping of the third and fourth grade teachers lessons as well as the interviews being completed. The initial findings from the interviews indicate both positive and negative aspects of the use of DN tools in the classroom. The constraints of the software include some activities being above the grade level of the students, as well as not being user friendly and time consuming. The affordances of the software include being a great dynamic visual representation of fractions for the students and the use of Dynamic Number tasks as a teaching tool to deepen the students understanding of fractions. The interviews with the teachers revealed that the DN tools for representing fractions were the only programs that they have worked with that allowed their students to manipulate and create their own fractions, and the teachers believe use of these tools aided students' learning of equivalent fractions, being able to compare fractions to one and adding fractions with a common denominator.

The third-grade teacher used a *Bluetooth* slate in order to give students access to the DN tools while working with the whole class on a projected screen, using one computer. The first class lesson used an activity focused on creating equivalent fractions, given a specific fraction using the DN *Fraction-Rectangle* tool. The second lesson focused on creating combinations of fractions with a given denominator that would sum to one whole using the DN *Fraction Number-line* tool. While the third grade teacher had positive experiences with the equivalent fractions lesson, stating "I think it went great, the kids took it far beyond what I thought they would, and I think they grasped the concept of equivalent fractions a lot faster with the program," she had thought some of the activities were not suitable for students at a third grade level saying that "it would have to be dead on with my standards and with my curriculum and have some training provided for my students." She felt that major modifications of the activities had to be made in order for her third graders to be able to complete them successfully on their own. In relation to this, she often pointed out that she had to spend too much time training her students on being able to manipulate the program for the minimal amount of time that the activities were used in class. The fourth grade teachers had similar sentiments and while they were able to successfully implement the two DN fraction activities in a small group setting, they also had concerns with a majority of the activities being above the grade level of their students.

Discussion

It is the hope that through a more detailed analysis of the lessons and interviews with the teachers, we will be able to delve more deeply into the affordances and constraints the teachers experience when implementing technology-based lessons at the elementary level. Since most of the focus has been on the students' interactions with the software, it is our plan to use the teachers' observations to help further evaluate the effectiveness of the DN software as a technology tool to aid instruction in the elementary classroom. The ability to work with teachers' at multiple grade levels with different students and activities provides a range of data on which to evaluate the potential of the DN tools and activities for enhancing the teaching and learning of fraction concepts and operations.

Our preliminary results do suggest that the potential of the DN tools is directly affected by the teacher's ZFM. Being restricted to using the tools with one computer and projector with the whole class limits what even an expert teacher can accomplish with these tools. The potential could be more likely realized if students could work in smaller groups to be able to better explore with the tools at their own pace; also, if the program allowed for more adaptation by the teachers to create activities more targeted to the grade level of their students. On a more positive note, all the teachers had positive comments on how the interactive visual models of Dynamic Number helped their students be able to connect to the mathematics. They were pleased with how the students were able to represent fractions, and compare side by side the fractions that they were working with. This allowed the students to have direct visuals of the fractions, and be able to compare if they were equivalent, greater than one, less than one, etc., which were all components of the lessons the teachers implemented. In its current form, however, there is a need for ongoing support for the teachers in order to address the limitations of using the DN software in their instruction. A more robust, child-friendly user-interface, with easy-to-use design features for the teacher, could enlarge teachers' *Zone of Free Movement* with respect to implementation.

It is important to explore pre-service secondary mathematics teachers' (PSMT) mathematical reasoning as it can influence their beliefs and future instructional practices. A cross-case analysis was conducted with PSMT's to better understand their ability to reason about mathematics and integrate relevant technology. By using the Mathematical Task Framework developed by Stein and Smith (1998), preliminary data analysis indicated that the mathematical task reasoning is lower than desired for preparation to teach certain concepts.

Keywords: Reasoning and Proof; Teacher Education–Preservice; Technology

Purposes

The National Council of Teachers of Mathematics (NCTM, 2000) identifies technology as an important principle for high quality mathematics education because it has the potential to enhance mathematics learning, support effective mathematics teaching, and influence what mathematics is taught. According to their view, technology can promote student understanding through use of multiple representations and experimentation (NCTM, 2000). When technology is used in this way, it has the potential to promote students' mathematical reasoning. There have been some studies to analyze pre-service mathematics teachers' mathematical reasoning with and without technology enhanced environments (Zembat, 2006; Christou et al., 2004). These studies were mostly conducted with elementary pre-service mathematics teachers. Studies investigating the quality of pre-service secondary mathematics teacher's (PSMT) mathematical reasoning with and without technology integration for pre-calculus or calculus subjects are limited in number (Ball, 1990; Simon & Blume, 1994; Zazkis & Campbell, 1996; Pandiscio, 2002).

To contribute to our currently limited understanding of the connections between technology and PSMTs' mathematical reasoning, this study addresses the research question "What is the level of reasoning that each PSMT exhibited in each mathematical task, with and without the use of technology?"

Mathematical Reasoning and Conceptual Understanding of PSMTs

Many pre-service mathematics teachers do not know why they use specific operations or follow a procedure (Ball, 1990; Simon & Blume, 1994; Lloyd, 2006). For example, Ball (1990) found that both secondary and elementary teachers demonstrated a narrow understanding of division that mostly emphasized remembering a particular rule without a conceptual frame attached. NCTM (2000) identifies combination of factual and procedural knowledge with conceptual understanding and mathematical reasoning as the key principle for students' learning of mathematics. PSMTs are expected to teach reasoning skills, but this lack of conceptual understanding often inhibits teachers' efforts to promote reasoning in their own classrooms (Ball, 1990; Simon & Blume, 1994; Lloyd, 2006).

Beliefs about Technology and Mathematical Reasoning

Another NCTM (2000) expectation from mathematics teachers is the integration of technology into the classroom to favor students' reasoning and sense making. The effectiveness of technology integration for students' learning depends on teachers' beliefs and views about technology. Chen (2011) found that pre-service math teachers viewed technology as an instrument to increase the efficiency of the instruction and educational outcomes rather than as a mediating component of students' learning. Chen claims that the different views of technology, either instrumental or substantive view, would determine the quality of reasoning and sense making activities during instruction.

Zembat (2006) found that dynamic geometry environment facilitated PSMTs' reasoning to deal with new situations and applications, whereas paper and pencil environment only allowed a type of reasoning on formulas and procedures to abstractly solve mathematics problems. Contrary to Zembat's findings, Pandiscio's study (2002) showed that technology inclusion did not amplify quality of teachers' reasoning on proofs in geometry.

Cognitive Load Theory (CLT) is an instructional theory that is grounded in the idea that working memory is limited with respect to the amount of information it can hold and the number of operations it can perform on that information (van Gerven et. al., 2003). Cognitive load is comprised of intrinsic load (the complexity of the information or task given), extraneous load (the techniques in which the information is presented), and germane load (the complex schema helping the learner move from novice to expert). One implication of CLT is that minimizing extraneous cognitive load will maximize the germane load (Chipperfield, 2006). This study is based on the hypothesis that the use of technological tools will reduce extraneous load, increasing germane load, and thus increasing the level of reasoning used by the participant.

Theoretical Framework

Stein and Smith's (1998) Mathematical Task Framework identifies three phases through which mathematical tasks pass, with four possible levels of reasoning in each phase. The three phases are (1) tasks as they appear in instructional materials, (2) tasks as set up and presented by teachers, and (3) tasks as implemented by students. All three phases are influential on what students learn. Due to the nature of this study, which did not involve direct instruction, only the first and third phases were addressed. Within each phase, the four possible levels of reasoning from lowest to highest are (i) memorization (reproduction of facts, formulas, or definitions with no connection to concepts or meanings); (ii) procedures without connections (algorithmic thinking without developing mathematical understanding); (iii) procedures with connections (algorithmic thinking with an emphasis on developing mathematical understanding); and (iv) doing mathematics (complex non-algorithmic thinking that demonstrates understanding of mathematical concepts, processes and connections) (Stein & Smith, 1998). To assess the potential of PSMT's ability to teach with mathematical reasoning, we seek to determine which level of reasoning they have exhibited and whether they can make strong arguments for how and why they solved various mathematical tasks of varying difficulty. Additionally, we will utilize the same framework to determine if their level of reasoning is altered by the use of a technological tool in completing similar tasks.

Methods

The participants for this study were secondary mathematics preservice teachers enrolled in a senior level methods course during the fall of 2011 at a large research institution in the southeastern United States. Data were collected from September to December of 2011. Data consisted of one semi-structured, one-on-one interview (approximately 20 minutes in length), one task-based interview (involving students solving mathematics with transcriptions of their verbal reasoning), and course artifacts (e.g. student reflections and lesson plans). The primary source of data used in this analysis was the task protocol with other data sources used to support findings. In this mathematical task interview, each participant was presented with four mathematical tasks, two tasks to be completed with only pencil and paper and two tasks to be completed with technology tools. Technology tools were chosen at the discretion of the participants from those provided by the interviewer, including a Casio® graphing calculator, Microsoft Mathematics 4.0®, SmartBoard Math Tools®, and Geogebra®. The set of tasks to be completed with technology tools were the same as the tasks in the set to be completed without technology tools, with the use of decimals in the tasks to be completed with technology tools. Therefore, Task 1 was similar to Task 3, and Task 2 was similar to Task 4. The level of mathematical reasoning was analyzed by all three researchers, using the four-level scale adapted from the Mathematical Task Framework of Stein and Smith

(1998). A cross-case analysis was conducted where each case was first considered individually (Yin, 2009). Reliability was ensured by triangulation of the multiple sources of data.

Results

Preliminary analysis indicate differences in how PSMT's reasoned through mathematical tasks with and without technology. Task 1 and Task 3 called for solving a 2-variable system of equations. When using only pencil and paper, All participants solved Task 1 with a level 2 reasoning involving procedures without connections, but when using a technology tool to solve the same problem in Task 3, four of the seven participants increased to a reasoning level 3 (procedures with connections) by graphing the equations and determining where they intersected for the solution. Task 2 and Task 4 involved determining the length of an h" square cut from each corner of a 4" × 6" rectangle to maximize the volume of a box that would be formed if the sides were folded up to form an open-top box. Completion of this problem in Task 2 without technology involved four of the participants determining the equation, finding the first derivative, and solving for the roots, while three participants used a guess-and-check method. The same problem was presented in Task 4 with more difficult dimensions and allowed the use of an applet in Geogebra® in addition to the other technology tools. Four of the participants maintained the same level of reasoning as in Task 2, while one participant decreased the level of reasoning and two participants increased their level of reasoning (see Table 1).

Table 1: Preliminary Reasoning Analysis

	Without Technology Tools		With Technology Tools			
	Task 1	Task 2	Task 3	Tool(s)	Task 4	Tool(s)
Participant 1	2	3	3	Casio® GC	3	Geogebra® applet
Participant 2	2	2	2	Casio® GC	3	Geogebra® applet
Participant 3	2	3	3	Casio® GC	2	Geogebra® applet & Casio® GC
Participant 4	2	3	2	Casio® GC	3	Casio® GC
Participant 5	2	2	3	Microsoft Math 4®	3	Geogebra® applet
Participant 6	2	3	3	Casio® GC	3	Geogebra® applet
Participant 7	2	2	2	Casio® GC	2	Geogebra® applet

Transcriptions of the task interviews revealed some reasons why PSMTs may not use a higher level of reasoning when utilizing technology to complete mathematical tasks. Participant 7 enthusiastically claims that technology should be used to "…enhance learning, not as a crutch." However, when asked about why the technology was an advantage for completing Tasks 3 and 4, this participant admitted "…the advantage was due to lack of my math skills." This was evidenced in how this participant completed Tasks 1 and 3, both problems asked to solve a 2-variable system of equations, in the same way with the calculator as with pencil and paper.

Preliminary results also indicated that PSMTs do not feel comfortable integrating a variety of technology tools with instruction. Participant 3 indicated a comfort with graphing calculators, but had only experienced the other tools during that semester. Participant 7 affirmed the same limited focus on technology integration due to "…lack of experience and competency…" with technology tools other than graphing calculators.

Discussion

Visions for mathematics instruction, such as encouraging students' reasoning, their construction of knowledge, and utilizing their understanding with technology integration, are expected from teachers with the emergence of curriculum standards (Frykholm, 1996). Initial findings from this study indicate that the level of reasoning PSTM's are using with and without technology is not ideal in actualizing these reform practices. This has implications for teacher education programs and how these programs can help provide opportunities to use higher level reasoning skills both with and without technology.

The purpose of this study was to examine the ways in which prospective teachers designed and implemented technology-based tasks with middle school students enrolled in a high school geometry course. Teachers designed geometry tasks that varied in scope and posed questions that focused students on features of the technology and mathematics in different ways. Analysis of six prospective teachers' implementation of their tasks is provided.

Keywords: Technology; Geometry and Geometrical and Spatial Thinking; Teacher Education–Preservice

Introduction

When preparing teachers to use technology to teach, it is imperative that they understand the specifics of the technology tools they are using. Even more important, teachers need to know how to design and implement mathematical tasks that support students' learning while using these tools. Dick (2011) states, "the value of technology to the teacher lies not so much in the answers it provides, but rather to the questions it affords" (p. 2). The importance for teachers to select and implement worthwhile mathematical tasks to engage all students in learning mathematics has also been emphasized as a significant pedagogical activity by the National Council of Teachers of Mathematics (NCTM, 1991) and shown by researchers to be a critical component of effective mathematics classrooms (Stein, Smith, Henningsen, & Silver, 2000). Some studies have examined how teachers design tasks for students that utilize technology (e.g., Laborde, 2002) or implement technology-based tasks with students (Hollebrands & Heid, 2005; Lee, 2005). And while there is research that has focused on the implementation of non-technology based tasks in mathematics classrooms (e.g., Stein, Grover, & Henningsen, 1996), few studies have considered how teachers design and implement mathematical tasks with students while using technology. The purpose of this study is to examine how prospective mathematics teachers (PSTs) design and implement geometry tasks using *The Geometer's Sketchpad* (GSP) with middle school students enrolled in a high school geometry course.

Background

When dynamic geometry programs were developed and introduced more than two decades ago there was great excitement about and enthusiasm for their uses with students. In particular, educators were encouraged about how students' uses of these tools could support students' movement from a focus on empirical drawings to theoretical generalizations (Cuoco & Goldenberg, 1997; Laborde & Laborde, 1995). However, teachers' adoption and use of this technology in high school classrooms has been slow (e.g., Becker, 2000, Kasten & Sinclair, 2009). This is perhaps related to the lack of time teachers perceive that they have to teach both content and technology skills. It may also be related to the need for teachers to redesign mathematical tasks and lessons to incorporate the use of this tool.

Designing tasks that effectively use technology tools requires teachers to carefully consider mathematics, learning, and teaching. In a three-year study of teachers learning to design tasks to incorporate dynamic geometry technology, Laborde (2002) found that several teachers initially designed tasks for which the technology served as a visual aid or used the tool to do similar non-technology based activities in a more efficient manner. However, over time teachers began to develop tasks that could only exist in the technology-based environment. Transformations of teachers' views about technology-based tasks were mediated by their knowledge of the tool, their knowledge of mathematics, and their apprehensions about what students were learning.

While the design of the task is a critical component of the learning process, its implementation by teachers is also important. How teachers introduce the task and technology, pose questions, and offer assistance to students as they are working can impact what is learned. In particular, how teachers and technology tools focus students' attention on particular aspects of mathematics can influence what students notice and learn from these interactions (Lobato & Ellis, 2002; Lobato, Ellis, & Munoz, 2003). Lobato and Ellis (2002) define the focusing effect of technology as "the regular direction of users attention toward certain subject matter properties over others" (p. 299) and expands this to consider the focusing phenomena, which relates to how other aspects of a classroom environment (e.g., teachers, curricula, tools) "direct attention toward certain mathematical properties over others" (Lobato, Ellis, & Munoz, 2003, p. 1).

In an instructional setting, questions can play an important role in focusing students' attention. Mason (1998) identified three types of questions: questions that test information, questions that seek information, and questions that suggest a particular focus. Questions that test information are particular to classrooms. The teacher poses a question to test what students know (What is the definition of a square?). Questions that seek information are common in our every day experiences (Where is the nearest gas station?). When teachers are implementing technology-based tasks they ask all three types of questions to which Mason refers. And as Lobato and her colleagues suggest, how these questions focus students influences what they learn. The research question that guided this study was: In what ways do prospective teachers focus students on technological features and geometric objects and relationships as they implement the task with students? This paper will focus on the second question.

Methods

Participants were paired and assigned to design, share, and implement a thirty-minute, exploratory task using *The Geometer's Sketchpad* (GSP). PSTs implemented their tasks individually with a middle school student. Following a case study design (Patton, 2002), six PSTs, representing different subgroups in the mathematics education program, were selected for closer analysis (Jessica and Matthew, Audrey and Victoria, Delta and Jonah). For these three pairs, the teaching session was videotaped. There were three components to the task: (1) a pre-constructed GSP file; (2) a Word document posing the task for the middle school student; and (3) a Word document describing anticipated responses, including a list of questions to guide students, and a description of how the task could be differentiated.

To analyze the ways in which teachers were designing and implementing their tasks, we considered how their questions (written and verbal) focused students. Codes were generated to analyze the focus of the questions, prompts, and statements exchanged between the PST and student while working on the task. The direction of the conversation (student to teacher or teacher to student) was also considered.

The data were analyzed using the qualitative data analysis tool, *Transana* (The Board of Regents of the University of Wisconsin System, 2010). The researchers coded a portion of a single transcript linked to the video recording and discussed differences in coding until a consensus was reached. Examples and definitions of codes were developed and refined during this process. This was repeated until there was a high level of agreement among the coders. Then each researcher analyzed one to two video recordings and met with another researcher to discuss commonalities and differences in the ways the PSTs implemented the same task. Codes were analyzed to identify trends and themes in questions and statements made by PSTs and students.

Conclusions and Summary

This study was designed to examine the ways in which prospective teachers designed and implemented geometry tasks using *The Geometer's Sketchpad* (GSP) with middle school students enrolled in a high school geometry course. For three pairs of PSTs, we identified similarities and differences in how their tasks were designed and implemented with students.

The mathematical goals for each of the three tasks were similar: discover a theorem, develop definitions, and describe geometrical relationships. Two of the pairs wanted the student to discover a theorem. In one case (Jessica and Matthew), the theorem was fairly obvious and did not require much investigation on the part of the student. In the other case, the pair of PSTs (Delta and Jonah) wanted students to observe that the hypotenuse of an inscribed right triangle is also the diameter of a circle. Unless the students had previously studied theorems related to circles, it was probably novel and perhaps also interesting. Audrey and Victoria chose to provide students with examples of different triangle centers and through students' interactions with these sketches develop definitions of the centers, identify relationships, and consider similarities and differences among them. In general, the PSTs did not push students to explain why a relationship might be true. Students were simply asked to record what they observed. All three of these tasks seemed to go beyond simply "amplifying" what they might also do on paper (Laborde, 2002). The tasks required students to construct or drag and observe measurements or other invariants; however, how these interactions were encouraged during task implementation varied.

The participants were paired when they designed their tasks and then they implemented individually with different students. For two of the pairs (Jessica and Matthew and Audrey and Victoria) there were similarities in how their questions focused students on mathematics and technology. However, there were striking differences in the way Delta and Jonah implemented their tasks. Because this task required students to construct, and their plan involved different accommodations for supporting students, their decisions about how to guide students in their technological work had profound effects on their interactions and they ways in which they focused students on mathematics and/or technology. The differences in their approaches are interesting and the consequences of the two approaches in terms of what each student learned are unclear. This could be a question that is considered in future research.

There also seemed to be a difference in the type of task and sketch that was designed and how consistently the task designers were able to implement the task with their student. Jessica and Matthew and Audrey and Victoria were working with closed and open-middled tasks, respectively, that were well coordinated with the pre-constructed sketches. These pairs of PSTs were very similar in their implementation of the task and use of GSP with their students. However, Delta and Jonah, worked with an open-ended task that required much construction within GSP and task questions that did not explicitly prompt for measurements or dragging actions, differed dramatically in their implementation.

Although these cases are not enough to make a strong statement, we wonder if it is more straightforward for new teachers, or teachers new to using technology, to implement a task using a pre-constructed sketch that aligns more carefully with Sinclair's (2003) design principles. In particular, it may require more effort in task and sketch design to have a strong connection between task statements that focus a student's attention or prompt for actions in GSP with elements made available in the pre-constructed sketch to draw students' attention and enable such actions. However, such effort might make implementations of the task more consistent across teachers.

PRIMARY SCHOOL TEACHERS' DISPOSITIONS TOWARD WEB-BASED INSTRUCTION IN MATHEMATICS

Fenqjen Luo
Montana State University
fluo@montana.edu

This study investigated 12 primary school teachers' dispositions toward web-based instruction. In terms of cognitive dispositions, more conceptual than procedural or strategic lessons were planned to be used. Still, compared to traditional classroom instruction, less conceptual and strategic activities were designed for web-based instruction. In terms of affective dispositions, the teachers believed that students can benefit from web-based instruction because of its instant feedback and motivating environment. Most of them felt confident and comfortable to conduct web-based instruction. However, most of them believed that web-based instruction can only be used to reinforce conceptual knowledge taught in a traditional classroom setting.

Keywords: Technology; Cognition; Beliefs and Attitudes; Number Concepts and Operations

Introduction

The applications of technology hold profound potential in mathematics teaching and learning (NCTM, 2000). Although the use of web-based instruction (WBI) is a relatively new phenomenon of technology applications, a number of studies have been carried out to determine the potential of WBI for enhancing mathematics teaching and learning in a range of contexts. While teachers have increasing opportunities to teach by utilizing web-based resources, their dispositions regarding the use of WBI in the mathematics classroom should become an important research topic for researchers and educators.

The purpose of this study is to investigate 12 U.S. primary schools teachers' dispositions toward WBI in a mathematics classroom. Teachers with productive dispositions show "habitual inclination to see mathematics as sensible, useful, and worthwhile, coupled with a belief in diligence and one's own efficacy" (National Research Council, 2001, p. 116). Teacher dispositions continue to be essential elements of teacher preparation and teacher quality. In this study, WBI is a teaching setting in which teachers use web-based resources to teach mathematics in a classroom. Traditional classroom instruction (TCI) is contrasted as a teaching setting in which no websites or related resources are applied in a classroom. The significance of this study is to provide useful information that enables administrators and teacher educators to better understand teachers' dispositions toward WBI in mathematics. Consequently, a better focused professional development course for mathematics teaching and learning could be designed, developed, and implemented.

Theoretical Framework and Literature Background

The overall theoretical framework guiding our attempt to explore teachers' dispositions toward using web-based resources and tools to teach students is based on Thornton's perspectives on dispositions (2006). Dispositions are viewed by Thornton as "habits of mind including both cognitive and affective attributes that filter one's knowledge, skills, and beliefs and impact the action one takes in a classroom or professional settings" (p. 62). Drawing from this perspective, we propose to capture not only the affective patterns of teacher beliefs and attitudes toward web-based instruction (WBI) in mathematics, but also the cognitive patterns of knowledge and skills that teachers expect their students to construct through WBI. Based on such a multidimensional perspective on dispositions, this study identified two major themes to facilitate the investigation of teachers' dispositions toward WBI.

The first theme focuses on teachers' cognitive dispositions, addressing the types of mathematics knowledge and skills they expect their students to construct. To advance the measurement of teachers' cognitive dispositions toward WBI, it is important to have an appropriate classification scheme to categorize the types of mathematics knowledge and skills. Based on the National Research Council's (2001) strands of mathematical proficiency and National Center for Education Statistics' mathematics achievement-level descriptions (NCES, 2011), we propose to categorize the mathematics knowledge and skills that expect their students to construct through WBI into three common types: (1) conceptual understanding (CU)—comprehension of mathematical concepts, operations, and relations, (2) procedural fluency (PF)—skill in carrying out procedures flexibly, accurately, efficiently, and appropriately, and (3) strategic competence (SC)—ability to formulate, represent, and solve mathematical problems by integrating conceptual and procedural knowledge.

The second theme focuses on teachers' affective dispositions, addressing their beliefs regarding WBI. Among relevant studies (e.g., Kao & Tsai, 2009; Lin, 2008), teachers' beliefs regarding the benefits of utilizing WBI, the importance of WBI, and their self-efficacy for using WBI are often explored. Lin, for example, investigated whether pre-service teachers think Web-based resources are enjoyable and stimulating, whether they believe it is imperative to utilize WBI, and whether they feel comfortable and confident regarding use of web-based resources in a mathematics classroom. Overall, research has supported positive beliefs on the use of WBI. In addition to the research interests described above, this study is interested in teachers' beliefs about how WBI should be implemented in a mathematics classroom, and in the potential impact of their beliefs on their actions.

Research Questions

The two themes identified above were used to generate the following two clusters of research questions. They are:

1. What are the types of web-based mathematics knowledge and skills that teachers expect their students to construct? What are the differences or similarities between web-based and traditional instruction in terms of the types of mathematics knowledge and skills that teachers expect their students to construct?
2. What are teachers' beliefs regarding the benefits of utilizing web-based instruction (WBI)? What are teachers' perceptions of the importance of WBI? What are teachers' self-efficacy beliefs regarding WBI?

Methodology

Participants

Participants included 12 in-service primary school teachers in southeastern United States. Since insightful perspectives are more likely to be identified from the teachers who have sufficient understanding of the nature and use of web-based instruction (WBI), the teachers were provided four professional development hours regarding how to use web-based resources and tools to deliver instruction and assessment before collecting data. In addition, the teachers were asked to review research and teaching literature to gain sufficient understanding about WBI.

Data Collection and Analysis

To add depth to our descriptions about primary mathematics teachers' dispositions toward WBI, this study collected and analyzed qualitative data in relation to two themes: (1) teachers' cognitive dispositions addressing the types of mathematics knowledge and skills, and (2) teachers' affective dispositions addressing their beliefs regarding WBI.

To enhance the validity, this study adopted the process of triangulation by which multiple methods were used to collect data (Gall et al., 1996). Data were collected through the following methods: First, data were collected from the participating teachers' web-based and traditional instructional plans. The data drawn from teachers' traditional instructional plans were used as a comparative referent to better unpack teachers' tendencies in selecting knowledge and skill types for a WBI setting. Second, data were collected from a survey with several open-end questions regarding the teachers' beliefs about the benefits of utilizing WBI, their perceptions of the importance of WBI, their self-efficacy beliefs regarding WBI, and their beliefs about how WBI should be implemented. Lastly, data were collected from the teachers' discourse which reflected their own overall dispositions toward both WBI and TCI.

Results

As discussed previously, we collected data related to two themes: (1) types of mathematics knowledge and skills in a web-based instruction (WBI) setting and traditional classroom setting (TCI), and (2) teacher beliefs toward WBI. The results below reflect each of the themes.

Types of Mathematics Knowledge and Skills in a Web-Based Instruction Setting

The participating primary teachers selected either addition or multiplication as their lesson topics. We found half of the participating teachers planned similar types of WBI and traditional classroom instruction (TCI) lessons while half of them did not. We also found that the teachers expected their students to construct more conceptual understanding types of activities (CU) than procedural fluency (PF) or strategic competence (SC) lessons in both the WBI and TCI settings. However, it was found that the teachers planned a more procedural fluency type of lessons in a WBI setting than in a TCI setting, and fewer strategic competence types of lessons in a WBI setting than that in a TCI setting. Further, only one of the 36 web-based lessons developed by teachers can be categorized as a strategic lesson. Generally speaking, compared to TCI, lessons for WBI placed more emphasis on conceptual understanding and procedural fluency than on strategic competence.

Teacher Beliefs toward Web-Based Instruction

The findings for teachers' beliefs regarding WBI are grouped according to predetermined questions:

Benefits from utilizing web-based instruction. Several teachers believed that students would benefit from the motivating learning environment provided by WBI. Others believed that WBI is beneficial because it effectively provides instant feedback. Different from the peers, one of teachers believed the benefits of WBI depend on the student's age. She felt web-based activities are more beneficial to older students.

Role of web-based instruction. As we live in a technological society today, there is no surprise that all of the participating teachers agreed that the use of WBI is essential. However, no matter how impressive WBI is, most of them only considered WBI as a supplemental method for enhancing concepts and strategies developed in a TCI setting. Generally speaking, in their perspective, WBI is less important than TCI.

Self-efficacy beliefs. Most of the teachers felt confident about doing WBI. This study found personal factors such as teaching and workshop experience often contributed to teachers' efficacy beliefs.

Discussion

The findings of this study were limited by a small sample of primary school teachers, and the limited number of tasks used in the investigation. Thus, the research results should be considered as insights rather than generalizations. The results of this study raise several questions. Let us discuss the results from the first theme—teachers' cognitive dispositions toward WBI. It is interesting to investigate why the teachers hesitated to plan strategic lessons in a web-based setting. Is it possible that it is less convenient to engage students in strategic lessons than conceptual or procedural lessons in a web-based setting? Are strategic lessons less available than conceptual and procedural lessons on websites? It is also interesting to know why the teachers have planned less conceptual and strategic lessons, and more procedural lessons in web-based settings. Is it possible that the teachers' cognitive dispositions depend on the type of instructional setting or their affective dispositions toward WBI such as the beliefs that conceptual understanding has to be taught in a traditional classroom setting first? Is it possible that the knowledge or skill types of available web-based teaching resources are different from those in traditional classrooms, or the others? It is interesting to examine these questions in the future.

Next, the results show most of the teachers hold similar affective dispositions toward WBI. Most of them believed that WBI is beneficial not because the nature of knowledge and skills provided by WBI but because of pedagogical features in a web-based setting such as providing instant feedback, entertaining and motivating environment, individual advancement and interactive opportunity. What changes should WBI to be made to make teachers feel beneficial due to cognitive growth as well? Most of them also believed that WBI should play a supplemental role for reinforcing concepts taught in a traditional classroom setting. Will this belief change with the progress of technology used to support WBI? Third, most of them believed they are effective and confident web-based instructor. However, although a lot of descriptive reflections regarding each affective question were provided, it remains unclear that how their affective dispositions can be connected as a triad. It is interesting for future study to explore how teachers' affective dispositions are networked.

STUDENT PERCEPTIONS ABOUT THE USE OF EDMODO

Diana L. Moss
University of Nevada, Reno
dmoss@unr.edu

Heather Glynn Crawford
University of Nevada, Reno
hcrawford@unr.edu

A case study methodology was used over an academic quarter to analyze students' perceptions regarding the incorporation of the educational blog Edmodo in their algebra class. Students that did not regularly participate in class were willing to be part of the class community on Edmodo. Edmodo contributed to the students' learning experience in their algebra class.

Keywords: Technology; Middle School Education; Beliefs, Attitudes

Introduction and Background of the Study

A significant amount of research into the use of technology in education exists (Conole, 2010) and much has been written about the potential of blogs to support learning in higher education (MacBride & Luehmann, 2008). However, little of this research is based empirically and even fewer of these studies have been peer-reviewed (MacBride & Luehmann, 2008). Moreover, limited research has occurred investigating middle school students' perceptions about the use of blogs in their learning. Therefore, a next logical step would be to consider the impact of a class blog on a middle school mathematics class. The purpose of this study was to explore the students' perceptions of the contribution of a social learning network, Edmodo, to their learning process.

Prior research has been conducted to illuminate the perspectives of teachers regarding educational blogs. Glass and Spiegelman (2007) discovered that blogs provide a platform from which students learned from each other as they shared their ideas. It has also been concluded that the incorporation of a class blog allows teachers to focus on creating additional forms of participation and that the educational value of blogs depends largely on how teachers choose to structure and use them (MacBride & Luehmann, 2008). Finally, according to Smith, Ferguson, and Caris (2003), communication in web courses is profoundly different than classroom courses, and this phenomenon results in greater student-instructor equality.

As noted above, student-teacher discourse on blogs is different from student-teacher interaction in classroom discussions. Blogs facilitate this beyond the traditional classroom in that they engage students in learning until they have achieved success (Spiegelman & Glass, 2008). Mathews's (2009) findings suggest that students increase their use and understanding of mathematical vocabulary by creating a community of discourse based on mathematics. Online discussions also allow students to get updated information easily in that they can access course materials at their own pace and at their own convenience (Chan & Waugh, 2007).

However, limited research pertaining to the perceptions of students and online learning has been conducted. Makri and Kynigos (2007) advocate that online learning provides a rationale for the change in roles and practices of the participants. These findings are based on the integration and use of a blog, both as a communication medium and as a mechanism for provoking reflection. My study focuses on the student perceptions of using the online social networking and blog site Edmodo.

Theoretical Framework: Social Constructivism

Social constructivism is primarily a theory of learning, in which the teacher's role is mainly to structure or guide the student discussion, as opposed to a theory of teaching (Brophy, 2002;Vygotsky, 1978). Additionally, scholars contend that constructivist learning must incorporate authentic learning tasks (Applefield, Huber, & Moallem, 2001). This study draws on a social constructivist perspective (e.g., Vygotsky, 1978) to frame and interpret this study because this theoretical perspective takes into account the critical role of social interaction and dialogue in student learning. Social constructivism provides a powerful lens for studying the use of blogs in education because a central tenet of this theory is that learners construct their own understanding by participating in meaningful shared discourse (Vygotsky, 1978).

A secondary theory I drew upon maintains that classroom experiences must mirror the complexity of society (Bereiter, 2002; Dede, 2000). In 2007, Pew Internet and American Life Project found that 55% of online teenagers, ages 12-13, are avid users of social networking sites. Because blogging has become such a common means of communication among this age group, the consideration of the educational potential of using blogs, such as Edmodo, in middle school instruction is worthwhile (as cited in Lenhart, 2007).

Context and Methods of the Study

A case study methodology was used over an academic quarter to provide an in-depth analysis of students' perceptions regarding the incorporation of the educational blog Edmodo in their algebra class. This study is an intrinsic case study because it is an in-depth exploration of a bounded system and the case itself is of interest (Creswell, 2002; Stake, 1995). The following question guided this study: what are the perceptions of eighth grade students about the use of Edmodo in their algebra class?

Researcher Role

I began teaching the Advanced Algebra class at this school in the fall semester of 2010. Prior to this, I taught math continually for four years at the local community college, as well as at the university level. I have been active as a private math tutor for over 10 years. Additionally, I taught mathematics to seventh and eighth grade students for one semester while completing my student internship. I have my master's degree in Applied Mathematics and a license to teach secondary mathematics. Currently, I am the advanced algebra teacher at a small private school and a mathematics instructor at the local university. My interest in this research topic stemmed from my personal experience with Edmodo while teaching my eighth grade algebra students.

I was the only math instructor for these students and was the principal and only investigator during this study. As a researcher-participant (Creswell, 2002; Stake, 1995), I instructed the students in their daily assignments and guided them in the use of Edmodo. In my role as investigator, I authored the questions and collected and analyzed the data.

Data Sources and Data Collection Procedures

Data was collected during the fourth quarter of the 2010-2011 school year (March 28, 2011 to May 2, 2011). Primary data sources included online journals, weekly questionnaires, online interviews, and one-on-one interviews (Creswell, 2002). Secondary data sources were lesson plans with memos and student work samples.

Data Analysis

The objective of this investigation was to gain insight from the students directly involved in the case study. The main categorizing strategy that I used was coding the data by organizing it into broader themes (Maxwell, 2005). Every weekend during the ongoing study, all text was systematically searched and organized by emergent themes in an iterative pattern over the research period, following the approach of qualitative data analysis outlined by Bogdan and Biklen (2003).

Discourse analysis was used to study the online blog interviews and discussions. Gee (2011) suggested that discourse analysis could be revealing about the identities, relationships, and actions behind language. The remaining posts were analyzed individually and categorized into emergent themes. Also, online journal entries were analyzed individually and separated into themes.

Furthermore, student work samples and lesson plans were used to help analyze the student perceptions of the blog. The collection of data using a variety of methods and sources is one aspect of triangulation (Maxwell, 2005). I triangulated the data to reduce the risk that the conclusion of the study reflects systemic biases. It also allowed me to gain a broader and more secure understanding of student perceptions about the use of Edmodo.

Results

Immediate Feedback and Multiple Perspectives

Edmodo allowed the participants, my students and me, to communicate online. The blog was an extension of the class in that students could go there to work together and get help from each other. This classroom community created the social setting for learning to occur outside of school. Students remained part of their learning environment, even when they were absent from school. Additionally, every member on Edmodo could share resources, such as homework due dates and test information. These findings coincide with those of Chan and Waugh (2007) in that the blog allowed students to get updated information easily because they could access course materials at their own pace and at their own convenience.

Pose Questions, Answer Questions, and Join Other Conversations

The blog is an open forum in which every member can view the discussion threads. This platform encouraged students to work together on their math homework and, through this communication, students engaged in question-answer discussions. For example, a student said, "On homework, when you forget the first step of the problem you can ask people on Edmodo." Moreover, student discussions informed my instruction on the following day. Thus, Edmodo created a student centered learning environment in my class.

Enrichment Opportunity

Students viewed the blog as an enrichment opportunity. For instance, one student commented, "My teacher uses Edmodo to post practice problems." Another student responded, "It's really easy to post stuff and send you messages and also find assignments and polls and all that stuff on the side." Others suggested that Edmodo be used for extra credit opportunities such as having them solve challenging math problems on the discussion board or by creating math-centered online games. Additionally, many students requested a chat application so that they could chat privately, as opposed to using the open discussion forum. Some students suggested that Edmodo allow them to see those blog members that are on the site and those that are not.

Conclusion

Multi-level Communication and Extended Learning Environment Beyond the Classroom

Edmodo not only allowed students to communicate with each other and me outside of class, but also gave them access to course materials and information. Moreover, I was able to assess the students' understanding of the algebra concepts by reading and analyzing their discussions on Edmodo. Additionally, some students that were not comfortable speaking or asking questions in class would pose their questions to me, or to other students in the class, using the blog. These students did not regularly participate in class, but were willing to be involved and to be part of the class community on Edmodo. This may imply that this social network site helped equalize the balance of power among students and their teacher similar to the findings of Smith et al. (2003).

This study was based on the theoretical framework of social constructivism (Vygotsky, 1978). Further research on Edmodo could include the theory of connectivism (Siemens, 2005) to show how learning is a network-forming process. In addition, further research needs to be conducted on how teachers implement the use of blogs to teach mathematics. Furthermore, the apparent differences between teacher implications and actual student uses of educational blogging sites might be of interest, especially with the emergent trend of the integration of technology in all levels of education.

SUPPORTING STUDENTS' CONSTRUCTIONS OF FRACTIONS SCHEMES: IS THERE AN APP FOR THAT, TOO?

Anderson Norton

Jesse L. M. Wilkins
Virginia Tech
wilkins@vt.edu

Steven Boyce
Virginia Tech
sboyce@vt.edu

We share results from a pilot study that investigated the effectiveness of the Candy Factory app in supporting the construction of new fractions schemes. Pre- and post-tests among three sixth-grade classes (two experimental and one control) indicate that substantial growth can be supported through game play, but that app design must account for students' existing ways of operating, as well as additional factors affecting engagement.

Keywords: Learning Trajectories; Middle School Education; Rational Numbers; Technology

Candy Factory is a freely available app for iOS devices, designed by the Learning Transformation Research Group at Virginia Tech (LTRG; see http://ltrg.centers.vt.edu/). The app is designed to elicit the coordination of partitioning and iterating operations, as students produce candy bars of specified sizes, relative to a given whole. Given a whole "candy bar" and a specified "customer order," students select an appropriate number of parts to project into the whole and then decide how many iterations of one part would be needed to produce the customer order. By challenging students in this goal-directed activity of coordinating partitioning and iterating operations, the app should support students' constructions of schemes and operations identified in the theoretical framework section. The purpose of this paper is to report on investigations of how game play supports students' development of new ways of operating.

Theoretical Framework

The partitive unit fraction scheme (PUFS) is the simplest scheme that coordinates partitioning and iterating operations within fractions contexts. Students use the PUFS to partition a continuous whole into equally sized pieces and then iterate any one of those pieces to check whether the pieces are appropriate in size and number. This sequential coordination of partitioning and iterating allows the student to make "an explicit numerical one-to-many comparison" and permits the student's "explicit use of fraction language to refer to that relation" (Steffe, 2002, p. 292). The two tasks illustrated in Figure 1 were designed to assess this way of operating.

Whereas the PUFS involves the sequential application of partitioning and iterating, splitting is the simultaneous composition of these two operations. The sequential operations of partitioning and iterating must be interiorized so that they can be coordinated as part of a single operation; at that point, partitioning and iterating become inverse operations. Students who can operate in this way can solve tasks that require them to partition the given whole in service of a goal that is iterative in nature: "This stick is three times as big as another stick; draw the other stick." The power of the splitting operation has been documented in reports from several teaching experiments (e.g., Norton, 2008; Steffe, 2002) and has been affirmed through quantitative analyses (e.g., Norton & Wilkins, 2009).

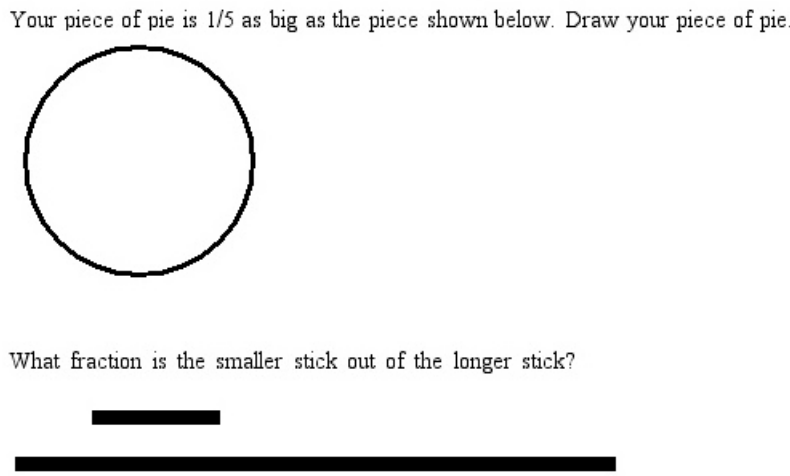

Figure 1: Tasks for assessing the partitive unit fraction scheme

Beyond its role in the construction of the splitting operation, the PUFS can be generalized to support conceptualizations of non-unit proper fractions as iterations of a unit fraction (i.e., *m/n* as *m* iterations of *1/n*). This generalization is referred to as the partitive fraction scheme (PFS). We hypothesize that students' engagement with the Candy Factory app will support their development from part-whole conceptions of fractions to partitive conceptions of fractions, in general. Due to the relationship between the PUFS and splitting, this hypothesis stipulates that the app should also, indirectly, support students' constructions of the splitting operation. Here, we operationalize the hypothesis in three testable parts:

- Hypothesis 1a (H1a): The app will support movement from PWS to PUFS.
- Hypothesis 1b (H1b): The app will support development from PUFS to the more general PFS.
- Hypothesis 2 (H2): Students who construct the PUFS go on to construct splitting operations with little or no instructional support.

Methods

Our study involved 72 students from three sixth-grade classrooms, all taught by the same teacher. One of the classes served as a control group (n = 23); one served as a low performing experimental group (n = 23, including 9 students with special needs); and one served as a high performing experimental group (n = 26, including 14 students on the honors track). We administered a pre-test on August 31, 2011 and as a post-test on November 9, 2011. Not all students took the test at both sittings; as a result, we were left with a working sample of 63 students with data from both the pre- and post-test. The test items on the test included four items each for the PUFS, the splitting operation, and the PFS. The first two authors independently rated student responses for each item. The raters assessed student responses based on all of the written work associated with the item to infer whether there was sufficient indication that the student had operated in a way that was consistent with a particular scheme or operation.

To measure the overall agreement (inter-rater reliability) for the PUFS, the splitting operation, and the PFS, we computed the kappa statistics, K, for the 66 students who took the pre-test, and the 69 students who took the post-test. The kappa statistics for the splitting operation (K_{pre} = .88, K_{post} = .85) and the PFS (K_{pre} = .82, K_{post} = .83) represent "almost perfect" agreement; the kappa statistics for the PUFS (K_{pre} = .76, K_{post} = .82) represent "substantial" and "almost perfect" agreement for the pre- and post-test, respectively (Landis & Koch, 1977, p. 165). These statistics provide strong evidence for the reliability of the ratings for the schemes and operations. For cases in which there was disagreement, the two raters re-examined the cases together to come to a consensus and create one rating for each student.

The two experimental groups played the Candy Factory app for the first 30 minutes of class each Wednesday, for seven consecutive weeks, beginning two weeks after the pre-test and ending two weeks prior to the post-test. On those days, the control group spent the first 30 minutes of class participating in "Jump Starter" review activities across various mathematical topics. No other instruction of fractions, decimals, or percents occurred in any class during this time period.

Descriptive Statistics from Pre- and Post-test

The number of students within each class limited possibilities for statistical analyses, so we use descriptive statistics to objectively characterize growth within and across classes. These results provide early tests of Hypotheses 1a and 1b, and provide further affirmation of Hypothesis 2 (beyond data used in Norton & Wilkins, 2012). We begin with Table 1, which summarizes student growth across all three groups of students.

Table 1: Frequency of Student Construction of PUFS, Splitting, and PFS for the Pre-test and Post-test

	Post								
Pre	000	100	010	001	110	101	011	111	Total
000	**14**	6	1	0	1	0	0	1	23
100	1	**1**	1	0	4	1	0	3	11
010	1	0	**0**	0	2	0	0	1	4
001	0	0	0	**0**	0	0	0	0	0
110	0	0	2	0	**9**	0	0	4	15
101	0	0	0	0	0	**1**	0	0	1
011	0	1	0	0	0	0	**0**	0	1
111	0	0	0	0	4	0	0	**4**	8
Total	16	8	4	0	20	2	0	13	63

Note: Codes represent whether students have (coded 1) or have not constructed (coded 0) PUFS, Splitting, and PFS; e.g., 110 stands for students who have constructed PUFS and Splitting, but not PFS.

Note that the most substantial movement occurred among students who had begun with the PUFS alone (see second row in Table 1). Consistent with Hypothesis 2, eight of these eleven students constructed the splitting operation by the post-test. Other notable changes between pre- and post-test occur in the construction of the PUFS and the generalization of the PUFS to the PFS. Unlike the first change, which should occur with little or no instructional support, these latter two changes were instructional goals built into the design of the Candy Factory app.

Table 2 presents the ratios (*a/b*) for numbers of students by class who had constructed no fraction schemes beyond the part-whole fraction scheme (*b*) and subsequently constructed a PUFS (*a*, H1a); and those who had constructed a PUFS and not a PFS (*b*) and subsequently constructed a PFS (*a*, H1b). Considering the data in Table 2 we find similar growth patterns among the students in the control group and the lower performing experimental group. However, growth among the higher performing experimental group is substantially higher. Because we measured growth from one stage to the next, this difference cannot be explained in terms of existing fractions knowledge. Rather, it seems that the higher performing experimental group engaged with the app more effectively, which might be a consequence of cognitive or social factors not measured in our study. Likewise, growth among the lower-performing experimental group might have been muted due to such factors.

Table 2: Development of Fractions Schemes by Class

	Control	Experimental (special needs inclusion)	Experimental (honors inclusion)
H1a: PWS → PUFS	4/10	4/12	3/5
H1b: PUFS → PFS	1/6	1/8	6/12

Conclusions

Results from this pilot study affirm Hypothesis 2, which stipulates that students who have constructed the PUFS go on to construct the splitting operation with little or no instructional support (Norton & Wilkins, 2012). Given the role splitting plays in the construction of advanced fractions schemes (Steffe & Olive, 2010) and multiplicative reasoning in general (Hackenberg, 2010), this finding further emphasizes the importance of supporting students' construction of the PUFS. Results also indicate that apps like the Candy Factory—which take seriously Olive's (2000) recommendation that we "think carefully about the contributions that the children need to make to the situation in order to build their own mathematical structures" (p. 260)—can provide an effective means to support new ways of operating. In particular, Candy Factory purposefully elicits students' partitioning and iterating operations to provoke the construction of partitive fractions schemes: PUFS and PFS. Descriptive statistics affirm Hypotheses 1a and 1b among the higher performing group. However, given the differences in growth between the two experimental groups, we need to further scrutinize cognitive and social factors that might limit meaningful engagement and, therefore, hinder growth among some students. Future app design, which is ongoing, will need to account for this disparity.

HIGH SCHOOL TEACHERS' USE OF DYNAMIC SOFTWARE TO EXTEND AND ENHANCE ANALITIC REASONING

Francisco Ortega-Moreno
Cinvestav-IPN
fortega@cinvestav.mx

We analyze and document the extent to which the use of a dynamic software helps high school teachers develop ways of representing, exploring, and solving analytic geometric tasks that complement and extend approaches based on the use of analytical methods. As a result teachers exhibited a way of reasoning about the tasks that differs when contrasted with traditional analytic approaches.

Keywords: Technology; Mathematics Problem Solving; Teacher Knowledge for Teaching

Introduction

In this report, we outline a teachers' professional development program that aims to review and enhance their mathematical and didactical knowledge through the use of computational technology. Thus, the research questions that guided the development of the study were: To what extent does the use of a dynamic software provide teachers with an opportunity to transform the nature of routine tasks, found in textbooks, into a series of learning activities involving empirical and formal approaches? What ways of reasoning do teachers construct and exhibit as a result of using a dynamic software during the tasks' solution process? Addressing these questions will provide us important information regarding the type of reasoning that teachers develop as a result of using computational tools in problem solving approaches.

Conceptual Framework

Delving into the teachers' preparation implies to recognize that there are multiple paths or programs and traditions to prepare teachers around the world. Some teaching models recognize the need and importance for teachers to develop the mathematical and didactic knowledge that can help them organize and implement proper conditions for students to learn the subject. This recognition does not imply an agreement on routes for teachers to study and develop the mathematical knowledge for teaching. For example, Even (2011) states that the assumption that "advanced mathematics studies would enhance teachers' knowledge of mathematics, which in turn will contribute to the quality of classroom instruction" (p. 941) needs to be reexamined in terms of what means for teachers to have adequate subject-matter knowledge to become an expert teacher and how a teacher can develop and use that knowledge in her teaching.

> Many practicing teachers, for different reasons, have not learned some of the content they are now required to teach, or they have not learned it in ways that enable them to teach what is now required. … Teachers need support if the goal of mathematical proficiency for all is to be reached. The demands this makes on teacher educators and the enterprise of teacher education are substantial, and often under-appreciated. (Adler et al., 2005, p. 361)

To shed light on the role of advanced mathematical knowledge in teachers' classroom decisions, Zazkis and Mamolo (2011) provide examples where teachers' awareness of that knowledge becomes useful to orient the development of a lesson. They use the construct horizon knowledge to refer to "teachers' advanced mathematical knowledge which allow them a "higher" stance and broader view of the horizon with respect to specific features of the subject itself (inner horizon) and with respect to the major disciplinary ideas and structures…occupying the word in which the object exist (outer horizon)" (p. 10).

We argue that the ways in which teachers study mathematics courses play a crucial role in developing resources and contents to be used in their teaching. That is, it is not sufficient for prospective teachers to take advanced courses; but they also need identify and explore diverse ways of reasoning and reflect on forms to connect mathematical results with other problems or situations. In this context, the systematic use of diverse digital tools can provide teachers with the opportunity to enhance and extend problem-solving approaches that involve the use of paper and pencil.

The Context, Participants and Methods

This report is part of an ongoing research project that aims to guide and orient high school teachers and students to use of several digital tools in problem solving activities. Six high school teachers participated in two hour weekly sessions during one semester. Teachers worked in pairs and they had the opportunity to work on mathematics problems that appear in textbooks with the use of a dynamic software. During the development of the sessions, two researchers coordinated the activities that involved initial pair work followed by pairs' presentation and whole group discussions. The research team formed by mathematicians, mathematics educators and teachers discussed the participants' contributions in terms of features of mathematical reasoning that characterize their approaches and were consistent throughout the sessions (Santos-Trigo & Camacho-Machin, 2009).

The Task

Points A(0, 0) and B(6, 0) determine a side (base) of a triangle. Find the locus of the third vertex C which is moved in such a way that the product of the tangents of angles formed with side AB (base) is always equal to 4 (Lehmann, 1980, p. 186)

To present how teachers approached the task, we organize the pairs' work in episodes that involves comprehension of the task statement; the construction of a dynamic model; the exploration of the model, and extension of the task. In addition, we contrast the software approach with the use of analytic methods to deal with this type of task.

Comprehension of the Task

Participants who used the software to represent the information of the task, began by drawing segment AB and a line AD to locate the third vertex. At this stage, the questions that helped them to represent the task involved: How can we find the third vertex? What about if we draw a particular angle? Is it possible to find the other asked angle? How can we determine the value of angle B by introducing the tangent product condition? The discussion of these types of questions led them to find a particular case where the conditions of the task statement were held.

The Dynamic Model and Model Exploration

During the comprehension phase of the task, the participants not only spent time making sense of the conditions embedded in the problem statement; but also they started thinking of ways to move objects within the problem representation or configuration. For example, drawing a circle with center at A and radius AD became important to control the movement of line AD. The use of the software allows moving the position of line AD maintaining the condition of the problem. That is, the measurement of angle B was determined by solving $\arctan\left(\frac{4}{\tan(45.24)}\right)$ and then side AB was rotated this angle (–75.85) around point B. On the rotated segment, a line was drawn and this line intersects line OD at E. Hence, the participants used the software to find the locus of point E (third vertex) when point D is moved around the circle. Figure 1 shows the resulting locus.

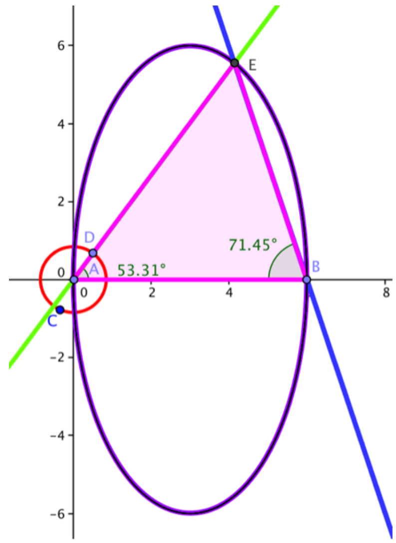

Figure 1: What is the locus of point E when point D is moved around the circle with center at A?

An Analytic Approach

The participants also thought and solved the task analytically by using the coordinate system and representing and operating the task conditions algebraically. They chose point E(x,y) (third vertex) on the locus and related the tangent conditions to the slopes of the lines that pass by the sides of the triangle. That is, they calculated the slopes of lines and expressed its product as:

$$\left(\frac{y}{x}\right)\left(\frac{y}{-(x-6)}\right) = 4 \text{ which led to the equation } \frac{(x-3)^2}{9} + \frac{y^2}{36} = 1$$

An Extension Episode

A question that the participants posed was: What happens to the ellipse when product of the tangents of the base angles of the triangle is another constant? For example, when the constant is –4. Again, the use of the software became important in exploring other cases. Can this approach be applied to others families of problems? What kind of learning opportunities can this dynamic approach offer to teachers and students? It is evident that the use of the tool offers opportunities for high school teachers to transform some routine problems into a set of activities that fosters mathematical reflection and connections between concepts.

Discussion and Remarks

We argue that mathematical tasks are the vehicle for teachers to both delve into mathematics concepts and to promote their students' mathematics knowledge and reflection. Hence, there is evidence that the use of a dynamic software provides teachers with an opportunity to transform routine problems (found in textbooks) into a set of activities where they exhibited not only different ways of reasoning to approach the tasks; but also ways of connecting analytic methods with their geometric meaning.

Dynamic models of the tasks became a platform to explore not only different forms to represent emerging relations; but also ways to extend and connect the initial statement of the task with a set of mathematical relations. In this process, it was possible to generate graphic behaviors of particular relations (locus of particular objects) without defining the algebraic model. In general terms, the use of the tool offered the participants the opportunity to examine graphically relations that later can be explored and contrasted algebraically. In this context, the use of the tool complements or extends mathematical reflection that learners engage in algebraic approaches. We contend that the use of computational tools plays a crucial role in extending high school teachers' mathematical knowledge.

Teachers were aware that the use of the tools opened up a window to explore tasks in a way that values visual and empirical arguments. In addition, the loci of points that emerged as a result of moving particular elements within the dynamic configuration become a source to launch a set of mathematical conjectures that needed to be supported. The use of the software made easy to explore cases in which the initial conditions of the task were changed. For example, what is locus generated by the third vertex when the product of tangents associated with the angles is –4? Here again, the use of the software showed that the locus became a hyperbola. While exploring different constants for the tangents product, they directed their attention to find intervals associated with the constant values to generate conic sections that involve circles, ellipses and hyperbolas. They also recognized that analytic approaches are useful to verify results obtained through the use of the tool. In this context, both approaches (the software and the analytic) are complementary and helpful for teachers and students to solve mathematical tasks. Throughout the development of the sessions, teachers recognized that routine problems could be conceptualized as departure point to engage in mathematical reflection.

Heid and Blume (2008) mentioned that "…as a reorganizer, [the use of] technology extends the existing mathematics curriculum by increasing the number and nature of examples that students encounter; as a reorganizer, technology changes the nature and arrangement of the curriculum" (p. 422) and it is clear that the study of analytic geometry with the use of computational tools need to be reorganized not only as a curriculum content; but also as a way to study the conic sections in intertwined manner favoring visual, empirical, and formal approaches.

Finally, we content that high school teachers should discuss mathematical tasks and the use of computational tools within a community that includes mathematicians, educators and practicing teachers. This type of interaction allows the community to discuss not only mathematical contents, problem solving strategies, and ways to support conjectures; but also possible didactic routes to implement problem solving approaches that enhance the use of computational tools.

TECHNOLOGY INTEGRATION IN PRE-SERVICE SECONDARY MATHEMATICS TEACHER EDUCATION: PROSPECTS, PRIORITIES, AND PROBLEMS

Shashidhar Belbase
University of Wyoming
sbelbase@uwyo.edu

Linda S. Hutchison
University of Wyoming
lhutch@uwyo.edu

Jennifer L. Edelman
University of Wyoming
jedelma1@uwyo.edu

This poster presentation aims to examine prospects, priorities, and problems of technology integration in preservice secondary mathematics teacher education. We employed autoethnographic reflective and reflexive accounts of experiences (Ellis, Adams, & Bochner, 2011) through a teacher education program as participant observer and instructors. The first co-author brought his etic perspective as a participant observer, and the second and third coauthors portrayed their emic perspective as instructors in mathematics methods course and student supervisors during residency. We developed narrative accounts of lived/living experiences of observing, teaching, and supervising students in relation to technology integration in mathematics methods course and subsequent practices during residency.

We reviewed related literatures to backup revelations and portrayals. Nordin et al. (2010) investigated the pedagogical usability of a digital module prototype that integrated dynamic geometry software—Geometer's Sketchpad (GSP)—in mathematics teaching. They used pedagogical usability criteria that included student control, student activities, objective-oriented, application, value added, motivation, knowledge value, flexibility, and response. Their prototype digital modules met the pedagogical usability criteria that facilitated integration of GSP in mathematics teaching. Hixon and So (2009) discussed five specific benefits of technology integration—exposure to various pedagogical environments, shared experiences, reflectivity, cognitive development of students, and knowledge of technology integration. We agree with Stigler and Hiebert (1999) that "one other approach to understanding the difficulties of integrating IT in the classroom stems from seeing teaching as a complex cultural activity" (p. 97) and this complexity of culture sometimes becomes a barrier for change in teaching and learning.

We identified key aspects of prospects, priorities, and challenges of technology integration in the preservice mathematics teacher education in terms of relevancy, applicability, sufficiency, and extensions (RASE) as a model within the institutional cultures of teaching and learning mathematics with technology from university to schools. Preliminary findings indicated that technology integration in preservice secondary mathematics teacher education program had a high prospect for reform based mathematics teaching as a priority, but still there were latent challenges of transferring these prospects from university to schools. Success of technology integration in mathematics education depends upon its use either as a means of presentation and instruction or it is used as a means of learning and development.

WHO'S AT BAT AND DOES IT MATTER? USING AGENT-BASED BASEBALL MODELS TO PROMOTE MATHEMATICAL REASONING

Tracy Dobie
Northwestern University
tdobie@u.northwestern.edu

Keywords: Technology; Reasoning and Proof; Middle School Education

This research examines the possibility of using computer models in mathematics classrooms to promote reasoning among students. There are several motivating factors for the design of these models. First, students often rely heavily on the memorization of equations and procedures when problem solving. David Hammer' suggests that students have a "range of epistemological resources, the activation of which depends on context" (Hammer & Elby, 2002, p. 24). Thus, students likely possess the resources necessary to reason about mathematics problems; however, the context of the mathematics classroom instead causes many students to activate resources that lead them to search for and use equations. One goal of this software is to create an environment that backgrounds equations and instead encourages students to utilize their own reasoning skills in solving problems. Second, Liping Ma's (1999) work with elementary mathematics teachers illustrates U.S. teachers' lack of understanding of the concepts behind equations. Ma suggests that teachers' difficulty might be due to missing connections and links in their knowledge. These missing links are likely to cause students to develop incomplete understandings, as well. Thus, a second goal of this software is to provide students with a space in which to explore mathematics concepts before attempting to connect those concepts to equations.

Researchers have shown that students can develop important knowledge through their own experimentation and construction (Papert & Harel, 1991), and agent-based modeling environments such as NetLogo (Wilensky, 1999) can be useful in creating spaces for such experimentation. This research centers on the design of two NetLogo models that allow students to experiment with the impact of a baseball team's line-up on its overall performance. Using this software, users can input baseball/softball players' statistics, choose a batting line-up comprised of any nine players, and simulate a series of games to see how many runs the team is able to score each game. Students are provided with a variety of displays to use when reasoning about a team's performance (including graphs indicating changes in individual and team statistics, as well as a visual of players' movement around the field). Additionally, users can make changes to a team's line-up and then simulate a second series of games in order to compare differences in individual and team performance given different batting line-ups. If used in a classroom, this software could encourage students to access epistemological resources that they might not typically access in a mathematics classroom through the foregrounding of reasoning and backgrounding of formulas.

TRACING STUDENTS' ACCOUNTABILITY AND EMPOWERMENT IN AN ONLINE SYNCHRONOUS ENVIRONMENT

Kate O'Hara
Rutgers University
katem222@comcast.net

Arthur B. Powell
Rutgers University
powellab@andromeda.rutgers.edu

Keywords: Classroom Discourse; Technology; High School Education; Affect, Emotions, Beliefs, and Attitudes

Tracing students' chat and whiteboard interactions in an online, synchronous environment as they collaborated to solve cognitively demanding, open-ended mathematical problems, our poster will document the emergence of discourse that was accountable to community and to standards of reasoning. Moreover, our analysis indicates that the students also transitioned into empowering stances about their ability to think mathematically.

Conditions in the online learning environment enable students to engage in the mathematics on their own terms, however, issues and challenges arise in how students' collaborate and form a learning community. With the increased demand for distant learning, it is important that we understand how students' engage with one another online without contemporaneous teacher involvement (Howell, Williams, & Linday, 2003). Our analysis revealed that the students displayed accountability to the learning community, accountability to the accepted forms of reasoning, as well as epistemological and mathematical empowerment as they practiced mathematics in an online environment. As they worked in small groups to solve open-ended mathematics problems they shifted away from individual, competitive work to more group cooperation and collaboration. They developed their own unique practice, expectations of one another, and most importantly, how to work together as a unique learning community. Our data also show that this accountability was an empowering experience, one that may affect their relationship with the subject of mathematics.

A THEORETICAL FRAMEWORK FOR IMPROVING MATHEMATICS TEACHERS' MANIPULATION OF CLASSROOM TECHNOLOGY

Thomas E. Ricks
Louisiana State University
tomricks@lsu.edu

Keywords: Learning Outcomes; Pedagogy; Reform; Technology

Thirty years ago, the available mathematical tools for teachers and students consisted mainly of chalkboards, slide-rulers, paper-and-pencil, and geometry sets. This situation has radically changed with technologies like calculators, graphing calculators, and computer software permeating modern mathematics classrooms; this rapid growth opens up the potential for change in the didactical field, as it affects decisions on *how* mathematics should be taught in the classroom with such aids. This poster presentation explores, through examples of technological implementation in mathematics classrooms, a theoretical lens for differentiating between effective and ineffective uses of technology. In particular, we use the metaphor of a double-edged sword to frame our discussions with illustrative episodes chosen from actual teaching practices.

Research has strongly advocated for the use of technology (Dede, 2008; Keengwe & Onchwari, 2008; Leung, 2006; NCTM, 2000). With all the availability and advocacy, technology appears to have the potential to address several desirable goals in mathematics education, like engaging students in meaningful tasks, allowing multiple representations, and creating critical thinkers. However, this is all conditioned on the appropriate use of technology to target these problems: the benefit education will reap from the technology "depends on what models of teaching and learning we use. If technology is simply used to automate traditional models of teaching and learning, then it'll have very little impact on schools" (O'Neil, 1995, p. 6). The power of technology is directly linked to its ability to open new pedagogical pathways for student learning. "Smart boards" are only as "smart" as the individuals using them.

Technology is a double-edged sword because it cuts in two directions: It can cut new pedagogical pathways, or if mishandled, severely "cut" the educational experience. Like a sharp two-edged sword, technology must be handled properly. While acknowledging the positive impact that technology can have, this poster presentation recasts technological merits in terms of the pedagogical objectives to argue that technology is beneficial to instructional activities only insomuch as it expands the pedagogical possibilities of a lesson. Such a view is a goal-based filter for judging technological merit, and is not emphasized in the extant literature.

INFLUENCE OF TEACHER BELIEF ON TECHNOLOGY INTEGRATION IN TECHNOLOGY ENHANCED MATHEMATICS CURRICULUM

Yiting Yu
University of South Florida
yyu3@usf.edu

Denisse R. Thompson
University of South Florida
denisse@usf.edu

Keywords: Curriculum; Middle School Education; Teacher Beliefs; Technology

The extent of technology use in mathematics instruction is generally a pedagogical choice of the teacher, potentially moderated by the availability of technology resources in the school. Over the past two decades, curriculum developers have integrated technology into curriculum materials on a regular basis. At the middle grades, scientific calculators are often assumed, but graphing calculator technology is typically less common. As this technology becomes more widely used across levels, mathematics teachers need to be ready to use such technology in teaching to enhance mathematics learning.

Research Questions

1. What are teachers' beliefs about the use of technology in teaching middle grades mathematics, particularly when using a curriculum (University of Chicago School Mathematics [UCSMP] *Transition Mathematics* [Third Edition]) in which technology (e.g., graphing calculators, geometric drawing tools) is integrated into the curriculum materials? Specifically, is technology considered a tool that hinders or enhances mathematics learning?
2. What are factors that influence changes in teachers' beliefs towards the use of technology?

Data Collection

Results are based on secondary analysis of data collected from 7 teachers who participated for an entire school year in an evaluation study of the UCSMP *Transition Mathematics* (Third Edition) curriculum, a middle grades curriculum which integrates technology on a regular basis. Teachers completed initial and final questionnaires related to their use of technology. Interviews conducted as part of classroom observations provided a means to validate questionnaire responses.

Data Analysis

ATLAS TI 6.2 was used to code teacher interview data to find common themes and issues regarding teachers' beliefs towards the use of technology, including beliefs about student performance and the implementation of technology into the curriculum. SPSS 20 was used to analyze changes over time in questionnaire responses.

Results

Analyses indicate that teachers generally began the teaching of the curriculum with little experience using graphing technology and tended to resist its use due to lack of familiarity with it, doubts about its effectiveness, or concerns about how it was embedded into the curriculum. Positive changes in teacher beliefs towards technology integration occurred after seeing improvement in student performance.

Conclusion

The findings of this study indicate there is potential for technology integrated curriculum to change teachers' beliefs about its use for mathematics instruction at the middle grades. However, technology support for teachers is necessary when implementing such curriculum so teachers feel confident in making pedagogical choices about the use of technology in their instructional practices.

ENACTING RESPONSIVE RESEARCH STRATEGIES IN MATHEMATICS EDUCATION: ANSWERABILITY AND ACTION IN CLOSE-TO-THE-CLASSROOM ETHNOGRAPHIC WORK

Amy Noelle Parks
University of Georgia
amyparks@uga.edu

Rachel Monette
University of Georgia
rach789@uga.edu

Researchers in education broadly, and in mathematics education in particular, have made progress in defining culturally responsive or relevant pedagogies and have documented a variety of contexts where these pedagogies have supported the mathematical learning of various groups of non-majority children. However, little attention has been paid to examining research practices in light of the demand to become culturally relevant. The purpose of this paper is to examine the impact of our conscious choice to make our methodological work responsive to the children involved.

In the last two decades, researchers in education broadly, and in mathematics education in particular, have made progress in defining *culturally relevant pedagogies* (Erickson & Mohatt, 1982; Ladson-Billings, 1995; 1997) and have documented a variety of contexts where these pedagogies have supported the mathematical learning of various groups of non-majority children (e.g., Brenner, 1998; Gutstein, Lipman, Hernandez, & de los Reyes, 1997; Ladson-Billings, 1994). As researchers concerned with equity issues within mathematics education, we share the goal of "helping students to accept and affirm their cultural identity while developing critical perspectives that challenge inequities that schools (and other institutions) perpetuate" (Ladson-Billings, 1995, p. 467). However, in addition to asking what pedagogies might meet this goal for children, we want our own research projects to work toward these goals. In addition, we would like to move beyond producing findings that are aimed at helping children to affirm their identities – in relation to both culture and mathematics—toward ensuring that our moment-to-moment engagements with our student participants also work toward these equity commitments. In response to this desire, we have begun to ask ourselves the following researchable questions:

- In what ways are our own research strategies responsive to the participants in our study?
- What tensions arise when we, as mathematics education researchers, make data collection decisions based on our desire to be responsive?

Purpose

The purpose of this paper is to explore the questions above within the context of a three-year ethnographic research project. The project's goal is to document the mathematical strengths of young children attending a rural school that serves a predominantly African American community. To do this work, we are following a cohort of children from preschool to first grade and collecting data about their mathematical learning in a variety of contexts (e.g., formal lessons, play, parent involvement events, assessment interviews) using videotape and fieldnotes as our primary data collection tools. As we approach the end of our second year of data collection, we find ourselves thinking a great deal about the responsibility we have as researchers, mathematics educators, and adults toward the children we visit each week and find that more and more of our actions during data collection are guided by our perceived responsibilities toward these particular children rather than toward the research project more broadly. For this presentation, we would like to closely examine three critical sites during our weekly data collection efforts where we have chosen to alter our actions within the school context out of a desire to be responsive our student participants.

Van Zoest, L. R., Lo, J.-J., & Kratky, J. L. (Eds.). (2012). *Proceedings of the 34th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* Kalamazoo, MI: Western Michigan University.

Literature Review

In defining culturally relevant pedagogy, Ladson-Billings (1995) differentiated her work from previous scholarship concerned with the cultural differences by arguing that previous work treated these differences as neutral. She posited that it was not enough to teach children the dominant communicative practices used in schools, but said that students must also be given opportunities to critically examine schooling practices. More specifically, through ethnographic analysis of successful teachers of African American students, she argued that culturally relevant pedagogies include a commitment to students' academic success, cultural competence, and critical sensibilities (Ladson-Billings, 1994, 1995).

Broadly, both within and outside of mathematics education, work focused on culturally relevant or responsive teaching has focused on ethnically homogenous classrooms, primarily in African American or Latino/a contexts (Morrison, Robbins, & Rose, 2008). As Morrison, Robbins, and Rose (2008) note in their meta-analysis of 45 research studies about culturally relevant pedagogy, this focus on ethnically monolithic classrooms is problematic because the knowledge base may not help teachers who want to teach in culturally responsive ways in diverse classrooms. But it is also problematic because it can contribute to an assumption that all children who claim similar ethnic or racial identities find the same schooling practices to be productive. Following Schmeichel (2012), we were wary of essentializing the students we work with by suggesting that particular pedagogies and practices were directly related to students' cultures and ethnicities, rather than, for example, individual temperaments, schooling histories, community norms, gender, class, etc. Scholars have dealt with this challenge in a variety of ways. For example, Ladson-Billings (1997) used footnotes to temper claims about the universality of certain features of African American culture. Civil and Khan (2001) dealt with this challenge by grounding claims about parent knowledge in a Latino/a community by emphasizing the hyper-local nature of that knowledge and the ethnographic investigation that had led to the understandings.

Theoretical Framework

In thinking about how to apply the body of work on culturally relevant teaching practices to research methods, we faced a number of challenges. Most importantly, teaching and research are quite different endeavors so it was difficult to think about how recommendations for teaching practice might translate for us as researchers. We, for example, had little control over what children experienced in the classroom moment-to-moment and thus had few opportunities to either work to align classroom experiences with at-home communication practices or to introduce opportunities for children to critically examine their school and classroom.

Second, little explicit direction on what constituted culturally relevant research practices existed and what we did find felt like an uncomfortable fit given our own subject positioning. For example, in discussing her own research methods, Ladson-Billings (1995) drew on the work of Collins (1990), a black feminist theorist, to articulate a research stance based on four big ideas: concrete experiences as central to meaning, dialogue as central to assessing truth claims, caring as central to the research endeavor, and personal responsibility as critical. While we felt drawn to these precepts, we felt we could not unproblematically take them up. A central idea in Collins' (1990) work is that it presents a "Black women's standpoint," informed by living as an "outsider-within" (p. 16). As white women working with primarily African American students we did not want to assume that we could fully comprehend this research stance only from reading published work. This is not to say that communication across lines of difference is impossible, only that it is important to be careful in these moments. Finally, we wanted to be sensitive to the two broad issues raised by our review of literature on culturally relevant or responsive pedagogies: the occasional sidling of critical perspectives and the danger of essentializing groups of children, again especially considering our own outsider status in the community.

To meet all of the above challenges, we decided to draw on the ideas of a theorist commonly used by our colleagues in literacy, Mikhail Bakhtin. In particular, we took up Bakhtin's notion of *answerability* as a guiding principle for our own in-the-moment decisions in the field as well as a framework for analyzing the extent to which our project was meeting Ladson-Billing's goals of helping children to both affirm their identities and develop a critical stance toward schooling. In a small collection of work (Bakhtin, 1990, 1993), Bakhtin articulated the ethical stance of answerability wherein "I myself – as the one who is actually thinking and who is answerable for his act of thinking – I am not present in the theoretically valid judgment" (Bakhtin, 1990, p. 4). Here Bakhtin rejects a priori ethical standards and argues that it is only in the moment with other human beings that we can determine what it means to be ethical or responsive to them. We cannot, Bakhtin argues, draw on alibis from other places to justify our behavior, although we may be informed by them, whether those alibi's come from state curriculum standards, NCTM guiding principles, culturally relevant practices, or commonly accepted research norms. Rather, we must be responsive to the demands of the people before us. Hicks (1996) writes about this stance as "more similar to faithfulness, even love, than adherence to a set of norms" (p. 107). We felt this stance captured the heart of culturally relevant pedagogy while addressing the concerns raised above. Following Bakhtin, we were not constrained by a set a principles and practices that better described the work of classroom teachers than our own work, and we could view our responsiveness to the children in front of us in light of their many legitimate demands for consideration including, but not limited to, culture, developmental stage, economic status, gender, and temperament.

Modes of Inquiry

As mentioned above, this project is situated within a larger three-year ethnography following a cohort of students from preschool to first grade. The data collection is primarily based on weekly visits that include video taping and writing fieldnotes about informal mathematical play, formal mathematics lessons, parent activities, and assessment interviews with the researcher. Our student participants include 16 children attending a rural, low-SES school. Thirteen of the 16 students are African American; one is European American; one is a recent Indian immigrant; and one is Hispanic. The children are currently in kindergarten. The research team includes two European American women (one the PI), one Asian American woman, and one Korean woman. Each week, three members of the team visited the school, with two researchers collecting data in the classroom.

During the first year of data collection, we took up relatively traditional participant observer roles (Erickson, 1986) video taping the classroom during math lessons while frequently speaking to students. The Pre-K teacher included little formal mathematics in the day, which meant that a great deal of our data collection occurred during play. Students handled manipulatives and engaged in mathematical thinking during unstructured activities. We loaded fieldnotes and video clips into a qualitative data analysis program, which we used to code the data for both mathematical content (such as problem solving and cardinality) and social features of the classroom (such as peer play and teacher interaction).

Moving into the second year of the study, we did not plan to change data collection methods. We began by recording and taking notes about the kindergarten math lessons, which were whole group. Many of the students who had expressed excitement and accomplishment the previous year were visibly upset during the math lessons. For example, over a period of three weeks, we observed five children crying during mathematics. In response to this situation, we made two significant changes to the project. First, we made an offer to the teacher, which was accepted, to have one member of the research team take a small number of students out of the classroom to work each week with the goal of both addressing mathematical needs and reducing unhappiness and anxiety for these students and their classmates. Second, we began to note, collect data about, and specifically code for our interactions in the classroom that were designed to be responsive.

For the first time in the 18 months of data collection, we began to intentionally video record interactions between the children and the other researcher in the room. Initially, we coded these moments as *researcher interaction*, but as our coding and theory became more sophisticated we also coded using the word *answerability*. For this presentation, we more closely analyzed data collected in relation to the small group of students we removed from the classroom and from video and fieldnote episodes marked with the codes *researcher interaction* and *answerability*. Following ethnographic (Emerson, Fretz, & Shaw, 1995; Erickson, 1986) analysis strategies, we searched these episodes for common themes, significant disparities, and social meaning. The following section describes three key sites we identified where our answerability as researchers was most apparent.

Critical Moments for Answerability

Removing Students from the Room

Our choice to tutor three students each week is perhaps the clearest, most systematic example of our enactment of answerable, or responsive, research methods. This practice was not a part of the original research plan and initially we did not know how data would be collected because the researcher working with the children could not teach and operate a video camera at the same time and a stand-alone camera proved too distracting. In addition, data collection was complicated by the inclusion of one child whose parents had not agreed to video taping; however, we included this child in the group because we believed it would be a positive experience for him. Ultimately, we relied on researcher journals and audio taping.

At the request of the classroom teacher, the focus of the small group was counting. In making recommendations for the small group, the classroom teacher expressed anxiety about the selected students' scores on benchmark tests and a desire to see these scores go up. Although the researcher working with the children was not unconcerned with their performance on assessments, she made a conscious choice to emphasize positive interactions with mathematics in the small group rather than tasks strictly related to the benchmark assessments on counting.

For example, during one session the researcher disregarded her plan to work on counting skills in favor of measuring objects because students said they had been studying measurement in class, but when asked what objects they had measured, responded "nothing." The students had listened to their teacher talk about measuring, had watched her measure, but they had not yet had the opportunity to measure themselves. In the small group that day, students chose objects to measure with various non-standard units. Although students practiced some counting during the measurement activity, the researcher leading the session felt some discomfort in abandoning the goals set by the teacher. However, in the moment, providing the children with an engaging experienced connected to their immediate learning seemed more responsive. Although the small group did give selected students opportunities to engage in more hands-on experiences in mathematics, it presented a few problems as well. First, students not chosen for pull out regularly begged to be included. Second, previous data collection plans for the researcher who worked with the small group had to be abandoned.

Introducing Mathematics to the End of the Day

The classroom moments most frequently coded for researcher interaction and answerability occurred during the last twenty minutes of the school day. Routinely, the mathematics lesson ended well before students needed to line up for the bus. The teacher and paraprofessional's typical practice was to pass out backpacks and folders throughout the last twenty minutes of the day while the children sat quietly at their desks. Typically, the researchers would sit near children during this time and chat quietly.

However, on one occasion after a geometry lesson in which students identified solid figures on a worksheet but did not handle any figures themselves, the PI got a box of solid figures down off the shelf and passed it around to the students at the table where she was sitting. Students immediately grabbed for the shapes, some stacking up multiple figures, some experimenting to see which figures would roll. During this interaction, the children and the PI both used quite a bit of geometric vocabulary from the lesson, including "cylinder," "cone," "cube," "circle," and "face." After a few moments, the children started to become loud and the PI shushed them. She also intervened on several occasions to ensure that all children at the table had access to at least one figure when one little girl tried to collect them all.

The decision to pass out these materials, even in the moment, felt uncomfortable because this action violated both the norms of the classroom—materials are not taken out during the last twenty minutes of the day – and the norms of ethnographic research—the participants define the social rules and ethnographers try to adopt them in the least intrusive way possible. However, informed by the theoretical language of culturally relevant pedagogy, which called for adopting a critical stance toward dominant schooling practices, and answerability, which called for a responsiveness to the children in the moment, the PI made the decision to do something uncomfortable. The result was an opportunity as a researcher to see what sense students were able to make of these figures, which features they noted and talked about, and what they found interesting. It was also an opportunity for an experienced classroom teacher to model what it might look like to engage students in geometric thinking in a more hands-on way and to give students the opportunity to experience mathematics in ways that felt engaging and fun. On the video, students' faces are far more animated during these moments than while completing the worksheet.

However, this moment also created complications. While passing out shapes to the table the PI was sitting with seemed possible, passing out shapes to the entire classroom felt like too much of an intrusion. As a result, a little more than half of the children did not get to participate. In addition, because she initiated the activity, the PI became responsible for the behavior of the children in her group, which shifted her role in relation to them not just in the moment but in future interactions.

Putting Down the Camera

The PK teacher who we began the project with was a 20-year veteran of the classroom. As a result, few lessons spiraled out of control and those that did were quickly adjusted. Although we had our own opinions about the teaching, we never felt that the PK teacher was in need of our help. In contrast, as a third-year teacher, the kindergarten teacher occasionally found herself in the midst of lessons that were not going the way she intended. During these lessons, as part of our orientation toward responsiveness, we began to move around the room as classroom helpers, sitting with small tables of children and directing their progress.

For example, in one activity, students were asked to roll a number on a die, write the numeral, write the number word, and color the correct number of spaces on a tens frame. Most students were able to do each of these tasks, but had a great deal of difficulty interpreting where on the sheet they were supposed to write each component. Both researchers in the classroom began to help groups of children. Some of the video clips show wavering footage as the researcher tried to continue taping while pointing and explaining. In other cases, the video simply shuts off as the researcher attended to the children in front of her. Over the course of the semester, this switch from researcher to teacher occurred during three lessons in significant ways. Again, this move demonstrated a responsiveness to the children in the room that helped them to feel successful and academically accomplished in mathematics in ways that probably would have been unlikely with out the researchers' intervention. Additionally, although we don't yet have evidence, these sorts of interactions may help to build relationships that will make parents more comfortable with us and our questions during parent events.

However, these moves were not without consequences for us as researchers. For example, in a lesson during the week following the one described above, the PI is repeatedly interrupted by a little girl saying "Can you help me now? Can you help me now?" while videotaping a boy who is completing a task independently. Similarly, although the total amount of time when we chose to stop taping was small, there were some moments we lost that later we wished we had on tape.

Discussion

Asking ourselves whether our research strategies were culturally responsive led us to a point where we felt obliged to continually ask ourselves whether our practice as researchers was answerable to the children in the room and as a result toward stances in the classroom that we would not have adopted if we had only been considering our roles as researchers. In many ways, the dilemmas described in this report are related to long-standing conversations in the field of qualitative research, where a number of scholars have argued that researchers, who are privileged in many ways, have ethical obligations to positively impact the people with whom they work (e.g., Duneier, 1999; Weis & Fine, 2000). However, as others point out (Bogdan & Biklen, 2003), decisions to involve oneself change what is possible in the research relationship. We believe that the historical failure of schools, in mathematics and beyond, to include and to educate all children places the same ethical burden on researchers as on classrooms teachers—to provide opportunities for children to experience academic success, cultural competence, and critical engagement (Ladson-Billings, 1994, 1995). We also believe Bakhtin's notion of answerability provided a way of framing research decisions with an appropriate emphasis on the children in the room. At the same time, there are possibly unresolvable tensions involved in making an ethical stance such a large part of one's work. Through inviting children (even implicitly) to critique classroom practices, we risked our unproblematic relationship with the classroom teacher, which is essential to gaining the access necessary to doing this work. Similarly, by engaging with children during lessons we lost our status as objective observers.

These tensions need to be explored in both philosophical and empirical ways. For example, we continue to question each other's decisions in the classroom and to ask each other to articulate the ethical principles by which we are making these decisions. Empirically, we are seeking to document our own roles in the classroom (a practice supported by the presence of multiple researchers) and to code, analyze and theorize these interactions as we would any other classroom episode. In putting this forward, we hope to launch a conversation with other researchers about the ways we can use our mathematical and pedagogical knowledge to support children while also carrying out research on current schooling practices.

DEMONSTRATING THE USEFULNESS OF THE PARTICIPATORY-ANTICIPATORY DISTINCTION

Nicora Placa

Martin A. Simon
New York University
msimon@nyu.edu

This paper demonstrates the explanatory power of the participatory-anticipatory distinction postulated by Tzur and Simon (2004). Using data from our current project, we show how this lens allows us to make sense of seeming inconsistencies in a student's development of a mathematical conception. More broadly, the distinction allows us to observe, analyze and conceptualize stages of learning a particular concept and, in turn, generate more thorough accounts of student learning. Furthermore, we draw attention to its usefulness in informing the design of subsequent tasks.

Keywords: Rational Numbers; Learning Trajectories; Design Experiments

Tzur and Simon (2004) postulated different levels of abstraction in the learning of a concept (see also Tzur, 2007; Tzur & Lambert, 2011). Specifically, they characterized two levels representing different learned anticipations (reviewed below). In our current project, this distinction provided a critical lens for our analyses. In this paper, we demonstrate the explanatory power of these fine-grained distinctions in accounting for student learning and, its usefulness in informing the generation of tasks.

The Problem

As we worked with Kylie, a 4th-grade student, we were struck by the following sequence. We presented her with a series of tasks designed to develop an understanding of the relationship between mixed numbers and improper fractions. In order to identify the equivalent improper fraction for a mixed number, she was shown a bar[1] made up of whole and fractional units (representing a mixed number). She partitioned the whole units into fractional parts. Having subdivided the bar, she was able to verbalize or write the equivalent improper fraction. As she worked through the sequence, she began to anticipate what the equivalent improper fraction would be *without* partitioning the bars. For example, when she was shown a quantity that was 6 and 1/4 units long and asked to express it as an improper fraction, she quickly answered, "Twenty-five fourths." Furthermore, she was able to explain her answer, "If that was all broken up into fours ..., four times six is twenty-four. Plus one is ... twenty-five fourths." She was able to respond similarly to several other tasks of this type.

We then presented the task without setting up the figure on the screen. We asked her for an improper fraction equivalent to 2 5/7. She was unable to provide a correct response. She answered, "Um …(pause) twenty-seven fifths? No — twenty-five sevenths?" How could we explain the discrepancy between what Kylie had done on the prior tasks and her inability to complete this task? She had previously shown that she could create a mixed number from the numeral representation. She could start with a mixed number represented on the screen and anticipate the equivalent improper fraction. Why was she not able to do this most recent task?

Background and Methodology

This report is based on research conducted during the second year of the five-year Measuring Approach to Rational Number (MARN) project.[2] The project is focused on two goals: (1) increasing understanding of how students learn through their activity, and (2) understanding how students can effectively learn fraction and ratio concepts based on activities grounded in measurement. The design builds upon aspects of the Elkonin–Davydov elementary curriculum (Davydov, Gorbov, Mikulina, & Savel'eva, 1995; Davydov et al., 1999) as well as research on rational number learning. In our second year, we are conducting one-on-one teaching experiments based on task sequences we have developed.

The data in this paper comes from a one-on-one teaching experiment with Kylie, a fourth grader in New York City. We began working with her in the fall of 2011 twice a week for hour-long sessions. Our team conducts an on-going analysis of the data after each session. We make inferences about her understanding and modify our trajectory for the upcoming session.

Conceptual Framework

We now review the conceptual framework we use in this research project, including the participatory/anticipatory distinction.

Abstraction from One's Activity

An emerging body of work (Tzur & Simon, 2004; Simon, Tzur, Heinz, & Kinzel, 2004; Simon et al, 2010) builds upon Piaget (2001) and Von Glaserfield's (1995) constructs of *goal-directed activity, reflection,* and *abstraction* in order to understand the process(es) of conceptual learning. *Goal-directed activity* is used to describe both the mental and physical activity of a learner. Conceiving of the activity as goal-directed supports the researcher in understanding the learner's choice of activity and attending to what the learner is focused on; the learner's goal determines her focus. *Reflection* refers to the ability of a learner to notice (consciously or not) commonalities in his or her experience. A*bstraction* is the process by which conceptual learning occurs. Abstraction involves reflection on one's goal directed activity. This reflection or noticing of commonalities in one's activity results in an anticipation, the ability to know the effect of that activity without actually engaging in it. We elaborate further on the idea of learned anticipation in the next section.

Participatory and Anticipatory Stages

Building upon the learning through activity framework,[3] Tzur and Simon (2004) postulated two stages of abstraction as a student is developing a new mathematical conception. The first stage, termed *participatory,* refers to the idea that a learner can anticipate the result of an activity. However this anticipation is limited.

> At the participatory (first) stage, the learner has learned to anticipate the effects of an activity and may also be able to explain why the effects derive from the activity. However, this knowledge is only available to the learners *in the context of the activity* through which it was developed. "In the context of the activity" means either that the learner is engaged in the activity or is somehow (e.g., chance, social interaction) prompted to use or think about the activity. (Tzur & Simon, 2004, pp. 12–13)

The second stage, which is labeled *anticipatory,* occurs when the student can anticipate the need to call upon the activity in response to a particular type of task. At this point they are not calling on the activity alone, but the activity *and* the learned anticipation of the effect of that activity.

Analysis

The sessions analyzed here occurred after our initial work with Kylie on fractions. Kylie completed a variety of tasks designed to foster the development of an understanding of a fraction as a partial measurement unit. Many of these tasks were done using the computer program JavaBars (Biddlecomb & Olive, 2000). After this preliminary work, she was able to create and identify fractional quantities, including mixed numbers. In the sessions described, Kylie worked on a series of tasks designed to foster an understanding of how to express equivalent mixed numbers and improper fractions.

Converting Improper Fractions to Mixed Numbers

The tasks created for this session used the context of measuring a beam and communicating to the owner of a hardware store the length of the beam. Using JavaBars, the student was presented with a bar (the beam) that was unmarked, a bar that represented the unit the store owner had, and a long "measuring strip" that had been marked with fractional parts (see Figure 1). The student was asked to measure the beam with the measuring strip.

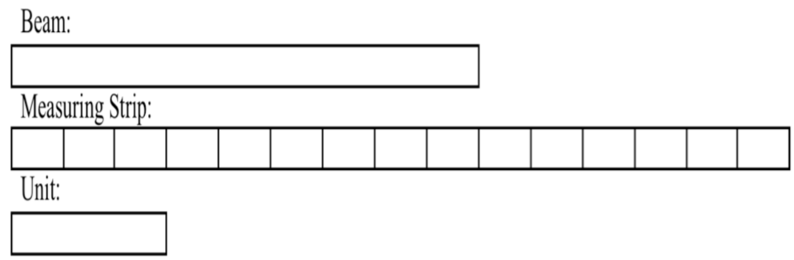

Figure 1: Context for the task

The activity she used to solve these tasks was the following. First, she measured the quantity with the long strip to determine the number of pieces in the quantity. She then measured the unit with the long measuring strip to determining the size of pieces. Because the earlier work had begun with mixed numbers, Kylie tended to give the answer as a mixed number either using division or more informal strategies. However, she was also able to give the answer as an improper fraction.

Kylie: It is two and one fifth.
Researcher: Or?
Kylie: Eh or eleven fifths.

In this example, we see she can anticipate what the quantity will be when it is grouped into units. She does not have to measure with multiple units. She can anticipate what the result of her activity of measuring with the unit would be given that she knows the number of partial units in the quantity and the number of partial units in the unit

After completing several tasks and demonstrating an anticipation of the results, she was asked a similar question but without the context.

Researcher: Okay. How about if I told you I had something that was ... thirteen thirds. Could you tell me another way to say it?
Kylie: (pause) Three ... no. Ten and three thirds? …
Researcher: Okay. Why do you say ten and three thirds?
Kylie: … cause there's ten … well, (pause) well, ten units and three thirds.
Researcher: (pause) you're just looking at these numbers separately?
Kylie: Yeah. Mhmm.
Researcher: Okay.
Kylie: Thirty-one thirds?

Although she had just demonstrated that she could anticipate what would happen if she measured an improper fraction like thirteen-thirds with a unit, she could not answer this question. In order to reconcile this disparity, we used the participatory-anticipatory distinction. The distinction suggests that two seemingly identical tasks could in fact demand different levels of abstraction, that is, different anticipations. We examined the distinction between the latest task and the previous ones in order to begin to articulate the differences in understanding. In the previous tasks, her attention was directed to the bar on the screen. Although she did not need to complete the activity in order to anticipate the result, she was cued to think about the activity. She saw the onscreen situation as being a question of measuring the unit and fractional parts of the unit. In the most recent question, she was not prompted to think about these particular measurement activities. In fact there was no measurement expressly asked for. We will present a detailed analysis of the tasks Kylie could not do after we present some additional data

Converting Mixed Numbers to Improper Fractions

This same phenomenon happened when Kylie was engaged in finding equivalent improper fractions from mixed numbers. In these tasks, was given a unit and asked to make a bar of a given length, such as three and two-fifths. She would create this quantity by iterating the unit three times, partitioning another unit into five pieces, pulling out two of the pieces and joining them to the three unit bar. After the creation of the quantity, the researcher asked how long the bar would be if it were cut into fifths. Her activity in these tasks involved partitioning each of the units into five pieces and then counting all of the pieces. When the numbers became cumbersome to count, she used multiplication to help her determine the number of the pieces. In addition, after she completed the initial task, the language used by the researcher changed so that she was asked what improper fraction the quantity was equal to, instead of how long it would be if it were cut into pieces. The use of the term improper fraction did not seem to confuse her or change her activity.

After completing several of these tasks, she began to anticipate the answer without partitioning the units. In the excerpt below, the researcher had made a bar that was five and five sixths units long.

Researcher: Do you know what improper fraction it's equal to?
Kylie: Uh ... (pause) If it was all cut up into...sixths?
Researcher: If this were all sixths, how many would there be?
Kylie: (pause) Oh! Thirty-five ...
Researcher: Why thirty-five?
Kylie: Cause there's five sixths over here, and if it was all cut up, this part would be thirty and then that would be five.
Researcher: Okay. How do you know this part would be thirty?
Kylie: Cause each one of these is six.
Researcher: Uh huh.
Kylie: Six, twelve, eighteen, twenty-four….
Researcher: How do you know each one of those is six?
Kylie: Cause this is sixths.

In this excerpt, she can anticipate the result of cutting the bars into sixths without having to perform the activity.

After successfully demonstrating she could anticipate the results of partitioning a mixed number on several tasks, she was asked the following.

Researcher: I have a candy bar that's ten and a third units long. Can you tell me what the improper fraction would be?
Kylie: (pause) ten thirds? Ten... (pause) ten ...

Similar to what happened earlier, she suddenly is unable to answer the question.

Enlisting the Participatory-Anticipatory Distinction

An implication of the participatory-anticipatory distinction is that if a difference in performance can be attributed to this distinction, the tasks must have demanded a different level of abstraction from the learner. By *task*, we must consider not just the written or oral articulation of the task, but its position in a sequence of tasks and the tools available to solve the task. Let us first look closely at the tasks in this section that Kylie was able to do correctly. Kylie was given (or asked to draw) a bar representation of the mixed number. She was then asked to identify the improper fraction equivalent, which she understood as the number of fractional parts if the whole units were also broken up so the whole bar was partitioned into equal parts. Through her activity of partitioning the whole units and determining the total number of fractional parts, she came to be able to anticipate the number without actually partitioning the unit. Thus, the tasks prompted her to look at the fractional part, consider the number of parts that the wholes would be broken into and then total the parts—often through multiplication followed by addition. To summarize, Kylie was carrying out the task of finding the number of partial units that would measure a bar that was initially measured in both whole units and partial units.

Did the last task (candy bar of length 10 1/3 units) require the same level of abstraction? Or did this task require an anticipatory level of knowing, whereas the prior tasks required only a participatory level? We argue for the usefulness of the latter. In this last task Kylie was asked to convert from a mixed number to an improper fraction. How was this different? Wasn't that what she was doing before? No. Before, the mixed number specified a bar to draw (sometimes drawn by the researcher), and then determine how many partial units were in that bar. Her focus was not on the equivalence of two representations. In the last task, she was asked to change a number written one way into a number written another way. She needed to know (to anticipate) to call on her prior activity, that is anticipate that if she thought about drawing a bar and partitioning it, that she would know the number of partial units and therefore the improper fraction. However, this was an anticipation that she had not yet developed. The following arrow diagram represents this claim.

Initially, Kylie developed an anticipation of the effect of her activity sequence: $A \rightarrow E$ (A is the activity, E is the effect). This anticipation was learned in a particular type of task for which the learner had a particular goal (e.g., determine the number of partial units in the bar on the screen). However the concept that was being developed (the researcher's instructional goal), represented by the last (anticipatory) task, required that she anticipate the need to call on that activity in response to a task that differed from the task through which the original anticipation ($A \rightarrow E$) was developed. This new anticipation that was needed can be represented as the relationship between a new goal G_1 and the activity A which is already linked to effect E by the original anticipation. Thus, the anticipatory stage requires the anticipation represented as $G_1 \rightarrow (A \rightarrow E)$.

Kylie did not have the anticipation between G_1 and the activity. She did not know (had not developed the anticipation) to call on her partitioning-and-totaling activity sequence in response to this equivalence question. When Kylie responded 10 1/3 = 10/3, the researcher created a bar that was 10 and 1/3 units long and prompted her to use the bars to see if she was correct.

> *Researcher:* Okay. So you said, you said it's ten thirds, right?
> *Kylie:* Mmhmm
> *Researcher:* Figure it out, is that ten thirds?
> *Kylie:* No.
> *Researcher:* How much is it?
> *Kylie:* It's ... (pause) one two three. Uh, three, six, nine, twelve, fifteen, eighteen … twenty- one, twenty-four ... (pause) twenty-seven? (pause) thirty. Thirty-one. It's thirty-one thirds.

The data excerpt above is consistent with the analysis. When prompted for the activity, she can make use of her anticipation regarding the number of partial units. We see she can successfully anticipate the results when prompted to think about the activity. It is clear that the anticipation required for the two tasks is different. When prompted to think about the activity, she needs to anticipate the results of the activity. When given a task that does not explicitly refer to the activity, she needs to anticipate the activity she needs to call upon. These two stages require distinct levels of understanding. It is clear she has the first anticipation, while the second type of abstraction remains outside of her current understanding. We leave it to the reader to make a similar argument relative to the first data segment (improper fraction to mixed number).

The diagram below (see Figure 2) is meant to represent Kylie's knowledge. The vertical arrows represent the anticipation that Kylie developed about the relationship between the diagram showing a mixed number and its equivalent improper fraction. The right arrow shows the reverse. The question Kylie is focused on for each vertical arrow has to do with the size of the bar. The dotted arrow reflects the lack of anticipation of the relationship between improper fractions and mixed numbers in response to the create-the-equivalent question.

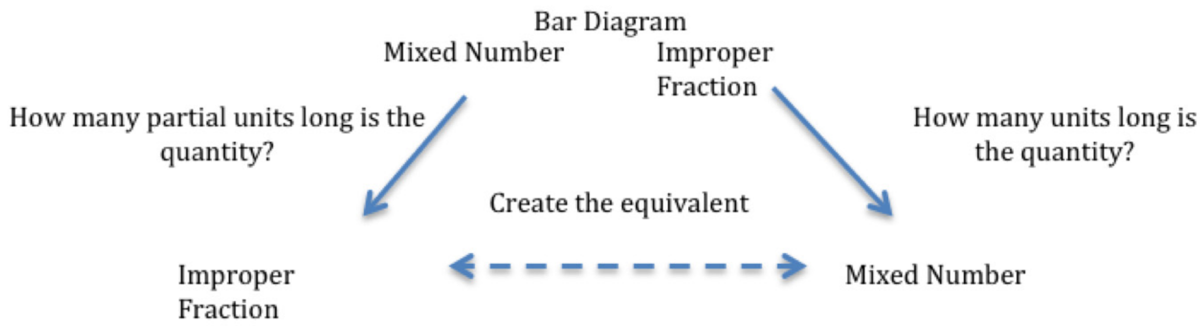

Figure 2: Diagram of Kylie's knowledge

The following data segment further strengthens the analysis. Kylie watched the researcher make a candy bar on the screen that was 2 and 5/7 units long. He then directed her the paper in front of her.

Researcher: Okay. How many... can you tell me two and five sevenths as ... (writing) as a, as an improper fraction?
Kylie: (pause) um. (pause) … twenty-five sevenths?
Researcher: Twenty five sevenths, look up there, does that look like twenty-five sevenths?
Kylie: No.
Researcher: What does it look like?
Kylie: … seven, fourteen … fifteen, sixteen, seventeen, eighteen, nineteen, nineteen sevenths.
Researcher: Nineteen sevenths.

Although the bar was on the screen in front of her, Kylie did not use it. One cannot be sure that she was aware that it was the length indicated on the paper. However, her failure to consider it when answering the question can be seen as her inability to connect the task and the activity she had used.

Conclusion

The data analysis provided demonstrates the explanatory power of differentiating between the anticipatory and participatory stages of conceptual learning. In Tzur and Simon (2004), the distinction was demonstrated with "the next day phenomenon," a common experience of educators. These data are even more compelling as the contrasting problems come one after the other in the same session (and with multiple examples). Without this construct, we would have struggled with understanding what seemed like inconsistent knowing on Kylie's part.

Researchers often expect that newly learned concepts might be inconsistently called on (Siegler, 1995). However, what percentage of those situations could be explained by this distinction? The distinction allows us to observe, analyze and conceptualize stages of learning a particular concept. It permits us to generate more thorough accounts of student learning. In some cases, we can use the distinction to anticipate aspects of a hypothetical learning trajectory (Simon, 1995) and in other cases, it allows us to notice in the data when we have failed to anticipate the challenge of moving from a participatory level to an anticipatory level. Explaining a data sequence as a move from participatory to anticipatory has a significant effect on task design in our teaching experiments. We can design tasks that aim directly at the new anticipation needed, the anticipation of the activity (linked to the effect) in response to the new goal. Continuing to provide experience at the participatory level would not benefit the student.

We close with a note about the use of the participatory-anticipatory distinction. The claim that an anticipation is at a participatory or anticipatory stage is relative to the particular concept in question and the related learner goal and activity. Thus, Kylie's ability to look at a bar measured in whole and partial units and anticipate the measurement in partial units only is neither participatory nor anticipatory. Rather it is useful to think of it as participatory relative to understanding conversion of mixed numbers to improper fractions, the goal of making the conversion, and the activity of partitioning whole units into partial units.

Endnotes

[1] This was done on a computer using JavaBars (Biddlecomb & Olive, 2000). The focus in these activities was only on length (horizontal dimension).

[2] This paper is based upon work supported by the National Science Foundation under Grant No. DRL-1020154. Any opinions, findings, and conclusions or recommendations expressed in this paper are those of the authors and do not necessarily reflect the views of the National Science Foundation.

[3] Originally, this work was based on a specific elaboration referred to as "reflection on activity-effect relationships" (Simon et al., 2004). Whereas Tzur has continued to work with that elaboration, Simon has chosen to embark on a program of research, using the underlying concepts of reflection, activity, and abstraction, to conduct particularly rigorous teaching experiments (see Simon et al., 2010) to build a strong empirical base for elaborating a mechanism or mechanisms for conceptual learning.

TRANSITIONING INTO CONTEMPORARY THEORY: CRITICAL POSTMODERN THEORY IN MATHEMATICS EDUCATION RESEARCH

David W. Stinson
Georgia State University
dstinson@gsu.edu

Erika C. Bullock
Georgia State University
ebullock1@student.gsu.edu

In this theoretical paper, the authors provide an overview of mathematics education as a research domain, identifying and briefly discussing four transitions or historical moments in mathematics education research. Using the Instructional Triangle as a point of reference for the dynamics of mathematics instruction, they illustrate how mathematics education researchers working in different moments explore different questions and use different theoretical perspectives. The authors then provide brief summaries of critical theory and postmodern theory, and suggest critical postmodern theory (CPT) as a hybrid theory that offers new possibilities for conceptualizing and conducting mathematics education research.

Keywords: Research Methods

Introduction

In this theoretical paper, to critically examine and deconstruct the persistent inequities of mathematics education or, more specifically, to open up the "fictions, fantasies and plays of power inherent in mathematics education" (Walkerdine, 2004, p. viii), we make a case for considering critical postmodern theory (CPT) (Kincheloe & McLaren, 1994; Stinson & Bullock, 2012a) in mathematics education research. We believe that CPT provides a means to make visible the Trojan Horse of the *mathematics for all* rhetoric (Martin, 2003). We structure the paper into two sections. In the first section, we provide an overview of mathematics education as a research domain, identifying and briefly discussing four transitions or moments in mathematics education research. We use the familiar *Instructional Triangle* (see National Research Council, 2001, p. 314) as a point of reference for the dynamics of mathematics teaching and learning to illustrate how mathematics education researchers working in different moments explore different questions and use different theoretical perspectives. In the second section, we provide brief summaries of critical theory and postmodern theory, and suggest CPT as a hybrid theory that offers new possibilities for conceptualizing and conducting mathematics education research. (For a significantly revised and expanded version of this argument see Stinson & Bullock, 2012a, 2012b.)

Theoretical Transitions in Mathematics Education Research

Our intent here is not to offer a comprehensive history of mathematics education as a research domain, that has been done elsewhere (Kilpatrick, 1992). But rather to briefly outline four transitions or historical moments of mathematics education research: the process–product moment (1970s–), the interpretivist–constructivist moment (1980s–), the social-turn moment (mid 1980s–), and the sociopolitical-turn moment (2000s–). We do not see these moments as linear phases of progress but rather as distinct yet overlapping and simultaneously operating theoretical perspectives or paradigms. Therefore, we do not identify end dates. Furthermore, we understand that our attempt to mark the beginning of a moment within a specific decade is somewhat misleading, given that there have been education scholars and researchers (mavericks) who began developing different possibilities for mathematics education research long before the decades that we identify (e.g., Marilyn Frankenstein [1983/1987] began exploring the sociopolitical implications of critical mathematics education several years before the sociopolitical-turn moment of the 2000s).

Because mathematics education draws from a number of disciplines, it is surprisingly difficult to characterize, and research in mathematics education is perhaps even more difficult to define (Silver & Kilpatrick, 1994). Nonetheless, as we acknowledge the difficulty in "defining" mathematics education research, we start our discussion with the 1970s and identify this decade as the beginning of the process–product moment. Most of the research in this moment attempts to quantify effective mathematics teaching;

quantitative statistical inference is the primary methodology. Here, mathematics teachers' classroom practices are described (process) and linked to student outcomes (product); limited effort is made to describe the decision-making processes of teachers or students (e.g., Good & Grouws, 1979). Securely embedded in the Enlightenment (i.e., the Age of Reason), this moment is theoretical grounded in positivism. Its aim is to predict social phenomena by "objectively" observing and measuring a "reasonable" universe. In the late 1970s and early 1980s, however, mathematics education researchers began transitioning away from a reliance on statistical inference. An analysis of manuscripts submitted to and published by the *Journal for Research in Mathematics Education* between the early 1970s to the mid 1990s showed that by the end of the 1990s "mathematics education had outgrown its dependence on statistical techniques in favor of qualitative methodologies adapted from such disparate research disciplines as anthropology, psychology, history, philosophy, and sociology" (Lester & Lambdin, 2003, p. 1676).

And because research methodologies are inextricably linked to theoretical perspectives (LeCompte, Preissle, & Tesch, 1993), this favoring of qualitative methodologies transitioned some mathematics education researchers into new theoretical perspectives such as interpretivism and constructivism. Although embedded in the Enlightenment, within the interpretivist–constructivist moment (1980s–), the aim of research is not to predict social phenomena, but rather to understand it (e.g., Steffe & Tzur, 1994; Thompson, 1984). Here, mathematics teaching and learning is examined within the dynamic interactions between teachers-and-students and students-and-students as they engage with mathematics in the classroom; often illustrated in the familiar *Instructional Triangle* (see National Research Council, 2001, p. 314).

But as mathematics education researchers continue to explore the complexities of mathematics teaching and learning, adapting theoretical perspectives and methodologies from other disciplines, some begin to understand the indispensable requirement of exploring not only the complexities of the Instructional Triangle but also the complexities of contextualizing students, teachers, and mathematics (Stinson, 2006). In so doing, they make the *social turn* in mathematics education research (Lerman, 2000). The social turn signals something different in mathematics education research, namely, the emergence of theoretical perspectives that "see meaning, thinking, and reasoning as products of social activity" (Lerman, 2000, p. 23) (e.g., Boaler, 1998; Carraher, Carraher, & Schliemann, 1987; Cobb, Perlwitz, & Underwood, 1996). Lerman cautioned, however, that the greatest challenge for mathematics education researchers who work within the social turn "is to develop accounts that bring together agency, individual trajectories…and the cultural, historical, and social origins of the ways people think, behave, reason, and understand the world" (p. 36). Researchers in this moment in general do not abandon psychology altogether—a discipline that has had a seminal influence (Kilpatrick, 1992)—but rather call for a sociocultural, discursive psychology in which mathematics teaching and learning might be understood as a particular moment in the zoom of a lens (Lerman, 2001).

By zooming out, researchers explore not only the complexities of the concentric contexts in which the Instructional Triangle is embedded (e.g., classroom, school, district, community, society) but also the multiplicities of the sociocultural and sociohistorical discourses that construct and continuously shape those contexts (Weissglass, 2002). By zooming in, researchers explore the dynamic complexities of how sociocultural and sociohistorical discourses have constructed and continuously shape students, teachers, and mathematics—thus, the possibility of the very existence of the triangle. This back-and-forth zooming of the lens motivates different questions to explore regarding the contextualization of the triangle as well as students, teachers, and mathematics. This back-and-forth zooming has also resulted in a small (but growing) number of mathematics education researchers abandoning theoretical perspectives that investigate understanding social phenomena such as interpretivism or constructivism to embracing theoretical perspectives that investigate emancipation from or deconstruction of social phenomena such as critical theory, critical race theory, feminist theory, and postmodern theory. In so doing, these researchers have adopted "a degree of social consciousness and responsibility in seeing the wider social and political picture" of mathematics education research (Gates & Vistro-Yu, 2003, p. 63).

Seeing the wider social and political picture characterizes the sociopolitical-turn moment (2000s–) in mathematics education research. Gutiérrez (2010) marked the *sociopolitical turn* as signaling "the shift in theoretical perspectives that see knowledge, power, and identity as interwoven and arising from (and constituted within) social discourses" (p. 4). Researchers who position their work within the sociopolitical-turn moment use familiar theoretical perspectives in novel and unexpected ways and/or embrace contemporary theoretical perspectives to formulate different questions and possibilities for mathematics education (e.g., Berry, 2008; Gutstein, 2003; Martin, 2010; Walshaw, 2001). The sociopolitical-turn moment, as we envision it, permits mathematics education researchers to problematize the Instructional Triangle—its existence, its assumptions, and its implications—by maintaining the exhausting process of concurrently zooming out and zooming in on the triangle only to zoom out and in yet again. This simultaneous zooming out/in steals the innocence of the Instructional Triangle, deconstructing it, as the discursive binaries used to name the vertices, and thus the triangle, are put under erasure (cf. Derrida, 1974/1997).

Here, students, teachers, and mathematics are understood as discursive formations (cf. Foucault, 1969/1972), named and re-named (but not determined) within hegemonic sociocultural, sociohistorical, and sociopolitical assumptions, conditions, and power relations. With this simultaneously zooming out/in, the vertices are no longer brought into focus, but become monsters, no longer intelligible, as they resist the surveilling and disciplining gazes of normalization (cf. Foucault, 1977/1995). As the vertices become unintelligible, it provides different possibilities for the vertices; thus, different possibilities for the Instructional Triangle and mathematics teaching and learning in general. The sociopolitical-turn moment has the potential to move mathematics education researchers away from the research agenda that explores "primarily questions of *how* to improve possibilities for teaching and learning of mathematics, toward a research agenda strongly concerned with the question of *why* mathematics education" (Pais, Stentoft, & Valero, 2010, p. 369, emphasis in original). In exploring this—in many ways, forbidden—why question, mathematics education as a research domain is cracked wide open, revealing its inclusions and exclusions (Skovsmose, 2005). Within the sociopolitical-turn moment, we believe that CPT provides a means to not only ask this forbidden why question but also other why and how questions, opening up different possibilities for mathematics education research.

Working Against Theoretical Fundamentalism

In this section, we briefly summarize critical theory and postmodern theory from our current understandings of these complex and far-reaching theories, and suggest that concepts from both theoretical perspectives might be used side by side—like tools pulled from a tool box—to short-circuit systems of power (Foucault, 1975/1996b). Although some researchers might view conflicting theoretical perspectives as incompatible, they also can be viewed as *complementary* (i.e., exploring different aspects of the same phenomena) or *incommensurable* (i.e., using different languages rather than really being incompatible) (Sfard, 2003). We believe that to capture the complexities and multiplicities of contexts when making sense of social phenomena, it often requires sifting data through one theoretical sieve, analyzing what is captured, and then catching that which remains with the next sieve of theory. Effective use of theory, therefore, requires that the researcher assume the responsibility of scholarly work; that is, the difficult intellectual work of studying the strengths and weaknesses and the convergences and divergences of different theoretical concepts pulled from (at times) conflicting theoretical perspectives (Paul & Marfo, 2001).

Critical Theory

Critical theory emerges from a Marxist tradition within the Frankfurt School (*circa* 1920) of challenging asymmetrical power relationships (Bottomore, 1991). As an activist and emancipatory project, critical theory calls its claimant to question the structures that are developed and maintained by "constructors" (Skovsmose, 2005, p. 140) and manifested as false consciousness for those who are constructed within hegemonic power. Hegemony constructs people as *objects*—those who are acted upon, rather than *Subjects*, those who act—who become so entrenched in their own oppressive condition that they do not realize their own subjugation or their complicity in the perpetuation of unjust social and economic systems (Freire, 1970/2000). Employing critical theory, therefore, requires the researcher to use her or his scholarship to dismantle the constructors' hegemonic power and the reproduction and execution of that power through institutions such as media and schools (Slott, 2002). She or he must consider how her or his scholarship—and even her or his language—supports or subverts hegemonic assumptions (Agger, 1991). In so doing, the critical theorist questions the production, validation, dissemination, and reproduction of knowledge through these institutions. Critical theorists, therefore, call for all efforts to disseminate knowledge to be accompanied by an investigation of not only its relation to ideology and power but also the subjectivities of the researcher (Leistyna & Woodrum, 1996). Through this investigation, critical theorists aim to transform existing power relations in a redemptive struggle for the humanization of people (Freire, 1970/2000). As a modernist project, embedded in the Enlightenment, critical theorists believe that as marginalized groups become critically aware of their "true" situation, intervene in its reality, and take charge of their destiny, they will exercise their right to engage in the sociohistorical transformation of their society (Crotty, 1998).

Postmodern Theory

Postmodern theory is a critique of the Enlightenment that rejects any static foundational systems of logic, resulting in truth—and thus, knowledge—becoming fluid and avoiding absolution (Seidman, 1994). Postmodern thought, however, is not a denial of the existence of truth but rather an acceptance of multiple forms of truth, made and remade within sociocultural, sociohistorical, and sociopolitical discourses (Foucault, 1984/1996a). But here discourses are no longer the mere intersections of things and words that might be spoken, heard, or read but rather "practices that systematically form the objects of which they speak" (Foucault, 1969/1972, p. 49). Knowledge then, for the postmodern theorist, is a discursive formation (cf. Foucault, 1969/1972); it no longer maintains its privileged status as an objective order of things but rather is subjected to and limited by the very sociocultural, sociohistorical, and sociopolitical assumptions, conditions, and power relations against which "true" knowledge within the Enlightenment claimed immunity (cf. Foucault, 1970/1994). Working in postmodern theory, therefore, is "a movement of 'unmaking'" (R. Wolin, cited in Crotty, 1998, p. 192). This unmaking pulls apart or deconstructs (cf. Derrida, 1974/1997) reductionist discursive binaries—truth/untruth, rational/irrational, objective/subjective, man/woman, white/black, teacher/student—as a means to unsettle and displace binary hierarchies, to uncover their historically contingent origin and politically charged roles, there inclusions and exclusions. The aim of deconstruction, however, is not to provide a "better" or "truer" foundation for knowledge and society but rather to dislodge the dominance (i.e., power) of discursive binary hierarchies, creating a social space that is tolerant of difference, ambiguity, and playful innovations which support autonomy and democracy (Seidman, 1994). In embracing difference and ambiguity, the postmodern theorist rejects the single story or grand meta-narrative (Lyotard, 1979/1984) that attempts to sanitize knowledge of difference and ambiguity. Here, the single story or grand meta-narrative of "science" is merely an illusion because it is not possible to control historical events that escape the clutches of reason and rationality (Usher & Edwards, 1994); objectivity is a mere fiction.

Critical Postmodern Theory

Employing concepts from critical theory and postmodern theory—or any other theoretical combination—side by side is messy work that is "necessary and fruitful in 'the search for meaning'" (Cook, as cited in Lather, 2010, p. 9). Working against theoretical fundamentalism (Lather, 2006), CPT operates as a differential consciousness, which Sandoval (2004) described as representative of the variance that emerges out of correlations, intensities, junctures, and crises. As we consider critical theory and postmodern theory independently, we encounter such variance from which CPT—the synergy of the two—emerges (Kincheloe & McLaren, 1994). To illustrate this synergy, we provide an example of how oppression (or marginalization) and resistance might be reconceptualized when considering the both-and theoretical perspective of critical postmodern theory rather than the either-or perspective.

While both critical theorists and postmodern theorists are concerned with oppression and resistance, their approaches are indeed significantly different. Critical theory addresses oppression by focusing, often to the point of tunnel vision, on the oppressed. Critical theorists see liberation or emancipation for the oppressed as a worthy and attainable goal achieved through praxis—a recursive process of critical reflection followed by action—what Lather (1991) defined as "philosophy becoming practical" (p. 11). Through praxis, the critical theorist works on behalf of the oppressed frequently without regard for ethical relations with the oppressor. The goal for the critical theorists becomes for the oppressed to reverse the oppressor/oppressed binary, for the oppressed to assume the position of power held by the oppressor. Once this reversal or power shift occurs, too often there is no further action (World history repeatedly validates this claim). This reversal leads us to see critical theory as a contradiction upon itself as an emancipatory project. By restricting itself to the oppressor/oppressed binary, the oppressed can assume no position beyond that of oppressor. This limiting of possibilities is still oppressive and yields no real sense of liberation. To speak more broadly, in the surge for liberation, the critical theorist is often seduced into overturning one régime of truth with yet another régime (cf. Foucault, 1977/1980).

Postmodern theory, on the other hand, provides a way out of this contradiction; it advocates for the erasure of all boundaries through decentralization, thus eliminating the need for emancipation, as it is not necessary to free one who is not bound. By deconstructing the binary between the oppressed and the oppressor and placing both binaries (i.e., oppressor/oppressed and oppressed/oppressor) under erasure, postmodern theory addresses the contradiction within critical theory by leaving the subject (i.e., the individual) open to infinite possibilities. Through deconstructing reductionist binaries and troubling emancipatory régimes of truth, the subject lives in a perpetual state of becoming her or his best self, while working within/against sociocultural, sociohistorical, and sociopolitical discourses. The irruption of the oppressed/oppressor binary eliminates the need for the us-them or self-other argument, allowing researchers to work the hyphen that separates the two (Fine, 1994). It is within this hyphenated space that ethics gains prominence. To exist with others within the hyphen, the subject must constantly be aware of the incompleteness of her or his ethical dealings with her or his self and with others. The emancipation of critical theory is too often not without casualties; postmodern theory requires a continuous ethical awareness of and responsibility for these casualties.

Closing Thoughts

Postmodern theorists in general advise caution with the emancipatory nature of critical theory because "any emancipatory perspective presupposes values which cannot be agreed upon universally or permanently" (Brown & Jones, 2001, p. 4). This cautious stance, however, causes critics of postmodern theory to claim that it "is an obstacle to the formation of open and radical perspectives that challenge inequalities and the deepening of the rule of capital in all areas of social life" (Rikowski & McLaren, 2002, p. 3). We believe, however, borrowing from Lather (2006), that both the seductions of and resistance to postmodern theory can assist us in getting smart about the limits of critical theory. Or, said in another way, the synergy between critical theory and postmodern theory is found in the "interplay between the praxis of the critical and the radical uncertainty of the postmodern" (Kincheloe & McLaren, 1994, p, 144). By integrating critical theory and postmodern theory, CPT cautiously uses the activist praxis of critical theory to restore hope—and therefore, action—to the (too often) inaction of postmodern theory.

In this paper, we problematize an ontological characterization of change within a complex system by illustrating how epistemological premises of interactionist, individualist, and collectivist theoretical perspectives reveal only specific aspects of a changing system. Methodological considerations resulting from our recognition that change is characterized subjectively within various theoretical perspectives are made.

Keywords: Research Methods; Measurement

Introduction

A central focus of work in mathematics education research is the characterization of change—which we view as the entailment of three processes: (1) identifying whether or not change has occurred, (2) identifying the amount of change that has occurred, and (3) identifying the potential causes of change. One may be interested in characterizing change in students' ways of understanding as they progress through a particular instructional sequence. Another may focus on explaining how the norms of a classroom environment evolve over the course of a semester and how individual students' perceptions of, and activity within, these norms change in tandem. Still another may focus on describing how institutions change in response to educational policies or reform initiatives. Change is everywhere, is occurring all the time, and whether one is studying students, teachers, or institutions, the characterization of change is an integral part of contemporary mathematics education research.

If one seeks to characterize change in a complex system, a key consideration must be to recognize the system within which that change occurs and to make assumptions about how that system can undergo change. The identification and explanation of change within a complex system depends largely on the epistemological assumptions one makes about knowledge and about learning as well as the ways in which agents of change are characterized within the system. While there have been articles that focus on describing the assumptions and practices of various theoretical perspectives (e.g., Cobb, 2007), none have explicitly focused on how specific theories of learning characterize change. The focus of the present article is to explain the basic assumptions regarding learning and knowledge, and its growth held by prominent theoretical perspectives in mathematics education research. In addition, we show how the assumptions of various learning theories serve as a lens through which change is perceived in order to illustrate how change within a single system can be characterized in different ways depending on the premises of the theoretical perspective that a researcher assumes.

In our view, any characterization of change will necessarily entail limiting the scope of analysis to specific aspects of the changing system. As a result, the epistemological assumptions made by the researcher as well as the unit of analysis chosen, constrain the type of change that can be characterized within a system, such as a classroom. Hence, we use the word *comprehensive change* to convey all aspects of the changing system, including all *anticipated* representations and causal conditions of change, that are hypothesized to collectively comprise some measurable change in a system that occurs over some interval of time.

A major focus in this article will be to problematize the notion that empirical mathematics education research characterizes change as if it is an ontological and agreed upon construct. Our review of the literature suggests that taken as a whole, current work has not rigorously addressed or defined comprehensive change. As a result, there have been few efforts that examine change in a learning system by conscientiously defining the learning system and its boundaries in order to characterize the mechanisms by which different variables within the system interact. We believe that any attempt to study change requires one to characterize a learning system and the interactions that take place within the learning system based on the assumptions of particular theoretical orientations. We propose that the theoretical perspective that one assumes serves as a lens through which one attempts to “control” specific aspects of the changing system to construct a viable characterization of change with respect to specific features of the changing system. We argue that the specific features of the changing system that one attends to, and their hypothesized effects on other aspects of the system, are largely determined by the epistemology of one’s theoretical orientation.

Survey of Theoretical Perspectives

Mathematics education researchers currently use a plethora of theoretical perspectives that originate from fields such as cognitive science, sociology, anthropology, and psychology. Such perspectives include but are not limited to, radical constructivism, behaviorism, sociocultural theory, situated cognition, cognitive information processing theory, cognitive psychology, experimental psychology, social cognitive theory, and social constructivism. To efficiently contrast the characterization of change among these perspectives, we have organized them into three general categories that account for their historical treatment of learning, and the unit of analysis by which these traditions assume learning can be understood: *interactionism*, *individualism*, and *collectivism*. Our rationale for this partition resulted from recognizing that the epistemological tenets in the theoretical perspectives prevalent in mathematics education research are not distinct, but instead are championed, shared, and modified by researchers in a learning system. This partition is helpful to understand the ways in which the field is conflicted in its message about change, the subsequent claims we can make about how change occurs, and the recommendations we can make regarding potential levers for enhancing growth in mathematical teaching and learning.

We begin by outlining the characteristics of interactionism, individualism, and collectivism; providing brief summaries of select theoretical perspectives that are encompassed within each class of perspectives relative to their characterization of individual agents in a learning system as well as their epistemological stance. This discussion highlights the potential conflicts arising in our field from people speaking the same words, but not meaning the same things regarding the study of change in teaching, learning, and policy. We conclude with methodological considerations resulting from our recognition that change is characterized differently within different theoretical perspectives.

Interactionism

Interactionism encompasses theoretical perspectives that consider cognizing agents as subjective interpreters situated in social and societal contexts. In interactionism, individual behavior is dictated by subjective interpretations of social experiences that cannot resemble an objective existence. To the interactionist, individual agents create their experiential world and act within their own experiential world. However, interactionism does not disregard an outside world, but at the same time makes no claims about the existence of a single ontological reality. This is because perspectives in interactionism assume that we cannot step outside of ourselves to observe a “real world”, as the world is a subjective reality. Thinking about the external world as a subjective reality allows interactionists to describe students’ learning as taking place within an experiential world that they are simultaneously organizing as they learn and create new knowledge. Perspectives that comprise interactionism include situated cognition, radical constructivism, and social constructivism.

Situated cognition. Situated cognition (Brown, Collins, & Duguid, 1989) frames the individual as a component of a reasoning *system* that is comprised of the individual’s *immediate* social, physical, and psychological environment. The external influence on one’s cognition is immediate in the sense that there is a consistent interaction between the individual and the reasoning system. Moreover, the external influence of one’s cognition is also dynamic in the sense that the reasoning system within which one participates is amenable to rapid change (i.e., is responsive to feedback from the environment). Learning, then, is characterized by the extent to which an individual is able to effectively coordinate elements of their immediate social, physical, or psychological environment as a reasoning aid. In other words, learning in the situated cognition perspective is characterized by an individual's ability to become a productive component of the reasoning system by using their immediate external resources productively.

Further, situated cognition assumes that knowing or understanding is inseparable from doing. Knowledge is characterized as competence with respect to norms of the setting in which one operates and accrues as one gains experience working within the constraints of a particular context. It is the individual's interaction with social norms, however, that takes precedence over group dynamics. Learning is characterized, then, as increasingly effective performance and higher levels of competency across situations (Wenger, 1998). As a result of these assumptions, a situated cognitivist might describe change as the level of familiarity one has working in a particular context or job, or the degree to which one is able to skillfully manipulate tools and representations in a discussion in the classroom. This is because change is not characterized by an accumulation of associations but instead is the attunement of actions between the agent and its environment, and that dynamic is necessary for the characteristics of learning and knowledge to be made manifest.

In the interest of full disclosure, we recognize that aspects of the situated cognition perspective lend themselves to the collectivist paradigm. However, as mentioned above, the analytical unit within the situated cognition perspective is the cognitive behavior of individuals situated within a reasoning system. Hence, we find it more appropriate for situated cognition to be considered principally a subset of interactionism rather than collectivism.

Constructivism. Radical and social constructivism are variants of a more general learning theory of constructivism. Constructivism is an epistemology asserting that humans construct knowledge and meaning from their perceptions of their own interactions with the experiential world. Formalization of constructivism is typically attributed to Piaget, who focused on the mechanisms by which learners internalize knowledge. Piaget's genetic epistemology emphasized how a cognitive organism, such as a human, becomes a cognizing agent. Piaget described adaptation and organization as the key principles to biological development. These principles of adaptation and organization are the key components of constructivism, but are interpreted in different ways by radical and social constructivists. For the sake of brevity, we detail only radical constructivism in this article.

Radical constructivism. Radical constructivism is a philosophical perspective on learning based on Piaget's more general notion of constructivism, which is concerned with the paradox of how one comes to "know" an ontological reality when one cannot step outside of his or her own ways of thinking and ways of perceiving reality. Radical constructivism posits that one perceives a subjective reality through adaptation and organization of ways of thinking, which von Glasersfeld (1995) operationalized as assimilation and accommodation.

von Glasersfeld (1995) and others (e.g., Thompson, 2000), often based on Piaget's genetic epistemology, have focused on the constructs of assimilation, accommodation, and equilibration to explain how one comes to create, refine, and evaluate a viable mental model of the world around them by focusing on conceptual analysis. Conceptual analysis is the construction of a scheme of meanings and ways of understanding that make one's actions sensible and coherent. In short, conceptual analysis allows an observer, who cannot observe another's subjective reality, to nonetheless create a viable model that makes ones actions coherent. The developmental of this mental model allows one not only to describe and explain, but also predict one's actions based on the model of one's ways of understanding a particular idea. Thus, a model can be a viable representation of the assimilation, accommodation, and equilibrium states of the student. At the same time, radical constructivists are constrained in explaining the thinking of another because they are dependent on making inferences about one's mental model from the language and actions. Thus, a characterization of change within the radical constructivist tradition depends on tracking the changes in the mental model of one's ways of understanding and ways of thinking.

Individualism

Individualist theoretical perspectives assert that individual's comprise the primary unit of reality and that societies emerge as a consequence of individual behavior. However, individualists contend that societies do not determine the identity, or govern the behavior of individuals within societies. Theoretical perspectives that comprise interactionism include cognitive information processing theory and experimental psychology.

Cognitive information processing theory. The essence of cognitive information processing is that human thought and cognition are treated as computational in nature. This theory assumes that existing mental structures process stimuli, and that knowledge is structured *in memory* as an association between concepts that have numerous branches to other concepts.

Cognitive information processing theory holds that attention is the primary mechanism by which knowledge is developed. Since individuals maintain the inherent propensity to organize information obtained from sensory input, the stimuli that individuals attend to among many potential inputs necessarily determines what information has the potential to be stored in working memory.

Information processing theory treats the processing of stimuli much like a computer program. In particular, our nervous system registers a sensory input, which is perceived and filtered through attention and interpretative structures into working memory. As a consequence, learning can be thought of as the process where new information is "fitted" into existing cognitive structures, often characterized as long term memory. Thus, the development of existing networks of understandings stored in long-term memory characterizes change within the cognitive information processing paradigm (Gagne, 1985).

Experimental psychology. Research within experimental psychology aims to develop a *collective abstract individual.* A collective abstract individual is collective in the sense that it is devised from a statistical aggregate of quantifiable attributes, and abstract in the sense that the individual need not correspond to the attributes of any particular individual in the group that comprised the statistical aggregate (Cobb, 2007). In the experimental psychology perspective, measurable characteristics of individual students are perceived to consist of discrete, isolatable attributes that can be measured with some fidelity and aggregated using quantitative methods. Thus, the amount that one has learned is measured by the extent to which one deviates from the statistical aggregate that comprises the collective abstract individual. More specifically, an aim of experimental psychology is to determine one's discrete, isolatable attributes at two or more moments in time and compare these attributes to those of the collective abstract individual. As a result of these assumptions, experimental psychology allows one to make probability estimates in the population regarding student thinking, motivation, or reactions. A decrease in deviation over time, which can be quantified, serves as evidence of learning within this perspective. However, experimental psychology does not explicitly define a lens through which causal factors for change of an individual within a learning system are identified. Rather, educational research within the experimental psychology paradigm has traditionally assumed a process-product orientation in which desired learning outcomes are attributed to observable teaching behaviors with an inattention to the cognitive or affective causal factors of learning. Hence, experimental psychologists limit the potential causal factors of change by considering only the independent variables that are hypothesized at the outset of an experiment. Therefore, causal factors of change do not have the opportunity of manifesting themselves throughout the conduct of research as a consequence of experimental psychology methodology.

Collectivism

Collectivist perspectives consider individual behavior and cognition to be fundamentally influenced by their situation within social and societal contexts. Accordingly, the analytical unit within collectivist theoretical perspectives is the activity of the culture or *collective.* Individuals serve as contributing agents in the collective as they participate in established cultural practices. As a complex system, the collective activity is an emergent property of the individual actions of its members and their interaction (Cobb &

Yackel, 1996). Norms and other social behaviors form the basis for understanding learning. Sociocultural theory is the predominant collectivist theoretical perspective.

Sociocultural theory. Sociocultural theory situates the individual within a general social environment and considers the individual's cognition inseparable from their more general social circumstances. Accordingly, many sociocultural theorists consider the individual-as-situated-in-a-cultural-practice as the appropriate analytical unit. Hence, learning in the sociocultural perspective is evidenced by "changes that occur in people's activity as they move from relatively peripheral participation to increasingly substantial participation in the practices of established communities" (Cobb, 2007, p. 24). That is, sociocultural theorists hold that cognitive behavior and participation in cultural practices co-participate in each other's evolution. This perspective differs from that of situated cognition in that situated cognitive theorists consider the relationship between cognizing subject and external environment to remain fixed. It is the recognition that intellectual development and cultural participation co-evolve that characterizes sociocultural theory as a collectivist perspective.

Sociocultural theorists identify change of an individual within a learning system by whether or not a social participant's activity is modified as they increase their participation in established cultural practices. The interaction between a participant and their social and cultural environment always serves as the causal factor for change within sociocultural theory.

Methodological Implications of Studying Change

We have thus far described major theoretical perspectives through the lenses of individualism, interactionism, and collectivism, and in doing so have shown that if one seeks to describe change within a complex system, the boundaries and assumptions about interaction of variables within the system constrain the type and amount of change that one can characterize.

We believe individualist, interactionist, and collectivist paradigms are uniquely powerful for characterizing various aspects of change within a complex learning environment, and claim that problematizing comprehensive change has important methodological implications. It is critical to understand the type of change at play, and we believe the individualist, interactionist, and collectivist perspectives are helpful in making this distinction. In this section, we consider methodological implications that one must consider in order to rigorously study change in a learning environment.

Research Question

Since a variety of aspects of a complex system are changing in tandem, and as we have argued, they cannot all be characterized simultaneously, researchers must assume the responsibility to explicate the ways in which the theoretical perspective they assume imposes a limit on the nature of change they are able to characterize. Demonstrating the recognition that one's theoretical orientation imposes conceptual blinders on specific aspects of the changing system in the statement of one's research questions is an essential aspect of communicating one's research in a way that promotes intersubjectivity among author and reader.

Because it is impossible to simultaneously characterize every type of change, a research question must address three issues. First, it must be specific enough so that the unit of analysis is unambiguous. Second, it must characterize the system within which the unit of analysis is to be studied. Third, it must specify a particular aspect of the complex system to be studied, including relevant variables and their interactions. These three considerations permit the researcher to specify what is to be studied, to determine at what grain level it is to be studied, and to demarcate boundaries and constraints within which the unit of analysis operates. These considerations not only confirm epistemological and theoretical coherence, but also allow the researcher to classify their characterization of change as individualist, interactionist or collectivist. This classification accordingly results in the recognition of changing aspects of a complex system that are not recognized by the researcher's method.

A research question that clearly identifies the unit of analysis and demarcates the boundaries within which the unit of analysis operates constrains the type of change that one can claim to characterize.

Constraining the type of change under consideration allows the researcher to identify a theoretical framework composed of descriptive and explanatory components that can characterize change in the unit of analysis. We do not claim that any of these frameworks are more appropriate than another. Instead, the usefulness of the framework in a study focused on characterizing arises from its ability to describe, explain, and even predict aspects of the complex system under study while fitting within the constraints of the boundaries of the system.

We recognize that in many cases the theoretical framing may constrain the development of the research question instead of the research question constraining the theoretical framework. In this case, one might start with the desire to characterize change using a collective, interactionist, or individualist perspective. Whatever research question develops from these constraints must still meet our three proposed specifications. This promotes the theoretical coherence of the framework and research question.

Design of Experiment: Data Collection

We believe the focus of experimental design must address the type of data that should be collected to adequately address the proposed research questions. Addressing this concern is critical to generating a data corpus that allows the researcher to characterize change within a particular component of a complex system. Accordingly, we describe the types of data collection crucial to characterizing change within the individualist, interactionist and collectivist paradigms.

Individualism recognizes change as a modification of an individual's behavior independent of their social practices and attributes the change to an individual's orientation to focus on behavior without regard to social influence. The amount of change can be measured by the displacement in alignment between an individual's behavior and idealized behavior between two or more moments in time. Thus, any data collected within the individualist paradigm must allow the researcher to make inferences about student's behavior patterns to generate a working model of those behavior patterns. Development of this working model is crucial to identifying any robust changes in behavior. Behavior patterns can be documented by tracking verbal cues, gestures, and written work as the student reasons through a particular problem, in a group of students, or with a computer program. A shift in verbal cues or gestures can suggest a change in behavior, which can then be studied in more detail. Whatever the setting in which the data is collected, when the focus of the data is on the student's individual actions, the data corpus can support characterizing change in an individualist paradigm.

Interactionism considers change as a modification of one's interpretation of experiential reality and attributes this change to a reorganization of cognitive structures initiated by an interaction with external stimuli. The amount of change is given by a displacement between one's interpretation and an intended interpretation between two or more moments in time. Any data collected within the interactionist paradigm must allow the researcher to make inferences about a student's model of the experiential world because change cannot be identified and explained without an initial working model. As with individualism, verbal cues, written text and gestures are most useful. In order to create a model of the student's experiential world, the researcher must create situations in which the student experiences constraints on their perception or thinking. It is not until the researcher experiences the constraints of the student that he or she can make a claim about the boundaries of a student's experiential world. Change then, can be characterized when the boundaries of the student's mental model of the world or a particular mathematical idea begins to shift. By focusing on the boundaries of a student's thinking, the researcher can continually generate and test hypotheses in order to create an increasingly viable and explanatory model of a student's mental model of the world.

Collectivism considers change as a modification of a social participant's activity as they participate in established cultural practices and attributes this change to the interaction between a participant and his or her culture. Accordingly, the amount of change is measured by the displacement in alignment between a social participant's activity and the established cultural practices between two or more moments in time. Data collected within the constraints of the collectivist paradigm must allow the researcher to characterize the social participant's activity as well as the cultural practices and the social participant's perception of those cultural practices. The collectivist paradigm requires the researcher to think about the social participant's perception and interaction as part of a collective, which might be the classroom in which they participate. The researcher must document the actions, including verbal cues, gestures, discussions, and written work of not only the individual student, but also the classroom as a whole. In collectivism, the classroom, not the individual, defines the boundaries of the system. The individual works within the boundaries of this larger system, but is not the focus within the collectivist paradigm. Thus, the researcher must be systematic about creating situations in which he or she can experience the boundaries of the classroom as a collective. The researcher can, at best, create a model that describes and explains the boundaries of the classroom as a collective, and this model can only come from the actions of the classroom as a whole. As the model of the classroom as a collective becomes more viable, just as in interactionism, the researcher is able to identify more subtle shifts (change) in the system.

Design of Experiment: Microgenetics and Density of Observations

Assuming that one has specified a type of data that adequately attends to the research question, how do we know if the amount of data is sufficient for creating a viable model of the individual or collective? The density and duration of time over which the observations are taken is critical. Siegler and Crowley (1991) addressed this issue with microgenetics, which has three properties. First, observations span the period from the initiation of a change to the end of a change, marked by the stability of a system under study. Second, the density of observations is high relative to the rate of change of the phenomenon. In short, the rate of change of number of observations with respect to time increases if one anticipates the system to be at a point of a critical change. Third, observed behavior undergoes trial-by-trial analysis with the goal of attributing causal agents to particular aspects of change in a system. (Siegler & Crowley, 1991, p. 606).

For example, suppose that a researcher is attempting to create a mental model of a student's thinking as he or she participates in a two-week long instructional sequence. The researcher believes that the major shifts in student's thinking will occur on days 1, 4 and 9 based on analysis of the instructional sequence. Thus, the researcher may increase the density of observations (i.e. number of documented actions, verbal cues, or gestures) on days 1, 4 and 9 relative to the other days in the instructional sequence. These observations take place at the moment the researcher anticipates a major shift to begin occurring and ends when the researcher's model of the student's thinking becomes relatively stable.

Discussion

In this paper, we have problematized an ontological characterization of change within a complex system by illustrating how epistemological premises of interactionist, individualist, and collectivist theoretical perspectives reveal only specific aspects of a changing system. Moreover, methodological considerations resulting from our recognition that change is characterized subjectively within various theoretical perspectives were made. The methodological recommendations advanced in this paper intend to support the intersubjective interpretation of research findings by promoting researchers' clarification of the ways in which their theoretical orientation constrains their recognition of various aspects of the changing system under study.

This qualitative study documented students' use of quantitative reasoning (QR) skills in an environmental science context. Student participants (N=39) were given one of three content assessments (carbon, water, or biodiversity) in a clinical interview setting. Themes emerged across the three categories of QR, quantitative literacy (QL), quantitative interpretation (QI), and quantitative modeling (QM). For QL, students attempted to utilize proportional reasoning, numeracy and measurement. Across QI, interpretations of tables, graphical representations, and science models were used to answer science content questions. Quantitative modeling was not utilized as frequently as QL or QI. Further development of assessments has taken place and a new data collection period will begin in May of 2012.

Keywords: Quantitative Reasoning; Environmental Literacy; Learning Progressions

Purpose

Challenges that face today's society are often centered around environmental issues. In order to understand these environmental issues, citizens are required to wade through *data* drenched political and scientific arguments as well as political commentary saturated with buzz words and slogans such as "global warming" and "drill, baby, drill." As a result, scientific discourse becomes muddled and often misleading in social commentary. In a democratic society, citizens must be able to participate alongside scientists and policy makers to solve problems and make informed decisions regarding environmental challenges (Steen, 2001). To do so, citizens must have a fundamental understanding of scientific principles as well as mathematics and statistics within an environmental context.

Quantitative reasoning (QR) is mathematics and statistics applied in real-life, authentic situations. QR problems are context dependent, interdisciplinary, open-ended issues that require critical thinking and the capacity to communicate a course of action (Author). The National Research Council (NRC) has stated that people will need to be able to apply quantitative approaches to predictions, analyzing and interpreting evidence, and developing models in order to make informed decisions as citizens (NRC, 2003, 2009). Therefore, people today need a fluency in quantitative tools in order to analytically think about how problems in the context of environmental science have an impact on an individual's life as a constructive, concerned, and reflective citizen.

Theoretical Framework

This research study is based on the theoretical frameworks of learning progressions and quantitative reasoning. Quantitative reasoning (QR) has four components: (a) act of quantification: mathematical process of conceptualizing an object and its measurable attributes with corresponding units, which entail a proportional relationship (linear, bi-linear, or multi-linear); (b) quantitative literacy (QL): sophisticated use of fundamental mathematical concepts in sophisticated ways; (c) quantitative interpretation (QI): ability to use models to make predictions and discover trends, which is central to a person being a literate citizen; and (d) quantitative modeling (QM): ability to create representations to explain a phenomena.

These components interact within a QR cycle when engaged in the process of science as model-building. The individual may begin with a qualitative science account of the phenomena based on their theory of the world, called force dynamic discourse. They might also respond in a school science discourse based on acquired knowledge, and then potentially progress to a full scientific discourse that uses science principles that explain phenomena. A quantitative science account is sought to provide support for the qualitative account. First the individual engages in the act of quantification by identifying objects, their attributes, and assigning measures. This provides variables that can be operated on mathematically or statistically. Second, depending on both the query of interest to the individual and the data they access, they engage in QR through one or more of the three processes of QL, QI, or QM. These three processes are interconnected and typically engaging in one requires elements of another.

Learning progressions are based on research in science education and cognitive psychology, foundational and generative disciplinary knowledge and practices, and strive for internal conceptual coherence. They are defined as being “hypothesized descriptions of the successively more sophisticated ways students think about an important domain of knowledge or how practice develops as students learn about and investigate that domain over an appropriate span of time” (Corcoran, Mosher, & Rogat, 2009, p. 37). The five essential characteristics of learning progressions are: (a) upper anchors which target performance or leaning goals that are the end points of learning progression and are defined by societal expectations, analysis of the discipline, and requirements for entry into the next level of education; (b) progress variables: dimensions of understanding, application, and practice that are being developed and tracked over time; (c) levels of achievement: intermediate steps in the developmental pathway(s) traced by a learning progression; (d) learning performances: tasks students at a particular level of achievement would be capable of performing; and (e) assessments: specific measures used to track student development along the hypothesized progression. The proposed QR learning progressions will build on these characteristics, incorporating mathematical and statistical frameworks.

Methodology

Study Participants and Recruitment

Four counties in the state of Wyoming were contacted via email and phone and invited to participate in this study. Three of the counties agreed to participate. Within the three counties, seven rural schools agreed to allow researchers access to students. An $N = 39$ students were interviewed, 18 females and 21 males. Students ranged in grade level from 6th grade to 12th grade and all self-identified as Caucasian.

Research Design

Establishing learning progressions requires conceptual coherence, compatibility with current research, and empirical validation (Anderson, 2009). Conceptual coherence means the learning progression tells a comprehensible and reasonable story of how naïve students develop mastery. Compatibility with current research requires learning progressions to adhere to research on science and mathematics content, pedagogy, and cognition. The learning progression identified from the data in this study will be treated as hypotheses that are to be empirically tested and validated.

There are five general approaches for hypothesizing progressions: (1) extrapolation from current and conventional teacher and curriculum practice (i.e., standards); (2) cross-sectional sampling of student performance using assessments, observations, or interviews; (3) longitudinal samples of student work over time; (4) closely observed classroom interventions; and (5) disciplinary understanding of the structure of the key concepts in the discipline (Corcoran, Mosher, & Rogat, 2009). This study utilized the second approach of cross-sectional sampling of student performance using assessments and interviews.

Clinical semi-structured interviews situated in the completion of activities and formative assessments were the initial method of gathering data to establish, validate and refine frameworks for developing the QR hypothetical learning progression. Guiding principles for developing the clinical interviews (Anderson, 2009) are that they are based on the progression framework, built around practices, linking processes, and standard representations, with branching probes to explore discourses, principles, and themes. There were three different interview assessments given; one on biodiversity, carbon, and water.

Data Analysis

The interviews were audio recorded and transcribed. Interviews were examined within and across interview questions for patterns in the participants' responses. Three researchers divided the transcripts evenly and analyzed 40% of the interviews. Using modified grounded theory (Glasser & Strauss, 1967) a list of themes by questions was developed after an initial read through of the transcripts. Discrepancies were discussed and resolved prior to the analysis of the remaining transcripts. After level one coding we found the frequencies of responses were similar across content areas (carbon, water, and biodiversity) and subsequent analyses were conducted on the individual content strands.

Learning progression matrices were created by cross tabulating achievement levels (rows in matrix) with progress variables (columns in matrix). The achievement levels were then linked with learning performances that are exemplars drawn from the clinical interviews and written assessments. The learning performances demonstrated student responses at different achievement levels. This provided for use of the learning progression as a means to classify student understanding.

Results

Within the three categories of QI, QL, and QM, the following themes were present across content assessments. For QL, students attempted to utilize proportional reasoning, numeracy, and measurement. In regards to proportional reasoning, students across grades 6 through 12 had difficulty with percent magnitude. They could not correctly identify part to whole concepts in order to answer the questions posed. With regards to numeracy, students in grades 6 through 8 avoided calculation even when prompted by researchers. Students in the upper secondary grades were able to attempt calculations, though there were variable misconceptions. Across the grade levels represented, students were unable to accurately use volume measurements and at time avoided discussing the concept of volume completely.

Table interpretations were used more often by students to determine the minimum and maximum values. This was a consistent observation across grade levels as well as across all three content strands. Graphical representations were interpreted with a variety of errors, except for those students at the upper secondary level. Students in 11th and 12th grade were able to not only correctly interpret information from graphs, but they were also able to create graphical representation to demonstrate their ability to predict trends in data. Student ability to interpret science models was inconsistent across grade levels.

Quantitative Modeling (QM) was not utilized as frequently as QL and QI although students did attempt to extend existing models in order to predict outcomes as well as create their own.

Discussion

Quantitative literacy (QL) is the ability to use basic mathematical and statistical skills in sophisticated ways. Environmental science information provided in a narrative or presented orally often has quantitative accounts embedded within it, accounts which may require the citizen to extract the information from the context, quantify it, manipulate it, and then interpret it within the science context. The mathematics and statistics required to do this are often simple arithmetic concepts, but applying them within the environmental context can be quite challenging for students.

Quantitative interpretation (QI) is an essential understanding for an environmentally literate citizen. Scientific data, findings, and models are often displayed in tables, graphs, visual science models, and equations. For a citizen to make informed decisions they must interpret information provided in these formats. We will explore 6th to 12th grade students' ability to interpret environmental science data and models represented in tables, graphs, analytic equations, and science models. Interpreting models requires a number of quantitative skills, including identifying variables and their correlation to a predicted variable, interpreting variables represented on axes of a graph, interpreting a model for a selected point or case, determining trends in a model, making predictions of future events, and translating between different models of the same phenomena. A learning progression for QI might use these skills as indicators of a student's level of understanding within the learning trajectory.

One could argue that QM is not an essential understanding for an environmentally literate citizen. That a citizen will likely not be building models from raw data, but interpreting models developed by others. While this may be the case, we believe that a student traversing the 6th to 12th grade should learn to view science as model building and testing, so that they have a better sense of the inherent strength and weaknesses of models they will interpret as citizens. The reluctance of students to question the discrepancies in the science models found in our assessments are examples of not understanding that global models are based on extensive estimations.

Future Research

The data from this study will be used to further inform researchers on quantitative reasoning learning progression development within an environmental science context. The assessments used for clinical interviews have evolved and now include six variations on: (a) carbon cycles, (b) carbon storage, (c) water cycles, (d) water transportation, (e) biodiversity communities, and (f) biodiversity extinction. Clinical interviews and written assessments will take place in May of 2012 to collect data using the new assessments.

In this paper we offer an account of how we are extending and adapting the Pirie-Kieren Dynamical Theory for the Growth of Mathematical Understanding to the collective domain. Through employing elements from our earlier work on collective understanding as an improvisational process we introduce and explore the new constructs of Collective Image Making, Collective Image Having, and Collective Folding Back and show how these contribute to the growth of understanding of a group of students working on a mathematical problem.

Keywords: Learning Theory; Cognition; Classroom Discourse

Purpose of the Study

The research reported in this paper forms part of our ongoing research program concerned with the nature of mathematical understanding and how it might be theorized and characterized. In recent years our specific focus has been the phenomenon of collective mathematical understanding—the kinds of learning and understanding we may see occurring when a group of learners work together on a piece of mathematics. We have characterized the growth of collective mathematical understanding as a creative and emergent improvisational process and illustrated how this can be observed in action (Martin, Towers, & Pirie, 2006; Martin & Towers, 2007, 2009; Towers & Martin, 2009). In this paper we offer an account of how we are extending and adapting the Pirie-Kieren Dynamical Theory for the Growth of Mathematical Understanding to the collective domain.

Theoretical Framework

In our work we have predominantly drawn on ideas from improvisational theory and applied these to the context of mathematical thinking and learning. However, our work has also continued to be informed by the Dynamical Theory for the Growth of Mathematical Understanding developed by Pirie and Kieren (Pirie & Kieren, 1994) and their characterization of mathematical understanding not as a static state to be reached or achieved, but as a dynamical, growing, and ever-changing process. While Pirie and Kieren's work offers a powerful theoretical framework for observing the growth of mathematical understanding, their model is still primarily one for the growth of *personal* understanding. Nevertheless, the framework proposes a series of modes of understanding that we suggest can, with elaboration, also offer a powerful language through which to talk about the growth of collective mathematical understanding. In this paper we take two of the modes of mathematical understanding from the Theory (Image Making and Image Having), and the key construct of Folding Back and extend their definitions to the domain of the collective. Full definitions and specific examples of these actions at the individual level can be found in Kieren, Pirie, and Gordon Calvert (1999), Pirie and Kieren (1994), and Martin (2008) and here we offer only brief descriptions of each.

When Image Making, learners are engaging in specific activities aimed at helping them to develop particular initial conceptions and ideas for the meaning of a mathematical concept. Image Making often involves drawing of diagrams, working through specific examples or playing with numbers. By the Image Having stage learners are no longer tied to actual activities; they are now able to carry with them a general mental plan for these specific activities and use it accordingly. Folding Back describes the way in which a learner might, while working at Image Having (or another layer) encounter a situation, problem, difficulty for which their current image is insufficient and it is thus necessary for them to return to more localized ways of working—perhaps through more Image Making. The metaphor of folding highlights the key notion that the learner takes his or her existing understandings back to the inner layer and uses these to build a "thicker" understanding.

Methods and Data Source

We illustrate our thinking through considering extracts of video data collected during a multi-year study whose key research question is, "In what ways can the Pirie-Kieren Dynamical Theory for the Growth of Mathematical Understanding be adapted to respond to contemporary concerns with the phenomenon of collective action?" In this paper we provide a preliminary response. The larger study has collected data from a range of school mathematics classrooms as well as from smaller group problem-solving sessions. In this paper we draw on data from one problem-solving session involving three students, aged between nine and ten years old, in which they were working on the well-known 'painted cube' problem. The students were given a printed sheet with the following question, and had available a large number of small interlocking cubes. "Imagine a large cube made up from 27 small cubes. Imagine dipping the large cube into a pot of yellow paint so the whole outer surface is covered, and then breaking the cube up into its small cubes. How many of the small cubes will have yellow paint on their faces? Will they all look the same? Now imagine doing the same with other cubes made up from small cubes. What can you say about the number of small cubes with yellow paint on?" The students worked on the problem for a period of about forty-five minutes. The third author acted as a participant observer—asking occasional questions to clarify the thinking of the students and/or to prompt further action if necessary.

Data analysis was conducted using the method described by Pirie (1996) as "sit, look, think, look again" (p. 556). Drawing on this method, the entire video set for each session was viewed multiple times in full and then subsequent times in smaller chunks to identify critical incidents relating to the students' growing understanding (as identified in relation to the layers of the Dynamical Theory for the Growth of Mathematical Understanding). This process was carried out independently by two of the authors, who then compared analyses for agreement. Once agreement was reached, the relevant excerpts of video data and the analyses were provided to the third author for verification and any discrepancies discussed and resolutions agreed by the whole team.

Results

In this section we offer brief definitions of Collective Image Making, Having and Folding Back and illustrate these with reference to the "painted cube" session. We deliberately choose here to present data extracts in a descriptive form as this more powerfully captures the collective nature of the interaction than would transcript (in our presentation we will illustrate our ideas with a short piece of video).

Collective Image Making—No single learner recognizes or is able to identify or engage in an appropriate action necessary for the making of a useful and appropriate image for the mathematical concept. Instead, what is seen in Collective Image Making is the offering, by individuals, of partial fragments of ideas and understandings, which are then picked up, elaborated, and acted on by others in the group. This process of interweaving individual contributions to create a coherent shared idea or representation is what gives the Image Making its collective nature. In the case of the "painted cube" the students begin the task by building a 3×3 cube from the smaller cubes. They decide to only build one model and actually all contribute to the physical making of the model. As they are constructing this they also start to collectively hypothesize about the solution to the problem, with individual students offering thoughts or ideas around how many cubes will have a particular number of sides painted. These ideas are reacted to, built upon, and acted on through ongoing interaction. For example as they are building the model (but before it is complete) one student says, "There are going to be four with three painted faces" and this is picked up by the others in the group. It is pointed out there are more than four corners, an answer of six is briefly suggested, but the group then quickly agree on eight (and verify with reference to their model). Here, they are making an image that "whatever size the larger cube there will always be eight small cubes with three painted faces." However, they do not state this—which would suggest a shift to

Collective Image Having. It is important to note here that no one student instantly tells the others a correct answer. Their contributions instead take the form of offering of an idea into the collective.

Collective Image Having—The group is at a point where they have a useable and workable idea, and nothing new is being introduced—in other words, an idea has been initiated, followed, and built upon by the interweaving contributions of the group members and now emerges as something useable by the group in the context of the task at hand. With the painted cube, the group reaches a point in their working where they are confident that they have correctly determined a solution for the 3 × 3 cube. They are then posed the question of what would happen if the cube were larger. Here they articulate a number of their images, including that there will always be eight small cubes with three sides painted, and that for the other numbers in a larger cube they simply need to multiply their solutions from the 3 × 3 case by some appropriate number. At this point they do not see the need to build any further models, as they believe they can simply predict and calculate answers from what they already know. That is, they have an image they can use without recourse to specific actions (e.g., building a 4 × 4 cube and counting).

Collective Folding Back—At points in mathematical activity an image is sometimes no longer viable or useable (often because it is too local or specific in nature). Thus, the group needs to return to Collective Image Making and to remake, rework, or rebuild their image. To do this, there needs to be agreement around the need to Fold Back and also as to what the new Image Making actions will involve. This willingness and capacity to build on a better idea and to alter the current way of acting is a collective process—often occurring through an awareness of the "group mind" (Martin & Towers, 2009, p. 14) and in response to tiny cues that suggest a new direction for appropriate mathematical action. In the context of the painted cube session, although the group believe that their collective image is a correct one, the observer knows it is not generalizable and that, although they are correct to be seeking a pattern, their current thinking will not give correct solutions for larger cubes. She therefore asks the group to build a larger cube "to show me" and they start to do this, still confident that their predictions will work. However, having built the larger cube (again something done by all three students) and then trying to apply their rules they come to realize they are not correct. They state that "it doesn't make sense" and then one student comments, "Let's count." At this point their actions shift from being a process of using and demonstrating their image (working at Collective Image Having) to needing to rework it (thus folding back to Collective Image Making). In once again counting numbers of small cubes they have collectively folded back to work with a specific case in order to then be able to say something more general (which would be evidenced through returning to Collective Image Having). When the suggestion is made to count cubes, the group collectively sees it as appropriate—there is a sense that this is an appropriate way forward as their image is no longer viable—and all participate in the counting process. What makes this new act of Collective Image Making different (thicker) from that when working with the 3 × 3 cube initially is that they are now purposefully looking for a pattern; they are looking not to discard totally their existing images, but to modify these, through finding which elements of their more general ideas are valid and which require modifying.

Conclusion and Significance

In this paper we are advancing a theoretical development of the Dynamical Theory that enables it to be used to analyze and interpret collective action. Our work emphasizes the significance of individual action *in context* and draws attention to those moments when such individual actions and statements interweave constructively to build understanding for a group of learners. We draw attention, in particular, to the way in which ideas are taken up, built upon, developed, re-developed, and shared within and by a group. In doing this we use the language and notions of the Dynamical Theory in order to focus specifically on what different kinds of collective action look like—and how collective growth occurs through shifting between different modes of working and acting. A strength of the Dynamical Theory, and our adaptation of it to the collective domain, is the way in which we are able to observe, recognize and talk about a group, such as the three students here, making and modifying a single shared image. This contrasts with other groups we have observed where actions remained individual in nature—with each student making and having his or her own image. We believe that such noticing and valuing of the complex, recursive and lengthy process of growing mathematical understanding is important to emphasize, particularly for teachers who are searching for ways to recognize their students' growth and to understand the value of collaborative work in classrooms.

Algebra has long been considered the foundation for higher-level mathematics and a gatekeeper for post-secondary opportunities. In recent decades, increasing enrollments in algebra have placed additional demands on algebra teachers for reaching a more diverse population of students. With the 2010 release and adoption of the Common Core State Standards for Mathematics (CCSSM) by all but a few states, questions arise regarding preparing teachers to teach the standards and practices described in CCSSM. In this paper, we describe the processes used to develop frameworks to study opportunities provided by secondary teacher preparation programs to learn about algebra, algebra teaching, achieving equity in algebra learning, and the algebra, functions, and modeling standards and mathematical practices described in CCSSM. In particular, we discuss opportunities and challenges encountered in our work.

Keywords: Algebra and Algebraic Thinking; Teacher Education–Preservice

Theoretical Perspective

For more than a century high school algebra courses have served as the foundation for higher mathematics and as gatekeepers for entrance to college mathematics (e.g., Moses, Kamii, Swap, & Howard, 1989). In recent decades, desires for equity and for higher achievement have resulted in suggestions that algebra be required for all students. Many states currently mandate completion of Algebra I or Algebra II for high school graduation (Teuscher, Dingman, Nevels, & Reys, 2008). However, failure rates in algebra are high (Loveless, 2008). The increasing numbers of students taking algebra and the corresponding high failure rates in algebra beg the question of how algebra teachers are prepared. With the 2010 release and adoption of the Common Core State Standards for Mathematics (*CCSSM*) by all but a few states, specific questions arise regarding preparing teachers to teach the standards and practices described in *CCSSM*.

Recent research highlights the importance of both strong content knowledge and pedagogical content knowledge for pre-service mathematics teachers. Specifically, teachers need preparation that "covers knowledge of mathematics, of how students learn mathematics, and of mathematical pedagogy that is aligned with recommendations of professional societies" (National Research Council [NRC], 2010, p. 123). The National Council on Teacher Quality also developed recommendations for mathematics teacher education programs, emphasizing the importance of making connections between the content in the mathematics courses taken by pre-service teachers and their methods courses and fieldwork (Greenberg & Walsh, 2008). The National Council of Teachers of Mathematics has, over the past several decades, made recommendations for changes in *what* mathematics should be taught and *how* it should be taught (e.g., NCTM, 2000, 2009). For example the NCTM emphasizes functions as a central topic in algebra; and highlights processes such as problem solving, reasoning and proof, and using multiple representations. But little is known about how such recommendations are incorporated into programs of study in mathematics for teachers (NRC, 2010).

Objectives

Preparing to Teach Algebra: A Study of Teacher Education (PTA), an NSF-funded collaborative project involving two universities, focuses on the following research question:

What opportunities do secondary mathematics teacher preparation programs provide to learn about algebra, algebra teaching, issues in achieving equity in algebra learning, and the algebra, functions, and modeling standards and mathematical practices described in the *Common Core State Standards for Mathematics* (*CCSSM*)?

The 2012 PME-NA theme, *Navigating Transitions Along Continuums*, is particularly salient in this study as we examine the transition of pre-service secondary mathematics teachers from students of algebra to teachers of algebra. Currently the *PTA* study is in its first year; so in this brief report we will share the processes and initial findings of our framework development and our plans for pilot work to be carried out in spring 2012. At the session in November 2012 we will be able to share results from the pilot study and our revised frameworks and protocols.

Methods of Inquiry used to Develop Frameworks

PTA is a mixed-method study that consists of a national survey of secondary mathematics teacher preparation programs and case studies of four diverse programs. In order to answer our research question, we developed frameworks to serve as the foundation for all aspects of our work, including constructing items for the survey, examining instructional materials, and preparing protocols for instructor interviews and focus groups of pre-service teachers. Given the four aspects of our research question, we developed four closely related frameworks. Here, we describe the process of developing the frameworks and the challenges encountered.

Algebra in *CCSSM* Framework

The initial *Algebra in CCSSM Framework* was developed based on the descriptions of the high school algebra, functions and modeling standards in *CCSSM*; relevant standards about algebra, functions and modeling in grades 6, 7 and 8; and the Standards for Mathematical Practice. Although the Standards for Mathematical Practice were not specifically written for algebra, they are recommended across all mathematical strands; therefore, we included them in the framework. The format of the framework followed the *CCSSM* format with three levels: (1) domains, (2) clusters, and (3) standards. The domains and clusters in the *Algebra in CCSSM Framework* were taken literally from *CCSSM*. However, the standards listed in *CCSSM* were edited and condensed for the framework.

Algebra Content in College Framework

The initial *Algebra Content in College Framework* was developed using recommendations from: (1) mathematicians (e.g., CBMS, 2001), (2) organizations charged with licensing teachers and accrediting teacher preparation institutions (e.g., NCTM, 2003), and (3) experts in teaching specific topics related to high school algebra (e.g., Cooney, Beckmann, Lloyd, & Wilson, 2010). First, statements about mathematical knowledge for teaching were extracted literally and listed as individual items. Second, items were organized by field (e.g., linear algebra) and practices (e.g., reasoning and proof). Finally, duplicated information was combined and items already included in *CCSSM* were deleted. The resulting framework had two main categories (each with multiple sub-categories): (a) Mathematics Content, and (b) Process, Practices and Perspectives.

Algebra Teaching Framework

The components of the initial *Algebra Teaching Framework* were developed using three primary sources: (1) algebra teaching and research literature (e.g., Kieran, 2007), (2) algebra teaching recommendations from professional organizations (e.g., NCTM, 2003), and (3) sample secondary mathematics education syllabi. The development process involved addition, deletion, and consolidation of categories and sub-categories in an iterative cycle. This led to a framework with two levels (and multiple categories): (1) Teaching Algebra, and (2) Teaching Mathematics.

Equity in Algebra Framework

The initial *Equity in Algebra Framework* was developed by consulting literature about equity issues in algebra and mathematics more generally (e.g., Moses, Kamii, Swap, & Howard, 1989; NCTM, 2000) and the ways in which equity issues in algebra/mathematics were addressed in sample syllabi. This led to a three-level framework: (1) Equity in Teaching and Learning Algebra, (2) Equity in Teaching and Learning Mathematics, and (3) Equity in Education.

Recommendations for Revision

The *PTA* Advisory Board is a multidisciplinary team, including two mathematics educators, a mathematician, and an expert in survey research. The initial frameworks and the following questions were sent to the Advisory Board two weeks prior to our first meeting with them:

- Are we missing important sources related to any of the frameworks?
- Are we missing important categories in the frameworks? Would you eliminate any categories?
- What advice do you have about sorting out learning algebra vs. teaching algebra?
- Is it reasonable to code syllabi from mathematics courses using only the two content frameworks and education courses using only the teaching and equity frameworks?

The Advisory Board members provided detailed feedback related to these questions and all frameworks at the meeting. They also had the opportunity to use the draft frameworks to code sample syllabi from relevant courses (e.g., Linear Algebra, Teaching High School Mathematics) offered at universities that offer teacher preparation programs.

Overall, the advisors made the following recommendations:

1. Streamline the frameworks; the initial drafts were long and cumbersome. For example, rather than list all recommended topics in mathematics related to teaching algebra, focus on a few important "big" ideas that might distinguish one program from another.
2. Maintain the focus of *PTA* on algebra. Especially in the *Algebra Teaching* and the *Equity in Algebra Frameworks*, delete the components that relate to mathematics or education in general, but not specifically to algebra.

Based on these recommendations, substantial revisions were made to all but the *CCSSM* framework. Based on the first recommendation, eight big ideas in algebra were identified and used to revise the *Algebra Content in College Framework* and the *Algebra Teaching Framework*; the pre-service teacher is a learner of the former and is in transition to become a teacher of the latter. These eight ideas are: (1) Reasoning and proof; (2) Contexts, applications, and modeling; (3) Treatment of functions; (4) Structure of algebra; (5) Nature of school algebra; (6) History of algebra; (7) Use of tools and technology in algebra classes; and (8) Connections between high school algebra and college mathematics courses related to algebra. Based on the second recommendation, the *Equity in Algebra Framework* is no longer focused on equity in mathematics education or education more broadly, but solely on the equity issues directly related to the teaching of algebra.

Challenges and Opportunities

Despite the importance of using carefully constructed frameworks for analysis in studies in mathematics education, researchers seldom discuss the process of developing their frameworks. In this paper, we endeavor to begin this conversation by highlighting the challenges and opportunities encountered in the process.

The lack of clear distinction between algebra curriculum, on the one hand, and algebra pedagogy on the other, proved challenging, particularly given our goal to avoid repetition across frameworks. In addition, accounting for the wide variation across recommendations and syllabi found on the Internet resulted in initially unwieldy frameworks that likely could not capture important differences among secondary mathematics teacher preparation programs.

However, the opportunity for critical collaboration in which colleagues ask challenging questions of one another's work with the goal of improving research and mathematics education figured critically into the revision of the frameworks. The *PTA* advisory board proved to be invaluable in this process as they were able to provide multiple perspectives and expertise related to each aspect of the study very early in framework development. In particular, they reminded us to keep our focus on algebra. The collaboration among the *PTA* team members (three faculty and six graduate and two undergraduate students) in weekly meetings also provided another set of perspectives that enhanced the quality of the resulting frameworks.

In spring 2012, these frameworks will be piloted to analyze instructional materials and develop protocols for interviewing instructors and students nearing the end of their mathematics teacher preparation programs. The results of these pilot studies will be used to make final revisions for the main data collection to take place during the 2012–13 academic year. Results from the pilot study and final revisions will be shared during the brief report session.

Since the 1980s, desires for equity and higher achievement in mathematics have given rise to changes in policies regarding enrollment in algebra. The federally funded project, Preparing to Teach Algebra (PTA), is designed to investigate opportunities for pre-service secondary mathematics teachers to learn about algebra, algebra teaching, equity issues in algebra learning, and Common Core State Standards for Mathematics. A mixed-method approach is used to integrate data using a web-based national survey of approximately 400 randomly selected secondary teacher preparation programs, case studies of four purposefully chosen secondary teacher preparation programs, and focus group interviews with eight pre-service teachers at the case study institutions. This brief report provides an overview of our sampling and survey development work, highlighting the challenges encountered throughout the process.

Keywords: Mathematics Education; Teacher Education; Algebra; Survey

Objectives

The project, *Preparing to Teach Algebra (PTA)* explores opportunities for pre-service secondary mathematics teachers to learn about algebra, algebra teaching, and equity issues in algebra learning and *Common Core State Standards for Mathematics (CCSSM).* A web-based national survey of secondary mathematics teacher education programs across the United States is utilized as a part of this project to provide a snapshot of the current conditions of preparing pre-service teachers to teach algebra, including attention to the recommendations of professional societies and *CCSSM*. The goal of this brief report is to provide an overview of the sampling process and the development of the survey, and to share the issues and challenges that have arisen in this process and the progress that we have made in addressing them.

Theoretical Framework

In developing the survey, we built upon the work of other scholars who have studied the characteristics of mathematics teacher education programs and how these programs were impacting pre-service teachers. We reviewed previous national surveys of mathematics education programs that included: The Mathematics Teaching in the 21st Century (MT21) Study (Schmidt et al., 2007), TEDS-M Institutional Program Survey (Tatto et al., 2008), Secondary Mathematics Teacher Education Programs in Iowa Survey (Murdock, 1999) and 2000 National Survey of Science and Mathematics Education School Mathematics Program Questionnaire (Horizon, Inc., 2000). Below we outline the goals and results of these studies.

The *2000 National Survey of Science and Mathematics Education Questionnaire* (Horizon, Inc., 2000) gathered information about K–12 mathematics teachers' beliefs, pre-service preparation and their teaching practice from a nationally representative sample of 5,728 mathematics and science teachers in schools across the United States. The survey revealed that a greater proportion of the teachers majored in mathematics than in mathematics education, high school mathematics teachers have relatively strong mathematics content backgrounds and teachers in the higher grades are better prepared to teach mathematics than those in the lower grades.

On the other hand, Murdock (1999) attempted to study all teacher education institutions in Iowa that granted licenses to teach secondary mathematics and provided a detailed description of these programs. The questionnaire he utilized in the study was designed based on the recommendations of the National

Council of Teachers of Mathematics (NCTM) for mathematics teacher education and a similar survey done on science education. The key findings of Murdock's study include: the larger universities had higher graduation rates of mathematics education teachers than the smaller private colleges, the larger universities also had a greater proportion of staff dedicated to mathematics education, and secondary mathematics methods was the most frequently required course by all universities that participated in the study.

Graham, Li, and Buck (2000) conducted an exploratory study of K–12 teacher education programs across 28 institutions. In their study, the survey was conducted to give an overall picture of the status of mathematics teacher education programs in light of the vision and recommendations provided in the following reform documents: *Curriculum and Evaluation Standards for School Mathematics* (NCTM, 1989), *Professional Standards for Teaching Mathematics* (NCTM, 1991), *A Call for Change: Recommendations for the Mathematical Preparation of Teachers* (MAA, 1991), and the *Principles and Standards for School Mathematics* (NCTM, 2000). The survey results from 28 institutions indicated that instructional and assessment practices of methods courses were consistent with recommendations, but mathematics content courses were not and the overall structure of teacher preparation programs was minimally impacted by reform. However, because no sampling design was described in the report, it is difficult to judge the generalizability of these findings.

Recently, international comparative research has been investigating how pre-service teachers acquire mathematical and related pedagogical content knowledge. The Mathematics Teaching in the 21st Century (MT21) Study (Schmidt et al., 2007) examined the backgrounds, course taking and other program activities, and knowledge relevant to teaching mathematics among pre-service teachers preparing to teach Grades 7 or 8 in six countries (Bulgaria, Germany, Mexico, South Korea, Taiwan, and the United States). The results indicated that U.S. pre-service teachers performed near the bottom among the six countries on the algebra and functions subtest.

The Teacher Education and Development Study [TEDS-M] (Tatto et al., 2008) extended the MT21 study by including additional countries to provide further evidence about the knowledge and beliefs of mathematics teachers, as well as the opportunities they had to learn and teach mathematics content and pedagogical knowledge for primary and secondary pre-service teachers. Although the final report of the study has not yet been released, it is worth noting that TEDS-M used a stratified sampling method with primary and secondary level and concurrent or consecutive routes for stratification.

Although these studies provided information about the current state of mathematics education programs in general, little is known about the preparation that pre-service teachers receive to teach algebra. In addition, the generalizability of the findings in most of these studies is rather limited. Thus, by focusing on algebra learning and teaching, the survey utilized by *PTA* is designed to gather information about teacher preparation across a nationally representative sample of secondary mathematics teacher education programs in the U.S.

Methods

Sampling Mathematics Education Programs

A stratified random sampling method was employed to select 400 secondary mathematics education programs within the fifty states. The *Carnegie Foundation's Basic Classification* of baccalaureate, master's and doctoral degree granting institutions was used as a sampling frame. The number of 400 was determined by a priori power analysis of possible statistical analyses which will be utilized on survey responses, and an expected non-response rate (i.e., 50%). With the use of appropriate representative percentages of degree granting institutions, 176, 160, and 64 colleges and universities were, respectively, included in the sample. The websites of the selected schools were then visited to determine the existence of a secondary mathematics education program and a contact person for the program. If no program existed, resampling occurred until 400 institutions with secondary mathematics education programs were found.

Item Development for the National Survey

The first draft of the survey was developed by adapting items selected from the previously mentioned surveys. The first draft consisted of five proposed sections: general program characteristics, opportunities to learn algebra specific content, qualifications for program entry, required courses and staffing information. However, the items gained from the aforementioned surveys primarily asked about general program characteristics. Since our survey seeks to gather information on more than just general program characteristics, new items for the remaining categories were developed extensively by the *PTA* researchers. Each item on the initial draft of the survey was thoroughly discussed and evaluated by research team members for its quality (including ease of response) and alignment with the research questions. As a result, the initial draft was significantly modified by reducing the number of items, changing item formats, and adding new items. The second draft of the survey was further revised based on the suggestions of two mathematics educators on the research team. The items were also evaluated further by a survey expert, a mathematician, and two mathematics educators who serve as the project's external Advisory Board.

Results

Sampling Secondary Mathematics Education Programs

One of the difficulties that arose while ensuring a representative sample of the target population was caused by the fact that there exists no comprehensive list of secondary mathematics education programs to use as a sampling frame. Confirming the difficulty of creating such a list, through the sampling process, we found significant variation in the paths that pre-service teachers can take to become secondary mathematics teachers within an institution and across institutions.

Survey Item Development

Based on the feedback received from multiple sources, the resultant pilot survey contains two sections: (1) general characteristics of secondary school mathematics teacher education programs, and (2) opportunities to learn about algebra, algebra teaching, issues in achieving equity in algebra learning, and the algebra topics included in the *CCSSM*. Questions regarding general characteristics were limited to information about institutional and program characteristics such as the department where the secondary mathematics teacher education program was housed, and where most secondary mathematics education courses were offered. Questions regarding opportunities to learn asked about learning opportunities in a specific course. For example, a sample question utilized in the study is: "*The following courses often offer opportunities to learn school algebra, which of these courses are offered by your program?"* accompanied with a list of ten mathematics content courses (e.g., College Algebra, Linear Algebra etc.). The respondent should give an answer about whether or not the course is offered, if it is required for the degree and the number of credit hours required for the course. Another example, of a sample question utilized in the study: "*The following courses may offer an opportunity to learn about CCSSM. Please select the courses from the list that your institution offers."* The respondent is asked to indicate if the course is offered, if the course is required, if there is an emphasis on algebra and the number of credits for the course

Discussion

Multiple challenges arose in the process of both the survey sampling and survey instrument development. For the survey sampling, confirming that institutions had an established secondary mathematics education program and locating the program coordinator or contact person via the school's website were the major challenges. In cases where we were unable to obtain confirmation of a program's existence or find a contact person, phone calls and/or e-mails were used. Through the process of designing and utilizing the sampling frame as well as gathering contact information, we have received a glimpse of the diversity and complexity of mathematics teacher education in the United States. For the survey development, the lack of previous related studies on mathematics teacher education and operational definitions for the terms to be used in the survey - particularly "Opportunity to Learn Algebra (OTL)" has been particularly challenging. For example, in terms of educational policy OTL can be used to describe the quality of schooling, equal treatment and the fairness of high-stakes accountability (Floden, 2002). The *PTA* researchers have spent a lot of time and effort in determining a definition of OTL that is in alignment with the guiding principles of *PTA* project. *PTA* survey will help describe the diverse nature of mathematics education in the United States

In the Japanese Lesson Study program in Japan and open research lessons in China, teachers work collaboratively to create and reflect upon *research lessons* in order to advance theory and improve on "best practices" (Lewis, 2002). Lesson study is seen to have great promise for improving U.S. math education by developing knowledge of anticipated student responses, contributing to curricular alignment, and developing teacher's self-efficacy (Sibbald, 2009). Research clearly shows that an online community can serve as an environment to support teachers' ongoing collaboration efforts (Barab, Kling, & Gray, 2004). Therefore, we developed a *hybrid lesson study*, an in-person and online collaboration to accommodate schedules and support teachers' ongoing professional development. We report on a partnership between two school districts (80 teachers in grades 3–Algebra 1) and a university in the southwestern United States. There are ten facilitators, or coaches, with prior experiences on lesson study assigned across 18 lesson study groups. Collaborative documents stored on the website include lesson plans, revisions, debriefing notes, as well as edited video clips. These educational objects can reveal aspects of and changes to teachers' *interpretive systems*. The quantitative and qualitative study answers the question, *What aspects of the hybrid model support communal interchanges, foster regular and inclusive participation, and what role do peer coaches and other outside experts play in fostering this?*

Methods

We conducted an analysis involving documenting who posts, how often, and what communal interchanges occur by monitoring and documenting the use of communication tools. Post-hoc analysis reviews thread topics across teams, characterizes topics, and analyzes whether some topics generate more posts. We administered and analyzed a Usage Survey to capture visits to the site without posts. We are conducting a final qualitative analysis, coding the actual content of discussions using grounded theory (Strauss & Corbin, 1994).

Results and Discussion

We are interested in patterns of interaction. The presence of 18 subgroups allows for an analysis of differences. Some of these differences are in the nature of postings at an explanatory level—a factual reporting versus a well-elaborated analysis, explanation, or reflection (Hakkarainen, Lipponen, & Järvelä, 2002). Our goal is to improve research lessons through an online component that evolves with the needs of the participants.

EXPLORING CLASSROOM DISCOURSE THROUGH AN AGENT-BASED MODEL

Elizabeth Dyer
Northwestern University
elizabethdyer@u.northwestern.edu

An important aspect of reform includes enabling mathematics teachers to support new forms of discourse that allow students to talk and do mathematics. However, supporting substantive student discourse around mathematics is very difficult for teachers (Sherin, 2002). Therefore, this poster introduces a tool to aid in the transition between teacher-directed discourse and student-directed discourse.

This poster will present a computer model of mathematics classroom discourse to help teachers learn about supporting discourse. The software is an agent-based model built in NetLogo that models different student and teacher interactions during a classroom discussion.

The model was built using several frameworks for classroom discourse from Hufferd-Ackles et al. (2004), Boaler and Brodie (2004), and Chapin, O'Connor, and Anderson (2003) to focus on the mathematical aspects of discourse and the varied teacher moves that support discourse. An agent-based model was chosen so that discourse could be modeled as an emergent phenomena resulting from interactions among students and the teacher (Wilensky, 2001). Following constructionist design principles (Papert, 1993), teachers engaging with the model can change different parameters about how the students and teacher interact with one another. Student parameters include likelihood of sharing ideas and directly responding to ideas of other students. Teacher parameters include likelihood of evaluation, asking generating questions, and asking clarifying questions. Students' ideas have varying levels of clarity, which determines the text students say when they participate. As the model is run, student parameters change based on the interactions in the classroom.

Students and the teacher are visible in the model and what is said each turn is shown above them (one person speaks each turn). The overall discourse can be seen through the transcript of the dialog, a graph of the types of student talk, and a graph of the different teacher moves. Different combinations of parameter levels will produce different types of discourse. Through experimenting with different parameter levels, teachers construct understandings of classroom discourse and the lower-level interactions that create the discourse (such as teacher moves). The model can also be switched to a mode where the teacher engaging with the model chooses the actions for the teacher agent in the model.

Keywords: Reasoning and Proof; Classroom Discourse; Research Methods

As part of our NSF MSP project, we have developed a rubric with 3 spectra for describing levels of justification made explicit in classroom discourse. Our poster will present this rubric, its framework and rationale, and illustrative examples from our classroom observations.

Spectrum 1 describes levels for *justification of a strategy, method, or procedure*, informed by Lambert's transition of focus in classroom discourse from answer to method to justification (1990), and by Simon's account of how generalization and justification co-develop as students reflectively abstract their own goal-directed activity (2011):

<table>
<tr>
<td>0. Students produce result (answer) but do not explain, justify, or show work.</td>
<td>1. Students "show work," listing the steps of the method they used to get the answer.</td>
<td>2. Students provide a basis for the steps, such as naming admissible actions based on what has already been established in the classroom.</td>
<td rowspan="2">3. Students provide an argument for why the steps must work to provide the correct answer. Even if they later check their answer, conviction is not treated as coming from this act. This can indicate an understanding (though not yet an articulation) of the generality of the method.</td>
<td rowspan="2">4. Students provide an argument based on necessity, but also articulate the generality of the method and, if appropriate, address the domain of applicability on which the method works.</td>
</tr>
<tr>
<td colspan="3">+ Students justify their answer by gauging its reasonableness or checking to see that it satisfies the original problem. (This could accompany any of the above discourse types.)</td>
</tr>
</table>

Spectrum 2 describes levels for *justification of a specific (non-general) claim*, particularly by appealing to a general basis. **Spectrum 3** describes levels for *justification of an articulated general claim or property*, adapted largely from Harel and Sowder's proof schemes (1998): (0) No justification; (1) External source of conviction; (2) Empirical reasoning; (3) Deductive reasoning, including recognition of the necessity of the conclusion following from a basis or bases, without attention to the generality of the claim; (4) Same, but with attention to the generality of the claim; and (5) Same, with explicitly-stated basis or bases. We construe "basis" broadly; it could include any established relationship, axiom, property, definition, strategy, theorem, principle, analogous situation, or structure apparent in a particular representation.

NAVIGATING ASSESSMENT FOR LEARNING AND FORMATIVE ASSESSMENT IN MATHEMATICS EDUCATION: ESTABLISHING A COMMON DEFINITION

Diane Rogers
Western Michigan University
diane.rogers@wmich.edu

Jonathan Engelman
Kettering College
jonathan.engleman@kc.edu

Lindsay Noakes
Western Michigan University
lindsay.noakes@wmich.edu

Keywords: Assessment and Evaluation

Purpose

Formative assessment (FA) and assessment for learning (AfL) are key phrases in the educational assessment community, yet the exact definitions of these terms remain unclear. Dunn and Mulvenon (2009) have called for "a clear and shared lexicon [to] be established and shared among all educational stakeholders to lead to more productive communication among teachers, researchers, policy makers, parents, and students" (p. 9). The purpose of this research (funded by NSF grant DRL-0733590) is to examine all of the major theoretical papers published on FA and AfL within the context of mathematics education and identify consistent themes to establish a common definition.

Methodology

An exhaustive search of the literature for "assessment for learning" or "formative assessment" along with "mathematics" was performed using Google Scholar and checked against ProQuest and ERIC. Resource lists of each paper were also reviewed. A theoretical sampling method was then used to narrow the sample (Marshall & Rossman, 2011).HyperRESEARCH software was used to open code each document followed by axial coding. Emergent themes were analyzed to develop a definition and model of FA and AfL (Creswell, 2007).

Results and Conclusion

As a whole, the literature suggests that there is no distinction between FA and AfL and the two phrases can be used synonymously. The coding process resulted four primary characteristics of FA and AfL (Student Involvement, Learning and Assessment Expectations, Instructional Changes, and Feedback), each with several overlapping sub-components, as depicted in our model of AfL/FA.This research began as a means to answer the call for clear definitions of the terms "assessment for learning" and "formative assessment." The resulting model is the first step toward providing this universal definition for researchers and practitioners. With this clearly defined, research-based definition of formative assessment and assessment for learning, researchers will be able to more accurately study these classroom actions and dissemination of research will be better able to influence teaching practices.

joi.spencer@sandiego.edu

As the title suggests, this Working Group has a dual focus on issues of mathematics teaching and learning and issues of equity and diversity. We have narrowed the topics discussed at the Working Group in 2009, 2010, and 2011, to focus on mathematics teacher education that incorporates issues of race and power. We will be working on a series of manuscripts attending to social justice, race, teacher educator racial identity, and supporting prospective teachers in mathematics methods courses to integrate students' in and out-of-school mathematics. This work attempts to take a multifaceted approach, aimed at multiple levels from the classroom to broader social structures, within a variety of contexts both in and out of school, and at relationships between researcher and study participants, teachers and students, and teachers and schools.

Keywords: Equity and Diversity; Teacher Education–Inservice/Professional Development; Teacher Education–Preservice; Teacher Knowledge

Brief History

This Working Group builds on and extends the work of the Diversity in Mathematics Education (DiME) Group, one of the Centers for Learning and Teaching (CLT) funded by the National Science Foundation (NSF). DiME is a group of emerging scholars who graduated from three major universities (University of Wisconsin–Madison, University of California–Berkeley, and UCLA). The Center was dedicated to creating a community of scholars poised to address some critical problems facing mathematics education, specifically with respect to issues of equity (or, more accurately, issues of inequity).

The DiME Group (as well as subsets of that group) has already engaged in important scholarly activities. After two years of a cross-campus collaboration dedicated to studying issues framed by the question of why particular groups of students (i.e., poor students, students of color, English learners) fail in school mathematics in comparison to their white (and sometimes Asian) peers, we presented a symposium at AERA 2005 (DiME Group, 2005). This was followed by the writing of a chapter in the recently published *Handbook of Research on Mathematics Teaching and Learning* which examined issues of culture, race, and power in mathematics education (DiME Group, 2007). Further, in an effort to bring together and expand the community of scholars interested in this work, DiME, at AERA in 2008, sponsored a one-day Professional Development session examining equity and diversity issues in Mathematics Education. In addition, DiME members have joined with other scholars in joint presentations and conferences. A book on research of professional development that attends to both equity and mathematics issues has recently been published (Foote, 2010). Many DiME members as well as other scholars contributed to this volume.

Moreover, the Center historically held DiME conferences each summer. These conferences provided a place for fellows and faculty to discuss their current work as well as to hear from leaders in the emerging field of equity and diversity issues in mathematics education. Beginning in the summer of 2008, the DiME Conference opened to non-DiME graduate students with similar research interests from other CLTs such as the Center for the Mathematics Education of Latinos/as (CEMELA), as well as graduate students not affiliated with an NSF CLT. This was initially an attempt to bring together a larger group of emerging scholars whose research focuses on issues of equity and diversity in mathematics education. In addition, DiME graduates, as they have moved to other universities, have begun to work with scholars and graduate students including those with connections to other NSF CLTs such as MetroMath and the Urban Case Studies Project in MAC-MTL whose projects also incorporate issues of equity and diversity in mathematics education. Funding for the DiME project has ceased and the PME Working Group has become a major way in which to keep the conversation going.

It is important to acknowledge some of the people whose work in the field of diversity and equity in mathematics education has been important to our work. Theoretically we have been building on the work of such scholars as Marta Civil (Civil & Bernier, 2006; González, Andrade, Civil, & Moll, 2001), Megan Franke (Franke, Kazemi, & Battey, 2007), Eric Gutstein (Gutstein, 2006), Danny Martin (Martin, 2000), Judit Moschkovitch (Moschkovich, 2002), and Na'ilah Nasir (Nasir, 2002). We have as well been building on the work of our advisors, Tom Carpenter (Carpenter, Fennema, & Franke, 1996), Geoff Saxe (Saxe, 2002), Alan Schoenfeld (Schoenfeld, 2002), and again Megan Franke (Kazemi & Franke, 2004), as well as many others outside of the field of mathematics education.

A significant strand of the work of the DiME Center for Learning and Teaching included implementing professional development programs grounded in teachers' practice and focusing on equity at each site. The research and professional development efforts of DiME scholars are deeply intertwined, and much of the research thus far produced by members of the DiME Group addresses issues of equity within Professional Development. Additionally, since the majority of the DiME graduates, as new professors are engaged in teaching Mathematics Methods courses, the integration of issues of equity with issues of mathematics teaching and learning in Math Methods has become a site of interest for research. We have learned through experience that collaboration is a critical component to our work.

We were pleased for the opportunity offered by the first three years of being a Working Group at PME 2009, PME 2010, and PME 2011 to continue working together as well as to expand the group to include other interested scholars with similar research interests. We were encouraged that our efforts were well received; more than 40 scholars from a wide variety of universities and other educational organizations took part in the Working Group each of the past three years.

Focal Issues

Under the umbrella of attending to equity and diversity issues in mathematics education, researchers are currently focusing on such issues as teaching and classroom interactions, professional development, pre-service teacher education (primarily in mathematics methods classes), student learning (including the learning of particular sub-groups of students such as African American students or English learners), and parent perspectives. Much of the work attempts to contextualize the teaching and learning of mathematics within the local contexts in which it happens, as well as to examine the structures within which this teaching and learning occurs (e.g., large urban, suburban, or rural districts; under-resourced or well-resourced schools; and high-stakes testing environments). How the greater contexts and policies at the national, state, and district level impact the teaching and learning of mathematics at specific local sites is an important issue, as is how issues of culture, race, and power intersect with issues of student achievement and learning in mathematics.

Existing research tends either to focus on professional development in mathematics (e.g., Barnett, 1998; Carpenter, Fennema, Peterson, Chiang, & Loef, 1989; Kazemi & Franke, 2004; Lewis, 2000; Saxe, Gearhart, & Nasir, 2001; Schifter, 1998; Schifter & Fosnot, 1993; Sherin & vanEs, 2003), or professional development for equity (e.g., Sleeter, 1992, 1997; Lawrence & Tatum, 1997a). Little research exists, however, which examines professional development or mathematics methods courses that integrate both. The effects of these separate bodies of work, one based on mathematics and one based on equity, limits the impact that teachers can have in actual classrooms. The former can help us uncover the complexities of children's mathematical thinking as well as the ways in which curriculum can support mathematical understanding in a number of domains. The latter has produced a body of literature that has helped to reveal educational inequities as well as demonstrated ways in which inequities in the educational enterprise could be overcome.

To bridge these separate bodies of work, the Working Group has begun and will continue to focus on analyzing what counts as mathematics learning, in whose eyes, and how these culturally bound distinctions afford and constrain opportunities for students of color to have access to mathematical trajectories in school and beyond. Further, asking questions about systematic inequities leads to methodologies that allow the researcher to look at multiple levels simultaneously. This research begins to take a multifaceted approach, aimed at multiple levels from the classroom to broader social structures, within a variety of contexts both in and out of school, and at a broad span of relationships including researcher to study participants, teachers to schools, schools to districts, and districts to national policy.

Some of the research questions that the Working Group will consider are:

- What are the characteristics, dispositions, etc. of successful mathematics teachers for *all* students across a variety of local contexts and schools? How do they convey a sense of purpose for learning mathematical content through their instruction?
- How do beginning mathematics teachers perceive and negotiate the multiple challenges of the school context? How do they talk about the challenges and supports for their work in achieving equitable mathematics pedagogy?
- What impediments do teachers face in teaching mathematics for understanding?
- How can mathematics teachers learn to teach mathematics with a culturally relevant approach?
- What does teaching mathematics for social justice look like in a variety of local contexts?
- What are the complexities inherent in teacher learning about equity pedagogy when students come from a variety of cultural and/or linguistic backgrounds all of which may differ from the teacher's background?
- What are dominant discourses of mathematics teachers?
- What ways do we have (or can we develop) of measuring equitable mathematics instruction?
- What is the role of both teachers' and students' academic and mathematics identity in achievement?
- How do students' out-of-school experiences influence their learning of school mathematics?
- What is the role of perceived/historical opportunity on student participation in mathematics?

Plan for Working Group

The overarching goal of the group continues to be to facilitate collaboration within the growing community of scholars and practitioners concerned with understanding and addressing the challenges of attending to issues of equity and diversity in mathematics teacher education. More specifically, we plan to work on a series of articles sharing our journeys with pre-service and in-service mathematics teachers as they: incorporate out of school practices, explicitly examine race, and analyze broader social structures (teaching math for social justice). In addition we intend to examine educator identity around race and teaching about race. The PME Working Group provides an important forum for these scholars to come together with other interested researchers who identify their work as attending to equity and diversity issues within mathematics education in order to develop plans for future research. Our main goal for this year, then, is to continue a sustained collaboration around key issues (theoretical and methodological) related to research design and analysis in studies attending to issues of equity and diversity in mathematics education, and more specifically to begin collaborating on manuscripts that attend to these topics.

Our plans for PME 2012 we will proceed as follows.

SESSION 1:

- Review and discussion of goals of Working Group.
- Introduction of participants.
- Present and discuss manuscript ideas.

SESSION 2:

- Continue presentations and discussions.
- Begin work on manuscripts.

SESSION 3:

- Continue work on manuscripts.
- Organize for ongoing collaboration on manuscripts.
- Developing a tentative agenda for future Working Group meetings.

Previous Work of the Group

The Working Group met for three productive sessions at PME 2009, PME 2010, and PME 2011. In 2009, we identified areas of interest to the participants within the broad area of equity and diversity issues in mathematics education. Much fruitful discussion was had as areas were identified and examined. Over the past three years subgroups meet to consider potential collaborative efforts and provide support. Within these sub-groups, rich conversations ensued regarding theoretical and practical considerations of the topics. In addition, graduate students had the opportunity to share research plans and get feedback. The following are topics covered in the subgroups.

Teacher Education that Frames Mathematics Education as a Social and Political Activity

This sub-group discussed teacher education that frames mathematics as a social and political activity, including multicultural education, teaching math for social justice, funds of knowledge, ethnomathematics, issues of equity and diversity in mathematics, and so forth. The goal was to share resources to improve our own work as teacher educators and to support each other in our research. Long term goals included developing an annotated list of articles, developing an annotated collection of resources (lessons, activities, syllabi, etc.), writing a paper about our differing meanings and approaches to teacher education that frames mathematics as a social and political activity, and conducting research about doing this work across contexts.

This sub-group acknowledged tensions in our work focusing on equity and social justice in relationship to reform mathematics. Frameworks are needed to understand these issues. These can build on work in culturally relevant pedagogy (Ladson-Billings, 1995), teaching for social justice (Gutstein, 2003), funds-of-knowledge (González et al., 2001) as well as more general issues of equity, diversity, social analysis, and critical pedagogy. We need to begin by defining what we mean by these terms (e.g., reform mathematics, social activity, political activity); and how we recognize them in the classroom.

Culturally Relevant and Responsive Mathematics Education (CRRME)

The title reflects our view that mathematics education needs to be both culturally responsive and culturally relevant and a primary goal of this group was to develop a comprehensive collection of the scholarship we draw on to define these terms. We were interested in language, discourse, ethnicity, ways of interacting, family, community, experiences, generational issues, expectations (not high and low, but individual or community's expectations). We wanted to examine what we mean by social justice. Issues such as teaching (a) about social justice (the context), (b) with social justice (status and participation), and (c) for social justice (power and question) were raised. Various aspects of CRRME include (a) local contexts, (b) local associations, (c) using cultural referents, (d) ethnomathematics, (e) critical pedagogy, and (f) teaching "classical" math. We were concerned as well with how literature on culturally relevant pedagogy is grounded in existing theory and research on culture and social constructivism.

Creating Observation Protocols around Instructional Practices

This group was developing a protocol that can measure instructional practice AND be a tool to help teachers improve their instructional practice. The focus was on the importance of improving instruction for students of color; this is our goal. We recognized that protocols have limits. For example, protocols do not necessarily look at microgenesis, teacher change, structural issues, dispositions. At the past PME-NA we reviewed various protocols to examine discuss existing protocols posted on google groups to stimulate rich discussions around questions such as: What do we like? What are they missing? How might we revise, combine, and extend them? Since group members were using various measures and it was not viable to have everyone use the same one, we began to develop a dimension that could be added on to the different protocols. To focus the work we decided to develop a dimension on expanding notions of competence in the classroom.

Language and Discourse Group: Issues around Supporting Mathematical Discourse in Linguistically Diverse Classrooms

This sub-group was interested in examining language diversity in the mathematics classroom. The goal was to define this broadly to be inclusive of the perspectives of teachers, students, and parents.

A Critical Examination of Student Experiences

This sub-group was interested in examining the intersectionality of students' experiences as learners of mathematics and in mathematics classrooms. This involves considering students' mathematics identity in relationship to one or more of their racial, social, cultural, and gender identities. This also includes understanding how structural inequalities shape students' mathematics experience, particularly students from non-dominant groups.

Anticipated Follow-up Activities

Drawing on the conversations that have taken place in the working groups over the past three years, we have developed a plan of action for a series of manuscripts. These manuscripts will build on the aforementioned topics to share experiences, practices, resources, and research in mathematics methods courses that focus on equity.

COLLABORATING TO INVESTIGATE LIVED AND LIVING MATHEMATICAL EXPERIENCES: THE DIME WORKING GROUP

Larry L. Hatfield
University of Wyoming
lhatfiel@uwyo.edu

Michelle T. Chamberlin
University of Wyoming
mchambe5@uwyo.edu

The "Developing Investigations of Mathematical Experience" (DIME) working group, initiated 2011, has focused on building a research-based understanding of the interiorized experiential world of a person's lived mathematics. Goals of this research are to characterize individual experiences in ways that acknowledge a person's active and reflective thinking efforts within mathematical contexts linked to emotive dimensions of their lived and living mathematical experiences, in order to inform mathematics teaching practices. To probe these largely unexplored complex domains, we are using both and phenomenological and constructivist theories and methods. We seek to identify and relate expressed indicators of intended and actual mathematical experiences, as they appear to occur in the complex relationships of participants involved in mathematics teaching and learning. The primary goal of the PME-NA Working Group is to involve interested scholars in the ongoing work of the DIME Research Team, through further conceptual analyses related to the phenomena of lived and living mathematical experiences, to extend our epistemological and psychological perspectives for characterizing critical elements, and to identify and address methodological issues inherent in investigating interiorized mathematical experiential phenomena.

Keywords: Affect, Emotion, Beliefs, Attitudes; Research Methods

Brief History of the Working Group

A core membership for this PME-NA Working Group was established through the initial invitational "Planning Conference for WISDOM[e]" conducted September 8–10, 2010 at the University of Wyoming. The background context for that conference was the establishment of three collaborative, interdisciplinary Research Teams connected to four new Ph.D. program research identities: quantitative reasoning, mathematical modeling, technology tools and applications, and lived/living mathematical experience. Each of the teams consists of UW mathematics education, mathematics, and educational cognate faculty, mathematics education doctoral students, and four-to-five young, active Mathematics Education researchers from a variety of national and international universities. Following four invited plenary papers prepared and presented at the conference by key active senior researchers, each team met to frame an initial program of collaborative work. The DIME (Developing Investigations of Mathematical Experience) Team currently includes six UW faculty members, six UW Mathematics Education Ph.D. students, and five faculty members from as many other universities. [Complimentary copies of Volume 1, *New Perspectives and Directions for Collaborative Research in Mathematics Education: Papers from a Planning Conference for WISDOM[e]*, in the WISDOM[e] monograph series were provided to all participants at the 2011 PME-NA conference (Chamberlin, Hatfield, & Belbase, 2011; Hatfield, 2011).]

Through the conduct of the initial Working Group sessions at the 2011 PME-NA conference, we established an important venue to continue and expand discussions of the background perspectives and issues related to investigations of lived and living mathematical experience, to share information, issues, and problems related to ongoing research, to promote interest and potential participation in furthering these and other disciplined inquiries into these phenomena, and to provide continuing support to the team members to collaborate within and across ongoing and future research.

The following individuals attended two or more of the three scheduled sessions in Reno. In addition to the eight individuals from the original WISDOM[e] DIME Research Team, this included seven new participants interested in joining, and contributing to, the collaborative DIME work.

Following an opening presentation and overall discussion, we quickly organized into four breakout groups to address more focused interest areas framed by the following:

A. Framing "problems and questions" for research on lived/living mathematical experience—what to study?
B. Addressing "issues and concerns" for research methodologies to be used—how it is to be studied?
C. Discussing techniques for using and transform ing data to describe, analyze, and interpr et in ways that illuminate and inform—how is data to be evidentially used?
D. Discussing approaches to reporting what is found and to applying to inform improved educational practices—how results are to be reported and used?

Groups C and D quickly merged as they shared their more specific questions and methods. While interests varied across questions of studying mathematical experiences of students, teachers, and others, many common themes related to fundamental issues of purposes, constructs, methodologies, and ways of reporting emerged. Reporting back sessions led to plenary discussions, followed by subsequent breakout group discussions.

Before we adjourned, participants identified plans for continued discussions toward developing several specific collaborative research efforts, and expressed a positive intention to return to the DIME Working Group at the Kalamazoo PME-NA conference. [The following rationale presents many ideas drawn from the original Working Group proposal, and other sources and discussions being formulated for this relatively new domain of research focused on lived and living mathematical experiences (Hatfield, 2012; Hatfield, Belbase, Chamberlin, & Schnorenberg, 2011)]

Perspectives on *Lived and Living Mathematical Experience*

Today, there is surely an implicit and implied emphasis globally upon high quality mathematical experiences within the goals and expectations for a sound mathematical education. Yet, within our literatures and advocacies for curriculum, for teaching, for learning and development, and for research knowledge there seems to be very little explicit attention to the phenomenal data of an individual's lived/living mathematical experiences. This may be partially explained by the nature of what most mathematicians and mathematics educators seem to focus upon within mathematically productive activity: cognition, thinking, sense making, reasoning, solving, explaining, etc. Research to build models of such focal emphases should surely be a fundamental cornerstone of mathematical education research. But, to further our knowledge of actual lived/living mathematical experience set against such mathematically productive activity frames an important goal DIME research efforts.

Some fundamental questions that we are seeking to investigate include the following:

- What is the nature of lived and living mathematical experiences?
- What are the particular qualities (essences) of human experience that make it a "mathematical experience"?
- Are these experiential qualities that are unique to mathematics, or are they also found more broadly in other human experiences?
- How do identifiable qualities of lived/living mathematical experiences relate to learning mathematics and to psychological models to describe mathematical thinking and feeling?
- In what ways do lived/living mathematical experiences vary or differ among humans, and why?
- What factors related to the individual or the experiential context might frame or affect the actual phenomenon of a high quality "living mathematical experience"?
- In what ways do the experiences of individuals vary within mathematical contexts, such as classroom situations that are intended to engender the "same" kinds of experiences for all participants?
- How do lived mathematical experiences accumulate within differing individuals, and with what more general intellective and emotive consequences?
- In what ways do thinking and feeling aspects of mathematical experience interact within a living experiential context, and with what kinds of impacts or outcomes?
- In what ways might a mathematics educator use what can be learned about lived/living mathematical experiences of students, parents, teacher educators, mathematicians, or others in society to improve educational practices?

These are some of the questions that serve as "starting points" for DIME research. In addition, we are confronting many research methodological questions that are challenging much of our initial struggles to conceptualize viable approaches to such phenomena.

If we want educational outcomes that mirror the empowerment that a deep knowledge and proficiency of mathematics can afford, we must now seek to move beyond our current perspectives and approaches that still seem to produce (for too many of our students) much less than we seek. If we are to understand deeply why so many of our students still achieve very poor understandings of the mathematical ideas and processes after experience with our reformed curricula and our improved teaching methods, materials, and tools, we must begin to penetrate beyond more superficial indicators, such as test scores or written work, or even observed classroom behaviors into the interior world of the student's actual lived/living mathematical experiences where we may be able to identify deeper explanatory aspects of the individual's progressive growth (or deficits) toward greater mathematical knowledge and proficiency.

There is one other rationale that seems increasingly important. Too many of our citizens bear negative feelings toward their own past mathematical education (Hersch & John-Steiner, 2011), but for us educators to help our current students avoid such debilitating beliefs, feelings and attitudes we must begin to understand the nature of their experienced emotions that occur and develop within the mathematical contexts we offer. That is, not only must we understand the intellective dimensions of a person's constructions and reconstructions of their mathematical knowledge and proficiency, but we must also understand the origins and dynamics of emotional dimensions of their experiences, and how the interplay of thinking and reasoning actually functions within their live experiential feelings, emotions and affective schemas in relation to engaged, productive mathematical thinking. It is time to seek to understand the "whole mathematical life" of our students.

The goal of such new understandings is the assumed potential that from such knowledge we mathematics educators will all be helped to engage in improved forms of mathematical education in which enhanced qualities of lived/living mathematical experiences occur for all persons. We seek a pedagogy that understands and honors the experiences of the other (surely a primary intention of humanist philosophy and constructivist epistemology).

It is the goal of the DIME research program to begin to study intentionally the phenomena of lived/living mathematical experiences. Why bother? Are not the traditional views emphasized in intended curriculum, instruction, learning, assessment, evaluation, and research on learning and teaching adequate? Indeed, it is exactly because the goals and strategies of a sound mathematical education today embody a major emphasis upon stimulating, nurturing, and demonstrating high quality thinking arising from particular kinds of intended experiences that we must now seek to understand more clearly the nature of what students and teachers are actually experiencing in the "flow of their math lives" (Csikszentmihalyi, 1990).

Issues in a Psychology of Mathematical Experience

We each know the centrality of our own lived experiences. Even modest personal reflection can lead an individual to a sense of realization that it is specific experiences that shape "who they are, what we know, how we think" in powerful and fundamental ways. This includes what is experienced "outside," in the so-called "real world" that involves our interactions within our proximal environment (our sensory-based physical experiences) and within our interactions and relationships with other minds (our socially-based logical and emotional experiences). But, this also includes interior experiences that occur in our mind within our "interiorized" constructed world, where our thinking and our feeling "being" (person) is shaped and functions in thought (mind).

In DIME, we acknowledge the significance of the typical "mathematical" environment that includes students, teachers, parents, discourse, textbooks, technology tools, classrooms in schools, tasks and tests, the structured contexts of lessons, local, state and national curriculum frameworks, professional preparation and development, mathematicians, societies and cultures, governance, politics—all of the usual cultural and social elements in and around a person's mathematical education today. In doing so, we also accept that the meaning structures for any or all of these elements is a totally idiosyncratic construction for any of the multitudes of persons attending to matters of mathematical education. Now, we seek to "look into" the interior phenomenal world of lived experiences where each individual dynamically encounters and processes their idiosyncratic "mathematical experiences that lead to "who they are and become," mathematically. As educators, perhaps a most important aspect of this involves the dynamics of lived/living experiences that might characterize how experience might possibly bring about change (transformations) in an individual's thought and feeling with respect to mathematics.

Phenomenology begins in the lived world, and seeks to bring to reflective awareness the nature of the events of lived experience (Hegel, 1977; Husserl, 1970, 1982). The principle of intentionality acknowledges an inseparable connection to the world (in our focus, the world of mathematical education) wherein "…we question the world's very secrets and intimacies which are constitutive of the world, and which bring the world as world into being for us and in us" (van Manen, 1990, p. 5). In DIME, we are choosing to study thematic meanings, adopting themes and conducting thematic analyses within our particular orientation to the phenomenon of mathematical experience as "people of mathematics:" all being teachers, teacher educators, students of learning and teaching, mathematically educated, and interested is pedagogic theories. We are trying to be explicit about our individual and shared intentions and orientations as a preparatory anchoring step in our research process.

As such, phenomenology accepts the curriculum of being and becoming (paideia), pursuing understanding of the personal, the individual, set against the background of an understanding of the other, the whole, the communal, or the social. It seeks to explicate phenomena as they present themselves to consciousness—the only access humans have to the world. But, consciousness cannot be described directly (the fallacy of idealism); the world cannot be described directly either (the fallacy of realism); real things in the world are only meaningfully constituted by conscious human beings, and these constructed meanings can only be revealed by the constructing human as inferences.

In our formative research approaches we presume the nature of lived/living experience to be fundamentally an internal construction/re-construction that emphasizes a consciousness of "sense-making," attempted within the unique idiosyncratic mental operations, schemas and constructive mechanisms as they exist and function in the mind of the individual within that lived/living experience. To emphasize Piaget's (Piaget & Inhelder, 1969) theoretical conclusions that both intellective and affective aspects are involved within experience leading to development, we seek to study both as a seamless whole, even as we reject many other dichotomies as false (such as "thinking versus feeling") typical of a strictly modernist structuralism.

Among the constructivist focal constructs we want to consider in our study of lived/living mathematical experience are representation and re-presentation, reflection and reflective analysis and abstraction, intuition and intuitive reasoning, and perturbation and equilibration, and particularly to search for where and how they may be found to function in, impact upon, and in turn be affected by particular experiential contexts. For example, in today's curricular frameworks one sees a major attention given to "representations" and representational activities; students are expected to learn to understand, use, and make various canonical mathematical representations. Yet, what from a study of lived/living mathematical experiences can we find about a student's actual conceptions and views of representations, and especially how they experientially use such images in problem contexts to re-present the conceptual ideas they are presumed to represent? Moreover, von Glasersfeld's (1991) view of cognitive functioning sees representation, re-presentation, and reflective abstraction as inseparable aspects; can we find this exhibited in lived/living mathematical experience?

Against these theoretical lenses, we have identified a variety of issues to confront as we attempt to study lived/living mathematical experiences. Some of these are identified below, and these will be addressed in the activities of the Working Group described next.

1. In what ways is it possible to study the lived/living mathematical experiences of anyone: one self? The "other"? We have found helpful literature that addresses important theoretical perspectives and methodological strategies for this question [e.g., Dewey, 1938; Hegel, 1977; Hurlburt & Akhter, 2006; McLeod, 1964; Moustakas, 1994; Petitmengin, 2006; van Manen 1990]. We have identified these guiding principles:

A. A research methodology for studying lived/living experience includes the theoretical precepts behind the methods—the values and assumptions of phenomenology and constructivism as briefly discussed above. Within a focus on actual experience, we are willing to yield upon procedures or techniques that certain methods, even in qualitative research, attempt to objectify or make more standardized.

B. Our overall framework is adapted from van Manen's (1990) structure "…seen as a dynamic interplay among six research activities:

(1) Turning to a phenomenon, which seriously interests us and commits us to the world;
(2) Investigating experience as we live it rather than as we conceptualize it;
(3) Reflecting on the essential themes that characterize the phenomenon;
(4) Describing the phenomenon through the art of writing and rewriting;
(5) Maintaining a strong and oriented pedagogical relation to the phenomenon;
(6) Balancing the research context by considering parts and whole." (p. 30-31)

C. Some views of phenomenology aim at being "presuppositionless," warding off a tendency to construct or enact a predetermined set of fixed procedures or techniques that would rule-govern the research. We will engage our observations and analysis with general acceptance of this view, while also making efforts to stipulate and articulate, a priori, as many of our individual values, assumptions, beliefs, and attitudes about the phenomenon of "mathematical experience as we can and seems relevant. One view (van Manen, 1990)—*our problem is not that we know too little about it, but that we know too much!* (p. 46). As such, we are predisposed to interpret the nature of the phenomenon before we have even come to grips with the phenomenological questions.

D. In those research contexts where our aim will be to stimulate new experiences within real-time, unfolding events, we adopt the dynamics of constructivist orientations but set aside "teaching or learning" aims, per se (e.g., where questions from the researcher-teacher would seek to provoke particular kinds of mathematical thinking or productions). Rather, within an initial problematic situation posed to provoke or engender lived mathematical experiences, we honor the paths as determined and taken by the person.

E. We seek to address the phenomenon of mathematical experience in a variety of ways. In doing so, we will seek attentively to orient to the phenomenon as we strive to deepen our formulation of the phenomenological questions.

F. We are building a team approach with a purposeful aim of including a variety of perspectives and voices, and this brings opportunities beyond research conducted by one, or even two collaborating scholars. As such, we have adopted views and tactics to mirror what we perceive as formative, developmental research, and to be alert to elements of our inquiry that includes aspects of team building, per se.

2. Whose experiences should be studied, and why? Who are to be the subjects of the research? How are they chosen? Because mathematics as a human endeavor in society and globally is so pervasive and seemingly universal, we foresee a full range of research participants who experience mathematics in a wide array of situations and for a diverse set of reasons. Of course, one orientation we bring to this is the "enterprise" of mathematical education, and this will greatly influence our choices for whose experiences we will try to investigate, and also determine how we frame the contexts and the templates of analysis and interpretation. We want to include at least these in our sampling of lived/living mathematical experiences—ourselves, mathematicians, mathematics teacher educators, mathematics education researchers, pre-service and in-service mathematics teachers across levels of school mathematics, mathematics students across levels of school mathematics, and parents of the students. Different types of participants will allow us to address a variety of aims; specific individuals will be chosen in terms of particular aims and purposes.

3. What are sources or forms of "data of lived/living experience?" How can these be generated in ways that yield penetration into phenomena? Be seen to be accurate (true to the phenomena)? Valid? Reliable? Viable? (Steffe, 2011) We accept the following views about the nature of "data of lived/living experience." The world of lived/living mathematical experience is for us both the source and the object of our research. We each bring strong (yet varying) orientations to it. But, we share a fundamental assumption: *experiential accounts are never identical to lived/living experience itself.*

We already see that the sources and forms of our "data of lived experience can be rich and varied. Yet, we will pursue in each the step of generating written descriptions, and these may be of two kinds: (a) an immediate description of the "*life-world as lived*," or (b) an intermediate (or a mediated) description of the "*life-world as expressed in symbolic form*." While we accept that in this step there occurs interpretation, among team members we will share in an analysis of the description as produced, and engage in intentional interpretation (hermeneutic) to produce a "second-generation description" that purposefully seeks to identify and describe "essences as deeper meanings of the lived mathematical experience."

4. In what ways can research subjects be directly engaged in experiential mathematical situations while informing the researcher about what they are experiencing? It is one of the basic assumptions of phenomenology that experience will be changed within an attempt to introspect—to "rise above" and give attention to the experience while it is occurring, and that the distinctions between what is introspection and retrospection are blurred (thus our use of "lived/living"). While we accept this assumption in theory, we also want to explore this phenomenon. Petitmengin (2006) used an interview method aimed at helping a person to become aware of her subjective experience and to describe it with great precision. Hurlburt and Akhter (2006) used a "descriptive experience sampling" method to explore inner experience. Their subjects were prompted by an electronic beeper which they carried as they moved in their natural environments. When the beep sounded, they were trained to "capture their inner experience and jot notes about it"; they discussed it during a later expositional interview.

As researcher-observers interactively engaged in mathematical situations we've posed for the purposes of engendering active involvement by, say, a student, we intend *to become a part of the student's experiences*, per se—to get into "the flow" of what the student is experiencing (Csikszentmihalyi, 1990).

"Being there" can mean (to the student) that, as a part of their unfolding experience, we ask questions. While these questions will primarily focus upon their activity and their "thinking aloud" verbalizations related to it, at times we will ask a question pointing more directly to their conscious reflection upon their experiences, per se. In some sense, we anticipate that such a question can result in a kind of interruption of the flow of experiences related to the posed mathematical situation; we intend to ask the student later about the effects of such questions upon their perceptions of the flow of their experience. We anticipate there will be variable impacts reported by different persons, but we also expect that across time and successive observational interviews, individuals will develop a greater capacity for minimizing (or perception of) the disruptive effects of such questions.

5. How do we, as researchers, conduct analysis and interpretation of data to build accurate portrayals of lived/living mathematical experience? Key to phenomenological or constructivist research is analysis and interpretation as an observer, or teacher-researcher. Critical to either are the struggles to maintain, as much as possible, open thinking in which one consciously acknowledges potential biases and avoids "projecting" one's own experiences onto the situation. Intentional "bracketing" is attempted; members of our team are trying to describe, *a priori* to individual or shared acts of analysis and interpretation, our individual perspectives on what we each may "see" in the phenomena of lived mathematical experience—we will refer to these as our "initial construct views" (ICV). We will share these written ICV descriptions, and try to use these when we are subsequently engaged in analyses and interpretations of our observations and descriptions. We are unsure about exactly how we will use these, but one could be when we disagree about what we "see" in a particular protocol or description; we may be able to find reasons for a researcher's interpretations in the anchoring viewpoints they expressed in their ICV.

We believe that through a team approach in which multiple descriptions can be generated independently and then discussed and debated, we will likely achieve more sensitively accurate interpretations of the phenomena—"negotiated meanings." Across experiential episodes we will look for consistencies as well as variation, thus being attuned to elements of cross-validation of the qualities to be found in a person's lived mathematical experiences. Also, in these we will look for how the nature of experiences for each subject may change; again, as educators we seek and expect change—growth and development as a consequence of something we call "mathematical experience."

6. In what ways can we "make sense of" our study of the observed lived/living mathematical experience in relation to its implications and potential applications? This question speaks to the important intent that our research results lead beyond information about the interior "mathematical life," although such research-based information is generally lacking today. Our goals include the possible implications for such new insights and understandings about lived mathematical experience to impact upon future mathematical experiences. We foresee possible benefits to the ways that mathematics teachers seek to stimulate and engage their students to engender certain qualities of experiences they might have. Information about what is occurring in the lived mathematical experiences of students may prompt changes in curricular topics, placements, or treatments. Deeper understandings from studies of experience may raise implications for testing and assessment strategies related to mathematics learning.

Specific Plans for DIME Sessions at PME-NA 2012

Overall, the three sessions will be conducted in "workshop/working" format, structured to inform and orient new, interested participants, while allowing returning WG participants to report and share, to interact toward clarifying basic issues and challenges in conducting research on lived/living mathematical experiences, and to extend individual and collaborative activities that could occur prior to PME-NA 2013. Specifically, the following tentative plans have been developed in collaboration with prior DIME WG participants.

Session 1

Overview and background for DIME research activities (Larry L. Hatfield; 15 min.)
Aspects of "mathematical experience" implied in mathematical education literatures (Travis A. Olson; 10 min.)
Investigating mathematical caring relations within lived mathematical experiences in cross-cultural classrooms (Amy Hackenberg; 10 min.)
Plenary group discussion (15 min.)
Breakout groups working discussions—issues and questions (30 min.)

Session 2

Investigating experiential aspects of student mathematical conjectures and conjecturing (Andy Norton; 10 min.)
Using lived-experience descriptions as a mathematics learning tool for teachers and students (Yuichi Handa; 10 min.)
Examining beliefs and practices of pre-service secondary mathematics teachers in terms of mathematical experiences (Shashi Belbase; 10 min.)
Plenary group discussion (10 min.)
Breakout groups working discussions—framing specific research ideas (30 min.)

Session 3

Reporting lived/living experiences from geometric problem solving of pre-service elementary teachers: A case study example (Larry Hatfield; 10 min.)
Plenary group discussion (10 min.)
Breakout groups working discussions—developing collaborative plans (30 min.)
Closing plenary session—reporting back; looking to PME-NA 2013 (25 min.)

Feedback and input from all discussions will be collected; post-conference written summaries for each sub-group will be prepared at UW and distributed to all WG participants, and posted to the WISDOM^e website.

Lack of appropriate and adequate mathematical knowledge of elementary teachers is a major concern in mathematics education. This new working group on ***Developing Elementary Teachers' Mathematical Knowledge for Teaching*** *aims to explore this issue from multiple, diverse perspectives and hopes that mathematicians and mathematics educators will come together to discuss this topic. At the initial meeting, participants will have an opportunity to share their current research, raise important questions for this work, and collectively bring together current thinking in the field. In the second matting, the group will identify possible directions for future research, and in the third meeting, collaborative groups will further specify areas of interest and plan future work together. The long-term goal is to develop an edited book that examines issues around the development of mathematics knowledge for teaching from various perspectives.*

Keywords: Mathematical Knowledge for Teaching; Elementary School Education; Teacher Education–Preservice; Affect, Emotion, Beliefs, and Attitudes

Most elementary teachers in North America are prepared as generalists during initial teacher preparation, ultimately assuming positions in schools that require the teaching of all subjects in the elementary classroom. Such all-purpose preparation has led to a corpus of elementary teachers needing improved mathematical knowledge for effectively teaching cognitively-demanding mathematics curricula. As this knowledge has been linked to student learning and achievement, the inadequate preparation of these teachers is disconcerting. Wu (2009) fittingly asserted:

> The fact that many elementary teachers lack the knowledge to teach mathematics with coherence, precision, and reasoning is a systemic problem with grave consequences. Let us note that this is not the fault of our elementary teachers. Indeed, it is altogether unrealistic to expect our generalist elementary teachers to possess this kind of knowledge. (p. 14)

This concern is pervasive in the field of mathematics teacher education (see Ball, Hill, & Bass, 2005; Hill, 2010; Ma, 1999; Rowland, Huckstep, & Thwaites, 2005), and has prompted many institutions of higher education to require specialized mathematics content courses for prospective elementary teachers. These courses, referred to here as *Math for Teachers* (MFT) courses, aim to provide a thorough understanding of elementary mathematics concepts in order to develop prospective teachers' confidence and flexibility in teaching mathematics (Kilpatrick, Swafford, & Findell, 2001; Williams, 2008). Such courses were endorsed in a report by the National Mathematics Advisory Panel (Greenberg & Walsh, 2008), which argued for increasing the number of required courses. In Canada as well, a recent policy statement constructed by a working group at the Canadian Mathematics Education Forum (Kajander & Jarvis, 2009) argued for the need for at least 100 hours of specialized mathematics content courses for prospective teachers. It is currently the case that many, although not all, MFT courses are taught in mathematics departments by mathematics faculty.

The purpose of this new working group is to examine how teacher preparation experiences, particularly those focused on developing specialized mathematical knowledge, can support the development of mathematical knowledge for teaching of elementary teachers. The group will critically consider several factors influencing this development, including: teacher mathematical preparation program and course experiences, teacher mathematical knowledge for teaching, and teacher mathematical beliefs and affect. This list is not intended to be all-encompassing, as the working group will be encouraged to initially consider any factors and issues of interest related to the broad topic. The following presents overviews of theoretical perspectives and research that are relevant to this working group.

Teacher Knowledge in Mathematics

Elementary teachers require well-developed knowledge of mathematics to be effective in their teaching (Hill, 2010), particularly to support their ability to create *standards-based learning environments* that promote classroom discourse and foster conceptual understandings of mathematics. Teachers with only procedural understandings of mathematics cannot be expected to teach at in-depth, conceptual levels that lead to the complex understandings needed for mathematical applications in today's society (Ma, 1999). Accordingly, a recent emphasis has been placed on *mathematical knowledge for teaching* (MKT) (Ball, Thames, & Phelps, 2008; Hill, 2010; Kajander, 2010a) as a necessary precursor for the effective use of knowledge of mathematics *in* teaching (Ball, Lubienski, & Mewborn, 2001).

Though there is general agreement on the need for highly developed mathematical knowledge, this knowledge is complex, and a breadth of viewpoints and assumptions complicate the discourse (Kajander et al., 2010). There have been multiple efforts to precisely define the nature of this knowledge (Ball, Hill, & Bass, 2005; Kajander, 2010b; Rowland, Huckstep, & Thwaites, 2005). Shulman (1986) defines *subject matter knowledge* (SMK) as knowledge of the discipline, including substantive and syntactic knowledge, and *pedagogical content knowledge* (PCK) as "ways of representing the subject which make it comprehensible to others" (p. 9). In Shulman's view, PCK includes teachers' knowledge of effective ways of representing concepts, particularly the most cogent examples, illustrations, explanations, or demonstrations, to make these concepts lucid to students. Foss and Kleinsasser (1996) explain that SMK and PCK, respectively, involve "knowing the content of a subject or discipline and being aware of the means by which the content is taught" (p. 430).

In recent years, researchers (Ball & Forzani, 2010; Ball, Hill, & Bass, 2005; Ball, Thames, & Phelps, 2008; Hill 2010) have further refined Shulman's distinctions between SMK and PCK, proposing a *specialized content knowledge* (SCK). SCK is defined as "mathematical knowledge needed to perform the recurrent tasks of teaching mathematics to students" (Ball et al., 2008, p. 399). Specifically, Schilling and Hill (2007) explain that SCK "consists of mathematical tasks such as representing numbers and operations with pictures or manipulatives, examining and generalizing from non-standard solution methods, and providing explanations for mathematical ideas or procedures" (p. 78).

Teacher Affect and Beliefs

Across many years, research has established a robust relationship between teachers' affect and beliefs and their instructional practices, especially teacher thinking and behaviors such as instructional decision-making and use of curriculum materials (Buehl & Fives, 2009; Clark & Peterson, 1986; Phillip, 2007; Raymond, 1997; Romberg & Carpenter, 1986; Thompson, 1992; Wilson & Cooney, 2002). Philippou and Christou (2002) suggest that affect is on a continuum, with feelings, emotions, and anxiety at one end, characterized as short-lived and highly charged. Beliefs are at the other end, typified as more cognitive and stable in nature. Teachers' affect and beliefs develop over time (Richardson, 1996), beginning with their own experiences as students in K–12 classrooms, during what Lortie (1975) terms the *apprenticeship of observation*, and are well-established by the time they enter college (Pajares, 1996). Phillip (2007) underscores the importance of beliefs about mathematics when he asserts, "For many students studying mathematics, the feelings and beliefs that they carry away *about* the subject are at least as important as the knowledge they learn *of* the subject" (p. 257). The affect and beliefs of prospective teachers have an influence on how and what they learn and should be targets of change during the teacher preparation process (Feiman-Nemser, 2001; Richardson, 1996), though programs are constrained by the limited time available to effect changes.

Two influential teacher belief constructs include pedagogical beliefs (i.e., beliefs about teaching and learning) and teaching efficacy beliefs (i.e., beliefs about capabilities to teach effectively and influence student learning). The reform perspective on teaching recommended by the National Council of Teachers of Mathematics (NCTM, 2000) requires substantial paradigmatic shifts for many prospective elementary teachers. This perspective includes the amalgamation of mathematical content and process standards, requiring a pedagogical approach different than the traditional instruction found in many classrooms. Many of the suggestions espoused by the NCTM (1991, 2000) are grounded in a constructivist-compatible method of teaching, in which teachers provide learning tasks intended to develop students' understandings of concepts and procedures in ways that foster students' abilities to solve problems and to reason and communicate mathematically. Studies on changing the mathematical pedagogical beliefs of elementary prospective teachers have largely focused on moving them toward this reform perspective. These studies often examined change during only one course or semester and although some reported success in achieving the desired effects, others did not (Holm & Kajander, 2012; Kalchman, 2011; Philipp et al., 2007; Swars, Hart, Smith, & Smith, 2007; Swars, Smith, Smith, & Hart, 2009; Wilkins & Brand, 2004).

Moreover, teaching efficacy beliefs have been linked with classroom instructional strategies, willingness to embrace educational reform, commitment to teaching, and student achievement. Disconcertingly, many prospective teachers' mathematics teaching efficacy beliefs are built on their past experiences with traditional, behaviorist methods of mathematics instruction, thus generating a tension between the development of cognitively-oriented pedagogical beliefs and a sense of efficaciousness with respect to teaching in this way (Smith, 1996). Although there are numerous studies on generalized teaching efficacy, there has been less research specifically on the mathematics teaching efficacy of elementary prospective teachers. Most of the extant studies examined the effects of one mathematics pedagogy course and indicated significant increases in mathematics teaching efficacy upon completion of the course (Huinker & Madison, 1997; Kajander, 2010a; Kalchman, 2011; Swars, Hart, Smith, & Smith, 2007; Swars, Smith, Smith, & Hart, 2009; Utley, Moseley, & Bryant, 2005).

Prospective Elementary Teachers' Experiences in Mathematics Content Courses

There is limited research on prospective elementary teachers' experiences in mathematics content courses, including MFT courses. A search of the literature revealed that most studies involving prospective elementary teachers were largely conducted in the context of mathematics pedagogy courses rather than content courses. As described below, the few found related to content courses examined the effects of reform practices on the students.

Royster, Harris, and Schoeps (1999) investigated general mathematics content courses that had been modified to align the curriculum and instructors' practices with reform recommendations. They surveyed 182 college students from various majors at the beginning and end of semester-long courses to assess changes in dispositions. The findings revealed elementary education majors showed the greatest positive changes in dispositions toward mathematics in comparison to other majors, suggesting a positive outcome of reform-based practices with prospective elementary teachers in mathematics content courses. In another study, Lubinski and Otto (2004), operating under the assumption that if elementary prospective teachers are expected to teach mathematics for understanding then they must learn mathematics in this way, implemented a reform curriculum in a semester-long MFT course comprised of 28 elementary education majors. After conducting pre- and post-surveys and post-interviews with the students, the findings revealed the students' beliefs and attitudes about mathematics had been positively influenced by the course. In an additional study focusing on MFT courses, Philipp et al. (2007) examined the effects of field experiences and focusing on children's thinking on the mathematical content knowledge and beliefs of prospective elementary teachers. Those who studied children's mathematical thinking while learning mathematics developed more reform-oriented beliefs about mathematics teaching and learning and improved their mathematical content knowledge more so than those who did not. Hart and Swars (2009) was the only study found that specifically looked at the experiences of pre-service teachers in traditional math for teachers content courses. The preservice teacher they interviewed reported that much of the coursework was highly traditional (e.g., lecture, power-points) and unrelated to their experience in elementary classrooms. They also reported that the mathematics they were learning was not *useful* for them as elementary teachers.

Post-Secondary Mathematics Instruction

Some studies have examined the student perspective on effective teaching of mathematics at the post-secondary level (Hart, Oesterle, & Swars, 2011; Hart & Swars, 2009; Powell-Mikle, 2003; Schulze & Tomal, 2006; Weinstein, 2004). Hart and Swars (2009) interviewed 12 prospective teachers to examine their experience in MFT courses. They reported that the students found traditional pedagogical practices such as lecture and power point were not effective for learning the mathematics, and strategies such as small-group work and discussions were more productive for learning. Powell-Mikle (2003) interviewed six college students, who reported specific classroom characteristics that supported their learning in mathematics courses: adequate instructor availability, clear instructor explanations, prevalent classroom discourse, and a caring classroom environment. In a similar study, Weinstein (2004) surveyed and observed 18 college mathematics students. The students indicated the most effective mathematics instructors spent less time lecturing and more time developing student confidence. In a much larger study, Schulze and Tomal (2006) surveyed 2,042 college students, identifying factors that contribute to a *chilly* mathematics classroom climate, i.e., a climate that creates a negative atmosphere for teaching and learning. Three factors most likely to contribute to this type of climate were: (1) the difficulty level of course content, (2) the teaching style and personality of the professor, and (3) the personality styles of classmates.

Studies including mathematics instructors as participants are sparse. VanMinden, Walls, and Nardi's (1998) compared the pedagogical knowledge-structure representations of 15 participants, including three university mathematicians, three university mathematics pedagogy professors, along with three elementary, three middle, and three high school teachers. Their findings showed the university mathematicians' pedagogical knowledge was the least learner-focused and most algorithmic compared to the other participants. The mathematicians characterized teaching and learning as didactic and unidirectional or as the transmission of information to passive learners. The researchers concluded that reflective practitioners at all levels "need links between subject-matter concepts in the mathematics domain and pedagogical content knowledge" (p. 354).

Speer and Wagner (2009) examined the knowledge needed by mathematics instructors (referred to in their study as professional mathematicians) to implement inquiry-oriented curricula in post-secondary mathematics courses. They identified three areas of requisite knowledge for successful implementation of reform teaching practices. The areas were: knowledge of typical ways students' think (correctly and incorrectly) about the task or content in question, knowledge of the curriculum in use, and knowledge to support the specialized type of mathematical work teachers do when dissecting and analyzing students' expressions of their ideas. In a related study, Wagner, Speer, and Rossa (2007) examined the teaching practices of one professional mathematician and identified similar forms of knowledge beyond content knowledge that are needed in reform-oriented teaching. They also pointed out that traditional instructional practices frequently fail to support student-centered learning.

Only one study focussed specifically on mathematics faculty who teach MFT courses. Through an analysis of interviews with ten MFT instructors, Oesterle (2011) found wide diversity in their interpretations of the course, including their goals with respect to knowledge-for-teaching, beliefs about mathematics, and the attitudes/emotions of their students (Oesterle & Liljedahl, 2009). These differences influenced how they set priorities for affective and cognitive goals within the course and their teaching approaches. Furthermore, instructors were found to experience tensions (Oesterle, 2010) as they strove to meet these goals within the contexts of their own experience, knowledge, and beliefs, their perceptions of their students, and the demands of their institutions.

Proposed Features of Effective Teacher Preparation Programs in Mathematics

In order to develop mathematical knowledge for teaching and positively change mathematical beliefs and affect, several features of effective teacher preparation programs have been proposed (National

Research Council, 2001; Sowder, 2007), though their actualization is wrought with challenges. One such feature is increased collaboration between mathematicians and mathematics educators, including a unification and coordination of mathematics content and teaching methods courses. This was also recommended in a study by Hart, Oesterle, and Swars (2011) after contrasting the perspectives of students and instructors in these courses. Further, effective programs are expected to build in-depth understandings of mathematics that are useful to prospective teachers. These understandings should be developed via inquiry and problem solving, grounded in theories of how people learn. Provision of sufficient time for problem-based mathematics learning is particularly challenging during programs in which the only available courses related to mathematics are pedagogy or "methods" courses. For example, Kajander (2010a) studied the development of mathematical understanding as needed for teaching during standard mathematics methods courses which included a substantial focus on mathematics content development, and found that while significant growth was evident, much more time would ideally be required.

Specific methods for prompting prospective teacher learning in mathematics have been suggested, including studying children's thinking, using K–12 curriculum materials, examining case studies of teaching and learning, and relating coursework to K–12 classrooms (Phillip et al., 2008; Sowder, 2007; Swars, Smith, Smith, Hart, & Carothers, 2011). In addition, there has been a call for increasing the number of MFT courses required of elementary prospective teachers to include 9 semester hours focusing on elementary mathematics (CBMS, 2001; Greenberg & Walsh, 2008).

The Working Group

This new working group aims to explore these and other issues related to developing the mathematical knowledge for teaching of elementary teachers. The group is interested in multiple, diverse perspectives and hopes that mathematicians and mathematics educators will come together to explore this topic. At the initial meeting, the organizers will ask participants to: briefly share current research they are engaged in, raise important questions and directions for this work, and collectively bring together current thinking in the field. The long-term goal is to develop an edited book that examines these issues from various perspectives.

Following are statements from the four organizers of the group regarding their current work and thinking on the topic:

Lynn Hart is a Professor of mathematics education at Georgia State University in Atlanta, Georgia. Her research on teacher change in the areas of beliefs and content knowledge spans over 2 decades. She is particularly interested in how the culture of mathematics departments and mathematics education departments impact the instruction received by elementary teachers, the mathematical learning of elementary teachers, and the beliefs and attitudes of the teachers. Most recently she participated in a 4-year study of potential elementary teachers examining their beliefs and content knowledge; and, she participated in a comparison study of the perspectives of instructors and students in mathematics content courses for elementary teachers.

Susan Swars is an Associate Professor of mathematics education and STEM Coordinator at Georgia State University in Atlanta, Georgia. Her research interests include the study of elementary teacher change and learning during mathematics teacher preparation, with a particular focus on the outcomes of mathematical knowledge for teaching and mathematical beliefs. As co-director for a master's degree program in elementary education with an embedded K–5 mathematics endorsement, she is currently studying the development of Elementary Mathematics Specialists in the context of this program. She is also involved in a longitudinal, comparative study of the effects of increased MFT courses on prospective elementary teachers' knowledge and beliefs. One key finding is that increasing the number of MFT courses did not result in notable differences in mathematical knowledge for teaching. This work also involved phenomenological exploration of prospective elementary teachers' experiences in MFT courses, which resulted in a two-dimensional model for learning in MFT courses around the dimensions of caring classroom practices and curricular relevance.

Susan Oesterle is a mathematics instructor at a two-year college who has been teaching content courses for pre-service elementary teachers for over 20 years. In a recent research study, she examined the experience of teaching MFT courses from the perspectives of ten mathematics faculty who teach these courses, exposing a wide diversity in the approaches taken and providing an analysis of the tensions experienced by these instructors as they seek to understand and meet the needs and expectations of their students, their institutions, and the community. Her current research interests are focussed on the knowledge, beliefs, and attitudes characteristic of effective teachers of mathematics, and more specifically on how to support development of these skills and attributes within mathematics content courses.

Ann Kajander is an Associate Professor of mathematics education at Lakehead University in Thunder Bay, Ontario, who has been involved in research on mathematical development of preservice teachers for eight years. She currently teaches a new course in mathematics-for-teaching for elementary teacher-candidates. Prior to teaching in the Faculty of Education, she taught mathematics at the secondary level as well as teaching an introductory mathematics course for prospective elementary teachers housed in the Mathematics Department for ten years. Teachers' understanding of the construction of mathematical models, in particular those that support linking concrete classroom explorations to the development of more formal methods in an explicit manner, are a particular focus of her research. Ann is currently completing a book manuscript for a new resource for prospective teachers on mathematics-for-teaching.

Plans for Three Working Group Sessions

Three sessions are planned for the working group. The organizers anticipate addressing the following ideas and questions in the sessions. The organizers will make sure that the discussion stays related to the broad topic of the development of mathematical knowledge for teaching of elementary prospective teachers during teacher preparation. Within the frame of mathematical knowledge for teaching:

Session 1: What do we know from the research . . .

(a) about the mathematical teacher preparation of elementary teachers;
(b) about what they bring to their teacher preparation programs;
(c) about what they acquire in their programs;
(d) and, about what they encounter in the schools during internships/field placements?

In this session participants will have an opportunity to share their current work on the topic, as well as relevant research. Topics could include, but are not limited to, program experiences, coursework, teacher beliefs and affect, pedagogy, and teacher knowledge.

Session 2: What do we want to explore about providing experiences during elementary teacher preparation that develop mathematical knowledge for teaching?

(a) How can we examine the effectiveness of program experiences and course topics/approaches/learning environments?
(b) Might a specific set of topics, tasks, and questions, as well as suggestions for learning environments, be developed that would best support mathematical development?
(c) What are the views of different stakeholders about program experiences and course topics/approaches/learning environments?
(d) Is there a best learning environment for mathematics courses for elementary teachers?

In this session participants will raise areas of interest for researchers and begin to form sub-groups to explore different questions.

Session 3: Setting goals for our work together

In this session, individual research teams will set goals for their work together; and the working group will set goals for our collective work to be continued in 2013. An overall long-term goal for the working group is to produce a book on current research in the area.

HOW CAN MODELS OF MATHEMATICAL DEVELOPMENT BE STRUCTURED, REPRESENTED, COMMUNICATED, AND USED IN FORMATIVE ASSESSMENT?

E. Caroline Wylie
Educational Testing Service
ecwylie@ets.org

Malcolm Bauer
Educational Testing Service
mbauer@ets.org

Steve Rhine
Willamette University
srhine@willamette.edu

The purpose of this working group is to identify ways in which teachers and students can use models of mathematical development (learning progressions, trajectories) productively as part of a formative assessment process. This is the second year for the group. Last year, we made progress on representing such models in ways that are relevant to instruction, and on ways to use them in the development of diagnostic tasks for use in formative assessment. The focus this year is the use of such models to organize curricula and lesson plans around student learning. In the sessions, we will build upon last year's work, and, starting from some existing "seed" examples, participants will identify and explore different ways of using these models to organize lesson plans, pacing guides, and learning activities in support of formative assessment. We will reflect on implications for organizational structures within schools, such as Professional Learning Communities. We will identify interesting research questions that may provide insight into how models of mathematical development might affect teachers' use of formative assessment. The session will balance issues in current practice and on-going research. Follow-on activities include expanding and evaluating different approaches through collaborations among participants, and convening again to learn from our collective experiences.

Keywords: Learning Trajectories (or Progressions); Teacher Education–Inservice/Professional Development; Teacher Knowledge

Models of mathematical development hold promise in driving teaching, learning, and assessment (Heritage, 2008) but significant progress needs to be made on several fronts for their effective use. Areas of exploration range from the identification of learning progressions as an essential attribute of effective formative assessment (CCSSO, 2008) to the role that learning progressions play in the articulation of standards, e.g., the Common Core State Standards (CCSSI, 2010), to their value in organizing teaching around how student learning develops. Given that this is a relatively unexplored area, but has substantial practical value in improving mathematical teaching and learning, this year's working group will focus on exploring issues related to the use of learning progressions in organizing curriculum, classroom activities, and assessment.

In previous work (Harris, Wylie, & Bauer (2011)) proposed an approach for teachers to develop teaching progressions (similar to hypothetical learning trajectories proposed by Simon & Tzur, 2004) that integrate models of student's mathematical development with broader curriculum materials to achieve targeted learning goals. In a research proposal that grew out of discussions at last year's working group, we began to refine these ideas to consider how such teaching progressions would affect and provide value to teacher professional development activities and lesson planning. While still falling into the overall scope of the working group, the intent this year is to focus on this more specific, and timely, question:

> "What are ways of using learning progressions to inform formative assessment, instructional approaches, support, and resources to help students learn?"

We will build on the interest and work completed last year with a coherent set of sessions that will address the question. We summarize last year's session to provide a context for the continued work, and then describe how the three sessions this year will be structured.

Activities and Outcomes from the 2011 PME Working Group

For the 2011 Working Group we focused on the question "How can models of mathematical development be structured, represented, communicated and used in formative assessment?" Our interest in conducting the session grew out of our work in building assessment tasks for formative purposes, and using models of mathematical development (also called learning trajectories or learning progressions) to guide development. Thus the title of the session captured the multiple aspects of our interest in developmental models: how can they be structured, represented, communicated, and used. While learning progressions can be used to inform summative assessment, our specific interest was in formative assessment, and we wanted to learn from the experiences of others to both inform our work and add to the general understanding of developmental models.

Our goal over the three sessions was to explore different ways of representing models of mathematical development with teachers and students specifically in mind, to apply some of the representation ideas to an example of a developmental model, and to consider how members of the working group might continue a dialogue around these issues beyond the conference. The first part of the first session provided set-up for what was to follow in the later sessions.

Session One

We set the stage using an example from Grant Wiggins (1998) in which industrial arts' students were able to compare their weld to a set of five welds that were characteristic of different levels of development in the skill of welding. In doing so students: assessed at what level they were performing; determined their next learning goals; and understood what specific next things they needed to do to improve. We posed the question of whether this could be done in mathematics, wondering how we could get students to compare their thinking to the different levels of development, and relatedly, how we might support their next steps in learning. Each session of the working group had a different focus, shown below:

1. Overview of project and working group goals. Focus on alternative structures/representations of the developmental models for use in formative assessment, and how to support students' use of the models.
2. Small group work on specific models and alternative representations.
3. Identify research questions and associated approaches for addressing them based on work in sessions 1 and 2.

During the first session we provided some background information on one of our current projects that was the catalyst for our interest, along with establishing common ground for the group's understanding of formative assessment. We have an IES-funded Goal 5 project (Grant Reference R305A100518) that runs from July 2010 to June 2014. The focus of this assessment development project is on the development of formative assessment, with respect to three developmental models or learning progressions, to support instruction for middle school mathematics teachers. The three developmental models focus on the following mathematical concepts: Equality and Variable; Linear Functions; Proportional Reasoning

Within this project we have two distinctly different, but complementary, approaches to formative assessment: a locator (or placement) test, and incremental tasks. These two assessment types play different roles in the instructional process. The locator test, as the name suggests, "locates" students with respect to their levels of understanding across the three models. The incremental tasks have a finer-grained focus, and target the transition between two levels, thus playing both an assessment and an instructional role. The incremental tasks can provide additional evidence of student knowledge and skills to update a teacher's understanding of where students are in their thinking, and to support student learning as they transition from one level to the next within a progression. We envision that the locator test would be used one or two times during a school year, whereas a teacher might draw on a much greater number of the incremental tasks to supplement instructional and assessment approaches in any given curriculum with a focus on topics related to these learning progressions.

We introduced three possible ways in which learning progressions play an important role within formative assessment. First, they can be used to inform assessment developers about important content and conceptual understanding to be assessed. Second, teachers can use learning progressions to better understand how student thinking can develop over time with respect to key disciplinary concepts. In addition, tying assessment evidence to the learning progressions helps teachers think how students cluster together in terms of similar learning patterns. The third role that learning progressions may play is informing students about their own mathematical thinking, in the same way that the examples of the welds with various problems helped the students assess their own welds and identify weaknesses. This is the area in which we had done the least exploration and so it seems like a fruitful topic to pursue with the working group. We finished the first session by asking the group to consider the following question: “What information should be included in a model and how should that be represented to developers, teachers and/or students to support learning?” Critical ideas and suggestions from the first session were as follows:

1. It is important to not only identify individually important learning progressions within mathematics, but also to show how they are interconnected to support teachers’ thinking across progressions. Within a progression, connection points to other progressions should be identified.
2. Connections should also be made to curriculum concepts to support teacher use of the learning progressions, for example, where in mathematics would a naïve understanding of variable present significant difficulties for students.
3. Multiple representations, such as concept maps, may be useful
4. It is critical to identify misconceptions within the levels of the progressions, in addition to how a student’s understanding of a concept evolves from novice to expert.
5. While the levels within a progression are presented as a linear sequence, it is important to clearly present the idea that we do not expect all students to progress similarly in an “upward” linear fashion: students’ level may vary with context, they may regress at times, and they may skip entire levels.
6. Example tasks with responses—or examples of student discourse—could be used to illustrate what student thinking looks like—or sounds like—at each level.

Session Two

During the second session, we presented one Linear Functions task to the group to provide a concrete example on which to base the discussion. The task was one of the incremental tasks that focused on the transition from level 3 to level 4 in the Linear Functions model. The group was asked to imagine a teacher and class of students using the learning progression and the task and to consider what they would change, and what additional elements or materials would be helpful for students and teachers. Ideas and suggestions from the second session were as follows:

- There needs to be a tool that helps the teacher evaluate student work—not just a single solution path, in other words a more extended rubric.
- As a supplement to the rubric, provide help with “distractor analysis” for relevant questions, and note things for a teacher to listen for, which might be evidence for particular student understandings or misunderstandings. Suggest appropriate probes or comments that a teacher might make.
- Consider ways to use the idea of student traffic lighting (signaling whether understanding is red (almost none), yellow (some confusion), or green (clear)) to support self-assessment through the task?
- Use the language of the transitions to write learning intentions for each task.
- Set up PowerPoint so that questions could be used one at a time, without revealing the entire task.
- Create an “overarching question” that is task specific that could be used as a pre/post question for students. For example, for the task reviewed, students could consider just the context provided with an overarching question, “Which fair costs more?” The question is quite open-ended, but if students track their thinking via journal entries, they should be able to recognize changes in their thinking.
- Support teachers’ information processing by giving them a flow chart to show branching points with the questions and suggest either specific actions or points at which action might be needed if students were struggling.

Session Three

During the third session, we had a broader conversation regarding next steps, although we had fewer attendees at this final session than we had at previous ones. There was definite interest in maintaining the relationships and continuing the work next year.

What We Have Done Since the Conference

Since the conference we have established a research partnership with one of the group members and submitted an NSF MSP grant proposal to further explore how learning progressions can be used as an organizing framework to support professional development for both pre-service and in-service teachers. It had become clear at the conference that we had developed complementary resources for mathematics teachers, and that both groups would be stronger together as a result of exploring these ideas.

Plan for This Year's Sessions

This year's working group sessions will focus on another important aspect of the use of learning progressions in supporting teaching and learning: organizing instruction that guides and is informed by teachers' formative assessment practices. Wiliam (2004) defines three steps for assessment to function formatively: "it needs to identify where learners are in their learning, where they are going, and how to get there" (p. 5). A learning progression provides both a longer term view to guide instruction along with more immediate goals. The full progression presents teachers with a view of the nature of expertise with respect to the particular concept or concepts that is the focus of the progression. In addition, the progression provides a description of more immediate learning goals. A learning progression can be structured as a series of transitions to identify important "starting and landing" places in learning to support the first two steps of formative assessment. Using learning progressions to organize material and activities across a series of lessons can enable teachers to gather evidence of students' level of understanding, help decide next learning goals, and then connect to new learning activities to move students toward those goals.

Figure 1 below presents a schematic of a family of approaches teachers may use to organize, carry out, and revise instructional plans. This process includes (1) identifying learning goals and curricular components, (2) identifying the learning progressions and other materials that inform patterns of student learning, (3) gauging students' current levels of understanding, (4) revising lesson plans to meet current student needs, (5) carrying out math activities that support learning, (6) updating understanding of student learning to continue the process. Layered on top of this cycle is a larger cycle of long term planning. Over the course of the three sessions we will engage in lesson plan design activities to develop and reflect on some possible ways of organizing instructional plans around learning progressions.

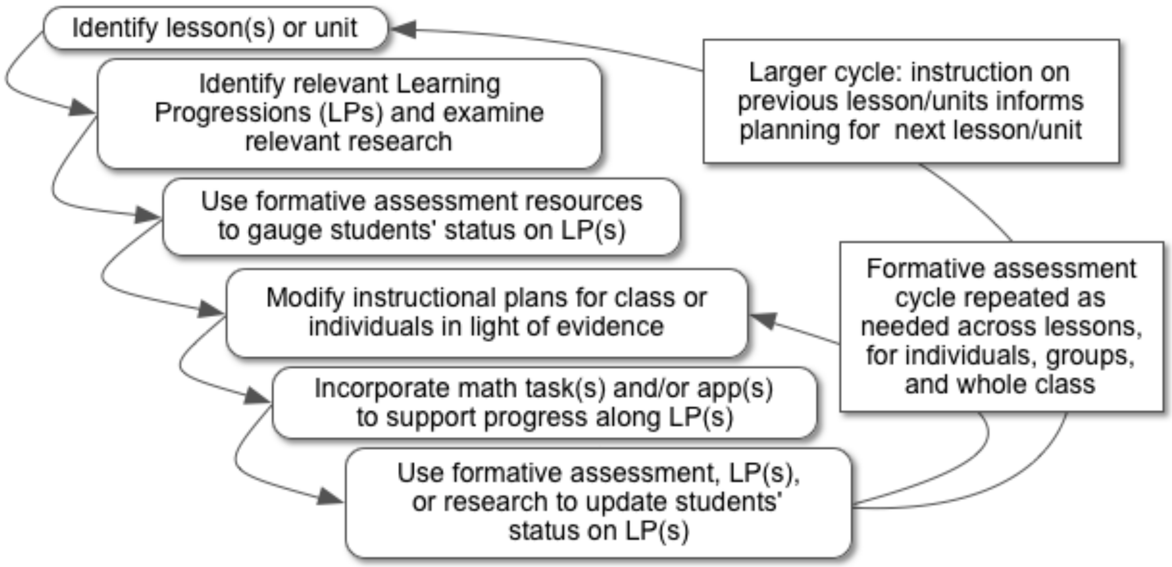

Figure 1: Cycles of formative assessment using learning progressions

In session one we will: (a) identify attendees' background and interests with respect to learning progressions and lesson planning; (b) review and discuss prior work of the group and advances in the field of learning progressions, with respect to lesson planning, identifying student thinking, and supporting next instructional steps; (c) identify one or more progressions of interest to the group, and one or more parts of curricula on which to focus the design activities in the remaining two sessions. We will also discuss the formative assessment process, with a focus on using evidence to take "next instructional steps" to ensure that lesson planning incorporates the idea of contingency planning into the initial development, in other words anticipating a range of student responses and planning instruction for those various categories of response.

In session two we will work in small groups to develop a lesson plan for a short series of lessons that would draw on one or more learning progressions, and some of the additional resources presented (Entries from ATP encyclopedia, incremental tasks and online manipulatives). As we debrief from the experience of organizing materials and activities, attending to curriculum while still drawing on the learning progressions, we will synthesize our experiences into a set of steps or routines that a teacher might follow in order to incorporate learning progressions into her lesson planning.

In session three we will reflect on the plans, discuss how to support teachers incorporating learning progressions into their instruction (what are the hindrances and affordances), and identify opportunities for tryouts and research questions.

As a result of the three sessions we expect to have (1) worked out examples of instructional plans organized with respect to learning progressions, (2) a set of approaches for creating instructional approaches based upon learning progressions, (3) research questions to further explore as a group, (4) ideas and specific plans for collaborative projects in 2013.

Follow-On Activities

Throughout the year, participants may explore the use of the representations of models and ideas for use in formative assessment in their research or in their practice. It is the hope of the organizers that early pre-proposal explorations are carried out and one or more research proposals may be generated. The work will also inform an aspect of an existing grant on which the organizers are working. As noted earlier the organizers have submitted an NSF grant that will provide opportunities to explore how best to support early career teachers which will provide some opportunities to pilot the emerging ideas from this working group session and will provide feedback to the working group participants on their ideas. The intent is to reconvene at the next PME-NA to share experiences on specific collaborations that developed, to discuss progress on aspects of the work, and to plan continued efforts in this area.

The purpose of this working group is to examine how students with mathematics learning disabilities (MLDs) can be effectively taught and assessed in mathematics. Traditionally, research and instruction related to students with MLDs has focused on procedural skills. However, this working group is rooted in a twofold premise: (a) students with disabilities are capable of and need to develop conceptual understanding and mathematical reasoning skills, and (b) special education instruction and assessment needs to transition towards this focus. Participants will discuss pairing conceptual diagnosis (assessment) with instructional interventions, in order to achieve better mathematical learning for students with disabilities.

Keywords: Equity and Diversity; Instructional Activities and Practices; Assessment and Evaluation

Brief Overview of the Working Group

A need exists to promote increased conversation, research, and practice in relation to the intersection of mathematics teaching and learning and students with MLD. Substantial work exists that focuses on cognition, learning, and development of students in general education. Yet, much of the available research related to students with MLD has historically focused on rote memorization of basic skills. As a result, much less is known about the mathematical thinking, learning, and development of students with MLD. Our Working Group is designed to create an opportunity for researchers and practitioners interested in disability and mathematics for collaborating in the examination of perspectives on this important dimension of the psychology of mathematics education.

Moving towards the active study of how students with MLD develop mathematics concepts and skills has several implications for both research and practice. First, practitioners in both general and special education can gain essential knowledge of how to differentiate instruction related to alternative pathways of understanding mathematics concepts evidenced by diverse learners. Secondly, by studying atypical development, researchers gain a richer understanding of how cognitive processes involved in learning essential mathematical concepts evidence themselves. As mathematical cognitive changes in MLD occur over a long period of time, research of these changes can provide insights into processes that may be hard to detect and document in general education. Finally, active study of the development of mathematics concepts and skills for students with MLD provides both researchers and practitioners mechanisms for moving toward a methodological focus on pedagogy rooted in assessment of what these students' *are* capable of learning. For the purposes of starting our conversations, "Disability" as it relates to students with MLD includes:

- learning disabilities specific to mathematics
- students with cognitive differences in how they understand and process number
- students with language-based learning disabilities who struggle with mathematics
- students who are placed in special education either through traditional assessments or are at Tier 3 of a Response-to-Intervention (RTI) learning disabilities identification program.

We plan to focus discussions around several central themes, including: (a) conceptually rich teaching and learning for students with MLD, (b) unique learning challenges facing students with MLD along with historical and alternative perspectives on disability, and (c) methodologies for assessing student's difficulties and evaluating the effectiveness of interventions. We invite researchers and educators interested in issues of disability and mathematics to participate.

Issues Relating to Psychology of Mathematics Education

A Case for Conceptually Rich Teaching and Learning for Students with MLD

Currently, special education researchers and teachers focus almost exclusively on students' mastery of procedural skills, such as basic number combinations and ability to execute mathematical algorithms (Jackson & Neel, 2006; Fuchs et al., 2010; Geary, 2010; Swanson, 2007; Kameenui & Carnine, 1998). A recent literature review comparing instructional domains for students with disabilities found that the majority of research conducted in the field of special education addressed basic computation and problem solving, with the primary focus placed on mnemonics, cognitive strategy instruction, or curriculum-based measurement (Van Garderen, Scheuermann, Jackson, & Hampton, 2009). Instructional practices, including task analysis (breaking up skills into steps), flash cards (Cole & Washburn-Moses, 2010), and turning complex problems into decontextualized steps that need to be memorized and followed, have been advocated for in order to increase the proficiency in problem solving and higher order mathematical skills of students with MLD. Yet the focus on primarily procedures-driven instruction and rote memorization of skills seems to result in students' incomplete and inaccurate understanding of fundamental mathematics concepts as well as a lack of retention and/or transfer (Baroody, 2011). The inability of students with MLD to transfer, retain, and fundamentally understand mathematical concepts continues to plague intervention research efforts in the field of special education (Rittle-Johnson & Alibali, 1999).

Crucial for rich mathematical understandings that enable retention and transfer of fundamental concepts is the iterative development of conceptual understanding along with procedural proficiency (Rittle-Johnson, Siegler, & Alibali, 2001; Rittle-Johnson & Koedinger, 2005). Rittle-Johnson and Alibali (1999) noted that conceptual knowledge constrained procedural generalization. In particular, conceptual knowledge could aid children in mindfully avoiding the use of procedures that fail to work in novel situations. Additionally, an ability to understand and manipulate different mathematical representations to conceptually navigate a mathematical context contributes to conceptual understanding and procedural skill (Ball, 1993; Kaput, 1987; Rittle-Johnson et al., 2001). It seems that any investigation into mathematical cognition, whether related to disability or not, must fundamentally engage with issues of conceptual understanding.

A focus on procedural skills limits students with disabilities' access to the general education curriculum, which is a requirement of the Individuals with Disabilities Educational Improvement Act (Maccini & Gagnon, 2002). In mathematics, access to the general education curriculum means addressing problem-solving, mathematical reasoning, and communication of mathematical thinking as advocated by the National Council of Teachers of Mathematics (NCTM) Standards (2000). To accomplish these Standards, mathematics educators need to actively engage students in making conjectures, justifying and questioning each other's ideas, and operating in ways that lead to deep levels of mathematical understanding (Kazemi & Stipek, 2001; Lampert, 1990; Martino & Maher, 1999; Yackel, 2002).

Unique Learning Challenges Facing Students with MLD: Historical and Alternative Perspectives on Disability

We are advocating that students with disabilities be given access to mathematically significant curriculum through a new emphasis on conceptual understanding and mathematical reasoning. We are not claiming that access to such a curriculum can be obtained by using the same techniques that have been used with the general education population. One important reason is that students with disabilities often have different activation patterns in their brains when solving mathematics problems than typically developing students (Butterworth, Varma, & Laurillard, 2011; Davis et al., 2009). Therefore, we should anticipate that they will have different ways of solving problems, will rely upon different resources, and also might need alternative instructional approaches.

Students with disabilities are often viewed by their teachers as less developed than their peers, as opposed to "differently developed." Such a deficit ("less") lens seems to underlie a view of these students' learning as including the same skills and happening in essentially the same ways as their peers, only several years behind. In turn, this lens seems to orient prescriptive pedagogical approaches focused on addressing only the lowest order basic skills. Reliance on a "deficit" model is fundamentally problematic because it involves defining a person in negative terms instead of what she or he *is able* to learn. Identifying an absence of something necessitates that researchers identify what an individual *should* have (or be "fixed"). Both the presumption of a "norm" and the practice of classifying some individuals as "deficient," have been widely criticized by scholars of disability studies (Gallagher, 2004). Davis (2006) argues that the concept of "normalcy" has long been used as a way of classifying some individuals as deficient with respect to race, class, and gender, and currently it is employed to "create the 'problem' of the disabled person" (p. 3). We argue that it is more productive to conceptualize disability in terms of natural biological differences, and will employ a positive lens on ability as the root for pedagogy and research.

Such a lens is supported by a Vygotskian perspective, which provides a productive alternative for conceptualizing disability. Vygotsky claimed that a student who has a disability "is not simply a child less developed than his peers but is a child who has developed differently" (Vygotsky, 1929/1993, p. 30). Thus, individuals' biological differences result not in deficient development but in a different path of development. The research supporting this theoretical orientation is strongest in the field of specific learning disabilities (SLD). Strong converging evidence supports the validity of the concept of SLD, and its subcategory MLD. This evidence is compelling because it converges across different indicators and methodologies. The central concept of specific learning disabilities (SLD) involves disorders of learning and cognition that are intrinsic to the individual. SLD affect a relatively narrow range of academic and performance outcomes. SLD may occur in combination with other disabling conditions, but they are not primarily due to other conditions, such as mental retardation, behavioral disturbance, lack of opportunities to learn, or primary sensory deficits.

Recently, Johnson, Humphrey, Mellard, Woods, and Swanson (2010) conducted a meta-analysis of 32 studies to examine the cognitive processing differences between students with SLD and typically achieving peers. With regard to mathematics, their main finding was that despite having intelligence scores within the average range students with MLD were severely impaired in mathematics ability. These students also had difficulties with executive functioning, processing speed, and short-term memory, which suggests that these processes may be implicated in their brains' execution of mathematics.

There is some evidence that MLD stems from neurological disorders that affect the brain's ability to receive, process, store, and respond to information (Dehaene, 1997; Dehaene & Akhavein, 1995). Recent neuroimaging studies have supported the neurological basis of MLD by demonstrating that students with MLD tend to have less activation in the parietal lobe when processing numbers, have less gray matter in the parietal lobe, and have fewer connections between the various parietal regions than typically developing students (Butterworth, Varma, & Laurillard, 2011). Davis et al. (2009) utilized functional magnetic resonance imaging (fMRI) to explore the brain patterns of activation associated with different levels of performance in exact and approximate calculation tasks. They found significant differences between well-defined cohorts of children with mathematical calculation difficulties (MLD) and their typically developing (TD) peers. Both groups of children activated the same network of brain regions; however, children in the MLD group had significantly increased activation in parietal, frontal, and cingulate cortices during calculation tasks. Most of the differences occurred in anatomical brain regions associated with cognitive resources such as executive functioning and working memory, which are known to support higher level arithmetic skills but are not specific to mathematical processing. These findings provided evidence that children with MLD use the same types of problem solving strategies as TD children, but their weak mathematical processing system causes them to employ a more developmentally immature and less efficient form of the strategies. As students with mathematical disabilities have different activation rates in their brains as they solve mathematics, we should anticipate that they may have different ways of solving problems, will rely upon different resources, and also might need alternative instructional approaches.

Recent research in the area of MLD has also made advances in understanding the cognitive and academic profiles of students with MLD (Compton, Fuchs, Fuchs, Lambert, & Hamlett, 2012; Davis et al., 2009). Compton et al. (2012) explained how students with MLD experience unexpected pockets of strengths and weaknesses across cognitive dimensions or academic domains. The idea, referred to as the specificity hypothesis, is that MLD involves specific rather than generalized learning difficulty and that for each individual neurological functions selectively impair some but not other areas of cognitive functioning. For example, a student with difficulties in retrieving math facts, may have a strength in understanding arithmetic properties (Geary et al., 2007). As we learn more about the relative strengths and weakness associated with MLD, we can build on a student's strengths to promote learning of weak areas of academic performance.

Common Characteristics of MLD

In spite of individual differences, there are some common characteristics of students with MLD. They tend to have a delayed adoption and understanding of efficient counting strategies (Geary, Bow-Thomas, & Yao, 1992), due to inadequate construction of one-to-one correspondence and an over-reliance on adjacency. Thus, students with MLD are slow to grasp and use retrieval strategies for adding basic facts, using back-up strategies such as counting all and counting from the first number throughout elementary school (Ostad, 1997). Their reliance on counting tangible objects means that they continue counting on their fingers long beyond the duration in typical peers (Butterworth, Varma, & Laurillard, 2011). Students with MLD also seem to have problems in many aspects of basic number sense, such as comparing magnitudes of numbers by quickly visualizing a number line or transforming simple word problems into simple equations (Jordan, Hanich, & Kaplan, 2003; Fuchs et al., 2005). In addition, two studies (DiPerna, Lei, & Reid, 2007; Fuchs et al., 2005) have found that teachers' ratings of a child's attention span and task persistence are good indicators of the student's subsequent problems in learning mathematics. Each student with MLD may exhibit all or a subset of these difficulties, and the precise nature of how they affect learning vary across students. This makes any profile of MLD difficult to validate, as every student may have qualitatively different strengths and weaknesses, and accordingly respond differently to instruction.

Conceptual Diagnosis Based Pedagogy—Assessing Students' Mathematics and Evaluating Effectiveness of Interventions

A pedagogical approach to be explored and advanced during this Working Group's meetings is one that focuses on promoting conceptual learning (cognitive change) in MLD. This approach is rooted in a constructivist stance (Piaget, 1985; von Glasersfeld, 1995), particularly the notion of assimilation, which stresses the need to build instruction on what students *already know* and are *able* to *think/do*. That is, teaching needs to be sensitive, relevant, and adaptive to students' available ways of operating mathematically (Steffe, 1990). To this end, teachers must learn how to: (a) diagnose students' available conceptions, and (b) design and use learning situations that both reactivate these conceptions and lead to intended transformations in these conceptions.

Building on Simon's core idea of hypothetical learning trajectories, Tzur (2008) has articulated such an adaptive pedagogy, which revolves around the *Teaching Triad* notion: (a) students' current conceptions, (b) goals for students' learning (intended math), and (c) tasks/activities to promote progression from the former to the latter. Key here is that in designing every lesson one proceeds from conceptual diagnosis of the mathematics *students are capable of thinking/doing*. That is, assessment methods need to focus on dynamic (formative) inquiry into student understandings, as opposed to on testing correct and incorrect answers per se. This day-to-day diagnosis, obtained via engaging students in solving tasks and probing for their reasoning processes, gives way to selecting goals for students' intended learning. Building on this diagnosis, a mathematics lesson begins with problems that students can successfully solve on their own, which Vygotsky (1978) referred as the *Zone of Actual Development* (see also Tzur & Lambert, 2011). Recent studies of mathematics teaching in China (Jin, 2012; Jin & Tzur, 2011) revealed a strategic, targeted method, *Bridging*, which is geared specifically toward both: (a) reactivating mathematical conceptions the teacher supposes all students know, and (b) directing their thinking to the new, intended ideas. While working with students with MLD, Tzur et al. (McClintock et al., 2011; Tzur et al., 2009; Woodward et al., 2009; Xin et al., 2009; Zhang et al., 2009) have been piloting and studying this adaptive approach with high levels of success in promoting substantial conceptual advances (e.g., concept of number, multiplicative reasoning). The adaptive pedagogy approach seems to assist in moving students out of previous 'disable' labeled grouping (Tzur et al., 2010) and in reducing such labeling due to inadequate teaching practices. Our Working Group will include brief presentations and further explorations (and theorizing) of the adaptive pedagogy (conceptual diagnosis based) approach, as we believe it can become a core for teaching and studying MLDs' conceptual understandings.

Plan for Working Group

The aim of this working group is to facilitate collaboration amongst researchers and educators concerned with mathematics education for students with disabilities. The main goal is to address the transition of instructional and assessment practices from an emphasis on (deficient) procedural knowledge to a more balanced and constructive focus on conceptual understanding and enhanced mathematical reasoning skills. Engaging in scholarly discussions of theoretical and pedagogical concerns as they pertain to both special and mathematics education will facilitate collaborative efforts to further support instructional needs of students with disabilities. This working group intends to accomplish the following: (a) examine evidence of students with MLD engaging in mathematical tasks, (b) discuss student engagement across varying perspectives (e.g. mathematics education, special education), (c) discuss means of assessing mathematical reasoning of students with disabilities, and (d) development of a research agenda addressing outcomes of the working group.

These goals are further outlined across sessions as follows.

Session 1: Mathematics Learning Disabilities—Mapping the Terrain

- Discuss goals for the working group
- Introduction of participants, including their interests in participating
- Presentation of video clips of students with MLD engaging in mathematics
- Small group discussion:
  - Varying perspectives/interpretations of the student work
  - Comparison of approaches for students with and without MLD
  - Challenges/differences of teaching students with MLD
  - Produce concept map
- Large group discussion:
  - Share out important points from small group discussions

Session 2: Assessment and Instruction

- View the same video clips as on Day 1, but look at it with a diagnostic pedagogy lens
- Small group discussion:
  - What did you learn about this student's mathematical thinking from this video?
  - What other questions would you ask the student to gain a deeper understanding of their mathematical thinking?
  - What other tasks would you pose to the student?
  - What could your next instructional move be in order to help the student develop a more sophisticated level of understanding?
  - How does this video clip fit in with current research? How does it challenge current research?
- Large group discussion:
  - Share out important points from small group discussions

Session 3: Developing a collaborative plan for research and teaching

- Develop research and teaching agendas based on discussions from session 1 and 2

Anticipated Follow-up Activities

This working group will continue working on research problems of common interest and will prepare/propose a monograph/special issue to a leading journal in the field.

This working group explores tools for measuring instructional activities and practices in relation to curriculum use. This work involves examining kinds of teacher capacities (knowledge, abilities, ways of understanding and acting) needed to design and enact lessons by using mathematics curriculum materials effectively. This working group consists of three projects that have investigated teacher knowledge and capacities by developing tools to measure instructional activities and practices. Each of the three subgroups presents their work regarding the tool they developed to measure instruction, in order to facilitate discussions and reflections on different approaches to measuring instructional activities and practices, and teacher capacities needed for effective design and enactment of a lesson. The goals of the working group are to generate interaction about instructional activities and practices and the relationship between written and enacted curricula, and to examine and critique tools developed to measure this relationship.

Keywords: Instructional Activities and Practices; Curriculum; Teacher Knowledge

This working group explores tools for and approaches to measuring instructional activities and practices in connection to curriculum material use. The goals of the working group are to generate interaction about instructional activities and practices and the relationship between written and enacted curricula, and to examine and critique tools developed to measure this relationship.

History of the Working Group

This working group focuses on the overarching question: *How can instructional activities and practices be measured to investigate the kinds of teacher capacities needed for effective curriculum use?* This question emerges from our ongoing explorations of the relationship between written and enacted curricula.

This working group consists of three subgroups: (1) Learning Mathematics for Teaching (LMT) project begun at the University of Michigan and continued in part at Harvard University, (2) CME Project Mathematical Practices Implementation (MPI) Study by the Education Development Center (EDC), and (3) Improving Curriculum Use for Better Teaching (ICUBiT) project by the University of Pennsylvania and Western Michigan University. All of these subgroups have investigated teacher knowledge and capacities that are required to teach mathematics effectively. The LMT project focuses on measuring the mathematical knowledge for teaching and mathematical quality of instruction revealed in actual teaching; the other two projects examine teacher knowledge and capacities that are required for effective curriculum use to design and enact instruction. Each subgroup has developed a tool to measure instructional activities and practices with slightly different emphases. The MPI study focuses on the secondary level and targets a particular curriculum program developed at EDC for high school students, whereas the other two examine the elementary/middle school level and do not have any particular type of curriculum in mind. In fact, the LMT and the ICUBiT projects intend to develop a tool to measure teacher knowledge and capacities regardless of the types of curriculum programs used in instruction. The LMT project has completed the development of their tool, the Mathematical Quality of Instruction (MQI) instrument. In contrast, tools by the MPI and the ICUBiT teams are still under development.

These three projects have a history of collaboration and exchange of ideas. Members of each team have served as advisors to and/or commentators on the projects of others. For example, the ICUBiT team referenced the MQI in their work to develop a tool, and members of the LMT project helped the ICUBiT team shape their initial approach; in turn, a member of the ICUBiT project helped LMT project members' multi-case studies investigating the relationship among teacher knowledge, MQI, and curriculum use. Moreover, the MPI and the ICUBiT teams organized a working group at the Research Presession of the annual meeting of the National Council of Teacher of Mathematics in April 2012. This NCTM session aimed at presenting tools in the process of development from the two subgroups and receiving feedback from the audience for further refinement. Building on our previous distinct yet related and collaborative work, we will organize this PME-NA working group to further elaborate teacher capacities required for instructional design and enactment, and issues involved in measuring instruction in terms of teacher capacities.

Issue: Measuring Instructional Activities and Practices

The issue that this working group explores in the psychology of mathematics education is measuring instructional activities and practices in relation to curriculum use. This work involves examining kinds of teacher capacities (knowledge, abilities, ways of understanding and acting) needed to design and enact lessons by using mathematics curriculum materials effectively.

Published curriculum programs, past and present, are relied upon heavily to improve instruction and increase student learning. This reliance is based on the assumptions that curricular programs are designed with a set of intentions, and that teachers will use curriculum programs in ways that are aligned with those intentions. Yet, there is substantial variation in how teachers use mathematics curriculum materials. These variations are functions of teachers' personal characteristics, such as knowledge and dispositions, as well as their pedagogical choices and interactions with students during curricular enactment (Stein, Remillard, & Smith, 2007). Curriculum materials designed to foster ambitious math instruction place even greater demands on teachers than conventional materials (Stein & Kim, 2009) and require different kinds of capacity to use them. Brown (2009) used the term *pedagogical design capacity (PDC)* to refer to "an individual teacher's ability to perceive and mobilize curricular resources in order to design instruction" (p. 29). This capacity is at the heart of how teachers use and enact the written curriculum. We see PDC as an interaction between teacher capacity and the resource available in the particular curriculum. Consider the following vignette that illustrates aspects of PDC.

This vignette is taken from a fourth-grade classroom in which students learn the concept of mean and the procedure to find the mean of a given data set. After a warm-up activity on median and mode, MR, the teacher, distributes square tiles to each group: five groups of 4 and one group of 5 students. MR asks each of the students in each group of four to count out 12, 8, 17, and 3 tiles, respectively. MR asks each of the five students in the last group to count out 12, 8, 17, 3, and 10 tiles, respectively. Then, MR asks each group to make one big pile of tiles in the center of their table and share/divide them evenly. A few minutes later, MR convenes a whole group discussion. MR summarizes student strategies. "Some students directly used paper and a pencil to do calculation without using the tiles [they remember this procedure from a science class]. Some students distributed tiles to each student until there were no more tiles left. And, some did both." Then, she collects tiles back from students and asks students to open their textbooks. She explains the computational approach of figuring out the mean, i.e., finding the sum of the numbers and dividing the sum by the number of those numbers. Then, she says that both strategies (i.e., computation and using tiles) work well. She emphasizes several times that the divisor is the number of data points. This is also done through several practice problems provided in student workbook pages of the lesson. Finally, students do practice problems individually.

The curriculum program (Charles et al., 2008) that this class uses includes in the student textbook the following statements:

> Like the median and the mode, the mean tells what is typical of the numbers in a set of data. The mean is sometimes called the average. To find an average, all the items are combined and divided equally. The diagram at the right shows that 5 is the average of 7, 4, and 4 (p. 404).

In the diagram (see Figure 1), there are three different-colored cube towers, representing 7 (blue), 4 (red), and 4 (green), respectively. To the right of these towers is a set of 3 cube towers of 5 cubes each, illustrating the redistribution of the cubes. The color coordination indicates two green cubes are moved from the tall green tower to the other shorter towers in the process of leveling out. Right below this diagram, the computational procedures to find the mean are introduced with two different example data sets. The guides/notes for teachers for this diagram include one sentence: "Explain that an average levels off or evens out the numbers in the data set so that all the numbers are the same" (p. 404). In the lesson overview at the beginning of the written lesson, there is a similar description: "Averaging involves distributing numerical data evenly across a set of numbers and provides a single number to describe what is typical in that set of numbers" (p. 404A). However, the rest of the guidance focuses on the computational procedures. Moreover, the cube towers presented were just an illustration, not suggested as an activity for students.

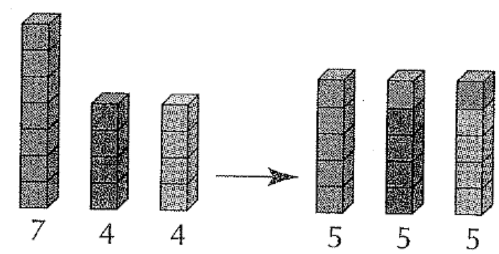

Figure 1: Diagram representing mean

A closer look at the vignette and the written lesson along with a follow-up interview with the teacher reveals a few things about MR's knowledge and capacities. On the one hand, she follows what is included in the book. For example, she uses tiles to help students explore mean, even though cubes, not tiles, are shown in the textbook and the way tiles are used does not clearly reflect the way the cube towers are shown in the textbook. She also highlights computational procedures as presented in the textbook. On the other hand, she creates her own data set for students to think about the mean using the tiles (i.e., 12, 8, 17, 3 instead of 7, 4, 4). She carefully chooses the four numbers that are easy to work with (e.g., $12 + 8 = 20$, $17 + 3 = 20$, and $40/4 = 10$) and includes a relatively large number, i.e., 17, and a very small number, 3, in the data set. Her intention is that by working with numbers that are easy for adding and dividing, students think about the mean rather than computation itself. She also wants her students to see that small and large numbers are leveled out to the mean. She recognizes the importance of "leveling out" in the meaning of the mean from the parts she read in the curriculum. In fact, she points out this right away when she is asked, "Did this [parts she indicated that she read, including the two quotes on the meaning of mean from pages 404 and 404A] help your planning or teaching? How? If not, why not?" She elaborates how important the meaning of mean is and how visual the tile activity is in illustrating the meaning.

Despite such recognition and careful planning, what students experience with the tile activity does not help them see the meaning of mean explicitly. This activity is not even clearly connected to the computational procedures in the observed lesson. The tile activity is hands-on and visual, and yet hardly accomplishes what the curriculum may intend. Students do not level the tile towers out; rather they make one big pile of tiles and divide them equally among four or five smaller piles as they are told to do so. The meaning of mean mentioned in the curriculum and recognized by MR (i.e., leveling out) is not visible or explored in any of the six student groups and in the subsequent whole group discussion. The focus is on the procedures to find the mean by using addition and division appropriately.

This vignette illustrates the centrality of teacher knowledge and capacities in designing and enacting lessons using curriculum materials. MR certainly exhibits her knowledge about mean, demonstrating her understanding of the conceptual meaning of mean. She also develops a thorough plan to teach the lesson by using the hands-on activity and carefully choosing a sample data set. Her capacity to teach the lesson that connects the conceptual representation and the procedures is, however, somehow limited. Her knowledge of the meaning of mean is not mobilized in the enacted lesson. Or, possibly her knowledge is not well formed or not sufficiently developed to teach mean conceptually as well as procedurally. Overall, her instructional emphasis is on the procedures, demonstrating and attending to them step by step. This approach might help students get the correct answers in the textbook. Also, the guidance given in the curriculum does not support MR's teaching to the extent that she needs. Other than the two sentences cited above, everything else in the curriculum is about combining the data set and dividing them evenly, reinforcing the procedure to find the mean. The diagram in Figure 1 is not accompanied by appropriate explanations in the textbook. What would her instructional activities and practices look like, if she were equipped with required knowledge and capacities to enact the lesson with the meaning of mean? In turn, what knowledge and capacities does it take for her to enact this lesson effectively? How can her instructional activities and practices be measured? Such questions need to be answered beyond this particular vignette.

As illustrated in the vignette above, examining instructional activities and practices is critical in our investigations of the kinds of teacher capacities that are needed for teachers to transform written to enacted curricula. Previous instruments for analyzing teachers' use of curriculum materials tend to focus on assessing fidelity to the curriculum, with a focus particularly on the aspects of the resources that teachers use (O'Donnell, 2008; Tarr, Chávez, Reys, & Reys, 2006). Each of the three subgroups has been investigating teacher capacities needed for mathematics instruction and ways in which enacted lessons are examined. Through such investigations, one project represented in this working group has developed a tool to measure teaching practice. The other two projects are developing new tools to measure teaching practice as it relates to the curriculum being used and the role that teacher capacity plays. The work being done by all three subgroups involves creating and adapting measures of instructional practice to get a broader and richer sense of the ways in which teachers make use of curriculum and learn from curriculum, and interactions among teacher knowledge and capacities, instructional practice, and curriculum use. One of our aims is to develop measures of curriculum use that are tied to central ideas in the curriculum being used and that capture the complex work of curriculum enactment in the classroom. Below, each subgroup's work is described along with their specific focus in measuring instruction. During the working group sessions, the participants will have an opportunity to work with and critique tools developed by the three subgroups.

Project 1 (Elementary and Middle School): Learning Mathematics for Teaching (LMT)

This project developed instruments to measure teachers' Mathematical Knowledge for Teaching (MKT), or the "mathematical knowledge needed to perform the recurrent tasks of teaching mathematics to students" (Ball, Thames, & Phelps, 2008, p. 399). These measures are multiple-choice and indicate teachers' MKT in a number of knowledge domains. To validate these measures, researchers used a wide variety of data sources including cognitive interviews with teachers, mathematicians and laypersons focusing on the different domains of content knowledge used in the interview; data correlating teachers' scores and their students' achievement; Item Response Theory and factor analysis; and a videotape validation study that linked paper-and-pencil scores with quality of instruction. When researchers sought to measure the quality of videotaped instruction, there were no instruments available that appraised teachers' mathematical knowledge for teaching, rather than just straight mathematical knowledge. Thus the project also developed its own observational measure of observed teaching, the Mathematical Quality of Instruction (MQI). Because other researchers were also looking for measures that could be used to evaluate programs and professional development, among other purposes, the MQI has become a widely used measurement instrument in its own right.

One of LMT's most recent large-scale videotape studies using the MQI investigated middle school teachers' mathematical quality of instruction in combination with their value-added scores, or student achievement (Hill, Umland, & Kapitula, 2011; Lewis, under review). Fortuitously, and not by design, several sets of teachers were videotaped teaching the same or very similar lessons from the same curriculum materials (Connected Mathematics Project [CMP] or lessons on similar content but from different curriculum materials). This serendipitous happening allowed researchers a unique opportunity to investigate the relationship among these teachers' MKT, MQI and their use of curriculum materials. In a recent multiple-case study (Charalambous & Hill, in press; Hill & Charalambous, in press a, in press b; Hill, Charalambous, & Mitchell, in press; Lewis & Blunk, in press; Sleep & Eskelson, in press), researchers simultaneously attend to teacher knowledge and curriculum materials to explore how they separately and jointly contribute to instructional quality. The pairs or triads of teachers featured in three of the case studies differed in their knowledge level and/or in the support their curriculum materials provided for lesson enactment. This allowed examining the respective contributions of MKT and the curriculum materials to instructional quality in the context of teaching a rich fractions problem that admits several solution approaches (case study 1), teaching integer operations for conceptual understanding and procedural fluency (case study 2), and teaching a linear algebra lesson (case study 3). In case study 4 (a lesson on adding fractions) teachers' differing dispositions toward their curriculum suggest yet another factor besides MKT or the materials themselves that may also account for the differences in the mathematical quality of instruction. LMT researchers will share findings from these case studies in the working group.

Project 2 (Secondary): CME Project Mathematical Practices Implementation Study (MPI)

This project explores teachers' use of a coherent high school mathematics curriculum organized around mathematical habits of mind, or ways of thinking central to the discipline of mathematics (Cuoco, Goldenberg, & Mark, 1996, 2010). The substantive focus on habits of mind mirrors the focus on mathematical practices in the Common Core State Standards for Mathematics, where standards for practice are as important as standards for mathematics content to be taught (Common Core State Standards Initiative, 2010). The habits of mind focus in the curriculum and professional development are intended to be educative for teachers on two levels: in supporting their instruction and in providing opportunities to learn mathematical practices and content. To test this theory, researchers have developed and adapted instruments to examine the role the curriculum plays in the design, selection, and modification of mathematical tasks, and in particular, the ways in which teachers make use of the mathematical habits of mind approach in their classroom. Our goal is to refine a set of instruments that can be used in future large-scale research studying the relationships among use of a principled curriculum and teacher learning, teaching practice, and student achievement in high school mathematics.

Specifically, the MPI study measures three aspects of teacher implementation around the CME Project Algebra 1 curriculum in the 9th grade. The Academic Rigor scales of the Instructional Quality Assessment (IQA) are used to evaluate the extent to which instruction maintains, diminishes, or increases the cognitive demand of the mathematical tasks in the curriculum (Mastumura et al., 2006). The IQA is being implemented with a full sample of 41 teachers using student work packets, and with a subsample of 20 teachers through live and videotaped classroom observations. The Mathematical Habits of Mind observation tool (MHoM) (Matsuura et al., 2011) assesses the extent to which the habits of mind which are the focal points of the curriculum, are developed and emphasized in the classroom, and by whom (students, teachers, or both). Finally, a battery of curriculum use instruments is used to identify components and design principles, including the mathematical approaches of the curricular materials that are and are not enacted by teachers in their first and second years of using the curriculum. Together, this set of tools provides a multifaceted view of curriculum implementation that moves beyond simple fidelity and curriculum use surveys, and links pedagogical and mathematical practices, curricular design principles, and curricular artifacts in a rich characterization of what it means to teach and learn from a high school mathematics curriculum.

Project 3 (Elementary): Improving Curriculum Use for Better Teaching (ICUBiT)

This project investigates teachers' curriculum use and the capacities and supports critical to it. After undertaking analyses of five elementary curriculum programs, ranging from reform-oriented to commercially-developed, researchers collected data on how teachers used the teacher's guides to plan lessons and also video-recorded enacted lessons. Analysis of video data focuses on *design moments,* which refer to instances during a lesson when the teacher makes decisions that are not specified in the book or his/her plans. Examples of design moments include instances where the teacher makes choices about who to call on, how to respond to student errors or questions, and even when to move on with the lesson. Our aim is to develop a coding scheme for analyzing teacher moves in these design moments that can be used with any curriculum programs and can be used to assess teacher capacity and to consider the role that features in the curriculum play in supporting teachers' designs during curriculum enactment.

Currently, the coding scheme has four categories in terms of teacher moves that seem particularly significant in design moments: (1) curriculum use moves, (2) teacher-generated mathematical moves, (3) teacher moves in response to students, and (4) moves to reinforce sociomathematical norms. Teacher curriculum use moves are coded by examining whether the teacher uses, changes, omits, or adds to what appears in the written curriculum, such as tasks, questions, and models/strategies. This category also examines whether the teacher changes the sequence of the entire lesson. The category of teacher-generated mathematical moves targets examining teacher decision-making and capacities when the teacher initiates certain mathematical moves. This includes whether the teacher exhibits a confusion or error, and, if so, whether the teacher corrects or clarifies it. Also, moments in which the teacher emphasizes certain mathematical ideas/concepts and moments in which the teacher clarifies student understanding are coded in this category. The third category is different from the second in that it is intended to capture instances where teacher moves are aimed at *responding to students* and are initiated by students' correct or incorrect responses or student-generated ideas or questions. The final category identifies instances in which the teacher's move appears to be aimed at communicating or reinforcing a sociomathematical norm. In these cases, the teacher might ask other students to respond to a student's answer or ask a student to justify his/her solution. The coding scheme is being used to analyze the classroom practices of 25 elementary teachers, using five different curriculum programs.

Plan for the Working Group Sessions

The three sessions of the working group will be organized around the tools the three subgroups developed, with one tool in each session. Each session will consist of a 20-minute presentation about each study, including main aspects that are focused on in the analysis of instructional activities and practices, and the preliminary tool developed to measure those aspects. Then, the participants will be asked to analyze a classroom video clip using the tool shared in the presentation and engage in discussion on this approach. Finally, the participants and organizers will discuss the issues related to measuring instruction using the following guiding questions:

1. What does it mean to measure instruction, especially in relation to curriculum use?
2. What considerations should guide the design of tools that aim to measure instruction?
3. What is the relationship between curriculum fidelity and high capacity curriculum enactment?
4. To what extent do the tools presented measure aspects of instruction that the studies intend to capture? What elements are missing?
5. Are the elements of the tools clearly described in order to produce consistent results? In what ways can they be improved?
6. What are the limitations of the tools? What additional tools can be used with them?

In the first session, members of the LMT project will present their work on the development of the Mathematical Quality of Instruction (MQI), guide the participants in terms of using MQI, and lead the discussion on measuring instruction. In the second session, a group from the MPI study will present their work to orchestrate the ongoing discussion on measuring instruction. The last session will be led by the

ICUBiT project team. They will share their work on the development of a tool to measure instruction and build on the two previous sessions to orchestrate discussion. On the last day, the working group will also summarize the ongoing discussion and generate future activities to further refine the tools shared and investigate ways in which written and enacted lessons are examined. This way of organizing the working group will help both the participants and the organizers examine different approaches to measuring instructional activities and practices, and elaborate teacher capacities needed for effective design and enactment of a lesson.

Anticipated Follow-up Activities

The three sessions of the working group will not only help each subgroup refine their thinking about the tool they developed and ways in which it measures instructional activities and practices, but also facilitate discussions on the relationship between written and enacted lessons and the role that the teacher plays in this relationship. The sessions will also help generate research interests among participants in relation to the work presented and issues discussed. Anticipated follow-up activities of the working group include:

- Each subgroup refines the tools, when needed, based on results of the working group.
- Each subgroup receives further feedback from the other subgroups and working group participants on the tool they refined.
- The three subgroups and working group participants interested in this work organize collaborative work and discussions on measuring instruction.

The work presented in this working group, which seeks to examine the relationship between written and enacted curricula, represents an important area of research that is currently underdeveloped in the literature. The anticipated follow-up activities of the working group will contribute to this research by exploring conceptual and methodological issues related to curriculum use and teacher capacity through measuring instructional activities and practices.

Relationship to the Conference Theme

Overall, this working group will facilitate discussions and reflections on *navigating transitions along professional learning continuum*. Identifying teacher knowledge and capacities needed for effective design and enactment of a lesson will help better design mathematics teacher preparation and professional development programs. It will also help curriculum developers create and organize “educative” (Davis & Krajcik, 2005) resources for teachers.

Brief History of the Working Group

This is the third meeting at PMENA of this Representations of Mathematics Teaching (RMT) working group. The idea of this working group emerged during a series of three-day conferences on representations of mathematics teaching held in Ann Arbor, Michigan in 2009 and 2010 (and earlier workshops in 2007 and 2008) organized by ThEMaT (Thought Experiments in Mathematics Teaching), an NSF-funded research and development project directed by Pat Herbst at the University of Michigan and Daniel Chazan at the University of Maryland. ThEMaT originally created animated representations of teaching using cartoon characters to be used for research, specifically to prompt experienced teachers to share the rationality they draw upon while teaching. The workshops were conceived to begin creating a community of researchers and teacher educators who were interested the use of representations of teaching and the analysis of data collected in response to these representations. The RMT conferences in 2009, 2010, and 2011 gathered developers and users of all kinds of representations of teaching (including video, written cases, dialogues, photographs, comic strips, and animations) to present their work and discuss issues that might be common to using these representations in teacher education and education research. A fourth conference took place on June 6–8, 2012. In proposing a continuation of the working group for PMENA 2012 we'd like to continue the discussion and work we had in recent PMENA working groups at Columbus in 2010, and Reno in 2011 around the elaboration and investigation of a pedagogical framework for teacher development that makes use of representations of teaching, and work toward an edited volume on the subject.

Issues in the Psychology of Mathematics Education that Will Be the Focus of the Work

The use of representations of practice, particularly those that are maintained in a digital form, calls for specialized pedagogical practices from teacher educators. They also open new areas for investigation of how future professionals learn teaching and the role that various technologies play in scaffolding that learning. In the 2010 PMENA discussion paper, Herbst, Bieda, Chazan, and González (2010) briefly reviewed the literature on the use of video records and written cases in teacher education. We noted that classroom scenarios sketched as cartoon animations have begun to be utilized for those purposes and argued that they have affordances that are distinct from those of video and written cases (see also Herbst, Chazan, Chen, Chieu, & Weiss, 2011). We also noted existing literature on the use of written and video cases in teacher education and cited examples that concern mostly face-to-face facilitation. We argued that the increased capabilities of information technologies for creating, manipulating, and collaborating over multimedia point to a promising future for teacher development assisted by representations of practice. A special issue of the *ZDM* journal dedicated to the theme of representations of teaching added new articles to this literature. In particular Ghousseini and Sleep (2011) and Nachlieli (2011) describe the facilitation of face-to-face discussions around representations of practice and provide two views on what makes these effective for studying practice. Yet the features of novel media and their use with digital technologies, for example in online or blended (face-to-face and online) interactions, may require other pedagogical strategies for teacher education that have not been sufficiently identified and explored.

In the discussion document for the working group meeting in 2011, we complemented the previous year's review by briefly accounting for three areas of emerging scholarship: (1) information technologies that support teachers' learning from representations of practice; (2) the particular challenge of helping prospective teachers understand students' thinking; and (3) research and theory about what is important or possible to achieve in having prospective teachers look at or work with representations of teaching.

In this document we come back to the central goal of the working group: What are the components of a pedagogy for teacher education assisted by representations of practice? Through an example we demonstrate how that question is anchored in scholarship and activities of interest to the PMENA community. Just as considerations of the subject matter being taught are key in examining pedagogy in K–12 mathematics education, a better grounding of the questions related to the use of representations of teaching in teacher education can benefit from specifications of what is being taught. In the case of mathematics educators, the content being taught to preservice teachers includes mathematics, students' thinking, and instructional practices. To anchor the need for a pedagogy assisted by representations of practice, we examine the use of representations to teach instructional practices. We focus this examination on a generic learning activity called *approximations of practice* and consider how these can be used to teach instructional practices and the kind of questions that arise from that use and that are of interest to mathematics educators gathered at PMENA.

Approximations of Practice

The expression *approximations of practice* was introduced by Grossman and colleagues (2009) to allude to "learning opportunities provided to novices" in which they can get actively involved in "the authentic practices they will be expected to enact." Grossman notes, "Students may be asked to simulate certain aspects of practice through activities such as role-plays. Simulating certain kinds of practice within the professional education classroom can allow students to try piloting the waters under easier conditions. Providing support and feedback while novices learn to paddle may better equip them to navigate the rapids of real practice." We argue that creating and supporting approximations of practice is critical for teaching instructional practices to novices. Two lines of argument contribute to this. On the one hand, Lampert's (2010) argument that teaching needs to be learned in, from, and for practice recommends the creation of opportunities to engage in aspects of the work of teaching that reproduce at least some, if not all, of the complexity of actual teaching practice. The more that the teacher candidate can be engaged in doing the practice, the more this learning will be "in" practice; and while learning "from" practice does not necessarily require representing practice in all its complexity, the more this complexity is represented the better it will ground the teacher education curriculum in actual practice. On the other hand, there is a long tradition of recommending active learning, or learning by doing, across educational levels (Bonweil & Eison, 1991). This approach to teaching seems to concurrently argue for learning activities for teacher candidates where they learn from their own experience engaging with authentic problems of practice and where reference materials such as readings play the role of supporting resources rather than focus. To mathematics teacher educators, approximations of practice offer opportunities and challenges that concern the creation of approximations, activities utilizing these approximations, and the investigation of teacher candidates' learning from these. Below we illustrate how representations of practice can feature in these approximations.

What form do approximations of practice take? One could argue that approximations of practice have always been included in teacher education programs that contain a practice curriculum—practicum experiences and student teaching are in fact approximations of practice. The literature on student teaching is vast enough to discourage a review, and it has been well represented in handbooks (e.g., McIntyre, Byrd, & Fox, 1996). Beyond practicum experiences in actual classrooms, university classes on teaching methods classes have also contained approximations of practice.

Microteaching (Allen & Eve, 1968; Cruikshank & Metcalf, 1990; McLeod, 1987), or the enactment of short lessons in front of peers, is an example of how approximations of practice have taken shape in the teacher education curriculum. While popular for some time, microteaching has not produced the desired results in supporting teacher candidates in learning to teach (McIntyre, Byrd & Fox, 1996). Over the years teacher educators have worked to improve this technique though the inclusion of targeted guidance and feedback as well as coupling microteaching with the observation of competent performance of the teaching practice being studied (for an example, see Chazan, Herbst, Sela, & Hollenbeck, 2011). A related variation has developed to match the medical education practice of the "standardized patient" (Stillman et al., 1991). Dotger, Harris, and Hansel (2008) have proposed a standardized-patient-type approximation for training teachers to talk to parents.

Yet a more recent incarnation of microteaching is that of teaching rehearsals (Lampert et al., 2010). In the process of engaging teacher candidates in performing targeted aspects of the work of teaching, some rehearsal cycles also rely on the use of video recordings of the teaching practice (Kazemi, Franke, & Lampert, 2009; Lampert & Graziani, 2009). In these activities the teacher educator guides the teacher candidates in observing live or pre-recorded exemplars of the practice that they will rehearse or watching and debriefing video of the novices' rehearsals.

Another recent approach to engaging teacher candidates with approximations of practice is through the construction and enactment of instructional dialogues, also called "lesson plays" (Crespo, Oslund, & Parks, 2011; Ghousseini, 2008; Zazkis, Liliejdahl, & Sinclair, 2009). These activities provide teacher candidates with opportunity to imagine how a classroom scenario might unfold and the specific consequences of the word choices of both the teacher and students.

Historically, teacher preparation programs have also engaged teacher candidates with approximations of teaching through lesson planning and lesson anticipation. Lesson planning, or asking teacher candidates to create a timeline for a lesson, has long been used as a tool for preparing teacher candidates for the work of teaching and scholars have begun to examine the techniques commonly used with teacher candidates and their effectiveness (Harris & Hofer, 2009; John, 1991, 2006; Mutton, Hagger, & Burn, 2011; Rusznyak & Walton, 2011). As Americans became more knowledgeable about Japanese lesson study (Hiebert & Stigler, 2000), some educators have begun to use lesson study in preservice education (Fernandez, 2002; Hiebert, Morris, & Glass, 2003; Parks, 2008.). Pre-service lesson study teams may be comprised of a group of teacher candidates, although some work has involved teams of mentor teachers and teacher candidates collaborating together (Burroughs & Lubeck, 2010). These teams may work in microteaching or lab-type settings (Fernandez, 2005), as well as in the context of actual classrooms. Distinctions in who contributes to planning, observing, and debriefing the lesson, as well the context of the lesson, determine how closely lesson study approximates actual teaching practice. For instance, when lesson study teams work on developing a lesson to be taught in an actual classroom, the school curriculum, norms, and student characteristics must be taken into consideration and heighten the authenticity of the lesson planning when compared to a lesson study for fellow teacher candidates in a microteaching setting. But approximations of teaching may also be deployed in virtual settings.

Approximations of teaching in virtual settings: A use of *Depict*. Herbst and Chieu (2011) introduced the *Depict* tool (a component of the *LessonSketch* environment in www.lessonsketch.org). *Depict* enables users to create a classroom scenario using text, inscriptions, and graphics (see also Herbst et al., 2011). Chen (2012) has shown that when preservice teachers were asked to anticipate a lesson using Depict they were able to think through the tasks they would propose in more detail than when they merely talked through a lesson plan they had written before. As a result it is possible to envision a new kind of approximation of practice that moves above and beyond activities in which novices construct dialogues to show how they would handle problems of practice. The teacher educator can depict the beginning of a classroom scenario, using text and graphics, and leave it to the novice to complete the scenario and submit it to the teacher educator, who in turn might insert comments or alternatives and return that to the novice. Thus approximations of practice can be deployed and transacted through the use of multimedia representations. We exemplify this use below.

Teaching the instructional practice of "explaining a concept" using approximations of practice. One thing the first author does as part of his methods course is teach novices how to explain concepts.

Explaining concepts can be a teacher-centered activity in that the teacher may "provide" all the explanation, but it may also be a blend, using discussion or brief explorations as parts of the explanation. In teaching novices how to explain concepts, however, the goal is not so much to identify the best activity type for them to use, but to teach novices about what things need to be included in an explanation of a concept. As Leinhardt and Steele (2005) have shown, dialogue-based lessons can be constructed to share features of instructional explanations found in the instructional explanations documented of expert teachers (Leinhardt, 1989, 2001). To support the teacher candidates in learning how to explain concepts, Herbst uses a decomposition of practice for the practice of "explaining concepts and propositions" (Herbst, 2011). This decomposition of practice builds on Leinhardt's work on instructional explanations by describing and exemplifying the components of an explanation in text form. Components such as problematizing the concept, exemplifying the concept, and so on are described and illustrated in documents such as Herbst (2011). Until 2011 students in Herbst's methods course would practice what they learn in the context of approximations of practice like the problem shown on Figure 1.

4. Abilene Clark has been teaching her Algebra II class the exponential function and properties about the multiplication and division of exponents. She wants to make sure students use those properties well so she points out possible errors related to operations with exponents. Write a dialogue in which you show how Abilene could

a. demonstrate one of those errors, and
b. explain why it is an error

Figure 1: A dialogue based approximation of the practice of explaining a concept (co-designed by Gloriana González, Pat Herbst, and Adam Poetzel)

In fall 2011, Herbst and his team started using an illustrated version of the decomposition for explaining concepts and created graphic approximations of practice using *Depict*. The problem in Figure 1, which gives novices the opportunity to practice examining common errors, which is one aspect of explaining concepts, was then posed using the depiction shown in Figure 2 and in the context of an online homework assignment including three problems like it. Novices were told that the depiction shows how what Ms. Clark has done so far and asks, "What are some of the conceptual errors that are at the root of common mistakes students could make when working with the logarithmic function? Write your comments in the box below." Then it prompts them, "Now, please press View and then Edit to edit the slideshow, so that you can complete what Ms. Clark should say to the class to point out common errors that students make when using the logarithmic function. Your edited slides should demonstrate one common error and Ms. Clark's explanation to the class of why it is an error (and how they might avoid it). [The red text on the whiteboard and the text between brackets in the speech bubbles] shows where you can fill in what the teacher should say and write on the board. Feel free to add more slides…."

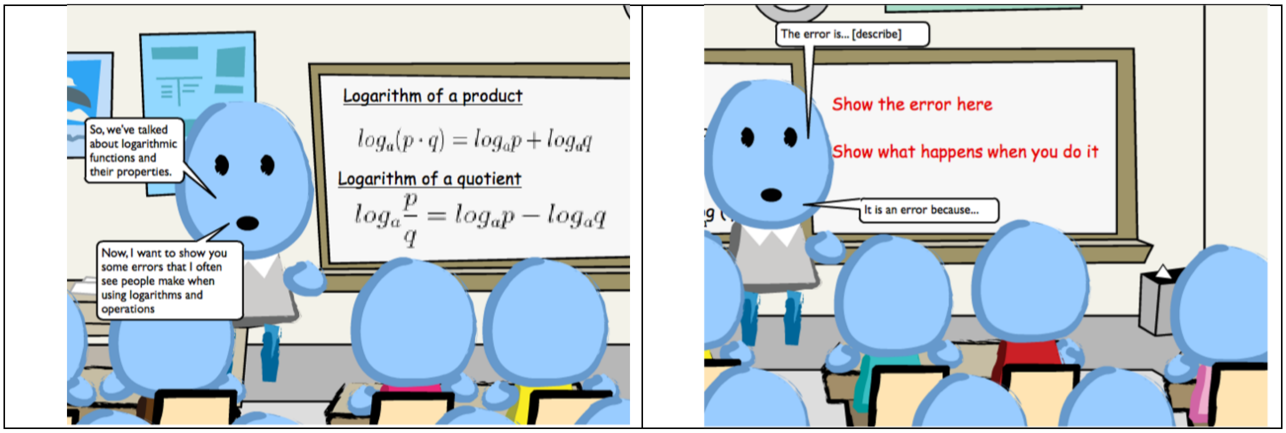

Figure 2: The context given for an approximation of practice using graphics

Figure 3 shows parts of the depiction that one novice (D) made continuing the provided slides. D's depiction contained five original frames that followed the provided ones. D's work shows not only how the approximation got novices involved in practicing but also, as Chen (2012) had found, it made them think of the details of tasks and multimodal student involvement.

A teacher educator could provide feedback to that depiction, or perhaps sketch an alternative scenario. In Herbst's class, teacher candidates not only created the depictions that showed what a teacher could say and do when providing an explanation, but they also rehearsed them in front of their peers on the following class. Peers and instructors could then provide constructive criticism about choices made in planning and about the qualities of their performance.

Through depicting the continuation of scenarios like those, teacher candidates can develop and display their knowledge of instructional practices. The decomposition of practice provides teacher candidates with a framework for thinking about the essential aspects of the practice while the work of depicting the scenario provides teacher candidates with the opportunity to explore the possibilities for what the practice will look like when it is enacted in the classroom.

As this example shows, approximations of practice can be used to create opportunities to learn a practice (explaining concepts, and its component of examining common errors) *in* practice (by providing an explanation in a depicted classroom) and *from* practice (where the feedback addresses alternative choices and ways of enacting them). A more sophisticated case of using approximations of practice has been proposed by Chieu and Herbst (2011), who describe the features of a teaching simulator, where teacher candidates practice teaching by choosing what the cartoon teacher would do and the simulator provides the ensuing events in a simulated class.

Clearly, *Depict* is only one example of how technology can support learning from approximations of practice (in the case shown, homework problems based on the work of teaching are used to support teacher candidates in learning how to preform an instructional practice). The same approximation could be realized using video; the teacher educator could record the initial scenes of the scenario, while playing the role of teacher, and could ask the teacher candidates to record themselves doing the ensuing actions. Feedback could come in the form of an annotation of the video or a video response, where the teacher educator demonstrates how he would modify what the teacher candidate did. In both cases one can see how technology-supported representations of practice can be used to create approximations of practice than blend active learning with learning in and from practice. This activity can involve novices in figuring out what to do in particular circumstances, while blended with microteaching it can also address the development of skills in performing the work of teaching; that is, learning *for* practice.

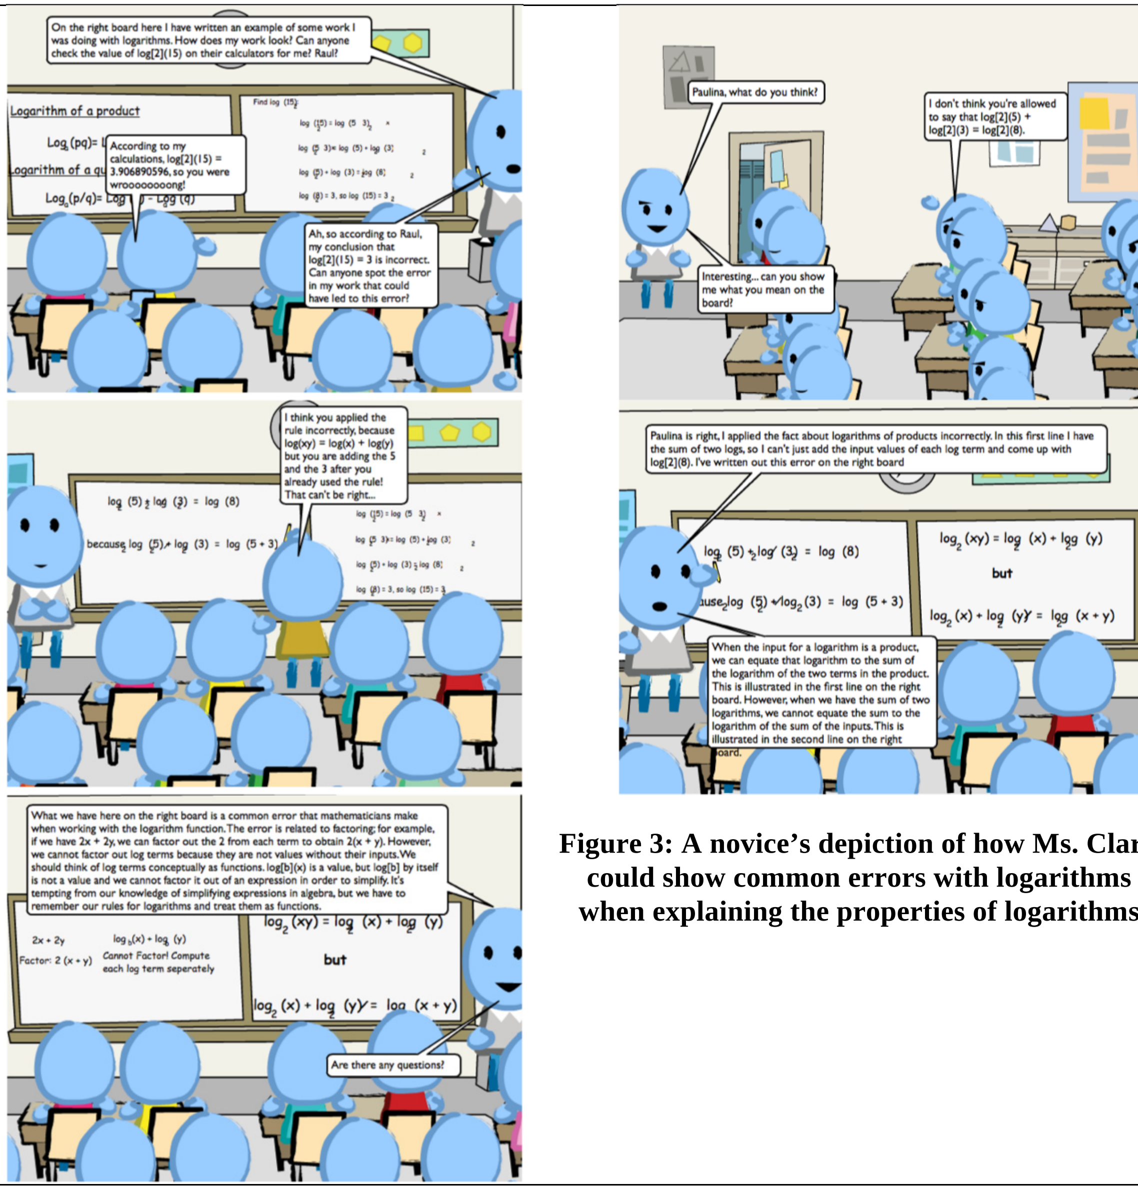

Figure 3: A novice's depiction of how Ms. Clark could show common errors with logarithms when explaining the properties of logarithms

The prior discussion of approximations of practice suggests that a generic learning activity in teacher education could involve teacher candidates in studying a practice (e.g., viewing illustrations that decompose a practice) then doing problems of practice where they engage in virtually enacting those practices. The learning materials and the problems could be posed in some information technology based environment such as LessonSketch, and the teacher candidates would produce their responses using tools integrated in that environment (in this case *Depict*). This generic learning activity helps raise questions that are of interest to the PMENA community and that illustrate why the working group fills a gap in the community. Some questions are about the novices' learning: What do novices learn by engaging with representations of teaching in the context of activities that approximate practice? Do different kinds of representations afford different learning opportunities when similar approximations of practice are used (e.g., text only vs. *Depict* vs. video)? In other words, are there cognitive or performance changes in novice teachers that go along (conceptually or statistically) with different kinds of representation-based activities or different kinds of representations? On the other hand the extent to which this kind of approximation of practice involves media and communication technologies provides a snippet of how much pedagogical innovation is possible and needed in order to handle representations of practice with novices. Teacher educators need to choose what their novices will learn indeed. But they also need to design how they are going to create opportunities for them to learn. Approximations of practice illustrate the complexities involved in this work. Teacher educators are not limited to selecting media artifacts; they can also produce them. This requires making choices of symbol systems, content, and form. Beyond producing or selecting representations to use, teacher educators need to design or choose activities in which novices will engage with those representations, and they need to design how to propose those activities to novices. Teacher educators need to identify the medium within which to share those activities and the representations associated with them. Face-to-face group encounters with a projector screen are only one of the many choices available, which include notably, online environments like *LessonSketch* that can be used at distance (e.g., when students are doing homework at home) or co-located (e.g., when students browse through a representation in class, using their own laptops). Teacher educators also need to design the tasks they pose to the novices—these tasks may be "what do you notice?" but they may also be "what would you do or say next?" In sum, teacher educators need to design learning environments for the learning of teaching—recent improvements in Internet broadband speed, web-based software, user experience standards, and graphics technologies have made the choices available for that design much greater, and more diverse, than ever before at least in terms of their possibilities. We argue that this presents the challenge and the opportunity of developing a pedagogical framework with which to conceive these learning environments. The case of approximations of practice and its application in the teaching of how to explain a concept in secondary mathematics methods exemplifies how the pedagogy of teacher education may be expanding in response to existing technologies. A framework can help us direct technology development as well.

Toward a Pedagogy for Teacher Development Assisted by Representations of Practice

Building on the proposals from previous years, the working group's purpose is to design a pedagogical framework for teacher development. The framework is aimed at assisting teacher educators who want to help teacher candidates actively learn teaching *in*, *from*, and *for* practice by taking advantage of representations of practice and new technologies. This enterprise may require conceptual developments, for example in articulating connections between theories of teaching and the design of a curriculum for teacher education. The enterprise also requires the creation of pedagogical templates or generic learning activities/environments that can be particularized for the specific goals of individual teacher educators, the needs of their students, and the media artifacts or software tools that are available. Thus far, the working group has proposed a framework articulated by a number of categories of things that are involved in different ways in the process of teaching with the assistance of representations of teaching. These categories include *boundary objects*, *activity types*, *technology tools*, *problem types*, and *teacher education goals*. Each of those categories contains elements from which choices can be made to design learning activities for novices. The working group has been operationalizing those categories by using *Plan*, a software tool included in *LessonSketch*. *Plan* allows teacher educators to design a learning module for their clients, putting together media artifacts, tools, and tasks and to sequence them in a desired order that may include individual or group work. In the discussion document for last year (Herbst et al., 2011) we described the framework in considerably more detail. Our work this year will include asking questions like: Given that a teacher educator has a specific learning goal in mind for her students, such as learning how to probe student thinking or learning how to demonstrate the subtraction algorithm, what are appropriate representations of teaching, activity structures, problems types, and technology tools to use to reach that goal? The group will work on articulating goals of teacher education and a pedagogy of teacher education.

The convenors of this working group are particularly interested in exploring how cartoon-based representations of practice facilitate teacher learning. Over the past few years teacher educators have begun to use *LessonSketch* in content and methods courses for teachers. This working group is an opportunity for users to share their experiences and insights. These contributions are invaluable to the life of the working group and, more generally, to the development of the knowledge base for use of these resources. We expect the continued use and development of *LessonSketch* will help improve the framework of the pedagogy and further develop specifications for yet other technologies that respond to the needs of the field.

We have proposed that a pedagogy of teacher preparation assisted by representations of practice needed at least four categories of elements: boundary objects (or open ended expressions), activity types, problem types, and technology tools or screens. This year we add the category of *teacher education goals* that one needs to consider when planning educative experiences for teacher candidates around representations of practice—since different resources and tasks may be needed depending on those goals. These teacher education goals can include having novices learn instructional practices such as "explaining concepts" or other, even "high-leverage practices" (Hatch & Grossman, 2009) such as "facilitating classroom discussions." The goals can be student-centered too (such as having novices develop capacity to notice, describe, and explain students' errors). Also, they can be mathematical, such as when one wants novices to map the terrain of a given problem (Lampert, 2001). We refer the reader to the discussion document of last year's working group for a detailed description of the other categories.

Plan for Active Engagement of Participants and Anticipated Follow-up Activities

The plan includes starting with a brief exposition by the authors of the structure and contents of the present framework for which we will illustrate how the use of approximations of practice narrated here maps onto elements of the framework. We will engage the audience in creating learning activities they would like to use to engage their clients. The idea is to use the collective planning of these sessions to probe the framework and possibly enrich it by adding more items to the lists considered, possibly also adding new categories of elements. Participants will then form groups and spend the second half of the first session and the first half of the second session creating exemplars. Then the second half of the second session and the closing session will be dedicated to sharing these exemplars and improving the framework, including discussions about the questions raised earlier in this document, paving the way for an edited publication.

By the time this working group meets we will have had the fourth conference on Representations of Mathematics Teaching in Ann Arbor (June 6–8, 2012). We will be proposing a session slot at the AMTE Annual Meeting in 2013 to continue this work. We plan to use that slot to mirror the work done at the PMENA meeting and to engage in further work on (1) improving the exemplars, and (2) using the exemplars to improve the taxonomies. We hope we will be able to use those products to continue this working group at next year's PMENA.

Endnote

Jinfa Cai
University of Delaware
jcai@math.udel.edu

This new Working Group is designed to engage members of PMENA in the conceptualization and development of a monograph series that will fill a unique niche in the set of publishing outlets for mathematics education researchers. Participants will engage in identifying and characterizing the hindrances to timely publication, the affordances of new technologies, and the resources of existing conferences and professional society organizations, and focus this conversation on building an infrastructure for the support of (particularly junior) faculty into creating records of their work that are publishable, and ultimately published—in a rapid time frame. The outcomes of this Working Group will be a set of recommendations for the design and management of such a monograph series, and an outline of initial volumes in the series, where participant teams are authors of articles in each volume.

Keywords: Research Reporting; Junior Faculty; Scholarly Publishing; Informal Education

The Nature of Scholarly Reporting

Since at least the advent of natural philosophy in the Renaissance period, scholars have depended upon each other to share their ideas and research findings, and to provide critique of these ideas and findings for their mutual advancement of knowledge. It was during this period in the West, coinciding with the invention of the printing press, that academic publishing became a universal criterion for membership in the academy. The Elzevir brothers opened an academic publishing house in the Netherlands 432 years ago to support (and benefit financially from) the knowledge boom afforded by moveable type.

The importance of scholarly writing and its dissemination cannot be overestimated in the advancement of knowledge in mathematics education. Both as a record of what has taken place, and as a continuing scholar dialogue about the nature of mathematics teaching, learning, policy and practice, the journal article, yearbook chapter, edited volume, and authored text constitute the primary means by which ideas become common knowledge. Without these media, we have neither cultural memory, nor a means of transcending our time and space limitations to engage in this larger conversation. We face unique problems now, as the number of scholars in our field grows, and as our paradigms and methods become more diversified, in vetting and compiling all this work into useful, organized media. Moreover, due to this diversification of perspectives, it is our opinion that our ability to understand each other is becoming compromised, thus limiting our ability to provide practical solutions to the problems of mathematics education.

This Working Group is designed to engage members of PMENA in the conceptualization and development of a monograph series that will fill a unique niche in the set of publishing outlets for mathematics education researchers. Participants will engage in identifying and characterizing the hindrances to timely publication, the affordances of new technologies, and the resources of existing conferences and professional society organizations, and focus this conversation on building an infrastructure for the support of (particularly junior) faculty into creating records of their work that are publishable, and ultimately published—in a rapid time frame. The outcomes of this Working Group will be a set of recommendations for the design and management of such a monograph series, and an outline of initial volumes in the series, where participant teams are authors of articles in each volume.

Current Problems in Academic Publishing

We have anticipated that there are a number of constraints that exist in the current landscape of academic publishing that hinder many of our colleagues from publishing their work. We briefly outline a few of these constraints to emphasize the need for a new model of publication support that would, in part, solve some of these issues and provide more opportunity for the equitable sharing of knowledge.

First, for the researcher, one of the problems facing education today is the length of time to publication of most studies. Traditional journals may have a backlog of manuscripts of greater than a year. If we factor in the review and acceptance process, revision and resubmission, and subsequent editorial work, it can take an average of at least 30 months for empirical work to find its way to the field where it can be used. Such a long process can have a number of negative impacts:

- Individual submission of work to a journal involves an extended review process, eliminating from contention works that have potential, but that are not yet ready for dissemination.
- These backlogs, delays, and restrictive attitudes work in a manner that is counterproductive for rapid deployment of ideas for the purpose of innovation in research and development.
- Further, for junior faculty, whose research is often the most innovative, their careers are dependent upon publication to receive tenure. With only 5 years to develop standing in the field, a huge bottleneck exists, preventing many promising scholars from publishing in venues that will actually be read.

Second, as a case in point, only seven English-language mathematics education research journals are listed in Social Science Citation index.

- *Educational Studies in Mathematics*
- *For the Learning of Mathematics*
- *International Journal of Science and Mathematics Education*
- *Journal for Research in Mathematics Education*
- *Journal of Mathematical Behavior*
- *Journal of Mathematics Teacher Education*
- *Mathematical Thinking and Learning*

Of those, an average of about 16 articles per journal are published each year (~100 each year in total). Data from 2003 show that there are about 80 PhDs awarded from U.S. institutions each year (Reys et al, 2008). Given that about 80% of these graduates move into the professoriate, that means between 80 and 160 papers each year must be published from this pool of candidates alone! If that number is multiplied by 5, the average number of years before going up for tenure, we have approximately 400 junior faculty, competing with at least as many experienced researchers, for only about 100 openings for their work in high quality journals. Of course, there are other outlets for much of our work: General education journals (e.g., *American Educational Research Journal*), and discipline specific journals (e.g., *Journal of Educational Psychology*). In addition, there is a current proliferation of online journals and other new venues that have not yet been fully acknowledged as “legitimate,” in terms of promotion and tenure decisions.

Despite these additional outlets, there still exists a significant bottleneck, particularly for junior faculty. Such a bottleneck impacts time to publication immensely, and it further prevents important ideas to reach the field where they can be shared, thus inhibiting innovation among researchers and practitioners.

Third, the need for rigorous empirical work in mathematics education is becoming more and more acute. The problems of education require that substantive changes be made in teaching, learning, curriculum, and policy. But the pace of innovation is rapidly outstripping the ability of the research community to provide disciplined guidance to the field. A means of organizing this knowledge proactively may be able to get the right ideas to the right people so as to make a difference, as opposed to having to wait until search engines and other indices catch up with current publications.

Brief History of the Working Group

This is a new Working Group intended to develop and help shepherd a new monograph series in mathematics education. The leaders, Jinfa Cai and James Middleton have met on several occasions, working out the need for group and its deliverables. We have consulted with Springer publishers who are interested in publishing a monograph series that meets the needs we have outlined in this paper. The series would be representative of the latest research in our field, and would be geared towards highlighting the work of bright, graduate students and junior faculty, working in conjunction with senior scholars. The audience will be the intersection between researchers and mathematics education leaders—people who need the highest quality research, methodological rigor, and potentially transformative implications.

The purpose of creating a Working Group at PMENA is to engage our colleagues in the design and development of this series, and to develop the structure, topics, and outline for papers in an initial volume.

Issues in the Psychology of Mathematics Education in the Proposed Working Group

Following up on the work of Reys et al. (2008), the needs of the mathematics education community, particularly those needs of junior faculty who are working towards tenure, and the practitioner-researcher who needs timely, quality research with which to improve their education system will be discussed, and a plan for addressing these needs, at least in part, through the design of a new monograph series will be developed.

Plan for Active Engagement of Participants in Productive Reflection on the Issues

Jigsaw (First Session): Problem Identification and Solution Finding

On the first day of discussion, we will use the issues outlined in the introductory sections of this paper as a starting point for participants. We will first provide the participants with the issues as we currently see them, and then solicit new issues and ask the audience to clarify and provide examples of the issues that both prevent and support them in their scholarly writing. Following this initial conversation, we will divide participants into discussion groups, each focusing on a particular subset of the identified problems. Discussion groups will be tasked with characterizing their problem(s), defining the key issues that need to be addressed in each area, and providing a set of creative potential solutions to the problem(s).

Following the discussion groups, we will divide participants up into "Design Teams." Design Teams will be tasked with sharing the problem characterizations and potential solutions from the discussion groups, and then to create a set of design specifications for the development of a monograph series that would optimally solve the set of problems identified.

After Design Teams have developed their solutions, the group will meet as a whole to winnow through the issues and create a collective design matrix upon which the design of an initial volume in the series, and its editing process, can be constructed.

Homework for participants is to create a 2-minute elevator speech to be delivered to the Working Group in the next meeting time.

The **first working group session** will also provide an introduction of the vision of the Springer monograph series, as well as the logistics for publishing each volume in the monograph series.

Volume Design (Second Session)

The second day of discussion, participants will deliver their elevator speech where they propose a topic of research that they are currently working on, that they would like to collaborate on with other members of the group. Each participant will give their speech, and the topics will be recorded on large sheets chart paper. Participants will then "vote" on the topics they would like to work on (one per participant) by signing their name to a piece of chart paper that has their intended topic listed.

We will then divide the audience up into small Writing Groups, to prepare a volume proposal, as well as an outline and work schedule for the production of possible papers in a volume. Participants will also read through the Proceedings of the conference to choose potential collaborators for the volume based on the research they have presented at PMENA.

Finalizing Volume Proposal

As a result, by the end of PMENA 2012, we will have support and management criteria for the series, an outline for a set of papers that will constitute a volume in the series. We anticipate at least one volume proposal from the working group, but it may have more than one volume proposal, depending on participants' research interests.

Anticipated Follow-up Activities

Following this initial meeting, the Working Group leaders will meet and develop an editorial board for the publication, develop the submission, editing, and support guidelines from the set of criteria developed in the Working Group, and begin to nurture the development of the initial volumes of the series. The anticipated publication of the volume resulting from PMENA is 12 months from the conference.

This discussion group will focus on exploring the use of conceptual frameworks in building mathematics methods courses for prospective mathematics teachers. Participants will consider (a) frameworks, (b) activities, (c) relationships between frameworks and activities, (d) the residue of activities and how they contribute to learning to teach, (e) research literature and attempts to explore these questions, and (e) development of a research agenda. Dialogues and collaboration among working group members will be encouraged by the development of teams to address facets of the emerging research agenda.

Keywords: Teacher Education–Preservice; Instructional Activities and Practices

Focuses and Aims for the Working Group

In light of the improved ability to track and compare student performance, mathematics teachers' impact on that performance has drawn increased scrutiny. Additionally, national accountability movements have begun to turn a lens toward mathematics teacher preparation in order to identify why some teachers are able to impact student performance, while others struggle. Although mathematics teacher educators (MTEs) have always examined and sought to justify their practices, studies have identified broad differences in emphases and instructional approaches (Harder & Talbot, 1997; Taylor & Ronau, 2006; Watanabe & Yarnevich, 1999) employed in teaching preservice teachers (PSTs). To begin to build descriptions, understanding, and theory about the work of MTEs in methods courses, we posed the question "What is the content of mathematics methods courses?" This question includes the idea of curriculum in a broad sense. We view learning opportunities and MTE's enactment of them with PSTs as content, but also realize that discussions during the working group will help us explore notions of content. The central question that emerged through our discussions was whether and how MTEs use research-based frameworks to build and explore their work and the impact of that work on our PSTs' learning and teaching. The exploration and development of frameworks used by MTEs will enable the field to build "a deeper and better understanding of the psychological aspects of teaching and learning mathematics and the implications thereof," one of the three main goals of PME-NA.

In the remainder of this proposal we interweave the focus of the working group with what we hope to accomplish during our working group sessions and beyond. First, we position ourselves as MTEs in the role as researchers who, collectively, must begin developing records of our practice in methods courses. Next, we summarize studies conducted on the content of methods courses. This prior research is then linked to a survey administered by our research team that asked MTEs to consider how they frame their methods courses. Finally, before outlining the working sessions, we discuss the goals of methods courses and the potential impact of selected methods course activity-types on PSTs' learning and practice. In each section we pose a few questions that may be of interest to working group participants.

Scholarly Inquiry in Teaching Methods Courses

In 2005, Mewborn identified confusions regarding frameworks and perspectives, or worldviews, in the reporting of research. In this work she called for the development of frameworks for individual researchers and at the level of the field of mathematics teacher education. In 2010, Arbaugh and Taylor (2008), drawing from Hiebert, Gallimore, and Stigler (2002), called for the development of "professional knowledge" they described as "knowledge that the research community establishes" or knowledge developed from empirical studies (p. 2). This knowledge was contrasted with "practical knowledge" that is built up by MTEs as they do the work of teaching and reflect on that work. Building from this view, in 2009, Lee and Mewborn, citing Richlin (2001), emphasized the significance of the development of scholarly inquiry and scholarly practices. Scholarly inquiry was described as explorations of "issues and practices through systematic data collection and analysis that yields theoretically grounded and empirically-based findings" (p. 3). This work could in turn be used to develop scholarly practices, "practices adapted from empirical studies of the teaching and learning of mathematics and the preparation of mathematics teachers" (p. 3). Within the tangle of terminology lies the idea that MTEs build practices for and through their interactions with PSTs and engage in the work of teacher as researcher by reflecting on and modifying the practices they enact. Such practical knowledge contains facets of scholarly inquiry, but is not often recognized as research. Yet MTEs know that they are doing what researchers might call a personally powerful form of action research. These pieces of work are powerful to individual MTEs and close colleagues, who are collaborators or confidants, but are often not shared more widely in the form of peer-reviewed articles in mathematics teacher education literature. In this working group we hope to build a collaboration that develops methods for communicating and synthesizing these personally powerful practices and comparing these practices to what we can find in the research literature.

Practices may be shaped by worldviews or frameworks as defined by Mewborn (2005). One example of this direction is provided by Kazemi, Franke, and Lampert (2009), who describe their work to develop "pedagogies of practice" and generate activities for prospective mathematics teachers using a view of practice from social practice theory. They assert,

> The future viability of professional teacher preparation requires that we systematically pursue appropriate ways to develop, fine tune, and coach novice teachers' performance across settings. These activities must find their way into university coursework rather than be relegated solely to field placements (Lampert & Graziani, 2009). Our hypothesis is that organizing professional education in mathematics education around core instructional activities and building links from the activities to student outcomes will enable us to support ambitious teaching. (p. 12)

Efforts such as this begin to build a perspective for the work of MTEs in which frameworks and goals for teacher practice are used to build instructional activities. As Kazemi et al. point out, we have empirical evidence of teacher practices that impact students in various ways; what is less clear is how MTEs' practices builds the sorts of teacher practices that can be sustained in the varied contexts of schools. Identifying and hypothesizing about pedagogical practices and their links to frameworks (not just worldviews) that enable the subtle modification of activity and analysis of associated evidence is critical for our field.

Studies of Methods Courses

Members of the mathematics education field have recognized both the lack of communication and the lack of consistency across methods instructors and courses in the United States, and studies have been conducted documenting these inconsistencies. For example, Harder and Talbot (1997) collected methods course syllabi from members of the Association of Mathematics Teacher Educators (AMTE), and examined the instructional approaches and assignments in the syllabi. The most commonly reported instructional approaches were whole class and group discussions, lab experiences (software, manipulatives, graphing calculators), student presentations, micro-teaching or peer-teaching, field-experience, lecture or direct instruction, and cooperative learning. The five categories of assignments reported were writing assignments, planning, presentations, participation, and resource files.

Watanabe and Yarnevich (1999) gathered survey data from elementary mathematics methods instructors, mathematics supervisors, inservice elementary school teachers, and preservice teachers. It is noteworthy that the survey used for this study asked respondents to rate pre-determined topics on a Likert Scale (1—topic should not be included, up to 4—topic must be included). This context is important when interpreting the findings of the study, given that participants were not able to say what was important to them in methods courses from their own perspective—they were limited by the choices on the survey, and they were also limited by their understanding of the meaning of the topics on the survey. The authors found substantial agreement between methods instructors, mathematics supervisors, and inservice teachers that mathematics methods courses should include current trends, doing mathematics, teaching a lesson, curriculum resources, manipulatives, problem-centered teaching, and questioning techniques. The inservice teachers and supervisors felt that demonstration lessons, lesson plan analysis/critique, writing in mathematics, lesson plans, authentic assessment, and performance assessment were important topics for elementary mathematics methods courses.

Taylor and Ronau (2006) approached this line of inquiry differently, examining methods course syllabi and identified seven common categories of goals and objectives: pedagogical skill, knowledge of content, dispositions, professionalism/leadership, pedagogical content knowledge, human development, and pedagogical knowledge. The authors noted,

> the most remarkable result is the surprising level of variability between mathematics methods courses … Syllabi that are clearly different from the de-facto consensus with respect to what they chose to include, or perhaps more strikingly, what they do not include, may offer quite different experiences for their students. We do not know if their students benefit from these differences or if they miss something crucial. (pp. 14–15)

These studies illustrate that there is substantial variation between mathematics methods courses in general. What is less understood is the source of such variation. Do MTEs draw from different frameworks as they develop activities? If different frameworks are drawn upon and a common activity is used, what are the impacts on PSTs?

Working Toward Frameworks

To explore the notion of framing in methods courses, we solicited MTEs on two listserves to respond to the following questions. Seventy-nine MTEs responded.

1. If you already have a frame for your mathematics methods course briefly describe how you organize/frame it.
2. If you do not have an existing framework, look through your syllabus and posit a framework to describe it.
3. Briefly describe the most impactful activities you engage in with your methods students.

We intentionally did not describe what we meant by “frame” to see how members of the field would interpret the term. In our conversations, we had come to view frames as more a way of *orienting* students to our course than of *organizing* our course. What we found in our categories, however, was more of an organizing structure. The categories ended up sounding more like the *topics* of the course more than the *framework* for the course. Responses of MTEs who named a framework and activities they shared are summarized in Table 1.

Table 1: Frameworks and Activities from Survey

Frameworks	Activities
1. Importance of knowing the learner 2. NCTM Process Standards and CCSS Standards for Mathematical Practice 3. Addressing the needs of all learners 4. Task selection and analysis 5. Understanding how students learn mathematics 6. Emphasis on students' mathematics 7. Manipulatives and concrete models 8. Cognitive or developmental stages and learning trajectories 9. Motivation and engagement 10. Curriculum 11. Modeling best practices for teaching 12. Reflection on mathematics teaching and learning practice 13. Integration of content and pedagogy/mathematical knowledge for teaching	1. General lesson planning 2. Manipulatives and technology 3. Making sense of PST's own mathematics 4. Microteaching 5. Interviews and interventions with K–12 students about their mathematical thinking 6. Assessment 7. Discourse-focused activities 8. State and national standards 9. Problem solving 10. Reading reflections 11. Facilitating lessons or tasks with undetermined audiences 12. Analyzing student work and error analysis 13. Unit planning

We hope to encourage participants to move beyond thinking about organizational structures and to think about frameworks as structures for orienting methods courses. We also hope to consider frameworks as something more specific than worldviews. How are framework(s) used in planning and exploring impacts of mathematics methods course? How do the results of activities help inform frameworks? To answer these questions, we need to consider goals for methods courses and the impact on our PSTs' learning and eventual teaching practice.

Goals for Methods Courses

NCTM (2007) outlines standards for the education and professional growth of mathematics teachers, focused around five issues: (a) teachers' mathematical learning experiences, (b) knowledge of mathematical content, (c) knowledge of students as learners, (d) knowledge of mathematical pedagogy, and (e) participation in career-long professional growth (p. 109). Although these standards do not constitute a framework as described by Mewborn (2005), they do provide a structure around which to identify specific goals that inform the development of frameworks for methods courses.

Despite the recommendations and vision statements from NCTM over the last few decades, much of the teaching in the United States focuses on helping students get through courses and pass standardized tests. If our PSTs experienced this type of mathematics, expecting them to teach in other ways can lead to cognitive dissonance for the PSTs and frustration for the MTE. However, this does not mean that MTEs should abandon expectations that new teachers teach in ways outlined by NCTM's vision documents. Instead, developing PSTs' proficiency "in designing and implementing mathematical experiences that stimulate students' interests and intellect" (NCTM, 2007, p. 5) might be addressed by many activities in methods courses, including task/lesson/unit planning and equity/diversity activities. Teachers must also be able to "orchestrate classroom discourse in ways that promote the exploration and growth of mathematical ideas" (p. 5) and "assessing students' existing mathematical knowledge and challenging students to extend that knowledge" (p. 6). To work toward becoming proficient in these areas, PSTs need to be provided opportunities to analyze student work—both written and verbal, to formatively and summatively assess student reasoning and understanding, and to interact with students in an effort to understand their thinking and learn to ask good questions.

Although methods courses might implicitly, or even explicitly, address the teachers' mathematical learning experiences and content knowledge, one might argue that these courses should launch PSTs into their careers with some knowledge of learners' mathematics, knowledge of pedagogical strategies, and a disposition toward continual growth and collaboration. We hope to generate discussion of these, and other, goals for the education of mathematics teachers, particularly at the preservice level. What additional goals might help us build frameworks for our methods courses? How can we design activities that support our goals?

Residue of Activities

In the process of envisioning and designing effective methods courses, MTEs must consider their goals and outcomes for PSTs and the activities or experiences they believe will be useful in helping PSTs reach these goals. One facet that is often neglected or unknown, however, is the ultimate impact methods courses experiences have on PSTs once they leave campus and enter their own classrooms. In a mathematics course, the term *residue* refers to the mathematics retained by students as a result of solving problems or completing a specific task (Davis, 1992). In considering an approach to the framing, content, and design of methods course activities, we posit it is crucial to consider, understand, and empirically examine the residue the methods course activities have on PSTs. A search of the *Journal of Mathematics Teacher Education* revealed approximately 70 articles about activities in methods courses; however, those articles do not paint a coherent picture of what is valued in methods courses or of the long-term residue of such activities on the PSTs' eventual teaching practice. Similarly, in examining our survey results, we realized that although some of the activities most commonly used in methods courses are supported by empirical evidence, we would do well as a field to engage in further study of the implementation and outcomes of specific activities and to findings about residue to systemically inform the design of methods courses.

Lesson planning activities. A few empirical studies of commonly used methods course activities have documented the residual effects, albeit short-term, of those activities. For example, in recent years, MTEs have used lesson study or modified versions of lesson study in their methods courses and have reported that the experiences help PSTs learn to become collaborative, reflective practitioners (Matthews, Hlas, & Finken, 2009; McMahon & Hines, 2008; Suh & Parker, 2010). McMahon and Hines also noted that the PST's post-lesson reflections were focused on student learning rather than on the role of the teacher. However, the PSTs indicated reluctance to instigate lesson study cycles with their collaborative teachers, citing concerns about inconveniencing the teachers. If the PSTs are not likely to engage in lesson study in the future, we might question the lasting residue from such activities. Matthews et al. found that PSTs benefitted from the ideas developed during lesson study in the short-term. They discussed the value in the 4-column lesson plan common in lesson study to focus PSTs' attention on how to build and support student understanding rather than to focus merely on what the teacher does during the class. Finally, Suh and Parker found that engaging PSTs with inservice teachers in the lesson study process helped develop the PSTs' mathematical knowledge for teaching, revealed gaps in the PSTs' mathematical knowledge, and increased the PSTs' awareness of the complexity of teaching and the importance of reflective practice. For each of the last two studies, because no post-methods course data were reported, MTEs are left wondering about the residue of using this 4-column lesson plan format, or lesson study in general, in methods courses.

Discourse activities. A synthesis of the types of discourse and associated research demonstrates the powerful impact of mathematical discourse on student learning (Franke et al., 2007). This impact was also reflected in the beliefs of our survey respondents; a number of MTEs reported inclusion of activities focusing around helping PSTs learn strategies and approaches to facilitate mathematical discourse. Specific examples reported in the survey include use of the texts, *Classroom discussions: Using math talk to help students learn* (Chapin, O'Connor, & Anderson, 2003) and *5 practices for orchestrating productive mathematics discussions* (Smith & Stein, 2011). These specific frameworks for discourse are readily used in professional development. Of interest would be activities used to support understandings of discourse and the impact of these activities on PSTs facilitations of mathematics discourse.

Understanding and extending students' current mathematical thinking. According to our survey results, another outcome valued by MTEs is the development of PSTs interpretations of and utilization of students' current ways of thinking. Research in this area has demonstrated the power of teachers' use of children's thinking as a basis for mathematics instruction (Franke et al., 2007; Koehler & Grouws, 1992). Recently, Jacobs, Lamb, and Philipp (2010) have introduced the *professional noticing of children's mathematical thinking* construct as a means to make sense of teacher actions in the classroom. Their study involved a group of PSTs as well as three other groups of increasingly more experienced teachers. The authors concluded that the constructs of noticing were much less developed in PSTs than would be expected. For MTEs the question might be how to provoke noticing that leaves residue useful in interactions with children. More importantly, the authors posit these skills are not a part of the typical knowledge of adult learners and presented evidence that with experience and training, teachers can become much more effective at attending, interpreting and responding to student thinking.

Equity and social justice activities. The Equity Principle of the NCTM (2000) calls for high expectations and support for all students to learn challenging mathematics. This call "challenges a pervasive societal belief in North America that only some students are capable of learning mathematics" (p. 12). NCTM also states that accomplishing equity, including providing the kind of accommodations, resources, and differentiation needed for all students to be successful requires teachers "to understand and confront their own beliefs and biases" (p. 14). Researchers have highlighted the difficulties of preparing PSTs to teach in ways that support a vision of equity described by Gutiérrez (2002) and NCTM (Garii & Rule, 2009). Yet work has begun to identify instructional activities (de Freitas & Zolkower, 2009; Rodriguez & Kitchen, 2005) and learning trajectories (Turner et al., 2012) that help MTEs understand learning to teach "effectively in diverse classrooms" (p. 67). Such work builds from existing research on noticing (Jacobs et al., 2010) and transformation. But will any of the short-term residue of these activities remain with the PSTs as they meet the daily challenges of their teaching contexts? How do differences in field experiences impact residue of such activities?

With the notion of residue in mind, it is crucial that we tie our activities closely to our goals and frameworks. Is residue the reflection of goals? Which activities are most likely to result in residue? Are there clusters of activities that might lead to residue? We also may need to consider how our goals and activities are supported or challenged by the teacher education programs in which our methods courses exist. How can we promote residue within the existing culture? Which activities have the most potential for residue within the existing culture?

Exploration of the content of methods, to build understanding of MTEs' use of frameworks to inform activities and activities to inform or develop frameworks, supports the PME-NA conference theme of navigating transitions in professional learning. While learners in this context are both MTEs and PSTs, they work together to navigate career transitions and understandings of the academic and school settings in which they work. Explorations of frameworks and activities will further allow MTEs to leverage their considerable practical knowledge to build lines of scholarly inquiry supportive of the development of scholarly practices.

Outline of Working Group Sessions

Our first session will include an introduction and overview of the working group. We will begin with a presentation describing the background and goals of the group. We plan to present the disparate knowledge base about methods courses and prior efforts to explore the content of methods courses. To orient the participants to the discussion of frameworks and activities, we will present one activity used by authors of the proposal and explore how it links to the framework for the course. In addition, participants will discuss how the framework can be used to gather evidence of residue that engagement in an activity might precipitate. Next, we will introduce two threads of inquiry with respect to frameworks, activities, and residue for the working group. The first thread is Framework-Activities-Residue and the second thread is Activity-Frameworks-Residue. Pictorial representations are provided in Figures 1 and 2, respectively.

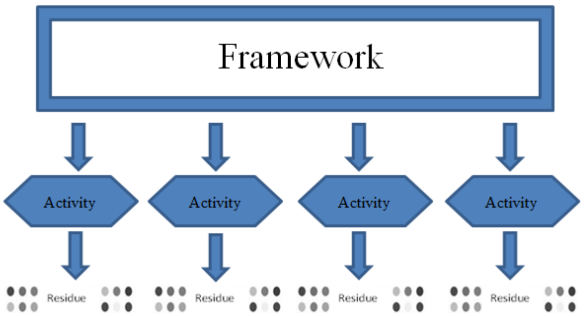

Figure 1: Framework-Activity-Residue

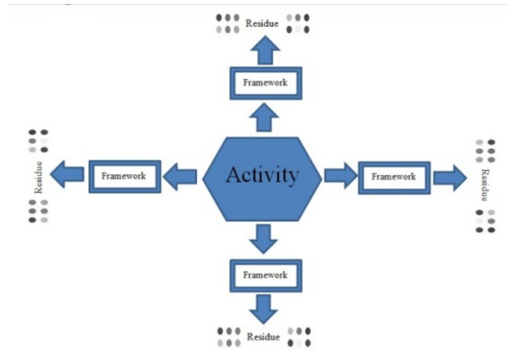

Figure 2: Activity-Framework-Residue

In the first thread, a particular framework is selected as a starting point. For example, consider the Task Analysis Framework (Stein, Smith, Henningsen, & Silver, 2009) for the cognitive demand of mathematical tasks. Authors have used the Task Analysis Framework to build activities for methods courses (e.g. Rutledge & Norton, 2008; Norton & Kastberg, 2012). We are interested in the residues of the activities. The question for the first thread of inquiry is:

> For a particular framework, what are the activities for which we have empirical evidence of residue, and what is the nature of that residue?

The second thread of inquiry takes as its starting point an activity. Here, let us take as an example video case analysis. Alsawaie and Alghazo (2010) used van Es and Sherin's (2002) Learning to Notice Framework. Stockero (2008) adapted van Es and Sherin's (2008) attributes of reflection by replacing their levels of reflection with those from Manouchehri (2002). The question for the second thread of inquiry is:

> For commonly used activities in methods courses (or novel ones that have been reported), what frameworks are supported, what empirical evidence of residue is available, and what is the nature of that residue?

Looking across both threads of inquiry, we seek to identify and describe existing findings. This inquiry will also reveal gaps in the literature, for which scholarly inquiry can be designed. In general we seek to describe gaps in the literature and answer the broader question:

> What does the research literature reveal about mathematics methods courses in terms of frameworks, activities, and residues with respect to mathematics methods courses?

The answer to this question sets a research agenda for scholarly inquiry into the practice of methods instruction.

In our second session, participants will start by unpacking frames and activities from courses. Participants will focus on looking at potential residue and relationship to frameworks. A series of presentations will serve to launch our conversations. One presenter will share activities and findings illustrating residue from the activities. Another presenter will share her study of MTEs frameworks, goals, and activities. Participant discussions of the work of the presenters will focus on connections between frameworks, activities, and residue and relationships to the two threads. Following the presentations, participants will break into smaller groups to work on the two threads of inquiry to propose syntheses of existing literature and research questions to be explored by the group as part of a developing research agenda. A database of articles, compiled by the authors of the proposal, exploring facets of MTEs' work with PSTs in mathematics methods will be used as a resource.

In our third session we will focus on building a plan for follow up activities.

1. Small groups will present a summary of discussions and plans for scholarly inquiry. This work will likely not be completed during the conference, but will be continued throughout the year electronically.

2. We will develop potential collaborations and plans to move forward on proposals for scholarly inquiry and opportunities to present at national conferences such as the national meetings of NCTM and AMTE.
3. We will discuss the use of Skype and Google Group for working as a group throughout the year.

The Quantitative Reasoning and Mathematical Modeling (QRaMM) working group is one of three research strands initiated by the Wyoming Institute for the Study and Development of Mathematical Education (WISDOM^e). QRaMM brings together researchers from multiple universities across the country to share ideas and conduct research on quantitative reasoning and modeling within an interdisciplinary context. In collaboration with the National Science Foundation MSP Pathways in Environmental Literacy Project, the QRaMM group has engaged in research collaborations resulting in presentations at national conferences, an International STEM Research Symposium: Quantitative Reasoning in Mathematics and Science Education 2012, and publications addressing QR. Focusing issues include: (1) middle and high school students' development of quantitative reasoning and mathematical modeling, (2) creation of QR learning progressions to explain such development, and (3) the impact and interplay of QR and modeling on students' development in mathematics and science. Participants in the QRaMM working group will join members of the QRaMM research team in interpreting data on QR in mathematics and science, critiquing QRaMM learning progressions, vetting QRaMM assessment items, and debating the QRaMM theoretical framework.

Keywords: Cognition; Learning Trajectories (or Progressions); Modeling; Mathematical Knowledge for Teaching

QR Research Collaborative

A core membership for this continuing PME-NA Working Group was established through the initial invitational **Planning Conference for WISDOM^e** conducted September 2010 at the University of Wyoming. During that conference three collaborative, interdisciplinary research teams were established: Quantitative Reasoning and Mathematical Modeling (QRaMM), Developing Investigations of Mathematical Experience (DIME), and Technology Tools and Applications in Mathematics Education (TTAME). The QRaMM and DIME research teams went on to host working groups at PME-NA in 2011. The QRaMM team consists of researchers focused on the cognitive act of quantifying in mathematics, which includes examining how students quantify an object through conceiving a measurable attribute of the object. Research on quantification has explored concepts such as function, covariation, multiple representations, continuity as smooth or chunky, and conceptions of angle measure. Another aspect of interest to the research team is the concept of QR within context; the ability to interpret quantitative models especially in the sciences and mathematics and the ability to create, test, and refine models. Since its inception the QRaMM team has been working collaboratively with the NSF Pathways in Environmental Literacy Project, that focuses on QR in environmental sciences. The Pathways Project is developing learning progressions for three content strands that are fundamental to the development of environmentally literate citizens from sixth to twelfth grades: carbon cycle, water cycle, and biodiversity. The Pathways Project includes a QR Theme team that is exploring the impact of quantitative reasoning on the development of environmental literacy. The outcome of the partnership has been a series of QR research collaborations including sessions at PME-NA 2011, NCTM National Conference 2012, an International STEM Research Symposium: Quantitative Reasoning in Mathematics and Science Education 2012, and publications on QR. The research papers and presentations are informing the field on the development of QR and its impact on the learning and teaching of mathematics, on the ability of students to apply QR within context including interpreting and creating models, on the development of QR learning progressions, including creation of QR assessment items for clinical interviews and written assessments of QR abilities in the context of environmental science.

The opportunity to conduct a second Working Group at PME-NA provides an important venue to continue and expand discussions of the background perspectives and issues related to investigations of quantitative reasoning and modeling. The Working Group will create a setting where participants can share information, issues, and problems related to ongoing research, to promote interest and potential participation in furthering these and other disciplined inquiries into these phenomena, and to provide continuing support to the team members to collaborate within and across ongoing and future research.

A Program of Research for QR

The central question for the QRaMM research team is: How do students reason quantitatively and what impact does that reasoning have on their learning in mathematics and science? For the Pathways project this question is focused on the impact of QR in understanding environmental science. The purpose of the Pathways QR Theme is to determine the quantitative reasoning aspects of the learning progression leading to the primary QR research question: What are the essential quantitative reasoning abilities that are required for the development of environmental literacy? The QRaMM research team incorporates these questions into a broader QR research program with the following research questions:

1. How does quantitative reasoning integrate and interact across mathematics and the sciences?
2. What is the role of learning progressions for quantitative reasoning in fostering interdisciplinary learning in mathematics and the sciences?
3. How do learning progressions for quantitative reasoning inform professional development in ways that support interdisciplinary mathematics and science teaching and learning?

Learning Progressions Supporting Students' Development of Environmental Literacy: Work of the Pathways Project

Quantitative reasoning and learning progressions underpin the work of QRaMM. The Consortium for Policy Research in Education (CPRE) defines learning progressions as follows:

> Learning progressions are hypothesized descriptions of the successively more sophisticated ways student thinking about an important domain of knowledge or practice develops as children learn about and investigate that domain over an appropriate span of time. (Corcoran, Mosher, & Rogat, 2009, p. 37)

A number of learning progressions in science are currently under development including: tracing carbon in ecological systems (Mohan, Chen, & Anderson, 2009), particle model of matter (Merrit, Krajcik, & Swartz, 2008), modeling in science (Schwarz, Reiser, et al., 2009), genetics (Duncan, Rogat, & Yarden, 2009), chemical reactions (Roseman, et. al., 2006), data modeling and evolution (Lehrer & Schauble, 2002), explanations and ecology (Songer, Kelcey, & Gotwals, 2009), buoyancy (Kennedy & Wilson, 2006), atomic molecular theory (Smith, Wisner, Anderson, & Krajcik, 2006), and evolution (Cately, Lehrer, & Reiser, 2005). Examples of three of these learning progressions are provided in (Corcoran, Mosher, & Rogat, 2009). However, QR learning progressions have not been developed. We argue that without quantitative accounts environmental literacy cannot fully develop.

The Pathways learning progressions for environmental literacy are based on research in science education and cognitive psychology, foundational and generative disciplinary knowledge and practices, and strive for internal conceptual coherence. The QR in environmental literacy frameworks builds on these characteristics, incorporating mathematical and statistical tools essential for science. Research on the act of quantification is essential to the progression, because quantifying is the prerequisite to QR and modeling.

The CPRE panel identified essential elements of learning progressions to be:

1. Upper Anchor: target performance or leaning goals which are the end points of learning progression and are defined by societal expectations, analysis of the discipline, and requirements for entry into the next level of education.
2. Progress Variables: dimensions of understanding, application, and practice that are being developed and tracked over time.
3. Levels of Achievement: intermediate steps in the developmental pathway(s) traced by a learning progression.
4. Learning performances: tasks students at a particular level of achievement would be capable of performing.
5. Assessments: specific measures used to track student development along the hypothesized progression.

The Pathways learning progressions have a lower anchor, which is the typical accounts of environmental issues given by students at the upper elementary and middle school level (Anderson, 2009). These accounts are empirically tested through a cyclic research process of clinical interviews informing the learning progression and leading to the development of written assessments given on a large scale. The Pathways learning progressions upper anchor is based on experts views of what a scientifically literate citizen should know and be able to do by the 12th grade. The upper anchor is much like a NSTA or NCTM standard, but learning progressions differ from standards in that the lower anchor and intermediate achievement levels are research-based, reflecting the actual trajectory of student learning. A limited number of achievement levels (4 or 5) are identified as plateaus in students' development of more sophisticated ways of thinking about enduring understandings, concepts, and processes.

The progress variables address both environmental literacy and QR. The environmental literacy progress variables for the Pathways project are the carbon cycle, water cycle, and biodiversity, which are considered areas in which students must develop conceptual understanding if they are to become environmentally literate citizens. The progress variables for QR include the act of quantification, quantitative literacy (QL) which consists of arithmetic understandings supporting science, quantitative interpretation (QI) which is the process of interpreting scientific models to determine trends and make predictions, and quantitative modeling (QM) which is the creation of models by the student. The fundamental process is the act of quantification, the cognitive processes essential to mathematizing within a context. Our goal of scientifically literate citizens necessitates the second progress variable of quantitative interpretation. Given a data table, graph, equation, or scientific model, the citizen must interpret the model to make data informed decisions. Finally, the quantitative modeling progress variable supports current approaches to have model building, testing, and refinement as drivers for science education.

Within the QL, QI and QM progress variables are hypothesized mathematical and statistical tools critical for science (Table 1). The Pathways project focuses not on the mastery of these tools, but on the act of quantification and the process of quantitative reasoning within science contexts.

The development of learning progressions is an iterative process typical of design-based research. The Pathways environmental literacy learning progressions began with hypothetical frameworks based on theories about reasoning about processes in socio-economic systems, including discourse, practices, and knowledge, as well as linking processes between lower and upper anchors. The QR Pathways Theme is using the learning progressions to research the impact of QR on students' development of environmental literacy. The overarching goal is to study the capacity of students to understand and participate in evidence-based discussions of socio-ecological systems.

A framework for the Pathways learning progression (Table 2) consists of progress variables (matrix columns), levels of achievement (matrix rows), learning performances (content of matrix cells), and linking processes which are common processes that are recognized by students at all levels of achievement (Anderson, 2009). Learning performances are exemplars drawn from the clinical interviews and written assessments that demonstrate student responses at different achievement levels. Learning progression matrices cross-tabulate achievement levels (rows in matrix) with progress variables (columns in matrix).

Table 2: QR Learning Progression Framework

	QR Progress Variable		
Achievement Level	**Quantification Act**	**Quantitative Interpretation**	**Quantitative Modeling**
Level 4 (Upper Anchor)	**4a** Variation: reasons about covariation of 2 or more variables; comparing, contrasting, relating variables in the context of problem **4b** Quantitative Literacy: reasons with quantities to explain relationships between variables; proportional reasoning, numerical reasoning; extend to algebraic and higher math reasoning (MAA) **4c** Context: situative view of QR within a community of practice (Shavelson); solves ill-defined problems in socio-political contexts using ad-hoc methods; informal reasoning within science context (Steen & Madison; Sadler & Zeidler) **4d** Communication: capacity to communicate quantitative account of solution, decision, course of action within context	**4a** Trends: recognizes and provides quantitative explanations of trends in model representation within context of problem, including linear, power, exponential trends **4b** Predictions: makes predictions using model with covariation and provides a quantitative account which is applied within context of problem **4c** Translation: translates between different models, at least categorically (ie this graph looks exponential) **4d** Revision: revise models theoretically without data, evaluate competing models for possible combination (Schwarz) **4e** Authority: question model by challenging quantitative aspects as estimates or due to measurement error, especially when contrasting models	**4a** Create Model: ability to create a model representing a context and trace through model correctly **4b** Refine Model: test and refine a model for internal consistency and coherence to evaluate scientific evidence and explanations; results; extend model to new situation (Duschl) **4c** Model Reasoning: construct and use models spontaneously to assist own thinking, predict behavior in real-world, generate new questions about phenomena (Schwarz) **4d** Methods: demonstrate ability to use variety of methods to construct model within context; least squares, linearization, normal distribution, logarithmic, logistic growth, multivariate, simulation models; **4e** Statistical: conduct statistical inference to test hypothesis (Duschl)
Level 3	**3a** Variation: recognizes correlation between two variables but provides a qualitative or isolated case account; lacks covariation **3b** Quantitative Literacy: manipulates quantities to discover relationships; measure, numeracy, proportional, statistical procedures **3c** Context: display confidence with and cultural appreciation of mathematics within context; number sense, practical computation skills (Steen)	**3a** Trends: expand recognition of patterns in models of one variable to recognizing linear vs. curvilinear growth **3b** Predictions: interprets models where one variable is categorical, identifying trends and making predictions with strong quantitative accounts; make predictions using model with covariation but only provide qualitative account **3c** Translation: attempts to translate between models if prompted but fails to relate variables between models	**3a** Create Model: create simplistic models for covariation situations that lack quantitative accounts; fail to trace model correctly **3b** Refine Model: test and refine model based on supposition about data; extend model without verifying fit to new situation **3c** Model Reasoning: construct and use multiple models to explain phenomena, view models as tools supporting thinking, consider alternatives in constructing models (Schwarz)

	QR Progress Variable		
Achievement Level	**Quantification Act**	**Quantitative Interpretation**	**Quantitative Modeling**
	3d Communication: capacity to communicate qualitative account of solution, decision, course of action within context; weak quantitative account **3e** Variable: mental construct for object within context is identified, conceptualized so that the object has attributes that are measurable (Thompson -act of quantification); uses variable in context	**3d** Revision: revise model to better fit evidence and improve explanatory power (Schwarz) **3e** Authority: question differences between models, but use erroneous qualitative accounts not error or approximations	**3d** Methods: demonstrate ability to use two different methods to model a situation **3e** Statistical: use descriptive statistics for central tendency and variation; make informal comparisons to address hypothesis
Level 2	**2a** Variation: sees causation in relationship between two variables, provides only a qualitative account; lacks correlation **2b** Quantitative Literacy: poor QL interferes with manipulation of variables; struggle to compare or operate with variables; ability to manipulate and calculate with one variable to answer questions of change, discover patterns, and draw conclusions; **2c** Context: lack confidence with or cultural appreciation of math within context; practical computation not related to context **2d** Communication: provides elements of account, but lacks capacity to communicate solution, decision, course of action within context; weak qualitative account **2e** Variable: object within context is identified, but not fully conceptualized with attributes that are measurable; object is named creating a variable (Thompson)	**2a** Trends: identify and explain single case (point) in model within context; recognize increasing/ decreasing trends but not relating to change in both variables (covariation lacking) **2b** Predictions: makes predictions for models with one variable but provides only qualitative arguments **2c** Translation: indicate preference for one model over another but do not translate between models **2d** Revision: revise model based on authority rather than evidence, modify to improve clarity not explanatory power (Schwarz) **2e** Authority: acknowledge quantitative differences in models but does not provide an explanation **2f** Interpret: identify variables in the model (i.e., graph axes, table headings, equation unknowns); provide qualitative account, avoiding quantities; form correct mental image to conceive problem; difficulty with models that embed variable or have more than two interrelated variables	**2a** Create Model: creates visual models to represent single variable data, such as statistical displays (pie charts, histograms) **2b** Refine Model: extends a given model to account for dynamic change but provides only a qualitative account **2c** Model Reasoning: construct and use model to explain phenomena, means of communication rather than support for own thinking (Schwarz) **2d** Methods: constructs a table or data plot to organization information but does not use as model **2e** Statistical: calculates descriptive statistics for central tendency and variation but does not use to make informal comparisons to address hypothesis

	QR Progress Variable		
Achievement Level	**Quantification Act**	**Quantitative Interpretation**	**Quantitative Modeling**
Level 1 (Lower Anchor)	**1a** Variation: does not compare variables **1b** Quantitative Literacy: struggles to manipulate and calculate with even one variable to answer questions of change, discover patterns, and draw conclusions; **1c** Context: does not relate quantities to context **1d** Communication: discourse is force-dynamic; avoids quantitative account, ignoring quantities providing weak qualitative account **1e** Variable: objects within context are not identified, no attempt to conceptualize attributes that are measurable	**1a** Trends: do not identify trends **1b** Predictions: avoid making predictions **1c** Translation: fail to acknowledge quantitative difference in models **1d** Revision: view models as fixed, test to see if good or bad replicas of phenomena (Schwarz) **1e** Authority: does not acknowledge difference in models **1f** Interpret: fail to relate model to context; avoid using model	**1a** Create Model: does not view science as model building and refining so does not attempt to construct models; forced dynamic or low level school science discourse, expect to receive facts and memorize processes **1b** Refine Model: no model created to refine **1c** Model Reasoning: construct and use models that are literal illustrations, model demonstrates for others not tool to generate new knowledge (Schwarz) **1d** Methods: no evidence of knowledge of methods for building models **1e** Statistical: does not use statistics; no calculation of even descriptive statistics

Aspects of the Pathways learning progression framework are highly quantitative in nature. For example, one such aspect is scaling. Students at the lower anchor often function at a macroscopic or "individual" scale in which they view the world from their sensory purview. Hence, their accounts of environmental issues are based within their daily perceptions at this scale. Moving students to the upper anchor requires that they scale up to a global view, as well as scale down to a microscopic-atomic view. Regardless of the scale, moving up or down the scale becomes intensively quantitative.

Challenges for the QR Theme researchers include determining which theories about reasoning carry over to QR aspects of environmental literacy and to discover potential theories that are more QR-centric. For example, students achieving the upper anchor in the environmental literacy learning progression should function as informed decision makers within the socio-economic system at three levels: discourse, practices, and knowledge. "Knowledge is embedded in practices, which in turn are embedded in discourses" (Anderson, 2009). We all participate in multiple discourses that associate us with communities of practice (Gee & Green, 1998) and as we gain understanding of a phenomena as our discourse around it matures. The lower anchor discourse for the environmental literacy progression is force dynamic, relying on students' theory of the world with a focus on actors, enablers, actor's purposes, conflicts between actors, and settings for the actions (Pinker, 2007; Talmy, 2003). At the upper anchor scientific discourse is essential, with students moving away from actors in settings to laws that govern the work of systems. Moving from knowing mathematical or statistical algorithms to understanding of enduring concepts can allow one to analyze scientific problems quantitatively.

QR: Perspective and Context

To support consideration of situations from a mathematical/scientific perspective one could have students work on tasks designed to promote QR. Often tasks designed to support QR describe situations that could be considered to have "real-life" contexts. As such, asking whether or not a student is familiar with a context seems a natural question. However, students' familiarity with the situation described by a task is only one aspect of the multifaceted interactions that can occur as students work on a task. Van Oers

(1998) asserted "What counts as context depends on how a situation is interpreted in terms of activity to be carried out" (p. 481). By considering individuals' perspective on mathematical tasks, context is no longer objective and external to an individual, rather it is steeped within an individual's interaction with a task.

When investigating students' QR, it is important to consider students' perspective of the problem situation posed by the task. Such tasks might include situations involving quantities that could change. For example, a task could involve a bottle of varying width filling with liquid being dispensed at a constant rate. As part of the filling bottle task, one could prompt students to consider how the volume of liquid would be changing as the height of the liquid in the bottle is increasing.

Secondary students working on the filling bottle task may not necessarily engage in QR. Students employing QR might consider relationships between the varying quantities of volume and height. Two types of relationships include (1) making comparisons between associated amounts of volume and height, and (2) considering variation in the intensity of the change in volume as related to the change in height (Johnson, 2011). Students engaging in (1) considered amounts of change in volume and height that *occurred* on particular intervals. The student engaging in (2) considered change in volume *as occurring* with respect to the changing height.

Despite the filling bottle task's design supporting QR, students may not employ QR when working on the task. A student could appeal to the sound of a filling bottle, as did one student in Johnson's (2010) study, who responded: "I'm thinking as the water bottle, you are filling it up and as the rim comes, you can hear it filling up faster." Although this student was working on the same printed task as students employing QR, she seemed to be wrestling with the problem of actually filling a bottle rather than considering quantities involved in the task.

Taken together, these student responses suggest that a student's perspective on the nature of the task to be solved might afford or constrain his or her quantitative reasoning. Further, a printed task itself does not indicate the quantitative reasoning in which a student might engage. Such considerations are not limited to secondary students with limited mathematical coursework. In working with college students solving a task involving constructing an open box from a sheet of paper, Moore and Carlson (2012) found that students' images of the problem context influenced the quantitative reasoning in which students' engaged. When engaging students in tasks designed to support QR, students' interpretation of the problem context and quantities involved is nontrivial and should not be taken for granted.

QRaMM Reflection Tasks

The three QRaMM working group sessions will actively engage the participants in discussion of the research questions, variables, and framework provided above. Each session will begin with a 15-minute plenary presentation by a member of the QRaMM research team to pose research issues and problems for discussion. Seminal readings related to the presentation will be provided to all participants in the first session, serving as support materials for discussions in later sessions. Breakout sessions for working subgroups will be organized around task-oriented discussions. The last session will provide plenary presentations summarizing subgroup work and report out discussions by the subgroups.

The sub-groups will focus on the following domains of discussion related to our research questions:

1. How does quantitative reasoning integrate and interact across mathematics and the sciences?
    a. How does the act of quantification play out within a mathematics and science context?
    b. How do alternative conceptions of science and mathematics concepts influence the use of QR?
    c. What is the role of context in QR?
    d. Context for whom—secondary students, collegiate students, or perspective teachers?
    e. What is the connection of QR to the common core mathematical practices?

2. What is the role of learning progressions for quantitative reasoning in fostering interdisciplinary learning in mathematics and the sciences?
   a. How do we best elicit information on learning progressions in QR from students (interviews, large scale quantitative assessments, etc.)?
   b. What role does discourse analysis and scale have in QR learning progressions?
   c. How do science learning progressions and QR learning progressions interact?
3. How do learning progressions for quantitative reasoning inform professional development in ways that support interdisciplinary mathematics and science teaching and learning?
   a. What role can the assessments related to QR learning progression development play in classroom assessment of QR?
   b. What should interdisciplinary teaching experiments focused on QR in STEM look like?

For each of the research questions, the subgroup will address the following related topics as well:

1. Address issues and concerns for research methodologies to be used.
2. Discuss techniques for using and transforming data to describe, analyze, and interpret in ways that will illuminate and inform the concept of quantitative reasoning.
3. Discuss approaches to reporting what is found and to applying it to inform improved educational practice related to interdisciplinary aspects of quantitative reasoning and mathematical modeling.
4. Discuss instruction, student learning, curriculum, policy, and future research with respect to quantitative reasoning.

QRaMM Follow-up Activities

We will sustain the efforts of the working group through the WISDOM^e research initiative, a proposed QR monograph targeting researchers in QR in STEM, collaboration with the NSF Pathways Project, and a second WISDOM^e Research Conference.
