Mathematics specialist candidates recognized complexities that they had not previously identified. One student considered socioeconomic status as she described equity, "All students should be provided with the same resources to learn mathematics. However, oftentimes, this is a challenge for students who are disadvantaged socioeconomically." This subtle shift indicates progress towards the critical axis (Gutiérrez, 2007) since the candidate acknowledges the position of the student in terms of societal power. Another candidate alluded to the institutional structures beyond the classroom which affect opportunities to learn. This candidate wrote, "Access is huge. If students are in a school or setting where they do not have access to quality instruction and safe learning environments, they do not have an equitable education." Again, this shift in language from the pre-program survey -- phrases such as "leveling the playing field" and "differentiating" -- to acknowledging systemic inequities in the mid-program survey indicates a deeper understanding of equity as the candidates shift their thinking from the dominant to the critical axis (Gutiérrez, 2007).

Increasing Understanding of a Teacher's Responsibility to Ensure Equitable Experiences

At the beginning of the program, mathematics specialist candidates communicated that students could achieve with sufficient access to resources. After class discussions about equity in the context of *Principles to Actions* and the TRU framework, they recognized that students brought their own mathematical understandings into K-12 classrooms. However, perceptions of equity emphasized resource allocation and achievement goals. For example, one candidate said, "We all know students work at different levels and all learn in different ways so providing equitable mathematics instruction would be providing our students with all the resources and tools they would need to achieve the same goal." When sharing potential additional supports, mathematics specialist candidates identified students as a means to provide support to one another "via peers and one-on-one tutoring." These solutions to addressing student understandings placed the responsibility of learning on the students and minimized a teacher's role in facilitating equitable mathematics instruction.

The majority of mathematics specialist candidates recognized that there was a need to take more action in their instructional practices but were unable to articulate specific actions beyond differentiation. For example, a candidate said, "The teacher knows their students best and will be able to differentiate the instruction to meet their students' needs." This candidate indicated some responsibility to the teacher but was unable to verbalize specifics.

However, in the mid-program survey mathematics specialist candidates identified specific ways in which a teacher could begin to facilitate equitable mathematics instruction by addressing issues of identity. Responsibilities of learning were still placed on students, but in an appropriate way that indicated students would construct their own meaning based on instructional strategies. Now, candidates were communicating about individual student participation in constructing meaning:

> Students need to feel that they have a voice and role in the classroom. Rather than just a few students doing that majority of the talking and sharing, all students need to have ways to contribute in class. The teacher's role needs to be a facilitator so that the students are doing the heavy lifting of the thinking and learning.

Similarly, another candidate shifted the responsibility of learning towards the teacher, viewing the teacher as a leader who empowered her students to take ownership of their own learning. Furthermore, this candidate recognized the identity of each individual student and the students' societal positionality.

> Students will take ownership when they feel empowered to think and reason through math problems. When they are successful, this contributes to a positive math identity. Another thing about identity is students may not see themselves as a "math person" because of gender, race, or socio-economic status. We need to empower all students to become math people.

As candidates' views towards learning responsibilities shifted, questions simultaneously arose in how a teacher might move forward. "Equitable instruction ensures that teachers are focusing on the specific needs of students. But, how can each student be successful? What do they each need?" Such questions acknowledge the complexities of equitable instruction and indicate that the candidates are engaging in critical reflection about equity.

Developing Knowledge of Facilitating Rich Mathematics Experiences to Promote Equity

Mathematics specialist candidates acknowledged their role in creating equitable classrooms as facilitators of rich mathematical experiences. Their knowledge of this role is defined through initial surveys as a teacher's ability to teach mathematics content equally to all students. They recognized that while they do not have control of grade-level content requirements, they do have control of the facilitation of rich mathematics experiences that are delivered with this content. They stated this limitation, however, in the initial survey. Candidates described the ways that they overcame this limitation with descriptions of fairness and equality as definitions of equity. One candidate responded that, "While there is a belief that not one math program has the content necessary for all learners to be successful, I do believe that every school should have a common textbook program to which teachers can add supplementary tasks and activities." Another candidate described equity through a teacher's decisions when delivering the content by stating that, "Content is set by the state. However, how the teacher structures the content experiences for students allows for equitable instruction." Further, a candidate stated that math content is inherently equitable because it can be delivered through various teaching practices.

> Math content contributes to equitable math instruction in focusing on the big ideas of math and conceptual understanding like equivalence, multiple representations, patterns, form, relationships, etc. that are also cross disciplines other than math. These are the enduring understandings that we want students to understand in the math content.

In each of these examples, the candidates are describing equity as equalizing access to content and/or the teacher's decisions in delivery of the content.

By the mid-program survey, the candidates shifted to describe equity as their ability to teach content through differentiation and student-centered tasks that value the uniqueness and individuality of each student. They began to value differences as an opportunity for rich mathematical experiences. One candidate reported a shift in their teaching by stating that s/he was "recognizing cultural and socio-economical differences and allowing students' experiences to guide task creation." As these candidates engage students in math tasks, they are not only recognizing differences, but valuing them by highlighting those differences through the mathematics content.

Also, candidates transitioned from defining equity as equality to equity as a teacher's ability to differentiate the mathematics experiences. For example, "If you teach the same content but differentiate it based on the varied abilities it is equitable." This differentiation is described as individualized by a candidate who stated that "When problems are presented it should be with content that students can make a connection to. If you know your students have never been to the beach, do not give them problems related to the ocean without first providing background knowledge" and "math is relatable to all students and there are multiple entry points to the problems." In differentiating the math experiences based on students' prior knowledge, they are facilitating student-centered math experiences, transitioning to individualization. Another candidate described rich content as individualizing content understanding and application:

> Content is content. Rich content goes beyond the surface and provides experiences with math that give pathways to a higher understanding of content. This is what we want for all children. Not a show and tell mathematics, but an environment where students can develop their own understanding, work collaboratively with others, and see the beauty in math.

Candidates began to focus on "all students" and how "students should be provided with ways to engage in the content." One candidate wrote, "All students need to be able to contribute to the classroom and have a voice. High quality tasks with multiple solutions provide ways for all students to have a voice and share their thinking." However, while the specialist candidates identified the need for students to take ownership of their own learning, no one discussed how teachers could develop opportunities for students to see themselves as doers of mathematics.

Discussion

We, as a program, reiterate that we are continuing to learn how to better prepare mathematics specialist candidates to engage in issues of equity and social justice. We embrace the call to change the structures which perpetuate inequities and recognize that we, as faculty, need to take a stronger stance. We acknowledge that the content and leadership experiences we provide to our candidates are valuable, but they are not aggressively moving the conversation forward to empowering our master's students as agents of change. This analysis of the candidates' descriptive language of equity and social justice can inform our future programmatic actions. *Principles to Actions* (NCTM, 2014) and the TRU framework (Schoenfeld, 2015) resonated with our students' conceptions of effective K-12 mathematics teaching and was a comfortable way to begin conversations that center on designing high-quality classroom experiences. The conversations that arose from using the NCSM/TODOS (2016) position statement on equity and social justice were more critical in nature and allowed our candidates to see the differences between good mathematics teaching and equitable mathematics teaching. However, our candidates need more opportunities to envision ways in which they can challenge inequitable structures.

We, as a program, also need to look at how we address issues of equity and social justice across our courses and develop a common vision that will promote the systematic change we desire. Our candidates need more experiences to grapple with ideas of equity and social justice. We are reflecting on critical questions: How do we begin these critical conversations with mathematics specialist candidates so that we have evidence of their growth? How does one develop excellent teaching practices and advocacy skills in parallel?

Although we are developing classroom teachers and leaders who are embracing *Principles to Actions* (NCTM, 2014) and the TRU framework (Schoenfeld, 2015), we need additional tools which promote critical awareness and prepare our candidates to act. We also need to re-examine our data collection tools, specifically the survey. We need to capture how our candidates not only describe equity, but we also need to gather data that illuminates what equity looks like in their daily practice. We anticipate some disconnect between beliefs and actions as our mathematics specialist candidates, like pre-service teachers, are challenged by the reconciliation of exploring what they are 'supposed to' say with what they perceive possible in their school contexts. We hope that our candidates will feel empowered to change the systems within which they work. Without taking any action or modeling equitable teaching practices in our own graduate classrooms, our practices will continue to center on instruction that does not contribute to systemic change.

WHAT DOES IT TAKE TO BE A FOX? NEW HORIZONS FOR MATHEMATICS COMMUNITIES OF PRACTICE

Nicole M. Wessman-Enzinger

Justin K. Dimmel
University of Maine
justin.dimmel@maine.edu

In this theoretical research report we reflect on the challenges of becoming more fox-like in mathematics education work. Using a communities of practice motivating theoretical lens, we compare and discuss the differences in defining, creating, and accessing knowledge between virtual and scholarly communities of practice in mathematics education. We present four claims that virtual communities of practice in mathematics education are inherently foxy work. As part of our claims, we discuss how scholarly communities of practices are inherently hedgehog work. We conclude with a list of recommendations of those within the scholarly communities of practice in mathematics education. These recommendations include looking toward the successful fox-like attributes of the virtual communities in mathematics education.

Keywords: Instructional Leadership; Systemic Change

Drawing on Berlin's (1953) essay, *The Hedgehog and the Fox*, Boaler, Selling, and Sun (2013), ask the question to the mathematics education field: "Where are the Foxes in Mathematics Education?" Berlin uses the metaphor of hedgehogs and foxes for illustrating two types of thinkers and writers: hedgehogs as those focused on a singular idea and foxes as those who draw across ideas and make changes. Boaler and colleagues challenge those in the academy to be more "foxy" in their collaborations and research with intentional outreach to other communities. They note "although the production of research ideas is extremely worthy, if research ideas in mathematics education do not get taken up and used, by teachers, parents, and other educators, then their worth diminishes significantly" (p. 191).

In this theoretical paper, we explore questions around this challenge including: What does it mean to be a fox in mathematics education? To what degree does the field support members in becoming foxes? How might foxes within mathematics education use online communities in their work? Moreover, we consider how newly formed virtual communities in mathematics education might serve as new horizons for traditional scholarly communities.

An Array and a Skulk

Berlin's (1953) essay developed the conceit of the hedgehog and the fox as a lens for assessing the life and work of Leo Tolstoy. What endures from the essay is the idea that there are hedgehog-like thinkers and writers and fox-like thinkers and writers. Kilpatrick (2013) captures the difference between the two as a matter of scale and humility: the hedgehog knows all there is to know about one big idea, uses this information to understand the world in its entirety, and fails to recognize that there aspects of the world that cannot be known or explained. The fox, on the other hand, knows just enough about many things and also knows that some things are unknowable. Berlin (1953), Kilpatrick (2013), and Boaler and colleagues (2013) use the hedgehog/fox dichotomy for describing individual or cooperative activities (e.g., the work of Tolstoy, specific mathematics education research projects). Our interest in discussing this distinction is not for focus on individual hedgehogs or foxes, but rather to consider *collections* of each and the collective behavior of these different groups. Moreover, we use the hedgehog/fox distinction as lens for examining the kinds of activities that take place by different collections of math educators: the arrays of hedgehogs in academia and the skulks of foxes in what we describe below as the network of virtual mathematics education communities of practice and scholarly mathematics education communities of practice.

Motivating Theoretical Lens: Communities of Practice

Our motivating theoretical lens is formed from perspectives of communities of practice (Lave & Wenger, 1991). We apply this lens to virtual mathematics education communities of practice (vMEC) and also scholarly mathematics education communities of practice (sMEC). Although we make the distinction of these two different types of communities, virtual and scholarly, we recognize that some members of the sMEC are also engaged participants in the vMEC. Because the overlap between vMEC and sMEC is so limited, we treat these communities as distinct in our subsequent discussion and claims. These communities, the vMEC and sMEC, each have the three essential characteristics discussed by Wenger-Trayner and Wenger Trayner (2015): (1) a shared domain; (2) an engaged community of participants; and (3) a focus on practice (see, e.g., Hertel, Wessman-Enzinger, and Dimmel, in press, for further discussion on virtual mathematics education communities of practice).

Virtual Mathematics Education Communities

As social media platforms (e.g., Facebook, Instagram, Twitter) have become integral to people's daily lives over the last decade, virtual communities have flourished. We draw a distinction between platforms (websites that facilitate interactions among users) and the multitude of virtual communities that reside on such platforms. Moreover, although we are focused on virtual communities, the interaction between virtual and physical communities is complex (Ellis, Oldridge, & Vasconcelos, 2004). As Ellis, Oldridge, and Vasconcelos (2004) note, virtual communities have different features than traditional social networks:

> Virtual communities are both narrow and specialized, in terms of the information posted, but at the same time broadly social and supportive. Consistent evidence suggests that many individuals go to virtual communities because of these social and supportive characteristics: the many weak ties supported by virtual communities provide access to a much wider network of people than conventional, social networks. The potential for invisibility regarding normal social cues such as gender, race, class, and age opens up the potential for networking and interaction that may be inhibited elsewhere. (p. 148)

We conceptualize these virtual communities as types of *communities of practice* (Lave & Wenger, 1991; Wenger, 1998; Wenger-Trayner & Wenger-Trayner, 2015) acknowledging that there are inherent differences between physical and virtual communities of practice. Moreover, within this theoretical paper we concentrate on vMECs that are focused on the teaching and learning of mathematics.

The shared domain of a virtual community of practice is independent of platform. Members of a particular vMEC might use several platforms concurrently (e.g., Pinterest, Facebook) or a single platform might host multiple vMECs. The shared domain of any particular vMEC is visible through the shared focus on teaching and learning of mathematics in the discussions, interactions, resources, etc. Additionally, smaller communities of practice each having a narrow focus may also be part of a larger vMEC (e.g., mathematics content at the elementary level, the professional development of mathematics teachers). Collectively vMECs make up a group that is different from other virtual communities of practice and, at the same, time they form smaller communities that are distinct from one another.

The individuals who constitute a vMEC share information and help each other. Through this interaction, members build relationships, collaborate, support one another, and engage in the shared domain. The methods and kinds of engagement are influenced by the structure of the platform on which the vMEC resides. Some platforms provide robust tools for interaction and knowledge building (e.g., Mathematics Stack Exchange) while others provide limited tools for structuring interaction. The presence or lack of tools influences that degree to which community members can shape discourse.

Practice is always social (Wenger, 1998) and involves performing an activity within a social as well as historical context. Practice includes:

> What is said and what is left unsaid; what is represented and what is assumed. It includes the language, tools, documents, images, symbols, well-defined roles, specified criteria, codified procedures, regulations, and contracts that various practices make explicit for a variety of purposes. But it also includes all the implicit relations, tacit conventions, subtle cues, untold rules of thumb, recognizable intuitions, specific perceptions, well-tuned sensitivities, embodied understandings, underlying assumptions, and shared worldviews. Most of these may never be articulated, yet they are unmistakable signs of membership in communities of practice and are crucial to the success of their enterprises. (Wenger, 1998, p. 47)

The explicit and visible practices of an vMEC may be quickly recognized and adopted by a newcomer. The implicit, untold, underlying assumptions, on the other hand, may go unnoticed. Moreover, the space in which a vMEC resides can also create room for miscommunication since, unlike physical communities, participating in a vMEC typically requires no more than visiting a publicly viewable website or registering a free account on a platform. Consequently, although newcomers can easily participate in a vMEC, they may do so without understanding the practices of the community and the assumed knowledge base.

Scholarly Mathematics Education Communities

The shared domain of sMECs is ultimately the academy. Although participants of the sMEC belong to different communities themselves, all participatns of the sMEC have an affiliation with a university in some capacity. The engaged participants are often graduate students, researchers, research assistants, tenured professors, or untenured professors. Becoming an engaged participant within the sMEC requires a vetting—this usually entails participation in thesis or dissertation work at some point (e.g., Golde & Walker, 2006; Reys, 2000). The expectations in the sMEC for vetting through theses and dissertations mimic research processes described in common mathematics education journals (e.g., Williams & Leatham, 2017) and conferences, such as the Psychology of Mathematics Education-North America (PME-NA). Although some members of the sMEC are participants of the vMECs, the two groups operate largely independently with participants of the sMEC knowing little about vMEC active members of the vMEC (e.g., classroom teachers, math coaches, consultants) outside of the sMEC.

Claims

We now discuss claims that we believe are critical issues in the discussion of hedgehogs and foxes within the field of mathematics education. As noted, our focus with these claims is on general behavior of collections of foxes and hedgehogs. This shift to focusing on collections rather than individuals allows for consideration of how sMEC and vMEC support different kinds of engagement with issues of teaching and learning in mathematics. We see these four claims as supporting the following position:

> The field is currently focused on generating hedgehogs (Claim 1) for work within sMECs and work within hedgehog systems. As a result, few within sMECs are positioned to obtain fox status (Claim 4). In contrast, vMECs offer a vision of mathematics education communities where there is more access and opportunity for becoming a fox (Claims 2 & 3).

Claim 1: The Scholarly Mathematics Education Communities are Designed to Produce Hedgehogs.

The very act of working on or obtaining a terminal degree (PhD, EdD, etc.) in mathematics education or a related field is a hedgehog idea. The academic journey members of sMEC undergo in graduate work is that of a hedgehog with narrow focus around developing robust knowledge of the field (pedagogy, research, etc.) before posing and researching a circumscribed, theoretically framed question whose investigation contributes to this knowledge base. This work is disseminated in hedgehog ways through a dissertation and (sometimes closed) defense. The structure of the dissertation itself is a hedgehog production built upon accepted norms of academic discourse—hundreds pages filled with complex, academic jargon that only insiders in that area read.

After graduate school, those in the field seek positions in the academy. Many in the sMEC obtain tenure-track positions at universities, which are built upon hedgehog systems. For example, tenure, whether at a teaching college or research university, is achieved through a combination of demonstrated proficiency in teaching, scholarship, and service. Related to scholarship, peer-reviewed publications are highly valued. Although some publications may be written for a more general audience, most are focused more narrowly on a subset of the sMEC community. Moreover, the articles themselves are produced to adhere to the norms of academic discourse and written for members of the sMEC community, rather the mathematics education community at large.

Claim 2: Hedgehogs Can Flourish in a Closed System; Foxes Require Access to Flourish.

Members of the sMEC are inherently part of systems where production of knowledge is more important than the access to knowledge. These mathematics education hedgehogs produce knowledge through research that is focused in a particular domain in the field (e.g., children's thinking about operations with fractions, student positioning in number talks). Likewise, the systems in which graduate students are trained to work (i.e., higher education) value the production of knowledge and the systems in which we work require the production of knowledge (e.g., dissertations, publications). This knowledge is disseminated through peer-reviewed articles, conference presentations, or other publications. Most of these publication venues are creations of the sMEC community itself although some may be owned by other entities. As such, these venues are maintained by members of the sMEC and access to them challenging for those in the vMEC who lack institutional financial supports. Likewise, an individual who is trained as a hedgehog, but resides outside of the academic structure, will struggle to access most of the newly created knowledge.

The monetization of knowledge generated by members of the sMEC showcases how access to knowledge is less important than the production of knowledge. This monetization occurs in various ways even beyond the required memberships to organizations or journals stated above. Only a few of the sMEC organizations have open access to the knowledge they curate or promote the freely sharing of knowledge to those outside the community. In fact, open access is not given a particular value by the field or the sMEC as a whole, which can lead to inconsistent policies within groups. For example, although the proceedings for PME-NA are freely available online, the proceedings of the larger parent organization, the International Group for the Psychology of Mathematics Education, are not free to download. Some scholars seeking to work around the prohibitive structures of academic publication make prepublication versions of their work (papers, book chapters, etc.) available for download. Although this shows the desire of many authors to work around the access-limiting structures, it is also evidence of the degree to which the field ignores the importance and challenge of access.

The very nature of the expectations in the academy, or the sMEC, limits what those in the academy consider transformational. Reaching out in transformational work beyond the research required for typical peer-reviewed journals is an afterthought or an "if we have time" mantra. Time constraints notwithstanding, there is also the risk, when reaching out to the general public, that one's scholarly work will become popular, at which time one's academic reputation may be impugned for doing unserious work. Or, one may spend time working with the general public and lose credibility within the academy for doing unscholarly work. This is evidenced by the academy's emphasis on scholarly production and de-emphasis on service.

Conversely, within vMECs the sharing of knowledge and the creation of knowledge are equally important. Reaching out to those beyond a niche community is the purpose of any post or work; this starkly contrasts many situations within sMEC. Even if those with large-scale funding (e.g., NSF) engage in transformational work, the access to this work is often lacking. This presents hedgehog findings making their way into thousands of teachers' classrooms in the same ways available from MEC. Likewise, although an individual in sMEC may spend years studying children's thinking about integer addition and subtraction deeply, sharing this work in an open and accessible way if the individual wishes to have an impact within the vMEC.

Members of the vMEC need to make sense of student's thinking about many domains of mathematical content and also the accompanying pedagogical work that leverages this thinking forward. Members of the vMEC come together and use social media platforms as a ways to share knowledge about making transformative work in mathematics education. Simply put, those in the vMEC are trained mathematics practitioners and inherently engage in foxy work (e.g., instructional coaches for a range of grades, teachers who teach many different topics). Despite the varying roles of vMEC (e.g., math coaches, teachers, math consultants), there is a common goal of connecting larger mathematical ideas and transforming education for students. Although those in the sMEC may value transformational education for students, the field is submerged in a hedgehog system that perpetuates closed structures (e.g., publications in peer-review journals, tenure).

Claim 3: The vMEC Presents Opportunities for Developing Foxes More than sMEC.

The vMECs have more opportunities for developing foxes than the sMECs. Moreover, we claim that vMECs are inherently foxy communities of practice. In the shared virtual spaces of the vMECs (e.g., Twitter chats like #mathchat, Facebook groups), the engaged participants wish to evoke change. This constitutes sharing things in public, free, open-source ways. Because the work is inherently foxy, there are more opportunities for the members of the vMEC to flourish when compared to those within the sMEC. Participants in the sMEC have less opportunities to engage in discussion of knowledge and shared knowledge. Most participants in the sMEC discuss their work through conferences or journal articles. Although they may get to speak with members of the sMEC about their work at a conference, the members of the sMEC have limited opportunity to discuss their work published in articles beyond receiving feedback from reviewers and editors. Members of the sMEC rarely know if their work is being taken up or are able to share it freely. Conversely, the very nature of knowledge expectations of the vMEC requires interactions with others publicly and freely shared.

There is clear evidence of the influence these communities have had on mathematics education. An example of the inherent foxy work of vMEC are 3-Act Tasks. 3-Act Tasks are mathematical cultural phenomenon that constitutes an ideal example of highlighting transformative, foxy work part of the vMEC. A 3-Act Task is a task presented as a way of mathematical storytelling in three specific parts or acts (e.g., http://blog.mrmeyer.com/2011/the-three-acts-of-a-mathematical-story/). In the first act, the story is visually told. This act entails beginning with a video of a contextual situation, like picking up eggs out of a cartoon or packing meatballs in a pot of water. The videos do not contain words, symbols, or questions. It is essential the videos are visual with a change happening and open-ended. The second act, the protagonist/student/learner has a need for overcoming an obstacle. This may entail mathematizing the situation, looking for resources, or creating tools. For example, in a video where the protagonist is packing meatballs in a pot of water, one may wonder how many meatballs can be packed without overflowing the water in the pot. Learners may mathematize this situation by starting to unpack ideas of volume and displacement. In the last act, act three, there is resolution to the story and conflict. This is the space where mathematical problem solving occurs. Due to the open nature of the video and conflict, it is likely that there are multiple strategies, solutions, and robust discussion about the conflict resolution.

Countless teachers and other practitioners know what a 3-Act Task is and use them routinely. Although 3-Act Tasks have recently found themselves in traditional, scholarly peer-review spaces (e.g., Lomax, Alfonzo, Dietz, Kleyman, & Kazemi, 2017), the inaugural roots of 3-Act Tasks began on a blog by Dan Meyer. Through the Mathematics-Twitter-Blogosphere (MTBoS) and vMECs, numerous educators began using 3-Act Tasks. Graham Fletcher categorized a vast array of 3-Act Tasks for elementary school; these tasks with videos are freely available (e.g., https://gfletchy.com/3-act-lessons/). Using the hashtag #3ActMath on Twitter platform reveals quick insight into the power of the MEC in these the virtual communities and transformational impact on mathematics pedagogy. In a way, the 3-Act Tasks have been “researched” by the engaged participants in the shared domains of the MEC. There are many examples of this within the vMEC. In fact, all of the examples in the vMEC are fox-like work. Yet, very little of the work in the vMEC is picked up or used within the sMEC.

Claim 4: Few Within the sMEC Are Positioned to Be a Fox Whereas Anyone Within the vMEC Has Potential to Become a Fox.

Our final claim is that only a handful of individuals within the sMEC are positioned to become foxes. This is because the path to becoming a fox from within the sMEC requires first demonstrating one’s competence and ability as a hedgehog. The practices and norms of the sMEC create narrow avenues for becoming a fox. For example, some members become foxes through their successes as hedgehogs (e.g., articles, books, grants). Others attain fox status through their work as leaders within professional organizations. The sMEC celebrates and rewards the achievements of hedgehogs through a variety of structures including awards, honors, and guest lectures. Foxy work that lies outside of typical hedgehog activities is not valued in the same way. For example, non-peer reviewed work (e.g., blog posts, Youtube Channel) that is open to the public is not seen in the same light as scholarly publications.

In contrast, foxes in the vMEC are typically individuals who exist outside of the traditional academy. These bloggers, writers, and teachers have built their credentials upon popularity.

Moreover, the popularity itself is made possible by open access to the created content and serves as a proxy for an individual's position within the vMEC. Thus, becoming a fox within the vMEC relies upon the actions of the individual rather than their position within a system.

One's position as a fox within either the sMEC or vMEC determines the amount of influence one is able to yield. Members of sMEC, for example, may listen to those who have earned prominence in a plenary speech with assurance that the structure of the academy has guaranteed the speaker's qualifications as a hedgehog. In contrast, within vMEC prominence is earned through popularity of content. As such, prominent foxes are those whose content creations have become well known. Furthermore, whereas foxes with the sMEC largely have doctorates, a long list of publications, and a history of groundbreaking research, those prominent in the vMEC, in contrast, do not necessarily have they characteristics. What vMEC foxes do have, however, are curated free, open-source content that is connected to many mathematical topics.

Encouraging a Skulk of Foxes from Within Academia

As others have identified (Boaler, Selling, & Sun, 2013; Kilpatrick, 2013) there is a need for more foxes within the sMEC. But what are the attributes of being a fox? How can those outside of privileged positions (e.g., tenure, prominence in field) do foxy work? As we argue above, the field is currently focused on generating hedgehogs (Claim 1) to work within a system that is closed to most of the outside world (Claim 2). This structure limits opportunities to become a fox (Claim 3) and positions few within sMEC to obtain fox status (Claim 4).

Calls for more foxes in mathematics education are important, but what we need are more *skulks of foxes*—groups of foxes—in mathematics education. This is not an individualistic endeavor; it is a group or systemic change that must take place. We believe that the field must begin to address some of the structural barriers toward becoming a fox. Most importantly, the limited access to content needs be addressed so that innovations within research and teaching from within sMEC can have a broader influence with vMEC. This is more than a call for increased open access journal articles. Rather, it is a call for structural changes and community expectations so that those in the sMEC can engage in work that integrates both the scholarly rigor our field requires alongside the outreach needed to reach the practitioners who reside outside the closed system.

Those within the sMEC have made initial steps toward structural changes and issues of access. For example, the journals *Teaching Children Mathematics*, *Mathematics Teaching in the Middle School*, and the *Mathematics Teacher* have monthly free-preview articles with accompanying Twitter chats. The *Mathematics Teacher Educator* (MTE) journal also started a podcast that is open access about select articles in the journal.

This is challenging work that needs to be done by the sMEC community—individuals alone cannot make systemic changes. Those in the sMEC need to think about collective ways they make changes to *access* of knowledge—particularly since views on creations of knowledge cannot be changed (e.g., dissertations, research). We challenge readers who belong in the sMEC to reflect and take-up the following questions:

How can we focus on access within the field?
How can we change those journals within the control of the sMEC (e.g., Journal for Research in Mathematics Education, MTE) to focus on open access?
How can we open up meetings at conferences (e.g., PME, PME-NA), where knowledge is being shared so that more practitioners benefit?

How can we integrate the work and tangible artifacts of the vMEC into the sMEC?
How can we value open access to a level similar to academic rigor?
How can we change the systems to focus on access and research, particularly for communities beyond the sMEC?

In some ways, being a fox counters the very nature of the academy, which supports and rewards hedgehog work. In this sense, the only way those in the sMEC can do foxy works is to be a rebel. A member of the sMEC may not feel it financially or personally worth it be a rebel; but, ultimately to engage in fox-like work, a member of the sMEC needs to push back on the closed systems that dictate hedgehog work.

Concluding Remarks

We affirm the need for more foxes in mathematics education (Boaler et al., 2013; Kilpatrick, 2013); we highlight that the calls are not individualistic, but collective. We emphasize structural concerns of the closed, hedgehog system that we reside in within sMECs. And, we hope that our field can begin the challenging, deep work of systemic change that encourages a skulk of foxes.

We recognize that there are challenges in using a strict dichotomy to describe mathematics education communities of practice and their members as either hedgehoges or foxes. Within a community, members might position themselves and their work along a continuum from all-fox on one end to all-hedgehog on the other. However, we contend that examining communities (vMECs, sMECs) through the lens of foxes and hedgehogs offers a way to re-examine and re-frame scholarly spaces. In doing so, this perspective incorporates a social justice stance that allows for examining institutional structures, practices of community engagement, and teaching and learning environments (NCSM & TODOS, 2016). Thus, by adopting this lens we can consider individual actions and identity the institutional and contextual factors that may support or constrain one's work along various points in the hedgehog-fox continuum.

The vMEC and the sMEC have differing expectations about knowledge, knowledge creations, and access to knowledge within their communities of practice. These differences dictate the type of work, hedgehog or fox, which occurs. The sMEC, with marginal involvement in virtual spaces, has different ideals of what constitutes transformative work. Boaler and colleagues (2013) challenge scholars for intentionality in reaching out to differing communities. The very nature of the expectations in the sMEC limits what those in the academy consider and value as transformational. Those in the vMECs preference open access are inherently foxy communities of practice (Berlin, 1953; Boaler et al., 2013). In the shared virtual spaces—i.e., Twitter, Facebook groups, Instagram—communities formed around shared domains with engaged participants who wish to evoke change. This constitutes sharing things in public, free, open-source ways. Even if members of the sMEC remain dedicated hedgehogs, we believe they should spend more time within social media platforms and begin to participate with active members of the vMEC. In this way, members of the sMEC may play a more active role in transforming these virtual communities and shaping the field in the future.

Mathematics Education Researchers (MERs) working in interdisciplinary research groups face challenges as the group members expose themselves to new ways of knowing and operating. To explore collaboration practices containing at least one MER, we conducted an examination of peer reviewed papers. Three common practices were identified: (1) partnering on similar research interests, (2) cultivating relationships that promote trust and open-mindedness, and (3) receiving institutional support. We contend that interdisciplinary research groups that involve MERs need to give consideration to these practices to set themselves up for success.

Keywords: Interdisciplinary Collaborations, Research Practice, Policy

Interdisciplinary collaborations have become common in the work of mathematics education researchers (MERs) since the integration of science, technology, engineering, and mathematics (STEM) was identified as a tool for solving large-scale problems and enhancing education (e.g., National Governors Association, 2007). To understand the workings of MERs involved in such groups, we conducted a pilot study to review research articles that explored interdisciplinary research collaborations (Walker et al., 2018). We found challenges that researchers experience in interdisciplinary groups derive from exposure to others' ways of knowing and operating. Following that study, we investigated the origins of disciplines (Schön, 1983; Williams et al., 2016) and frameworks to conceptualize interdisciplinary collaborations (e.g., Akkerman & Bakker, 2011). Historically, disciplines developed under a positivist epistemology of practice (Schön, 1983) which positioned researchers as problem-solvers with little attention given to problem settings. We argue that practices are needed to guide MERs in interdisciplinary research groups. We examine: what practices do MERs use in interdisciplinary groups?

Conceptual Framework

At the 13th International Congress on Mathematical Education, MERs recommended positioning mathematics as interrelated with other disciplines (Williams et al., 2016). Disciplinarity is described as a "phenomenon" involving "specialization" of work and discourse (Williams et al., 2016, p. 4). From this view, disciplines include specialized identities, practices, and knowledge bases that develop and are transmitted. As a discipline develops, inquiry activities take up practices and discourse from other disciplines, leading to levels of integration including mono-, multi-, inter-, trans-, and meta- disciplinarity (Williams et al., 2016).

A defining characteristic of disciplines are the practices developed and used by its members. Practices are methods or techniques that become tacit, spontaneous, and automatic ways of operating or knowing within a discipline (Schön, 1983). Differences in practices and knowledge bases among researchers bring challenges related to communication, work processes (e.g., research methodologies), institutional support, and translating findings into viable results of existing domains (Bruce et al., 2017; Walker et al., 2018). This makes MERs' interactions within interdisciplinary groups a phenomenon to be studied.

Researchers who are members of a discipline have a reflexive relationship with the discipline. They contribute to the development of the discipline and the discipline enables and constrains their activities (Walshaw, 2016). When MERs join an interdisciplinary group, they are people with personal qualities and experiences, familiar with mathematics education research and practices that influence the particular ways they interact within the group. For MERs to conduct successful interdisciplinary projects, the interactions and negotiations of goals among researchers should be given consideration.

Successful interdisciplinary collaborations provide opportunities for researchers to learn new practices and develop knowledge. Yet, MERs' participation in interdisciplinary work exposes them to challenges, which can discourage them from joining others. In our previous search, we found that there are a few published articles that present these issues and consider them from the position of the researcher working with others in an interdisciplinary group (Walker et al., 2018). We assert this is due to the development of disciplines from a positivist epistemology of practice (Schön, 1983), which has contributed to deemphasize the reflexive relationship between individuals and their discipline.

Schön (1983) described how the positivist epistemology of practice in the nineteenth century promoted science and technology and their achievements to improve humans' lives. This movement with industrialism and the technological program became a dominant horizon in the Western society and contributed to a common understanding that the primary way to generate knowledge was through empirical science (Schön, 1983). Under this horizon, disciplines are seen as a problem solving process (i.e., researchers from different disciplines came together to solve a problem). With "this emphasis on problem solving, we ignore problem setting, the process by which we define the decision to be made, the ends to be achieved, the means which may be chosen" (p. 40). Uncertainty, uniqueness, instability, and value conflict are troublesome for practitioners of a discipline because dealing with these is not seen as productive practice. Thus, we argue that not acknowledging MERs' practices could limit the ability of an interdisciplinary group to conduct research.

Methods

We conducted a case study (Flyvbjerg, 2011) to explore what practices existed or emerged when MERs work with researchers from other disciplines. We identified peer reviewed papers in mathematics education journals, written in English, as the data for this study. The papers included at least two researchers from different disciplines, one of them a MER. For this research we considered mathematics and mathematics education as two different disciplines. To find research articles that involved at least one MER, we performed a search using Ebsco and Scopus databases. The keywords used for the search in titles, abstracts, and keywords were: interdisc* AND mathematics AND education. These searches resulted in 45 articles. Afterwards, each member of our research group reviewed the abstracts according to these criteria: (1) Is it a research article (i.e., we did not include commentaries, essays, book review, or theoretical papers)? (2) Are there at least two authors (researchers)? (3) Are the authors coming from at least two different disciplines or does the topic of the article explore an idea using at least two different disciplines, where one involves mathematics education? Five of the 45 articles fit these criteria and comprise the data for this study. We describe each article here. Bruce et al. (2017) explored spatial reasoning across mathematics education, mathematics, psychology, and neuroscience. Goos and Bennison (2018) investigated faculty collaboration in mathematics content and methods courses. Krummheuer, Leuzinger-Bohleber, Müller-Kirchof, Münz, and Vogel (2013) used a socio-constructivist approach from mathematics education and psychoanalysis to explain a child's mathematical creativity. Ramful and Narod (2014) explored proportional reasoning in stoichiometry problems. Thompson et al. (2013) described revising a curriculum for college biology.

We examined the five articles using Schön's (1983) definition of practice. Each article was analyzed by each member of our research group to identify the purpose of the study, disciplines involved, and practices used by the authors. Practices were identified using phrases from the research articles. For example, the following quote was identified as practices for partnering researchers: "our Spatial Reasoning Study Group (SRSG) first gathered in 2012 to explore possible research synergies" (Bruce et al., 2017, p. 144). Practices that were similar to each other were grouped and given a descriptive title. The quote above was grouped with similar quotes using the title *partnering on similar research interests.* Using this method, we identified three groups of practices that comprise the findings of this paper.

Findings

Our analysis of the practices MERs used within the five articles resulted in the following groups of practices: *partnering on similar research interests, cultivating relationships that promote trust and open-mindedness*, and *receiving institutional support*.

Partnering on Similar Research Interests

Researchers in the five studies had a common research interest that aligned with their personal and discipline-based research paths. For example, the faculty in Thompson et al. (2013) were committed to the common goal of infusing quantitative approaches to the biological sciences curriculum and faculty partnered according to their research agendas. In Bruce et al. (2017), researchers formed a study group to explore the "role of spatial reasoning in mathematics teaching and learning" (p. 144). In Ramful and Narod (2014), Ramful, a MER, wanted to explore the role of proportional reasoning in stoichiometry problems. "I guess my intention in doing cross disciplinary research is to apply the theoretical understanding in mathematics education in the sciences" (A. Ramful, personal communication, December 20, 2018).

Cultivating Relationships that Promote Trust and Open-mindedness

Researchers described the need for trust and open-mindedness among the group to understand each other's points of view. Goos and Bennison (2018) described how MERs and mathematicians recognized the importance of trust to improve the mathematics content and methods courses. Bruce et al. (2017) explained that working with people from different disciplines "entails careful study of discipline-specific vocabularies and methodologies, alongside the articulation of problems in ways that permit all potential research collaborators to identify and situate themselves. It might also require patience and perseverance" (p. 158). In Thompson et al. (2013), a core set of faculty and staff participated in nearly all efforts to revise the curriculum, which contributed to strengthening interpersonal relationships in the project.

Receiving Institutional Support

Personal and common research interests are not sufficient to promote interdisciplinary research collaborations. Institutional support was also identified as a key practice among the articles. Bruce et al. (2017) described, "[t]ransdisciplinary will not always be a comfortable fit in institutions that have been traditionally defined by rigid boundaries, vertical hierarchies, and fixed agendas" (p. 158). Thompson et al. (2013) noted that building a shared vision, college-level support for the work (e.g., release time, funding, alignment to college goals), and open conversations about course outcomes allowed the interdisciplinary curricula to be built by the group. Noting a lack of institutional support, Goos and Bennison (2018) described struggles that faculty faced due to distant campus locations, or because their work was not seen as part of their workload, but as they were seeing as "doing extra stuff" (p. 266).

Discussion and Conclusion

We explored the practices MERs used when working in interdisciplinary groups. In our data, MERs were studying concepts using multidisciplinary or interdisciplinary lenses or designing interdisciplinary curriculum. These articles included descriptions of practices that were important features of their collaborations. These practices are described in this research as *partnering on similar research interests, cultivating relationships that promote trust and open-mindedness,* and *receiving institutional support*.

Our work followed Schön's (1983) view of attending to problem settings when working in interdisciplinary groups. Our study brings attention to limitations of seeing interdisciplinary research groups as solvers of problems, which neglects group members that want to be trusted and heard (Bruce et al., 2017; Goos & Bennison, 2018; Thompson et al., 2013). It is important for researchers to acknowledge the individuals involved in the groups to successfully conduct their studies.

While the focus of the articles was not to highlight the practices researchers used while conducting their studies, almost all of them referred to practices. Goos and Bennison (2018) is an exception to this because the purpose of their research was to explore practices and learning mechanisms experienced by mathematicians and MERs during their collaboration. This article in particular, prompted us to consider how practices influenced the outcomes of research collaborations.

Being exposed to other methods brings opportunities for MERs to develop new understandings of a topic. In our data, the authors describe how collaborating with people from other disciplines brought them to know concepts in a new way. In Krummheuer et al. (2013), using a socio-constructivist perspective of mathematics learning with a psychoanalytic attachment theory helped the research team describe a child's mathematical creativity. Ramful and Narod (2014) learned that stoichiometry problems had different levels of difficulty for students when the problems involved proportional reasoning. Bruce et al. (2017) concluded that using a transdisciplinary approach could address "complex issues related to teaching and learning mathematics" (p. 157). As the field of mathematics education explores issues that are of interest to other disciplines, Bruce et al. (2017) called for MERs to "combine insights and the interdisciplinarian's practice of conducting parallel analysis" (p. 157).

We acknowledge the challenges of defining boundaries in a literature review search (Kennedy, 2007). Our findings were restricted to mathematics education journals identified by Scopus and Ebsco databases. We recognize that some journals, chapters, and commentaries are left out of these databases. Given that our search for data resulted in only five articles, we plan to interview interdisciplinary groups containing at least one MER to explore their practices and compare them with the ones identified in this paper.

Although interdisciplinary research is often portrayed as researchers coming together to solve a problem, we illustrate how consideration of problem setting helped identify three practices that were important for success of an interdisciplinary research group that included a MER. We hope these findings contribute to the construction of a new horizon where MERs feel fulfilled when engaging in multi-, inter-, trans-, and meta- disciplinary research projects.

MORE THAN "DOING A GOOD JOB": COACHING FOR MEANINGFUL ENGAGEMENT WITH MODEL-ELICITING ACTIVITIES

Courtney K. Baker
George Mason University
cbaker@gmu.edu

Tammy S. Kraft
George Mason University
tkraft2@gmu.edu

Terrie M. Galanti
George Mason University
tgalanti@gmu.edu

Mathematics specialists are often challenged with shifting instructional practice in school settings. This qualitative study examines two mathematics specialists' facilitation of The Box Turtle model-eliciting activity (MEA) in their schools. While the mathematics specialists had received multi-year professional development on the potential affordances of MEAs, the initial implementations in K-6 classrooms challenged their presumptions about how mathematics needed to be taught and learned in their schools. Preliminary analysis identified two important findings about the mathematics specialists' positioning in bringing innovative STEM curricula to their schools. They witnessed the potential for MEAs to equitably engage students in mathematics process standards, and they were ready to advocate for more meaningful change as they began to design future MEA implementations to connect to content standards.

Keywords: Mathematics specialists, Model-eliciting activities, Equity, Instructional vision

Purpose of Study

This project drew upon educational research expertise across the STEM disciplines to develop and implement a model-eliciting activity (MEA) using data from the Smithsonian Conservation Biology Institute. University researchers collaborated with mathematics specialists, teachers and administrators in Port City Public Schools (PCPS) to develop and pilot the Box Turtle MEA. This paper explores how mathematics specialists supported the early adoption of this innovative curricular resource in K-6 settings. It will contribute to the base of research on mathematics specialist-teacher facilitation of modeling experiences and interpretation of student mathematical thinking. This research team aims to advance the relevance and affordances of MEAs across multiple fields. Specifically, we theorize the mathematics specialist as an agent of sustained curricular change within K-6 settings. We explored the following research question: In what ways does the positioning of mathematics specialists influence the outcome of MEA implementations in K-6 classrooms?

Theoretical Framework

School divisions and policymakers across the United States have "embraced" STEM (Bybee, 2010), yet mathematics may be set up to play only a supporting role in STEM integration (Fitzallen, 2015) when it is characterized as the computations or the data representations in science classrooms and technology labs. MEAs encourage ideation, testing, and revision (Zawojewski, Hjalmarson, Bowman, & Lesh, 2008) and engage elementary school students with mathematics in novel ways. MEAs also promote greater equity in mathematics assessment by shifting the focus from memorization of procedures toward "spurring, nurturing, and supporting mathematical contributions from a larger pool of students" (Lesh, Hoover, & Kelly, 1992, p. 1). Prior research has described mathematics specialists' beliefs in the power of MEAs to elicit a new vision of STEM integration for their teachers through open-ended mathematics problems with client-driven, real-life contexts (Baker & Galanti, 2017). However, there is limited research on how mathematics specialists can build this capacity in their schools.

McGatha and Rigelman (2017) define a mathematics specialist as “a professional with an advanced certification as a mathematics instructional leader or who works in such a leadership role” (p. xiv). The National Council of Teachers of Mathematics (NCTM, 2014) acknowledges the critical role of mathematics specialists in enhancing teacher capacity to enact research-based teaching practices. Mathematics specialists face many challenges, including meeting the expectations of multiple stakeholders in the school system (Chval, et al., 2010), while teaching the learning of mathematics to those involved (Felux & Snowdy, 2006). The impact of these unique challenges and environments highlights the varying roles and responsibilities mathematics specialists take on and the stakeholders they must support (Chval, et al., 2010). However, changing the mathematics practice within a school takes time, and it is essential to examine both how mathematics specialists position themselves as change agents in addition to the results of their actions.

Method

Design-based implementation research (DBIR) is a methodology in which stakeholders are committed to iteratively developing an educational innovation with a goal of broader and sustainable impact (Penuel, Fishman, Cheng, & Sabelli, 2011). This collaborative PD connected an emerging body of research on MEAs which “engage learners in productive mathematical thinking” (Hamilton, Lesh, Lester, & Brilleslyper, 2008, p. 5) to STEM integration efforts within one school division and built upon a multi-year school-university partnership (Baker & Galanti, 2017).

Setting and Participants

PCPS is located approximately 30 miles from a major city and has 7,605 students; (60.6% Hispanic, 18.4% white, 12.1% black). Within PCPS, 42.4% of students have limited English proficiency (STATE, 2015a), 73% are traditionally underserved and 53% are economically disadvantaged (STATE, 2015b). All seven elementary schools in this division hold Title I designation. Four have subgroups with proficiency gaps in mathematics of 15% or higher in either the black or Hispanic subgroups (STATE, 2015a). Specifically, this qualitative research examines the positioning of two full-time mathematics specialists: Mary, a veteran mathematics specialist situated in one school (grades K-4) full-time, and Katherine, a novice mathematics specialist equally split between two intermediate schools (grades 5-6).

Data Collection

The university-school division partnership drew upon research on specific enactments of MEAs as tools in mathematics education and explicitly focused on mathematics coaching as an in-situ resource to advance mathematics content in K-6 classrooms. Purposeful sampling was utilized as the nature of the stakeholders’ interactions warranted further exploration of these groups (Patton, 2002). Qualitative data sources such as participant surveys, observations, individual and focus group interviews, and MEA work samples were used to characterize the enactment as a vehicle for STEM integration.

The Box Turtle MEA

The Box Turtle MEA drew upon data from the Smithsonian Conservation Biology Institute and was aligned with state standards in mathematics, literacy and science so that the K-6 school stakeholders could flexibly implement the MEA to meet their instructional needs. Triads of mathematics specialists, classroom teachers and administrators were came to the Smithsonian-

University School of Conservation to experience and reflect on this novel MEA firsthand prior to implementing at their schools. The initial exploration allowed school stakeholders an opportunity to not only analyze their own collaborative engagement with this particular MEA as learners but also to reflect on transferring these ideas to their practice. The focus of the Box Turtle MEA centered on determining individual turtle's ages and creating a generalizable procedure for the client, a county park ranger. MEA materials included images of eight box turtle plastrons (bottoms), a map of where each turtle was found, and a description of the specific terrain.

Data Analysis

We identified relevant information through the use of open coding (Merriam, 2009) and collaborated to categorize codes after examining documents. Upon completion of the analyses, categories were grouped and the reduction of these categories led to the emergence of a select few themes. Internal validity was developed by searching for alternative explanations. Incorporating multiple sources into the research design was a purposeful decision that provided validation for our findings and helped to achieve construct validity (Maxwell, 2005).

Results

Mary positioned herself as a co-teacher. She identified a first-year teacher to work with in order to "build capacity" with "a willing participant." Katherine positioned herself as a provider of resources. She identified twelve teachers across two grade levels who collaboratively implemented the MEA. Findings indicated that there were two primary outcomes of the mathematics specialist positioning as they responded to their contextual needs: the potential for MEAs to equitably engage students and productive reflection to inform and advocate for future implementations.

Potential for MEAs to Equitably Engage Students

Mathematics specialists and the classroom teachers they collaborated with cited their enjoyment in the MEA training as the motivating factor for implementing the Box Turtle MEA within their schools. Prior to the implementation, mathematics specialists expressed concerns about school buy-in, teacher beliefs that MEAs were only for advanced learners, and MEA mathematical content not aligning with content standards and pacing. After implementation, mathematics specialists and teachers found that their initial concerns were unwarranted as MEAs afforded them and their students' opportunities to access new understanding of content and pedagogy.

> I've learned that it's important for teachers to see that all students can access MEAs and have entry points into the lesson. It's important to give teachers opportunities where they can see that their students can do things they think they can't. (Katherine)

Specifically addressing the "our students can't do this" concern, teachers noticed that "their" students found multiple entry points, were engaged and willingly took on the roles of collaborators, communicators, problem-solvers, and citizen scientists - making hypotheses and exchanging ideas. In this manner, students took ownership of their learning and the products of their thinking. "The equity for all kids to be able to jump in at any level was built in so that every single child felt as if they could participate at their level" (Mary).

Over the course of the implementation, teacher views evolved from MEAs as "fun" activities to MEAs as rich mathematics tasks with the potential to engage learners in productive mathematical thinking. Mathematics specialists played a major role in fostering these evolving views by facilitating discussions prior to and after the implementation.

> I don't think (the teacher) saw the richness of the math until we had the discussion about the process goals. She and I have talked about the process goals and how those overarching pieces are so much more important to be able to facilitate math long term and that way she sees the math application in the project. (Mary)

Reflection on MEAs to Inform and Advocate for Future Implementations

At the conclusion of each MEA implementation, the mathematics specialists reflected on specific actions required to continue the relationships with the identified teachers and generate additional buy-in from other school stakeholders. Katherine spoke of the need to ensure everyone involved understood the embedded mathematics content within the MEA. "All teachers need to experience the MEA before facilitating with their students - coaches need to do the math (with their teachers?) before they collaboratively design the lesson." Mary identified ways in which she could connect future MEAs to other school initiatives and even the district pacing guide. "I would like to use MEAs to kick off units. I would love for students to delve into an open-ended problem and use that as background information [that is applied] as they go through a unit of study." Katherine also spoke of the essential work required to connect MEAs to teachers' current instructional practices in order for MEAs to be sustained within the school district. "A long-term goal for me with MEAs is to incorporate them into a unit of study to really deepen students and teachers understanding of the units and to build their connections" (Katherine).

Discussion

While MEAs have been an instrument for research on modeling in K-16 mathematics education for nearly 20 years, recent studies in elementary classrooms describe MEAs as rich mathematics tasks with problem solving potential (Bostic, 2012; English, 2017). The mathematics specialists' experiences with the Box Turtle MEA, first as learners and then as teacher leaders, allowed then to see the curricular potential of MEAs as more than fun, supplementary activities. The Box Turtle MEA connected their personal commitments to making mathematics learning more equitable in their schools and their pedagogical goals of engaging students in more meaningful STEM content experiences. Each mathematics specialist described the multiple entry points as the key to engaging all learners in problem solving and communicating. Thus, the Box Turtle MEA provided a vehicle for mathematics specialists to challenge the status quo of mathematics instruction and to promote more equitable instructional experiences. MEAs more generally became a window on the realizable potential of promoting positive math identities for students who may not have previously experienced success.

> One of our students who just really has a hard time focusing on school and is always a behavior concern, was doing the best I've ever seen him do. He was so engaged which was very interesting to me. I [shared with his teacher] that she needed to document that, needed to write that down. He's working with a group. He's doing a really good job. What more could you ask for? (Emma, intermediate classroom teacher)

However, it is important to purposefully reflect on what it means to do a "good job" in mathematics classrooms. As we continue to collaborate, design, and facilitate future MEAs as equitable curricular elements, the following question needs to be at the forefront of our thinking: How do we make sure that doing a 'good job' translates to learning? Identifying ways in which mathematics specialists not only highlight these critical content connections but also relate particular MEAs to their mathematical objectives will define the next steps in our research.

CONTROLLING FOR RACE IN MODELING MATHEMATICS TEACHERS' "VALUE-ADDED"

Phi Nguyen
University of Missouri
phinguyen@mail.missouir.edu

Cara Haines
University of Missouri
carahaines@mail.missouri.edu

We analyzed district leaders' and mathematics teachers' interpretations of race as a control variable in value-added measures of teaching effectiveness and found three distinct interpretations. Participants argued that controlling for race: (1) produces more precise statistical models; (2) removes dis-incentives from teaching particular student populations; and/or (3) creates fairer teacher evaluations. Implications for equity and policy are discussed.

Keywords: Value-added, Teacher assessment, Policy, Equity

Using value-added modeling (VAM) to assess teacher effectiveness has been a controversial issue. Though some have embraced VAM, many researchers have criticized the approach for its statistical limitations (Darling-Hammond, Amrein-Beardsley, Haertel, & Rothstein, 2012; American Statistical Association, 2014) and its role in high-stakes evaluation systems that determine compensation or termination of employment (Harris, 2009; Konstantopoulos, 2014). One consistent point of contention has been the relation between student background factors, such as race and socioeconomic status, and measures of achievement. In investigating this issue, the Value-Added Research Consortium compared multiple value-added models, with and without race and other demographic factors, and found that teachers' contributions to student achievement were often sensitive to these variables (University of Florida, 2000). In contrast, Ballou, Sanders, and Wright (2004) reported that the introduction of student background controls to the Tennessee Value-Added Assessment System (TVAAS) had only a negligible impact on predicted teachers' contributions. Prior, TVAAS had only implicitly controlled for student demographic factors to the extent that their influence on post-achievement data was already reflected in pre-data. Though much of the discourse around VAM, particularly the influence of student-level factors, has been concerned with statistical validity and reliability, some scholars have also considered issues of equity. For example, Rivers and Sanders (2002) asserted that VAM data could aid school leaders in problematizing and addressing existing policies that disproportionately assign less-effective teachers to schools with low-income, marginalized student populations. In contrast, Johnson (2015) argued that evaluation based on value-added measures may discourage effective teachers from working in high-need schools.

As one of the two most tested subjects (U.S. Department of Education, 2002; 2015), mathematics is especially vulnerable to implications of student achievement-based teacher assessment policies such as VAM. Differences in test scores have also attracted considerable attention to racial "gaps" in mathematics opportunity and achievement (Flores, 2007). If value-added policies are to improve teaching and learning, particularly for historically marginalized populations, it is important to attend to how district leaders and mathematics teachers frame race as a control variable, as their discourse can help to either maintain or transform institutional culture (Bertrand, Perez, & Rogers, 2015). For example, the ways teachers frame VAM as being unfair to those who work in more challenging schools are rooted in deficit assumptions about African American, Latinx, and Native American students (Jiang, Sporte, & Luppescu, 2015).

Consequently, discourses around value-added policies contribute to the social devaluation of these students and reinforce the racial hierarchy of mathematical ability narrative (Martin, 2009). In this paper, we draw on critical race theory to pursue the question of how district leaders and mathematics teachers interpret race as a control variable in teacher value-added measures.

Theoretical Perspectives

Originating in legal scholarship (Bell, 1992) and introduced into education by Ladson-Billings and Tate (1995), critical race theory (CRT) challenges the view of racism as a problem of individual beliefs and prejudices and instead interrogates how structures and discourse reproduce and normalize racism. Aligning with perspectives that view race as socially and politically constructed, we see district leaders and teachers as consumers and producers of racial ideologies and discourses. In examining their interpretations of race as a control variable, CRT's theoretical arguments, including the view that racism is endemic and skepticism towards claims of objectivity and meritocracy, guided us in interpreting the race-related structures of inequity that are reproduced through the formulation and enactment of value-added policies. As an enterprise, it is important for mathematics educators and policy makers to understand how value-added policies might allow racism to function in the teaching and learning of mathematics and contribute to broader narratives about who is (and is not) good at mathematics (Martin, 2009).

Methods

Our investigation originated from a multi-year, multi-institutional partnership with an urban school district in the northeast US focused on addressing racial (in)equity in secondary (6-12) mathematics. At the time, the district was focused on launching a new teacher evaluation system that included observation, student surveys, and value-added modeling of standardized state test scores. Unlike the state's value-added model that used a longer history of achievement, the district's model incorporated demographic control variables including race. The district was also pursuing equity-focused efforts such as establishing a central equity office and attending to equity in district initiatives, including curriculum and professional development, and personnel evaluations. The student population was approximately 55% African American and 33% White, with 62% identified as economically disadvantaged.

A variety of data was collected for the partnership's primary efforts, including annual interviews with district leaders and mathematics teachers. All interviews were audio-recorded and transcribed. For the investigation discussed in this paper, we focused only on interviews in which participants addressed the district's teacher VAM. Within these interviews, our main focus was district leaders' and teachers' discussions of race as a control variable, but we also considered general responses about teacher VAM to understand the broader district policy context. The data set for this analysis included 20 interviews with 19 individuals. The individuals held a range of positions at the district and school levels. Nine participants were district leaders (e.g., assistant superintendents; directors of district departments) and the other 10 were teachers from seven different middle or high schools. We analyzed interview transcripts with the purpose of identifying different interpretations that emerged from the data for controlling race in teacher value-added models. Our analysis was informed from the literature previously reviewed, including arguments for statistical precision (e.g, University of Florida, 2000), not dis-incentivizing teachers to work in high-need schools (e.g., Johnson, 2015), and fairness for teachers (e.g., Jiang, Sporte, & Luppescu, 2015). We analyzed the interviews and identified a single response category in some, and multiple in others, and then revisited our initial pass to refine our characterizations of the categories. Peering through a CRT lens, we also considered whether and how district leaders and teachers reinforced deficit assumptions of historically marginalized student populations and perpetuated claims of objectivity and meritocracy.

Results

Our analysis resulted in the identification of three distinct interpretations among district leaders and teachers for why and/or what it entails to control for race in teacher VAM. We present each of the explanations accompanied by relevant interview data and brief discussions.

The Statistical Precision Interpretation

The first rationale is that controlling for race and other demographic factors results in more precise statistical models. For example, Taylor, a district leader, discussed:

> Our value-added measure only looks back at up to 2 years of previous assessment results, and then pulls in student demographic information like race. [The state model] pulls as many years as back as they have available in terms of assessments and so essentially, those 2 approaches end up being very very similar in terms of the extent to which, um, the results are controlled for things are outside of teachers' control, right? So, for what we lack in terms of only pulling two years of data back, we kind of gain with the demographics. And then, essentially, [the state model] doesn't need to include the demographics because going all the back to all the assessments that are possible, they kind of build a full picture from that lens… we've actually done analyses looking at teacher level [state model] and value added, and for the vast majority of teachers, they're getting pretty similar signals from both of the systems.

In both the district and state VAMs, the focus was on producing precise estimates of what an individual teacher contributes to a student's success as compared to what a history of achievement (or demographic factors) would suggest. In comparing the two, Taylor suggested that controlling for demographic factors is a statistically valid substitute for a longer history of achievement. By invoking statistical precision as basis for comparison, both models claim objectivity, yet fail to account for why the correlation that supports such a substitution exists. In particular, neither model explicitly attended to the influence of institutional racism on achievement. As such, both value-added models contribute to color-blind ideologies in which race (beyond its framing as a categorical variable) is portrayed as irrelevant to understanding students' learning and school experiences.

The Removing Dis-incentives Interpretation

The second rationale is that VAMs include demographic control variables so that teachers are not dis-incentivized to work in schools with particular student populations. In explaining the decision for incorporating race as a control variable, Morgan, a district leader, said:

> It came down to the idea that we want to incentivize our best teachers to work with our most challenged students. And if we are not recognizing the additional challenge that these students present and don't give them essentially, you know credit for that then, we would be dis-incentivizing that. And you know we felt really comfortable about using this as a control when we're looking at teachers because this is not something that's within the teacher's control.…And we're actually encouraging schools to work towards evidencing significantly higher contributions for African American students than all their other students in the school, because it's only through achievement of that type of pattern that we will actually be unpacking and eliminating any sort of racial disparities.

Morgan suggested that including race as a control variable in the district's value-added model might incentivize teachers to work in predominantly African American schools, as doing so would account for the "additional challenge that these students present." Though Morgan acknowledged the role of structural inequities (e.g., distribution of high-quality teachers) in student achievement differences, the cause of those differences was attributed to student characteristics. That is, rather than recognizing inequitable social structures that often affect schools that are predominantly African American (e.g., a lack of resources), Morgan suggested that teachers are unmotivated to teach at such schools due to the inherent qualities of its students. Moreover, Morgan's framing of students' racial identities as an "additional challenge" communicates (and reinforces) deficit narratives of African American children.

The Fairness Interpretation

The third interpretation we found is that, in controlling for race, teachers are more fairly evaluated. This argument stems from the notion that student characteristics (e.g., race) and circumstances (e.g., economic status) influence their achievement, and therefore mediate teachers' contribution to student achievement. For example, Mason, a teacher, explained, "I do like [the district's] value added measures as far as they take in more factors based on kids' individual issues… Our population is much different than our suburbia populations. I don't think it's fair that we're under the same microscope as teachers at other districts." Like Morgan, Mason engaged in deficit discourse by attributing differences in achievement to student qualities rather than structural disparities such as the inequitable distribution of resources and quality teachers. In doing so, this interpretation perpetuates the myth of meritocracy in which students' academic achievements depend on their individual merits rather than the (lack of) structural resources and opportunities they are afforded. Mason's interpretation also centers teachers and their evaluation rather than students and their learning opportunities.

Discussion & Conclusion

Our study contributes to the research base on value-added measures by exposing issues of equity that are often overshadowed by statistical concerns. In their interpretations of race as a control variable, district leaders and teachers employed deficit-oriented talk in attending to student qualities – in some cases, even as they were describing the district's VAM policy as part of a broader set of equity-focused initiatives. Though, in failing to account for the reality of institutional racism, they reinforce the "discourse of deficiency" that views these communities as lacking the resources to be academically successful, alongside a mathematics education discourse that mathematics is a discipline in which those who are successful are White, middle-class males (Martin et al., 2017; p. 623). Using CRT to analyze one district's framing of race in VAM uncovered the ways deficit discourses reproduced the inequitable status quo.

Our purpose for this paper was not to argue if/how race should be controlled in teacher value-added measures, nor to uncover all the possible interpretations of controlling for race. Rather, in revealing the ways racial discourses were operating and being perpetuated in district leaders and teachers' interpretations, we provide evidence for why researchers and policy makers should move beyond methodological considerations in the formulation and enactment of value-added policies. If such policies are to address racial (in)equity, our findings suggest a need for a more critical conceptualization of race that centers student learning and school experiences rather than teacher evaluation. This includes not only an explicit attention to the influence of institutional racism on achievement, but also a consideration of the ways in which the enactment of and discourses around value-added policies shape students' learning opportunities.

This research report discusses a study of mathematics specialist candidates' response to and reflection on equity supporting practices in a K-12 setting. In this study, mathematics specialist candidates learned a structure that encourages mathematics discourse and sense-making. They received English learner-specific professional development in implementing number routines and reflected on their practice as it relates to their learning, student learning, and the learning of the professional community. Preliminary findings suggest that EL-specific professional development increases understanding of equitable instructional practices and supports culturally responsive instruction.

Keywords: Instructional leadership, Equity, Teacher educators, Teacher knowledge

Mathematics education is compelled to address issues of equity in mathematics classrooms by preparing teachers and school leaders for working with diverse populations. One of the challenges faced by school districts is that the number of mathematics teachers who are adept at differentiating for the needs of ELs is not keeping pace with the demand for these highly-qualified teachers. While there has been a consistent increase of ELs in the schools, professional development for teachers on EL-specific knowledge and skills has not increased at the same rate (Lucas & Villegas, 2013; Quintero & Hansen, 2017; Ross, 2014).

Providing appropriate professional learning for in-service mathematics teachers to work with ELs in the mathematics classroom is a complicated task. Given the large number of mathematics teachers, a systematic way to provide accessible, ongoing professional development for in-service teachers is required to develop the specific linguistic and cultural knowledge and skills for working with ELs (de Araujo, Roberts, Willey, & Zahner, 2018; Lucas & Villegas, 2013; NCSM/TODOS, 2016). We began this study to consider a method for fostering equity of student voice through professional learning around number sense routines for mathematics specialist candidates in a master's program at George Mason University (MASON). This targeted professional development experience offered candidates a structure to share with teachers in order to promote productive language use in mathematics classrooms.

Research Question

How do math specialist candidates respond to and reflect on professional learning around supporting ELs in classroom number routines?

Theoretical Framework

Equity

Understanding that our context matters (Gutiérrez, 2012), and given that we are all White, female educators from a highly-resourced area that is linguistically and culturally diverse, and our mathematics specialist candidates are also predominantly White and female, it is important that we intentionally focus on equity as part of the mathematics specialist program. We must recognize our positionality in relation to access to high-quality education and our responsibility for making high-quality education accessible for the culturally and linguistically diverse learners in the settings where our candidates work. Gutiérrez (2012) identified dimensions of equity supporting a *dominant axis*, the traditional role of students and education in society, and a *critical axis* that reflects the position of students in society. This study was designed to support equity on both axes by providing professional learning for the mathematics specialist candidates around understanding the assets and needs of ELs in a classroom discourse activity. Candidates learned to provide opportunities for access (*dominant axis*) and supportive practices for empowering students as classroom discourse participants (*critical axis*) (Gutiérrez, 2012).

The Roles of Language in Learning

There exists an assumption that good teaching for native English-speaking students is adequate for teaching ELs (de Jong & Harper, 2005), so teachers are not given specific training for working with linguistically diverse learners. De Jong and Harper (2005) offer a framework for the consideration of the role of language in education that makes explicit what mainstream teachers need in terms of knowledge, skills, and dispositions to successfully meet the needs of English learners. Language allows teachers and students to tap their individual and common funds of knowledge to anchor new learning. As such, teachers need an understanding of the language acquisition process to be able to support student development in language and literacy through the content (Bunch, 2013; de Jong and Harper, 2005; Faltis & Valdés, 2016). They also need the ability to identify the language demands of a mathematical task (Lucas & Villegas, 2013) and a collection of scaffolding strategies for ELs. Providing EL-specific professional learning for teachers around the roles of language and culture supports increasing teachers' sense of self-efficacy for working with ELs (Ramos, 2017; Ross, 2014) and promotes the positive dispositions of teachers for the roles of language and culture instruction, in addition to the content (de Jong & Harper, 2005).

Number Routines

A number routine is a brief, planned classroom activity that enhances students' ideas of magnitude, supporting calculation strategies and skills in manipulating numbers. As an oral and aural activity, a number routine promotes language use. Mathematics education is called to move beyond rote memorization of procedures and focus on conceptual understanding and mathematical reasoning (CCSSI, 2010; NCTM, 2000). Number routines may help educators make the shift to fostering reasoning and sense-making through oral routines that also provide access for ELs who may be stronger in oral language skills (Chen & Bofferding, 2017; Humphreys & Parker, 2015) by having students communicate their thinking and develop "more accurate, efficient, and flexible strategies" (Parrish, 2011, p. 199). Teachers' roles as facilitators (Chen & Bofferding, 2017) of the discussion are reliant on their ability to anticipate student responses and have strategies to respond and move the conversation along with appropriate instructional moves that support all students' participation (Anderson, Chapin, & O'Connor, 2011).

Method

Context

Participants were candidates in a Mathematics Education Leadership Master's Degree Program at MASON. The program consists of 10 courses, five content-related and five leadership-related. The mathematics specialist master's program at MASON develops teacher leader skills and dispositions (Baker, Bitto, Wills, Galanti, & Eatmon, 2018) that support our specialist candidates to provide ongoing support for teachers with whom they work and to advocate for best practices that foster equitable access for all students. The candidates were enrolled in two sections of a mathematics content course in Fall 2018, Number Systems and Number Theory for K-8 Teachers: one a traditional face-to-face format; the other a 100% synchronous online format. The course is designed to meet NCTM content and process standards for mathematics specialists (NCTM, 2012) and uses the *Principles to Actions* (NCTM, 2014) as reference for equity practices.

As part of the course, candidates learned about using oral number routines in mathematics classrooms to develop conceptual understanding and fluency while also supporting mathematics discourse. The assignments contained two opportunities to research, design, and implement a number routine. After the first number routine assignment was completed, and before the second number routine was planned and presented, a short intervention was provided to each class as a mini-lesson on understanding the role of culture and language for ELs during number routines and possible scaffolds and supports that could be used to support EL participation. The WIDA English language development standards (WIDA, 2012) provided the framework, including examples of appropriate questioning and responses to be expected at each level of English language development.

Participants

There was a total of 31 mathematics specialist candidates across the two sections; the majority (90%) were female. They were 77% White, 16% African American, and 7% Other. The candidates represented various public school districts in Common Core and non-Common Core states, and one was overseas in a Department of Defense Education Activity (DoDEA) school.

Data Collection and Analysis

Reflection assignments for each shared number routine submitted by the candidates were collected and analyzed. One experience preceded a brief lesson on EL assets and strategies for supporting ELs during a number routine, and one followed. In addition, researcher observations and shared slides from each experience were also considered in the analysis.

The student work was analyzed qualitatively using a phenomenological approach (Creswell & Poth, 2017), looking for patterns in participant behavior or expression. Specifically, any mention of consideration for EL needs or supports to facilitate participation by ELs or specific groups of students was noted. In addition, in vivo coding (Saldaña, 2016) was used to capture the participants' words as they expressed examples of the reflections discussed below.

Results

Reflection Prior to Intervention

Prior to the explicit instruction on language and cultural understandings needed to support ELs in mathematics and, specifically, during a number routine, the reflections of the mathematics specialist candidates were focused solely on the procedures for the number routine and their role as teacher more than the students' role as participants in learning. None of the reflections noted differentiation for ELs or students who require additional support. While there was little reflection on supporting diverse learners, there was a good amount of reflection on the learning of the practice of number routines and some potential challenges. One candidate noted, “There were a lot of people sharing their thinking, but there were also many people who didn’t get a chance to share at all. Those students were only able to practice their receptive communication skills.”

Reflection After Intervention

In the second round of number routines several groups tried “Which One Doesn’t Belong” (WODB, 2013) and similar routines noting that the multiple possible responses, as well as multiple strategies for answering, was supportive of increasing participation among the students, “The visual nature of the WODB routine was the first layer of support we selected to give English language learners (ELLs) an entry point in discourse,” using sentence frames as scaffolds.

Candidates also reflected on a significantly increased number of strategies they employed to support participation of students, and ELs in particular, in the routine based on English language proficiency levels (WIDA, 2012). These included such supports as leveled sentence frames, word banks, pictorial representations, visualization strategies, and anchor charts. Several candidates noted the increased confidence of their students in addition to their own increased confidence with the routines.

Discussion

We recognize that the intervention provided on knowledge and skills for working with ELs was not the only factor that supported the growth of the mathematics specialist candidates in this study. However, the significant increase in their consideration and implementation of EL-specific strategies and their increased reflection on participation of all students is notable in the second round of reflection papers.

For mathematics specialist candidates, this experience with classroom number routines is one that can be easily replicated for supporting teachers of diverse learners with little impact on instructional time; teachers can see it as a routine that is easy to try and implement. One participant reflected, “I plan on using some of these resources with new teachers at my school during a planning meeting. I want them to have another option of things they can do with their students to activate prior knowledge.”

For future consideration of these methods and outcomes, we may consider changing the assignment to include a requirement for considering differentiation strategies in the candidates’ preparation for the initial number routines to provide consistency in assignment expectations for both experiences. Additionally, having similar opportunities in subsequent courses in the cohort may provide a more longitudinal look at the effects of EL-specific professional learning.

By providing dedicated professional development on support strategies for EL students, mathematics specialist candidates, and by extension, the classroom teachers in their practice, directly promote the language use and contributions of EL students. The number routine shows evidence of being a high-leverage practice given the short time commitment and focus on oral language. They have the potential to support sense making around numbers and also to support a wide variety of oral language practices appropriate for ELs. To meet the growing need for mathematics teachers who are knowledgeable of language and cultural factors, scalability of this professional development is an area for future study.

HOW AN IMMERSIVE SCHOOL-BASED PARTNERSHIP SURFACED CRITICAL TENSIONS IN PRACTICE FOR PRESERVICE TEACHERS

Corey Webel
University of Missouri
webelcm@missouri.edu

Stephanie Hopkins
University of Missouri
sand54@mail.missouri.edu

Field experiences present an opportunity for preservice teachers to practice teaching skills in an authentic educational context. In this paper, we describe the case of a partnership between a teacher preparation program and an elementary school that included daily one-on-one sessions pairing junior-year preservice teachers with individual students to discuss mathematics (the "Math Buddies" program). The partnership brought significant tensions to the surface, including a conflicting vision of mathematics instruction between the partner school and the preparation program, which led to the eventual abandonment of the partnership.

Keywords: Field experiences, School partnerships, Joint work, Boundary practices

Research in teacher education has long emphasized the importance of clinical sites as an authentic opportunity to practice teaching skills (e.g., Darling-Hammond, Hammerness, Grossman, Rust, & Shulman, 2005). However, clinical work for preservice teachers (PSTs) occurs in spaces where there are a variety of programs, stakeholders, and potentially conflicting goals at play, and we argue that our field would benefit from detailed descriptions of the ways that the particulars of such clinical spaces get negotiated.

In this paper, we describe an example of a partnership between a teacher preparation program and "Briar Elementary School," which we frame in terms of "joint work" (Penuel, Allen, Coburn, & Farrell, 2015). Using interview and survey data, we describe the initial goals of the partnership from multiple perspectives, the ways in which those goals came into conflict as the partnership was implemented, the negotiation of specific features and logistics of the partnership over the course of the program, and the concerns that were and were not able to be addressed. We conclude our analysis with potential explanations for why the program was eventually abandoned, including implications of what might be seen as a failed attempt at joint work.

Rationale and Literature Review

Recently, there has been a shift in focus from developing knowledge *for* teaching to developing knowledge *through* teaching (Ball & Forzani, 2009). This could include a focus on specific teaching particular skills, like noticing or responding to children's thinking (Jacobs & Empson, 2016), or particular instructional activities that draw on children's thinking, like enacting a sorting task (Baldinger, Selling, & Virmani, 2016). These practices and activities are often developed through cycles of enactment to explore, rehearse, enact, and debrief (Lampert et al., 2013). However, *enacting* teaching practices requires contexts in which teaching is occurring; for preservice teachers, this usually involves field experiences.

In early field experiences, PSTs typically spend time in a classroom with a cooperating teacher while they take courses at the university. These experiences can be important sites of learning for preservice teachers (e.g., Borko et al., 2000), but the quality of such experiences can be highly variable (Darling Hammond et al., 2005). In many cases, field placement schools have only loose relationships with teacher education programs, resulting in the relegation of the school to a source of children to “practice on” rather than a more democratic partnership where all stakeholders contribute to the learning experiences (Zeichner, Payne, & Brayko, 2015).

Penuel and colleagues (2015), in describing partnerships between researchers and schools, contrasted “translation,” in which schools are expected to translate research findings into practice, with “joint work,” in which “both district goals for improvement and aspects of the research are defined and evolve through interaction, rather than being planned fully ahead of time or defined by either researchers or practitioners independently of one another” (p. 183). They describe “boundary practices,” which are “routines that only partially resemble the professional practices of researchers and practitioners” (p. 187) and include the crossing of typical boundaries in order to increase shared understanding of problems.

The boundary practice we focus on in this paper consists of structured one-on-one mathematical interactions between PSTs and elementary students (“Math Buddies”) that was negotiated as part of the partnership between the teacher preparation program and Briar Elementary. PSTs worked at the school from 8:00 am to 2:00 pm every weekday. Elementary children were selected from Grades 3 – 5 to be Math Buddies based on teacher recommendations. PSTs met with their Math Buddies for 30 minutes each morning and would spend the rest of the day either in methods classes or in their host teacher’s class. The partnership lasted two semesters, after which the program was discontinued, primarily based on the judgment of the director of elementary education at the teacher preparation institution.

Our goal in this paper is to document the tensions and conflicts that arose as stakeholders negotiated the details of how the Math Buddies boundary practice would be structured and supported. Our research questions are: 1) *What are the tensions between the goals articulated by major stakeholders in the proposed partnership?* 2) *How do these tensions play out in the negotiations of the details of the joint activities?*

Methods

Data Collection

Multiple interviews and meetings were conducted with the major stakeholders in the partnership, including the principal of Briar Elementary School (Kyle), the university instructors who held their classes at the school, and the director of elementary teacher education (Brittany). All names are pseudonyms except for Corey, the first author and instructor for the mathematics methods course. A meeting with teachers comprising the “math team” at Briar School was also recorded. In addition, we also analyzed data from PSTs enrolled in the elementary teacher preparation program, including three reflection papers spaced out across the semester, an anonymous survey collected mid-way through the semester, and anonymous course evaluations.

Data Analysis

Recordings of interviews and meetings were analyzed using V-Note, a software program that can be used to assign codes directly to audio/video data. We initially coded the data according to the goals each participant articulated about the partnership, as well as the strengths and concerns that were articulated as the semester progressed. On a second pass through the data, we identified tensions between how different stakeholders expressed their goals, strengths and concerns regarding the partnership. In the results section, we share these tensions in relation to specific components of the partnership (the schedule and the vision for mathematics teaching), highlighting the ways in which the tensions were undiscussed and unresolved at the administrative level, while becoming sources of increasing conflict for the PSTs.

Results

Shared Goals

Broad goals discussed by multiple stakeholders included supporting students' mathematical learning and providing opportunities for PSTs to practice teaching. The school principal, Kyle, described a need for additional resources to help with struggling students: "I wanted to have additional tutoring for our kids… I was worried that we would have students who were struggling and no one to help. I was trying to figure out, how can we get help?" Kyle met with university administrators to develop the idea of Briar Elementary hosting methods classes, with the rationale that PSTs would get more and better access to elementary children, and in turn would provide support for struggling students via one-on-one interactions. As Kyle described,

> The university would benefit in that their students will be exposed to lots of different teaching methods and be around the kids more, and we would benefit through the extra tutoring that we could get the students to do. It seemed like a win-win to me.

In Spring 2017, Brittany met with faculty who typically teach in the program to discuss the possibility of partnering with Briar Elementary. Corey, the instructor for the math methods course, was particularly drawn to the possibility of increasing the quantity and quality of opportunities for methods student to interact with children and their mathematical ideas: "our [PSTs] would get so much more time to talk to kids about math than they currently get." He also hoped that Math Buddies would constitute a more equitable partnership: "[The district] often doesn't feel like they are benefitting from this relationship and this is a way they can." Brittany, the director of elementary education at the university, saw the partnership as an opportunity to more authentically position the PSTs as professional educators and to help them understand the daily work of teaching: "being in this environment all the time, we are going to treat them like teachers." In summary, each stakeholder believed the partnership could be mutually beneficial, providing new learning opportunities for both elementary students and PSTs.

Tensions Over Specific Goals

The Math Buddies schedule. Over the course of the partnership, one substantial tension arose around the weekly schedule. Kyle wanted Math Buddy sessions every day of the week in order to provide as much support as possible to children, but Corey expressed concern about the time that would be needed for PSTs to debrief and make sense of children's thinking. At the same time, he wrestled with an obligation to ensure that the Math Buddies program was meeting a "felt need" for the Briar community: "we have been trying to be responsive to what is happening in [the Briar] class and what we are talking about in [our methods] class."

The schedule remained a source of tension throughout the semester. According to Brittany, PSTs voiced concerns amount of time they spent preparing for Math Buddies and their lack of time in host teachers' classes. Eventually a new schedule was negotiated for the Spring semester in which PSTs did not come to Briar Elementary on Fridays.

Vision for mathematics instruction. While Kyle did not fully articulate a vision for mathematics instruction, he provided a specific "Daily Five" routine in which groups of students (usually determined by "similar ability") rotated through stations. The teacher worked with each group for about 15 minutes, while other groups worked on other activities (games, fluency practice, a mathematics software program) that might not be related to the main lesson.

In contrast, the vision of mathematics instruction promoted in the methods course, drawing on recommendations set forth by the National Council of Teachers of Mathematics (2000; 2014), focused on posing problems, encouraging sensemaking, facilitating discussion between students, and developing understanding through a "launch, explore, summarize" lesson format in which all students work on the same task at the same time. While Corey hoped that Math Buddies would provide PSTs opportunities to practice skills like eliciting and responding to student thinking, he also acknowledged that the vision of teaching promoted in the course would likely be difficult to enact within the "Daily Five" structure expected at Briar.

These differences in vision for mathematics instruction created tension for the PSTs, who were asked to work on the practices being encouraged in the methods class and also respond to obligations to their Math Buddies. For example, in their reflections and evaluations, they conveyed many sentiments such as: "I am unsure about how meeting every day will help my math buddy in her math class," and "This experience probably helped [my Math Buddy] with word problems but not much else. Also, I wasn't allowed to tell her if she was correct or not when she answered each word problem which honestly seemed to be confusing for her…. While it is important to learn how to observe and ask guiding questions, I think it is also valuable to learn how to actually teach math too."

Our data showed that several PSTs perceived a clear distinction between the practices emphasized the methods class ("observe and ask guiding questions") and the needs of their Math Buddies. While both Corey and Kyle agreed that the program should help children and PSTs, they did not discuss the details of *how* it would do so, and did not connect the different contexts that children would experience to a coherent vision for mathematics teaching and learning.

The dissolution of the program. Though changes were made the second semester that seemed to improve Math Buddies, the change to a four-day schedule resulted in fewer opportunities for PSTs to see classroom teaching. This led them to question the benefits of being at Briar Elementary School, and their end-of-program evaluations were overwhelmingly negative. Based on these, Brittany decided not to commit to the program for the next year.

Discussion and Conclusion

From our analysis, we draw the possibility that the program did not create new tensions between the methods course and the field placement so much as it brought existing tensions to the surface in ways that PSTs could not ignore. Unlike typical arrangements, where PSTs fulfill obligations to the school context and university context in largely separate settings, in our project, PSTs had to respond to the pressures of the methods class and the pressures of the field placement *simultaneously*—that is, during their interactions with their Math Buddies (see Figure 2). On the one hand, they were obligated to demonstrate particular types of moves to elicit, support, and extend students thinking (Jacobs & Empson, 2016), which some seemed to interpret as being forbidden from confirming or critiquing student solutions. On the other hand, because they knew the Math Buddies and their teachers well, they felt obligated to support student learning, which many did not see as consistent with the use of supporting and extending moves. We conjecture that such tensions are always at play when PSTs move between their university courses and field placements, but the Math Buddies partnership made these particularly salient because PSTs were expected to respond to both sets of obligations in the same setting.

Other lessons learned from the partnership include a lack of attention to the needs and perspectives of the host teachers. At the December math team meeting, the teachers described a lack of clarity about what the Math Buddies were doing, and seemed to experience little agency in deciding what the program entailed or how it would meet their needs. In future such partnerships, we suggest a more substantive and inclusive process to develop and strengthen a shared vision across contexts, one that addresses the details of instruction and draws on a common conception of what it means to learn and do mathematics.

THE DISTANCE BETWEEN US: MATHEMATICS AND SPECIAL EDUCATION TEACHER EDUCATORS' EVALUATION OF PURPOSEFUL QUESTIONS

Rob Wieman
Rowan University
gomathman@yahoo.com

Mollie Sheppard
Saint Joseph's University
msheppar@sju.edu

Keywords: (Dis)ability Studies; Teacher Beliefs; Instructional Vision

Background

Just as special education and mathematics teachers are increasingly called upon to collaborate, special education teacher educators and math teacher educators increasingly share responsibility for training *all* teachers to work together to teach mathematics to a diverse population of students. However, research in math education and special education has led to different descriptions of "best practice," stemming from different ideas about content, students, learning and teaching (Boyd & Bargerhuff, 2009). Despite the apparent lack of alignment between special education and mathematics education *research*, there have been few attempts to examine whether special education and mathematics education faculty differ in their *practice*.

Our Study

In designing our study, we chose a problem of practice that would be very familiar to both mathematics teachers and special education teachers – posing purposeful questions (NCTM, 2014) to an elementary student with learning disabilities who asked for help with a word problem. We then asked a group of special education and mathematics teacher educators to rank a set of possible purposeful questions from most effective to least effective. We wanted to see how their rankings compared.

Findings

Our findings indicate that special education and math education teacher educators do have some general areas of agreement. All groups of teachers gave high rankings to initial assessment questions that probed the student's understanding and prior knowledge. Questions that focused on operations or directed students to a particular solution method were ranked low and described as overly leading by all groups. One interesting difference was in how the two groups ranked a question asking the student to underline important words in the problem. We hypothesize that mathematics teacher educators may see it as advocating a key-word strategy, while special education teacher educators may see it as an essential literacy and language support.

We see this work as pushing mathematics and special education teacher educators to move beyond the horizons that define their fields towards a shared understanding of mathematics teaching and learning for diverse groups of students. While we cannot say how different groups of teachers would use the information that they gain from their initial questions, our findings indicate that there may be fertile ground for future work in this area.

DEFINING STEM AND MATHEMATICS IN A STEM STANDARDS DOCUMENT

Miriam Gates
Boston College
gatesmd@bc.edu

Min Jung Kim
Boston College
kimbzw@bc.edu

Even though mathematics is part of STEM education, how the subject should be conceptualized is uncertain due to a lack of common definition and goals of STEM education. This paper addresses how STEM and mathematics are conceptualized in a state standards document by using a frame analysis and Ernest (1989)'s categories of mathematics.

Keywords: STEM, Mathematics, Policy analysis

As of 2016, forty-one U.S. States provide K-12 standards contain references to STEM education (Carmichael, 2017); however, there is no agreement in field about the definition of STEM (e.g., Breiner, Harkness, Johnson, Koehler, 2012; Sanders, 2009). Further, educators have expressed the concern that STEM experiences cannot replace courses within individual disciplines. In light of this concern and the explosion of policy documents around STEM, the purpose of this study, is to examine policy documents to understand how policymakers conceptualize mathematics in the context of STEM education policies. For this study, we have focused on the Maryland STEM Standards. The policy documents clearly lay out an integrated view of STEM, whereby the disciplines are supportive of each other (Carmichael, 2017). Both English (2015) and Fitzallen (2015) argue that in integrated applications of STEM education, mathematics has the tendency to be underrepresented or represented as only an applied science.

We undertook a frame analysis (Reese, 2001) to understand how STEM and mathematics were conceptualized in the Maryland STEM standard policy documents. To understand how mathematics was defined we analysed the policy documents using Ernest's (1989) categories: instrumentalist, Platonist, and problem-solving. The instrumentalist conception suggests mathematics is a collection of skills for application to another context; the Platonist conception identifies mathematics as a coherent static body of knowledge; and the problem-solving conception centers mathematics is a constructive, creative, human endeavor (Ernest, 1989).

As a result, we discovered that the instrumentalist view of the subject has the highest frequency, both in mathematics and STEM standards. This implies that mathematics in this document is generally conceptualized as a tool or set of tools that can be applied in contexts outside of mathematics itself. After the instrumentalist view follows the Platonist perspective. Finally, the view that considers mathematics as a creative human endeavor came in last. Similar to this pattern, we found that 62% of the standards are designed to enhance students' career-related skills. With a heavy emphasis on how STEM education prepares students for future careers, mathematics is considered a set of knowledge that can be used to seek complicated solutions in interdisciplinary contexts. We believe that the findings raise a very important question - what is the purpose of STEM education as separate or the same as mathematics education? We suggest that the way that mathematics will be portrayed in future STEM projects depends on the purpose of those projects.

INTEGRATING 360 VIDEO INTO A MATHEMATICS METHODS COURSE

Karl W. Kosko
Kent State University
kkosko1@kent.edu

Keywords: Instructional activities and practice; Technology; Teacher Educators

Use of videos, and other representations of practice, to prepare preservice teachers (PSTs) in methods coursework is commonplace (Grossman et al., 2009). The effectiveness of such representations is often tied to various technological scaffolds that help to better approximate the practices of educators (Herbst et al., 2016; Stockero et al., 2017; van Es & Sherin, 2002). Although evaluation of both representations of practice, and related technology, has shown how their use affects PSTs, there is relatively little work on examining mathematics teacher educators' (MTEs) experiences integrating such representations and technology.

The purpose of this study is to examine my own experience as an MTE integrating a novel video medium: 360 video. 360 video differs from traditional video by recording in a spherical direction and allowing the viewer to adjust and choose what is viewed in this recorded sphere. Experiences included creating three videos of math instruction (multiplication/division & fractions), and using VR headsets and tablet technology for PSTs to view these videos.

To evaluate my experiences, I engaged in a narrative-based self-study (Loughran, 2007; Tzur, 2001). Data included written reflections, emails with colleagues, and a yearlong text message based conversation between myself and a colleague in educational technology. These written sources were evaluated for themes in how I integrated 360 videos for teaching PSTs. Analysis of written records revealed three themes that influenced my pedagogical decision making: accessibility, perceptual capacity, and attending to mathematics. *Accessibility* of the 360 media emerged in my evaluation of various platforms for disseminating 360 videos (YouTube, Kaltura, Vimeo, etc.). This theme also was influential in identifying virtual reality (VR) headsets to use with PSTs, as some allowed for casting (sharing on a viewable screen) what a headset wearer sees, but may not function in certain wifi network conditions. *Perceptual capacity* refers to what aspects of a scenario are available to view (Ferdig & Kosko, in review). This theme emerged regarding how video resolution differed by recording device (brand of 360 camera), platform, and VR headset. Additionally, I began to experiment with extending perceptual capacity to allow for multiple vantage points by recording with multiple 360 video cameras. *Attending to mathematics* focused on my own efforts to scaffold PSTs' professional noticing. Often, this theme interacted with the prior two. PSTs attended to specific mathematics when viewing 360 videos on their own, but this was less effective when I adapted the viewing for small groups. Within small groups, one PST watched a 360 video with a headset and cast their view to tablet shared by others. When a group size was too large (> 4), some PSTs lacked accessibility to the video. Additionally, when too many PSTs attempted to direct where the headset wearer should look, it served to limit what was viewable in the scenario. This self-study is ongoing. Preliminary findings provide potential themes to inform MTEs in implementation of representations of practice in preparing PSTs.

HOW COACHES DEVELOP EFFECTIVE ONLINE COACHING PRACTICES

Cynthia D. Carson
Warner School of Education - University of Rochester
ccarson3@u.rochester.edu

Keywords: Technology, Instructional Leadership, Professional Development

Online professional development is growing in popularity (Bates, Phalen, Moran, 2016). Online programs can be adapted to teachers' schedules, provide avenues to draw on resources that may not be available locally, and provide work-embedded training with sustained support (Dede et al., 2009). Online environments remove geographic barriers, giving access to high quality experts regardless of physical location (Butler, Whiteman, & Crow, 2013; Prouty, 2009).

We designed an online content-focused coaching model (West & Staub, 2003) that included typical coaching components such as pre- and post-lesson conferences, and atypical components, such as video-recorded lessons that could be viewed and annotated. We hypothesized that online coaching might lead to the development of new coaching practices due to the online platform. Although none of the coaches (n=9) in our project were new to coaching, seven of these coaches were new to online coaching, which led us to develop a mentor-apprentice coaching model to acculturate them to the online environment. We implemented this mentor-apprentice coach model (see Figure 1) in one coaching cycle for 2 years.

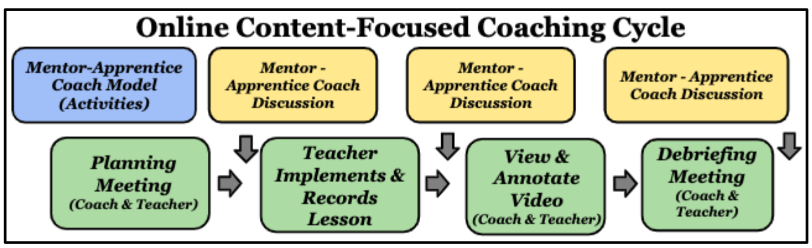

Figure 1: Mentor-Apprentice Coaching Model

We gathered data from semi-structured interviews, surveys, mentor and apprentice coaching interactions, and apprentice coach and teacher discussions from coaching cycles. We grounded the analysis of the development of the apprentice coaches in Lave and Wenger's (1991) theory of legitimate peripheral participation and Rogoff's (1994) theory of transformation of participation within a community of practice. We analyzed the coaches' development to understand changes in their coaching practices as a result of interacting with the more experienced coaches and the online platform.

Preliminary findings suggest that mentor coaches engaged the apprentice coaches as thinking partners by sharing coaching challenges, asking for new ideas and feedback on their coaching practices. For example, Alvarez, a mentor coach, characterizes her goal for the work with her apprentice coach: "It's not really that we're doing a mentorship relationship here. I figure we're just both in here figuring this out together" (all names are pseudonyms). These findings also suggested that apprentice coaches who helped the mentors reflect on their own practice; simultaneously developed their own coaching practices in ways that showed they could be effective coaches after the support of the mentors concluded. These findings and future research could inform training programs for supporting coaches and developing more effective coaching practices.

MATHEMATICS EDUCATORS' PERCEPTIONS OF PASSING THROUGH THE GATEWAY OF OCCUPATIONAL POLITICIZATION

Daniel L. Clark
Western Kentucky University
daniel.clark@wku.edu

Keywords: Policy Matters, Standards (broadly defined), Teacher Education-Inservice/Professional Development, Elementary School Education

Studies concerning the implementation of the Common Core State Standards for Mathematics (CCSSM) have been requested by the mathematics education research community (Heck, Weiss, & Pasley, 2011). This study sought to document educational stakeholders' views as CCSSM implementation turned into a political controversy. More specifically, this study sought to answer the following research question: In what ways were the job performances of State Department of Education (SDE) officials, regional professional development providers, and elementary teachers affected by the emerging political nature of CCSSM implementation?

SDE officials, regional professional development providers, and elementary teachers were surveyed and interviewed as part of this mixed methods study. Responses were analyzed for commonalities and differences in the perceptions of participants at the varying levels of the state's education system.

SDE Officials' Perceptions

At the state level, many of the participants from the SDE felt micromanaged by the legislature. The legislature passed laws revoking and later reinstating funding for CCSSM implementation and also threatened to remove responsibility for CCSSM-aligned assessments from the SDE entirely. In short, this caused morale at SDE to suffer. This contentiousness followed the pattern of what McDonnell and Weatherford (2016) referred to as the politics of enactment versus the politics of implementation.

Regional Professional Development Providers' Perceptions

Professional development providers were affected in a variety of ways as well. First, despite being long-time advocates for quality mathematics education, they found being called to testify at legislative hearings in front of legislators who had already seemed to have made up their minds on the issue to be frustrating. This sentiment has been corroborated by Polikoff, Hardaway, Marsh, and Plank (2016). Furthermore, the professional development providers found that engaging teachers at inservice training sessions was more difficult. This was partially due to the uncertainty around CCSSM-aligned assessments caused by the legislature.

Elementary Teachers' Perceptions

Elementary teacher participants in the study generally identified themselves as being apolitical with respect to the CCSSM political controversy. While they said the controversy had affected their work with everyone from students' parents to their own family members asking them pointed questions about the CCSSM, they said they would teach their students the best way they knew how regardless of what the standards were.

Chapter 8:
Mathematical Knowledge for Teaching

PRESERVICE TEACHERS' UNDERSTANDING OF TWO-VARIABLE INEQUALITIES: APOS THEORY

Kyunghee Moon
University of West Georgia
kmoon@westga.edu

This study investigated preservice secondary mathematics teachers' difficulties with and understanding of graphs of two-variable inequalities with the lens of the APOS theory. The analysis showed that most teachers understood inequality graphs as actions, at best, and used informal rules to construct graphs. They also had difficulty justifying graphs, such as overgeneralization of linear inequality graphs, lack of understanding of the meaning of solutions and the Cartesian Connection, and inability to transfer algebraic/verbal to geometric rays. This study suggests two methods for the visualization of inequality graphs, which uses the concepts of variable and parameter.

Keywords: Inequality, Graph, Cartesian Connection, APOS theory

Inequalities is an important topic in mathematics due to its relations to equations and functions as well as its applications to real-life situations. Research on inequalities has been, however, under-represented to date despite calls for more research from the mathematics education community (Boero & Bazzini, 2004; Vaiyavutjamai & Clements, 2006). In the case of one-variable inequalities, studies have suggested that many of students' difficulties are associated with the properties of inequalities or the meaning of inequalities. For instance, students multiply a negative number to an inequality without changing the direction of the inequality sign (Kroll, 1986), overgeneralize the Zero Product Property to inequalities (Kroll, 1986), solve inequality problems by solving parallel equations (Almog & Ilany, 2012; Blanco & Garrote, 2007; Sfard, 1994; Tall, 2004; Vaiyavutjamai & Clements, 2006), and fail to interpret "solve" as finding values that make inequalities true (Blanco & Garrote, 2007; Frost, 2015).

In the case of two-variable inequalities, an article by Switzer (2014) describes how a guided discovery approach helps students understand the meaning/graph of a linear inequality in a specific form. Yet due to a lack of in-depth research on the topic, not much is known about what issues are involved in understanding various kinds of two-variable inequalities. In this paper, I study this under-examined area with the research question: What are the difficulties and understandings in constructing and justifying graphs of two-variable inequalities?

Theoretical Framework

This study utilizes the notion of the Cartesian Connection (CC) in equations and inequalities. The CC in equations is a relationship between an equation and its graph, which stipulates that 'a point is on the graph of a mathematical relation $R(x,y) = 0$ if and only if its coordinates satisfy the equation.' Past studies have reported that this seemingly trivial idea is rather complex, especially when individuals encounter the idea in non-typical tasks (Moon, Brenner, Jacob & Okamoto, 2013; Moschkovich, Schoenfeld, & Arcavi, 1993). 'CC in inequalities' is a newly minted terminology I created for this study. It means either 'a point is on the graph of the mathematical inequality $R(x,y) < 0$ if and only if its coordinates satisfy the inequality' or 'a point is on the graph of the $R(x,y) > 0$ if and only if its coordinates satisfy the inequality.'

On the other hand, as a graph of $R(x,y) = 0$ is a locus of points whose coordinates satisfy the equation, a graph of $R(x,y) < 0$ is a locus of points whose coordinates satisfy the inequality. As such, an understanding of the graph of $R(x,y) < 0$ may involve both localization and globalization: localization to attend to a pair of x and y values that satisfies $R(x,y) < 0$ and its representational transfer to a point in a plane, and globalization to attend to *all* such pairs and the graph of their corresponding points as a whole (see Even, 1998 for equations).

To transition from localization to globalization, one may need a mental mechanism that elevates actions and thoughts. Examples of such transitions include: a point-wise view to a global view (Monk, 1992), an operational view to a structural view (Sfard, 1991), and an action conception to a process conception in the APOS theory (Dubinsky & Harel, 1992). In this study, I use the APOS theory, which seems to best explain the phenomena involved in the visualization and understanding of graphs of two-variable inequalities.

An *action* is a mental or physical manipulation of objects that can transform one object into another. It can be a single-step action performed explicitly, including recalling memorized facts, or a multi-step action involving a number of steps without conscious control (Arnon et al., 2013; Cottrill et al., 1996). When actions are repeated and interiorized, the actions collectively become a mental *process* (Breidenbach et al., 1992). As such, an individual with a process conception may execute actions without explicitly running through each action.

Research has suggested that many individuals conceive graphs of one-variable functions or two-variable relations only as actions. They may plot and trace points to represent function equation graphs, but do not understand the existence of infinitude points or the continuity of the graphs (Kerslake, 1981; Leinhardt, Zaslavsky & Stein, 1990). They also overgeneralize linear function graphs to other graphs, even with their abilities to perform actions of transformations, from a table of x and y values to points in the plane (Presmeg & Nenduradu, 2005). Many calculus students also have, at best, an action view of two-variable functions. They can neither make connections between algebraic and geometric objects other than points nor explain cross sections of $y = x+z+3$ at fixed values of x (Trigueros & Martinez-Planell, 2010).

On the other hand, it has been shown that covariational reasoning (Weber & Thompson, 2014) is essential in the visualization of two-variable function graphs. A student who understands the graph of $y = x^2–2x$ as a collection of points on a plane (a process in one-variable functions) can visualize the graph of $y = z(x^2–2x)$ as a sweeping out of the $y = a(x^2–2x)$ graph, with a acting as a parameter and then as a variable (a process in two-variable functions). In comparison, another student who sees the $y = x^2–2x$ graph only as a shape is unable to visualize the graph of $y = z(x^2–2x)$.

Methodology

The participants were 15 preservice secondary teachers (referred as "teachers") at a mid-sized state university in the Southeast region of the United States. Their mathematical backgrounds were varied, with four taking Precalculus, one taking Calculus I, and the other ten taking Calculus II or above. The participants were individually interviewed twice, for about one-and-a-half hours each time, in a form of semi-structured clinical interview. The interviews were recorded with a video camera and were transcribed. Their written responses were collected.

The interview items used for this study are the two questions included in the first interview.

Q1: (a) Find a solution of an inequality, $x+2y–32 < 0$.
(b) Represent all the solutions of the inequality above in the Cartesian plane.

Q2: (a) Find a solution of a system of inequalities, $y < x^2+1$ and $x^2+y^2 > 1$.
(b) Represent all the solutions of the system of inequalities above in the Cartesian plane.

During the interview, I asked the teachers why they represented the solutions in certain ways or why the x and y coordinates of all the points in their shaded regions satisfied the inequalities. I also asked the teachers to represent mathematical statements, in words or in algebraic forms, graphically in the plane when opportunities arose.

Genetic Decomposition

The genetic decomposition in APOS theory is a hypothetical model describing learners' mental structures and mechanisms for a certain concept (Arnon et al., 2013). For inequality graphs, I created a genetic decomposition by incorporating the action and process conceptions in the APOS theory and covariational reasoning (Weber & Thompson, 2014) to make up for the deficits in the current methods of teaching inequality graphs: the solution method and the ray method. The details follow.

In general, the solution method (ST) for the $y < f(x)$ graph involves two steps:

ST-1: A graph of $y = f(x)$ is drawn in a Cartesian plane.
ST-2: One or a few points are chosen from the plane, followed by the testing of the truth values of the points on $y < f(x)$. The graph is then determined as one of the two regions divided by the $y = f(x)$ graph in which points with true truth-values lie—normally shaded in gray or color (see, for example, David et al., 2011).

The first step of the ray method—see, for example, the CME Project, Algebra I (Cuoco et al., 2013)—is identical to ST-1. In the second step, however, the ray method uses verbal descriptions of rays to determine and justify inequality graphs.

> Try $x = 0$. The point on the line with x-coordinate 0 would be (0, 5). Any point on the vertical line with equation $x = 0$ with y-coordinate less than 5 is part of the solution set. Next try $x = 5$. … It would take forever to write out the situation for every possible value of x, but you can see that any point that is below the line is part of the solution set. (p. 756).

The $y < 3x+5$ graph is then represented as the region under the $y = 3x+5$ graph, shaded in pink.

Both methods provide tools to construct and/or justify inequality graphs, yet they fall short of emphasizing the variable concept as a critical idea in inequality graphs, logically and/or graphically. To explain, the solution method yields inequality graphs by generalizing a few points with true test values to the entire region, with no justification provided; the ray method does not incorporate their verbal descriptions of rays in geometric representations, and inequality graphs are represented as static objects. The genetic decomposition, which I created and named the "concept of variable" (COV) method, addresses these issues. In COV, one simultaneously constructs and justifies graphs with the actions and process below:

- COV-1: One converts $R(x,y) = 0$ to its graph—a probable action as one generally depends on one's memory from the previous learning of equation graphs in this context.
- COV-2: One performs an action of assigning a value for the x variable in $R(x,y) < 0$, such as $x = k$, and performs algebraic treatments (Duval, 2006) on $R(k,y) < 0$ to solve for y. (It is possible that one fixes y as constant k and performs treatments on $R(x,k) < 0$)

- COV-3: One performs a conversion from the algebraic—$x = k$ and $R(k,y) < 0$—to a geometric object—line segment(s), ray(s), or line—depending on the nature of $R(k,y) < 0$.
- COV-4: With similar actions repeated for other values of x, one interiorizes the actions into a process and visualizes the $R(x,y) < 0$ graph as a sweeping out of segments, rays, and lines—similar to the two-variable function graphs through covariational reasoning (Weber & Thompson, 2014).

It is possible that one uses a combination of ST and COV to construct and justify inequality graphs: ST for construction and COV-related reasoning for justification. Although it is inefficient, some individuals may use this method, especially if they justify their graphs after they have constructed inequality graphs using ST.

For analysis, in addition to the genetic decomposition, I used an open coding strategy (Strauss, 1987) to examine teachers' difficulties with and understanding of inequalities, by using a priori codes such as action/process, algebraic/verbal/geometric, treatment/conversion, and equation/inequality. The initial coding showed patterns, and thus yielded categories and subcategories. I then performed the second stage of coding: reexamining and revising the prior codes, and at the same time performing an axial coding (Strauss, 1987) to focus on the categories and subcategories from the previous coding.

The results are presented in the next two sections. The first section focuses on teachers' understanding of inequalities with the lens of genetic decomposition, and the second their difficulties with inequalities in general.

Understanding Inequalities: Genetic Decomposition

Linear Inequality

Eleven teachers attempted to construct the $x+2y–32 < 0$ graph, with seven successfully doing so. All seven teachers with a correct inequality graph drew the line graph of $y = –x/2+16$, converted from $x+2y–32 = 0$ (ST-1, or equivalently COV-1), but none used the rest of ST or COV when constructing the inequality graph. Instead, five of them applied a rule, such as "less than is lower," and two simply shaded the lower part of the line with no explanation.

When justifying their graphs, two of the seven teachers with a correct inequality graph performed actions of checking the truth values of a few points under the line to $y<–x/2+16$, and then generalized the few points to the entire region. When asked why they included the entire region below the line, however, they could not articulate their reasoning. Another two teachers followed COV-2, making comments such as, "my y-values are never going to be bigger than 16 when $x = 0$," which were verbal representations of rays. However, when they were asked to represent their words in a plane, they claimed the entire region under the $y = –x/2+16$ graph as the geometric representation of their words, failing COV-3. The other three also failed to provide correct reasoning with various issues, including a shaky understanding of the Cartesian Connection, which I will explain in more detail in the next section.

Among the four teachers with an incorrect inequality graph, three teachers incorrectly drew a $y = 16–x/2$ graph (ST-1), with two using the "less is under" rule and one claiming the line graph itself as the inequality graph. One remaining teacher did not provide any explanation.

Parabolic Inequality

Seven teachers attempted to construct the $y < x^2+1$ graph, with six correctly representing the $y = x^2+1$ graph and three the $y < x^2+1$ graph. All three teachers with a correct $y < x^2+1$ graph first drew $y = x^2+1$ (ST-1) and then either performed ST-2 or used the rule, "less is under," to construct a graph. Among the three teachers with an incorrect inequality graph, but with a correct $y = x^2+1$ graph (ST-1), one claimed that the upper part of the parabola was the inequality graph by guessing, and two claimed that the lower part of the $y = 1$ graph was the inequality graph, using the rule, "less is under." The remaining teacher represented $y = x^2+1$ as a curve similar to the $y = x^2$ graph (ST-1) and claimed that the curve itself was the inequality graph.

When justifying their graph, two of the six teachers who had a correct $y = x^2+1$ graph did not provide any explanation, and one teacher used the "less is under" rule. The other three teachers followed COV-2 by fixing x values and by saying such things as "I will make x equals 0, then you will get y is less than 1." However, all three incorrectly represented their words in a plane, failing COV-3. One represented his words as the half plane under the $y = 1$ graph, and the other two represented them as the entire region under the $y=x^2+1$ graph.

Circular Inequality

Seven teachers attempted to construct the $x^2+y^2 > 1$ graph, with five providing a correct graph and two an incorrect one. All five teachers with a correct inequality graph drew a $x^2+y^2 = 1$ graph (ST-1) and used a "greater is outside" rule to determine the inequality graph. The other two with an incorrect inequality treated $x^2+y^2 = 1$ into $y = \sqrt{1 - x^2}$ and sketched the latter as a curve similar to the $y = \sqrt{x}$ graph (ST-1). One teacher then shaded the upper part of the curve using the rule, "greater is upper," and the other claimed that the curve itself was the inequality graph.

When justifying the graph, one of the five teachers with a correct inequality graph used ST-2 as a justification; another teacher used a verbal description of a ray, "at $x = 2$, anything plugged in for y could be greater than 1" (COV-2), without performing the rest of COV; and another teacher did not provide any explanation at all. The other two teachers used an idea of $x^2+y^2 = k$ as a part of $x^2+y^2 > 1$—more generally, $R(x,y) = k$ as a part of $R(x,y) > 0$, implicitly utilizing the concept of parameter (COP), which I will explain in more detail in the Discussion and Conclusions section.

As for the two teachers who had a $y = \sqrt{x}$-like curve, one teacher provided reasoning by using a verbal description of a ray (COV-2), but represented his words as the entire region above the curve, failing COV-3. The other teacher was not asked to justify as she did not provide any justification for the linear and parabolic inequalities.

Difficulties with Inequalities

The teachers in general struggled to construct and justify inequality graphs, with fewer than half of them providing a correct graph—seven for the linear, five for the circular, and three for the parabolic inequality. The sources of their difficulties were various and intermingled, with some implicitly shown in the previous section. Below are the four most noteworthy characteristics of their difficulties.

Misunderstanding the Meaning of Solution

Some teachers did not understand the meaning of "solution" of an inequality and/or of a system of inequalities. Four teachers claimed that $y < –x/2+16$ (or $y <$ something) was a solution of $x+2y–32 < 0$. There were also three teachers who correctly interpreted the meaning of solution in a single inequality, but not in the system of inequalities. Instead of finding solutions of the system of inequalities, they found a solution for each inequality separately as if they had been given two independent inequality problems. Considering the fact that they had successfully found a solution of a system of equations—$y = x^2+2$ and $y = –2x$—in a different question, they

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

did not seem to understand the role of the *and* connective in the system of equations and inequalities.

Lacking Understanding of the Cartesian Connection

Four teachers successfully found the solutions of inequalities; however, they either falsely claimed the graphs of parallel equations themselves as the graphs of inequalities, or could not determine the inequality graphs due to their lack of understanding of CC. In one case, my questioning helped a teacher revise his thinking, reflect on the meaning of solution, and change his answer to a correct inequality graph. However, for the other three teachers, my questioning did not help them reorient their thinking.

> I: Why do you think everything on the line is a solution [of the inequality]?
> S: I see 1, 16 [in x+2y-32<0]. Oh no, that will be greater than 0. It is 0, 16. No, it wouldn't be because 0 is not less than 0. So, I guess when x is 1, y is 15.5, so 1+31 is 32 minus 32 is 0.
> I: Would everything on the line make [x+2y-32] zero?
> S: Well, we will see. 2 gives me 15. It seems like everything on this line will give me 0.
> I: So how does that help you determine the answer?
> S: It doesn't. I am confused.
> I: You are saying everything on the line is 0. But you can't determine what values will make it less than 0.
> S: Right.

As shown above, when asked whether the x and y coordinates of any point on the line would satisfy $x+2y–32 = 0$, the teacher was compelled to find another solution of $x+2y–32 = 0$, after having already found two such pairs meeting the condition, showing a lack of understanding of CC in equations. Further, when he had a pair of x and y values, $x = 1$ and $y = 16$, which made $x+2y–32$ greater than 0, he was unable to use the pair to determine the graph of $x+2y–32 < 0$; instead, he adjusted the x value to 0 to have a pair that satisfied $x+2y–32 = 0$, showing a lack of understanding of CC in inequalities.

Overgeneralization of Linear Inequality Graphs

The teachers' overgeneralizing behavior of linear inequality graphs appeared when two teachers represented the parabolic inequality graph. Despite having a correct $y = x^2+1$ graph, they shaded the half plane under the $y = 1$ graph instead of the region under the $y = x^2+1$ graph. One teacher provided valid reasoning, but an incorrect graph, by inserting the $y = 1$ graph. The other teacher simply said, "I don't know how to do this one," and shaded under the $y = 1$ graph. It was noteworthy that this behavior came from two higher performing teachers and, in particular, from a teacher whose reasoning was otherwise in the right direction.

Figure 1: Teachers' Representations of Rays in $y<x^2+1$

Problems with Ray Conversions

Teachers also struggled with ray conversions. Of the five teachers who were asked to do the conversions, with two of them being asked twice, four teachers could not convert from algebraic/verbal rays to geometric rays. For the linear inequality, four teachers verbally described a ray, saying such things as “when x = 31, y is less than 0,” but three of them falsely claimed the entire region under the y = 16-x/2 graph as the graph of their verbal ray. For the parabolic inequality, one teacher represented the statement, “$y < x^2+1$ when $x = 0$,” as the entire region below the y = l graph instead of a ray on the y axis (Figure 1a). Another teacher represented the statement, “$y < x^2+1$ when $x = 3$,” as a ray on the y-axis instead of a ray on the line, x = 3 (Figure 1b).

Discussion and Conclusions

This study examined preservice secondary teachers’ abilities to construct and justify inequality graphs by applying the framework of the APOS theory (Dubinsky & Harel, 1992). The results showed that the vast majority of the teachers had, at best, an action conception of inequality graphs. They used rules, such as “less is lower” or “greater is upper,” when constructing or justifying graphs, rather than reasoning relevant to the concept of variable or the Cartesian Connection. Even when they were able to implicitly use the concept of variable in their argument, they could not utilize the concept to construct or justify graphs, due partly to their lack of ability to convert their arguments of verbal/algebraic rays to geometric rays.

Their difficulties with inequalities were comparable to individuals’ difficulties with inequalities and functions shown in other studies. Some teachers incorrectly found solutions of two-variable inequalities from parallel equations, similar to those who struggled with one-variable inequalities in earlier studies (Almog & Ilany, 2012; Blanco & Garrote, 2007; Frost, 2015). Some teachers falsely claimed that graphs of inequalities were the graphs of parallel equations, despite knowing the meaning of solutions in algebraic forms—similar to the individuals who could not make the Cartesian Connection in two-variable equations in other studies (Moon et al., 2013; Moschkovich et al., 1993). Some teachers also falsely represented the graph of a parabolic inequality with a linear inequality graph, similar to the teacher who represented the table of a non-linear function with a line graph in Presmeg and Nenduradu (2005).

Teachers also showed struggles that were comparable to those of college students in the case of two-variable functions. Many teachers knew the shapes of inequality graphs by memory, or by using rules, but did not understand inequality graphs at fixed values of x, similar to students who could not visualize the cross-sections of two-variable functions in other studies (Trigueros & Martinez-Planell, 2010; Weber & Thompson, 2014). As such, visualizing an inequality graph as a sweeping out of rays, line segments, or lines— similar to the way that a student visualized a two-variable function graph as a sweeping out of curves in Weber and Thompson (2015)—was out-of-reach for the teachers.

On the other hand, two teachers’ reasoning shown in the circular inequality graph, which implicitly utilized the concept of parameter, inspired me to generate a new method for inequality graphs. In this concept of parameter (COP) method, inequality graphs can be constructed and justified as a sweeping out of curves or lines. To use the COP method, one first converts $R(x,y) = 0$ into a graph (COP-1, identical to COV-1). One then performs an action of assigning a value k to $R(x, y)$ by seeing $R(x,y) = k$, with $k > 0$, as part of $R(x,y) > 0$ (COP-2). One then converts

$R(x,y) = k$ to its graph, which is a curve (including lines) (COP-3). After repeating these actions for various k, one interiorizes these actions into a process and visualizes the inequality graph as a sweeping out of all curves (COP-4).

The results of the COV and COP methods are quite different when the graphs are shown as dynamic processes. While COV represents a graph as a collection of vertical or horizontal rays, lines, and line segments (Figure 2a & 2b, respectively), COP represents it as a collection of lines or curves (Figure 2c). As shown in the work by Moon (2019), the COV and COP methods have their own merits. As such, both methods deserve to be considered in the instruction of inequality graphs.

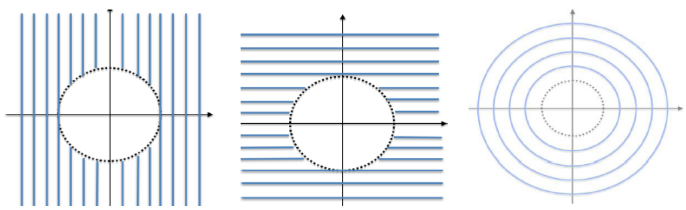

Figure 2: Graphs of $x^2+y^2>1$ through COV and COP Methods

I conclude this paper with a suggestion for those who contemplate implementation of the concepts of the variable and parameter methods. I believe that instructors should not use the methods as rote means to draw graphs of inequalities. Rather, they should focus on the concepts and ideas embedded in the methods: the meaning of inequalities, variable and parameter, the meaning of solutions, and the connection between algebraic and graphical inequalities, including the Cartesian Connection and ray connection.

HORIZON CONTENT KNOWLEDGE IN PRESERVICE TEACHER TEXTBOOKS: AN APPLICATION OF NETWORK ANALYSIS

Joanna G. Jauchen
George Mason University
jjauchen@gmu.edu

Horizon Content Knowledge (HCK, Ball, Thames & Phelps, 2008), knowledge that teachers hold about the interconnectedness of mathematics, has been recognized as an integral component of Mathematics Knowledge for Teaching, yet little is known about how or where it is taught in the preservice teacher (PST) curriculum or how researchers should study HCK. This study used network analysis to examine HCK in the context of undergraduate PST textbooks. I describe my approach to the study and report on the analytical questions I encountered. I then describe the affordances and constraints of network analysis for understanding HCK and reflect on the power of this tool to understand HCK in a variety of contexts.

Keywords: Curriculum Analysis, Data Analysis and Statistics, Mathematical Knowledge for Teaching, Teacher Education-Preservice

Ball, Thames, and Phelps (2008) developed a framework for the Mathematical Knowledge for Teaching (MKT) which divides MKT into six subdomains, three of which are oriented around subject matter knowledge (SMK) and three around pedagogical content knowledge (PCK). SMK is further divided into three dimensions: Common Content Knowledge (CCK), Specialized Content Knowledge (SCK) and Horizon Content Knowledge (HCK). CCK is mathematical content that is generally known outside of the world of teaching; SCK is mathematical content that teachers rely on to teach; and HCK is often noted as knowledge teachers hold about the interconnectedness of mathematics. One example of HCK is the knowledge that teachers possess regarding how addition and multiplication are connected mathematical domains.

Little work has been done to examine what HCK is being taught to PSTs. One place to look for answers to these questions is in PST textbooks. Because of the varying definitions of HCK in the literature, and because the interconnectedness of mathematics may be more difficult to define and analyze than CCK or SCK, the study of HCK presents unique analytical challenges that network analysis may address. For this study, I examined three texts for a mathematical content course for elementary PSTs using network analysis to examine HCK in the context of addition of whole numbers. I present my methodological approach to this study, along with reflections on the use of network analysis for examining HCK. I discuss the analytical choices that I encountered and the affordances and constraints of network analysis for understanding HCK in PST textbooks. Finally, I outline how network analysis may be used in future work on HCK.

Theoretical Framework and Purpose of Study

PSTs come to understand disciplinary knowledge within a socio-cultural environment. As Lave and Wenger (2007) note: “This world is socially constituted; objective forms and systems of activity, on the one hand, and agents’ subjective and intersubjective understandings of them on the other, mutually constitute both the world and its experienced forms” (p. 51). Thus, the HCK of individual teachers is the result of a process of socially reproducing culturally and socially situated knowledge. In that process of social reproduction, PST textbooks, as artifacts, transmit cultural tools the mathematics community values in the education of PSTs (Wertsch, 1998). As such textbooks play an important role in cultivating the HCK of PSTs.

This study, situated in a socio-cultural framing, makes three major assumptions. First that PST textbooks, as cultural artifacts, describe some of the cultural tools PSTs are exposed to during a math content course. Second, that the Common Core State Standards for Mathematics (CCSSM; National Governors Association Center for Best Practices, Council of Chief State School Officers, 2010) as a community-generated artifact, represents the domains of CCK that teachers are expected to be familiar with. The final assumption is that I, as a full participant in the mathematical community and the community of teacher educators, understand the cultural tools and norms of this community. This positions me to create a reflection of the HCK that I recognize in PST textbooks. A result of this framing is that the HCK I have identified is one of many representations of HCK that may facilitate PST understanding of the interconnectedness of mathematics. Results about HCK from this study are bounded by the cultural artifacts included in the analysis and by my own knowledge. This is a socially, culturally, and historically situated analysis of HCK from three textbooks.

Though the MKT framework is well-established, there is not full agreement in the literature on what constitutes HCK (Ball & Bass, 2009; Ball, Thames & Phelps, 2008; Figueiras, Ribeiro, Carrilo, Fernández, and Deulofeu, 2011; Zazkis & Mamolo, 2011). Ball, Thames, and Phelps (2008) defined HCK as "an awareness of how mathematical topics are related over the span of mathematics included in the curriculum" (p. 403). The following year, Ball and Bass (2009) expanded on this idea and outlined four aspects of HCK: (1) "A sense of the mathematical environment surrounding the current ‘location’ in instruction"; (2) Major disciplinary ideas and structures"; (3) Key mathematical practices; and (4) Core mathematical values and sensibilities (p. 6). For this study, I operationalize HCK using Ball and Bass’s (2009) first and second aspects of HCK and also integrate a similar definition proposed by Figueiras et al. (2011) which defines HCK as "connections between mathematical concepts and ideas, grounded in the coherence of mathematics, in which all concepts and ideas are precisely defined and logically interwoven" (p. 28). Based on these two definitions, I identify eighteen broad mathematical concepts (major disciplinary ideas) present in four cultural artifacts (the CCSSM and three PST texts). I consider HCK present when two or more of those eighteen mathematical concepts are connected by the textbook author in a coherent way (within a single paragraph).

Method

Sampling and Coding

Three textbooks were chosen for this study on the HCK based on a single criterion: the needed to be reasonable to use in a mathematical content course for elementary undergraduate PSTs. The three books selected were: Manes and Holmes (2018); Sowder, Sowder and Nickerson (2017); and Caldwell, Karp, and Bay-Williams (2011). Manes and Holmes (2018) authored an Open Educational Resource written to help students "think like a mathematician," (p. 1) and which emphasized the Common Core Standards for Mathematical Practice (SMP). Similarly centering the SMP, Sowder et al. (2017) aimed to support classrooms where "students take an active part in learning" (p. xi) and provide students insight into "children’s mathematical thinking" (p. xi). Caldwell et al. (2011) is a text written solely about addition and subtraction as part of a larger series of texts published by the National Council of Teachers of Mathematics. I consider this to be a high-level text for an undergraduate PST content course and a possible exemplar of HCK. After texts were chosen, I selected a single topic for study: addition of whole numbers. Sections of the book that explicitly referenced addition of whole numbers were coded and analyzed. Data were chunked into paragraphs, using one paragraph as the base level of analysis. Relying on the definitions by Ball and Bass (2009) and Figueiras et al. (2011), paragraphs were coded as containing HCK if they connected two different mathematical concepts in a coherent picture of mathematics. I did not code paragraphs as containing horizon content knowledge if the text only implicitly relied on previous concepts, as many new mathematical concepts rely on existing mathematical knowledge. For this study, I was interested in the information explicitly presented to students, not what they might intimate from the text. I also chose, because of the exploratory nature of this study, to code two concepts as “connected” without being more specific about the relationship of that connection (Carley, 1993). For this analysis, I make no assumptions about the linearity in mathematical domains. For example, I do not assume counting precedes addition or that addition precedes subtraction. I only document that the textbook describes a “connection” between the two concepts by discussing them in the same paragraph. This choice impacts the resulting analysis and I discuss those limitations below.

The study relied on the CCSSM to identify disciplinary ideas that Ball and Bass’s conceptualize. When applied, the CCSSM was problematic for uncovering HCK in the textbook content because of differences in the level of content detail between the CCSSM and the PST textbooks. Once I identified this analytical issue, I developed emerging categories from the PST texts, in light of CCSSM standards. I formalized these emerging categories into new conceptual codes (Saldaña, 2016) and these were used to code the disciplinary ideas that defined HCK. These conceptual codes, developed in the first round of coding, more faithfully described the sort of concepts that were connected in the textbooks. The final eighteen codes arose from the CCSSM in the context of the PST textbooks, and described eighteen different disciplinary ideas that I found to be present in the textbooks and standards. The codes are addition (A), subtraction (S), multiplication (M), division (D), word problems (WP), concrete models (C), decomposing (DEC), properties (P), place value (PV), unknown addend (or the relationship between addition and subtraction; UA), counting (CNT), mental math (MM), equations (EQN), algorithms (ALG), definition of addition (DEF), measurement (MEAS), estimation (EST), and functions (FCN). For consistency, all paragraphs were coded a second time using the conceptual codes. Finally, the conceptual codes were checked against the initial CCSSM codes for alignment.

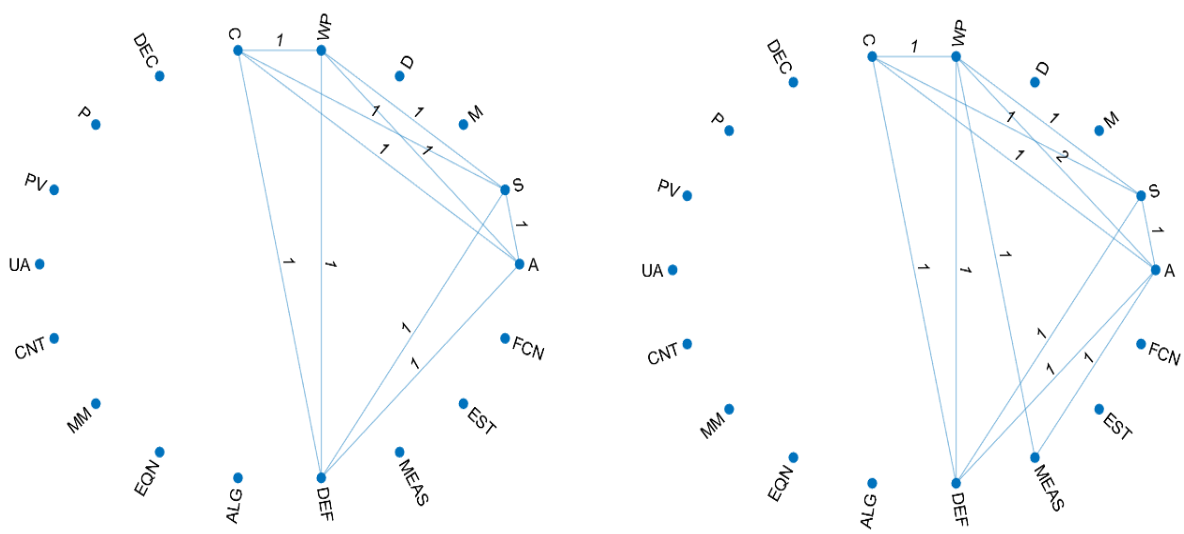
Analysis

Once data was coded, I used network analysis to examine the connections (Borgatti, Mehra, Brass, & Labianca, 2009). Network analysis relies on nodal graphs to visualize connections between objects (in this case, mathematical disciplinary ideas). Borgatti et al. (2009) list several types of analysis that can be conducted using network theory, including an analysis of types of connections, and an analysis of the underlying structure of connected systems. Network analysis has been used in education in a variety of contexts (Carolan, 2013) and network analysis is widely used outside of education to understand connected or relational data (Scott, 2013).

Since network analysis has not been previously used to analyze HCK, I briefly describe how the resulting visualizations originate from the initial coding. Here is an example paragraph from Sowder, Sowder, and Nickerson (2017). This paragraph was coded as containing addition, subtraction, concrete representations (the paragraph references a picture of addition which I omit for space considerations), word problems, and definitions. Codes are noted in brackets. The paragraph mentions “situations” which, in context, is about word problems. A network graph of this paragraph is given on the left side of Figure 1.

> Although the above distinction between meanings for addition [A; DEF] may be subtle, the distinction between meanings for subtraction [S] is quite stark. In Take-from situations [WP], part of a quantity is removed and another part is left over. Such situations [WP] are consistent with the familiar take-away meaning of subtraction [S]. This meaning tends to be emphasized in instruction in the primary grades and tends to be more familiar to students. In Compare situations, by contrast, there is no removal action. Two quantities are simply being compared additively. Children who associate subtraction with take-away may have difficulty solving Compare problems (p. 48).

Each of the eighteen conceptual codes is represented by a node on the graph. The entire network (all nodes) are displayed, even if there are no connections to them. Lines are drawn between nodes that are connected in the paragraph (these are called edges). The five codes from the example paragraph will lead to ten total connections. All codes in the paragraph are connected with edges, so addition is connected to each of the other four topics, subtraction is connected to each of the other four topics, word problems is connected to each of the other four topics, and similarly for concrete representations and definitions. In my analysis, these connections were considered bidirectional, though unidirectional analysis is possible. The number 1 written along the edge is called the edge weight, and it indicates that one paragraph connected these two topics.



Example paragraph Example and second paragraphs

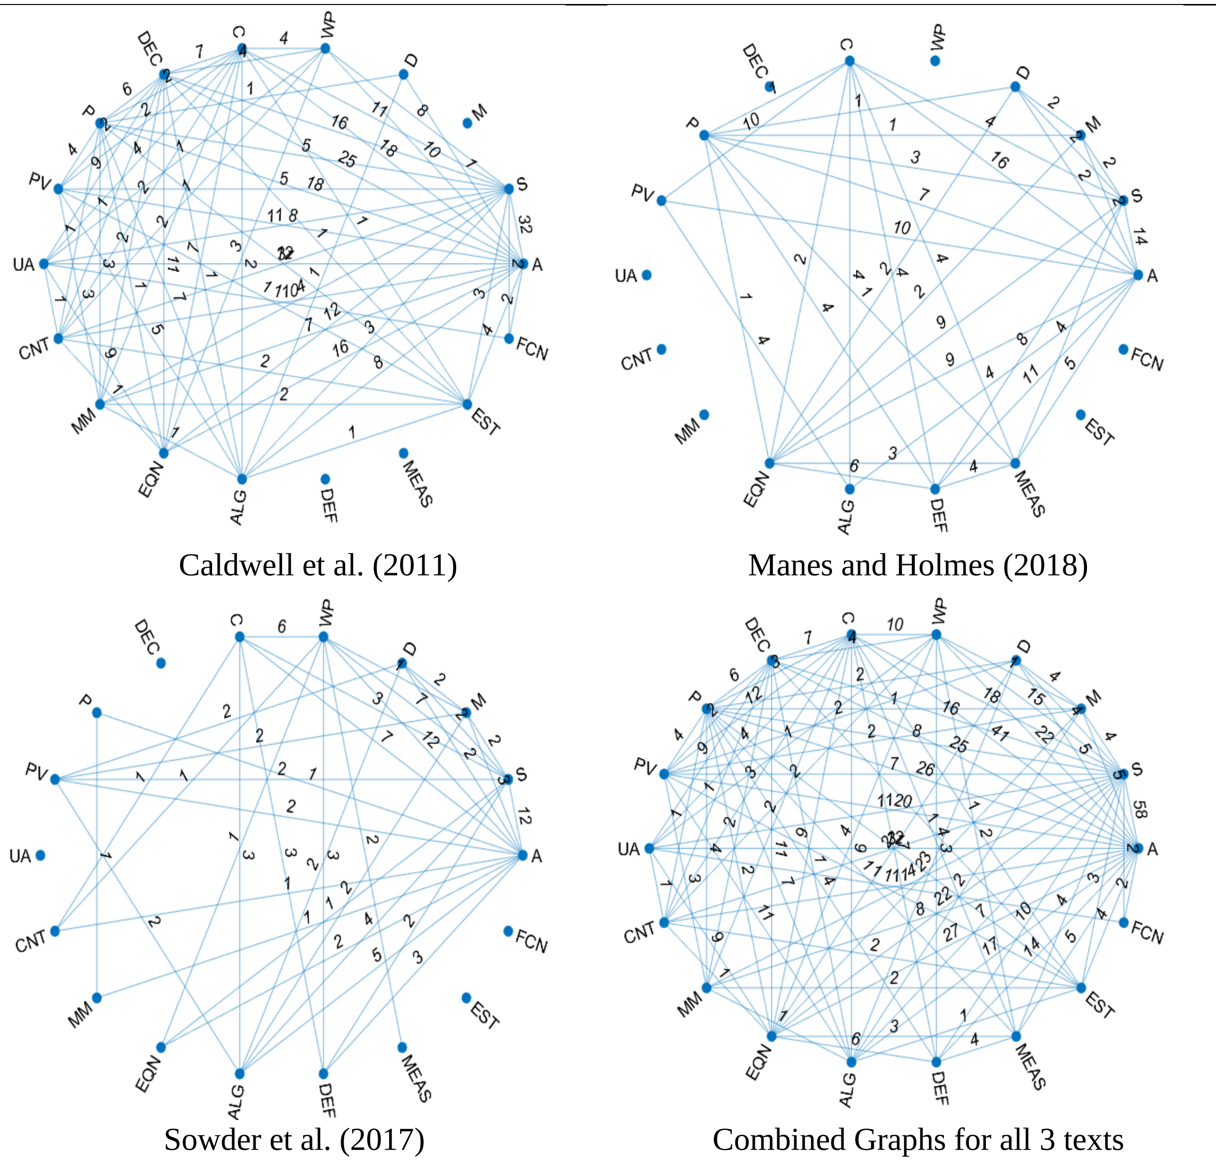
Note. Codes begin with A on the west pole of each graph and progress counter-clockwise
Addition (A), Subtraction (S), Multiplication (M), Division (D), Word Problems (W), Concrete (C), Decomposing (DEC), Properties (P), Place Value (PV), Unknown Addend (UA), Counting (CNT), Mental Math (MM), Equations (EQN), Algorithms (ALG), Definition of Addition (DEF), Measurement (MEAS), Estimation (EST), and Functions (FCN).

Figure 1*: Example Network Analysis Graphs of HCK*

If I add another paragraph coded with addition, word problems, and measurement, the graph changes to look like the right side of Figure 1. The edge weight for addition to word problems now increases to 2 (meaning 2 paragraphs contain this connection) and new edges are added linking addition to measurement and word problems to measurement. Each new paragraph adds edges or adds to the edge weight in the visualization.

Results and Discussion

For HCK, I present a nodal network for each textbook and discuss the results. I consider these results the affordances of using network analysis, namely, the ability to structure and visualize the sorts of HCK textbook authors have discussed. These results are best analyzed as a comparison, so in Figure 2, I provide the three individual graphs for Caldwell et al. (2011), Manes and Holmes (2018) and Sowder et al. (2017), along with a graph that combines their HCK across texts. Looking at Figure 2, Addition and Subtraction are connected in 32 paragraphs in Caldwell et al. (2011). Addition and division are only connected in eight paragraphs, and surprisingly, addition and multiplication are never connected (there is no line between addition



Note. Codes begin with A on the west pole of each graph and progress counter-clockwise
Addition (A), Subtraction (S), Multiplication (M), Division (D), Word Problems (W), Concrete (C), Decomposing (DEC), Properties (P), Place Value (PV), Unknown Addend (UA), Counting (CNT), Mental Math (MM), Equations

(EQN), Algorithms (ALG), Definition of Addition (DEF), Measurement (MEAS), Estimation (EST), and Functions (FCN).

Figure 2: Network Analysis Graphs of HCK

and multiplication). Because this analysis centered on addition of whole numbers, addition is well connected to many topics with significant edge weights, indicating its importance in this network. Subtraction is similarly connected, again with significant weights, as is decomposing indicating that Caldwell et al. routinely linked these concepts. However, division is only linked to three other topics (properties, algorithms and addition) and all with a weight of 1, indicating that Caldwell et al. did not strongly connect division to other topics in the addition section. Topics that were not connected by Caldwell et al. (2011) include multiplication, measurement, and the definition of addition. Caldwell et al. is the only text that connected to functions.

The graph for Manes and Holmes (2018) is less dense than the one for Caldwell indicating fewer paragraphs were coded as containing connections. The graph shows seven disconnected nodes: word problems, decomposing, unknown addend, counting, mental math, estimation and functions. Nodes that connect heavily with addition in Manes and Holmes (2018) are concrete models (16), place value (10), equations (9), and the definition of addition (11). Concrete models are also heavily connected to place value. The graph is less dense for Manes and Holmes than for Caldwell et al., but it is difficult to tell if that is the result of a real difference or because of the disproportionate number of paragraphs coded for Caldwell et al. (2011). Finally, the graph for Sowder et al. (2017) shows even fewer connections. Addition is still heavily connected. Nodes that are completely disconnected are decomposing, unknown addend, estimation, and functions. Word problems connect to eight other topics, which confirms that word problems were heavily emphasized in this text. Thirteen is the highest edge weight here (between word problems and addition) with weights decreasing significantly away from the addition subtraction or word problem nodes. Counting is only related to concrete models, word problems and addition, all with a weight of 1. Finally, the combined graph that visualizes the connections present across texts is useful to analyze what sort of HCK textbook authors were emphasizing across texts. So, if the research question were not comparative, but interested in the sort of HCK knowledge that the community of textbooks authors valued, the combined graph would be the tool to answer that question. I consider decisions to make that knowledge more accessible in the next section where I reflect on my analytical techniques and suggest future work.

Analytical Questions and Constraints

Operationalizing HCK and Descriptive Validity

This paper presents a fundamentally new approach to analyzing HCK. As such, there are still ongoing analytical questions and decisions that need to be made before utilizing network analysis. I operationalized HCK by claiming that HCK was present if two concepts were present in a single paragraph in a cohesive way, even if the book did not make the exact nature of the connection explicit. For example, my results claim that addition to subtraction HCK is present if addition and subtraction were present in the same paragraph. This operationalization and the resulting analysis raised questions about the descriptive validity of my operationalized variable as compared to the definitions by Ball and Bass (2009) and Figueiras et al. (2011). First, is addition to subtraction HCK “present” in a textbook, if a single paragraph mentions addition and subtraction together? This answer must be no. Single mentions of two topics in one paragraph do not present a "sense of the mathematical environment surrounding the current ‘location’ in instruction" (Ball & Bass, 2009, p. 6). However, if a textbook contains 34 paragraphs that all mention “addition and subtraction,” does that present a more cohesive picture of mathematical terrain? I believe the answer here is yes.

Given these observations, I propose it may be useful to set a bottom required edge weight. Consider the graphs in Figure 3, which represent the same network as Figure 2, but assume, for discussion, a required bottom edge weight of 4 (meaning, four separate paragraphs need to mention the connection in order to be included in the graph). This bottom edge weight privileges concepts that are mentioned at least four times in the text, which may help to more precisely operationalize HCK in texts. Setting a bottom edge weight also lowers the visual complexity of the figure, allowing the most prominent connections to be easily understood. It highlights both the interconnectedness of the Caldwell text and that most of the connections in Sowder et al. had an edge weight of 1, 2 or 3.

Figure 3: Network Analysis Graphs of HCK with Bottom Edge Weight of 4

But other questions arise about how to define and operationalize connections between content. Other types of connectedness in the context of HCK may be present. For example, HCK can refer to both knowledge across grade bands as well as knowledge across domains. It is possible that the four types of HCK (Ball & Bass, 2009) should be coded independently. Other ways to possibly categorize HCK may be: explicit connection made in the text, implicit connection made in the text, across grade band connection, or within grade band connection. It may also be possible to conceptualize an analysis that does rely on a linear conception of these mathematical ideas, for example, using the knowledge from learning trajectories to map the unidirectional connections present (Clements & Sarama, 2004; Confrey et al., 2011). Regardless of the refinement, refining the operationalization of HCK is necessary for more nuanced analysis and a fuller understanding of the content present in texts.

Sampling and Bounding the Analysis

As Scott (2013) noted, inorganic bounding of relational data can lead to false conclusions about the full network. In the context of textbook analysis, bounding is a necessary pragmatic decision. In this study, the sample was bounded to paragraphs that were explicitly focused on addition. Because of this, my network does not faithfully represent the entire network of connections authors made *even for addition* because I did not code every paragraph in the text that mentioned addition. In other words, sampling decisions in network analysis not only impact the edges present in the network, they impact the network nodes as well. For example, perhaps an author does not mention the connection between addition and multiplication in the sections on addition but mentions that connection in the section on multiplication. In that circumstance, and because of the way I have bounded my analysis here, the network I create would obfuscate the actual HCK presentation in the text. If a researcher wanted to create a full network for a text, it is reasonable to expect significant difficulties in generating the network (i.e. the coding scheme) for all content knowledge that PSTs are exposed to across textbooks. Understanding that network analysis of a bounded sample leads to a partial network is essential for interpreting these results.

Conclusion

I have presented what PST texts present as HCK as defined by Ball and Bass (2009), outlining the affordances and constraints of network analysis for HCK and posing some of the analytical questions that require further work and reflection to optimize network analysis for HCK. If these questions can be answered, network analysis can be a significant tool to examine the connectedness of HCK in a variety of situations, not just PST textbooks. A logical next step after textbook analysis is a study of the impact of HCK heavy textbooks on PST knowledge.

The amount and density of information presented in a text for PSTs should be a conscious and strategic choice by textbook authors and teacher educators. There are real differences across populations of students; different teaching environments require different texts. Teacher educators need to be aware of the choices they are making in order to select an appropriate text for their own classes. Further, the teacher education community needs to reach a consensus around what HCK should be included in PST content courses. Taking a careful inventory of what HCK may currently be presented in PST textbooks is one step in that process. An understanding of HCK is essential to the teacher education community so we can understand what textbooks emphasize, what they leave out and develop consensus in the community about what should be taught in an undergraduate content course for PSTs. Because of the vital role of content courses in PST education, careful attention to HCK in these courses is warranted.

AN EXPLORATION OF TEACHERS' ABILITIES TO IDENTIFY PROPORTIONAL SITUATIONS AND MAKE SENSE OF STUDENTS' THINKING

Rachael Eriksen Brown
Penn State Abington
reb37@psu.edu

Chandra Hawley Orrill
UMass Dartmouth
corrill@umassd.edu

In this paper we extend our previous work acknowledging teachers, like students, struggle to make sense of a pseudoproportional situation. For this study, we further analyzed to determine the significance of this problem in terms of teachers' abilities to support a range of students' thinking. We found teachers who were able to reason appropriately about the original situation were also able to make sense of students' varied approaches to solving the task, whereas teachers who struggled to reason about the situation were less able to make sense of students' thinking. Implications for teaching and professional development will be discussed.

Keywords: Teacher Knowledge, Mathematical Knowledge for Teaching, Number Concepts and Operations

Purpose

Research on students' persistent use of proportional reasoning in non-proportional situations suggests that this is a concept with which students struggle. In one study, De Bock, Van Dooren, Janssens, and Verschaffel (2002) examined the persistence of proportional thinking using an item we call the Santa Task (a version modified for our study is shown in Figure 1). In their study, the researchers posed the Santa Task to high school students, then provided five scaffolds to help the students work toward attending to the area relationship. De Bock et al. found participants struggled to recognize the Santa task focused on area not height. Initially only two students were able to answer the task correctly. After examining the five scaffolds, 32 of the 40 participants were able to determine a correct answer.

Building from the De Bock et al. (2002) study, we modified the task to both Americanize it (e.g., changing "Father Christmas" to "Santa") and to make it appropriate for teachers. Thus, we removed some scaffolds and situated scaffolds as student approaches. Our version of the Santa Task for teachers included these scaffolds:

1. Ms. Yarbrough's class had two favorite answers. About 40% of her class chose 18 ml and about 40% chose 54 ml. What might the students who were wrong been thinking about?
2. One of Ms. Yarbrough's students drew rectangles around the images. Do you think this is a helpful strategy for a student? Why or why not?
3. One of Ms. Yarbrough's students tried to solve the problem with easier numbers. She thought of the smaller picture as taking 1 tube of red paint and tried to figure out how much red paint would be needed for the larger picture. She decided that the right amount would be 9 tubes. Does this method work? Is the student's answer reasonable?

In previous analysis (Orrill & Brown, 2018), we found several teachers were misled by the task. Of the 32 participants, only nine (28%) initially used an area-interpretation. Two teachers corrected their error in Scaffold 1, one more corrected their approach in Scaffold 2, and Scaffold 3 led to no changes. One additional teacher corrected her response, but was not clear about when she realized her error as she updated her answers to all parts of the task. By the end of the task, only 14 of the 32 (44%) teachers had correctly applied the area interpretation.

In this paper, we extend the analysis of teachers' interactions with the scaffolds to determine (a) whether they engaged with students' reasoning and (b) whether they could determine the reasonableness of a student's approach. Our purpose was to explore whether there is a connection between teachers' demonstrated content knowledge and their ability to make sense of students' reasoning.

Painting Santa Task

Part 1

Bart is publicity painter. In the last few days, he had to paint Christmas decorations on several store windows. Yesterday, he painted a 56 cm high Santa on the door of a bakery. He needed 6 ml of paint. Now he is asked to make an enlarged version of the same painting on a supermarket window using the same paint. This copy should be 168 cm high. How much paint will Bart need to do this?

Ms. Yarborough gave her students the question above. Please take a moment to work the problem so you're comfortable with it, then we will look at sample responses.

Figure 1: Santa Task

Perspective

Teaching mathematics requires facilitating students' interactions with mathematics in ways that allow them to develop meaning. A variety of resources exist that provide guidance for such engagement. As Kilpatrick, Swafford, and Findell (2001) argue, teachers decide when to ask questions, provide guidance, and allow students to struggle. They also shape classroom conversations. These moves require teachers to engage with students' mathematical reasoning. *Principles to Actions* (NCTM, 2014) suggested mathematics teachers be able to "elicit and use evidence of student thinking" (p. 10), including being able to assess students' understanding as a means for making instructional decisions.

While scholars have included making sense of students' understanding as an aspect of the knowledge teachers need (e.g., Shulman, 1986; Ball, Thames, & Phelps, 2008), little research has been done linking teachers' understandings of mathematics to their understandings of students' ideas about mathematics. This study seeks to address that opening in the literature.

Methods

For this study, we analyzed the data from the same 32 teachers as in our previous work. The participants were a convenience sample of middle school teachers from four states. They ranged from one to 26 years of experience. Twenty-four participants identified as female.

Each participant completed a think-aloud interview that included the Santa Task. They were asked to solve the Santa task, then respond to each scaffold. For this study, the authors considered in the verbatim transcript (a) whether the participant's answer to the prompt was correct; (b) whether the participant was able to make sense of each approach; and (c) whether the participant identified the reasonableness of the approach. For the participants who changed their solution, we analyzed only those responses that were given after the switch to area reasoning. (Note: no participants switched to linear reasoning.) Our aim was to determine whether there were relationships between participants' own mathematical thinking and their engagement with making sense of the students' thinking. Transcripts were coded by each author independently and then discussed to reach 100% agreement.

To determine whether participants made sense of each scaffold, we looked for particular evidence. In Scaffold 1, the evidence was an explanation about how students arrived at the answer the participant thought was incorrect. In Scaffold 2, the evidence was understanding the ability to compare the bigger Santa to the smaller one using tiling or similar approaches. In Scaffold 3, the evidence was understanding every aspect of the image could be thought of as the bigger Santa being nine times larger.

To determine whether participants identified the reasonableness of the answer, we considered whether a rationale for the approach was provided. In Scaffold 1, were participants able to explain why students might have chosen that scale factor? In Scaffold 2, were they able to see the benefit of the rectangle? In Scaffold 3, were they able to understand this was a mathematically viable way to reason about the paint?

Findings

Overall, there was a connection between participants' engagement with students' ideas and their abilities to solve the task. For Scaffold 1, participants who answered the task correctly (n=12) were able to both make sense of the approach and provide a reasonable explanation for that approach. For example, Charlotte (all names are pseudonyms) noted:

> Well, the students who were wrong were just thinking that the Santa is three times as high. So, they were thinking that…just means three times as much paint. So, what's interesting is what they were not thinking about. They were not thinking about that the Santa is not expanding in just one direction. The Santa is expanding in two directions.

In contrast, of the participants who answered the task incorrectly (n=20), only 11 were able to make sense of the students' approach and none were able to determine the reasonableness. For example, Matt was able to determine how students got the "wrong" answer, but offered no explanation about why: "…instead of multiplying both by three, they multiplied the milliliters times nine and ended up with fifty-four."

For Scaffold 2, we found similar results. Of the 13 participants who answered correctly, all were able to make sense of the student's approach and to determine reasonableness. For example, Alan said, "So, yes, I think this is a helpful strategy because the rectangles that they drew around the images would perhaps lead them to think that this problem is about the area being proportional to the amount of paint as opposed to the height alone being proportional to the amount of paint." In contrast, only 13 of the 19 participants who were incorrect on the task were able to make sense of using rectangles and only one was able to determine why. One kind of answer these participants offered focused on only one attribute of Santa (e.g., height) similar to their initial solutions. For example, David was coded as making sense of the student's thinking but not being able to determine a reasonable way to use the representation when he explained, "this is a good way because if you look at the height of the rectangle the big one is three times bigger than the little one. Three lines to nine lines from top to bottom so that means they can multiply the first ratio by three thirds is equal to one whole." Participants who were unable to make sense of the student's thinking often introduced information into the task that was unnecessary, for example questioning whether the images were drawn to scale or answering vaguely. Brenda provided one such response, "I think it will show them that the two Santas are proportioned... proportional, but... but they would still have to figure out where their numbers go, where… I'm sorry where the numbers would be placed to find the solution."

Finally, for Scaffold 3, of the 13 participants who attended to area, 12 were able to make sense of the student's approach and 10 were also able to articulate the reasonableness. For example, in a particularly insightful response, Georgia commented:

> There's so much left out of this explanation… I wouldn't understand how she got the 9 if this is all that I would know about it. But I would assume this method works because the factor is the main thing. And if she understands how to use the factor once she knows what the factor is, then I would accept this as a reasonable answer. I would need to know more about this answer or approach. But I wouldn't mind my students using this type of logic. Because it shows understanding of the problem, even though they may lack the number sense to use those numbers. It may be a good way to get the same level of critical thinking...

This was an important response because it shows that participants who were able to make sense of student thinking may not have initially understood that thinking. Of the 19 linear-focused participants, only seven were able to make sense of the approach and none were able to see how it was reasonable. One common approach for these participants was to link the 1:9 ratio to the 6:56 ratio the participants believed was correct. This led them to misinterpret the approach. One example of this was offered by Eileen who said, "So if this student is going to use these easier numbers and they're going to say that 1 tube of red paint will paint the entire 56 centimeter Santa, then following that 2 tubes should paint 112 centimeters and 3 tubes should paint 168 centimeters. So, I'm getting 3 tubes. I don't know where the 9 tubes came from."

Significance

This study provides insight into teachers' mathematical knowledge and their ability to make sense of students' thinking. The participants who answered the task using an area-focused approach provided more insight into how students were thinking. Despite unfamiliarity with an approach, as shown in Georgia's example from Scaffold 3, correct participants were still more often able to understand students' thinking and determine reasonableness.

We lack the data to know whether the incorrect participants' lack of sensemaking around the students' work was caused by teacher disposition or ability; however, if a mathematics teacher's job includes sensemaking, as suggested above, then this study uncovers an area for serious consideration. Teachers cannot be correct 100% of the time and need to be able to engage with students' ideas even when they (teachers) are not correct. More research is needed to understand why teachers in this study with a correct mathematical approach were more able to do this: Is it a disposition toward students? Is it a disposition toward mathematics? or Is it that more mathematics knowledge better prepares one to make sense of ideas? These are important questions as the field continues to refine our understanding of what knowledge matters for the work that teachers do.

CONOCIMIENTO PEDAGÓGICO DEL FORMADOR PARA ENSEÑAR LA ADICIÓN A FUTUROS PROFESORES

Ana Rosa Arceo Luna
Universidad Autónoma de Aguascalientes
aanarceo@gmail.com

David Alfonso Páez
CONACyT- UAA
dapaez@correo.uaa.mx

Enseñar la adición a futuros profesores requiere del formador un conocimiento matemático y didáctico en el marco de las demandas curriculares y contextuales. El objetivo del presente estudio es identificar el conocimiento pedagógico inmerso en la práctica del formador al enseñar el algoritmo de la adición y su didáctica. Para ello, se observaron cuatro sesiones de un formador de profesoras de educación primaria en México al desarrollar este contenido. El análisis de los datos fue de tipo descriptivo e interpretativo a través de categorización. Los resultados muestran que en este formador destaca el subdominio del Conocimiento del Contenido y la Enseñanza, ya que instruye a sus alumnas principalmente sobre la didáctica de la matemática en función de cómo los niños de educación primaria se acercan al algoritmo de la adición.

Keywords: Conocimiento del profesor, Preparación de Maestros en Formación, Conceptos de Números y Operaciones

Diversas investigaciones han dado cuenta que el conocimiento didáctico y matemático del profesor es una característica clave para la mejora y la calidad en el aprendizaje (Ball, Thames, & Phelps, 2008; Jaworski, 2008). El docente que imparte matemáticas en instituciones formadoras de maestros tiene como tarea principal ayudar a los profesores en su formación inicial a desarrollar y mejorar las tareas docentes de modo que construyan el conocimiento profesional necesario para enseñar matemáticas (Jaworski, 2008; Rojas, & Deulofeu, 2015). Ello significa que este actor, también conocido como formador, requiere un mayor dominio de conocimientos pedagógicos sobre actividades de aprendizaje, aspectos referentes al currículum y evaluación, además del contexto social, características personales, conocimientos previos y procesos de aprendizaje de los estudiantes (Ball et al., 2008; Jaworski, 2008). Al considerar la práctica del formador de educación primaria (6 a 12 años de edad) como una preocupación a nivel nacional e internacional (Llinares, 2013), se ha enfatizado el interés por estudiar su conocimiento didáctico y matemático, con la intención de hacer propuestas de intervención donde tenga la posibilidad de discutir sus conocimientos inmersos en la práctica para la mejora de la enseñanza (Ball et al., 2008), en particular, aquellos que emplea para desarrollar contenidos que, por las habilidades que ponen en juego, constituyen una herramienta valiosa para la construcción de algoritmos matemáticos, como lo es la adición (Godino, Font, & Wilhelmi, 2006). El estudio aquí reportado tiene como objetivo: Identificar características del Conocimiento Pedagógico del formador inmerso en su práctica al enseñar el algoritmo de la adición.

Marco teórico

Para estudiar el Conocimiento Pedagógico del formador se retoma el modelo Mathematical Knowledge for Teaching (MKT) propuesto por Ball, Thames y Phelps (2008), desde la perspectiva de quien enseña a los futuros profesores; es decir, que tenga un dominio mayor del objeto matemático y cómo este debe enseñarse a los niños (Zopf, 2010).

El MKT expresa una relación recíproca de dos dominios del conocimiento para la enseñanza de las matemáticas: del Contenido y de la Pedagogía del Contenido. La relación entre ambos constituye una composición que "implica una idea o procedimiento matemático particular y la familiaridad con los principios pedagógicos para enseñar ese contenido" (Ball et al., 2008, p. 402), por lo que en conjunto forman un insumo para analizar múltiples aspectos inmersos en la práctica de quien enseña matemáticas. El primer dominio constituye un conocimiento particular y característico de quienes se dedican a la enseñanza de las matemáticas (Hill, Ball, & Schilling, 2008) y se compone, a su vez, de tres subdominios: Conocimiento del Contenido y de los Estudiantes (KCS), Conocimiento del Contenido y de la Enseñanza (KCT), y Conocimiento del Contenido y el Currículo (KCC). Respecto a la adición, el formador debe poseer una comprensión sobre este contenido matemático, sus significados (Godino, Font & Wilhelmi, 2006), representaciones y modos en que el niño construye el algoritmo convencional (Vergnaud, 1985/2013) con la intención de mostrar la didáctica.

Metodología

Se trata de un estudio de caso en el que, desde un enfoque cualitativo, se percibe la realidad como un sistema complejo que se encuentra integrado y sujeto a un análisis (Cohen, Manion, & Morrison, 2007). El participante es un formador que labora en una escuela mexicana para profesoras e imparte la materia *Aritmética. Números Naturales,* en la que se enseña la adición y su didáctica en la Licenciatura en educación Primaria 2018 (Secretaría de Educación Pública [SEP], 2018). Cuenta con una formación inicial como docente de educación básica,y tiene doce años de experiencia en las escuelas para maestros, de los cuales en nueve ocasiones ha enseñado las materias en las que se muestra la adición.

Para la obtención de los datos se utilizó la observación no participante centrada en captar explicaciones, ejemplos e interacciones que dan cuenta del Conocimiento Pedagógico del formador (Ball et al., 2008). El formador fue observado (videograbado) en cuatro sesiones de clases (duración: dos horas cada una) en las tenía prevista el tratamiento de la adición según su planeación didáctica y el programa de la materia.

Se llevó a cabo un análisis interpretativo descriptivo, por lo que las videograbaciones fueron vaciadas en una matriz de acuerdo a las categorías del Conocimiento Pedagógico para Enseñar Matemáticas (Ball et al., 2008) y los indicadores propuestos por Sosa y Carrillo (2010). En este sentido, se determinaron tres categorías deductivas conformadas por subcategorías: KCS, *conocimiento del estudiante de primaria, y conocimiento del estudiante para profesor*; KCT, *didáctica del profesor de primaria, uso de ejemplos, preguntas y, respuestas de los estudiantes*; KCC, c*urrículum oficial y currículum real*.

Además, otras tres subcategorías emergieron de los datos: *Conocimiento del estudiante de primaria,* que se refiere al reconocimiento que hace el formador acerca de los modos de pensamiento de los niños con quienes trabajaran las futuras docentes; *Didáctica del profesor de primaria,* que se refiere a las estrategias de enseñanza que se sugieren para mostrar la adición a los niños; *Currículum real* (Casarini, 2015), alude a los saberes que el profesor ha aprendido en su experiencia previa como docente y, sin indicarse oficialmente, emplea en su práctica.

Resultados

1. KCS

En la práctica del formador se observó un conocimiento acerca de dos tipos de alumnos: el niño de educación primaria y las futuras profesoras. El primer tipo de conocimiento fue mostrado al hacer alusión a los modos de pensamiento del niño que el docente debe considerar para abordar el contenido de la adición; por ejemplo, el formador menciona que "antes de plantear situaciones convencionales, primero hay que poner al niño a que haga conteo de situaciones en las que hay que agregar o quitar, de ahí se trabaja la composición y la descomposición". Además el formador sugirió a sus estudiantes considerar las dificultades de los niños al enseñar la suma, en particular la comprensión de los problemas matemáticos donde hay dificultad para discriminar los datos necesarios, identificar el tipo de operación -como el restar en lugar de sumar- y al uso del algoritmo escrito; por ejemplo, comentó a sus estudiantes: "los niños no mantienen un orden en el sentido de las unidades, decenas y centenas, por lo que llegan a cometer errores al ubicar el valor posicional".

El conocimiento de las estudiantes para profesoras se observó cuando el formador reconoció que tienen procesos de pensamiento distintos a los niños, en particular en la resolución de ejercicios matemáticos: "ya ustedes son expertas en este procedimiento, por eso lo resuelven de una manera más rápida. Pero pensemos en el trámite de los niños de apropiarse de un procedimiento que ellos desconocían". En este sentido, a las futuras profesoras les solicitó que además de la participación en los juegos sugeridos para trabajar con los niños y la resolución de problemas, diseñaran actividades, considerando el conocimiento previo de la resolución de problemas y el empleo de la suma y la resta: "diseñen una actividad donde comiencen a introducir los signos de sumar y restar". En general, predomina el conocimiento del estudiante de primaria, por lo que las actividades y sugerencias estuvieron centradas en el proceso de los niños y cómo éstos se acercan al contenido de la adición, por ejemplo ante resoluciones equivocadas, el formador hizo expresiones como: "sucede con los niños", enfatizando que es el estudiante central.

2.KCT

El subdominio del KCT fue mostrado por el formador a través de cuatro subcategorías: a) Didáctica del profesor de primaria, b) Uso de ejemplos, c) Preguntas y d) Respuestas de los estudiantes. En lo que refiere al inciso *a* se observaron dos aspectos principales: el primero respecto a las consideraciones acerca de los procesos que debe seguir el profesor para guiar al niño desde la fase manipulativa al algoritmo convencional de la adición, pues dijo que el docente de primaria "tiene que ponerlos a jugar, a contar, a que iluminen, a que comparen, que pongan los signos, primero, y ya al final el procedimiento usual" ya que considera que esto hace que para el niño sea más "fácil y divertido, al niño le interesan más este tipo de actividades y hacemos algo distinto". El segundo aspecto es la delimitación de roles o tareas que debe desempeñar el niño y el profesor; el formador expresó que las nociones acerca del signo y los elementos que conforman la suma –sumandos, resultado y signo- "deben ser enseñados por el profesor, pues el niño no los descubre solo", mientras que en la resolución de problemas la función del profesor es "darle libertad al niño para que represente las colecciones […] ya al final el maestro lo representa de manera horizontal y vertical, pero no le dice al niño que lo resuelva así, el niño lo resuelve como puede ".

Respecto al inciso *b,* algunos ejemplos consistían en la introducción al tema de forma expositiva, por ejemplo para presentar nociones y conceptos relacionados con la adición se utilizó una proyección en el pizarrón, otros ejemplos servían para presentar problemas en el pizarrón en los que se involucran situaciones que el formador denomina de "agregar o quitar". Estas situaciones tuvieron dos intenciones: que las estudiantes ejercitaran el proceso de resolución de problemas en los que utilizan el algoritmo escrito de la adición, y mostrar la didáctica del contenido enfatizando cómo se integran los conceptos matemáticos revisados en la clase de formación para profesoras –como cambiar la expresión "sobra" por el término "transformaciones", y hacer sugerencias sobre el uso de material manipulativo.

En lo que refiere al inciso *c*, las preguntas se plantearon principalmente con cuatro intenciones: para enlazar contenidos de la clase con la experiencia previa de las estudiantes; "¿Cómo les enseñaron a ustedes a sumar y a restar cuando eran niñas?" "¿Les ponían problemas o les ponían ya el algoritmo?" y contrastarlo en cómo deben enseñarlo a sus futuros estudiantes de primaria. Para valorar la didáctica y estrategias propuestas por el formador: "¿Por qué es necesario trabajar el tablero y en general actividades lúdicas antes del algoritmo usual?". En las operaciones matemáticas, para comprobar procedimientos y hacer propuestas de mejora a los recursos; "¿qué necesitaría este problema para hacerlo más comprensible para el niño?", y para construir reflexiones acerca de la enseñanza.

Por su parte, las respuestas de las estudiantes fueron consideradas por el formador para profundizar en los contenidos así como para hacer correcciones a los procedimientos y a los conceptos, por ejemplo, al pasar una estudiante al pizarrón y utilizar expresiones como "sobrantes", el formador la corrige y le señala que "se transforma en una decena" haciendo alusión al empleo de un concepto más de tipo matemático que de sentido común. Las respuestas dadas por las estudiantes son utilizadas también para generar discusión acerca de la práctica futura de las docentes y los procedimientos que los niños siguen al utilizar el algoritmo de la adición; por ejemplo, cuando las estudiantes explican cómo han resuelto un problema, el formador comenta "tú lo hiciste con tu mente y con ayuda de los dedos, tú lo hiciste en la libreta, el cálculo mental, tú usarías el ábaco […] así como ustedes, también los niños utilizan diferentes materiales para poder contar" y a partir de ello, el formador explica cómo los niños resuelven la suma.

3. KCC

En el KCC se observaron dos tipos de currículum en el aula; el oficial y real. Respecto al primero, el programa de estudios (SEP, 2018) señala que en este curso se espera estudiar la didáctica y la matemática, que es una intención observada en la práctica del formador, además utilizó la metodología sugerida por este programa, donde se da prioridad a la resolución de problemas. Sin embargo, la secuencia de actividades es distinta a la propuesta del programa, lo que hace suponer que el formador ha utilizado referencias que surgen de su experiencia previa como profesor de primaria, por lo que se observa un currículum real en el que el formador hace propuestas didácticas y matemáticas que surgen de su experiencia y son distintas a los planteamientos del currículum oficial.

Conclusiones

Este trabajo permitió plantear el dominio del Conocimiento Pedagógico del MTK en la práctica de los formadores y con ello dar cuenta que éstos actores manifiestan características distintas a las de los docentes que tienen como objetivo de su práctica el enseñar la adición y no la didáctica. Los ejemplos –KCT- constituyeron un eje central para el desarrollo del contenido y sirvieron para enseñar o reaprender la matemática en las futuras profesoras (Rojas & Deulofeu, 2015), en especial, los conceptos relacionados con la adición. Los subdominios que se retoman de la práctica del formador presentaron subcategorías diferentes a las del estudio de Sosa y Carrillo (2010) relacionadas con la enseñanza de futuros profesores; por ejemplo, en el KCS las actividades y exposiciones fueron diseñadas atendiendo al nivel cognitivo y los procesos de los niños para adquirir el algoritmo, priorizando este estudiante, mientras que en el KCC el formador lleva a cabo un currículum real que utiliza su propia experiencia como herramienta principal. En síntesis, se pudo observar que el Conocimiento Pedagógico al enseñar la adición a futuras profesoras se presenta con un énfasis particular en las tareas de instrucción, las cuales se relacionan con los procesos que el niño lleva a cabo. Conjuntamente, se mostró la relevancia del KCT en la práctica del formador (Zopf, 2010) y además de reconocer los conocimientos inmersos en la práctica, sería necesario desarrollar estudios encaminados a estudiar la reflexión que el formador puede realizar para mejorar su práctica.

PEDAGOGICAL KNOWLEDGE OF THE TEACHER EDUCATOR TO TEACH THE SUM TO FUTURE TEACHERS

Teach the sum to future teachers requires from the teacher educator a mathematical and didactic knowledge within the framework of curricular and contextual demands. The objective of the present study is to identify the pedagogical knowledge in the teacher educator's practice when teaching the algorithm of the sum and its didactics. For this, four sessions of a teacher educator of primary education in Mexico were observed when developing this content. The analysis of data was descriptive and interpretative through categorization. The results show that in this teacher educator highlights the subdomain of Knowledge of Content and Teaching, he mainly instructs his students mainly on the didactics of mathematics according to how primary school children approach the algorithm of the sum.

CONNECTING ADVANCED AND SECONDARY MATHEMATICS: INSIGHTS FROM MATHEMATICIANS

This paper reports a preliminary analysis of mathematicians' detailed accounts on why and how advanced mathematical knowledge matters for secondary mathematics teaching, and what specific connections can be made between advanced and secondary mathematics. Drawn from interviews with 18 mathematicians from 9 universities, the findings indicate that having advanced mathematical knowledge would allow secondary mathematics teachers to 1) develop an appropriate framework of mathematics; 2) gain mathematical experiences that would enhance their students' experience with mathematics; and 3) grow awareness of the extent of one's mathematical knowledge. Specific examples that connect linear algebra to secondary mathematics are presented and discussed.

Keywords: Advanced mathematical thinking, High school mathematics, Teacher knowledge, Mathematicians.

Introduction

How important is advanced mathematics for good teaching? While Monk's (1994) study shows that teachers' mathematical background, as measured by the number of mathematics courses a teacher took in university, is positively related to how much mathematics students learn at the secondary level, it is not always clear how and why advanced mathematics contributes to teaching. In fact, teachers often struggle to find specific examples that connect advanced and secondary mathematics (e.g., Zazkis & Leikin, 2010). Previous studies sought the relevance and contribution of academic mathematics to teaching by taking into account mathematicians' views on curriculum planning and course design (e.g., Goos, 2013; Hoffmann & Even, 2018; Leikin, Zazkis & Meller, 2018). However, many questions remain unanswered regarding which connections between advanced and school mathematics are important, and how they might lead to the improvement of teachers' practice (Murray et al., 2017). This paper reports a preliminary analysis of mathematicians' view on why advanced mathematical knowledge matters for secondary mathematics teaching, and what specific connections can be made between linear algebra and secondary mathematics.

Theoretical Background

Our paper builds upon 1) the notion of advanced mathematical thinking (AMT) and advanced mathematical knowledge (AMK); and 2) previous studies on mathematicians' perspectives on the importance of advanced mathematical knowledge for teaching.

Tall (1991) examined differences between elementary and advanced mathematical thinking as transitions from *describing* to *defining*, from *convincing* to *proving* based on abstract entities. These transitions, considered challenging processes for most prospective teachers, must be addressed and overcome during their undergraduate education. In exploring secondary mathematics teachers' conceptions of the role and usage of AMK in their teaching practice, previous studies have shown that while some teachers acknowledged the importance of AMK, others are unaware of the connections between secondary and advanced mathematics, and are often dismissive of their upper-level training (e.g., Goulding, Hatch, & Rodd, 2003; Zazkis & Leikin, 2010). To help motivate practicing and prospective teachers in deepening their mathematical understanding, previous studies also investigated how abstract algebra might support teachers' efforts to unpack a secondary mathematics topic, and how an understanding of advanced mathematics might shape pedagogy in the secondary classroom (Christy & Sparks, 2015; Murray et al., 2017).

Considering mathematicians' perspectives on teaching, Leikin, Zazkis, and Meller (2018) noted that, "mathematicians act as teacher educators de facto, without explicitly identifying themselves in this role" (p. 452). Indeed, mathematicians and teachers typically have different approaches to the knowing of mathematics: while mathematicians focus on the epistemic nature of the subject, teachers often focus on cognition and pedagogy without rigorous justification (Cooper & Arcavi, 2018). Despite these differences, Bass (2005) argued that mathematicians' knowledge, practices, and habits of mind are relevant to school mathematics education because their mathematical sensibility and perspective are essential for maintaining the mathematical balance and integrity of the educational process. This preliminary research report aims to further investigate mathematicians' perspectives on possible connections between advanced and secondary mathematics.

Method

The participants were 18 mathematicians from 9 universities: 15 were actively engaged in mathematics research and 3 were focused on teaching only. Of the 18 participants, 15 were teaching undergraduate or graduate courses in mathematics at Canadian research universities; two were professor emeriti; and one was a visiting professor from outside of Canada.

The main corpus of data was comprised of individual semi-structured interviews with the participating mathematicians. The aim was to gain insights into their views on advanced mathematical knowledge and its relevance to secondary school mathematics teaching. The interviews included two main guiding questions:

1. How do you think advanced mathematical knowledge might contribute to secondary school mathematics teaching?
2. What are specific examples that reveal connections between advanced and school mathematics?

All the interviews were audio-recorded and transcribed. Additional written artifacts generated by the interviewees were collected for the qualitative analysis. Recurring themes were identified and categorized using an iterative and comparative process. In this paper, all participants were coded starting with M, followed by a number assigned to each participant.

Findings

Why Advanced Mathematical Knowledge Matters

Three major themes emerged from the mathematicians' responses to "how do you think advanced mathematical knowledge might contribute to secondary school mathematics teaching?" The results of the analysis show that advanced mathematical knowledge would allow teachers to 1) develop an appropriate framework of mathematics; 2) gain rich mathematical experience that would enhance their students' experience with mathematics; and 3) grow awareness of the extent of one's mathematical knowledge.

Developing the framework of mathematics. Some of the mathematicians claimed that a clear vision of what mathematics is and robust understanding of a mathematical concept comes from advanced mathematical knowledge. For M5, "the conceptual framework that underpins complex procedures and mechanical applications" is a component of AMK. Along the same line, M10 explained the framework of mathematics with an analogy:

> If you are knitting something, you must get some kind of overarching concept of what it is that you are doing. You are working locally but there is some framework in your mind that how your local thing is sort of fitting in.

In this sense, the importance of advanced mathematical knowledge lies in the heart of developing or changing the framework of mathematics. Having advanced mathematical knowledge would allow a teacher to see the fundamental structure and to reach "a kind of gestalt," as M10 stated, "I mean it is the same idea but somehow you are looking at a piece of mathematics on completely different terms."

The framework of mathematics was also elaborated in the sense of the scope of the subject. For example, "What comes next in the material? And how is it used later on?" (M14). As M16 put it, "This is what you teach now, but maybe this will appear again in a slightly different form; because definitions and problems are adjusted to students' comprehension level. How will they appear later on? That is the key." Concerning teaching at the secondary level, M14 stated that, "Having more knowledge means more tools, more examples, and a deeper understanding. […] It allows you to bring the material to life via a compelling narrative."

Gaining mathematical experience. Mathematics is not a spectator sport (Phillips, 2005). The mathematicians interpreted advanced mathematics not only as a form of knowledge, but also as "the process and experience of gaining that knowledge and thinking about how that knowledge impacts what they [teachers] are going to try to put forth to their students" (M11). As M10 suggested, "Roll up your sleeves and do it […] because it embodies structure and you have to get into it and understand the structure." M9 also explained:

> It [mathematics] is the study of complex structure and especially when there are simple elegant aspects to the structure. So they [teachers] need to understand how to work with such a structure. How to take it apart so they can understand how the different pieces interact and then put it back together? The only way to get that understanding and experience is to spend time doing it.

One of the benefits from doing a lot of mathematics, for M13, is that learners would be able to attack a mathematics problem using a "power drill" rather than some very simple "screwdrivers" that by definition take longer (see example 3 in Table 1).

Growing awareness of the extent of one's mathematical knowledge. Another aspect of the importance of AMK lies in the growth of awareness that guides and enables actions. M15 regarded the importance of AMK as a reflective process that allows teachers to identify their strengths and weaknesses in mathematics:

> If people are going to be teaching, they should be able to tell they actually know something well or more importantly whether they are still confused. Really getting that distinction down

> is one of the goals of undergraduate training at the level of a major. I think that only if you study a certain amount of mathematics [you] can do that [make that distinction].

Other mathematicians also shared this view. For example, M4 pointed out that one of the expectations in the undergraduate mathematics program at his university was to learn the limits of both students' knowledge and mathematicians' knowledge. This suggests that being aware of the extent of one's mathematical knowledge would consequently enable prospective teachers to mediate between elementary and advanced mathematical thinking.

Connections Between Advanced and Secondary Mathematics

The examples provided by the mathematicians span a wide range of topics in mathematics. In this paper, we focus on three examples in linear algebra to illustrate the connections drawn between advanced and secondary mathematics.

Table 1: Examples in Linear Algebra

A High School Problem	AMK	Advantages of AMK for Teachers
1. Solve systems with 3 or more equations.	- *Gauss-Jordan elimination*: "A systematic way to simplify a set of equations" (M5). - *Matrices and the idea of inverse*: "Use the inverse matrix if it is invertible, then you know you get a unique solution" (M8).	- "'Read off' the solution" (M5); - Identify whether a system has unique, many, or no solution.
2. Solving $\begin{cases}\mathbf{x}+\mathbf{y}=\mathbf{2}\\ \mathbf{x}-\mathbf{y}=\mathbf{0}\end{cases}$ A student's incorrect method $\mathbf{x}+\mathbf{y}-\mathbf{2}=\mathbf{x}-\boldsymbol{y}\Rightarrow\boldsymbol{y}=\mathbf{1}$, thus the solution set is y=1, x any number.	- *Solution to a system of equations*: "In the background of [the] Gauss-Jordan elimination is the abstract idea of what algebraic operations are permitted on the system of equations (manipulating them) that don't change the solutions set" (M5).	- Understanding that "equating two or more equations together is NOT an allowed operation; it could alter the solution set" (M5).
3. Find the equation of a line through the points (2, 7) and (8, 10).	- *Use of the determinant of a 3 by 3 matrix*. (M13) e.g. (2,7) and (8,10). $0 = \det\cdot\begin{bmatrix} x & y & 1\\ 2 & 7 & 1\\ 8 & 10 & 1\end{bmatrix} = x\cdot\det\begin{bmatrix}7 & 1\\ 10 & 1\end{bmatrix} - y\det\begin{bmatrix}2 & 1\\ 8 & 1\end{bmatrix} + 1\cdot\det\begin{bmatrix}2 & 7\\ 8 & 10\end{bmatrix}$ $= -3x - y\cdot(-6) - 36 = 0$ Then solve to get $6y = +3x+36$ $\boxed{y = \frac{x}{2}+6}$	- Offer an alternative solution; - Create a need for a justification of why the method works, which may lead to a formal proof.

Discussion

In response to why advanced mathematical knowledge matters for good teaching, the mathematicians placed emphasis on the understanding of the breadth and depth of mathematical knowledge in relation to mathematical structure. Two of their ideas – to establish the framework of mathematics and to gain rich mathematical experience resonate with Mamona-Downs and Downs' (2008) elaboration on the importance of the process of mathematical thinking rather than the product of mathematical thought. This is also in line with Burton's (1999) suggestion that mathematicians often see connections set within a global image of mathematics as an important part of knowing mathematics. The third idea regards the importance of teachers' awareness of the extent of their own knowledge, and their ability to distinguish between what they know and what requires further mathematical investigation. Additionally, by providing examples in linear algebra that may require AMK for an explanation, an alternative method, or simply a quick solution, the mathematicians provided insightful connections between advanced and secondary mathematics. Nonetheless, the analysis of the data set is still at its early stages. Further investigation and a more in-depth analysis would help us better understand the nature of advanced mathematical knowledge, and its relationship to school mathematics.

We report the results of a validity study of a multidimensional fraction arithmetic test with a sample of 371 Chinese middle school mathematics teachers. The test was originally developed and validated in the U. S. using diagnostic classification models (DCMs). It contains four attributes related to fraction multiplication and division reasoning. The results provide cross-cultural support for DCMs to reliably measure multidimensional constructs. The response patterns from the Chinese sample were compared to those of a US sample of 990 middle school teachers and provide a strong rationale for international collaboration.

Keywords: Mathematics Knowledge for Teaching, Rational Numbers, Measurement, Middle School Education

The field of mathematics education has seen a growing interest in cross-national studies of teaching and learning. Cross-national comparisons of teacher knowledge are afforded by measures such as those developed in the contexts of (a) the Teacher Education and Development Study: Learning to Teach Mathematics (TED-M) and (b) Learning Mathematics for Teaching (LMT). In 2012, the journal *ZDM: Mathematics Education*, devoted an entire issue, *44*(3), to *Assessment of Teacher Knowledge across Countries*, which served as a platform for international scholars to engage in rich discussions about the various methodological challenges surrounding cross-cultural measures of teacher knowledge (e.g. Delaney, Ball, Hill, Schiling, & Zopf, 2008; Stylianides & Delaney, 2011). Delaney et al., in particular, recommend that researchers, when adapting measures to use internationally, first employ psychometric and interview-based methods to determine a correspondence between the constructs being measured.

We believe that studies of Eastern Asian and Chinese learners and teachers in the past (e.g., An, Kulm, & Wu, 2004; Ma, 1999; Stigler & Perry, 1988) have not only helped mathematics teachers better understand the practices in their own societies and cultures, but also enhanced their awareness of the various alternative models, methods, and possibilities, and will continue to have a profound impact on the development of practices and policies in mathematics education.

Theoretical Perspectives

Mathematical Perspective

The instrument we use for this validity study was developed by an interdisciplinary team of psychometricians and mathematics education researchers in the context of a National Science Foundation-funded project, Diagnosing Teachers' Multiplicative Reasoning (DTMR). The DTMR fractions survey was designed to measure knowledge of middle grades mathematics teachers (grades 5-7) in multiplicative reasoning about fraction arithmetic. It emphasizes standards-based practices (CCSSO, 2010; NCTM, 2000) in which numbers are embedded in problem situations as measures of quantities (e.g., lengths and areas) and are accompanied with drawn models (e.g., number lines, rectangular areas). For a detailed discussion of the test construction process and sample test items, please see Izsák, Jacobson, and Bradshaw (2019). The final version of the instrument includes four attributes or components.

In brief, the first attribute is called *referent unit* (RU), which is closely related to Lamon's (1996) notion of unitizing, i.e., assigning a given quantity a unit of measurement. The second attribute, *iterating and partitioning* (PI), combines two closely related aspects of reasoning about fractions into a single construct, similar to Steffe's (2001) splitting construction scheme. *Partitioning* refers to subdividing a given quantity into equal-sized pieces. *Iterating* refers to the process of concatenating a unit of length, which is particularly important for developing meaning for improper fractions (e.g., Tzur, 1999, 2004). The third attribute, *appropriateness* (APP), is tied to the difficulties that teachers tend to experience when making distinctions among situations that call for dividing by a fraction, dividing by a whole number, and multiplying by a fraction (e.g., Ball 1990; Ma, 1999; Sowder, Philipp, Armstrong, & Schappelle, 1998). The fourth and last attribute, *reversibility* (REV), usually deals with returning to a starting point after some process (Iszák et al., 2019), for example, after partitioning a non-unit fraction (n/m) into n parts to produce the unit fraction ($1/m$), and then producing the original whole (m/m) from which the unit fraction is a part (also see Tzur, 2004).

Psychometric Perspective

In the majority of the large-scale studies on mathematics knowledge for teaching (e.g., Hill, Sleep, Lewis, & Ball, 2007; Center for Research in Mathematics & Education, 2010), researchers have developed measures for use with unidimensional item response theory models. However, measures based on unidimensional item response theory are not suitable for measuring multiple attributes of reasoning simultaneously.

Diagnostic Classification Models (DCMs) is a family of recently developed psychometric tools that can be used to construct practical, multidimensional tests. For example, DCM analyses provide specific feedback to individual teachers in terms of their strengths and weaknesses on each component of reasoning. In addition, these attributes are determined based on research literature and theory prior to analyses. Compared to multidimensional IRT (MIRT), DCMs need far fewer items per dimension to yield reliable examinee estimates (Templin & Bradshaw, 2013). Bradshaw, Izsák, Templin, and Jacobson (2014) were the first to report an instrument that successfully measures a multidimensional construct using a generalized form of DCM, *log-linear cognitive diagnostic model* (LCDM, see Henson, Templin, & Willse, 2009) with the support of empirical data. Prior studies involving DCMs relied on retrofitting DCMs to existing test data that was originally designed for unidimensional IRT. We know of no cross-cultural validity studies of any DCM-based instrument for mathematical knowledge for teaching.

In this study, we ask two research questions. First, can a multidimensional U.S. diagnostic instrument for mathematics teacher knowledge in a specific domain (i.e., fraction arithmetic) be used to reliably measure the same attributes with Chinese teachers? Second, what is the distribution of proficiency with these attributes among Chinese mathematics teachers?

Methods

We distributed our instrument to a convenience sample of middle grades Chinese teachers (Grades 6-9) from two districts in Shanghai. Among the 450 surveys we sent out, 414 surveys were returned with a response rate of about 92%. Among the 414 returned surveys, 43 surveys were blank, and subsequently were removed from further analysis, resulting in 371 usable surveys. All the Chinese teachers in our sample have at least a Bachelor's degree in mathematics. Some have a Master's degree. Their average years of teaching is about 16 years. About 1/3 of our sample are male teachers. We used forward and backward translation to prepare the Chinese version of the instrument. The two English versions were deliberated and compared among a panel of mathematics educators and doctoral students. Conceptual equivalence, accuracy, and appropriateness were established by the panel. A generalized form of DCM, *log-linear cognitive diagnosis model* (LCDM; see Henson, Templin, & Willse, 2009) was used to fit the test data. All the analysis below were performed in *R* i386 3.5.1 using the *cdm* package.

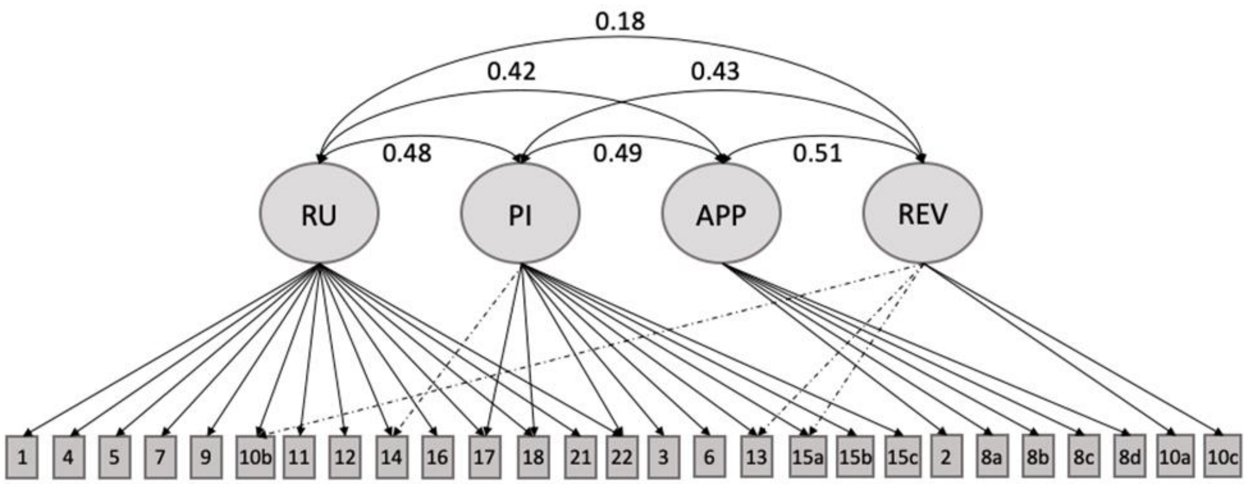

Figure 1: Path Diagram for DTMR Fractions Survey

Results and Discussions

Model Specifications

Figure 1 depicts our final model, which is highly comparable to the final model in the earlier study with 990 U.S. middle school teachers (Bradshaw et al., 2014). A few paths in our study did not show reasonable effect sizes and were signified with dotted lines. The results show that these items only had significant contribution to measure one of the two attributes they were intended to measure. For example, Item 14 significantly contributed to the measures of RU and PI in the U.S. study, but in our study, Item 14 only significantly contributed to the measure of RU but not PI. We also modeled the bivariate relationships between attributes using tetrachoric correlations as shown in Figure 1. The correlation coefficients ranged from .18 to .51. These slightly-to-moderately positive correlations provide evidence that the four attributes are distinct, although related. This result supports the conclusion from the earlier study for using a multidimensional model rather than a unidimensional model. If the underlying trait was unidimensional, we would expect that these correlations to be close to 1.

Item Parameter Estimates and Diagnostic Utility

Odds ratios were determined to indicate the effect sizes for the final 28 items. Conventional criteria for evaluating effect size (Chin, 2000) are small (between 1.44 and 2.47), medium (between 2.47 and 4.25) and large (above 4.25). Two of the items had extremely small effect sizes (Item 2 and Item 10c), which may be interpreted as these items contributed little to the measure of the specified attributes. Among the rest of the 25 items, 9 yielded small effect sizes; 4

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

medium effect sizes, and 12 large effect sizes. These 25 items demonstrated reliable diagnostic utility.

Item Reliability

All the above results focused on item-attribute validity. To quantify reliability of the attribute classifications, we used the DCM measures of reliability from Templin and Bradshaw (2013). Classification reliabilities are extremely high based on the item responses from the Chinese teachers, even for attributes that are measured by only a small set of items. These reliability scores are 0.902, 0.995, 0.994, and 0.999 for RU, PI, APP, and REV respectively.

Attribute Classifications

Because the DTMR fractions survey measures four binary attributes, teachers are classified into 2^4 or 16 possible patterns of attribute mastery or latent classes. The LCDM estimates the probability that each teacher is a member of each latent class. These estimates were aggregated across examinees and are provided in Figure 2. The most likely attribute profiles for our sample of Chinese middle school teachers were (a) all four attributes were mastered (40%) followed by (b) mastery of three attributes except for RU (25%). The earlier U.S.-based study showed that the most likely attributes for U.S. middle school teachers were all attributes were mastered (25.5%), followed by none of the four attributes were mastered (21.2%), and then followed by all attributes but RU were mastered (13.5%). These results demonstrate that RU is a common challenge for teachers in both countries.

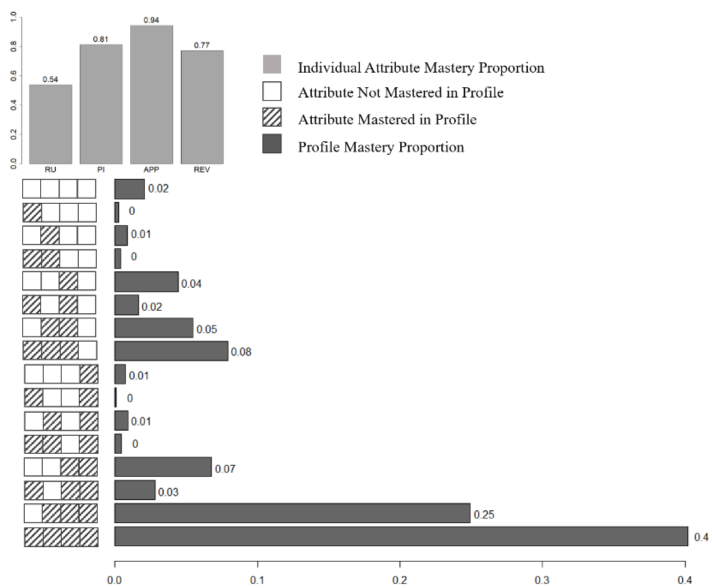

Figure 2: Attribute Profile Mastery Proportions. Profiles Use 0 or 1 to Indicate Nonmastery or Mastery in the Following Order: RU, PI, APP, and REV.

Conclusions and Implications

In terms of psychometric development, this study provides empirical support for the capacity of DCMs to reliably model and measure multidimensional constructs in a new cultural context. The overall responses from the Chinese and U.S. teachers to the DTMR fractions survey have revealed some similar patterns. For example, the lack of proficiency in identifying and choosing appropriate referent units is a common challenge for practicing teachers in both countries. We recommend that international mathematics educators continue to harness the recent advances in psychometric models such as DCMs to build common theoretical grounds for rich and deeper dialogues and for collaboration in developing teacher education and professional development programs.

CORRELATIONS BETWEEN PROFESSIONAL NOTICING OF STUDENTS' MATHEMATICAL THINKING AND SPECIALIZED CONTENT KNOWLEDGE

Raymond LaRochelle

Behailu Mammo
Hofstra University
Behailu.Mammo@hofstra.edu

Professional noticing of students' mathematical thinking and mathematical knowledge for teaching are two constructs that appear to have much overlap. However, empirical studies investigating connections between the two constructs have not found much. In this study, we narrowed our focus to specialized content knowledge (SCK), which is a sub-domain of mathematical knowledge for teaching, and found a connection between SCK and professional noticing expertise.

Keywords: Professional noticing of students' mathematical thinking, mathematical knowledge for teaching

In instructional styles where teachers regularly elicit and use student thinking throughout the lesson, it is crucial for teachers to be able to make sense of their students' mathematical thinking in-the-moment as well as productively decide how to respond to students' emergent ideas (Lampert, Beasley, Ghousseini, Kazemi, & Franke, 2010; Stein, Engle, Smith, & Hughes, 2008). This crucial practice is called *professional noticing of students' mathematical thinking*, and studies have shown that it is not always an easy practice for teachers to develop (Casey, Lesseig, Monson, & Krupa, 2018; Jacobs, Lamb, & Philipp, 2010; LaRochelle, Nickerson, Lamb, Hawthorne, Philipp, & Ross, in press). One way to think about helping teachers develop their professional noticing expertise is by investigating what knowledge teachers need in order to effectively "professionally notice" a student's work. Some researchers have hypothesized that teachers' *mathematical knowledge for teaching* (MKT; Ball, Thames, & Phelps, 2008) plays an important role in teachers' professional noticing of students' mathematical thinking, but empirical connections between the two constructs have been tenuous (Fisher, Thomas, Schack, Jong, & Tassel, 2018; Skultety, 2018). In this brief research report, we share preliminary findings that show a connection between teachers' *specialized content knowledge* (SCK; which is a subset of MKT) and teachers' professional noticing of students' mathematical thinking, a relationship that has been eluding studies.

Literature Review

Professional noticing of students' mathematical thinking is a particular noticing expertise that happens during instruction, when a teacher notices a student's mathematical idea (Jacobs et al., 2010). It consists of three component-skills: the teacher (a) *attends* to the details of the student's strategy, (b) *interprets* the student's mathematical understanding, and (c) *decides* how to respond to the student based on the student's mathematical understanding. Jacobs and her colleagues defined these three component-skills as happening simultaneously, as three interrelated and interdependent processes, that occur before the teacher responds.

Mathematical knowledge for teaching is defined to be the mathematical knowledge used in the profession of teaching. Ball, Thames, and Phelps (2008) defined six domains of mathematical knowledge for teaching, such as common content knowledge (CCK), specialized content

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

knowledge (SCK), and knowledge of content and students (KCS). In this study, we focus on SCK, which is defined as “the mathematical knowledge and skill unique to teaching” (p. 400). In particular, this includes mathematical knowledge that is not typically needed in areas outside of teaching. For example, this includes knowing the different meanings of division and being able to deduce when a student’s non-standard method works.

Thomas, Jong, Fisher, and Schack (2017) highlighted many connections between MKT and professional noticing of students’ mathematical thinking. For example, an important component of enacting MKT is being able to *interpret* the mathematical thinking of each learner. Conversely, robust professional noticing expertise involves consistency with *the research on children’s mathematical development*. Citing numerous other examples of overlap between the two, they posited that effective professional noticing occurs at the intersection of well-developed MKT and a high level of responsiveness to the mathematical activities of students.

However, empirical connections remained elusive. Thomas et al. (2017) and Skultety (2018) looked for connections between teachers’ performance on a professional noticing assessment (e.g., Jacobs et al., 2010), and the Learning Mathematics for Teaching assessment (LMT; Hill, Schilling, and Ball, 2004). In both studies, the authors chose a content domain of the LMT closest to the content domain of the professional noticing assessment. Using a Spearman’s correlation test, Thomas et al. (2017) found no significant correlations between MKT and any component-skill of professional noticing in the pre-test, and only one in the post-test between MKT and attending. Skultety (2018) used a linear regression model to see if MKT might predict changes in professional noticing, and did not find evidence for this hypothesis. As Thomas et al. (2017) remarked, “Given the strong theoretical connections between MKT and professional noticing, such findings are… surprising” (p. 19).

In their conclusion, Thomas et al. (2017) questioned whether the mathematical content in the LMT assessment was too broad in comparison to the content domain of their professional noticing assessment. In this preliminary study, we followed this line of reasoning and wondered what would happen if we significantly narrowed our attention to teachers’ SCK surrounding a single type of problem, and teachers’ professional noticing expertise related to that problem. In particular, we ask the following research question: Are there correlations between teachers’ professional noticing of students’ mathematical thinking skills and teachers’ specialized content knowledge, when assessed in the domain of missing-value proportional reasoning tasks?

Methods

In this study, 15 practicing middle and high school mathematics teachers from the northeast region of the United States completed a survey that captured data about their professional noticing expertise and SCK (see LaRochelle, 2018, for the math tasks and solution strategies). Participants had on average 4.6 years of teaching experience, with a range of 0 to 8 years.

Data Collection: Survey

The survey consisted of three parts, but only the first two parts collected data about teachers’ professional noticing expertise and SCK, and so we only describe those two parts. In each of the first two parts, participants first solved a missing-value proportional reasoning task (Kaput & West, 1994). Participants were invited to solve the task in two ways, and all 15 participants provided two strategies for both tasks. The mathematical knowledge needed to solve a task in multiple ways is considered SCK because teachers are expected to know how to solve mathematical tasks in multiple ways, while those in other professions are not.

Next, participants considered three students' strategies solving that same task, and responded to the following professional noticing prompts (adapted from Jacobs et al., 2010):

1. Please describe in detail what you think each student did in response to the problem.
2. Describe the mathematical understandings of these three students.
3. Pretend you are the teacher of these students. What problems might you pose next, and why?

Each of these prompts related to a different component-skill of professional noticing; the first related to attending, the second related to interpreting, and the third related to deciding how to respond. Parts one and two were identical in structure. The difference between the two parts was in the mathematical task (in part 1 the task exhibited integer ratios, while in part 2 the task exhibited non-integer ratios) and the subsequent solution strategies.

Data Analysis

In order to investigate correlations between teachers' SCK and professional noticing expertise, we rated SCK on a three-point scale, and then rated each component-skill on a three-point scale. We then calculated three Spearman's rank correlations, and tested each for statistical significance: between SCK and attending, SCK and interpreting, and SCK and deciding. In the next two sub-sections we describe how we scored teachers' SCK and professional noticing skills.

Rating teachers' SCK. Each teacher provided two strategies for solving two missing-value tasks, for a total of four strategies. Carney, Hughes, Brendefur, Crawford, and Totorica (2015) claimed that an important goal with missing-value tasks is to develop flexibility using both the *scalar* multiplicative relationship (e.g., 24 caterpillars is four times as big as 6 caterpillars; notice the relationship is between caterpillars and caterpillars) and the *functional* multiplicative relationship (e.g., each caterpillar eats three leaves; notice the relationship is between caterpillars and leaves). The first author chose numbers that equally lent themselves to either multiplicative relationship, so that teachers might be primed to use both when solving the tasks (Carney, Smith, Hughes, Brendefur, & Crawford, 2016). Hence, we coded each strategy for whether the teacher utilized a scalar or functional multiplicative relationship. Cross-multiplication strategies did not count as using either relationship because many students use this strategy without understanding proportional reasoning (Cramer & Post, 1993). Teachers received a score of 2 if they used both multiplicative relationships, 1 if they only used one of the multiplicative relationships, and 0 if they used neither relationship (i.e. they used cross multiplication for all four strategies).

Rating teachers' professional noticing skills. For each response, we followed Jacobs et al. (2010) and coded for the *amount of evidence* exhibited in the response that teachers were consistent with the students' strategies and were consistent with the literature on students' proportional reasoning (e.g., Carney et al., 2015; Lobato & Ellis, 2010). In the attending prompts, this included completely describing important mathematical details of each strategy. For the interpreting prompts, this included differentiating among the students and identifying specific understandings related to multiplicative reasoning. For the deciding prompts, this included selecting problems tailored to each of the three students (sometimes teachers selected multiple problems; this was not a requirement though), and clearly specifying how the problems related to the students' understandings of multiplicative relationships. (For a complete description of these analyses, see LaRochelle, 2018.) For each component-skill, teachers received either a 0 (lack of evidence), 1 (limited evidence), or a 2 (robust evidence).

Results

Results can be seen in Table 1. We did not find significant correlations between attending and SCK, or between interpreting and SCK. However, we did find significant correlation between deciding how to respond and SCK. This meant that higher scores in SCK occurred with higher scores in deciding how to respond based on the students' mathematical understandings.

Table 1: Correlations Between Professional Noticing Component-Skills and SCK

N = 15	**Correlation**	**T-statistic**	**p-value**
Attending vs. SCK	0.2484	0.9244	0.1861
Interpreting vs. SCK	0.2875	1.0822	0.1494
Deciding vs. SCK	0.6989	3.5227	**0.0019***

*Significant at the $\alpha = 0.0166$ level, after adjusting using a Bonferroni correction.

Discussion

The correlation between deciding how to respond and SCK was about 0.7, which is considered to be a strong correlation. Our measure of SCK implicitly measured teachers' understandings of the various multiplicative relationships embedded in missing-value proportional reasoning tasks (Carney et al., 2015). The strong correlation indicated that there was a relationship between teachers' deciding skills and teachers' knowledge of multiple strategies for solving these proportional reasoning tasks. This may indicate that the ability to find (or knowledge of) multiple strategies to a particular task is related to the ability to decide how to respond to students based on their understandings, as exhibited in that task. Hence, this study implies that knowing multiple solution strategies is an important knowledge that teachers use when deciding how to respond to students based on students' mathematical understandings.

We did not find statistically significant correlations between attending and SCK nor interpreting and SCK. However, we wondered if a more rigorous study could shed light on these relationships. We recognize that our sample size was small, and this limited our potential for uncovering relationships. Additionally, we only invited teachers to share two solutions to each proportional reasoning task. It is also possible that attending and interpreting might relate to different domains of MKT. For example, other studies have found relationships between teachers' MKT and teachers' analyses of classroom situations (Kersting, Givvin, Thompson, Santagata, & Stigler, 2012; Kersting, Givvin, Sotelo, & Stigler, 2010). Although these researchers did not specifically investigate teacher noticing, their construct of "useable knowledge" and its related methodology is similar to studies of teacher noticing. Overall, more work must be done to understand the relationship between MKT and professional noticing.

With this study, we question the appropriateness of using MKT assessments such as the LMT for finding relationships between MKT and professional noticing expertise. These assessments collect data on teachers' knowledge with respect to multiple aspects of mathematics, teaching, and learning, and may be too broad for researchers to find direct relationships between MKT and professional noticing. We conjecture that assessing our teachers' MKT with respect to one problem type allowed us to uncover the correlation we found.

While searching for connections is important, we also believe it is important to recognize theoretical differences between the two constructs. For example, noticing is a teaching practice and MKT is a teaching knowledge. As a practice, researchers investigate teacher noticing by documenting what teachers notice; there are fewer inferences to be made because what the researcher documents is what the teacher noticed. However, the scope of MKT is much broader, and allows researchers to consider multiple teaching actions simultaneously. These theoretical differences afford researchers with different opportunities for studying teacher learning.

REFUTING A FRACTION MISCONCEPTION: A BRIEF INTERVENTION PROMOTES TEACHERS' CONCEPTUAL CHANGE

Jessica Rodrigues
University of Southern California
jessica.rodrigues@usc.edu

Ian Thacker
University of Southern California
ithacker@usc.edu

Research shows that some teachers overgeneralize the whole number rule of "multiplication always makes bigger" to multiplication with fractions. The present study explores this misconception not only with fractions with unfamiliar denominators (e.g., thirty-fifths) but also fractions with familiar denominators (e.g., halves) and evaluates an intervention for remediating the misconception. In- and pre-service teachers (N = 100) completed a direction of effects task prior to and after random assignment to either read a control text or a refutation text that directly refuted the misconception. The misunderstanding was present among items with unfamiliar and familiar denominators, demonstrating the pervasiveness of the misconception. Overall, the intervention was found to be effective, showing promise of refutation texts for promoting teachers' mathematics conceptual change.

Keywords: Rational Numbers, Teacher Knowledge, Number Concepts and Operations, Elementary School Education

Studies of teachers' mathematics knowledge have shown that many teachers possess a limited conceptual and procedural understanding of fractions (e.g., Ma, 1999; Moseley, Okamoto, & Ishida, 2007), limiting their preparedness to support their students' fraction learning. Preservice teachers struggle to comprehend the most foundational conceptual understanding of fraction arithmetic, which is the *direction of effects* that an operation produces (e.g., whether multiplying by a given value makes a number smaller or larger; Siegler & Lortie-Forgues, 2015).

Research on direction of effects errors has concentrated on multiplication of fractions (Siegler & Lortie-Forgues, 2015). A common misconception that individuals hold is to overgeneralize the whole number rule that "multiplication always makes bigger" to multiplication with fractions, when in fact, multiplying a positive number by a fraction that is less than one does *not* make that positive number bigger. In a study conducted by Siegler and Lortie-Forgues (2015), 41 preservice teachers completed a direction of effects task for which they were asked to predict without calculating whether the answer to an inequality would be larger or smaller than the larger fraction in the multiplication problem. The fractions used in the task were selected to be too large and uncommon so that the items could not be solved easily with mental arithmetic (e.g., "True or False: 41/66 x 19/35 > 41/66"; Siegler & Lortie-Forgues, 2015). The preservice teachers answered correctly less often than chance on multiplication items designed intentionally to capture the misconception (i.e., multiplication items with fractions between zero and one).

The present study adds to the literature in two important ways by (a) examining the presence of the direction of effects misconception for items involving unfamiliar denominators and items involving familiar denominators and (b) evaluating a brief intervention for remediating the misconception.

Theoretical Framework

Individuals who transfer the whole number rule that "multiplication makes bigger" to all multiplication problems with fractions may need to undergo conceptual change to overcome this misconception. Conceptual change is a process in which individuals restructure conceptual knowledge and shift misconceptions prompted by discrepant information (Carey, 2009). We draw from the Cognitive Reconstruction of Knowledge Model (CRKM) model of conceptual change that discerns between characteristics of the learner (i.e., their prior conceptions and motivation) and of the message (i.e., whether the learning material is comprehensible, coherent, compelling, and plausible; Dole & Sinatra, 1998). This model is particularly useful for our research because it explains why individuals might shift their misconceptions about fraction multiplication based on novel information presented in a refutation text.

Refutation texts have been shown to be an effective tool for promoting conceptual change in science education (e.g., Broughton, Sinatra, & Nussbaum, 2012; Tippet, 2010). These texts are designed to state a misconception, refute those ideas, and then present the accurate explanations as plausible and fruitful alternatives (Hynd, 2001). Whereas positive effects of refutation texts for the remediation of misconceptions have been demonstrated in science education for years (e.g., Diakidoy, Mouskounti, & Ioannides, 2011), the texts have not yet been explored extensively for addressing mathematics misconceptions. A noted exception is research conducted by Lem and colleagues (Lem, Onghena, Vershaffel, & Van Dooren, 2017) that explored the use of refutation texts for correcting students' misconceptions about box-and-whisker plots.

Present Study

To our knowledge, there are currently no studies investigating the presence of the "multiplication always makes bigger" misconception when fractions being multiplied have common denominators (e.g., halves, fourths) and no work investigating an instructional intervention for remediating this specific misconception. In response, the present study was designed with the following two objectives: (a) to assess if pre- and in-service teachers correctly answer less often than chance on easy, medium and hard direction of effects problems involving multiplication of fractions between zero and one and (b) to evaluate the effectiveness of a refutation text that targets the misconception for promoting conceptual change.

Method

Participants

Participants were pre-service and in-service elementary school teachers (N = 100), 38% self-reported as male, 42% White, 45% Asian American/Pacific Islander, 1% Hispanic, 3% Black/African American, 8% Mixed and 5% Other. The mean age was reported as 21.1 years (SD = 3.7). All participants were recruited via a Qualtrics survey panel that exclusively targeted in- and pre-service elementary teachers.

Measures

Texts. Two texts were created, a refutation text and a control text. The refutation text consisted of 364 words, had an 11th grade Flesch-Kincaid reading level, and stated and directly refuted the "multiplication always makes bigger" misconception. For example, an excerpt reads: "When multiplying numbers, you may think that the product will always be greater than the original number. This is incorrect! It is only when you multiply a positive number by a number greater than 1 that the product will be greater than the original number." This direct refutation was followed by a description of when multiplication makes bigger, and does not. The control text was a 100-word expository text paired with an illustration that was adapted from Hake (2007) that describes a strategy for multiplying fractions: "We often translate the word *of* into a multiplication symbol. We find 1/2 of 1/2 by multiplying: 1/2 of 1/2 becomes $1/2 \times 1/2 = 1/4$."

Direction of effects task. The direction of effects task assessed participants' understanding of the direction of effects of arithmetic, which was used to measure participants' conceptual understanding of fraction addition and multiplication (Siegler & Lortie-Forgues, 2015). Participants were asked to evaluate the accuracy of addition inequalities in the form of $a/b + c/d > c/d$ and multiplication inequalities in the form of $a/b \times c/d > c/d$. Participants answered four addition inequalities and four multiplication inequalities within three categories of varying difficulty, resulting in 24 total items. The "easy" items all included the fraction 1/2 paired with a fraction with a familiar denominator such as fourths (e.g., $3/4 \times 1/2 > 1/2$); "medium" items included familiar denominators but did not present any unit fraction such as 1/2 (e.g., $9/10 \times 2/5 > 2/5$); and "hard" items included the items used in a previous study (Siegler & Lortie-Forgues, 2015) with unfamiliar denominators (e.g., $19/35 \times 41/66 > 41/66$). For each inequality, participants were instructed to decide, without calculating, whether the answer would be greater than the answer indicated in the inequality.

Procedure

All materials were presented via an online Qualtrics survey. After agreeing to participate, teachers completed the pretest direction of effects task. Then, teachers were randomly assigned to either the refutation text or the control text group. After reading the text, teachers were asked to complete the direction of effects task again which served as a posttest assessment. The total survey required an average of 18 minutes ($SD = 19$).

Results

We conducted a simple one sided test of proportions to determine if teachers correctly answered multiplication problems with fractions between zero and one less than half of the time. Analysis of teachers' pretest performance on the easy and medium items with familiar denominators and hard items with unfamiliar denominators revealed that teachers chose the correct item about 49% of the time, which was not significantly different than chance (50%; chi-squared = .375, $p = .27$). When considering all 24 pretest items, 31% of teachers were correct on 100% of the 18 addition and multiplication items for which the greater-than inequality was true and 0% on the 6 multiplication items for which the greater than inequality statement was false. In other words, 31% of teachers at pretest showed the true misconception that "multiplication always makes bigger."

Of the 57 participants in the refutation text group, 9 participants continued to show the true misconception (16%) at posttest. We then looked more closely at participants' performance on the six multiplication items that were designed to capture the misconception. We focused attention on the refutation group participants who answered at least one of the misconception items incorrectly at posttest ($n = 28$). Of this subgroup, participants correctly answered at a rate similar to chance for five of the six items ($p > .05$) and less often than chance on one of the six items with unfamiliar denominators: $19/35 \times 41/66 > 41/66$ (71.4%; $p = .01$).

To assess the effectiveness of the refutation text intervention, we ran a repeated measures ANOVA with Arithmetic Operation (addition or multiplication) as a within-subject factor and text condition (refutation text or control) as between-subject factor and number of correct judgments as the dependent variable yielded significant main-effects of Arithmetic Operation ($F(1,98) = 64$, $p < .001$, *partial-eta squared* = .395) and main effects of condition that are

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

approaching significance ($F(1,98) = 2.24$, $p = 0.14$, *partial-eta squared* = 0.022). These were qualified by a significant Operation x Condition interaction ($F(1,98) = 4.462$, $p < .001$, *partial-eta-squared* = 0.043). As expected, post hoc comparisons with Bonferroni correction showed no significant differences between ref-text and control groups in addition knowledge (89% vs 89%, $t(42) = 0.03$, $p = .98$, *Cohen's d* = 0.00). However, we found significant differences between refutation text and control groups in multiplication knowledge (74% vs 63%, $t(42) = 2.45$, $p = .02$, Hedge's $g = 0.56$).

Discussion

We assessed the effectiveness of a refutation text intervention for the remediation of a misconception regarding fraction arithmetic. Though there is some research on the use of refutation texts to shift students' misconceptions about mathematical topics (Lem et al., 2017), our study investigates the use of a refutation text to shift teachers' misconceptions about fraction multiplication. We also explore whether the misconception is specific to multiplication of unfamiliar fractions or common fractions more generally. Overall, we found that teachers answered easy, medium and hard fraction multiplication problems correctly at about the same rate as guessing, suggesting that the misconception is even more widespread and problematic than demonstrated in prior research (Siegler & Lortie-Forgues, 2015). Furthermore, we found that teachers who read a refutation text had fewer misconceptions about fraction multiplication compared with those who read a control text. That is, refutation texts have the potential to substantially impact teachers' mathematics misconceptions. This finding has important implications for research on conceptual change in mathematics and refutation texts.

Teachers Hold the Multiplication Misconception

Our results showed that a sample of pre- and in-service teachers answered fraction multiplication problems with fractions between zero and one at about the same rate as by chance. This finding is consistent with prior research showing that pre-service teachers were not successful in answering items regarding directions of effects in multiplication at a rate better than chance (Siegler & Lortie-Forgues, 2015). This replication of the finding suggests that many pre- and in-service teachers are in need of remediating misconceptions that may be limiting their readiness to advance their students' fraction understanding.

Refutation Texts Support Mathematics Conceptual Change

Teachers who were randomly assigned to read a refutation text that directly refuted the "multiplication always makes bigger" misconception had fewer misunderstandings at posttest than those assigned to read a control text, with modest effect sizes (Hedge's $g = 0.56$). Refutation texts targeting specific misconceptions thus hold potential as a relatively quick method for promoting teachers' conceptual change.

Future Directions

Although the present study shows promise of a refutation text serving as an instructional approach for targeting a specific fraction misconception, replication studies are required before widespread recommendation of refutation texts for supporting mathematics conceptual change. In light of the limited studies thus far exploring refutation texts for mathematics learning, there are multiple research curiosities that future work can explore, such as refutation texts for remediating not only other fraction misconceptions but also misconceptions in other mathematics content areas. Researchers should also explore the effectiveness of refutation interventions among not only teachers but also students, as such texts may hold promise for professional development opportunities and classroom instruction alike.

In this brief report, we describe preliminary results for a study in which we identify and analyze the types of knowledge activated by 101 elementary math teachers in response to a question from about short video clips of mathematics instruction (classroom video assessment; Kersting, Givvin, Sotelo, & Stigler, 2010; Kersting, Givvin, Thompson, Santagata, & Stigler, 2012). Conceptualizing knowledge representations as (re)structured into domain- and context-specific usable knowledge (Kersting et al., 2012), we operationalize the grades 3-5 Common Core State Standards (CCSS; Council of Chief State School Officers & National Governors Association Center for Best Practices, 2010) to capture the mathematical knowledges activated in teachers' written responses. Preliminary results suggest the CCSS might provide a valuable classifier for analyzing teachers' mathematical knowledge bases and offer insights into patterns of knowledge activation.

Keywords: Mathematical Knowledge for Teaching, Teacher Knowledge, Cognition

Since Shulman's (1986, 1987) conception of pedagogical content knowledge (PCK) as knowledge that integrates content and pedagogy, PCK has become the central knowledge domain for teaching. Ball and colleagues (Ball, Thames, & Phelps, 2008) elaborated on Shulman's notion of PCK in the area of mathematics, identifying the Mathematics Knowledge for Teaching (MKT) construct consisting of 6 subdomains. Little progress has been made, however, in capturing the knowledge as it is activated in classroom teaching. One possible reason might be that in order to capture the knowledge teachers activate and use in real classroom situations, teachers' need to engage in assessment tasks that approximate the perceptual-interpretative processes teachers engage in in the process of teaching (Blömeke, Gustafsson, & Shavelson, 2015).

To study teachers' usable knowledge, we developed an assessment approach that uses video clips of authentic mathematics instruction that teachers view along with various prompts to which they respond. Under the CVA-M approach we hypothesize that the teaching episodes shown in the video clips (i.e., the visual auditory input) are sufficiently proximal to an actual classroom situation, tapping into teachers' usable knowledge. We further proposed that for knowledge to become usable it must be restructured to form an interconnected, domain- and situation-specific knowledge teachers can access in a classroom situation (Kersting et al., 2012).

Here we present preliminary results from an attempt to further understand usable knowledge as it is activated. We used the CCSS grades 3-5 math standards as an ontology (c.f. Giaretta & Guarino, 1995) to classify the different knowledge categories activated in a teachers' responses. This approach affords the possibility to capture the variability of knowledge activation across teachers and teaching situations. In this study we investigate three questions:

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

1. How applicable are the CCSS as an ontology for capturing mathematical knowledge activation?
2. Do teachers' responses reflect the activation of multiple knowledges?
3. Are the most frequently activated knowledges those associated with students struggle in the clip?

Methods

Data were collected as part of an on-going study using the classroom video assessment (CVA; (Kersting et al., 2010, 2012) administered online to a sample of grades 4 and 5 teachers from one of the largest districts in the US (N = 101). The teachers' classroom experience ranged from 1 (n = 4) to 33 (n = 1) years with a mean of 14 and median of 15. About half of the teachers held a master's (n = 50), the other half a bachelor's (n = 47) degree; 2 teachers reported earning a Ph.D. and 2 teachers reported earning an education specialist degree.

Video Clip

Each teacher watched to the same 3-minute video clip in which the teacher poses the following word problem to the whole class: *If 132 cupcakes are distributed evenly among 6 containers, how many cupcakes would end up in each container?* The clip begins with the students noticeably confused by the problem, so the teacher asks for a student to offer a hint without giving away the answer. A student responds by suggesting dividing 132 by 6. The teacher asks the class if the hint is helpful, but when students confirm they are still unsure, the teacher takes a different approach by asking students what $\frac{1}{6}$ of 132 means and instructing them to talk about this question at their tables.

After a moment for group discussions, the teacher asks one student (who she noticed had arrived at 22 in her group) to explain how she arrived at the answer at the overhead projector. The student fills each box of the tape diagram displayed on the projector with 22. The teacher then follows up with asking her what $\frac{1}{6}$ of 132 means. The student responds that $\frac{1}{6}$ is 22 cupcakes because there are 6 boxes, so $\frac{1}{6}$ would be 22. The clip finishes with the teacher asking the class for any questions they have for the student.

After watching the clip, teachers were prompted: "If you were the teacher in this situation, what mathematical question might you pose to the class, and how would your question help improve the students' mathematical understanding?"

Data Analysis

First, we coded all teacher responses (N = 101) for response type. (a) Responses that included a mathematically specific question that directly addressed the students' struggle were coded as TQP (n = 40); (b) responses that included mathematically specific questions not primary to the students' struggle were coded as TQS (n = 28). Responses that did not include a mathematically specific question or that repeated questions already asked by the teacher in the clip were coded as PS (n = 29); responses containing incorrect math were coded as IM (n = 4). Second, we identified in each response the underlying activated knowledge using the grades 3-5 CCSS-M standards (see Table 1). To capture non-mathematically specific responses, we created three categories: Representational strategies (e.g., Can you draw a picture or write a number sentence that shows us or helps us answer?*)*, simplification (decreasing cognitive demand of the task), or other (e.g. commenting on the teacher in the clip).

Responses were coded exhaustively, but categories were not mutually exclusive. For instance, a statement could be coded as both a representation strategy and a mathematical knowledge if a statement contained both category types. Based on pairwise comparisons, interrater reliability measured by direct agreement ranged from 85% to 100% across all dimensions with an average of 93%.

Results and Discussion

CCSS as an Ontology

We found that the CCSS were useful to capture the mathematical knowledge activated by teachers in response to the video clip. The standards provided enough sensitivity for the different mathematical knowledges reflected by teachers' responses as well as sufficient coverage (i.e. all mathematical responses could be categorized). Teacher responses contained other usable knowledge, such as general mathematical and pedagogical strategies, which indicates the need for additional frameworks.

Analysis of Knowledge Activation

Across response types, most teachers demonstrated more than one knowledge activated, with an average of two per response (TQP: M = 2.23; TQS: M = 2.04). Interestingly, even responses coded as IM had a similar average of knowledge activation. Responses revealing activation of non-mathematical knowledge tended to reflect mostly a single knowledge base (M = 1.69). The results provide preliminary evidence that carrying out common teaching tasks, such as generating teacher questions, require the integration of different knowledges.

Which Knowledge is Activated?

Further investigation of TQP-coded responses illustrates the most frequent mathematical categories were those more relevant to the students' struggles (Table 1). Predictably, responses mostly reflected basic fractions understanding, fractions-as-division, and the partitioning relationship of a quantity and a fraction. We were surprised, however, by the variety of other knowledges referenced in support. Each teacher watched the same video clip and answered the same prompt, but not all teachers demonstrated the same knowledge activation. The results provide evidence on the complexity and idiosyncrasies of teachers' usable knowledge.

Table 1: Knowledge Activation by Response Type

Knowledge Type (*CCSS code*)	Frequency				Knowledge Type (*CCSS code*)	Frequency			
	TQP	TQS	PS	IM		TQP	TQS	PS	IM
Equivalent fractions (*4.NF.A.1*)	3	0	0	0	Representation *(NA)*	7	12	10	2
Addition of fractions (*4.NF.B.3.A*)	4	0	0	0	Simplification *(NA)*	3	1	5	2

Fractions-as-division (*5.NF.B.3*)	13	2	2	1	Long division (*4.NBT.B.6*)	4	8	4	1
$\frac{a}{b} \times q = q \times a \div b$ (*5.NF.B.4.A*)	16	5	5	1	Multiples/Factors (*4.OA.B.4*)	1	0	1	1

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

Interestingly, the most frequently activated knowledges across response types were non-mathematical categories: representation strategies and other. While the pedagogical other category might be artificially inflated by being a broad category for non-mathematical statements, the representation category is a defined category. The relatively high frequency of these types of statements suggests the most frequently activated knowledges for teachers in our study for this prompt are non-mathematical knowledges; surprising given the explicit focus on the mathematics in the prompt. The results might provide some evidence for what has been identified in the literature as one of the challenges for improving teaching: Teachers' ability to generate targeted questions that can help students improve or further their mathematical understanding. While our findings could be a consequence of our measure (analyzing video clips as opposed to being in a real classroom), we hypothesize that they are indicative of the knowledge that gets activated in their classroom. Teachers whose go-to response to the video clip reflects a non-mathematical strategy, might rely on that same knowledge also in their classroom. In other words, some teachers' usable knowledge might be heavily influenced by or weighted towards general strategies.

Implications and Conclusion

In this brief report, we identified and analyzed the different underlying knowledges evident in teachers' response to the CVA task, using CCSS as a classifier. For the given clip, most teacher responses demonstrated the activation of more than one knowledge category with the most frequently activated knowledges being knowledges of pedagogical strategies. However, for responses that contained a mathematical question, most responses leveraged relevant mathematical knowledge and a variety of different knowledges activated in support of the most relevant knowledge for the clip.

This work is still in an exploratory phase. In future work, we plan to incorporate this type of feature scaling to create a knowledge base for automated scoring of CVA responses. We hypothesize by better accounting for the complexity of knowledge activated in teachers' responses, we improve measurement of usable knowledge. Additionally, our approach affords mapping knowledge activation to further support more complex computational modeling of usable knowledge involved in in-the-moment decision making, which can then lead to more focused professional development to overcome knowledge "blind spots".

TOWARDS A CONCEPTUALIZATION OF THE DENSITY PROPERTY OF DECIMAL NUMBERS: A STUDY WITH TEACHERS IN TRAINING

Mayra Suárez-Rodríguez Olimpia Figueras
Centro de Investigación y de Estudios Avanzados del IPN
mayra.suarez@cinvestav.mx figuerao@cinvestav.mx

Understanding the density property of rational numbers involves a process of conceptual change from 'the discrete' to 'the dense'. With mathematics teachers in training in Mexico City, a didactic sequence on this property in the decimal number system was tried out. Evidence that this change can be promoted is shown in this document. Some middle-school teachers in training were able to visualize a six-digit expansion to prove that there are more decimals between two numbers. However, others continued with the idea that a decimal number has a successor.

Keywords: Concepts of numbers and operations, Rational numbers, Teacher knowledge, Mathematics knowledge for teaching

Difficulties to understand decimal numbers have been of interest to researchers worldwide. In Indonesia, Widjaja, Stacey, and Steinle (2008) conducted a study with teachers in training and found evidence that they only consider numbers with a limited number of decimals. They argue that such situation reflects contents contained in the textbooks. Ávila and García (2008) found that elementary-school teachers in Mexico often claim that there are no more numbers between two decimal numbers due to the belief that decimals have at most two decimal places. This way of thinking affects the understanding of the density property of decimal numbers. Tirosh, Fischbein, Graeber and Wilson (1999) in a research with future teachers in the United States, found difficulties of a high percentage of the participants because they think that there is a finite number of intermediate numbers between two rational numbers and that a rational number has a successor. Vamvakoussi and Vosniadou (2004), in studies with Greek students of 15 years of age, typified those ideas as an image of 'false consecutives'; that is, between 1/4 and 1/5 or between 0.05 and 0.06 there are no other numbers. Their evidence showed the students' thinking is closely linked to 'the discrete', a property of natural numbers. Valencia and Ávila (2015) and Ni and Zhou (2005) have also emphasized this issue. Vosniadou and Vamvakoussi (2004, 2010, and 2012) hold that a process of conceptual change is required: a re-conceptualization of the properties of natural numbers those of rational numbers.

Aims of the Research

The main purpose of the study carried out is to promote, using a didactic sequence, meta-conceptual awareness among teachers in training to promote a conceptual change regarding the density property of decimal numbers (see Suárez-Rodríguez, 2017). Meta-conceptual awareness is a recognition process in which a person tests his beliefs and presuppositions (Vosniadou, 1994). To describe explanatory frameworks —different ways to express students' interpretations (Vamvakoussi, Vosniadou & Van Dooren, 2013)— of future mathematics teachers about the density property of decimal numbers, the following research aims were proposed: 1. To describe conceptions on the density property of decimal numbers, and 2. To identify performances while solving activities that indicate elements associated with a conceptual change.

Theoretical Foundation

Researchers such as Vamvakoussi and Vosniadou have used the cognitive-development approach of conceptual change proposed by Carey (1987) to study mathematics learning. The human being begins the process of knowledge acquisition through the development of a 'naive theory' (Vosniadou, 2013). The term theory is used to refer to a relational and explanatory structure based on daily experience and information from culture and surrounding situations regarding events or concepts, particularly before entering school (Vosniadou, 2002). Learning science requires a fundamental restructuring of the naive theory that can be named as a theoretical change. Specifically, Vosniadou (2013) defines conceptual change as the result of a complex cognitive and social process of the naive theory.

From the Conception of the Discrete to the Density Property

Based on the results of their study with 15-year-old students, Vamvakoussi and Vosniadou (2004) characterized the thinking of a subject regarding finite or infinite quantities of numbers in an interval (see Table 1). The results obtained support the hypothesis that understanding density is a slow and gradual process limited by the presupposition of 'the discrete.'

Table 1: Thinking Characterization Regarding the Quantity of Numbers in an Interval

Naive thinking about 'the discrete'	It is thought there is no other number between two consecutive false rational numbers; that is, it is thought there is a successor of a rational number.
Advanced thinking about 'the discrete'	It is thought there is a finite quantity of numbers between two consecutive false rational numbers.
Mixed thinking between discrete and dense	In some cases, it is thought that between two rational numbers there is an infinite quantity of numbers; and in other cases, it is thought there is a finite quantity of intermediate numbers.
Naive thinking about 'the dense'	It is understood that there is an infinite quantity of numbers in an interval, but the fact is not justified using the density property. The symbolic representation of the extremes of an interval influences the way of thinking; it is believed there can only be an infinite quantity of decimal numbers between decimals and an infinity of fractions between fractions, but not an infinity of fractions between decimals or otherwise.
Advanced thinking on the dense	There is a sophisticated understanding of the density property; that is, it is evidently understood that there is an infinite quantity of numbers between two rational numbers, regardless of their symbolic representation and this is justified through the use of the density property.

Methodology

The experimentation of a didactic sequence was carried out with 10 students from an institution in Mexico City that trains secondary school teachers. The sequence was structured in 2 stages: one stage to identify initial explanatory frameworks of participants through a paper-and-pencil test and individual interviews. The other stage included collective activities mediated with instruction. This part of the sequence was carried out in 4 sessions. The sessions are about: 1. The perception of the dense in concrete materials, 2. Addition and subtraction, 3. Location in intervals, and 4. Comparison.

Results

This report includes evidence of the trainee teachers' performance in 3 different activities, which are elements of the conceptual change from the discrete to the dense.

Performance Linked to Addition and Subtraction with Decimal Numbers

For the second session of the teaching sequence, 2 activities inspired by those created by Broitman, Itzcovich and Quaranta (2003) were designed in order to identify skills for writing numbers with decimal expansions. In one of the activities, one of the participants chooses a number between 0 and 5 and another student chooses one between 5 and 10 and write them down in a table. The first one adds a positive number to the chosen number in such a way that its sum is strictly less than the number written by the other participant. The latter subtracts a positive number from the selected number so that the result is strictly grater than that written by the other member, and so on.

In Karen and Karina's performances, an underlying notion of a 'infinite' process through adding digits was observed; it was also seen they introduce zeros in the middle of the decimal part of a number (see Figure 1). In this activity, it was also observed that Karen, who in the test showed 'discrete thinking' and believed that a decimal number only had tenths, has extended the number of decimal places. This fact evidences the beginning of a process of conceptual change, since Karen is expanding her knowledge system by adding digits, especially zeros in the subtrahends (see right side in the box, Figure 1). Likewise, both managed to visualize the existence of several decimals between 5.5 and 5.8 (see the numbers written outside the box, Figure 1). The other participants had a similar performance to that of Karen and Karina.

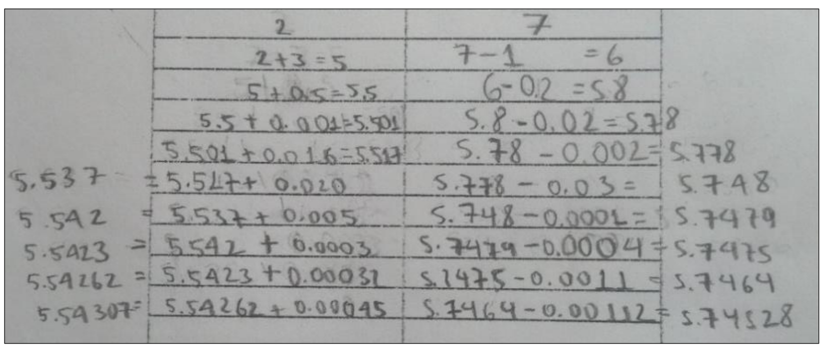

Figure 1: Karen and Karina's Records on the Addition and Subtraction Activity

Performances Linked to the Location of Decimal Numbers in Intervals

The third session of the sequence contains activities related to the location of a number in an interval, which were inspired by an item elaborated by Brousseau (1981). In one of these activities, the student has to find the interval in which the number 'hidden' by a classmate is located; the extremes must be numbers with consecutive decimal digits. Figure 3 has part of a couple' dialogue. Fabiola wrote down the number *13.415* in a piece of paper and her classmate Amanda tries to find the interval where the number hidden by Fabiola is located. At the beginning, Amanda had recorded several intervals before finding one whose extremes were natural consecutive numbers. Then she starts to consider the extremes with tenths and finally with hundredths. For Amanda, this is the beginning of a process of conceptual change since she exhibited a naive thinking about the discrete in her answers to the questions in the test.

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

Amanda: -13.4 and 13.5?
Fabiola: -Yes, but now with hundredths.
(Fabiola means that the extremes of the Interval must have two decimals).
Amanda: -13.42 and 13.48?
Fabiola: -No.
Amanda: -Is it between 13.45 and 13.47?
Fabiola: -No … [silence], this interval is in the other one you mentioned.
Amanda: -Ahhh … the number is between13.42 and 13.43?
Fabiola: -Mmm … yes, ah, no!
Amanda: -I'm confused again. I meant, is it between13.41 and 13.42?
Fabiola: -Yes! It is the Interval.
Amanda: -Which one is it?
Fabiola: -13.415.

Figure 2: Interaction Between Amanda and Fabiola in the Activity of the Hidden Number

Performances Identified in the Activities on Comparison of Decimal Numbers

Comparison activities were based on an activity proposed by a future teacher who took part in the research done by Castillo (2015) in Mexico. The aim of the task was to understand the density property of decimal numbers through comparison. In one of the activities of the fourth session, each couple took a piece of paper with an interval written on it. The teacher-researcher took out from an envelope cards that had numbers with up to six decimals written on them. Those who had the interval in which the number drawn was located, would ask for the card. At the end, the cards were pasted on the board (see Figure 3). With the intention that teachers in training acquire meta-conceptual awareness that the density property helps to visualize the non-existence of consecutive decimal numbers, it was shown that between pairs of false consecutive there is at least one decimal number, consequently, an infinity. For example, in the third row (listed with 3 on the right in Figure 3), 21.001 and 21.002 are false consecutives. It was shown that between this pair, one could find at least four decimal numbers greater than the first one and lower than the second, namely 21.0011, 21.0017, 21.00175, and 21.0018.

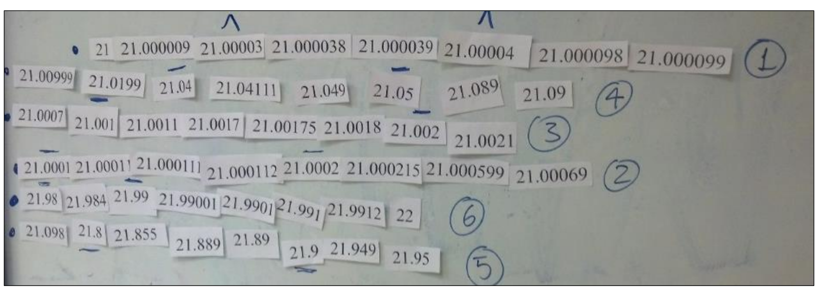

Figure 3: Record of Six Sequences in the Activity of Locating Numbers at Intervals

Conclusions

The didactic sequence promotes performances that can be linked to components of an initial process of conceptual change regarding the explanatory frameworks that teachers in training have about the density property of decimal numbers. The 10 participants showed naive or advanced thinking about the discrete at the beginning of the study. During the application and development of the didactic sequence, most of the future teachers extended the decimal expansion: they wrote numbers of up to six decimal digits and, in some cases, they included interleaved zeros in the decimal part of a number. This strategy helped the participants to visualize that numbers in an interval can always be found. The didactic sequence constitutes an innovative teaching model that can be interesting for mathematics teachers. It can be also used to initiate the study of density in basic education.

Acknowledgments

The Conacyt and the Cinvestav financed the research project. A recognition to the teachers in formation, who voluntarily attended all the sessions.

HACIA UNA CONCEPTUALIZACIÓN DE LA PROPIEDAD DE DENSIDAD DE LOS NÚMEROS DECIMALES: UN ESTUDIO CON PROFESORES EN FORMACIÓN

La comprensión de la propiedad de densidad de los números racionales conlleva un proceso de cambio conceptual de 'lo discreto' a 'lo denso'. Con profesores de matemáticas en formación, de la Ciudad de México, se puso en marcha una secuencia didáctica acerca de esa propiedad en el sistema de los números decimales. En este documento se muestran evidencias de que se puede promover ese cambio. Algunos estudiantes para docentes de secundaria lograron visualizar una expansión de hasta seis cifras decimales para mostrar que hay más decimales entre dos números; empero, otros continuaron con la idea de que un número decimal tiene un sucesor.

TEACHERS' UNDERSTANDING OF THE CONNECTION BETWEEN CONGRUENCE AND TRANSFORMATION IN CONGRUENCE PROOFS

Julia St. Goar	Yvonne Lai	Rachel Funk

We are called by recent standards to promote teachers' learning of a transformation approach in geometry and its proofs. Teachers who learned geometry from a perspective based on Euclid's Elements are now called to teach geometry using different proofs and axioms from what they learned. Moreover, there is little literature on teachers' learning of geometry from a transformation perspective. To begin to address this problem, we analyze the teachers' use of the conceptual link between congruence and transformation in the context of constructing proofs. We identify possible key developmental understandings involved in using the definition of congruence and in the construction of transformation proofs, pointing to concepts that may need to be specifically addressed in teacher education.

Keywords: Teacher Knowledge, Geometry and Geometrical and Spatial Thinking, Reasoning and Proof

Teacher preparation programs face a transition in geometry instruction. In the past several decades, geometry has been taught primarily from a perspective based on Euclid's *Elements* (Sinclair, 2008); in recent years, *geometry from a transformation perspective* has come to the fore (National Governors Association Center for Best Practices, Council of Chief State School Officers, 2010; NCTM, 2018).

These changes in geometry standards have implications both mathematically and pedagogically. For instance, consider the well-known triangle congruence criterion "Angle-Side-Angle (ASA)": *If* ΔABC *and* ΔDEF *are triangles such that* $\overline{AB} \cong \overline{ED}$, $\measuredangle BAC \cong \measuredangle EDF$, *and* $\measuredangle ABC \cong \measuredangle DEF$, *then* $\Delta ABC \cong \Delta DEF$. In secondary and college geometry texts using an *Elements* approach, this criterion is often taken as a postulate: it is intended to be accepted as mathematical truth without proof (e.g., Education Development Center, 2009; Musser, Trimpe, & Maurer, 2008; Serra, 2008; Boyd, Cummins, Mallow, Carter, & Flores, 2005). These and other texts help teachers establish conviction in ASA through empirical exploration – a scheme for conviction, that taken by itself, can be unproductive when the objective is to construct a deductive proof (Harel & Sowder, 2007). In contrast, from a transformation approach, if a teacher is to show that two triangles ΔABC and ΔDEF in a plane are congruent, they must show that no matter the triangles' locations, there exists a sequence of translations, rotations, and/or rotations that map ΔABC to ΔDEF. (See Wu (2013) for a schematic for such a proof.) In the transformation approach, even if empirical exploration is beneficial, the goal is to establish a deductive proof of ASA. In the *Elements* approach, a proof would be mathematically impossible.

Consequently, teachers, who may have learned geometry from one perspective but are called on to teach geometry from another perspective, may not be familiar with what can be proven, what cannot be proven, or how particular proofs operate. It is critical for teachers to understand not only the abstract notion that different axiom systems result in different proof approaches (Van Hiele-Geldof, 1957), but also that they may be teaching students from an axiomatic system different from the one they learned first. Our study addresses this problem from the perspective of developing knowledge for teacher educators, including understanding how teachers learn. We investigated: *What concepts are entailed in teachers' construction of congruence proofs?*

We focused this study on constructing congruence proofs, as.this topic is fundamental to the study of geometry, and it is one where differences between *Elements* and transformation approaches are salient.

Conceptual Perspective

Following Usiskin and Coxford (1972), we take a *transformation approach* to geometry as one that features:

- Reflections, rotations, and translations which are assumed without proof to preserve geometric properties such as length and angles; and
- Definition of congruence in terms of transformations: two subsets X and Y of the plane (e.g., two triangles) are said to be congruent if there exists a reflection, rotation, or translation, or sequence of these transformations, that maps X and Y.

The details of these features may differ across texts. For instance, different statements of postulates of transformations may be taken. However, they have in common that the postulates are about transformations, rather than congruence criteria for particular objects such as triangles.

Hence, from a transformation perspective:

- Two objects in the plane, such as two triangles, are congruent if and only if there exists a single one of or a sequence of reflections, rotations, or translations that maps one object to the other.

We take an *Elements approach* to be one that features the postulation of at least one triangle congruence criterion (e.g., SSS, ASA, or SAS), and definition of congruence in terms of individual geometric objects (e.g., congruence for triangles is defined separately from congruence of circles).

As Jones and Tzekaki (2016) reviewed, there is "limited research explicitly on the topics of congruency and similarity, and little on transformation geometry" (p. 139). To our knowledge, there have been few studies on teachers' conceptions of congruence *proofs* from a transformation perspective. One exception is Hegg, Papadopoulos, Katz, and Fukawa-Connelly (2018), who examined how teachers managed their prior knowledge of congruence criteria when showing the congruence of two triangles. They found that teachers preferred to use triangle congruence criteria rather than transformations, but could, when asked, successfully complete proofs using transformations. However, their study did not examine the case of proving congruence of figures that are not triangles.

Data and Method

Data

A post-hoc analysis was conducted of 20 prospective secondary teachers' responses to two congruence proof tasks, the Line Point Task and the Boomerang Task (below). The tasks were distributed as part of an in-class midterm examination in a mathematics course taught by one of the authors in Fall 2017.

Tasks Used

The tasks for this study were:

- **Line Point Task.** Let ℓ, m be lines. Among all the points that are a unit distance from ℓ, choose one point P. Among all the points that are a unit distance from m, choose one point Q. Prove that no matter what points P and Q you chose, it is always true that $\ell \cup P \cong m \cup Q$.
- **Boomerang Task.** Let ΔABC and ΔDEF with congruences marked as shown. Let O be a point on the inside of ΔABC and P be a point on the inside of ΔDEF so that the angle measures $\alpha = \gamma$ and $\beta = \delta$ as shown. Given the all the above, prove that $\Delta AOB \cup \Delta ABC \cong \Delta DPE \cup \Delta DEF$ (Figure 7).

These tasks allowed us to examine teachers' capabilities for writing congruence proofs beyond standard triangle congruence proofs. The tasks used were two in a sequence of tasks intended for developing teachers' understanding of using definition of congruence from a transformation perspective to prove or disprove the congruence of given figures. This sequence was designed using variation theory (Lo, 2012) to support not only finding sequences of transformations between familiar objects, but showing that a sequence could simultaneously map the objects in a *union* of these objects to another *union.* Furthermore, these tasks included working with lines and points—objects which, though familiar—are not often discussed in the context of congruence proofs.

Analysis

The analysis focused on identifying potential *key developmental understandings* (KDU: Simon, 2006) used in constructing congruence proofs. A full conceptualization of KDU is beyond the scope of this brief report, but we emphasize that a KDU affords a learner a different way of thinking about mathematical relationships (Simon, 2006). For our purposes, this meant that to determine whether something may be a KDU, we must be able to identify how having or not having the KDU could make a difference in teachers' capacity to construct congruence proofs. We proceeded by coming to consensus about the logic of each teacher's response to the tasks, then generating potential descriptions of ways of thinking about congruence and proof that account for differences among responses. These descriptions became provisional codes. We consolidated or distinguished codes based on how and whether the use of the definition of congruence changed what was possible mathematically later in the argument.

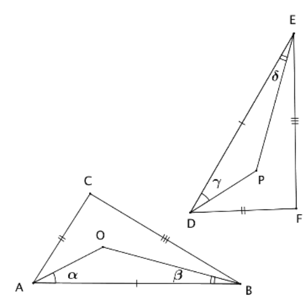

Figure 7: A figure Distributed with the Boomerang Task

Results

Potential KDU 1: Understanding that applying the definition of congruence to prove congruence of two figures means establishing a sequence of rigid motions mapping one <u>entire</u> figure to the other <u>entire</u> figure.

Teachers without this KDU may know that rigid motions are involved in congruence proof, but they may not understand that figures remain fundamentally un-altered with every motion. For instance, we found responses that established rigid motions and thus congruence between parts that compose a whole (such as between ℓ and m as well as P and Q, or ΔAOB and ΔDPE as well as ΔABC and ΔDEF) but that did not necessarily establish congruence of entire wholes ($\ell \cup P$ and $m \cup$ Q, or $\Delta AOB \cup \Delta ABC$ and $\Delta DPE \cup \Delta DEF$).

To illustrate, in the Boomerang Task, some responses used the premise that $\overline{AB} \cong \overline{DE}$ to claim abstractly the existence of a transformation mapping $\overline{AB}$ to $\overline{DE}$, but then the responses concluded that $\Delta AOB \cup \Delta ABC \cong \Delta DPE \cup \Delta DEF$ because $\Delta AOB \cong \Delta DPE$ and $\Delta ABC \cong \Delta DEF$ – and not because the transformations could extend to the unions.

Additionally, some teachers' responses described rigid motions that mapped some or all corresponding parts of the first figure to the second, but the rigid motions constructed did not extend to the entire figures – in this case, the responses exhibited different rigid motions for different components that could not extend. Other responses constructed rigid motions that did extend to the entire figure, but this extension was not recognized explicitly in the responses. Furthermore, some teachers defined a transformation that did "double-duty", that is the teacher noted that two parts of the figures are congruent and therefore claimed the existence of a single transformation that mapped both pieces to their corresponding parts at the same time.

Potential KDU 2: Understanding that using a sequence of transformations to prove that two figures are congruent means justifying deductively that the image of one figure under the sequence of transformations is exactly the other figure.

To understand the necessity of proving that two figures need to be superimposed, one must conceive of the possibility that they may *not* be superimposed. Being able to conceive of this possibility allows for a learner to realize that there is more to show than identifying a candidate sequence of transformations.

Teachers without this KDU may declare the proof complete after defining the transformations or providing minimal justification. For instance, on the Line Point Task, some teachers defined a sequence of rigid motions and claimed that $\ell \cup P$ had been mapped to $m \cup Q$ without further justification. Several other teachers minimally attempted to justify superposition by stating that rigid motions preserve distance. We note that in this case, teachers showed evidence of potential KDU 1 but not potential KDU 2.

Discussion/Conclusion

In this study, we analyzed teachers' responses to tasks, designed using variation theory, for underlying understandings that support constructing congruence proofs. Based on this analysis, we proposed two potential KDUs for the use of the definition of congruence in congruence proofs.

Applications of this work may include the construction of lessons, assignments, and assessments that directly address each above potential KDUs and conceptual links. Such materials may help instructors as they attempt to help teachers learn the subtle concepts listed above in addition to those involved in notation. Future work is needed to interrogate the accuracy of these KDUs.

En este trabajo se presenta un análisis de los argumentos de dos grupos de profesores de primaria, uno de México y otro de Estados Unidos. A ambos grupos se les presentó un problema que apareció en un libro de texto mexicano de quinto de primaria el cual involucraba un polígono irregular imposible de existir con las medidas de los lados que exhibía. Los dos grupos de profesores encuestados proporcionaron diversos argumentos para sostener la existencia o no del polígono. Aquí se presentan las diferentes garantías o apoyos utilizados por las profesoras de Estados Unidos y se comparan con los de los profesores mexicanos reportados en una investigación anterior. La intención de este trabajo ha sido aportar al conocimiento de los recursos argumentativos de los docentes del nivel básico.

Keywords: Teacher Knowledge, Geometry and Geometrical and Spatial Thinking, Reasoning and Proof

Propósito del estudio

En Juárez, Hernández y Slisko (2014) se reportaron los argumentos proporcionados por un grupo de 69 profesores de primaria para validar la existencia o no de una figura geométrica que, con las medidas que presentaba, no era posible que existiera. La mayoría de los argumentos de estos profesores fueron para aceptar que la figura existía y las garantías que aportaron eran pragmáticas. "En la variedad de argumentos que presentan los docentes, observamos que la gran mayoría hace un análisis superficial, se centra en la forma del terreno e ignora las medidas de los lados indicadas numéricamente" (Juárez et al, 2014).

En Alatorre, Flores y Mendiola (2012) los autores observaron un divorcio entre los trazos y sus longitudes cuando cuestionaron a profesores de primaria mexicanos sobre la posibilidad de construir triángulos con medidas arbitrarias. Ellos concluyeron en su estudio que la desigualdad triangular no formaba parte de la práctica profesional de los participantes. Estos trabajos nos motivó a preguntarnos: ¿Qué argumentos presentarían profesores de primaria de Estados Unidos para validar la existencia o no de una figura geométrica inexistente?

La argumentación es una de las habilidades que se plantea desarrollar en los estudiantes a lo largo de la vida escolar. En los planes de estudio de México y Estados Unidos se busca la formación de ciudadanos críticos, reflexivos y con capacidad de análisis y de argumentación. Aunque en el currículo no se plantean actividades explícitas para desarrollar esta habilidad, es usual que se recomiende que los estudiantes validen sus procedimientos y resultados. Es claro que, a nivel institucional y social, se espera que los docentes de todos los niveles educativos posean dicha habilidad, así como suficientes recursos para promoverla en sus alumnos.

Por lo anterior, el objetivo de la investigación que presentamos aquí fue: obtener una categorización de los argumentos que proporcionaron un grupo de profesoras de primaria de Estados Unidos ante el cuestionamiento de la existencia o no de un polígono irregular con medidas imposibles y comparar dichos argumentos con los de un grupo de profesores de primaria mexicanos.

Marco teórico

En esta investigación se considera que un argumento es un enunciado que utilizan las personas para validar algo y convencer a otros. Se utiliza el modelo de Toulmin (1958) en el que un argumento está constituido por datos, justificaciones o garantías y una conclusión. Dependiendo del campo de la argumentación, existen diferentes tipos de garantías y éstas le dan diferentes grados de fuerza a la conclusión. Para clasificar los argumentos se ha recurrido a Balacheff (2000) quien distingue los tipos de pruebas o demostraciones entre pragmáticas e intelectuales, dependiendo del tipo de argumentos que se utilicen. En las primeras, los enunciados se validan con acciones concretas o mentales, e incluyen dos niveles, empirismo ingenuo y experimentos cruciales. Las segundas basan sus argumentos en conceptos y en el lenguaje e incluyen dos tipos: ejemplos genéricos y experimentos mentales.

Metodología

Este es un estudio cualitativo de tipo exploratorio interpretativo. Se comparan las respuestas dadas por dos grupos de profesores de primaria, uno de Estados Unidos y otro de México, a un cuestionario común.

Participantes

Grupo de Estados Unidos. 26 maestras de educación primaria que participaron en un programa de desarrollo profesional de dos semanas en el verano. Las maestras eran de tres escuelas en el medio oeste de los EE. UU. y enseñaban a niños de jardín de infantes a quinto grado de primaria.

Grupo de México. 69 docentes de educación primaria en servicio que se encontraban terminando un curso de capacitación en matemáticas al momento de contestar el cuestionario. Su preparación era de educación normalista con 15 años de servicio en promedio.

Instrumento

Se elaboró una hoja de trabajo que contenía un polígono irregular que representaba a un terreno y que formaba parte de una actividad de un libro de texto de matemáticas mexicano del quinto grado de primaria (SEP, 2010). La actividad pedía calcular el número de rollos de malla necesarios para cercar el terreno. Este instrumento se aplicó a los profesores de México y fue traducido al inglés para encuestar a los maestros estadounidenses. El terreno es el de la figura 1.

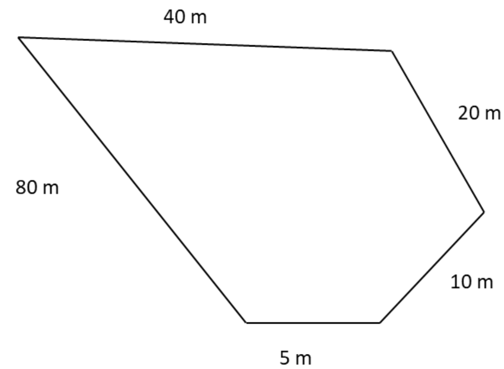

Figura 1: Polígono irregular incluido en la hoja de trabajo

En el instrumento se dice explícitamente que la tarea de los docentes no es resolver el problema planteado en la actividad, sino responder la pregunta acerca de la existencia o inexistencia del terreno y dar los argumentos que apoyan su respuesta. La instrucción en inglés fue:

Your task is not to solve the problema, but rather to respond to the question: Can the piece of land described in the problem above exist in reality?

a) It can exist b) It cannot exist c) I cannot decide

Justify your answer with as many details as you can to support your response.

Respuesta esperada

Se esperaba que los profesores eligieran el inciso b) It cannot exist y que en su justificación utilizaran conceptos matemáticos como los siguientes:

1. Las longitudes de los lados no corresponden con los números o medidas proporcionadas. El lado más largo tiene la etiqueta de 80 m, el segundo en longitud se dice que mide 40 m. Sin embargo, se aprecia en el dibujo que el segundo no cabe dos veces en el primero. El resto de los lados están marcados con 20, 10 y 5 metros, pero igual que los dos primeros el lado que "mide" 5 m no cabe dos veces en el que "mide" 10 m y así sucesivamente.
2. Este terreno tiene un lado cuya medida es mayor que la suma de los demás lados, relación que no puede ocurrir en los polígonos. El lado que tiene la etiqueta de 80 m mide más que la suma del resto de los lados, que es de 75 m, lo cual es imposible. Tal imposibilidad se demuestra aplicando la desigualdad del triángulo, sucesivamente, en los triángulos cuyo vértice común es el punto que une a los lados de 80 y 40 metros.

Resultados

Los porcentajes de respuestas dadas por las profesoras de primaria de Estados Unidos se muestran en la tabla 1, y debajo de ellas las de los profesores de México (Juárez et al, 2014).

Tabla 1: Porcentajes de Respuestas en Cada Inciso del Instrumento

Profesores	It can exist	It can not exist	I cannot decide	No response

Estados Unidos	38.5%	46.1%	15.4%	0%
México	89.9%	4.3%	1.4%	4.3%

Los porcentajes de las profesoras que afirmaron que sí podía existir el terreno en la realidad y las que afirmaron que no, son muy parecidos, alrededor del 40 por ciento cada uno. Resulta mayor la cantidad de profesoras que afirmaron que el terreno no puede existir en la realidad con una diferencia de casi siete puntos porcentuales. Hubo cuatro profesoras que no supieron cómo contestar y ninguna dejó en blanco su respuesta.

En contraste con este resultado, la gran mayoría de profesores mexicanos afirmó que el terreno sí podía existir (casi 90%), y el porcentaje de los que afirmaron que esto no era posible fue solo del 4.3%, sorprendentemente bajo.

Dos profesoras de Estados Unidos que respondieron que el terreno no podía existir en la realidad se dieron cuenta que el lado de 80 m es mayor que la suma del resto de los lados y que de esta forma la figura no podría cerrar. Este es un argumento que alude a una propiedad matemática, la desigualdad triangular (argumento esperado número 2). Siete profesoras argumentaron que los lados no eran proporcionales, por ejemplo, que el de 80 m no era cuatro veces el de 20 m. Estas profesoras apreciaron visualmente que las medidas de los lados no corresponden con la longitud trazada y que no cumplen con ser proporcionales cuando las comparan (argumento esperado número 1). Una profesora dijo que con esas medidas no se formarían esos ángulos. Otra profesora anotó, “simplemente, no se ve bien”. Así, la mayoría de las que respondieron que no puede existir en la realidad, se dio cuenta que las medidas no corresponden con la longitud real de la figura. La propiedad matemática que identificaron con mayor frecuencia fue la de proporcionalidad. De esta forma, un 40% de los argumentos presentados en este grupo fue de tipo intelectual.

Las profesoras que afirmaron, -sí puede existir -, argumentaron en su mayoría, que “los terrenos pueden tomar cualquier forma”. Algunas apoyaron su argumento en que los terrenos toman cualquier forma por los límites naturales como ríos o caminos, o porque “no todos son rectangulares”. Dos profesoras no dudaron en la existencia del terreno ya que “las medidas son realistas” o porque “es una figura cerrada”. Una más contestó que “todo es posible”. A dos profesoras de este grupo les pareció extraña la pregunta y cuestionaron la intención de cercar un terreno tan pequeño. Así, encontramos que las profesoras que respondieron que sí puede existir, fue porque observaron la forma de la figura superficialmente y no detectaron ningún problema con las medidas. Por lo tanto los argumentos de quienes sostuvieron la existencia del terreno fueron pragmáticos y sus garantías fueron similares a las de los profesores mexicanos.

Al comparar los argumentos de las profesoras de Estados Unidos con los de México detectamos claramente que las estadounidenses tuvieron una mayor capacidad de análisis al responder la pregunta sobre la existencia. Los argumentos de las profesoras de Estados Unidos contenían propiedades matemáticas como garantía o apoyo, para justificar la imposibilidad de la existencia del terreno, como proporcionalidad y la desigualdad triangular. Mientras que en los argumentos de los mexicanos no aparecieron estos recursos, aun entre los que respondieron que la figura no podía existir en la realidad.

En ambos grupos se observó que, quienes respondieron que el terreno sí podía existir en la realidad, se basaron únicamente en la forma de la figura. Lo visual e inmediato les fue suficiente para responder y para justificar su selección. Sin embargo, esto ocurrió en mayor proporción entre los profesores mexicanos que entre las estadounidenses.

Discusión y Conclusión

Aunque las profesoras de Estados Unidos fueron capaces de detectar una inconsistencia entre las medidas de los lados que aparecían en la figura y las longitudes reales de la misma, y lograron establecer argumentos de tipo intelectual, en un porcentaje mucho mayor que el de los mexicanos, observamos que tal porcentaje es menor al 50%. Por lo que es posible hablar de una tendencia, en los profesores de primaria, a reponder después de un análisis superficial y a proporcionar argumentos pragmáticos. En estos dos estudios, los resultados coinciden con lo reportado por Alatorre, Flores y Mendiola (2012) en la que observaron un divorcio entre los trazos y sus longitudes, y en la cual concluyen que “el razonamiento y la argumentación no son parte de la práctica profesional de muchos docentes de primaria”.

A COMPARISON OF AMERICAN AND MEXICAN PRIMARY TEACHERS’ MATHEMATICAL ARGUMENTS FOR A NONEXISTENT GEOMETRIC FIGURE

This paper presents an analysis of the arguments of two groups of primary teachers, one from Mexico and the other from the United States. Both groups were presented with a geometry problem that appeared in a fifth-grade Mexican textbook. The problem involves an irregular polygon that can not exist. The two groups of teachers provided various arguments to support the existence or not of the polygon. An initial analysis of different arguments used by the teachers in the United States are presented and compared with those of the Mexican teachers, which were reported in a previous study. The intention of this work is to contribute to the knowledge of the argumentative resources of elementary school teachers.

CROSS-CASE EXAMINATION OF MIDDLE SCHOOL MATHEMATICS TEACHERS' TOPIC-SPECIFIC CONTENT KNOWLEDGE IN THE U.S. AND RUSSIA

This cross-case study examined the U.S. and Russian teachers' topic-specific knowledge. Teachers (8 – from the U.S., and 8 – from Russia) were selected using a non-probability purposive sampling technique based on scores on the teacher content knowledge survey. Teachers were interviewed on the topic of fraction division using questions addressing their content and pedagogical content knowledge. The study revealed that there are explicit similarities and differences in teachers' content knowledge as well as its cognitive types. The findings also suggest that in the cross-national context teachers' knowledge could vary depending on curricular and socio-cultural priorities placed on teaching and learning of mathematics.

Keywords: teacher knowledge, cross-national study, number concepts and operations, middle school mathematics

Focus of the Study

Cross-national studies allow understanding of how teacher education is contextualized in different countries which requires "a range of analytical methods that draw out conflicting views, contested areas and shared beliefs" (LeTendre, 2002). In last decade, a number of studies on teacher education were focusing on unpacking "culturally contextualized and semantically decontextualized dimensions" in order to create "a more balanced comparative perspective" (Ewha, Ham, Paine, 2011).

However, few comparative studies addressed in-service teachers' content knowledge. Moreover, the field lacks research that provides an in-depth analysis of teacher knowledge at a topic-specific level. Considering the importance of teachers' topic-specific knowledge, the study focused on the following *research question*: to what extent is the U.S. and Russian lower secondary mathematics teachers' content knowledge similar and/or different in the topic-specific context?

Framework

Existing studies vary in a scope addressing different issues including general aspects in teacher education, teacher knowledge, different types of teacher knowledge, connections between teacher knowledge and student performance, to name a few. Studies suggest that international comparisons in teacher education should be sensitive to the social, historical, and cultural contexts. Few studies aimed at the international comparison of the effects teacher mathematics knowledge and pedagogy have on student achievement (Baumert, Kunter, Blum, Brunner, Voss, Jordan, Klusmann, Krauss, Neubrand, & Tsai, 2010; Marshall & Sorto, 2012).

Analysis of a body of literature in cross-national research in teacher education and teacher knowledge demonstrates that the field is short of studies that provide a close evaluation of teacher knowledge at a topic-specific level. Addressing this deficiency, the proposed study attempts to qualitatively examine the U.S. and Russian lower secondary school mathematics teachers' content knowledge in the topic-specific context – the division of fractions.

Methodology

We selected the interpretive cross-case study design (Merriam, 1998) to examine the U.S. and Russian teachers' topic-specific knowledge of one of the important themes in the lower secondary mathematics curriculum in both countries - division of fractions.

The Teacher Content Knowledge Survey (TCKS) instrument employed at the initial stage of the study consisted of 33 multiple-choice items addressing main topics of lower secondary mathematics curriculum as well as different cognitive types of content knowledge with its' reliability as measured by the Cronbach alpha coefficient at .839 (Tchoshanov, 2011). The TCKS was administered to the initial sample of lower secondary mathematics teachers in the USA (grades 6-9, N=102) and Russia (grades 5-9, N=97) (Tchoshanov, 2011; Tchoshanov, Cruz, Huereca, Shakirova, & Ibragimova, 2017). A non-probability purposive sampling required that selected the U.S. and Russian teachers represent different quartiles of the total scores on the TCKS measure. It was also required that selected teachers teach at similar school settings (e.g. urban public schools). Addtitionally, both the U.S. and Russian participants have similar teaching assignments – lower secondary school mathematics. Thus, 8 teachers from the U.S., and 8 from Russia were selected for the study.

The study used structured teacher interviews on the topic of the division of fractions. Teachers were interviewed using the following five questions related to the topic: (1) When you teach fraction division, what are important terms, facts, procedures, concepts, and reasoning strategies your students should learn? (2) What is the fraction division rule? (3) Apply the rule to the following fraction division problem: $1\frac{3}{4} \div \frac{1}{2} =$. (4) Construct a word problem for the given fraction division: $1\frac{3}{4} \div \frac{1}{2} =$. (5) Is the following statement $\frac{a}{b} \div \frac{c}{d} = \frac{ac}{bd}$ (a, b, c, and d are positive integers) ever true?

Taking into account the categorical nature of the quantitative data (e.g., frequency counts) collected in the study, we used a non-parametric Chi-square technique to compare two groups on a response variable (Huck, 2004, p. 463). Considering a small sample size, in the 2x2 contingency case of the chi-square test, for expected frequencies less than 5 Yates' correction is employed. In order to analyze qualitative data, we conducted meaning coding and linguistic analysis of teacher narratives as a primary method of analysis (Kvale & Brinkmann, 2009). To increase the credibility of the qualitative data analysis, the meaning coding and linguistic analysis were performed and cross-checked by two independent raters.

Findings

We selected the interpretive cross-case study design (Merriam, 1998) to examine the U.S. and Russian teachers' topic-specific knowledge. The data analysis clearly demonstrated that the participants had similarities and differences while responding to the interview questions. The analysis below unpacks teacher responses to each question.

Teacher responses to question 1 were coded using the following categories: 1) vocabulary, 2) facts and procedures, 3) concepts and connections, and 4) reasoning.

Table 1: Frequency of the U.S. and Russian Teachers' Responses to Question 1

Category	US teachers	Russian teachers	χ^2
Vocabulary	33	38	*2.003*
Facts and Procedures	27	32	*3.471*
Concepts and Connections	20	23	*0.893*
Reasoning	0	6	*6.667***

*p<.05, **p<.01

As reported in Table 1 with chi-square statistic and p-values, the most frequently used category in response to question 1 was "vocabulary" with no significance observed between the groups ($\chi^2=2.003$). With regard to categories "facts and procedures" and "concepts and connections", we also didn't detect any significant differences ($\chi^2=3.471$ and $\chi^2=0.893$ accordingly). The only category where the significance was detected is the category of "reasoning" ($\chi^2=6.667$).

In Table 2, we present the frequency of terms used by the U.S. and Russian teachers while explaining the rule for fraction division in response to question 2 along with chi-square values for each reported term. All U.S. and Russian teachers correctly responded to this question.

Table 2: Frequency of Terms Used By the U.S. and Russian Teachers

Terms used by teachers	US teachers	Russian teachers	χ^2
Flip	7	1	6.250*
Reciprocal	7	8	1.067
Dividend	0	6	6.667**
Divisor	0	6	6.667**
First fraction	6	2	2.250
Second fraction	6	2	2.250
Quotient	0	1	1.067

*p<.05, **p<.01

As expected, teachers' responses to the procedural question 3 (divide two given fractions) were the least insightful. Most of the teachers in both groups silently performed the division on a scratch paper that was provided to every participant. All participating teachers correctly solved the given fraction division task. Slight differences were observed in the representation of the answer. One of the U.S. teachers illustrated the division by a pictorial model.

There are several distinct meanings of the division of fractions discussed by scholars. Ma (1999, p. 72) claimed that there are three main models and corresponding meanings to represent the division of fractions: measurement, partitive, and product and factors. Question 4 was challenging to the U.S. teachers - only five teachers were able to construct a correct word problem compared to eight Russian teachers.

Table 3: Frequency of Meanings Used By the U.S. and Russian Teachers

Meanings of fraction division	US teachers	Russian teachers	χ^2
Part-to-whole (partitive)	0	2	*0.571*
Measurement (quotitive)	5	2	*2.286*
Rectangular area model (product and factors)	0	4	*5.333**
Incorrect	3	0	*3.692*

**p<.05, **p<.01*

In Table 3, chi-square analysis showed statistically significant difference not only for the rectangular area model but also an overall difference in performance of the U.S. and Russian teachers on this particular task ($\chi2 = 10.286$, $p<0.05$).

Question 5 was challenging to both the U.S. and Russian teachers. As depicted in Table 4, we were not able to observe any significant differences between groups in a number of correct responses (only one correct and one partially correct solution proposed from the U.S. teachers compared to three correct and one partially correct solutions provided by Russian teachers).

Table 4: Frequency of Solutions Proposed By the U.S. and Russian Teachers

Teacher responses	US teachers	Russian teachers	χ^2
Never true	5	4	*0.254*
True if a=b=c=d	1	1	*0*
True if c=d	1	3	*1.333*
No solution provided	1	0	*1.067*
Using numerical values to prove	4	0	*5.333**

**p<.05, **p<.01*

Discussion and Conclusion

Most insightful finding in teachers' responses to question 1 was the fact that both U.S. and Russian teachers quite similarly define learning objectives for the division of fraction. Both groups clearly outlined the main vocabulary students should learn, facts and procedures students should master, and concepts students should understand. The revealing difference was observed in the teachers' response to the reasoning category.

Despite the fact that question 1 explicitly asked to articulate "what are important … reasoning strategies your students should learn?", none of the U.S. teachers responded to this part of the question compared to six Russian teachers who highlighted the importance of "developing logical reasoning" (4 teachers) as well as "checking for reasonableness" (2 teachers). This finding may suggest that the U.S. teachers do not see a "reasoning" potential in the topic of the division of fractions whereas their Russian counterparts emphasize the development of students' critical thinking as one of the important learning objectives for the topic of fraction division.

As mentioned earlier, both the U.S. and Russian teachers emphasized the importance of developing students' mathematical vocabulary related to the topic of the division of fractions. Between two groups of teachers, there were 13 terms recorded in response to the "vocabulary" category of question 1. Most frequently used term among the U.S. teachers was "division" (6 frequency counts) whereas "reciprocal" (7 counts) and "multiplicative inverse" (6 counts) were the most frequently used terms by Russian teachers. This result may suggest that the U.S.

teachers focused on the operation in general (e.g. division) whereas Russian teachers emphasized the operation specific to the division of fractions (e.g. reciprocal, multiplicative inverse).

Next observation is concerned with the use of accurate mathematical terminology: "dividend" vs. "first fraction" and "divisor" vs. "second fraction" which was statistically significant in both cases as depicted in table 2. Our observation also revealed a strong tendency on the part of the U.S. teachers to use the term "flip" as a sub-language for reciprocal/ multiplicative inverse with a reported $\chi 2=6.250$ at $p<0.05$.

Following on the models used by teachers for fraction division, we found that the measurement model was the most popular one (5 frequency counts as presented in table 3) and the only one model used by the U.S. teachers in response to question 4 asking to construct a word problem for the given problem. In contrast, Russian teachers applied three different models for the fraction division meaning with the rectangular area model being the statistically significant ($\chi 2=5.333$, $p<0.05$).

Analysis of teacher narratives to question 5 did not show significant differences between groups in a number of correct responses. Whereas the U.S. teachers proposed only one correct (c=d) and one partially correct solution (a=b=c=d), their Russian counterparts provided three correct and one partially correct solutions. A statistically significant difference ($\chi 2=5.333$, $p<0.05$) was reported with regard to a method of proof used by teachers. None of the Russian teachers attempted to prove the statement numerically compared to four U.S. teachers who tried to plug in different numbers to check if the statement works.

Synthesizing the main findings of the study, we report that the topic-specific level of analysis helped us to unpack hidden insights in terms of differences and similarities in teacher knowledge among participants. Considering the qualitative nature of the study, we are cognizant of its limitations and, congruently, we are sensitive do not overgeneralize its results. The granualized methodology used in the study to unpack and analyze teacher topic-specific knowledge could be considered as a potential contribution to the field of cross-national studies on teacher knowledge. The study suggests close comparison and learning about issues related to teacher knowledge in the U.S. and Russia with a potential focus on re-examining practices in teacher preparation and professional development.

TEACHERS' MATHEMATICAL KNOWLEDGE FOR TEACHING FUNCTION REPRESENATIONS: AN EXPLORATORY STUDY

Stacey C. Zimmerman

This exploratory study attempts to learn more about mathematical knowledge for teaching by examining the knowledge teachers use to teach in secondary mathematics classrooms. Drawing upon Ball and colleagues' (2008) mathematical knowledge for teaching framework and the literature, we construct an initial model of teacher knowledge for function representations. Using written responses and interview data, findings indicate that the nature of secondary mathematics teachers' knowledge can be broadly categorized as subject matter knowledge and pedagogical content knowledge.

Keywords: Mathematical Knowledge for Teaching, Teacher Knowledge

For the past three decades, researchers have worked to develop detailed descriptions and categorizations of teacher knowledge. Of note in mathematics is the work of Ball and colleagues (Ball, Thames, & Phelps, 2008) who expanded upon Shulman's (1986) notion of pedagogical content knowledge to develop the mathematical knowledge for teaching (MKT) framework. This framework has been instrumental in detailing ways of knowing elementary grades mathematics useful for teaching, and studies have demonstrated a strong association between MKT and student achievement (Hill, Rowan, & Ball, 2005) and MKT and the quality of instruction (Hill, Ball, & Schilling, 2008).

Unlike MKT for elementary grades, there are far fewer studies examining MKT for secondary mathematics. While some secondary researchers use Ball et al.'s (2008) MKT framework, others question the transferability of the frameworks' constructs, specifically common content knowledge and specialized content knowledge, to the secondary level (Speer, King, & Howell, 2015). However, considering the usefulness of the MKT framework in elementary mathematics, the dearth of secondary mathematics MKT research, and the disagreement about the nature of secondary MKT, this two-phase exploratory study investigates the extent to which the MKT framework can aid in the understanding of secondary MKT by answering the question: *What is the nature of secondary mathematics teachers' MKT related to the multiple representations of functions?*

Background

To investigate how well the MKT framework models secondary MKT, this study focuses on a significant topic in secondary mathematics, function representation. Functions are a "unifying theme in United States mathematics curricula" (Steele, Hillen, & Smith, 2013, p. 454). Instruction on functions can begin as early as elementary school and continue to grow in complexity throughout middle school, high school and college. For students to be successful in mathematics, they must develop a rich conceptual understanding of functions (Cooney, Beckmann, & Lloyd, 2010), grounded in the ability to move flexibly among representations (Even, 1998; Kaput, 1992; National Council of Teachers of Mathematics, 2000; Thompson, 1994). Key aspects of understanding the concept of function include an awareness of the limitations and strengths of a particular representation and knowing when one representation is more useful than another. Considering the prominence and importance of functions in the secondary mathematics curriculum in the United States, insights into secondary teacher knowledge related to the multiple representations can add to our understanding of MKT at the secondary level.

Ball's MKT framework is composed of two overarching domains, subject matter knowledge (SMK) and pedagogical content knowledge (PCK). When considering the SMK domain and knowledge related to the multiple representations of functions, the National Council of Teachers of Mathematics (NCTM) has identified several understandings, termed "essential understandings" (Cooney et al., 2010, p. 10). Essential understandings are a vital component of teacher knowledge. Such knowledge enables teachers to support students in developing deep conceptual understandings. Three of the essential understandings (denoted *EU* in Table 1) serve as an initial conjecture as to what constitutes SMK related to the multiple representations of functions.

Unlike SMK, knowledge-specific statements like NCTM's essential understandings are not readily available or lack the detail needed to describe PCK. While there are few studies focused on both PCK and multiple representations of functions, research examining student learning and multiple representations offer a starting point for conjecturing PCK related to multiple representations of functions. A review of the existing literature suggests that students typically focus on local rather than global aspects of a function (Leinhardt, Zaslavsky, & Stein, 1990), may prefer algebraic representations over other representations (Dubinsky & Wilson, 2013), may not make the necessary switch between representations to assist in solving problems (Even, 1998), and lack the conceptual understandings of functions needed to perform accurate algebraic calculations (Kalchman & Koedinger, 2005). Knowledge of students' tendencies connects what teachers teach to how they teach it, an underlying concept of PCK.

To build our initial framework for secondary MKT for representing functions, we considered NCTM's essential understandings as key aspects of SMK and selected literature focused on student learning and multiple representations as PCK. The two domains of this conceptual mapping (see Table 1, categories column) represented an initial, conjectured framework for secondary MKT for which we sought empirical support with an exploratory study.

Methods

This two-phased exploratory study used mathematical tasks to investigate secondary teachers' mathematical knowledge related to multiple representations of functions. Guided by the Mathematical Work of Teaching Framework (Selling, Garcia, & Ball, 2016), six open ended-tasks were specifically designed to elicit teachers' understanding and use of multiple function representations when teaching. Four tasks were adapted from tasks previously used in studies examining student learning (Eraslan, Aspinwall, Knott, & Evitts, 2007; Even, 1998; Kalchman & Koedinger, 2005; Leinhardt et al., 1990) and two were based on our personal experiences as mathematics instructors.

Participants and Data Collection

In the first phase, an invitation to complete the online survey was distributed to secondary mathematics educators statewide via social media, an email listserv, and word of mouth. Those electing to participate were randomly assigned two of the six tasks to complete. The survey was open for two weeks and task responses served as the primary data for phase one. Using the initial framework, we coded these responses for evidence of SMK and PCK and used these preliminary results to focus our investigation in the second phase of the study on MKT domains not well represented in phase one**.**

In phase two, we used semi-structured interviews based on the survey tasks to elicit additional evidence of MKT for representing functions. Ten teachers involved in a yearlong professional development focused on mathematics teaching practices completed the entire survey (all six tasks) as a part of the professional development activities. Four teachers volunteered to participate in a follow-up interview to discuss, modify, provide additional details to their initial survey responses, and discuss their instructional uses and perceptions of function representations.

Data from phase one and two were analyzed using a hypothesis coding approach (Miles, Huberman, & Saldana, 2014). In this approach, codes are predetermined based on the framework for the study. For data not mapping to the codes, four additional codes representing some "other" type of SMK, PCK, or the lack of evidence of SMK or PCK were added for a total of 11 codes. Survey and interview responses could receive multiple codes. After hypothesis coding, we then focused on the "other" codes in an attempt to elaborate the initial framework.

Findings

Table 1: Categorizations of Responses

	Categories	**Survey**	**Interview**
SMK	*EU1*: Functions can be represented in various ways	129 (52%)	32 (80%)
	EU2: Changing a function's representation does not change the function, although different representations highlight different characteristics, and some may show only part of the function	89 (39%)	29 (73%)
	EU3: Some representations of a function may be more useful than others, depending on the context.	11 (9%)	25 (63%)
	Other SMK demonstrated	98 (43%)	8 (20%)
	No SMK demonstrated	2 (<1%)	0 (0%)
	Total Demonstrating SMK	**227 (99%)**	**40 (100%)**
PCK	Focus on local rather than global aspects of a function	19 (8%)	3 (7%)
	Students may prefer algebraic representations	2 (<1%)	0 (0%)
	Students may not make the necessary switch between representations to assist in solving problems	16 (7%)	6 (15%)
	Weak conceptual understandings of functions inhibit accurate algebraic calculations	31 (14%)	8 (20%)
	Other PCK demonstrated	96 (42%)	22 (55%)
	No PCK demonstrated	77 (34%)	6 (15%)
	Total Demonstrating PCK	**152 (66%)**	**34 (85%)**

As shown in Table 1, all but two responses (99%) demonstrated some category of SMK. Although essential understanding EU1, *functions can be represented in various ways*, was evident in over 52% of the survey responses, NCTM's essential understandings did not fully categorize all the responses that demonstrate SMK. Consequently, 43% of the survey responses were evaluated as demonstrating some other type of SMK. As compared to the survey responses, the interview responses mapped somewhat better to the essential understandings; 80% to essential understanding EU1, 73% to essential understanding EU2, and 63% to essential understanding EU3. In the interviews, participants tended to elaborate more on their survey responses which often highlighted several categories of SMK. However, with 43% of the survey responses and 20% of the interview responses being categorized as “other SMK” it is evident that the SMK domain in our initial framework is moderately characterized by the three essential understandings.

Our findings in Table 1 also suggests the need to further develop the PCK domain in the initial framework. Whereas 66% of the survey responses and 85% of the interview responses demonstrate PCK, many of these responses did not map to either of the four PCK categories selected from the literature. As a result, of the before mentioned 152 survey responses, 42% demonstrate some type of PCK not included in the initial framework. Likewise, 55% of the interview responses demonstrate some *other* type of PCK. Only one PCK category in the initial framework, *weak conceptual understandings of functions inhibit accurate algebraic calculations,* exceeds 10% in both survey phases and the interview. Agreeably, responses that illustrate the knowledge of students is an aspect of PCK, but with the high number of responses categorized as “other PCK”, evidence does not confirm that the current subdomains of the initial framework are adequate to describe the nature of teachers’ knowledge.

Discussion

These findings provide empirical support for aspects of the initial framework, implying that Ball’s MKT framework can aid in the exploration of secondary level MKT. The SMK domain, along with the essential understandings as SMK subdomains, is effective in describing the nature of teachers’ MKT related to multiple function representations. Although evidence for the PCK subdomains is not as compelling, findings did support the overarching domain of PCK as being a part of the initial framework. While the initial framework provides a foundation for this initial exploration, the considerable number of responses classified as “other” in both the SMK and PCK domains suggests that additional or revised subdomains are needed for a thorough representation of the nature of secondary teachers’ MKT related to teaching multiple representations of functions.

Gaining insights into teachers’ MKT is important to the field as we constantly seek to improve mathematics education. The Conference Board of Mathematical Sciences clearly states that “all teachers need continuing opportunities to deepen and strengthen their *mathematical knowledge for teaching*” (2012, p. 68). In order to provide *all* teachers, including secondary mathematics teachers, the opportunity to expand their MKT, we must first identify what MKT is and possibly could be. This study is a step in that direction.

HIGH SCHOOL MATHEMATICS TEACHERS' DISCERNMENT OF VARIANCE AND INVARIANCE IN A DYNAMIC GEOMETRY ENVIRONMENT

Gili Gal Nagar
UMass Dartmouth

corrill@umassd.edu

Stephen Hegedus
Southern Connecticut State University
hegeduss1@southernct.edu

In this study we investigated the ways high school teachers deal with the task of looking for invariant properties in a Dynamic Geometry Environment (DGE). We also examined if they even attend to invariant properties; and what invariant properties they discern, describe and discuss. We found that the teachers tend to discern and discuss invariant properties using a DGE, but this occurred mostly when they were probed to consider invariance. We also found four categories of invariant properties that seem to be important for a rich and deep understanding of geometrical objects in the context of invariance and DGE. It appears also that the use of DGE allowed teachers to see and interact with invariant properties, thus suggesting that accessing geometry dynamically may have structural affordances especially when seeking for invariance. Possible future research directions and implications to teacher education are discussed.

Keywords: Teacher Knowledge, Geometry and Geometrical and Spatial Thinking, Technology

Purpose and Background

In conceptualization of and reasoning about geometrical objects, the literature suggests that variance plays a crucial role in that it invites the individual to look for invariant properties (Baccaglini-Frank, Mariotti, & Antonini., 2009; Sinclair, Pimm, & Skelin, 2012). Discerning invariant properties helps to explain and organize experiences (Gruber & Voneche, 2005), and such discernment is an essential part in understanding objects in the context of invariance (Sinclair et al. 2012). Yet, this can be a complex task because the variability of geometric objects is often invisible, especially, when the geometric property most of the time is expressed as dealing with a single static object (Laborde, 2005). Sinclair et al. (2012) explained that because invariance is part of any geometric theorem, teachers should develop skills and understandings to seek for and discern certain invariant properties and relationships in a given geometric situation.

What is not clear yet is how teachers themselves deal with the task of looking for invariant properties in Dynamic Geometry Environment (DGE) settings; do they even attend to invariant properties; and what invariant properties they might discern, describe and discuss. Thus, the current exploratory study investigates the following research questions: (a) Do six high school mathematics teachers tend to discern invariant properties in a Dynamic Geometry Environment? And (b) what types of invariant properties these teachers discern and discuss? Such an examination is important because what teachers know is associated with what they are likely to be able to do when they teach in their classrooms (Thompson, Carlson & Silverman, 2007).

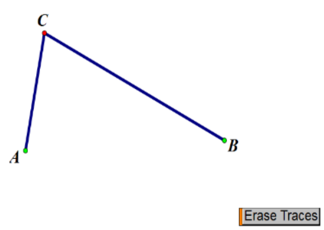
Theoretical Framework

We define conceptualization and reasoning in a DGE as a symbiosis between three key elements: (a) a DGE Object, (b) the individual formal (definitions, axioms, theorems) and non-formal knowledge of the object, and (c) the operations and actions that a person enacts. In this work, conceptualization and reasoning in a DGE, in terms of variance and invariance, deals with dynamic objects that can be perceived, conceived, understood, and reasoned about, by attending to specific aspect of variance and invariance - *discernment of invariant properties*. The prevalent way scholars define invariance in a DGE is through referring to certain invariant geometrical properties (e.g., Baccaglini-Frank et al., 2009; Hadas, Hershkowitz, & Schwarz, 2000; Laborde, 2005) that remain unaltered by transformations.

Methods

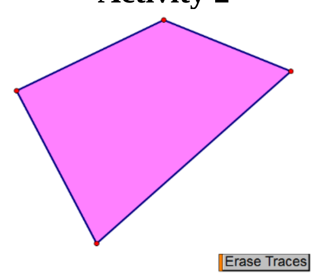
Six high school mathematics teachers were recruited for this study. The participants included four females - Amanda, Lisa, Diana and Susan, and two males - Andy and Mark (pseudonyms). Four participants had 2-4 years of mathematics teaching experience, Andy had 10 years and Susan had 30 years. The primary data for this study came from a set of two 45-minutes videotaped interviews with each teacher. As shown in Figure 1, we designed four activities using Sketchpad® Explorer (Jackiw, 1991, 2009) to provide teachers with opportunities to explore variance and invariance as they examined tasks appropriate for high school geometry. Two activities were based on similar ideas that other scholars who investigate variance and invariance in a DGE used in their work (the ideas in Activity 1 were presented by Leung (2003); and the ideas in Activity 3 were used by Baccaglini-Frank & Mariotti (2009)). Every activity has two parts: In Part 1 (called *Noticing*), participants were asked to describe what they notice when they drag one or more points in the space; and in Part II (called *Maintaining*), participants were asked to think about ways to drag one or more points in a way that maintains an invariant property. All draggable aspects left a colored trace when dragged. We focused our data analysis on descriptions in which participants discerned and described invariant properties. The analysis process included two cycles of coding (Miles, Huberman, & Saldaña, 2014) that laid the ground for a further analysis of the data in looking for themes and patterns. We used *descriptive coding* (Miles et al., 2014) to look at what participants said (verbally) and did (through actions).

Activity 1



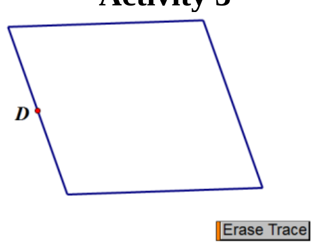
Participants could manipulate a draggable point (point C) connected to two fixed points. In Part II, participants were asked to think about ways to drag C so that there exists a circle passing through A and B with C as its center; and then to maintain a circle.

Activity 2



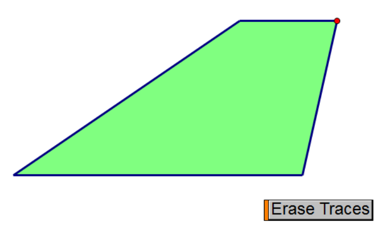
Participants were able to manipulate a dynamic polygon, by dragging one or more vertices. In Part II, participants were asked to try and drag one or more points, so the area of the figure stays the same.

Activity 3



Participants were able to manipulate a dynamic parallelogram by dragging D (a midpoint). In Part II, participants were asked to drag point D to create a rectangle and then to try and maintain the rectangle.

Activity 4



Participants could manipulate a dynamic trapezoid by dragging the red vertex. In Part II, the task was to think about ways (if possible) to drag the red point, so the area of a trapezoid is maintained.

Figure 8: Screenshot of the Four Activities Used in the Study

Results

We found 152 descriptions referring to invariant properties. Participants discussed invariant properties in 49 descriptions in the first part of the activities (*Noticing*) versus 103 descriptions in the second part of the activities (*Maintaining*).

Teacher's Tendency to Discern Invariant Properties

In all activities, we found many more descriptions referring to invariant properties in the second part of the activities than in the first part. In the first part, participants were mainly asked to describe what they notice (we found 39 descriptions of invariant properties), and if participants did not discuss about invariant properties, they were asked to describe what is changing and not changing (we found 10 descriptions of invariant properties). On the other hand, in the second part, the exploration was directed by asking participants to think about how it is possible to maintain an area of a figure the same, how to maintain a circle/rectangle, etc.

Types of Invariant Properties Discerned and Discussed by Teachers

We found four categories of invariant properties: (a) shape, (b) measurement, (c) location, and (d) calculation. In all four activities, descriptions were mostly focused on an invariant property of the visible visual dimensions of the shape of the figure (n=65), i.e., instances in which participants explained that the shape remains unchanged under a transformation and this suggested that participants might have identified the shape based on visual features that are maintained (the shape remains: an angle, triangle, parallelogram, etc.).

(a) (b)

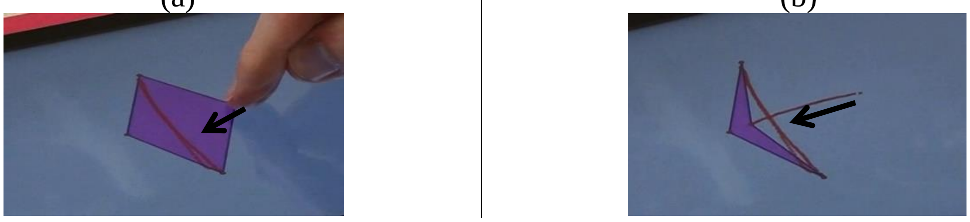


Figure 9: Mark Drags a Vertex When the Polygon is: (a) Still Convex and (b) Not Convex

For example, in Activity 2, Mark explained that by "dragging one of the corners" the shape stays convex, but "if you go far enough then it sort of starts to self-intersect and, it's no longer convex". Mark emphasized this by dragging the right corner horizontally to the left and showing how the polygon stays convex (see Figure 2a) until it is no longer convex (Figure 2b).

(a) (b)

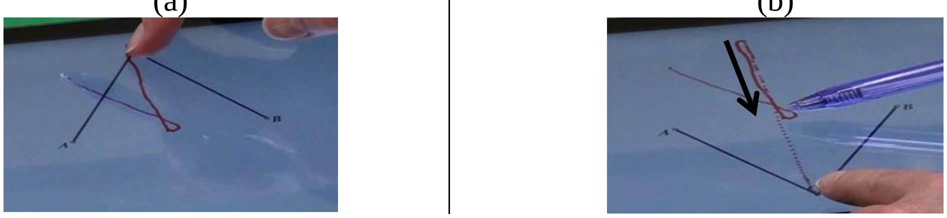

Figure 10: Susan's Reflection of Point C

We also found that many descriptions were related to properties of measurement of attributes (n=53) as being preserved under different transformations. This is interesting given that the teachers were not provided with access to the Sketchpad measurement tool. For instance, Figure 3 shows how in Activity 1, Susan reflected point C to maintain the distance of the midpoint of

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

the segment AB and point C the same. Susan used her fingers and a pen to emphasize and explain that the measure of the length of the distance is the same before and after the reflection.

Across all activities, we found descriptions of a location of a geometrical object as being preserved under transformations (*n*=25). Participants discussed these properties in two ways: (a) Invariant property of a location of an attribute as staying fixed in terms of not moving (e.g., points A and B in Activity 1); versus (b) an invariant property of location of an aspect that moves but stays fixed with respect to other objects, e.g., Andy translated point D in Activity 3 to maintain a rectangle and explained that he "sees them [three rectangles that he created] being different lengths and widths, but with point D always being the midpoint of one side".

Several descriptions (*n*=9) referred to a property of a calculation between attributes of a figure as being maintained under a transformation (e.g., the product 'height times base'). We also found that participants were also able to describe invariant properties (*n*=13) that were not visually presented on screen, e.g., a *Circle* in Activity 1; *Height Times Base* in Activity 2, etc.

Conclusions

One of the skills necessary to develop rich and deep understanding of geometrical objects, in terms of variance and invariance, is to look for and discern invariant properties (Sinclair et al., 2012). Related to our first research question, teachers in this study were able to discern and discuss invariant properties when asked about them but did not seem to naturally offer discussions of invariance without prompting. This finding suggests that careful consideration should be given to activities to ensure learners are engaging in identifying both the things that stay the same and the things that change – noting that invariance is often not as readily apparent.

In answering our second research question, we found four categories of invariant properties that seemed to be important for these participants in discussing variance and invariance in a DGE. Based on our interviews, we argue that discerning invariant properties of a shape of the figure might be an important starting point in making connections to valid domains, in unpacking a situation, and in looking for different ways to approach a problem. Leung and Lee (2008) showed that the measurement tool in DGE can be powerful in creating manipulations that can be guided and directed by the user. Moreover, the use of calculations and measurements is an integral part of problem solving in mathematics. Thus, attending to invariant properties of measurement and calculations might be an important component of rich understanding of objects and problem solving in DGE. As evidenced in our data, attending to invariant properties of location may help in sensemaking in geometric situations. Thus, teachers might benefit from learning opportunities that include explicit reference to the pursuit of these four different types of invariant properties and for developing skills to use such invariant properties in unpacking a geometric situation, problem solving, argumentation, etc.

Laborde (2005) explained that the invisible nature of invariant properties makes the task of discerning them a complex one. However, in this study, using the DGE allowed participants to see and interact with those properties, thus suggesting that accessing geometry dynamically may have structural affordances especially when considering invariance. The findings also show that it is possible to discuss and describe invariant properties that are not visible on the screen. This ability to talk and think about invisible attributes that have invariant properties is an important skill worth developing among teachers and should be further examined.

This paper reports a preliminary analysis of mathematicians' detailed accounts on why and how advanced mathematical knowledge matters for secondary mathematics teaching, and what specific connections can be made between advanced and secondary mathematics. Drawn from interviews with 18 mathematicians from 9 universities, the findings indicate that having advanced mathematical knowledge would allow secondary mathematics teachers to 1) develop an appropriate framework of mathematics; 2) gain mathematical experiences that would enhance their students' experience with mathematics; and 3) grow awareness of the extent of one's mathematical knowledge. Specific examples that connect linear algebra to secondary mathematics are presented and discussed.

Keywords: Advanced mathematical thinking, High school mathematics, Teacher knowledge, Mathematicians.

Introduction

How important is advanced mathematics for good teaching? While Monk's (1994) study shows that teachers' mathematical background, as measured by the number of mathematics courses a teacher took in university, is positively related to how much mathematics students learn at the secondary level, it is not always clear how and why advanced mathematics contributes to teaching. In fact, teachers often struggle to find specific examples that connect advanced and secondary mathematics (e.g., Zazkis & Leikin, 2010). Previous studies sought the relevance and contribution of academic mathematics to teaching by taking into account mathematicians' views on curriculum planning and course design (e.g., Goos, 2013; Hoffmann & Even, 2018; Leikin, Zazkis & Meller, 2018). However, many questions remain unanswered regarding which connections between advanced and school mathematics are important, and how they might lead to the improvement of teachers' practice (Murray et al., 2017). This paper reports a preliminary analysis of mathematicians' view on why advanced mathematical knowledge matters for secondary mathematics teaching, and what specific connections can be made between linear algebra and secondary mathematics.

Theoretical Background

Our paper builds upon 1) the notion of advanced mathematical thinking (AMT) and advanced mathematical knowledge (AMK); and 2) previous studies on mathematicians' perspectives on the importance of advanced mathematical knowledge for teaching.

Tall (1991) examined differences between elementary and advanced mathematical thinking as transitions from *describing* to *defining*, from *convincing* to *proving* based on abstract entities. These transitions, considered challenging processes for most prospective teachers, must be addressed and overcome during their undergraduate education. In exploring secondary mathematics teachers' conceptions of the role and usage of AMK in their teaching practice, previous studies have shown that while some teachers acknowledged the importance of AMK, others are unaware of the connections between secondary and advanced mathematics, and are often dismissive of their upper-level training (e.g., Goulding, Hatch, & Rodd, 2003; Zazkis & Leikin, 2010). To help motivate practicing and prospective teachers in deepening their mathematical understanding, previous studies also investigated how abstract algebra might support teachers' efforts to unpack a secondary mathematics topic, and how an understanding of advanced mathematics might shape pedagogy in the secondary classroom (Christy & Sparks, 2015; Murray et al., 2017).

Considering mathematicians' perspectives on teaching, Leikin, Zazkis, and Meller (2018) noted that, "mathematicians act as teacher educators de facto, without explicitly identifying themselves in this role" (p. 452). Indeed, mathematicians and teachers typically have different approaches to the knowing of mathematics: while mathematicians focus on the epistemic nature of the subject, teachers often focus on cognition and pedagogy without rigorous justification (Cooper & Arcavi, 2018). Despite these differences, Bass (2005) argued that mathematicians' knowledge, practices, and habits of mind are relevant to school mathematics education because their mathematical sensibility and perspective are essential for maintaining the mathematical balance and integrity of the educational process. This preliminary research report aims to further investigate mathematicians' perspectives on possible connections between advanced and secondary mathematics.

Method

The participants were 18 mathematicians from 9 universities: 15 were actively engaged in mathematics research and 3 were focused on teaching only. Of the 18 participants, 15 were teaching undergraduate or graduate courses in mathematics at Canadian research universities; two were professor emeriti; and one was a visiting professor from outside of Canada.

The main corpus of data was comprised of individual semi-structured interviews with the participating mathematicians. The aim was to gain insights into their views on advanced mathematical knowledge and its relevance to secondary school mathematics teaching. The interviews included two main guiding questions:

1. How do you think advanced mathematical knowledge might contribute to secondary school mathematics teaching?
2. What are specific examples that reveal connections between advanced and school mathematics?

All the interviews were audio-recorded and transcribed. Additional written artifacts generated by the interviewees were collected for the qualitative analysis. Recurring themes were identified and categorized using an iterative and comparative process. In this paper, all participants were coded starting with M, followed by a number assigned to each participant.

Findings

Why Advanced Mathematical Knowledge Matters?

Three major themes emerged from the mathematicians' responses to "how do you think advanced mathematical knowledge might contribute to secondary school mathematics teaching?" The results of the analysis show that advanced mathematical knowledge would allow teachers to 1) develop an appropriate framework of mathematics; 2) gain rich mathematical experience that would enhance their students' experience with mathematics; and 3) grow awareness of the extent of one's mathematical knowledge.

Developing the framework of mathematics. Some of the mathematicians claimed that a clear vision of what mathematics is and robust understanding of a mathematical concept comes from advanced mathematical knowledge. For M5, "the conceptual framework that underpins complex procedures and mechanical applications" is a component of AMK. Along the same line, M10 explained the framework of mathematics with an analogy:

> If you are knitting something, you must get some kind of overarching concept of what it is that you are doing. You are working locally but there is some framework in your mind that how your local thing is sort of fitting in.

In this sense, the importance of advanced mathematical knowledge lies in the heart of developing or changing the framework of mathematics. Having advanced mathematical knowledge would allow a teacher to see the fundamental structure and to reach "a kind of gestalt," as M10 stated, "I mean it is the same idea but somehow you are looking at a piece of mathematics on completely different terms."

The framework of mathematics was also elaborated in the sense of the scope of the subject. For example, "What comes next in the material? And how is it used later on?" (M14). As M16 put it, "This is what you teach now, but maybe this will appear again in a slightly different form; because definitions and problems are adjusted to students' comprehension level. How will they appear later on? That is the key." Concerning teaching at the secondary level, M14 stated that, "Having more knowledge means more tools, more examples, and a deeper understanding. […] It allows you to bring the material to life via a compelling narrative."

Gaining mathematical experience. Mathematics is not a spectator sport (Phillips, 2005). The mathematicians interpreted advanced mathematics not only as a form of knowledge, but also as "the process and experience of gaining that knowledge and thinking about how that knowledge impacts what they [teachers] are going to try to put forth to their students" (M11). As M10 suggested, "Roll up your sleeves and do it […] because it embodies structure and you have to get into it and understand the structure." M9 also explained:

> It [mathematics] is the study of complex structure and especially when there are simple elegant aspects to the structure. So they [teachers] need to understand how to work with such a structure. How to take it apart so they can understand how the different pieces interact and then put it back together? The only way to get that understanding and experience is to spend time doing it.

One of the benefits from doing a lot of mathematics, for M13, is that learners would be able to attack a mathematics problem using a "power drill" rather than some very simple "screwdrivers" that by definition take longer (see example 3 in Table 1).

Growing awareness of the extent of one's mathematical knowledge. Another aspect of the importance of AMK lies in the growth of awareness that guides and enables actions. M15 regarded the importance of AMK as a reflective process that allows teachers to identify their strengths and weaknesses in mathematics:

> If people are going to be teaching, they should be able to tell they actually know something well or more importantly whether they are still confused. Really getting that distinction down is one of the goals of undergraduate training at the level of a major. I think that only if you study a certain amount of mathematics [you] can do that [make that distinction].

Other mathematicians also shared this view. For example, M4 pointed out that one of the expectations in the undergraduate mathematics program at his university was to learn the limits of both students' knowledge and mathematicians' knowledge. This suggests that being aware of the extent of one's mathematical knowledge would consequently enable prospective teachers to mediate between elementary and advanced mathematical thinking.

Connections Between Advanced and Secondary Mathematics

The examples provided by the mathematicians span a wide range of topics in mathematics. In this paper, we focus on three examples in linear algebra to illustrate the connections drawn between advanced and secondary mathematics.

Table 1: Examples in Linear Algebra

A High School Problem	AMK	Advantages of AMK for Teachers
1. Solve systems with 3 or more equations.	- *Gauss-Jordan elimination*: "A systematic way to simplify a set of equations" (M5). - *Matrices and the idea of inverse*: "Use the inverse matrix if it is invertible, then you know you get a unique solution" (M8).	- "'Read off' the solution" (M5); - Identify whether a system has unique, many, or no solution.
2. Solving $\begin{cases} \mathbf{x+y=2} \\ \mathbf{x-y=0} \end{cases}$ A student's incorrect method $\mathbf{x+y-2=x-}\boldsymbol{y} \Rightarrow \boldsymbol{y}=\mathbf{1}$, thus the solution set is y=1, x any number.	- *Solution to a system of equations*: "In the background of [the] Gauss-Jordan elimination is the abstract idea of what algebraic operations are permitted on the system of equations (manipulating them) that don't change the solutions set" (M5).	- Understanding that "equating two or more equations together is NOT an allowed operation; it could alter the solution set" (M5).
3. Find the equation of a line through the points (2, 7) and (8, 10).	- *Use of the determinant of a 3 by 3 matrix*. (M13) e.g. (2,7) and (8,10). $0 = \det \cdot \begin{bmatrix} x & y & 1 \\ 2 & 7 & 1 \\ 8 & 10 & 1 \end{bmatrix} = x \cdot \det\begin{bmatrix} 7 & 1 \\ 10 & 1 \end{bmatrix} - y \det\begin{bmatrix} 2 & 1 \\ 8 & 1 \end{bmatrix} + 1 \cdot \det\begin{bmatrix} 2 & 7 \\ 8 & 10 \end{bmatrix}$ $= -3x - y \cdot (-6) - 36 = 0$ Then solve to get $6y = +3x + 36$ $\boxed{y = \frac{x}{2} + 6}$	- Offer an alternative solution; - Create a need for a justification of why the method works, which may lead to a formal proof.

Discussion

In response to why advanced mathematical knowledge matters for good teaching, the mathematicians placed emphasis on the understanding of the breadth and depth of mathematical knowledge in relation to mathematical structure. Two of their ideas – to establish the framework of mathematics and to gain rich mathematical experience resonate with Mamona-Downs and Downs' (2008) elaboration on the importance of the process of mathematical thinking rather than the product of mathematical thought. This is also in line with Burton's (1999) suggestion that mathematicians often see connections set within a global image of mathematics as an important part of knowing mathematics. The third idea regards the importance of teachers' awareness of the extent of their own knowledge, and their ability to distinguish between what they know and what requires further mathematical investigation. Additionally, by providing examples in linear algebra that may require AMK for an explanation, an alternative method, or simply a quick solution, the mathematicians provided insightful connections between advanced and secondary mathematics. Nonetheless, the analysis of the data set is still at its early stages. Further investigation and a more in-depth analysis would help us better understand the nature of advanced mathematical knowledge, and its relationship to school mathematics.

EXAMINING PRESERVICE TEACHERS' MATHEMATICAL CONTENT KNOWLEDGE THROUGH PROBLEM SOLVING

Monte Meyerink
Montana State University
montemeyerink@montana.edu

Fenqjen Luo
Montana State University
fluo@montana.edu

Prior studies have highlighted the importance of teachers' mathematical content knowledge and its impact on teaching practices and students' learning. Applying the mathematical knowledge for teaching framework and problem-solving strategies framework, this small-scale study sought to examine preservice teachers' mathematical content knowledge and problem-solving tendencies. Participants' examples of various problem-solving strategies are discussed, as well as recommendations for future research.

Keywords: teacher knowledge, number concepts and operations, algebra and algebraic thinking

Problem solving has become an area of emphasis in mathematics education (Chapman, 2015; Lesh & Zawojewski, 2007; Schoenfeld, 2013). This emphasis can be observed on the Smarter Balanced mathematics assessment – one of the four domains tested is problem solving (SBAC, 2018). An important aspect of problem solving is the development of algebraic thinking. Emphasizing algebraic thinking at an early age has been shown to better prepare students for future applications of algebraic thinking (Carraher & Schliemann, 2018), and the Common Core State Standards for mathematics address algebraic thinking beginning at the kindergarten level (CCSSI, 2010). However, studies have shown that teachers may be insufficient in algebraic thinking, as "preservice elementary teachers' conceptions of algebra as subject matter are rather narrow" (Stephens, 2008, p. 33). Researching potential causes of this lack in algebraic thinking may prove beneficial for teacher education programs. This study's research question is the following: What problem-solving strategies do PSTs tend to use most frequently?

Theoretical Framework

The mathematical knowledge for teaching framework proposed by Ball et al. (2008) highlights six separate domains of teaching mathematics. One of these domains, common content knowledge (CCK), refers to teachers' abilities to solve mathematics problems correctly. Knowledge of problem-solving strategies is an essential aspect of CCK – one must first identify potential problem-solving strategies in order to solve a problem correctly. Problem solving is highlighted by the various strategies that can be implemented to reach a solution. While the comprehensive list of these strategies has evolved over time, Van de Walle, Karp, Lovin, and Bay-Williams (2018) presented a list of problem-solving strategies that were well-aligned with the research of both Polya (1957) and Schoenfeld (1985). The problem-solving strategies used in this study were: (a) visualize; (b) look for patterns; (c) predict and check for reasonableness; (d) formulate conjectures and justify claims; (e) create a list, table, or chart; (f) simplify or change the problem; and (g) write an equation (Van de Walle et al., 2018, p. 22). This study focused on investigating PSTs' CCK related to problem solving while understanding that CCK is just one aspect of mathematical knowledge for teaching.

Methodology

Participants in this study were PSTs (n = 25) enrolled in K-8 Mathematics Methods during the spring 2019 semester at a large university in the Northwest US. Participants were asked to

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

independently complete Smarter Balanced mathematics problem solving sample items for sixth (n = 2), seventh (n = 2), and eighth (n = 4) grade. These specific sample items were selected due to their potential to be solved using either number operations strategies (NOS) or algebraic thinking strategies (ATS). Problem-solving strategies were coded according to the categories highlighted by Van de Walle et al. (2018) and two additional categories: (a) multiple strategies demonstrated and (b) no strategies demonstrated. Additionally, strategies were coded according to whether NOS or ATS strategies were employed. Correctness was not considered when coding.

Results

Problem-solving strategies were coded in regard to two factors: (1) whether NOS or ATS strategies were demonstrated and (2) which strategy(ies) presented by Van de Walle et al. (2018) best described the strategy(ies) demonstrated by PSTs. Examples of each coding category observed in this study are presented in Figure 1. Participants' names have been replaced with aliases to protect participants' identities.

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

Number Operations, Write an Equation (NE) - Nancy	Lenny bought a motorcycle. He paid 12.5% in tax. The tax added $1,437.50 to the price of the motorcycle. What was the price of the motorcycle, not including tax? (7B) Number Operations, Multiple Strategies (NM) - Karlie	Sample Item 8C Algebraic Thinking, Predict and Check for Reasonableness (AG) - Mike	Sample Item 8D Algebraic Thinking, Write an Equation (AE) - Cindy	Sample Item 8D Algebraic Thinking, Multiple Strategies (AM) - Karlie	Sample Item 8B 
Table 2 displays the frequencies of problem-solving strategies demonstrated by PSTs. Overall, it appears that PSTs tended to use NOS (n = 167) more frequently than ATS (n = 28). When examining the data more closely, it appears that PSTs tended to write equations that rely on NOS (e.g., solving a series of simple arithmetic operations) on the sample items designed for lower grades, while the tendency to write equations that rely on ATS (e.g., solving a system of equations) appears to have increased as the grade level increased. It also seems that PSTs' tendency to employ "guess and check" strategies (i.e., predict and check for reasonableness) increased as the demand for algebraic thinking increased. Particularly, ATS are arguably most appropriate for sample items 8A, 8B, 8C, and 8D. However, "guess and check" strategies relying on NOS were not utilized on sixth- or seventh-grade sample items but were demonstrated on eighth-grade sample items (n = 19). Additionally, NOS were more frequently demonstrated (n = 77) on eighth-grade sample items, rather than employing ATS (n = 23). Possible explanations of this finding might be a lack of PSTs' knowledge in regard to ATS or a greater comfort or confidence level in solving problems with NOS.

Table 2: PSTs' Problem-Solving Strategies

	NV	NP	NG	NT	NE	NM	AG	AE	AM	None	Total
6A	–	–	–	–	24	1	–	–	–	–	25

PSQ	1	8	19	3	123	13	1	25	2	5	200

Discussion and Implications

Based on the findings of this study, PSTs tended to rely on NOS rather than ATS when working on problem-solving items. While the collected data revealed PSTs' tendencies related to the use of NOS or ATS and the problem-solving strategies highlighted by Van de Walle et al. (2018), little insight was provided regarding PSTs' thought process while working on the PSQ. For example, consider Jasmine's solution to sample item 8B (Figure 1). One possibility might be that she initially placed five books in Simone's square. Then, her next step could have been to place a book in Nang's square, then Simone's, etc., until she reached the total number of books, 23, read by Simone and Nang. Another possibility is that she solved the sample item mentally, using a "guess and check" strategy, and simply used the visual representation to explain or check her solution. Solutions of this type leave uncertainly as to how PSTs solved sample items.

Additionally, the collected data on problem-solving strategies did not provide information regarding PSTs' reasons for utilizing or avoiding certain problem-solving strategies. For example, consider Suzi's solution to sample item 8D (Figure 1). Suzi demonstrated a "guess and check" strategy that relied on NOS. However, why she chose this strategy is unclear. One possibility is that Suzi does not feel comfortable applying ATS, so she decided to try out several combinations of adult and child tickets until she discovered a pair that met the criteria for the sample item. Another possibility is that Suzi discovered how to solve the sample item more efficiently. She may have noticed that the total price of tickets, $120, has a 0 in the ones place, and the price of multiple child tickets must end in a 0 or a 5, since a child ticket is $5. Using this information, Suzi could have recognized that the price of adult tickets must have a ones place that matches the ones place of the price of child tickets. Thus, the number of adult tickets must be 5 or 10. Discovering this "shortcut" creates a scenario where she would only need to use "guess and check" a maximum of two times. Therefore, Suzi's reason for not applying ATS is unclear. Qualitative data will be included moving forward, as individual follow-up interviews may enhance this study by: (a) providing additional information regarding how PSTs solved sample items, (b) improving criteria for coding problem-solving strategies, and (c) providing information regarding PSTs' rationale for using or avoiding certain problem-solving strategies.

In this case study, we uncover that a key taken-as-shared concept, quantity, may not have the shared understanding assumed in the literature. We discuss implications for research and practice if this teacher is typical.

Keywords: Teacher knowledge, Number concepts, Mathematical knowledge for teaching

Purpose and Perspective

Across the literature, the term *quantity* is used to describe something important about numbers and their relationships. Lamon (2007), Lobato and Ellis (2011), and Thompson, Carlson, Byerly, and Hatfield (2014) all provide different facets of a definition of quantity. In our own work, we previously took quantity as having a shared meaning and focused on more complex proportional-reasoning ideas. In this study, we describe one teacher's experience in one session of a professional development (PD) course as her understanding of *quantity* evolved.

Methods

The six-hour pilot PD program focused on proportional relationships. Twenty-one teachers met three days after school for two hours each day. In the first two days, teachers engaged with mathematics through dynamic applications designed to support conjectures and arguments about proportional relationships. The third day focused on classroom applications. Each class session was recorded using multiple video cameras to capture whole class and small group conversation.

We analyzed video from the third day when a rare moment in PD was captured in which a participant, Diane (pseudonym), clearly experiences and explains a pivotal "aha!" moment regarding her understanding of quantity and how she has been teaching this concept.

Results and Discussion

Participants began discussing the importance of language and how difficult it can be to engage students in using proper mathematical language. Through this conversation, Diane began to ask questions about quantity. She indicated she had been focusing on labels with ratios. The facilitator reinforced that ratios are comprised of two quantities and quantities are measurable. Diane exclaimed this was an "aha" moment for her and would impact her teaching. This brief case suggests more research is needed about how teachers understand, communicate, and teach the topic of quantity.

MATHEMATICAL KNOWLEDGE FOR TEACHING: A COMBINATORIAL UNDERSTANDING OF ALGEBRAIC IDENTITIES

Erik S Tillema
Indiana University
etillema@indiana.edu

Desiree Ippolito
Indiana University
drippoli@iu.edu

Keywords: Mathematical Knowledge for Teaching, Algebraic Identities, Combinatorics

Mathematical knowledge for teaching (MKT) has received a significant amount of attention over the last three decades (e.g., Ball, 1990). At the secondary level, researchers have used two broad approaches to specifying secondary teachers' MKT. One approach has focused on specifying this knowledge as it relates to particular topical areas (e.g., geometry, fractions, complex numbers) (e.g., Heid, Wilson & Blume, 2015; Herbst & Kosko, 2014; Izsak, Jacobson, de Araujo, Orill, 2012). A second approach has focused on specifying this knowledge as it relates to key developmental understandings (KDUs) (Simon, 2002) that cut across multiple topical areas (e.g., co-varational reasoning) (e.g., Thompson, 2016).

For the purposes of this poster we adopt the second approach. Specifically, we report on a year-long design experiment conducted with four PSSTs whose focus was on helping the PSSTs to: a. establish an increasingly general understanding of the role that combinatorial reasoning can play in understanding common algebraic identities in 8^{th}-12^{th} grade; and b. support them to design and teach a sequence of lessons in their student teaching placement that was connected to what they had learned. The following research question guides this poster: What were the central components of PSSTs establishment of a combinatorial understanding for algebraic identities?

The PSSTs worked to develop a combinatorial understanding of algebraic identities using problems like the Card Problem:

> *The Card Problem.* You have a 2, 3, and King of Diamonds. You draw a card, replace it, draw another card, replace it, and draw a third. How many possible three card hands could you make? How many three card hands have no kings? Exactly one king? Exactly two kings? Exactly three kings?

The aim of this problem was for PSSTs to develop the equivalence that $3^3 = (2 + 1)^3 = 2^3 + 3\cdot(2^2 \cdot 1) + 3 \cdot (2 \cdot 1^2) + 1^3$. We conjectured that this equivalence could grow out of reasoning that there were a total of 3^3 possible three-card hands, that this total could be quantified as $(2 + 1)^3$ because each person had 2 non-face cards and 1 face card, and also that this total could be quantified as $2^3 + 3 \cdot (2^2 \cdot 1) + 3 \cdot (2 \cdot 1^2) + 1^3$ because: the number of three card hands with no face cards was 2^3; there were 3 ways to have one face card with each way having $(2^2 \cdot 1)$ three card hands, etc. The students were then asked to generalize this situation to one in which they drew from an unknown number of face and non-face cards, and to expand this generalization to a range of related situations.

For the poster, we highlight two results from the study: a. important points along the path in the PSSTs development of a combinatorial understanding of algebraic identities; and b. differences in the quality of the MKT among the four PSSTs. One key point along the path for the PSSTs was the transition they made from thinking about an algebraic identity as tied to a particular combinatorial situation (with whole number possibilities known or unknown) to seeing the underlying structure of the partial products that could be applied to fraction and integer values. Two of the four PSSTs developed a combinatorial understanding that enabled this transition. We will outline the reasons for these differences among the PSSTs on our poster.

REFUTING A FRACTION MISCONCEPTION: A BRIEF INTERVENTION PROMOTES TEACHERS' CONCEPTUAL CHANGE

Jessica Rodrigues
University of Southern California
jessica.rodrigues@usc.edu

Ian Thacker
University of Southern California
ithacker@usc.edu

Research shows that some teachers overgeneralize the whole number rule of "multiplication always makes bigger" to multiplication with fractions. The present study explores this misconception not only with fractions with unfamiliar denominators (e.g., thirty-fifths) but also fractions with familiar denominators (e.g., halves) and evaluates an intervention for remediating the misconception. In- and pre-service teachers (N = 100) completed a direction of effects task prior to and after random assignment to either read a control text or a refutation text that directly refuted the misconception. The misunderstanding was present among items with unfamiliar and familiar denominators, demonstrating the pervasiveness of the misconception. Overall, the intervention was found to be effective, showing promise of refutation texts for promoting teachers' mathematics conceptual change.

Keywords: Rational Numbers, Teacher Knowledge, Number Concepts and Operations, Elementary School Education

Studies of teachers' mathematics knowledge have shown that many teachers possess a limited conceptual and procedural understanding of fractions (e.g., Ma, 1999; Moseley, Okamoto, & Ishida, 2007), limiting their preparedness to support their students' fraction learning. Preservice teachers struggle to comprehend the most foundational conceptual understanding of fraction arithmetic, which is the *direction of effects* that an operation produces (e.g., whether multiplying by a given value makes a number smaller or larger; Siegler & Lortie-Forgues, 2015).

Research on direction of effects errors has concentrated on multiplication of fractions (Siegler & Lortie-Forgues, 2015). A common misconception that individuals hold is to overgeneralize the whole number rule that "multiplication always makes bigger" to multiplication with fractions, when in fact, multiplying a positive number by a fraction that is less than one does *not* make that positive number bigger. In a study conducted by Siegler and Lortie-Forgues (2015), 41 preservice teachers completed a direction of effects task for which they were asked to predict without calculating whether the answer to an inequality would be larger or smaller than the larger fraction in the multiplication problem. The fractions used in the task were selected to be too large and uncommon so that the items could not be solved easily with mental arithmetic (e.g., "True or False: 41/66 x 19/35 > 41/66"; Siegler & Lortie-Forgues, 2015). The preservice teachers answered correctly less often than chance on multiplication items designed intentionally to capture the misconception (i.e., multiplication items with fractions between zero and one).

The present study adds to the literature in two important ways by (a) examining the presence of the direction of effects misconception for items involving unfamiliar denominators and items involving familiar denominators and (b) evaluating a brief intervention for remediating the misconception.

Theoretical Framework

Individuals who transfer the whole number rule that "multiplication makes bigger" to all multiplication problems with fractions may need to undergo conceptual change to overcome this misconception. Conceptual change is a process in which individuals restructure conceptual knowledge and shift misconceptions prompted by discrepant information (Carey, 2009). We draw from the Cognitive Reconstruction of Knowledge Model (CRKM) model of conceptual change that discerns between characteristics of the learner (i.e., their prior conceptions and motivation) and of the message (i.e., whether the learning material is comprehensible, coherent, compelling, and plausible; Dole & Sinatra, 1998). This model is particularly useful for our research because it explains why individuals might shift their misconceptions about fraction multiplication based on novel information presented in a refutation text.

Refutation texts have been shown to be an effective tool for promoting conceptual change in science education (e.g., Broughton, Sinatra, & Nussbaum, 2012; Tippet, 2010). These texts are designed to state a misconception, refute those ideas, and then present the accurate explanations as plausible and fruitful alternatives (Hynd, 2001). Whereas positive effects of refutation texts for the remediation of misconceptions have been demonstrated in science education for years (e.g., Diakidoy, Mouskounti, & Ioannides, 2011), the texts have not yet been explored extensively for addressing mathematics misconceptions. A noted exception is research conducted by Lem and colleagues (Lem, Onghena, Vershaffel, & Van Dooren, 2017) that explored the use of refutation texts for correcting students' misconceptions about box-and-whisker plots.

Present Study

To our knowledge, there are currently no studies investigating the presence of the "multiplication always makes bigger" misconception when fractions being multiplied have common denominators (e.g., halves, fourths) and no work investigating an instructional intervention for remediating this specific misconception. In response, the present study was designed with the following two objectives: (a) to assess if pre- and in-service teachers correctly answer less often than chance on easy, medium and hard direction of effects problems involving multiplication of fractions between zero and one and (b) to evaluate the effectiveness of a refutation text that targets the misconception for promoting conceptual change.

Method

Participants

Participants were pre-service and in-service elementary school teachers (N = 100), 38% self-reported as male, 42% White, 45% Asian American/Pacific Islander, 1% Hispanic, 3% Black/African American, 8% Mixed and 5% Other. The mean age was reported as 21.1 years (SD = 3.7). All participants were recruited via a Qualtrics survey panel that exclusively targeted in- and pre-service elementary teachers.

Measures

Texts. Two texts were created, a refutation text and a control text. The refutation text consisted of 364 words, had an 11th grade Flesch-Kincaid reading level, and stated and directly refuted the "multiplication always makes bigger" misconception. For example, an excerpt reads: "When multiplying numbers, you may think that the product will always be greater than the original number. This is incorrect! It is only when you multiply a positive number by a number greater than 1 that the product will be greater than the original number." This direct refutation was followed by a description of when multiplication makes bigger, and does not. The control text was a 100-word expository text paired with an illustration that was adapted from Hake (2007) that describes a strategy for multiplying fractions: “We often translate the word *of* into a multiplication symbol. We find 1/2 of 1/2 by multiplying: 1/2 of 1/2 becomes $1/2 \times 1/2 = 1/4$.”

Direction of effects task. The direction of effects task assessed participants’ understanding of the direction of effects of arithmetic, which was used to measure participants’ conceptual understanding of fraction addition and multiplication (Siegler & Lortie-Forgues, 2015). Participants were asked to evaluate the accuracy of addition inequalities in the form of $a/b + c/d > c/d$ and multiplication inequalities in the form of $a/b \times c/d > c/d$. Participants answered four addition inequalities and four multiplication inequalities within three categories of varying difficulty, resulting in 24 total items. The “easy” items all included the fraction 1/2 paired with a fraction with a familiar denominator such as fourths (e.g., $3/4 \times 1/2 > 1/2$); “medium” items included familiar denominators but did not present any unit fraction such as 1/2 (e.g., $9/10 \times 2/5 > 2/5$); and “hard” items included the items used in a previous study (Siegler & Lortie-Forgues, 2015) with unfamiliar denominators (e.g., $19/35 \times 41/66 > 41/66$). For each inequality, participants were instructed to decide, without calculating, whether the answer would be greater than the answer indicated in the inequality.

Procedure

All materials were presented via an online Qualtrics survey. After agreeing to participate, teachers completed the pretest direction of effects task. Then, teachers were randomly assigned to either the refutation text or the control text group. After reading the text, teachers were asked to complete the direction of effects task again which served as a posttest assessment. The total survey required an average of 18 minutes ($SD = 19$).

Results

We conducted a simple one sided test of proportions to determine if teachers correctly answered multiplication problems with fractions between zero and one less than half of the time. Analysis of teachers’ pretest performance on the easy and medium items with familiar denominators and hard items with unfamiliar denominators revealed that teachers chose the correct item about 49% of the time, which was not significantly different than chance (50%; chi-squared = .375, $p = .27$). When considering all 24 pretest items, 31% of teachers were correct on 100% of the 18 addition and multiplication items for which the greater-than inequality was true and 0% on the 6 multiplication items for which the greater than inequality statement was false. In other words, 31% of teachers at pretest showed the true misconception that “multiplication always makes bigger.”

Of the 57 participants in the refutation text group, 9 participants continued to show the true misconception (16%) at posttest. We then looked more closely at participants’ performance on the six multiplication items that were designed to capture the misconception. We focused attention on the refutation group participants who answered at least one of the misconception items incorrectly at posttest ($n = 28$). Of this subgroup, participants correctly answered at a rate similar to chance for five of the six items ($p > .05$) and less often than chance on one of the six items with unfamiliar denominators: $19/35 \times 41/66 > 41/66$ (71.4%; $p = .01$).

To assess the effectiveness of the refutation text intervention, we ran a repeated measures ANOVA with Arithmetic Operation (addition or multiplication) as a within-subject factor and text condition (refutation text or control) as between-subject factor and number of correct judgments as the dependent variable yielded significant main-effects of Arithmetic Operation ($F(1,98) = 64$, $p < .001$, *partial-eta squared* = .395) and main effects of condition that are approaching significance ($F(1,98) = 2.24$, $p = 0.14$, *partial-eta squared* = 0.022). These were qualified by a significant Operation x Condition interaction ($F(1,98) = 4.462$, $p < .001$, *partial-eta-squared* = 0.043). As expected, post hoc comparisons with Bonferroni correction showed no significant differences between ref-text and control groups in addition knowledge (89% vs 89%, $t(42) = 0.03$, $p = .98$, *Cohen's d* = 0.00). However, we found significant differences between refutation text and control groups in multiplication knowledge (74% vs 63%, $t(42) = 2.45$, $p = .02$, Hedge's $g = 0.56$).

Discussion

We assessed the effectiveness of a refutation text intervention for the remediation of a misconception regarding fraction arithmetic. Though there is some research on the use of refutation texts to shift students' misconceptions about mathematical topics (Lem et al., 2017), our study investigates the use of a refutation text to shift teachers' misconceptions about fraction multiplication. We also explore whether the misconception is specific to multiplication of unfamiliar fractions or common fractions more generally. Overall, we found that teachers answered easy, medium and hard fraction multiplication problems correctly at about the same rate as guessing, suggesting that the misconception is even more widespread and problematic than demonstrated in prior research (Siegler & Lortie-Forgues, 2015). Furthermore, we found that teachers who read a refutation text had fewer misconceptions about fraction multiplication compared with those who read a control text. That is, refutation texts have the potential to substantially impact teachers' mathematics misconceptions. This finding has important implications for research on conceptual change in mathematics and refutation texts.

Teachers Hold the Multiplication Misconception

Our results showed that a sample of pre- and in-service teachers answered fraction multiplication problems with fractions between zero and one at about the same rate as by chance. This finding is consistent with prior research showing that pre-service teachers were not successful in answering items regarding directions of effects in multiplication at a rate better than chance (Siegler & Lortie-Forgues, 2015). This replication of the finding suggests that many pre- and in-service teachers are in need of remediating misconceptions that may be limiting their readiness to advance their students' fraction understanding.

Refutation Texts Support Mathematics Conceptual Change

Teachers who were randomly assigned to read a refutation text that directly refuted the "multiplication always makes bigger" misconception had fewer misunderstandings at posttest than those assigned to read a control text, with modest effect sizes (Hedge's $g = 0.56$). Refutation texts targeting specific misconceptions thus hold potential as a relatively quick method for promoting teachers' conceptual change.

Future Directions

Although the present study shows promise of a refutation text serving as an instructional approach for targeting a specific fraction misconception, replication studies are required before widespread recommendation of refutation texts for supporting mathematics conceptual change. In light of the limited studies thus far exploring refutation texts for mathematics learning, there are multiple research curiosities that future work can explore, such as refutation texts for remediating not only other fraction misconceptions but also misconceptions in other mathematics content areas. Researchers should also explore the effectiveness of refutation interventions among not only teachers but also students, as such texts may hold promise for professional development opportunities and classroom instruction alike.

Keywords: Teacher Knowledge, Geometry and Geometrical and Spatial Thinking

A persistent challenge facing any instructor is to "continually find ways to expose [learners'] thinking" (Kennedy, 2016, p. 12). When the learners are prospective mathematics teachers (PTs), this challenge can take the form of exposing mathematical thinking, especially related to mathematical knowledge in and for teaching (MKT; Ball, Thames, & Phelps, 2008; Rowland, Thwaites, & Jared, 2016; Thompson & Thompson, 1996). However, as a recent review of research in MKT suggests, it is not clear how task design impacts the MKT that is visible (Hoover, Mosvold, Lai, & Ball, 2016). This issue is additionally complicated by the potential for differently designed assessments, such as submitted written or video assignments, to expose different aspects of PTs' thinking or MKT.

To investigate this issue, we analyzed 36 representations of secondary geometry teaching practice (Grossman et al., 2009) generated by 6 PTs in a college geometry course. We asked: *In what ways do video and written representations of practice expose different aspects of PTs' MKT?* We argue that attending to potential differences in video and written representations is critical to developing PTs' MKT from an asset-based perspective.

We take the theoretical perspective that development of MKT involves key developmental understandings of mathematical topics (Silverman & Thompson, 2008) and decentering in teaching practices (Ader & Carlson, 2018). Our analytic framework draws from this theoretical perspective and is elaborated in Lai, Strayer, and Lischka (2018). The study design involved six representations of practice per PT. In three of these representations, PTs were asked to write a plan for a whole class discussion. In the other three, PTs prospective teachers were asked to video-record themselves giving a response to a student. Written and video tasks were designed in pairs to address the same particular content standards. In all tasks, secondary student thinking on definitions in geometry (e.g., reflection) were provided to teachers.

To illustrate differences represented across the data, we use the case of one PT's (Heidi) responses. In Heidi's video responses, she demonstrated fluent MKT. She built on student thinking presented, used mathematical language in precise ways, and posed questions that supported advancing the learner's key developmental understandings. In contrast, Heidi's written responses to an assignment addressing the same mathematical ideas included few mathematical statements, and did not use the student thinking. Heidi's responses make a compelling case for the importance of examining the impact of different formats of approximations of practice on instructors' perceptions of PTs' knowledge and a commitment to asset-based perspectives on what teachers know.

PROFESSIONAL EXPERIENCES OF RURAL TANZANIAN MATHEMATCS TEACHERS

Michael Lolkus

Jill Newton
Purdue University
janewton@purdue.edu

Keywords: Teacher Knowledge, Instructional Activities and Practices, International Education, Social Justice

Aligning with the redistribution component of Cazden's (2012) education-oriented framework for social justice, many education reform efforts have been aimed at improving infrastructure as opposed to instructional development (Pryor, Akyeampong, Westbrook, & Lussier, 2012). Many of the professional experiences of rural Tanzanian mathematics teachers (RTMT) are currently centered on issues in the school, and less on curriculum and effective pedagogical practices (Kafyulilo, 2013). Conversations with RTMTs and anecdotal evidence from one author's experiences have revealed a need for professional experiences that will create opportunities for RTMTs to reflect on their pedagogical practices, collaborate with their peers, and enhance their prestige and mobility in their instructional careers. We utilize collective case study methods (Stake, 2003; Yin, 2017) to examine how RTMTs develop pedagogical content knowledge (PCK) (Ball, Thames, & Phelps, 2008 2008; Shulman, 1986) through both formal and informal collaborative experiences.

Methods

This study explores current professional experiences with and for RTMTs that address the redistribution of teacher development resources through investigation of (a) how RTMTs develop PCK through formal and informal collaborative experiences and (b) how RTMTs are supported in developing their PCK. We use a collective case study with an embedded multiple case design (Yin, 2017) to investigate RTMTs professional experiences and the development of their PCK. Participating RTMTs serve as embedded units within each of the cases, the partner schools. Data were collected from RTMTs through questionnaires as well as individual and group interviews. We used descriptive and provisional coding methods for the first cycle of data analysis (Saldaña, 2016).

Summary of Findings

Preliminary findings suggest that RTMTs' develop their PCK through frequent and informal collaboration with their school-based colleagues resulting in a replication of pedagogical practices (Pryor et al., 2012). RTMTs are participating in formal collaborative conversations in bi-annual panel discussions composed of RTMTs in the district in order to overcome challenges in their mathematics classrooms. While national trends in Tanzania's teacher credential levels reveal that RTMTs generally hold "lower-grade" instructional certifications (Komba & Nkumbi, 2008), all of the teachers we interviewed held at least a diploma from a two-year teacher's college, with over half of all interviewed RTMTs holding a bachelor's or master's degree in education. This project highlights openings to work with RTMTs to develop ongoing professional experiences that can continue to improve upon instructional practices and further develop PCK amongst RTMTs.

INVESTIGATING PRESERVICE TEACHERS' CONCEPTUALIZATIONS OF MATHEMATICAL KNOWLEDGE FOR TEACHING THROUGH ANALYSIS OF VIDEO LESSONS

Bima Sapkota
Purdue University
bsapkota@purdue.edu

Keywords: Instructional Activities and Practices, Mathematical Knowledge for Teaching, Teacher Education-Preservice, Video Analysis Activities

It has been suggested that mathematics pre-service teachers (M-PSTs) conceptualize their mathematical knowledge for teaching (MKT) (Ball, Thames, & Phelps, 2008) through various instructional activities, including video-lesson analysis; however, particular dimensions of video analysis activities are underexplored. Previous studies (e.g., Nilsson, 2008; Santagata, Zannoni, & Stigler, 2007) have indicated that discussion and reflection on the video-lessons were major instructional strategies used during the activities. In this study, I adopted a collective case study approach (Stake, 2003; Yin, 2017) to investigate how four M-PSTs, enrolled in a secondary mathematics methods course, conceptualized MKT when they analyzed a video lesson using the MKT framework, and discussed and reflected on the lesson. On the first and third days of the activities, the participants watched a video lesson from an eighth-grade classroom and offered their written reflections/analyses on the lesson. They analyzed their Day 1 reflection papers using the MKT framework on Day 2. After each day's written reflections/analyses, the participants discussed teacher and student actions from the video that seemed productive/unproductive for mathematics teaching and learning. In addition, the participants evaluated those actions using the MKT framework during the Day 2 and Day 3 discussions. Data analysis involved bottom-up and top-down interactive modes of analysis (Chi, 1997), which included identifying codes using descriptive and simultaneous coding methods (Saldaña, 2016), categorizing the codes using the MKT framework, and identifying themes.

The findings suggested that, in their initial (i.e., Day 1 and Day 2) analyses of the video lesson, the participants considered "content" and "pedagogy" as two separate and distinct bodies of teacher knowledge, resulting in their evaluation of teacher knowledge either as pedagogical or content knowledge. As such, M-PSTs divided classroom events into two categories: "what teachers do" vs "how teachers do." They then evaluated those events as *subject matter knowledge (SMK)* and *pedagogical content knowledge (PCK)* respectively. Furthermore, the participants evaluated SMK in a way that generalized it as *common content knowledge (CCK)*. They seemed to think that teachers' instructional decisions were not explicitly associated with their content knowledge. In their Day 3 analyses, however, the participants distinguished the notion of MKT from generic pedagogy and/or CCK and began to consider how teachers' professional content knowledge influences their instructional decisions. Since the M-PSTs reflected on and discussed the MKT-framework domains between their initial and second analyses, I argue that the changes in the participants' conceptions were due to these discussions and reflections. However, some participants still tended to evaluate SMK as CCK and PCK as general pedagogy after their participation in the discussions. Given the complexity of the framework, the short discussion sessions were not enough to reasonably conceptualize the MKT framework domains. I propose that had the participants engaged in additional discussion and reflection sessions, their understanding of MKT would have been further enhanced.

STEM WAYS OF THINKING

David Slavit	Elizabeth Grace	Kristin Lesseig
Wash. St. U. Vancouver	Wash. St. U. Vancouver	Wash. St. U. Vancouver
dslavit@wsu.edu	elizabeth.grace@wsu.edu	kristin.lesseig@wsu.edu

We explore the epistemological issues that arise when considering STEM as a curricular and instructional construct. Our approach is somewhat unique in that we are not focused on the curricular or instructional boundaries of STEM education, but consider the nature of the cognitive activity at play during STEM-focused activity, with an emphasis on mathematical thinking. We focus specifically on the epistemological underpinnings of mathematics and other STEM disciplines, and the possibility of an epistemology of STEM as a curricular construct. The implications on students' STEM ways of thinking (SWoT) are discussed in detail from a theoretical and empirical lens. Future research directions are identified.

Keywords: Advanced mathematical thinking; Learning theories; Reasoning and proof

Objectives

This paper explores various theoretical perspectives on what we are terming *STEM ways of thinking* (SWoT). We provide an extensive review of the literature on the perspectives taken on this topic, followed by a discussion of our own empirical work in this area. We are not focused on the nature of STEM itself, but on the ways in which students think about STEM in interdisciplinary curricular contexts. We focus specifically on SWoT as **argumentation in STEM contexts (argumentation)** and **thinking about STEM interdisciplinary concepts (explanation).** The roles of epistemology, content, schooling, and cognition are considered.

Theoretical Perspectives

Teachers' facilitation of classroom conversations that both model and provide opportunities for students to use reasoning and conceptual understanding is an ambitious practice receiving significant attention in teacher education (Ball, Sleep, Boerst, & Bass, 2009; Lampert & Graziani, 2009; Franke, Borko, & Whitcomb, 2008) as well as within STEM education policy and standards (CCSSI, 2010; NRC, 2001; NGSS, 2013). Argumentation or explanation, as well as other valued mathematical practices such as perseverance, modeling, and attending to precision (CCSSI 2010), can develop from conceptually-based conversations embedded in problem-solving contexts. In mathematics, problem-solving processes utilize representations (e.g., numbers, polygons, graphs) in support of arguments and explanations, but different representations and processes are often foregrounded in other STEM areas. For example, in science, student arguments usually derive from experimental evidence linked to scientific principles. In engineering, they usually derive from the testing, data analysis, and redesign efforts central to design-based project activities. The claims, evidence, reasoning (CER) framework is a widely-used perspective on scientific thinking related to argumentation (McNeill & Krajcik, 2012) that can be generalized to both mathematics and engineering (Figure 1).

In addition to differences in representations, processes, and expectations for the certainty of evidentiary claims, each STEM discipline also has its own theoretical frameworks for discussing content-specific ways of thinking in relation to the development of conceptual understanding (Wasserman & Rossi, 2015). For example, there are specific ways that children think about fractions, including as part-whole relations, ratios, and numbers (Lamon, 2012). Middle and high school students often initially conceive of functions as an output-producing action before developing a more object-oriented understanding grounded in domain-range correspondences and the properties possessed by function classes, such as lines and parabolas (Sfard, 1991; Slavit, 1997). There are numerous other frameworks in mathematics, science, and engineering that help describe students' ways of thinking about disciplinary concepts.

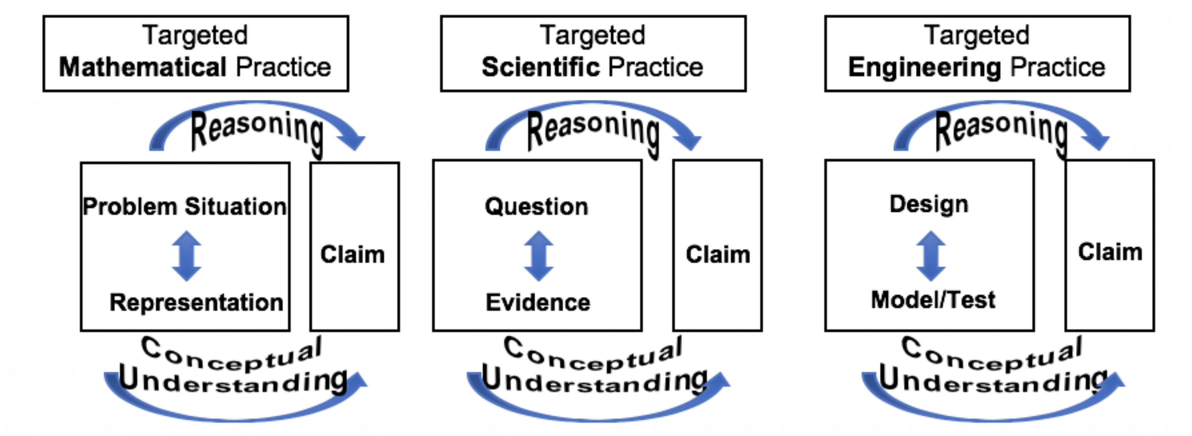

Figure 1: Disciplinary Ways of Thinking; Using Reasoning to Make Claims in Mathematics, Science, and Engineering

We are interested in the theoretical notion of SWoT and its particular relationship to mathematical ways of thinking. This theoretical endeavor has three immediate challenges. First, there are virtually no current frameworks on which to draw. Second, there are differences in the epistemologies of each individual STEM discipline, making the construction of an epistemology of STEM difficult to conceive. Herschbach (2011), one of the few scholars who have addressed this issue, states the following:

> The four STEM fields, in sum, have epistemological characteristics that differ markedly. These characteristics must be fully recognized and accommodated in programming in order to preserve the intellectual integrity of each field. Otherwise a very limited understanding results that undervalues specific intellectual contributions or ignores the collective value of each. (p. 110)

Third, STEM is not a well-defined term, making the construction of a theory related to SWoT problematic. For example, Holmlund, Lesseig, and Slavit (2018) illustrated the variety of perceptions of STEM education held by content teachers, administrators, and policy makers. However, we hypothesize that STEM-focused instruction could support the development of cognitive processes consistent with our view of SWoT, delineated further in this paper. This hypothesis includes the development of the discipline-focused ways of thinking discussed above, including mathematical thinking. However, it might also include a way of thinking specific to STEM when manifested in interdisciplinary contexts.

Our theoretical approach to SWoT consists of two related but different cognitive processes: **argumentation in STEM contexts**, and **thinking about STEM interdisciplinary concepts**. These types of thinking are not independent, but not necessarily interdependent.

Because science, mathematics, and engineering are grounded in their own epistemologies, ontologies, and practices, it is an open question as to whether such cross-disciplinary SWoT can actually exist. Can STEM be a discipline in and of itself with its own ways of thinking? If so, what are the ways of thinking that define it? This paper will explore the theoretical issues related to the above questions. We begin with a discussion of five distinct ways of considering SWoT found in the current literature. These include relationships between SWoT and 1) learning theory, 2) 21st-century skills, 3) disciplinary lenses, 4) curricular foci, and 5) epistemology.

Learning Theories Related to SWoT

Some researchers have explored the notion of SWoT by relating it to specific theories of learning. Asunda (2014) presented a conceptual framework for attaining STEM integration based on principles of pragmatism that drew from four different theoretical underpinnings: systems thinking, situated learning theory, constructivism, and goal orientation theory. Denick and colleagues (2013) emphasized social learning theory and discourse, as SWoT and integrated thinking require understanding concepts from multiple perspectives. Kelley and Knowles (2016) presented a conceptual framework grounded in situated cognition that foregrounded SWoT in the context of engineering design. They suggest that both students and practitioners engage in communities of practice to integrate and develop interdisciplinary thinking, including engagement with mathematicians and other STEM experts. Because of the common use of interdisciplinary, real-world projects in STEM education, it seems natural that the theories of learning most commonly related to SWoT involve discourse and draw from a situated or community of practice perspective.

SWoT as 21st-century Skills Applied in Real-world Contexts

From this perspective, SWoT is more than thinking across the four disciplines of STEM. Instead, primary importance is given to the presence of 21st-century skills, such as inquiry processes, problem-solving, critical thinking, creativity, and innovation (English, 2016). While content-based thinking and knowledge are important, these are secondary in focus to the above-mentioned process skills. Hence, SWoT can bridge disciplinary thinking by deemphasizing content-isolating topics, and emphasizing more general thinking processes. Chalmers et al. (2017) suggest that STEM-encompassing endeavors (or “grand challenges”) promote the exploration and transfer of “big ideas” across disciplines, using these broader ways of thinking. The encompassing big ideas are important problems that can invoke a particular SWoT, which students need to solve these problems. From this perspective, STEM is more than the sum of its parts and fostering 21st-century skills is fundamental.

While also emphasizing the influence of curriculum on SWoT, Chalmers et al. (2017) proposed that students need to be inducted into STEM “habits of mind” that will promote application of STEM ideas. They presented three types of “big ideas” that can facilitate in-depth STEM learning: within-discipline ideas, cross-discipline ideas, and encompassing big ideas. Within-discipline ideas are those primarily found in one STEM discipline that have application in another (e.g., scale, ratio, proportion, energy). Cross-discipline ideas are represented by content or processes found in two or more STEM disciplines (e.g., variables, patterns, models, computational thinking, reasoning and argument, etc.). The final type, encompassing big ideas, can also be manifested by either concepts or content. Chalmers et al. claim that conceptual encompassing big ideas (e.g. representations, conservation, systems, coding, change) create interdisciplinary lenses across the STEM disciplines to be utilized on important, thematically-based problems that relate to global challenges.

SWoT Through a Disciplinary Lens

Some researchers argue a specific content area should be the framework for analyzing STEM thinking. Bennett and Ruchti (2014) suggested using the Standards for Mathematical Practices (SMPs) from the CCSSM to provide links across the four disciplines of STEM. This approach could serve two purposes; the SMPs would make the mathematical connections across STEM contexts clear and more accessible, and it would also help emphasize the role of practices in the development of content knowledge. Bennett and Ruchti mention that other standards (e.g., the NGSS Science and Engineering Practices) could also serve this role, but the mathematical connections would not be as clear and connected in such an approach. While English (2016) highlighted the need for a more balanced integration of STEM subjects, she suggested mathematics should be foregrounded to more explicitly emphasize this discipline.

A focus on other STEM disciplines is also present in the literature. Asunda (2014) suggested that the *Standards for Technological Literacy* provide an approach to integrate STEM, and that Career and Technical Education (CTE) be the platform for STEM integration. Sengupta, Dickes, and Farris (2018) argued that computational thinking serves as a disciplinary entrée into STEM due to its uncertain and complex nature. Many researchers, either implicitly or explicitly, assign engineering as the framework for SWoT, with mathematics and science as supporting roles (English & King, 2015). Denick et al. (2013) suggested that engineering design through model-eliciting activities supports an “integrated thinking” in STEM, specifically in informal environments. Kelley and Knowles’ (2016) conceptual framework, grounded in situated cognition, suggests that engineering is the context in which all four STEM disciplines can exist on an equal platform, and thus where STEM thinking best takes place. While focused on “learning by design,” Purzer et al. (2015) considered SWoT as “making knowledge-based decisions” using a combination of scientific inquiry and engineering design. They highlighted the similarities between engineering design and scientific inquiry that support this framework, including an emphasis on reasoning and the role of uncertainty as a starting point for SWoT.

SWoT as a Product of a Curricular Focus

Some researchers claim that interdisciplinary student thinking in STEM is dependent on how the teacher frames the STEM task, and the type of integration emphasized by the curriculum. There are several examples of this in the literature. In an engineering design context, English and King (2015) found that students were able to identify mathematics and science concepts, particularly in the latter stages of the design process (including redesign), but only 1/3 of the students did so, and after the teacher intervened and explicitly highlighted this content. Kelley and Knowles (2016) argued that students might not naturally know how to integrate content and thinking across disciplines. Like English and King, this suggests that SWoT are not natural cognitive processes for students, or perhaps the complexities of SWoT do not lend themselves to easy development. Mathematics can be more difficult to integrate than other STEM disciplines, as there is evidence that effect sizes of STEM integration on student achievement are lower when M is integrated than other integrated curricular models (e.g., S-T and E-S-T) (Becker and Park, 2011) Kelley and Knowles claim that students have difficulty knowing which ideas are relevant across disciplines when engaged in interdisciplinary content. For example, students need support to elicit relevant science and mathematics ideas in an engineering design task and to reorganize their thinking to be interdisciplinary, rather than a composite of different kinds of content-based thinking. However, current instructional norms do not always lend themselves to this way of thinking. Chalmers et al. (2017) applied their disciplinary framework, discussed above, to discuss how to introduce topics and develop contexts for SWoT. They suggest a sequence that begins with a *worthwhile task*, then an exploration of *big ideas*, followed by *a synthesizing activity* to provide closure and attempt to make the big ideas explicit knowledge objects of thought through reflection on and refinement of the students' understandings and SWoT.

Purzer et. al (2015) found that while engaging in design work, the focus of two students' thinking was primarily on engineering processes. However, near the end of the project, when the students were asked to examine the different affordances and constraints of their designs, the students began to engage in scientific inquiry, particularly when working within the explicit constraints of the problem. This suggests that the intentional introduction of specific constraints in an engineering design task could elicit more integration of science content knowledge and inquiry, which aligns with the claim of English and King (2015) that interdisciplinary thinking tends to take place in the latter stages of engineering design. The lack of presence of mathematical thinking is notable, and English (2016) called for more research on whether sequenced and structured mathematics instruction hinders in-depth STEM learning. It seems that mathematics is not normally perceived as the central content focus of STEM, and that mathematical thinking can be difficult to include in SWoT or need explicit scaffolding. This somewhat nebulous role of mathematics in the above findings surfaces several questions about the role of mathematics in SWoT. For example, what are the implications of Bennett and Ruchti's (2014) recommendations to make mathematics the overarching framework of STEM? Does the above evidence support the need to foreground mathematics when designing curriculum, or does it discourage educators from including mathematics in integration?

SWoT Through an Epistemological Lens

There are very few treatments of STEM in the context of its underlying epistemology that exist in the current literature base. Sengupta et al. (2018) argue that an "epistemology of computational thinking" can foreground the uncertainty and complexity that should exist in STEM classrooms. Their discussion of epistemology highlights the role of abstraction and representation in thinking, as well as the contexts that ground this thinking in use. They suggest that computational thinking can bring in other disciplinary ways of thinking and highlight modeling as a key potential tool for integration. Herschbach (2011) developed an "organization of knowledge" framework to argue for the incompatibility of epistemologies across the STEM content areas, and the resulting challenge this yields for STEM education. Treating STEM as a curricular concept best represented through activities, he distinguishes formal and applied knowledge, constructs he claims are inherent in STEM, to further argue for the difficulty in a coherent STEM epistemology.

Limitations of the Current Literature

While useful in a variety of theoretical and practical ways, the above theoretical perspectives and empirical findings have collective limitations. Perhaps most notably, not much research exists on STEM ways of thinking, with only a few researchers broaching the role of epistemology. Variations in defining STEM education can also create differences in STEM education models, and subsequent differences in conceptualizations of SWoT. This can lead to a variety of methodological issues related to how SWoT might be measured, and a lack of consistency across studies. The many different models for how STEM content should be integrated, or which content should be foregrounded, makes analyses of SWoT not applicable to all STEM scenarios. Current methods also have limitations; for example, English and King (2015) used annotations in students' notebooks and verbal explanations in their empirical analysis, but these might not accurately represent the students' actual SWoT. The existing research also tends to report small samples and effects (e.g., English and King, 2015; Becker and Park, 2011), and more research is needed on students from diverse groups (Purzer et al., 2015).

Many of the existing empirical studies target the effectiveness of STEM in increasing student learning outcomes, but do not address student thinking. Becker and Park (2011), in a meta-analysis of 28 studies that related the impact of STEM education on student achievement, found no study that explicitly highlighted student thinking. English (2016) has argued the need to better highlight connections among STEM disciplines, and make them more transparent to both teachers and students. Finally, we note that our literature search did not reveal interdisciplinary ways of thinking as a model of SWoT, with perhaps the best approximation found in the set of studies related to SWoT as 21st-century skills in interdisciplinary contexts. Thus, we see a distinct theoretical need for such a perspective.

Modes of Inquiry

Our basic research question is: What SWoT are evident in student activity and discourse during classroom activities involving STEM content and practices, and what role does mathematical thinking play in these cognitive processes? Our analysis is exploratory and qualitative in nature. Our primary data source is 69 videotaped segments of second grade (24), middle (35), and high school (10) classrooms during interdisciplinary, project-based instruction. The videos ranged from a few minutes to over one hour, with the majority lasting approximately 15 minutes. Our sampling was opportunistic, as we leveraged our relationships with local schools and teachers doing project-based instruction. Most episodes were of design-based engineering activity and included examples of interdisciplinary thinking grounded in argumentation. Our observations targeted the nature of the SWoT enacted by students during student-student interactions, although instructional segments and whole-group discussion were also included in the longer videotaped segments.

Two researchers (the first two authors) individually coded all videotaped segments, and met regularly to discuss coding decisions and results. Due to the exploratory nature of the analysis, open coding (Merriam & Grenier, 2019) was used. Three levels of analysis were progressively initiated, with codes based partly on the five ways of describing SWoT discussed above. First, we conducted a “meta” analysis to identify and describe the target content and the nature of collaboration that was occurring amongst the students. For example, a video segment might be coded as a design-based project that highlighted mathematical functions, with brief lecture followed by student group investigation. Codes related to the nature of the SWoT were then added, which were later refined through the use of analytic memos to include specific attention to the epistemological stances taken by the students, particularly when using reasoning to make claims (see Figure 1). Finally, codes related to interdisciplinary thinking were constructed to more fully articulate the SWoT being observed. For example, students who used geometric ideas and explanations to make a claim about the design of a lunchbox, and perhaps how this might help keep items inside cool, were noted as interdisciplinary across S-E-M. Students who modeled a buoyancy situation with a quadratic function to find its maximum were noted as superficially interdisciplinary, with an emphasis on mathematical skills.

Results

Although the observed content revolved mostly around engineering ideas, the instructional context shifted this focus on several occasions. For example, an exploration of water flow by a group of middle school students shifted from engineering principles to mathematical formulas related to force when the teacher inserted this focus into the discussion. A noted shift in the epistemological stance taken by the students was revealed in this episode, and the nature of claims and reasoning shifted from conceptual-based claims on aspects of force in a boating context to procedural-based claims related to force using abstract, mathematical formulas.

Our collective observations suggest that integration in the realm of SWoT consists of shifting disciplinary practices across STEM contexts. Student thinking that explored real-world problems and drew on 21st-century skills possessed such fluidity, but when the disciplinary content and practices became more explicit (we refer to this as being “hardened”), the different tools, practices, representations, and epistemologies within the STEM disciplines provided barriers for interdisciplinary thought. When the interdisciplinary ideas that were the subject of SWoT were not hardened, the individual epistemologies mattered less.

Several student groups were seen exploring STEM content that was accessible and perceived as “fun,” with a focus on successful task accomplishment. This led to a variety of ways of thinking about the STEM activity. Other times, the presence of a specific content objective, such as solving algebraic equations, grounded thinking and limited the nature of SWoT present. For example, a group of second-grade students exhibited interdisciplinary thinking when designing a lunch container with a cold bottle attached to the top. The SWoT observed in this action had aspects of mathematics (solids and volume, area and measurement), science (heat flow, energy transfer), and engineering design. But the S, E, and M emerged very informally, and the epistemologies of each discipline were not in conflict. We assert that the notion of SWoT is highly dependent on the nature of each discipline, the nature and intent of the activity, the instructional oversight, and the (internal and external) epistemological forces that drive student thought. We hypothesize that the existence of shifting practices across the STEM disciplines allows for more fluid SWoT. It also appeared that shifting practices occurred more frequently during exploratory phases of STEM activity, and less frequently when seeking solutions, as occurred in the case above when a mathematical formula was inserted into the SWoT.

Discussion

STEM as a curricular construct is usually considered through a disciplinary lens (single or interdisciplinary), or as a forum for the application of 21st-century skills in real-world problem contexts (Holmlund et al., 2018). STEM education consistently balances student curiosity and subsequent “natural” ideas with the need to explore predetermined academic content, a situation complicated by the competing epistemologies of the STEM disciplines. From a cognitive perspective, claims and reasoning tend to drive the activity (Figure 1), but the practices and ways of thinking often shift depending on the content and nature of the activity. Mathematical problem solving might be bypassed because of the curricular or instructional focus, or because of the current epistemology at play during student exploration. Prior research, such as English and King (2015), suggests that teacher scaffolding of mathematics content through the design process can allow for a more integrated way of thinking that aims to balance the representation of all STEM subjects. Specifically, students should be given sufficient time to complete the engineering design process so that the latter stages can be highlighted. One possible implication of this work is that students do not have natural SWoT, but rather that SWoT need to be facilitated in explicit ways. We claim the place of any content-specific cognitive activity, including mathematical thinking, is ill-defined in many STEM education contexts, and needs explicit nurturing.

Our observations suggest that when content becomes hardened, epistemological stances change and interdisciplinary thought becomes more difficult. We do not claim that there is a universal epistemology around STEM, or that the individual STEM disciplines are either universally compatible or incompatible. Our observations suggest that the nature of certain STEM activity, particularly that which does not involve hardened content and facilitates shifting practices across STEM disciplines, lends itself to more conceptual and fluid interdisciplinary thought, as epistemological barriers matter less.

This paper yields more questions than answers. When exploring STEM contexts, do students shift between disciplines, or think about them collectively? What is the implication of siloed content-based instruction, or interdisciplinary STEM instruction, on SWoT and/or mathematical thinking? What curricular and instructional adjustments might be necessary to promote SWoT or mathematical thinking in STEM contexts? Our limited observations indicate curriculum and instruction that limits the hardening of content can facilitate interdisciplinary SWoT. More research is needed to identify the nature, and even presence, of a SWoT and its relationship to mathematical thinking. Further delineation of SWoT can aid researchers' and mathematics educators' efforts to engage students in conceptually-based argumentation and explanation.

MEASUREMENT AND DECOMPOSITION: MAKING SENSE OF THE AREA OF A CIRCLE

Dana C. Cox
Miami University
Dana.Cox@MiamiOH.edu

Jane-Jane Lo
Western Michigan University
Jane-Jane.Lo@wmich.edu

As a component of a course on geometry for preservice elementary teachers (PSTs), we derive area formulas for a variety of polygons including triangles, quadrilaterals, and both regular and irregular shapes whose areas can be measured empirically using decomposition. Decomposing a circle to justify why its area can be measured using the standard formula is more challenging as it requires both empirical and deductive reasoning involving limits. In spite of the challenge, we expected decomposition strategies to transcend work with polygons and support PSTs when thinking about the area of circles. Results show that few PSTs utilized decomposition and instead focused on finding meaning in the symbolism of the formula. Concept images related to area will be discussed.

Keywords: Geometry and Geometrical and Spatial Thinking; Mathematical Knowledge for Teaching; Teacher Education-Preservice; Reasoning and Proof

Background

As a component of a course on geometry for preservice elementary teachers (PSTs), we derive area formulas for a variety of polygons including triangles, quadrilaterals, and both regular and irregular shapes. Generalized formulas for finding the area of these types of shapes can be justified using the actions of composition and decomposition. For example, one way to derive a general formula for the area of a trapezoid is to decompose it into two triangles (with altitude equal to that of the original trapezoid and each taking one of the parallel sides as a base) and then summing the two areas.

Being able to give an informal derivation between the circumference and the area of a circle is a common middle-grades standard (CCSSO, 2010), yet the curved boundary lends challenge to students used to working with polygons. There are multiple justifications possible. Tent (2001) describes one method of figuring out the area of a circle through the action of composition and decomposition that were commonly used in the sixteenth and seventeenth centuries. A circle with radius, *r* is sliced into sectors, which are then rearranged to approximate a parallelogram with height equal to the radius and width equal to half of the original circumference. When the sectors are sliced infinitely thin, the parallelogram becomes a rectangle. The area of which, we deduce, can be measured as πr^2 *(See Fig. 1).*

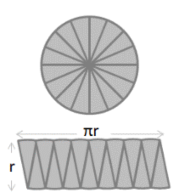

Figure 1: Decomposing a Circle to Reason About Its Area

We want to better understand how PSTs might transfer strategies for conceptualizing area in the context of polygons to the circle. At the end of our instructional unit on area of polygons, and before any instruction on circles, we gave a pre-assessment where we asked 69 PSTs to justify the standard formula for the area of a circle. Through the analysis of this set of written work, we sought to gain a better understanding of the claims and supports PSTs utilized when justifying why the standard formula for area of a circle, Area = $\pi(radius)^2$. This study sought to answer the question: how can we characterize PST's justifications of the general formula for finding the area of a circle?

Theoretical Perspective

Mathematics education research community knows very little about students' (PSTs included) conceptions of the area formula of the circle beyond memorizing and applying the formula to simple routine problems. In a recent review of research on the teaching and learning of measure (Smith and Barrett, 2017), discussion focused on area in the context of rectangular regions alone. Other than the general notion that area is an attribute that measures the amount of space inside the boundary of a 2-D shape and can be quantified by counting the number of area units, research studies focusing on rectangular regions or polygons provide limited insights into the challenges students face when trying to make sense of the area formula of the circle.

First of all, the boundary of a circle is curved instead of straight which makes the idea of tiling the space inside with square units seem impossible. Second, a justification of why the area can be measured using the standard formula, Area=$\pi(radius)^2$, requires an infinite number of subdivisions. The challenge emerges in our inability to physically decompose the shape (using common tools such as grid paper or scissors) into an infinite number of subshapes that can be used to quantify the amount of surface inside a circle. To do so conceptually requires a good understanding of the concept of limit through approximation metaphor (Oehrtman, 2004). Lastly, researchers have found that the idea of a non-repeating, non-ending number is very challenging for both preservice teachers and students (Fischbein, Jehiam, & Cohen, 1995; Güven, Çekmez & Karataş, 2011). So the presence of π in the area formula can pose an additional challenge for sense-making.

In addition to this analysis of the challenges in making sense of area formula of the circle, the design of this study was guided by prior work on proof and justification. Based on Stylianides's (2007) conception of proof and proving in elementary school, we take justification to mean a viable argument that supports a new claim with previously established definitions and facts as well as a connected sequence of assertions backed by by sound reasoning. We had worked with our PSTs' previously on justifying area formulas for various special polygons and we expected that some of them might even use diagrams to augment their argument.

Theoretical Framework

Harel and Sowder's (1998) proof schema were initially helpful in framing categories for the written responses. Specifically, we used *externally-based*, *empirical* and *analytical* proof schemes to organize the data. A written response is classified as an externally-based proof scheme when either 1) the argument is based on a textbook or other authoritative figure (authoritarian proof scheme), or 2) manipulation of symbols without meaning (symbolic proof scheme). The empirical proof scheme consists of arguments based on 1) multiple numerical examples (inductive proof scheme) or 2) rudimentary mental images (perceptual proof scheme), that is, 'images that consist of perceptions and a coordination of perceptions but lack the ability to transform or to anticipate the results of a transformation," (Harel & Sowder, 1998, p. 255). When an argument is based on logical deduction, it is said to use an analytical scheme.

Methods

Setting and Participants

This study was conducted in a Midwestern university. All participants (n=69) were enrolled in one of two sections of a course on geometry for preservice elementary teachers taught by the first author. The data used in this study were collected at the end of a unit on measurement in which significant work had been done toward a deep understanding of linear and area measurement. This work included activity related to the meaning of perimeter and area in the context of simple and composed polygons. Participants in this study had previously been asked to justify the area formulas for a variety of polygons including triangles, rectangles, parallelograms, and trapezoids using decomposition as a technique with tools such as dot and grid paper, tracing paper, and geoboards. At the time of data collection, participants had not engaged in course activity involving circles, including the measurements of radii, diameters, or circumferences nor the ratio of π.

Data Collection and Analysis

Students were asked to justify individually why the area of a circle could be found using the formula $Area = \pi r^2$. This formula was explicitly given, though accompanied by no additional guidelines or specifics. PSTs had been asked to justify or derive formulas for other shapes prior to this work, though they had not had any instruction regarding circles or the meaning of π. Their work was done by hand on blank white paper.

We used the proof schemes by Harel and Sowder (1998) to sort all written justifications into three piles: those used external authority based, empirical based and analytical based proof schemes. While some data fit clearly within the framework, we did not find it was useful in all cases. We needed the flexibility to group responses that lacked the coherence of an intentionally written proof or who blended schema from across the framework; also, the writing was informal and spontaneously generated. We then turned to grounded theory (Corbin & Strauss, 1990) to categorize responses in order to bring out themes that had been visible to us, but were not emerging through the framework. Specifically, we wanted to understand how PSTs were using what they had been learning about area and decomposition to justify the area of a circle.

Our process of categorization was to first read through a subset of the data to look for similarities and differences. Once an original set of categories were identified, we used an iterative process of reading through the data and refining the categories. In all cases, the entire response was used to garner meaning. In other words, we used the figures that were drawn as a means to interpret what was written and vice versa. Through this process, it became apparent to us that the drawn figures were being used as tools for different purposes and we will speak more to that in the discussion. When a response seemed to span two categories, we refined the categories when possible. However, when the category did not warrant subdivision, we placed each response according to the most sophisticated reasoning provided. For example, if a PST used a worked example, but also provided a justification for decomposing the circle into sectors, we chose to place it within the decomposition category.

Findings

We present five different categories of responses, grounded in the work of Harel and Sowder (1998). Second, we look across our categories to identify key conceptual challenges indicated by the responses. Reasoning about π and conflicting area concept images are visible within attempts at justification.

Characterizing PSTs' Written Justifications

Non-justification. We begin by noting that about 27.5% (n=19) of PSTs in this study made no attempt at justification. In a few cases PSTs defined *r* as the radius of a circle or noted that π was a number, but were not able to make use of that information relative to the formula. In other cases, PSTs simply wrote explicitly that they did not know or provided a description of a circle (i.e. infinite or round) that was not related to the formula, such as Malana, who wrote, *"the circle is shaped like a pie, so the formula works!"* These responses did not supply a viable argument to support new claim based on these definitions, so we did not categorize them as a justification (Stylianides, 2007).

Externally-based and empirical schema. We found 7 cases that fit the proof scheme framework by Harel & Sowder (1988). Six of them possessed the characteristics of an externally-based proof scheme by invoking authorities such as "mathematicians who discovered it" or simply reciting the formula from memory: "*multiply radius x itself and then multiply by π*". The remaining student submitted a true "proof by example" within the induction scheme.

The framework proved limited in analyzing the remaining 43 responses. While the majority of them (n=30) were motivated by a study of symbolism, there were clear attempts to go beyond and give meaning to those symbols. So, they did not quite fit under the big umbrella of externally-based schema. We created a new category for these which we called "Dimensional Analysis" (DA). This helped us capture one way PSTs attempted to give meaning to the area formula of a circle. The remaining 13 responses were classified either as Approximation Strategies or Decomposition Strategies. We will go on to describe each of our new categories illustrated by the responses that fit within them. Table 3 provides an orienting view of the entire data set according to these categories.

Table 1: Justifications by Category

Strategy	**Frequency**
Non-Justification	19
Externally-based	6
Empirical	1
Dimensional Analysis	
Diameter is r^2 *(only)*	10
Circumference (π) times diameter (r^2)	8
Other	12
Approximation	6
Decomposition	
Summation of Linear Measures	2
Summation of Equal-sized Sectors	5
Total	**69**

Dimensional analysis. In our study, 43.5% (n=30) of PSTs justified the area formula through a process of symbolic deconstruction aimed at associating meaning with the symbols and operations within the general formula. In most cases, this meant finding meaning in the isolated terms r, r^2, and π. While r was always defined as the radius of the circle (and often accompanied by a drawn and labeled figure), there was more variation in the ways that PSTs found meaning in r^2 and π.

In 10 cases, PSTs associated the square of the radius with measuring the diameter of the circle and then ended their justification without connecting that meaning back to the area of the circle. Within that group, some justified the squaring action on the basis of the relationship between the radius and the diameter, "*You square it because the radius is half of the diameter*" while others explicitly said that squaring was a doubling action, or indicated that r^2 was equivalent to the measurement of the diameter. Rhoda was the opposite, finding no meaning behind r^2, except to say that "*in order to go around the circle, it takes the r^2 3.14 times.*" Rhoda, like the others, was finding a way to associate the symbolism with measurement.

In 8 more cases, PSTs went one step further to include π in their sense-making, claiming that the formula worked because it multiplied that diameter (r^2) by the circumference (π). While that group of 8 is the largest cluster of similar meaning we could find, there were 12 other PSTs who also created symbolic combinations that focused on identifying measurements, but were either less specific in their meaning or unique in their interpretation. We present three examples of justifications from that category to highlight both the level of specificity and uniqueness of the responses:

> Brandon: "Because radius is half of a circle in order to get the full circle, you must square the radius. You then multiply by π because π is a measurement used in circles,"
>
> Bree: "Squaring the radius will get you the diameter of the circle going up and down and π will get you a measurement of the insides."
>
> Katie: "We do πr to find the distance around the entire circle. Then, you must multiply that number r again to account for all the area from the edge of the circle to the center of the circle."

Seneca, whose response is also included in this category, is the only one in our sample who explicitly mentioned that area was measured in square units, although her attention to those units was limited to a justification of why we square the radius and was diluted by a comparison to finding the area of a rectangle by multiplying length times width "*but just squaring the one length.*"

Approximation strategies. Six PSTs justified the area formula for a circle by comparing it to the area of a square made up by r^2 or $(2r)^2$. Four of them supported their arguments with a diagram of either a square with an inscribed circle or circumscribed square (Figure 2 shows both). The analysis of their diagrams indicated the struggle they had with the relationship between the square they had imagined and its relationship to the radius. This tension can be seen in Heather's written below (Figure 2).

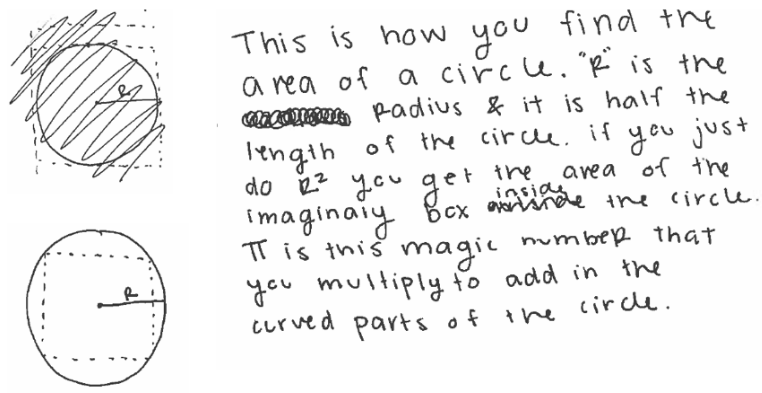

Figure 2: A PST's Attempted to Approximate the Area of a Circle with a Square

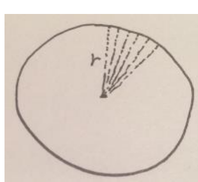
Five of these PSTs, including Heather, used π to justify the difference between the area of the circumscribed square and the area of the circle. Only one PST was able to successfully label the square with the circle inscribed (similar to the one crossed out by Heather) as $(2r)^2$, and acknowledged that the true area of the circle lied in-between those two approximations.

Decomposing strategies. Seven PSTs tried to make sense of the area formula for a circle by decomposing the circle in some fashion. Two of them imagined sweeping the region inside of the circle with a line segment (either *r* or *2r*) through *π*. For example, Chase wrote "*The radius is half the diameter of the circle, so you have to square the radius or r.*" (Note: On Hir paper, ze drew a diagram to support this). Ze went on to write, "*A circle is a symmetrical shape that is never ending. You multiply it by π to incorporate all of the degrees and angles of the circle."* At first glance, this justification seemed to have some validity, but further examination reveals a common misconception that area can be found by summing linear instead of area measures.

Another 5 PSTs decomposed the circle into equal-sized sectors. They made different associations between the decomposed shape and the formula as our class had done with polygons. Four struggled, but based reasoning on the belief that area was calculated by multiplying two length measures. For example, two PSTs (including a student named Audrey) made a distinction between the multiplied radii: they thought of one *r* as the length of the radius and the other as the number of sections, describing π as "*each of the sections in between the radii*", in another words, the arclength of the pie shape.

Only one PST's written justification (Figure 3) showed some glimpse of the idea of finding the area of circle through the concept of limit. The drawings and the accompanying explanation, though too brief to be classified as having an analytical proof scheme, showed evidence of finding the area of the circle by first decomposing a circle into many tiny sections and then summing the area of these tiny sections, which would resemble triangles.



I will cut a circle into a lot of pieces of triangles and get the area of one triangle and then add them together.

Figure 3: One PST's Decomposition Strategy to Justify the Area Formula of the Circle.

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

Discussion

This data was collected after instruction on justifying the area formulas for polygons, but prior to any instruction related to circles or π. As such, we should assume that these justifications are just quick snapshots or rough drafts and that PSTs ability to reason about the general formula and area in general would evolve and change with exposure to these concepts in class, or if this assignment had first been given to small groups to discuss.

While it was useful to utilize proof-based framework to categorize some responses, there were a number of responses that existed somewhere in between empirical and analytic schema. Those that we categorized into the new Dimensional Analysis schema were applying more analytic reasoning than empirical, though the resulting justification sought more to find meaning in this particular arrangement of symbols than in measurement concepts or imagery. In each of these 30 justifications, PSTs are searching among the symbols for cues as to which two dimensions would yield a 2-dimensional measurement. Becca sums it up when she says, *"This works because the radius squared is similar to bxh which is area of a parallelogram."*

Those we categorized within an approximating schema utilize empirical methods that are more solidly grounded by measurement concepts. However, as their arguments include some generality, they cannot be categorized under the empirical umbrella. Lastly, those that we categorized within the decomposition schema represent what we think of as pre-analytic arguments. While it can be useful to create sectors within the circle, finding the areas of individual sectors for the final sum creates a circular argument as these areas are often expressed as fractions of the whole circle. In order to make full use of the individual sectors, it's easier to rearrange them to form a new whole.

Conceptual Challenges

In the remaining space, we will identify two more conceptual challenges that were apparent when looking across the data. We will talk about concept imagery and the contradictions that created struggle. Then we explore in some depth the role π might have played in that struggle.

Concept imagery. While we did not expect PSTs to be able to fully carry out similar arguments, we were surprised to see only 7 of them even made an attempt to use the decompose/compose strategies they had learned when trying to justifying the area formula for polygons. Given that all of the participants had learned geometry in classrooms supported by the CCSS for mathematics, certainly they had previous knowledge of the geometry of circles. However, the curved boundary appeared to be a challenge for the PSTs in this study. Furthermore, only 3 PSTs acknowledged that the area of the circle could be calculated by summing up the area of an infinite number of smaller pieces in a way similar to the one by Chase discussed above. Looking across our data, we can see evidence of conflicting area concept images. In Seneca, we see her association with square units acting in contradiction to her reasoning about the curved boundary. She, like almost half of her colleagues, struggled to assimilate the formula with their image of area as the product of two one-dimensional measurements. We will share more of this in our presentation.

Meaning of π. Our analysis of PSTs' uses of π in their written justification also indicated their limited conception of this number. Just over half of our PSTs mentioned π in their written justifications. Of those that did mention it, some simply referred to it as a number attributed with important, yet indescribable power; "*an important ingredient of a circle*" or as Pat said, "*π is this magic number that you multiply to add in the curved parts of the circle.*"

Measurement was another theme in the way PSTs addressed π, whether in terms of length, area, or angle. It was common for PSTs to connect π with a measure of circumference. For example, Lynn wrote, "*π is the standard circumference of a circle with a radius of 1 unit*." Often PSTs who had this conception of π drew a diagram (like the one in Figure 4) to support their justification. Rose considered it an area measure when she said, "*π gives you area because the number is exactly how many times that radius can fit in the circle."* Just five PSTs thought of π as a ratio, either as a ratio between the circumference and radius or the circumference and diameter.

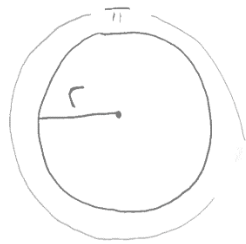


Figure 4: A PST's Diagram to Illustrate the Meaning of π and Radius

Implications

The fact that decomposition/recomposition did not factor more heavily into PSTs responses indicates that it is not enough to exclusively explore area concepts in the context of polygons. While concept imagery related to area such as *covering, iteration* and *decomposition* might be well-developed in the context of polygons, it seems necessary to carry over conceptual development to figures with curved boundaries including measuring circles with square units.

The variation that we saw in PSTs struggle to carve out dimensional measure from within the formula is of heightened interest to us. Jumping to an application-based instructional model (one that emphasizes plugging in values for π and r) earlier in their education might have increased our PSTs willingness to analyze each symbol separately and to overlook a more cohesive or conceptual justification based on existing images. It was clear that most were not cognizant of the relationship between circumference and area formulas, even if they might have recalled them on a different type of assessment. Moving away from plug-and-chug instruction and practice would better serve students of all ages.

There are some interesting concept images present in some of the approximation and decomposition justifications that might point to ways to extend the study of circles. First, approximating the area of the sectors using the radius and arc length might be an interesting activity. Second, using this context to make a connection to exponents and algebra might be a way to help students return to this concept to make additional sense outside the scope of an algebra lesson. At the very least, making the difference between doubling and squaring explicit in this context would raise awareness among PSTs about language and mathematical precision. Last, we were really compelled by those arguments that are based on accumulation. Specifically, the accumulation of length to create a measure of area. This reasoning could be developed further, specifically related to defining angle as a turn (Keiser, 2000) or as an early representation of radian measure.

One activity that models the sector strategy (Tent, 2001) is to have students use scissors to physically decompose and recompose the shape. However, Or (2012) suggests that a digital applet that uses sliders to guide the process (and incorporates far more precision) might help students bridge the epistemic gap between approximation and an exact value.

Setting Up Future Study

While the written justifications were the target for analysis in this study, we suspect that the nature of and ways in which PSTs use images or drawn figures will change after exposure to the types of activities mentioned in the previous section and that this would be an interesting line of inquiry for future studies.

A second area for future work will be to revisit and expand the proof schema to make room for the types of reasoning shown here. In particular, we think there is work to be done to expand the ways in which we reason about and with symbols. We believe that categorizing the ways in which people enact proof is something that merits more study and validation.

COVARIATIONAL REASONING SUPPORTING PRESERVICE TEACHERS' MATHEMATIZATION OF AN ENERGY BALANCE MODEL FOR GLOBAL WARMING

Dario A. Gonzalez
Center for Mathematical Modeling, Universidad de Chile
dario.gonzalez@fulbrightmail.org

I discuss how three preservice mathematics teachers' (PSTs') covariational reasoning supported the mathematization of a simple energy balance model (EBM) for global warming, and how such mathematization shaped PSTs' understanding of the link CO2 pollution and global warming. I use Thompson & Carlson's (2017) levels of covariational reasoning and Thompson, Carlson, Byerley, and Hatfield (2014) descriptions of understanding and meaning to inform the discussion of results. The PST completed the EBM Task during an individual, task-based interview. The analysis revealed that Chunky Continuous Covariation level supports the mathematization of the EBM in terms of a covariation's rapidity of change. The analysis also revealed that particular mathematizations resulted in particular meanings for radiative equilibrium, which in turn have implications for understanding the link between CO2 pollution and global warming.

Keywords: Modeling, Advanced Mathematical Thinking, and Teacher Knowledge

Introduction and Purpose

Global warming refers to an increase in the mean global surface temperature caused by human emissions of greenhouse gases. The planetary scale of this phenomenon makes it difficult for a single person to experience it in its entirety. Mathematical modeling can make global warming visible for people (Barwell & Suurtamm, 2011; Barwell, 2013a, 2013b; Gonzalez, 2016, 2018; Mackenzie, 2007), thus helping them understand it and take action against this new horizon. I consider preservice mathematics teachers an important group to be informed about global warming because they will educate the members and future leaders of this democratic society. Thus, there is a need for studies examining how preservice mathematics teachers can learn the mathematics behind global warming.

Lambert and Bleicher (2013) have found that there are two key concepts from climate sciences that preservice science teachers need to learn about in order to understand global warming: (a) the Earth's energy balance, and (b) the link between carbon dioxide (CO2) pollution and global warming. Extending this premise to mathematics education, preservice mathematics teachers (PSTs) can model global warming by reasoning about these two concepts as dynamic situations involving covariation between quantities. In this paper, I discuss how three PSTs' covariational reasoning supported the mathematization of a simple energy balance model (EBM) for global warming, and how such mathematization shaped PSTs' understanding of the link CO2 pollution and global warming.

Conceptual Framework

Covariational reasoning refers to "the cognitive activities involved in coordinating two varying quantities while attending to the ways in which they change in relation to each other" (Carlson, Jacobs, Coe, Larsen, & Hsu, 2002, p. 354). Thompson and Carlson (2017) have identified six distinctive levels of covariational reasoning (Table 1). Thompson and Carson suggested that "a researcher could use [the levels] to describe a class of behaviors, or she could use it as a characteristic of a person's capacity to reason … covariationally." For the current study, I used Thompson and Carlson's levels as a framework to characterize PSTs' covariational reasoning as they mathematize the EBM. Mathematization refers to the process of translating a real-life, non-mathematical situation into a mathematical problem, and then using mathematical tools and processes to solve it (Freudenthal, 1991).

I also made use of Thompson and colleagues' (Thompson, Carlson, Byerley, & Hatfield, 2014) descriptions of understanding, meaning, and way of thinking, in order to characterize PSTs' understandings of the EBM and meanings for radiative equilibrium. Thompson et al. suggests that a person's understanding is an in-the-moment state of equilibrium resulting from assimilating sensory information to the person's current schemes, or from accommodating those schemes to assimilate the new information. A person's meaning, then, is the space of implications that emerges from the assimilation to or accommodation of the person's current schemes. A person's way of thinking is that person's "pattern of utilizing specific meanings or ways of thinking in reasoning about particular situations" (Thompson et al., 2014, p. 12).

Table 1: Major Levels of Covariational Reasoning

Level	Description
Smooth continuous covariation	The person envisions increases or decreases (hereafter, changes) in one quantity's or variable's value (hereafter, variable) as happening simultaneously with changes in another variable's value, and the person envisions both variables varying smoothly and continuously.
Chunky continuous covariation	The person envisions changes in one variable's value as happening simultaneously with changes in another variable's value, and they envision both variables changing by intervals of a fixed size (not necessarily of the same size). The person imagines, for example, the variable's value varying from 0 to 1, from 1 to 2, from 2 to 3 (and so on), like laying a ruler. Values between 0 and 1, between 1 and 2, between 2 and 3, and so on, "come along" by virtue of each being part of a chunk—like numbers on a ruler—but the person does not envision that the quantity has these values in the same way it has 0, 1, 2, and so on, as values.
Coordination of values	The person coordinates the values of one variable (x) with values of another variable (y) with the anticipation of creating a discrete collection of pairs (x, y).
Gross coordination of values	The person forms a gross image of quantities' values varying together, such as "this quantity increases while that quantity decreases." The person does not envision that individual values of quantities go together. Instead, the person envisions a loose, nonmultiplicative link between the overall changes in two quantities' values.
Preccordination of values	The person envisions two variables' values varying, but asynchronously—one variable changes, then the second variable changes, then the first, and so on. The person does not anticipate creating pairs of values as multiplicative objects.
No coordination	The person has no image of variables varying together. The person focuses on one or another variable's variation with no coordination of values.

Methodology

This paper is part of a larger study that investigated how PSTs make sense of introductory mathematical models for global warming. Three secondary PSTs —hereafter Jodi, Pam, and Kris— enrolled in a mathematics education program at a large Southeastern university participated in the larger study. These PSTs had completed Calculus I and II and an Intro to Higher Mathematics course and were completing a Math Modeling for Teachers course by the time the larger study took place. The PSTs were asked to complete an original sequence of mathematical tasks while participating in individual, task-based interviews (Goldin, 2000). In this paper, I focus on the PSTs' responses to the EBM task.

The Energy Balance Model (EBM) Task

An *energy balance model* (EBM) describes the continuous heat exchange between the sun, the planet's surface, and the atmosphere (Figure 1a). The sun warms up the planet's surface at an approximately constant rate S. As the surface heats up, it radiates heat to the atmosphere (R), the majority of which (B) is absorbed by *greenhouse gases* (GHG). The atmosphere then re-radiates a fraction of the absorbed heat back to the surface (A), further increasing its temperature. The continuous heat exchange between the surface and the atmosphere is known as the *greenhouse effect*, which is responsible for enhancing the *planet's mean surface temperature* T(t). Changes in the greenhouse effect result in changes in T(t). Let $N(t) = [S + A(t)] - R(t)$ be the *net planetary energy imbalance*, then it is said that the energy balance is in radiative equilibrium when $N(t) = 0$, which implies that T(t) remains constant. There are *forcing agents* that can push the energy balance out of radiative equilibrium, resulting in $N(t) \neq 0$. My study focuses on modeling the impact that an increase in the atmospheric CO_2 concentration has over the Earth's energy balance, and how such impact affects the planet's mean surface temperature. CO_2 pollution is one of the main drivers of global warming (Intergovernmental Panel on Climate Change [IPCC], 2013).

The Energy Balance Model (EBM) Task (Figure 1b) describes a simplified scenario with a unique, instantaneous increase in the *Atmospheric CO_2 Concentration Function*, C(t), at time t = 0. This increase results in an initial positive heat imbalance $N(0) = [S + A(0)] - R(0) > 0$. This initial imbalance is known as *positive forcing by CO_2* and is denoted by $F = N(0)$. The positive forcing results in a surface absorbing heat at a higher rate than that at which it is releasing it. Thus, the surface warms up as time passes, which causes it to radiate heat at an increasing rate R(t). The atmosphere then absorbs more heat from the surface, which causes it to radiate heat back to the surface at an increasing rate A(t). This feedback process continues until radiative equilibrium is restored so that $N(t) \to 0$ and $T(t) \to T_{NE}$ as time increases, where T_{NE} represents a new and higher equilibrium temperature.

The EBM Task thus required PSTs to reasoning about the above process and draw the graphs of the functions N(t) and T(t). The EBM Task has two prompts: (a) Determine how N vary over time t (in years) and sketch the graph of N(t) and (b) Determine how T vary over time t (in years) and sketch the graph of T(t).

Data Collection

PSTs watched a 7-minute long video introducing the concept of EBM, followed by a Q&A session with me. I next gave them the EBM task. PSTs were also given a diagram of the EBM showing initial values for S, R, B, and A. They were expected to sketch the graphs of N(t) and T(t) assisted by the recursive rules $B_i = 0.794 \cdot R_i$, $A_i = \frac{1}{2} \cdot B_i$, $R_{i+1} = S + A_i$, and $N_i = [S + A_i] - R_i$ (for *i* = 0, 1, 2, …). The rules were meant to give PSTs a sense of how the heat flows change after a positive forcing. Each PST completed the task in a 60-minute, semi-structured, task-based interview (Goldin, 2000). The interview was video recorded and transcribed for analysis. PSTs' work on paper was also collected for analysis.

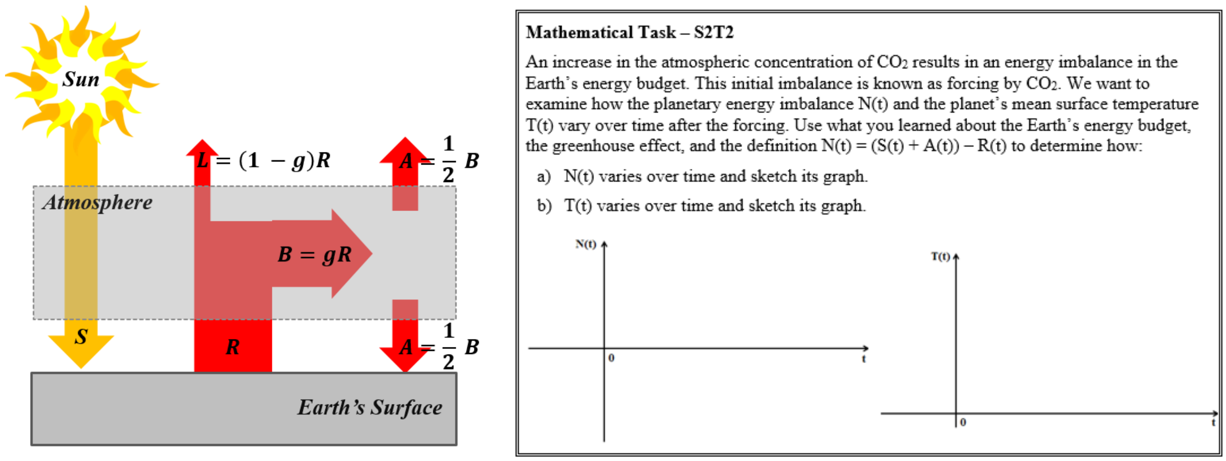

Figure 1: (a) The Earth's Energy Balance (Left) and (b) The EBM Task (Right)

Data Analysis

Videos and transcripts were analyzed through Framework Analysis (FA) method (Ward, Furber, Tierney, & Swallow, 2013). FA has five stages of data analysis: the familiarization with the data, the development of the analytic framework, indexing and pilot charting of the data, summarizing data into the analytic matrix, and the synthetization of the data by mapping and interpreting. Through these stages the research develops an analytic framework and uses it to analyze, reduce, and index data into analytic matrices, FA's distinctive feature.

I watched all interview videos and took notes while doing so. The videos were separated into shorter, more manageable *episodes*. An *episode* showed evidence of PSTs' ways of understanding the EBM or ways of reasoning about covariation. The notes informed my first round of coding. Then, the episodes were sorted according to particular ways of understanding the Earth's energy balance. Looking for patterns in participants' responses, I developed six *energy balance (EB) codes*. I repeated the process with PSTs' ways of envisioning covariation, which resulted in four *covariational reasoning (CR) codes*. These codes represented the *Analytic Framework* for the study.

Using the analytic framework, I indexed all episodes into three analytic matrices, one per participant. I looked for patterns in the distribution of CR codes in relation to EB codes across all three matrices, examining ways in which covariational reasoning supported PSTs' mathematization of the EBM. Then, I compared EB codes across participants in order to identify particular ways of thinking about the EBM. The analysis of such patterns provided the information needed to meet the research goals.

Results

The analysis of PSTs' responses revealed that coordination of values and coordination of change are key to mathematize the EBM for global warming. The analysis also revealed that particular mathematizations resulted in particular meanings for radiative equilibrium.

Covariational Reasoning and Mathematizing the EBM

Coordinating values represented a key step in mathematizing the notion that the energy balance restores radiative equilibrium over time. Coordinating values allowed PSTs to translate radiative equilibrium into a quantity, N(t), that decreases as time increases (direction of change). For instance, Jodi's initial understanding of the EBM did not include an energy balance restoring radiative equilibrium after a positive forcing. For her, the increase in C (atmospheric CO_2 concentration) *pushed* the energy balance out of its *normal* state, and it would remain out of that *normal* state unless C decreased to its original value, which is reflected in the way she described change in N(t) ("[N] wouldn't increase or decrease if CO_2 is kept stable"). Coordinating t-values and N-values using the given recursive rules allowed her to create and plot a collection of pairs (t, N) with which she drew a accurate graph for N(t) (Figure 2a). She interpreted the graph as follows "[the graph means] that we are going back to an equilibrium, or we are not as far from equilibrium as we were." While looking at her graph, she added "each time we are increasing t, we are decreasing N by smaller amounts." Jodi's understanding of the EBM extended to include: (a) the idea of radiative equilibrium being restored over time, and (b) a mathematized representation of such process in terms of a covariation, N(t), that decreases (direction of change) by decreasing amounts of change (rapidity of change) as t increases. Describing rapidity of change of N(t), I would argue, reveals a more sophisticated mathematization of radiative equilibrium than describing direction of change alone; it represents a higher degree of complexity in understanding and describing a covariation.

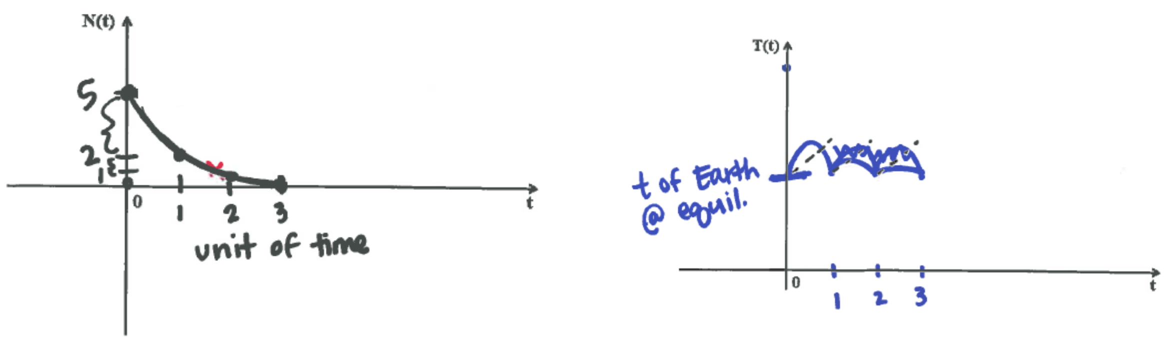

Figure 2: (a) Jodi's Graph of N(t) (Left) and (b) Jodi's Graph of T(t) (Right)

Pam's initial understanding of the EBM included the idea of radiative equilibrium being restored over time; she correctly anticipated N(t) to be a decreasing function of time. Her mathematization of radiative equilibrium, however, was limited to indicating direction of change alone ("[N] was five, and then it would decrease to be zero again") and did not support drawing a graph for N(t). After coordinating t-values and N-values using the given recursive rules, Pam noticed that:

> [N] decreased pretty quickly, like 3 units of J/s/m^2. Then, it decreased by about 1 J/s/m^2 … I am assuming [N] is going to decrease by a little bit, and a little bit, and a little bit, until it reaches zero again.

Coordinating values allowed Pam to think about changes in t in relation to changes in N. This, in turn, helped her draw an accurate graph for N(t) (Figure 3a). Pam's mathematization of radiative equilibrium extended from describing *direction of change* alone ("[N] was 5, and then it would decrease to be zero again") to describing *rapidity of change* ("[N] is going to decrease by a little bit, and a little bit, and a little bit, until it reaches zero again"). Pam reasoned about rapidity of change by coordinating two sequences indicating change in N: the sequence of values of N and the sequence of amounts of change $\Delta_i N$. The coordination of these two sequences allowed her to mathematize radiative equilibrium as a covariation, N(t), that decreases by decreasing amounts of change as t increases.

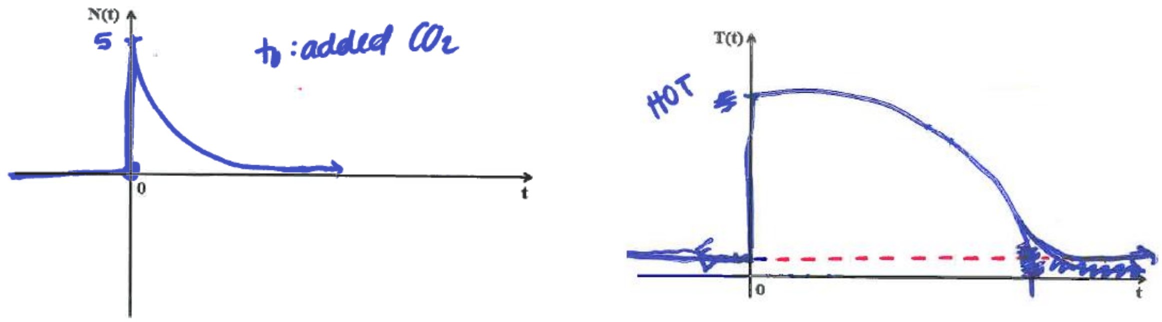

Figure 3. (a) Pam's Graph of N(t) (Left) and (b) Pam's Graph of T(t) (Right)

Kris's initial understanding of the EBM included the idea of radiative equilibrium being restored over time. She, however, struggled to see that idea reflected in the covariation N(t). Since the heat flows R and A were increasing as t increased, Kris thought that N(t) would be increasing too given that $N(t) = [S + A(t)] - R(t)$. She, however, expressed surprise about her conclusion "So, as R increases, A increases [*points at R and A in* $N = (S + A) - R$] … [N] can't just keep increasing!" Coordinating values by using the given recursive rules helped Kris clarify her confusion. She noticed that the heat flow B(t) was increasing by decreasing amounts of change

> Well, this difference right here, between 320 and 328 ($\Delta_1 B = 328 - 320 = 8$), is greater than the difference between these two values, the 328 and 331.5 ($\Delta_2 B = 331.5 - 328 = 3.5$), and the difference between these two ($\Delta_3 B = 332.9 - 331.5 = 1.4$) is less than those [*points at 328 and 331.5*], which is less than that [*points at 320 and 328*]. That tells me that there is eventually going to be a limit … Yeah, it is going to reach a new equilibrium point somewhere

The coordination of values helped Kris reconcile (and mathematize) radiative equilibrium with (and in terms of) the covariation N(t). Her analysis of the rapidity of change of B(t) supported drawing an accurate graph for N(t) (Figure 4a). Like Pam, Kris's extended her mathematization of radiative equilibrium from direction of change to rapidity of change by coordinating two sequences indicating change in B: the sequence of values of B and the sequence of amounts of change $\Delta_i B$. The coordination of these two sequences allowed her to mathematize radiative equilibrium as a covariation, N(t), that decreases by decreasing amounts of change as t increases.

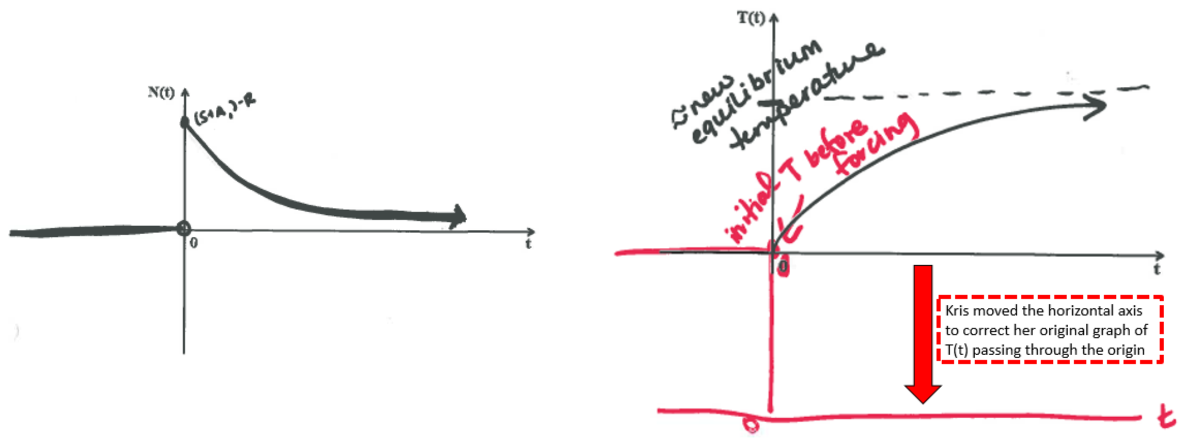

Figure 4. (a) Kris's Graph of N(t) (Left) and (b) Kris's Graph of T(t) (Right)

PSTs use the recursive rules to coordinate values of an independent variable *t* and a dependent variable *y*. Coordination allowed them to mathematize radiative equilibrium in terms of the direction of change of a covariation N(t). Coordination also made sequences of values and graphs available to PSTs. They used such objects to coordinate changes in *t* with changes in *y*. The coordination of changes, in addition to the coordination of values, helped them extend their mathematization of radiative equilibrium from direction of change (N(t) decreases as t increases) to rapidity of change (N(t) decreases by decreasing amounts of change as t increases). The later represents a higher level of complexity in describing covariation.

Mathematization and Understanding Global Warming

PSTs' ways of thinking about their mathematization of EBM resulted in two different meanings for radiative equilibrium: *Single Equilibrium Meaning* (SEM) and *Multiple Equilibrium Meaning* (MEM). The distinctive feature between the two meanings for radiative equilibrium was the PSTs' conception of *what is measured* by N(t) in the EBM.

I asked PSTs to interpret their graphs of N(t) in terms of whether the energy balance was losing heat (cooling down) or gaining heat (warming up) as time increased. Jodi and Pam concluded that the energy balance was losing heat or cooling down as time increased. Jodi stated that "the line (the graph of N(t)) is going in the negative direction, and we know that as N decreases, the surface is losing energy," while Pam stated that "we are losing because if we have gained energy [the surface] would get hotter, but it is not getting hotter because N is smaller so it's cooling off." It seems that Jodi and Pam arrived to such conclusion because they conceived N(t) as a measure of *how much heat* needs to be lost for the energy balance to *return* to radiative equilibrium (e.g., Jodi: "when the input is greater than the output, then we need to decrease N [*writes* $-N$ *on the right side of* $(S + A) = R$] so we can get back to equilibrium"). Jodi and Pam saw N(t) as an amount of excess heat in the energy balance. Therefore, if N(t) is decreasing, then the energy balance must be losing heat. Notice that seeing N(t) as excess heat also involves envisioning the energy balance *returning* to radiative equilibrium. I use the word *returning* to indicate that Jodi and Pam thought of radiative equilibrium as a unique state, the original state before the forcing by CO_2. For her, the energy balance is *returning* to its original equilibrium because the excess heat, caused by the initial forcing by CO_2, is decreasing. I called this meaning of radiative equilibrium Single Equilibrium Meaning (SEM).

SEM led Jodi and Pam to draw graphs of T(t) showing an overall decline in temperature as time increased (Figure 2b and Figure 3b, respectively). The particular shape of Jodi and Pam's graphs for T(t) were rooted in the way they reasoned about graphs and covariation, particularly in terms of the rapidity of change. A discussion of Jodi's case is presented elsewhere (Author, 2018). As for Pam, a discussion of the particular shape of her graph is beyond the scope of this paper. For now, I am drawing attention to the fact that both, Jodi and Pam, drew a graph of T(t) showing an overall decline in temperature. Their graphs indicate that the planet's surface warms up *solely* when C increases. Thus, if C stops changing, then the energy balance returns to its original radiative equilibrium and the planet's surface cools down as time increases.

When I asked Kris to interpret her graph of N(t) in terms of whether the energy balance was losing heat or gaining heat, she concluded that the energy balance was gaining heat.

> Well, [the surface] keeps in taking. I think it is warming up because once we added more CO_2, that is less of the emitted energy that is getting just like shut out passed the atmosphere, leaks from it. So then, more [radiation] is going to be absorbed by the atmosphere … Whatever is absorbed by the atmosphere [*points at B*] is going to be absorbed back into the [*points at the planet's surface*] … which is going to keep increasing.

Kris did not demonstrate any conflict between the energy balance gaining heat and N(t) decreasing as t increased. This suggests that Kris saw N(t) as another representation of heat gain in the EBM. A possible explanation is that Kris conceived N(t) as measuring *how much heat* needed to be gained for the energy balance to reach a *new* radiative equilibrium. When Kris drew the graph of the Planet's Mean Surface Temperature T(t) (Figure 4b), she wanted to show that T(t) was increasing but stabilizing at a certain value. Such graph implied that: (a) the energy balance gains heat to reach radiative equilibrium, and (b) radiative equilibrium is not unique and can occur at higher levels of heat. These are distinctive characteristics of a *Multiple Equilibrium Meaning* (MEM) for radiative equilibrium. This meaning includes attention to the increasing values of R, B, and A, and their implications in the context of the EBM. It also includes understanding the feedback of heat between the atmosphere and the surface: a fraction of the heat released by the surface is reabsorbed by it, enhancing its temperature.

Conclusion

I use Thompson and Carlson's (2017) levels of covariation to characterize PSTs' covariational reasoning. PSTs needed to reason about covariation at the Coordination of Values Level in order to mathematize radiative equilibrium in terms of *direction of change* of the Net Planetary Energy Imbalance N(t). Through coordinating values, PSTs can notice that N(t) decreases as time increases, which indicates that the Earth's energy balance is restoring radiative equilibrium. When PSTs coordinated changes $\Delta_i y$ with equal changes Δx, in addition to coordination of *y*-values with *x*-values, they were able to mathematize radiative equilibrium in terms of the *rapidity of change* of N(t). In other words, PSTs envisioned changes in t and N as occurring simultaneously and by intervals of fixed size. This suggests that covariational reasoning at the Chunky Continuous Level supports the mathematization of radiative equilibrium in terms of rapidity of change.

PSTs' mathematizations of the EBM resulted in two different meanings for radiative equilibrium; these meanings have different implications for understanding the link between CO_2 pollution and global warming. In particular, PSTs' conception of what is measured by N(t) led to two meanings for radiative equilibrium. SEM includes conceiving N(t) as an amount of *excess heat* that must be lost for the energy balance to *return* to radiative equilibrium. SEM also includes understanding radiative equilibrium as a unique state, the original equilibrium. SEM leads to the idea that the planet's surface cools down after a positive forcing by CO_2. This way of thinking about global warming is unproductive because CO_2 pollution has long-term and long-lasting effects on the planets mean surface temperature (IPCC, 2013). SEM may also open the door for misconceptions regarding global warming (e.g., "we can stop global warming at the moment we stop CO_2 emissions" or "as long as we maintain our current level of CO_2 emissions, the planet wouldn't get any hotter"). MEM includes conceiving N(t) as an amount of *heat to be gained* for the energy balance to *reach* radiative equilibrium. MEM also includes understanding that there are radiative equilibriums at higher levels of heat. MEM leads to the idea that the planet's surface warms up after a positive forcing by CO_2, even after the atmospheric CO_2 concentration is stabilized. This way of thinking about the link between CO_2 pollution and global warming is a productive one. It supports an understanding of the real impact of CO_2 emission in the climate, as well as their long-lasting effect in the planet's mean surface temperature.

En este estudio se analizan los acercamientos que muestran estudiantes de bachillerato al resolver problemas verbales aritmético-algebraicos con el uso de un Sistema de Geometría Dinámica (SGD). Se analizan los recursos, representaciones, estrategias y formas de razonamiento matemático que exhiben cuando utilizan GeoGebra durante el proceso de resolución de los problemas. Los resultados muestran que el SGD favorece en los estudiantes diferentes formas de razonamiento y da la posibilidad de transitar de una representación geométrica a una representación algebraica.

Palabras clave: Resolución de Problemas, Álgebra y Pensamiento Algebraico, Tecnología

Introducción

La imagen tradicional que ha caracterizado el estudio del álgebra en el bachillerato enfatiza la manipulación de expresiones algebraicas, la resolución de ecuaciones lineales y cuadráticas, y la modelación algebraica de problemas verbales que contienen variables e incógnitas (Kaput, 2000; Kieran, 2014). Sin embargo, Kieran (2014) considera que el álgebra escolar no debe limitarse a estas actividades, sino también debe incluir procesos que permitan al estudiante tener la capacidad de describir relaciones y resolver problemas que involucren la construcción y uso de relaciones funcionales. En otras palabras, no es suficiente estudiar aspectos simbólicos en la actividad algebraica, sino también resulta importante que los estudiantes construyan formas de razonar asociadas con el pensamiento relacional que subyace en el razonamiento algebraico.

En este sentido, la agenda de investigación en esta área se ha enfocado hacia estudios donde los estudiantes construyan significados o le den sentido a los objetos y procesos algebraicos, de tal manera que se favorezca la comprensión conceptual y la resolución de problemas (Kieran, 2014). Al respecto, la NCTM (2010) hizo una propuesta, que incluye el uso de tecnología, que buscó darle sentido a los procesos algebraicos que llevan a cabo los estudiantes de bachillerato. Además, señaló algunas áreas que presentan retos: expresar generalidad con notación algebraica y con la notación de función, razonar sobre la pendiente, construir y usar funciones algebraicas, plantear ecuaciones apropiadas para resolver problemas verbales.

En un estudio realizado por Gómez-Arciga, Olvera-Martínez, Aguilar-Magallón, y Poveda (2018) con futuros profesores de matemáticas se observó, mediante la interpretación geométrica de problemas verbales con el uso de GeoGebra, cómo la herramienta permitió analizar el comportamiento de los objetos matemáticos involucrados, desarrollar diferentes formas de razonamiento, implementar nuevas estrategias y transitar de la representación geométrica a la algebraica. Se seleccionaron los problemas verbales porque, a pesar de estar incluidos en los planes de estudio desde nivel básico hasta superior, no se ha discutido lo suficiente sobre qué aspectos del razonamiento matemático construyen realmente los estudiantes durante su proceso de aprendizaje al trabajar este tipo de problemas (Verschaffel, Depaepe, & Van Dooren, 2014).

La pregunta de investigación que se planteó para este estudio fue: ¿cómo el uso de un Sistema de Geometría Dinámica (SGD), específicamente GeoGebra, favorece el desarrollo de recursos, estrategias y formas de razonamiento en los estudiantes de bachillerato cuando se enfrentan a resolver problemas verbales aritmético-algebraicos? Se documentan los diferentes acercamientos dinámicos que desarrollaron los estudiantes durante la resolución de problemas verbales y se identifican sus recursos, estrategias y formas de razonamiento.

Marco Conceptual

Álgebra escolar, resolución de problemas verbales y uso de tecnología digital

Uno de los objetivos que se busca en el álgebra escolar es que los estudiantes perciban al álgebra, entre otras cosas, como el estudio de las relaciones entre las cantidades (NCTM, 2010). Por ejemplo, si un estudiante se enfrenta a un problema verbal que involucre una ecuación algebraica del tipo $a = b/x$ en el proceso de su resolución, entonces el análisis puede orientarse hacia la comprensión y análisis de qué sucede con a si el valor de x se acerca a cero o, viceversa, si aumenta.

Las competencias que se han identificado como necesarias para resolver problemas matemáticos, en particular, problemas verbales, involucran: dominio de conocimiento conceptual y procedimental, métodos heurísticos o estrategias cognitivas, estrategias metacognitivas y actitudes positivas ante las tareas que se desarrollan (Schoenfeld, 1985, 1992; Verschaffel, Depaepe, & Van Dooren, 2014).

Las actividades o problemas se desarrollaron alrededor de episodios que incluían las fases de comprensión, exploración del problema, búsqueda de diversas maneras de resolver la tarea, y la visión retrospectiva del proceso de solución y extensión de la tarea (Santos-Trigo & Camacho-Machín, 2013). Los episodios son elementos esenciales de un marco que sustenta y promueve el uso de diversas tecnologías digitales en la resolución de problemas. La principal característica del marco es el uso de un SGD para construir modelos dinámicos de los problemas para explorar y buscar relaciones, así como generar conjeturas que puedan establecer las bases para una posterior búsqueda de los argumentos formales que las respaldan. Otro elemento del marco propuesto por Santos-Trigo y Camacho Machín fue la importancia de plantear preguntas durante todas las fases de resolución de problemas.

Metodología

Este estudio se llevó a cabo con un grupo de 25 estudiantes en un curso de álgebra de primer semestre de nivel bachillerato. Se trabajó durante siete semanas, dos sesiones de dos horas por semana. El desarrollo de las sesiones se realizó en un aula de cómputo donde cada estudiante tuvo acceso a una computadora con el SGD, GeoGebra, instalado. En las primeras cuatro sesiones, con la finalidad de que los estudiantes comenzaran a familiarizarse con GeoGebra, se trabajó en la construcción de una representación geométrica de un problema verbal (Problema 1). Cabe señalar, que dicha tarea fue guiada por el profesor y que el problema que se seleccionó era de nivel básico para darle énfasis al uso de la herramienta. Posteriormente, los estudiantes abordaron diversos problemas verbales aritmético-algebraicos como, por ejemplo, de porcentajes, de velocidades, de trabajo, de edades, que presentaban mayor grado de complejidad en el proceso de comprensión y donde el profesor se limitó a resolver dudas asociadas con la herramienta.

En este reporte se analizan los acercamientos que tuvieron los estudiantes a dos problemas verbales con el uso de GeoGebra. El primero fungió como problema introductorio y permitió sentar las bases para la resolución del segundo problema, el cual se implementó en las últimas sesiones.

Problema 1: Un barco navega a la velocidad de 45 km/h, ¿en cuánto tiempo recorrerá 180 km?

Problema 2: Un estanque se llena por una de dos llaves en 4 horas y la segunda lo llena en 6 horas, ¿cuánto tiempo tardarán en llenar el estanque vacío si se abren ambas llaves al mismo tiempo?

Cada problema se representó geométricamente en el sistema cartesiano para contrastar y analizar cómo se relacionan los conceptos y datos descritos en cada enunciado. Después de la exploración y análisis de cada modelo, se determinó la solución analítica y la respectiva ecuación algebraica.

Los datos se recolectaron a través de los reportes escritos, videograbaciones de las sesiones, archivos de GeoGebra con las construcciones dinámicas que elaboraron los estudiantes y las notas de campo de los investigadores.

Resultados

En esta sección se muestran los modelos geométricos planteados por los estudiantes y se discute sobre los recursos y estrategias que utilizaron. Se exhiben y analizan los resultados del Problema 1 (problema introductorio) y, posteriormente, se discute cómo estos resultados impactaron o influyeron en el desarrollo de un problema con mayor grado de complejidad. En el caso del Problema 1 se divide en dos momentos: el primero contempla la solución con el uso de papel y lápiz y el segundo la exploración hecha con GeoGebra. El primer momento permitió observar los recursos con que contaban los estudiantes, así como las estrategias que utilizaban. En el segundo momento, además de apropiarse de la herramienta, se mostró la forma en la que se puede transformar una actividad rutinaria en una no rutinaria con el uso de un SGD.

Problema 1

Solución con el uso de papel y lápiz

Antes de explorar el problema con el SGD, se les pidió a los estudiantes que resolvieran el Problema 1 con el uso de papel y lápiz con la intención de evaluar la comprensión del enunciado. Se observaron diferentes procedimientos que surgieron de identificar una relación de proporción directa en los datos proporcionados en el problema, en la Figura 1 se muestran los tres acercamientos que surgieron en esta etapa: plantear una regla de tres, construir una tabla y plantear una ecuación, cabe resaltar que todos los estudiantes lograron resolver el problema.

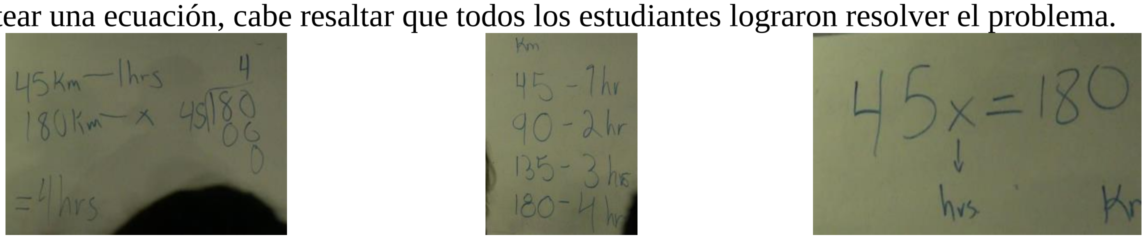

Figura 1: Resultados del problema 1 con el uso de papel y lápiz.

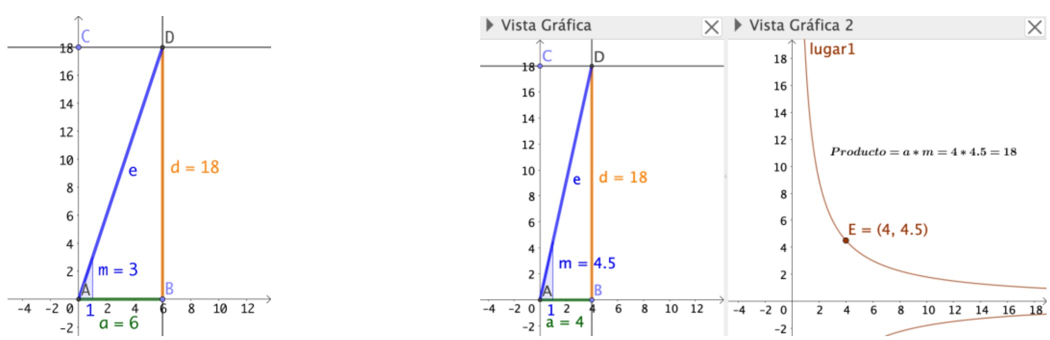
Solución con el uso de GeoGebra

A continuación, se muestra cómo se desarrollan los cuatro episodios propuestos por Santos-Trigo y Camacho-Machín (2013) cuando se incorpora un SGD en la resolución de problemas matemáticos destacando los recursos, estrategias y formas de razonamiento que surgen en este proceso.

Episodio de comprensión. ¿Cómo representar la información descrita en la situación problemática con el uso de un SGD? Buscar formas de representar el problema en un ambiente dinámico implica identificar los conceptos involucrados y asociarlos a objetos geométricos. En este sentido, se utilizó el plano cartesiano no solo para representar el problema geométricamente, sino también para explorar e identificar posibles relaciones entre los datos proporcionados.

La Figura 2a muestra el modelo dinámico que se construyó para explorar el problema. El *eje x* representa tiempo (medido en horas) y el *eje y* la distancia (medida en kilómetros) en escala de 1:10. Así, el *segmento a* representa el tiempo que viaja el barco, el *segmento d* la distancia total que recorrió (la cual se mantiene constante) y la pendiente del *segmento e* la velocidad a la que viaja el barco.

Episodio de exploración. ¿cómo se resuelve el problema utilizando el modelo dinámico? En el modelo es posible explorar la variación de la velocidad del barco en función de la posición del punto *B*, de esta manera, el problema se reduce a encontrar la posición de *B* que haga que la velocidad del barco sea de 45 km/h (Figura 2b). ¿Cómo cambia o varía la velocidad del barco al mover el punto *B*? En la exploración del modelo se puede observar que al mover el punto *B*, la velocidad del barco asociada a la *pendiente m*, cambia (al observar directamente el valor de *m* cuando *B* se mueve). Por lo tanto, tiene sentido investigar la variación de la *pendiente m*. Con la ayuda de GeoGebra se puede generar una representación gráfica de la variación de la pendiente. Es decir, se establece una relación entre el *segmento a* (tiempo del recorrido) y el valor de la *pendiente m* (velocidad del barco). Para explorar esta relación, se define el punto *E* con coordenadas *(longitud del segmento AB, valor de la pendiente correspondiente)*, es decir, *E* = (*a*, *m*) (Figura 2b). El punto *E* describe la relación entre el tiempo y la velocidad del barco y, por lo tanto, su análisis se hizo en una segunda vista gráfica, en un sistema cartesiano donde el eje *x* representa tiempo y el eje *y*, velocidad, ya que, el modelo dinámico del problema y la relación descrita por el punto *E* no pueden coexistir en el mismo plano. Se observa que cuando el punto *B* se mueve sobre el eje *x*, la posición del punto *E* cambia. ¿Cuál es el lugar geométrico descrito por el punto *E* cuando el punto *B* se mueve sobre el eje *x* y cómo se interpreta en el contexto del problema? La Figura 2b muestra que el lugar geométrico descrito por el punto *E* es una curva que indica que, si el tiempo aumenta, la velocidad disminuye o viceversa. Además, se observa que el producto de las coordenadas del punto *E* es constante e igual a 18. Esto permite concluir que la relación que hay entre el tiempo y la velocidad es inversamente proporcional. Pero esta interpretación solo es posible cuando el punto *B* se mueve en el lado positivo del eje *x* debido a las características del contexto del problema. La representación gráfica de la variación de la velocidad se obtiene sin tener de manera explícita un modelo algebraico.



a) En esta configuración se considera un viaje de 6 h con una velocidad de 30 km/h.

b) Modelo dinámico y visualización de la variación de la velocidad.

Figura 2: Representación dinámica de los conceptos involucrados en el problema

Episodio de búsqueda de distintos acercamientos a la solución. ¿cómo proponer una solución geométrica del problema a partir de la exploración del modelo dinámico? En la búsqueda de una solución geométrica del problema resulta importante analizar el lugar geométrico que describe el punto *E* de forma analítica. Es decir, se busca construir el modelo algebraico del lugar geométrico y encontrar su intersección con $y = 4.5$ (Figura 3). La solución del problema en el modelo se obtiene cuando $m = 4.5$. Por esa razón, la solución geométrica se encuentra en la intersección entre la recta $y = 4.5$ y la curva $y = 18/x$ (punto F).

Partiendo del punto $E = (a, m)$ se tiene que: $x= a$ y $y = m$.
Escribiendo a m en términos de a: $y = d/a$
El valor de d es constante e igual a 18, también se sustituye a a por x que es la incógnita del problema: $y = 18/x$
Por lo tanto $y = 18/x$ es el modelo algebraico del lugar geométrico que describe la variación de la velocidad.

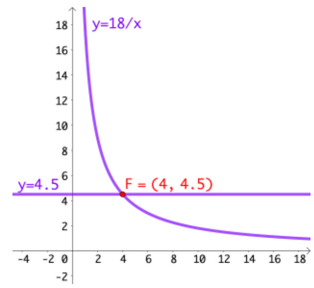


Figura 3: Modelo algebraico del lugar geométrico y solución geométrica del problema

Finalmente, la representación algebraica del problema, es decir, la ecuación que permite resolverlo resulta de igualar las funciones graficadas. Esto es, $4.5 = 18/x$.

Episodio de integración y reflexiones. ¿cuáles fueron las ideas principales en este proceso? Tanto el profesor como los estudiantes discutieron sobre el significado o la interpretación geométrica de los conceptos involucrados en el enunciado del problema. Por ejemplo, algunas preguntas que surgieron de este resultado fueron: ¿qué valores puede tener la pendiente *m* en relación con el segmento *a* y cómo se interpreta eso en el problema?, ¿cuál es el valor de *m* cuando la longitud del segmento *a* se reduce a 0 y cuando la longitud de *a* tiende a infinito?, ¿en dónde debe estar situado el punto B para que el modelo tenga sentido según el contexto del problema?

Conceptos como la velocidad y la proporcionalidad están conectados al concepto de pendiente y fueron esenciales para representar el problema mediante un modelo dinámico. El movimiento controlado del punto *B* permitió a los estudiantes identificar la relación entre el tiempo y la velocidad. El hecho de que GeoGebra no permita intersectar lugares geométricos, necesario para obtener la solución mostrada en la Figura 3, motivó la búsqueda de un modelo algebraico.

Problema 2

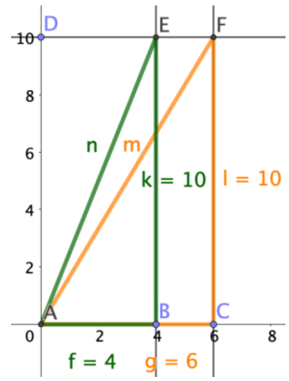
Solución con el uso de GeoGebra

En la Tabla 1 se presenta el desarrollo de los episodios en la resolución del problema 2. En este proceso, los estudiantes exhibieron dos modelos que exploran diferentes propiedades o conceptos y, en consecuencia, distintos acercamientos a la solución.

Tabla 1: Modelos dinámicos del problema 2

Episodio de comprensión

En ambos modelos se consideró el eje *x* como tiempo (medido en horas) y el eje *y* como volumen (medido en litros). ¿Cómo representar dinámicamente la relación entre la cantidad de agua acumulada en el estanque con el tiempo de llenado de cada llave? Los segmentos *f* y *g* representan el tiempo en el cual la primera y la segunda llave llenan el estanque y los segmentos *k* y *l* el volumen total del estanque, que está asociado a la posición del punto *D* (*D* es cualquier punto del eje *y*). Finalmente, se trazaron los segmentos *m* y *n*. En términos del problema, las pendientes de los segmentos *m* y *n* representan una razón de cambio constante entre el volumen y el tiempo, es decir, la velocidad de llenado. Asimismo, los puntos que se encuentran sobre estos segmentos proveen información sobre la cantidad de litros que ha llenado cada llave en un tiempo específico.



Ambos acercamientos fueron explorados por los estudiantes y se describen a continuación.

Episodio de exploración

Primer modelo: Pendientes de *m* y *n*	**Segundo modelo: Puntos sobre *m* y *n***
Para la exploración se construyó una tercera llave. El segmento *p* representa las horas que se ha abierto la llave, el segmento *r* la cantidad total de litros del estanque y la pendiente m_3 la velocidad con la que se llena el tanque en *p* horas. Esta construcción depende del punto *G* (punto con movimiento ordenado sobre el eje *x*). Cuando el punto *G* se mueve el valor de la pendiente m_3 cambia. La solución se alcanza cuando $m_3 = m_1 + m_2$ (m_1 y m_2 son las pendientes de *n* y *m*, respectivamente). En el contexto del problema, esto es, observar en qué momento la velocidad con la que llena la tercera llave es igual a la suma de las velocidades de las dos llaves descritas en el problema. En la imagen se observa que la solución se obtiene cuandoes $p = 2.4$, es decir, se necesitan 2.4 horas para llenar el estanque a una velocidad de 4.17 litros por hora. Para analizar la relación entre la longitud del segmento *p* (tiempo) y la pendiente m_3 (velocidad), se definió el punto I = (p, m_3) y se obtuvo su lugar geométrico en la vista gráfica 2. Nuevamente, se puede concluir	Si las dos llaves se abren al mismo tiempo ¿cuántos litros llenan del estanque en *x* horas? Para responder a esta pregunta, se define un punto *G* sobre el eje *x* y se traza una perpendicular al mismo eje que pase por *G*. Con esto, se definen el segmento *p* (tiempo), el segmento $GI=r$ (litros llenados por la primera llave en *p* horas) y el segmento $GJ=s$ (litros llenados por la segunda llave en *p* horas). Cuando el punto *G* se mueve sobre el eje *x* las longitudes de los segmentos *r* y *s* cambian. ¿Cómo se interpretan estos trazos en términos del problema? La suma de las longitudes de los segmentos *r* y *s* determina la cantidad de litros que han llenado las dos llaves en *p* horas. La solución se obtiene cuando $r+s = k= l$. En la imagen se observa que la solución es cuando $p = 2.4$, esto es, las dos llaves abiertas al mismo tiempo llenan el estanque en 2.4 horas. Se definió el punto $K = (a, r+s)$ en la vista gráfica 2 para analizar la relación entre la longitud del segmento *p* y la suma de las longitudes de los segmentos *r* y *s*. Se identificó que hay una proporción directa porque la razón de $(r+s)/p$ es constante.

<table>
<tr><td>que hay una relación de proporción inversa como en el problema 1.</td><td></td></tr>
<tr><td></td><td></td></tr>
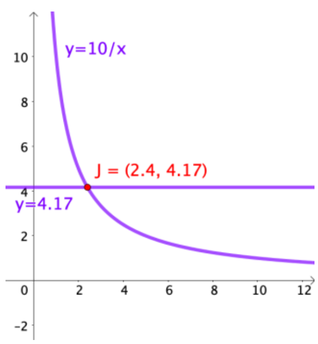
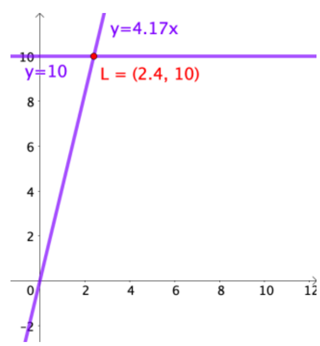
<tr><td colspan="2">Episosdio de búsqueda de distintos acercamientos a la solución</td></tr>
<tr><td>Algebrización del lugar geométrico:
$I = (p, m_3)$ entonces $y = m_3$;
$y = r/p$; m_3 se escribió en términos de p;
$y = 10/x$; p es la incógnita y $r = 10$ (puede tomar cualquier valor según la posición del punto D).
Por lo tanto, se graficó $y = 10/x$.
La solución analítica se obtiene al intersectar la función $y = 10/x$ con la recta $y = m_1 + m_2$, que para la posición del punto D se obtiene la recta $y = 4.17$.



Solución algebraica:
Se obtiene de igualar las funciones $y = m_3$ y $y = m_1 + m_2$. Entonces,
$m_3 = m_1 + m_2$;
$r/x = k/4+l/6$ pero $r = k = l$, así
$r/x = r/4+r/6$ se divide todo entre r
la ecuación es:
$1/x = 1/4+1/6$</td><td>Algebrazación del lugar geométrico:
$K = (a, r+s)$ entonces $y = r+s$;
$y = (k/4)p+(l/6)p$; $r+s$ se escribió en términos de p;
$y = (10/4)x+(10/6)x$; p es la incógnita y $r = l = 10$ (puede tomar cualquier valor según la posición del punto D).
Por lo tanto, se graficó $y = (10/4)x+(10/6)x$.
La solución analítica se obtiene al intersectar la función $y = (10/4)x+(10/6)x$ con la recta $y = k$, que para la posición del punto D se obtiene la recta $y = 10$.



Solución algebraica:
Se obtiene de igualar las funciones
$y = (10/4)x+(10/6)x$ y $y = 10$. Entonces,
$(10/4)x+(10/6)x = 10$.
La ecuación simplificada es:
$(1/4)x+(1/6)x = 1$</td></tr>
<tr><td colspan="2">Episodio de integración y reflexiones</td></tr>
</table>

Proporcionalidad, velocidad y razón de cambio, son conceptos que están conectados con el concepto de pendiente. Esto permitió representar el problema geométricamente y explorar dos modelos partiendo de analizar diferentes propiedades. La estrategia de visualizar el comportamiento de dos objetos del modelo a partir de un punto con movimiento controlado fue esencial para identificar las relaciones entre estos.

Discusión de los resultados

El Problema 1 es una tarea rutinaria que se resolvió aplicando operaciones aritméticas básicas cuando se trabajó en un ambiente de lápiz y papel. Introducir un SGD para resolver la misma tarea, permitió transformarla en una serie de actividades no rutinarias características del proceso de resolución de problemas. Fue decisivo seleccionar las herramientas que ofrece el SGD adecuadamente para que los estudiantes pudieran enfrentarse a la resolución de problemas verbales aritmético-algebraicos con el uso de éste. Así, el objetivo inicial fue representar los conceptos y la información descrita en el enunciado del problema de forma geométrica. Las estrategias que implican mover puntos de forma ordenada, cuantificar o medir atributos, definir relaciones de objetos mediante un punto y trazar su lugar geométrico, fueron importantes para explorar el modelo y obtener distintos acercamientos a la solución del problema. Un recurso importante además del concepto de pendiente, que permitió conectar con los conceptos de velocidad, razón de cambio y proporcionalidad, fue el de dominio del problema. Es decir, en qué intervalo del eje x tuvo sentido explorar las relaciones u objetos involucrados en el modelo del problema.

En el Problema 2 se observó que con el nivel de apropiación del SGD que tenían los estudiantes, así como los recursos y las estrategias con las que contaban, les permitió generar dos modelos dinámicos en donde se exploraron y analizaron conceptos matemáticos diferentes. En ambos se logró llegar a la solución del problema sin necesidad de plantear un acercamiento algebraico de manera inicial. También, en el episodio de exploración los estudiantes identificaron si la relación que se analizaba era una proporción directa o inversa a partir de visualizar el lugar geométrico. Sin embargo, esto exigió que argumentaran las conjeturas planteadas.

La construcción y exploración de los modelos dinámicos permitió que los estudiantes lograran representar algebraicamente el problema al dar seguimiento a los pasos de la construcción. De esta manera, los estudiantes pudieron interpretar y contextualizar las expresiones algebraicas, y dar sentido a diferentes objetos y conceptos matemáticos como la pendiente.

Conclusiones

El uso de un SGD en la resolución de problemas verbales aritmético-algebraicos ofrece la posibilidad de que los estudiantes busquen nuevas rutas para resolverlos. Por ejemplo, un enfoque novedoso fue representar los problemas con modelos dinámicos en GeoGebra ya que estas configuraciones se construyen con base en el análisis de las propiedades matemáticas de los objetos asociados a la tarea y exige que los estudiantes les asignen un sentido geométrico. Estos modelos permiten al estudiante identificar y explorar relaciones y patrones. Además, resulta fácil cuantificar o medir atributos como longitudes de segmentos, pendientes y observar cómo estos atributos cambian cuando ciertos objetos de la configuración se mueven. Un aspecto relevante es que las representaciones gráficas funcionales que se construyeron, en la vista gráfica 2, no requieren de una representación algebraica inicialmente y que con la ayuda del SGD se puede obtener y representar gráficamente en otro sistema de referencia independiente al asignado al modelo dinámico.

Buscar distintos acercamientos a la solución fue clave en el desarrollo de diferentes formas de razonamiento y favoreció el transitar de la representación geométrica a la representación algebraica y permitió a los estudiantes, transformar o extender los problemas verbales, dándoles la posibilidad de generar y conectar ideas matemáticas en un contexto geométrico dinámico.

De manera general, los rasgos que se muestran en los distintos episodios en la resolución de los problemas esbozan elementos de un marco inquisitivo donde se resalta la importancia de que los estudiantes problematicen su aprendizaje. Es decir, que formulen preguntas, que utilicen distintas representaciones, busquen conjeturas y relaciones y donde el uso de un SGD les ayude a explorar y sustentar con argumentos que van desde aspectos visuales y empíricos hasta acercamientos formales.

Agradecimientos

Se agradece el apoyo recibido del proyecto SEP-Cinvestav-12 durante el desarrollo de esta investigación.

GEOMETRIC APPROACHES TO VERBAL PROBLEMS IN A GEOGEBRA PROBLEM SOLVING ENVIRONMENT

In this study we analyze the approaches that high school students show when solving arithmetic-algebraic verbal problems with the use of a Dynamic Geometry System (DGS). The resources, representations, strategies and forms of mathematical reasoning that they exhibit when they use GeoGebra during the process of problem solving are analyzed. The results show that the DGS favors in the student's different forms of reasoning and gives the possibility of transiting from a geometric representation to an algebraic representation.

LEARNING THE FOURIER TRANSFORM AND THE Z-TRANSFORM: UNDERSTANDING INSTRUMENTAL AND UNDERSTANDING RELATIONAL

Antonio Rivera-Figueroa

The Fourier and Z-transforms are important topics in communications and electronics engineering careers. Given the difficulties implied by the mathematics involved in these transforms, we conducted a research with students from a Mexican university about their understanding they achieved once they had completed a course on these transforms. As a theoretical framework we take Richard Skemp's ideas on instrumental understanding and relational understanding. For the research a questionnaire was used for whose design a conceptual map was elaborated according to the ideas indicated and unstructured interviews were made to deepen on the conceptions of the students. The results suggest the need to attend in classroom the understanding of basic mathematical concepts as well as the nature of the mathematical objects involved in these transforms.

Keywords: Understanding Instrumental, Understanding Relational, Fourier Transform, Z-Transform.

Introduction

In this paper we present the results found on the students comprehension into the mathematics involved in the Fourier transform (FT) and Z-transform (ZT), quite fundamental in communications and electronics engineering career, whose construction is based on diverse concepts and mathematical objects and their correlations. These, when translated into a conceptual map with the mathematical contents as a whole, play an important role in the relational understanding of the FT and ZT, in the sense of how Skemp (1976) conceives. A characteristic of the relational understanding in a mathematical topic is the understanding of meaning and of the nature of mathematical objects involved. Following the Richard Skemp's ideas we focuse first on the construction of a conceptual map about FT and ZT, to then build the instrument used in this research and carry out the results analysis.

Problem Statement and Research Question

The Fourier series (FS), FT and ZT, are usually taught in university engineering careers in communications and electronics. This is the case of the careers offered by the Escuela Superior de Ingeniería Mecánica y Eléctrica (ESIME) of Instituto Politécnico Nacional in México city, among others. The FS, FT and ZT, have a certain degree of intrinsic mathematical complexity so, it explains somehow the learning difficulty, as shows the evaluations in the transforms subjects in ESIME. For the above, we decided to find out the level of understanding of the students in themes and basic mathematical concepts involved in FT and ZT. Here, the general question that we ask is:

- To what extent the students understand the fundamental concepts and the nature of the mathematical objects involved in the Fourier transform and Z-transform?

At this point, we formulated a second question pursuing to specify the mathematical contents:

- Which are the contents and the mathematical concepts involved in the Fourier transform and Z-transform?

Some of these contents are prerequisites for the student to be able to study the FT and ZT and some others are he learns during the study of these transformations, so acquiring new knowledge. After reviewing exhaustively, the related textbooks used by students and teachers, such as Hwei (1970) and Glyn (2002), we highlight the contents and concepts involved in the FT and ZT that we consider relevant, which we present in a conceptual map later on.

Instrumental Understanding and Relational Understanding

Skemp (1976) describes, in a simple and didactic way, what is meant by instrumental understanding and relational understanding, as follows. Suppose a person arrives at a town for the first time, and somebody teaches him how to move from a point X, where he lives, to a point Y in the town (for instance, his new job), with several indications such as ' you turn right in that corner', 'after the post office, you walk two streets and then turn left'. He repeats the round paths so many times that at the end he is certain of the routes. Similarly, he learns how to move from point X to point Z (as could be a branch of his job) and from Z to X, and in all of them he knows how to make the round trip and so on for another routes, all of them with initial and final fixed points. Later on, he explores other places by himself, with no a fixed destination, just to find an interesting place, but mainly to try to construct a cognitive city map. These two ways of routes are quite different, because in the first case the trial is to go from fixed initial point to a fixed final point with well-defined instructions that he learns properly, and he gets them easily. For the second case the objective is to expand and consolidate a mental city map, which is a stage of Skemp´s knowledge (1976).

A characteristic of the realization in this way of a route is the knowledge of what to do at each step. But, if any mistake, the person will surely be lost and will be in troubles to return to the right path. Also, a mental city map makes one better to create different starting and end points routes without becoming lost and, if a mistake, the right path will be recovered. From these ideas, we draw a conceptual map of either mathematical concepts, objects or subjects as a description of the fundamental elements and objects to their construction, including their relationships or connections between them, for the FT and ZT.

Methodological Considerations

First, from the answers to the second question, we analyze the mathematics involved just to create a conceptual map with the Skemp's ideas, in order to identify the associated relevant parts.

Secondly, that map is used to designed 10 questions with the main concepts, etc., for FT and ZT, and then asked to 20 students just finishing their courses on Transformations in the Communications and Electronics Engineering career at ESIME, with previous one semesters courses on differential and integral calculus, on elements of Linear Algebra and on Differential Equations. For the third semester they followed courses on Transformations and on elements of Complex Variable Functions.

The obtained information was supplemented by unstructured interviews to deep on the arguments of the students on which they support their answers. The analysis of four selected questions-answers is given in Results and Conclusions.

Conceptual Map of the Fourier and Z Transforms

Some of the mathematical knowledge that FT and ZT requires are a standard course of university calculation, which includes concept of function, elementary functions, limits, continuity, derivative and integral and properties. Further, an important concept here is the improper integral from 0 or $-\infty$ to $+\infty$, as well as a basic knowledge of complex variable functions, such as: derived from complex variable functions, contour integrals and developments in power series and Laurent series.

For the conceptual map on FT and ZT, the Fourier series is the starting point to construct the transforms. Figure 1 shows the most relevant aspects of the map, where boxes connected by arrows display objects, definitions, deductions or demonstrations. Intrinsic difficulties of some mathematical objects or relationships must be noted, which deserve special teaching attention, as for the integral Fourier formula and the Dirac delta function.

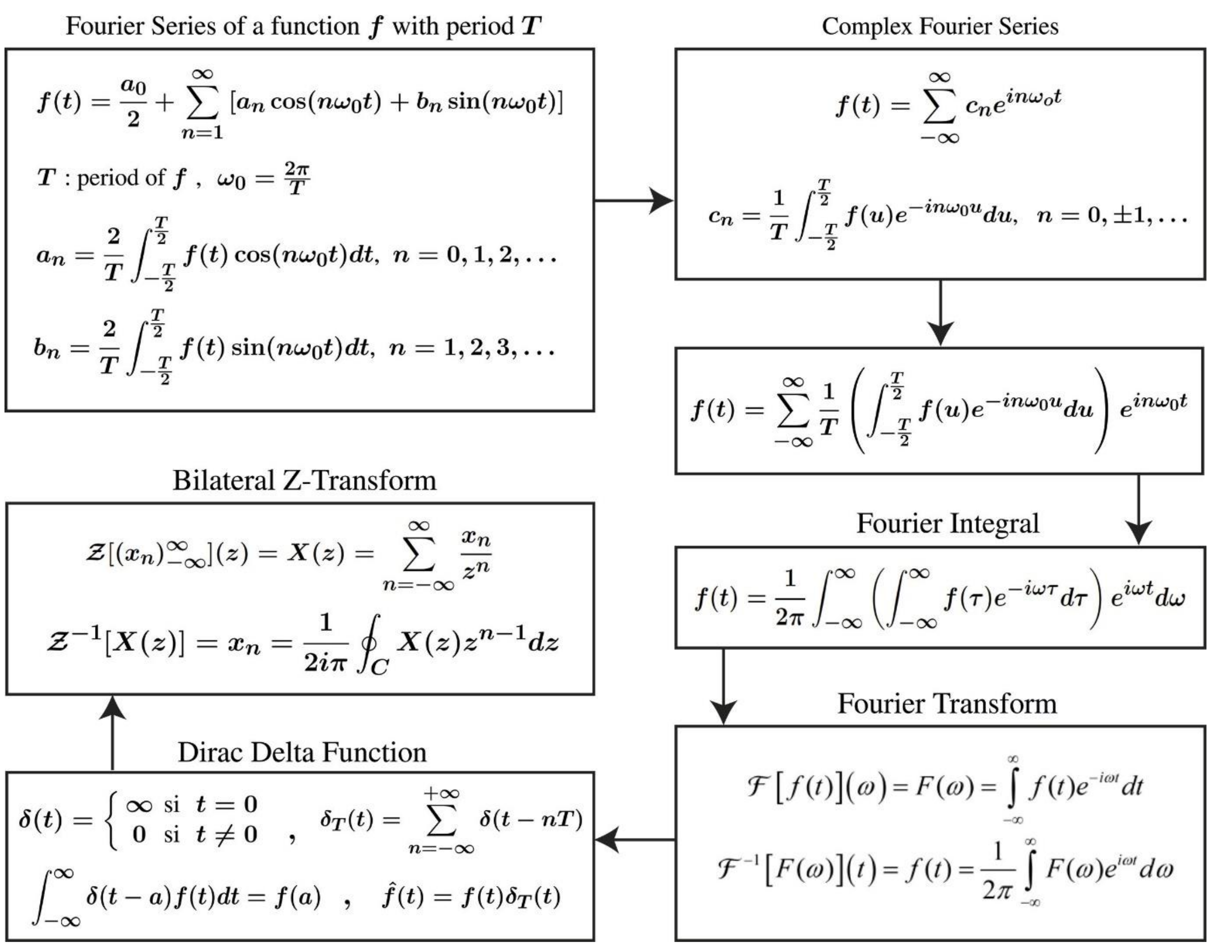

Figure 1: Diagram that Synthesizes the Conceptual Map of FT and ZT

Sometimes, as often happens in the ESIME, the formulas for the coefficients of the FS:

$$a_k = \frac{2}{T}\int_{-\frac{T}{2}}^{\frac{T}{2}} f(u)\cos(k\tfrac{2\pi}{T}u)du \quad \text{and} \quad b_k = \frac{2}{T}\int_{-\frac{T}{2}}^{\frac{T}{2}} f(u)\sin(k\tfrac{2\pi}{T}u)du$$

are given with no explanation and then applied to specific functions, being useful its deduction and explanation to the students that the partial sums

$$s_n(t) = \frac{a_0}{2} + \sum_{k=1}^{n}\left[a_k\cos(k\tfrac{2\pi}{T}t) + b_k\sin(k\tfrac{2\pi}{T}t)\right]$$

play a very important role in FS theory, since from here one gets the infinite sum. FT is usually explained and established through the limit

$$f(t) = \lim_{T\to\infty}\sum_{n=-\infty}^{\infty}\left(\frac{1}{T}\int_{-\frac{T}{2}}^{\frac{T}{2}} f(u)e^{-in\omega_0 u}du\right)e^{in\omega_0 t} = \frac{1}{2\pi}\int_{-\infty}^{\infty}\left(\int_{-\infty}^{\infty} f(u)e^{-i\omega u}du\right)e^{i\omega t}d\omega \ . \quad (1)$$

This is a crucial moment on teaching of FT. The calculation of the previous limit lacks mathematical rigor, even though it is quite common in engineering mathematics books, see for example Hwei (1970, pp.72-73), its full demonstration demands knowledge of advanced mathematical analysis, see for example Rudin (1987, pp.180-181) and Beerends et al. (2003, pp. 164-186).

The following functional symbology strengthens the relational understanding of the students

$$f(t) \overset{\mathcal{F}}{\mapsto} F(\omega) = \int_{-\infty}^{+\infty} f(t)e^{-i\omega t}dt \ , \quad F(\omega) \overset{\mathcal{F}^{-1}}{\mapsto} f(t) = \frac{1}{2\pi}\int_{-\infty}^{+\infty} F(\omega)e^{i\omega t}\,d\omega \ .$$

In the reviewed textbooks, an approach to the ZT is to apply the FT to a particular function, here the Dirac delta function, introduced and used by Paul Dirac (1926, pp. 621-641) and Oliver Heaviside (1899, pp. 54-57), plays a very important role. Actually, the δ function is not a function as seen in classical mathematical analysis, where it is like a sophisticated object with a formal definition, but very useful in engineering (Lathi, 1998) and physics, where it works properly. Its definition through its properties allows us a proficient developing of the theory while teaching. The theory of Distributions created by Laurent Schwarz (1950) gives a rigorous treatment for this function, here a generalized function. Then the impulse train function is defined for any positive real T, $\delta_T(x) = \sum_{n=-\infty}^{+\infty}\delta(x - nT)$ (Hwei, 1970; Glyn, 2002), so $\delta_T(x) = 0$ outside of the points of the form $nT(n \in Z)$ and $\delta_T(x) = +\infty$ in these points. A weighted impulses train $\hat{f}$ is defined as $\hat{f}(x) = f(x)\delta_T(x)$, for $f: \mathbb{R} \to \mathbb{R}$ an arbitrary function, being a paradox that the functions $\hat{f}$ and δ_T take the same values, but the formal FT calculations give different results, which follows from the same condition of the integral for δ, which does not correspond to any rigorous definition of classical mathematical analysis. It must be recognized in the classroom that the calculations are carried out in a formal way, and thus avoid in the student a feeling of low self-esteem due to his lack of understanding of these mathematical objects.

The FT of $\hat{f}$ is defined by

$$\hat{F}(\omega) = \int_{-\infty}^{+\infty}\left(\sum_{n=-\infty}^{+\infty} f(t)\delta(t-nT)\right)e^{-i\omega t}dt = \sum_{n=-\infty}^{+\infty}\int_{-\infty}^{\infty} f(t)\delta(t-nT)e^{-i\omega t}dt = \sum_{n=-\infty}^{+\infty} f(nT)e^{-i\omega nT}.$$

or

$$\sum_{-\infty}^{+\infty} f(nT)e^{-i\omega nT} = \sum_{-\infty}^{+\infty} f(nT)z^{-n}\,, \qquad (2)$$

with $z = e^{i\omega T}$. If we think of $\hat{F}$ as a function of z and not of ω, the formula (2) is written as:

$$\hat{F}(z) = \sum_{n=-\infty}^{+\infty} f(nT)z^{-n}\,. \qquad (3)$$

Some authors of engineering mathematics books, after an independent variable change for a function of one or more variables, usually do not change notation for the new function, see for example Roberts (2004, pp. 762-763), Pipes (2014, pp.956-957), Kreyszig (2011, pp.392-394), Wylie (1966, pp. 550-551), Sokolnikoff (1958, pp.230-235), but they are however, conceptually different functions. For instance, the functions $\hat{F}$ of (2) and (3) are different, because they have different domain. The function $\hat{F}$ of (3) is the ZT of the succession $\left(f(nT)\right)_{n=-\infty}^{+\infty}$ and we write:

$$\mathcal{Z}\left[\left(f(nT)\right)_{n=-\infty}^{+\infty}\right](z) = \hat{F}(z) = \sum_{n=-\infty}^{+\infty} f(nT)z^{-n}\,.$$

In general, the ZT of a succession $(x_n)_{n=-\infty}^{+\infty}$ it is defined as the Laurent series

$$\mathcal{Z}\left[\left(x_n\right)_{n=-\infty}^{+\infty}\right](z) = X(z) = \sum_{n=-\infty}^{+\infty} x_n z^{-n} = \sum_{n=0}^{+\infty} x_{-n} z^{n} + \sum_{n=1}^{+\infty} x_n \frac{1}{z^n}\,. \qquad (4)$$

The inverse of the ZT assigns to each function $X(z)$ that allows a representation as in (4), the succession of coefficients x_n, and it is obtained by means of a contour integral on a circle C with center z = 0 and with adequate radius r. After multiplying both members of $X(z) = \sum_{-\infty}^{+\infty} x_n z^{-n}$ by z^{k-1}, and the line integration, we get

$$x_k = \frac{1}{2\pi i}\oint_C X(z)z^{k-1}\,dz \quad \text{for all } k \in \mathbb{Z}.$$

This formula is found in a first course of functions of complex variable when calculating the coefficients of a Laurent series. As for FT, the following notation helps to understand the nature of the ZT and its inverse

$$\left(x_n\right)_{-\infty}^{+\infty} \overset{\mathcal{Z}}{\mapsto} \mathcal{Z}\left[\left(x_n\right)\right](z) = \sum_{n=-\infty}^{+\infty} \frac{x_n}{z^n}, \quad X(z) \overset{\mathcal{Z}^{-1}}{\mapsto} x = \left(x_n\right)_{-\infty}^{+\infty}, \text{ where } x_n = \frac{1}{2\pi i}\oint_C X(z)z^{n-1}\,dz.$$

Questionnaire

This has 10 questions on the meaning or nature of the mathematical objects involved in FT and ZT. Here we present four of the questions. As noted earlier, to understand (1) it is required an advanced mathematical analysis tool, so the teacher must recognize and explain that what he presents is an empirical deduction; with the question three we try to realize if the teacher clarified this situation.

1. Choose the options that describe the convergence region of a Laurent series

$$\sum_{n=-\infty}^{\infty} a_n z^n = \sum_{n=0}^{\infty} a_n z^n + \sum_{n=1}^{\infty} a_{-n} \frac{1}{z^n}\,.$$

They are the values of z for which:

a) $\sum_{n=0}^{\infty} a_n z^n$ converges together with the values of where $\sum_{n=1}^{\infty} a_{-n}\frac{1}{z^n}$ converges.

b) One of the two series $\sum_{n=0}^{\infty} a_n z^n$ or $\sum_{n=1}^{\infty} a_{-n}\frac{1}{z^n}$ converges.

c) $\sum_{n=0}^{\infty} a_n z^n$ converges, due to that the series $\sum_{n=1}^{\infty} a_{-n} \frac{1}{z^n}$ always converges.

d) Both series $\sum_{n=0}^{\infty} a_n z^n$ and $\sum_{n=1}^{\infty} a_{-n} \frac{1}{z^n}$ converge.

e) $\sum_{n=0}^{\infty} a_n z^n$ converges except for the value of z where $\sum_{n=1}^{\infty} a_{-n} \frac{1}{z^n}$ is divergent.

2. Choose one or more of the options that are true. A Fourier series is:
   a) Any series of the form $\sum_{k=0}^{+\infty} \left[X_k \cos(k \frac{2\pi}{T} t) + Y_k \sin(k \frac{2\pi}{T} t) \right]$.
   b) Any finite sum $\frac{a_0}{2} + \sum_{k=1}^{n} \left[a_k \cos(k \frac{2\pi}{T} t) + b_k \sin(k \frac{2\pi}{T} t) \right]$ or any infinite sum $\frac{a_0}{2} + \sum_{k=1}^{+\infty} \left[a_k \cos(k \frac{2\pi}{T} t) + b_k \sin(k \frac{2\pi}{T} t) \right]$.
   c) Any series of the form $\frac{a_0}{2} + \sum_{k=1}^{+\infty} \left[a_k \cos(k \frac{2\pi}{T_1} t) + b_k \sin(k \frac{2\pi}{T_2} t) \right]$.
   d) Any series of the form $\frac{a_0}{2} + \sum_{k=1}^{+\infty} \left[a_k \cot(k \frac{2\pi}{T} t) + b_k \tan(k \frac{2\pi}{T} t) \right]$.
   e) Any series of the form $\frac{a_0}{2} + \sum_{k=1}^{+\infty} \left[a_k \cos(k \frac{2\pi}{T} t) + b_k k \sin(\frac{2\pi}{T} t) \right]$.
3. The Fourier integral formula is usually obtained as the following limit:
$$f(t) = \lim_{T \to +\infty} \sum_{-\infty}^{\infty} \frac{1}{T} \left(\int_{-\frac{T}{2}}^{\frac{T}{2}} f(u) e^{-in\omega_0 u} du \right) e^{in\omega_0 t} = \frac{1}{2\pi} \int_{-\infty}^{\infty} \left(\int_{-\infty}^{\infty} f(u) e^{-i\omega u} du \right) e^{i\omega t} d\omega .$$
   Choose one of the items that corresponds to your learning of the integral formula.
   a) The professor never made such a deduction and only established the integral formula without explanation.
   b) The professor calculated with mathematical rigor the limit, but I never understood it.
   c) The professor calculated with mathematical rigor the limit, at that moment I understood his explanation, but now I do not remember it.
   d) The professor obtained the limit, but he commented that the calculation he made was heuristic, therefore it was not rigorously mathematical.
   e) The professor established the integral formula, but he said that his demonstration was done in advanced books of Mathematical Analysis.
4. Indicate which of the following statements are false and which are true. The bilateral Z transform:
   a) Transforms a function into an impulse train function.
   b) Transforms an impulse train function into a complex variable function.
   c) It is equivalent to the Fourier transform due to that Z-transform is deduced from Fourier transform.
   d) Transforms a sequence into a complex function that is generally defined in an annular region $R < |z| < r$.

Results and Conclusions

Although the 20 students, who completed their course of transforms, show an instrumental learning of FT and ZT, however in general they do not achieve a relational understanding of the involved objects and concepts. For example, 15 of the 20 students were unable to discriminate the definition of convergence region of a Laurent series, three of them chose only one of the two true options that they could choose but they did it in combination with other incorrect options.

On question 2, only four of the 20 answered correctly. The remaining 16 students even though were able to work with the Fourier series, they could not identify them of a list of similar trigonometric series.

Regarding question 3 on the Fourier formula, three students answered that the professor mentioned that the demonstration of Fourier formula was lies in advanced books of mathematical analysis and that they would only enunciate it there, another three students said that the professor indicated that the calculation they were doing was heuristic, so it lacked mathematical rigor. Six students said that their teacher rigorously calculated the limit, but that they either did not understand it or had already forgotten it. Their answers were not entirely reliable because none of the texts used by teachers justify such a limit in a rigorous way.

In question 4, which refers to the mathematical nature of the ZT, seven students answered correctly that the statement in the option (a) was false, but they answered incorrectly that the false statement in the option (b) was true, their answers were not consistent. In the option (c) which refers to the false assertion that FT and ZT are equivalent, six students answered that the statement was true, they knew the connection between FT and ZT, which was revealed in the interview, but the students did not understand that these transformations cannot be considered equivalent. The affirmation of the option (d), which is the only true one, was correctly chosen by only five students.

In summary, we can say that the students were not able to discriminate, from a list of statements that differed subtly from a correct statement, the concept of the radius of convergence of a power series, region of convergence of a Laurent series, nor were they able to recognize the form of an FS from a list of trigonometric series. On the other hand, it was not clear to students what kind of mathematical object is the domain over which the FT operates, the majority of the participants responded that FT applies to periodic functions, its confusion comes from the fact that the FT is deduced from the FS, which are calculated for periodic functions. The students showed incomprehension about the meaning of the improper integrals of Riemann and the contour integrals for complex functions. Finally, in general the students are not clear that ZT transforms a succession of real numbers into a complex Laurent series, nor do they understand the meaning of the inverse ZT.

These results reveal that, in the best case, students learn FS, FT and ZT instrumentally but do not get a relational understanding.

Acknowledgements

The authors would like to thank the reviewers for their valuable comments and suggestions to improve the quality of this article. Also, thanks to Dr. J. M. Rivera-Rebolledo Lecturer of Physical Department of the Escuela Superior de Física y Matemáticas, del Instituto Politécnico Nacional, México, for his helpful comments. The authors acknowledge the support received from Sistema Nacional de Investigadores of Consejo Nacional de Ciencia y Tecnología, México.

Las transformadas de Fourier y Z son temas importantes en las carreras de ingeniería en comunicaciones y electrónica. Dadas las dificultades que entraña la matemática involucrada en estas transformadas, llevamos a cabo una investigación con estudiantes de una universidad mexicana acerca de la comprensión lograda una vez culminado su curso sobre estas transformadas. Como marco teórico tomamos las ideas de Richard Skemp sobre la comprensión instrumental y comprensión relacional. Para la investigación se utilizó un cuestionario para cuyo diseño se elaboró un mapa conceptual de acuerdo con las ideas señaladas, además se hicieron entrevistas no estructuradas para profundizar sobre las concepciones de los estudiantes. Los resultados sugieren atender en el aula la comprensión de conceptos y objetos matemáticos básicos involucrados en estas transformadas.

Palabras clave: Comprensión Instrumental, Comprensión Relacional, Transformada de Fourier, Transformada Z.

Introducción

En este artículo presentamos los resultados de una investigación acerca de la comprensión de los estudiantes de la matemática involucrada en la transformada de Fourier (TF) y la transformada Z (TZ) que son fundamentales en las carreras de ingeniería en comunicaciones y electrónica. La construcción de estas transformadas está sustentada en diversos conceptos y objetos matemáticos y relaciones entre ellos. Estas relaciones, traducidas a un mapa conceptual de este contenido matemático como un todo, juega un papel crucial en la comprensión relacional de las TF y TZ, en el sentido de como lo concibe Skemp (1976). Una de las características de la comprensión relacional de un tema matemático es la comprensión del significado y naturaleza de los objetos matemáticos involucrados. Hemos adoptado las ideas de Skemp como marco de referencia, enfocándonos primero en la construcción de un mapa conceptual sobre la TF y TZ, para después construir el instrumento empleado en esta investigación y llevar a cabo el análisis de los resultados.

Planteamiento del problema y preguntas de investigación

Las series de Fourier (SF), TF y TZ suelen enseñarse en las carreras universitarias de ingeniería en comunicaciones y electrónica. Este es el caso de las carreras que ofrece la Escuela Superior de Ingeniería Mecánica y Eléctrica (ESIME) del Instituto Politécnico Nacional en México, entre otras. Las SF, TF y TZ tienen un cierto grado de complejidad matemática intrínseca por lo que, de alguna manera se explica que los estudiantes tengan dificultades en su aprendizaje, como lo revelan los resultados en las evaluaciones en las asignaturas sobre transformadas en la ESIME. Por lo anterior decidimos averiguar el nivel de comprensión de los estudiantes, de temas y conceptos básicos matemáticos involucrados en la TF y la TZ. La pregunta general que planteamos es

¿En qué medida los estudiantes han comprendido los conceptos fundamentales y la naturaleza de los objetos matemáticos involucrados en la transformada de Fourier y la transformada Z?

Para tratar de responder la pregunta anterior nos formulamos una segunda pregunta con el propósito de precisar los contenidos matemáticos:

¿Cuáles son los contenidos y conceptos de la matemática involucrados en la transformada de Fourier y la transformada Z?

Algunos de estos contenidos son prerrequisitos para que el alumno esté en condiciones de estudiar la TF y la TZ y, otros son contenidos y conceptos que el alumno aprende durante el estudio de estas transformadas, son nuevos conocimientos que el estudiante adquiere. Después de revisar de manera exhaustiva los libros de texto sobre la TF y TZ utilizados por alumnos y profesores, por ejemplo, Hwei (1970) y Glyn (2002), destacamos los contenidos y conceptos involucrados en la TF y TZ que consideramos relevantes, los cuales presentamos en un mapa conceptual más adelante.

Comprensión instrumental y comprensión relacional

Skemp (1976), en su artículo describe, de manera simple y didáctica, lo que significa comprensión instrumental y comprensión relacional lo cual ahora explicamos. Supóngase que una persona llega por primera vez a una gran ciudad. Alguien le enseña a esa persona a trasladarse caminando de un punto X, lugar donde reside, a un punto Y de la ciudad (por ejemplo, el lugar donde va a trabajar). Las instrucciones que recibe consisten en varias indicaciones como ‘en la esquina de la farmacia das vuelta a la derecha’, ‘cuando llegues a la oficina de correos camina dos calles y das vuelta a la izquierda’. La persona aprende ese camino de ida y vuelta y lo hace tantas veces que con el paso de los días adquiere confianza para realizar los trayectos. Después le enseñan a trasladarse del punto X al punto Z (por ejemplo, una sucursal de la empresa donde trabaja) y del punto Z al lugar de su residencia X, todos estos trayectos aprende a realizarlos de ida y vuelta. Con indicaciones similares, aprende otro número determinado de trayectos, todos ellos con puntos de partida y puntos destino, fijos, de manera automática. Después, la persona en sus ratos libres decide explorar por su propia cuenta otros lugares de la ciudad, pero ahora sin tener un destino fijo, lo hace sólo por el placer de conocer la ciudad y averiguar si hay algún punto interesante, pero sobre todo por tratar de construir un mapa cognitivo de la ciudad. Estas dos maneras de recorrer trayectos son bastante diferentes. En el primer caso se trata de una caminata en donde el objetivo es ir de un punto de partida fijo a un destino fijo con instrucciones bien determinadas que aprende al pie de la letra y llega a realizarlas sin pensar mucho en ellas. En el segundo caso el objetivo es ampliar y consolidar un mapa mental de la ciudad, que es un estado de conocimiento Skemp (1976).

Una característica de la realización de un trayecto basado en una serie de instrucciones es que se le indica a la persona qué hacer en cada punto del trayecto. Pero, si en algún momento la persona comete un error, probablemente se perderá y no podrá retomar el camino correcto. Por el contrario, una persona con un mapa mental de la ciudad está en mejores posibilidades de crear trayectos con diversos puntos de partida y puntos finales sin perderse y, cuando cometa un error le será más fácil retomar o rehacer un camino de manera correcta. Basados en estas ideas concebimos un mapa conceptual sobre un concepto, objeto o tema de matemáticas como la descripción de los elementos y objetos fundamentales que permite construirlo (concepto, objeto o tema), la cual incluye sus relaciones o conexiones entre ellos. Esto es lo que llevamos a cabo para la TF y TZ.

Consideraciones metodológicas

La primera parte de la metodología utilizada en esta investigación para responder las preguntas antes planteadas, consistió en un análisis de la matemática involucrada en el estudio de las TF y TZ con el propósito de crear un mapa conceptual, en el sentido de las ideas de Skemp, que nos sirviese para identificar las partes relevantes de la matemática cuya comprensión es fundamental en el estudio de las TF y TZ.

Basados en este mapa conceptual, como segunda parte de la metodología, se diseñó un cuestionario de 10 preguntas en donde predominaron las ideas, conceptos y objetos matemáticos básicos sobre los que se desarrolla la teoría sobre las TF y TZ. El cuestionario se aplicó a un grupo de 20 estudiantes de la ESIME que en ese momento recién completaban su curso sobre transformadas en la carrera de ingeniería en Comunicaciones y Electrónica. La preparación matemática previa de los estudiantes consistía en un curso semestral de Cálculo diferencial e integral, uno de elementos de Algebra Lineal y otro de Ecuaciones Diferenciales. Durante el tercer semestre ellos estudian de manera simultánea su curso de Transformadas y otro de elementos de Funciones de Variable compleja.

La información obtenida del análisis de las respuestas a las preguntas del cuestionario se complementó mediante entrevistas no estructuradas para profundizar en los argumentos de los estudiantes en los que sustentaron sus respuestas. Para este reporte hemos seleccionado cuatro preguntas del cuestionario cuyo análisis de las respuestas de los estudiantes presentamos en la sección de resultados y conclusiones.

Mapa conceptual de la transformada de Fourier y la transformada Z

Algunos de los conocimientos matemáticos que el alumno requiere para estudiar la TF y la TZ son los de un curso anual de cálculo universitario. Esto incluye, el concepto de función, el conocimiento de funciones elementales, los conceptos de límite, continuidad, derivada e integral y sus propiedades básicas. Un concepto que juega un papel importante en el tema de transformadas es el de integral impropia con límite inferior 0 o $-\infty$ y límite superior $+\infty$. También se requiere que el estudiante tenga conocimientos básicos sobre funciones de variable compleja, como son: derivada de funciones de variable compleja, integrales de contorno y desarrollos de funciones en series de potencias y series de Laurent.

Para construir el mapa conceptual sobre las TF y TZ, consideramos como punto de partida las series de Fourier, a partir de las cuales podemos comenzar a construir las trasformadas. En el diagrama de la Figura 1 mostramos los aspectos que consideramos más relevantes del mapa conceptual. En cada uno de los recuadros aparecen los objetos o definiciones importantes, las flechas muestran las conexiones entre ellos, que en algunos casos conllevan deducciones o demostraciones. Al respecto hacemos notar sobre las dificultades intrínsecas de algunos objetos matemáticos o relaciones entre ellos, que merecen especial consideración en la enseñanza. Este es el caso, por ejemplo, de la fórmula integral de Fourier y de la función delta de Dirac.

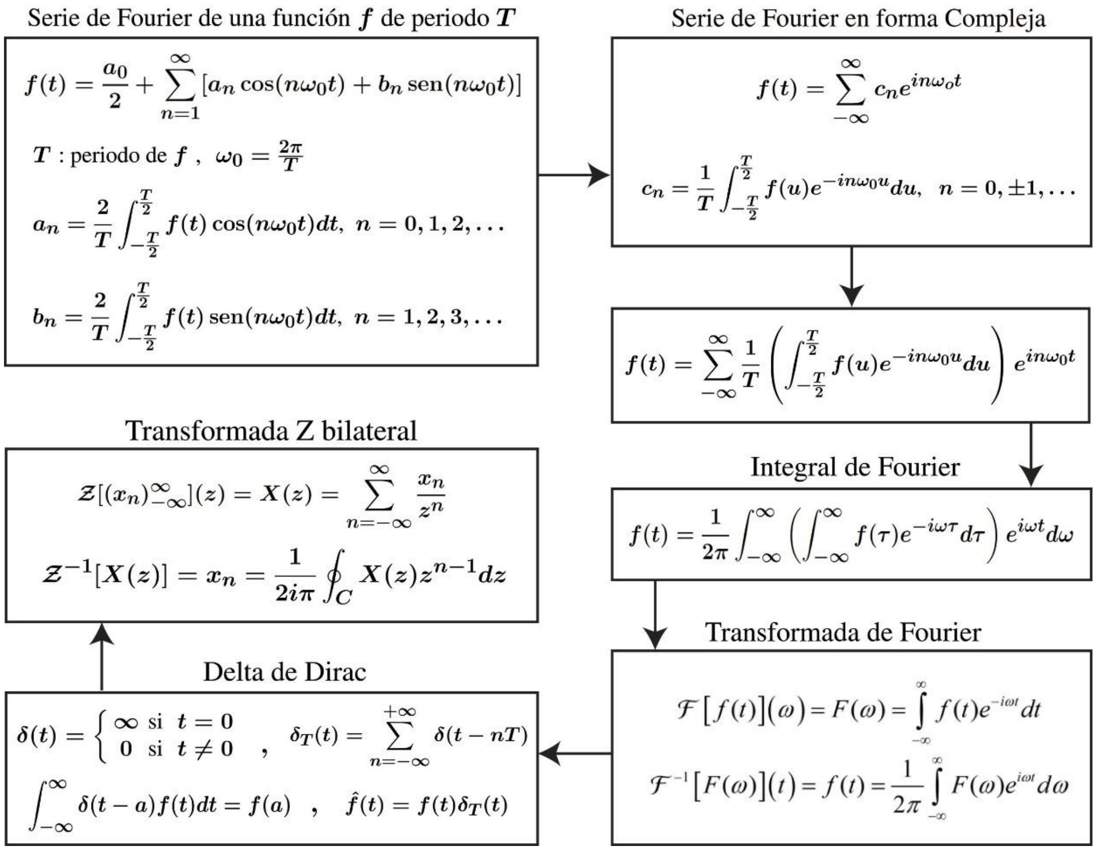

Figura 1: Diagrama que sintetiza el mapa conceptual de TF y TZ

En ocasiones, como suele ocurrir en la ESIME, las fórmulas para los coeficientes de la SF

$$a_k = \frac{2}{T}\int_{-\frac{T}{2}}^{\frac{T}{2}} f(u)\cos(k\tfrac{2\pi}{T}u)du \quad \text{y} \quad b_k = \frac{2}{T}\int_{-\frac{T}{2}}^{\frac{T}{2}} f(u)\operatorname{sen}(k\tfrac{2\pi}{T}u)du$$

se presentan en el aula sin explicación alguna y se procede a aplicarlas a funciones específicas. Sería conveniente deducirlas, también es importante explicar a los alumnos que las sumas parciales

$$s_n(t) = \frac{a_0}{2} + \sum_{k=1}^{n}\left[a_k \cos(k\tfrac{2\pi}{T}t) + b_k \operatorname{sen}(k\tfrac{2\pi}{T}t)\right]$$

juegan un papel muy importante en la teoría de las SF, pues son las que permiten darle sentido a la suma infinita. La TF suele explicarse y establecerse mediante la obtención del límite

$$f(t) = \lim_{T\to\infty} \sum_{n=-\infty}^{\infty}\left(\frac{1}{T}\int_{-\frac{T}{2}}^{\frac{T}{2}} f(u)e^{-in\omega_0 u}du\right)e^{in\omega_0 t} = \frac{1}{2\pi}\int_{-\infty}^{\infty}\left(\int_{-\infty}^{\infty} f(u)e^{-i\omega u}du\right)e^{i\omega t}d\omega\ . \quad (1)$$

Este es un momento crucial en la enseñanza de la TF. El cálculo del límite anterior carece de rigor, pero es un acercamiento común en los textos de ingeniería o de matemáticas para ingeniería, véase por ejemplo Hwei (1970, pp.72-73), lo cual es explicable pues la demostración rigurosa de la fórmula (1) demanda conocimientos de análisis matemático avanzado, véase por ejemplo Rudin (1987, pp.180-181) y Beerends et al. (2003, pp. 164-186).

La siguiente simbología funcional fortalece la comprensión relacional de los estudiantes

$$f(t) \overset{\mathcal{F}}{\mapsto} F(\omega)=\int_{-\infty}^{+\infty} f(t)e^{-i\omega t}dt \ , \quad F(\omega) \overset{\mathcal{F}^{-1}}{\mapsto} f(t)=\frac{1}{2\pi}\int_{-\infty}^{+\infty} F(\omega)e^{i\omega t}d\omega \ .$$

Un acercamiento a la TZ, que se observa en los libros de texto revisados consiste en aplicar la TF a una función particular. En este acercamiento, la función delta de Dirac δ, introducida y usada por Paul Dirac (1926, pp. 621-641) y Oliver Heaviside (1899, pp. 54-57), juega un papel muy importante. En realidad, δ no es una función en el sentido del análisis matemático clásico, pero es un objeto matemático de suma utilidad en ingeniería (Lathi, 1998). Se trata de un objeto sofisticado que en el análisis matemático clásico no tiene una definición rigurosa, pero que en ingeniería y física trabaja muy bien. En la enseñanza ha de destacarse que son las propiedades de δ, las establecidas en su definición, las que nos permiten desarrollar con éxito la teoría. El área de la matemática que le da un tratamiento riguroso a δ, en la que recibe el nombre de función generalizada, es la teoría de Distribuciones creada por Laurent Schwarz (1950). Con base en la función generalizada δ se define, para cualquier real positivo T, la función tren de impulsos $\delta_T(x)=\sum_{n=-\infty}^{+\infty}\delta(x-nT)$ (Hwei, 1970; Glyn, 2002). Esta función toma el valor cero fuera de los puntos de la forma $nT(n\in Z)$ y en ellos toma el valor $+\infty$. Si $f:\mathbb{R}\to\mathbb{R}$ es una función arbitraria, la función $\hat{f}$ definida como $\hat{f}(x)=f(x)\delta_T(x)$ es llamada tren de impulsos ponderado. Aquí resulta paradójico que las funciones $\hat{f}$ y δ_T toman los mismos valores, sin embargo, los cálculos formales de la TF de cada una de ellas conducirán a resultados diferentes, esto es algo que causa conflicto a estudiantes y profesores. Todo esto se desprende de la misma condición de la integral para δ, que no corresponde a definición rigurosa alguna del análisis matemático clásico. Debe reconocerse en el aula que los cálculos se llevan a cabo de manera formal para no provocar en el alumno un sentimiento de baja autoestima por su incomprensión de estos objetos matemáticos.

Por definición, la TF de $\hat{f}$ está dada por

$$\hat{F}(\omega)=\int_{-\infty}^{+\infty}\left(\sum_{n=-\infty}^{+\infty} f(t)\delta(t-nT)\right)e^{-i\omega t}dt=\sum_{n=-\infty}^{+\infty}\int_{-\infty}^{\infty} f(t)\delta(t-nT)e^{-i\omega t}dt=\sum_{n=-\infty}^{+\infty} f(nT)e^{-i\omega nT}.$$

Si el número complejo $e^{i\omega T}$ lo denotamos por z, $e^{-i\omega nT}$se escribe como z^{-n} y entonces

$$\sum_{-\infty}^{+\infty} f(nT)e^{-i\omega nT}=\sum_{-\infty}^{+\infty} f(nT)z^{-n} \ . \qquad (2)$$

Si concebimos $\hat{F}$ como función de z y no de ω, la fórmula (2) se escribe como

$$\hat{F}(z)=\sum_{n=-\infty}^{+\infty} f(nT)z^{-n} \ . \qquad (3)$$

Algunos autores de libros de texto de ingeniería o de matemáticas para ingeniería, al hacer un cambio de variable independiente para una función de una o varias variables suelen conservar la misma letra para la nueva función con la nueva variable, vea por ejemplo Roberts (2004, pp. 762-763), Pipes (2014, pp.956-957), Kreyszig (2011, pp.392-394), Wylie (1966, pp. 550-551), Sokolnikoff (1958, pp.230-235), sin embargo, conceptualmente se tienen funciones diferentes. En nuestro caso, aunque hemos usado la misma letra, la función $\hat{F}$ de (2) es diferente de la función $\hat{F}$ de (3), pues tienen dominios diferentes, entonces son diferentes. La función $\hat{F}$ de (3) es la TZ de f relativa a T. En realidad, la TZ se aplica a sucesiones, en este caso a la sucesión $\left(f(nT)\right)_{n=-\infty}^{+\infty}$ y no a la función f. Entonces es mejor escribir

$$\mathrm{Z}\left[\left(f(nT)\right)_{n=-\infty}^{+\infty}\right](z)=\hat{F}(z)=\sum_{n=-\infty}^{+\infty} f(nT)z^{-n} \ .$$

En general, la TZ de una sucesión $(x_n)_{n=-\infty}^{+\infty}$ se define como la serie de Laurent

$$\mathrm{Z}\left[\left(x_n\right)_{n=-\infty}^{+\infty}\right](z)=X(z)=\sum_{n=-\infty}^{+\infty} x_n z^{-n}=\sum_{n=0}^{+\infty} x_{-n} z^n+\sum_{n=1}^{+\infty} x_n \frac{1}{z^n} \quad . \qquad (4)$$

La inversa de la TZ asigna a cada función $X(z)$ que admite una representación como en (4), la sucesión de coeficientes x_n. El cálculo de la transformada inversa se obtiene mediante una integral de contorno sobre un círculo C con centro $z=0$ y, por ejemplo, radio 1. Si después de multiplicar ambos miembros de $X(z)=\sum_{-\infty}^{+\infty} x_n z^{-n}$ por z^{k-1} integramos sobre un círculo C apropiado obtenemos

$$x_k=\frac{1}{2\pi i}\oint_C X(z) z^{k-1}\, dz \text{ para toda } k\in\mathbb{Z}.$$

La fórmula anterior no es otra cosa que la estudiada en un primer curso de funciones de variable compleja, para calcular los coeficientes de una serie de Laurent. Como en el caso de la TF, la siguiente simbología ayuda a comprender la naturaleza de la TZ y su inversa

$$\left(x_n\right)_{-\infty}^{+\infty} \overset{\mathrm{Z}}{\mapsto} \mathrm{Z}\left[\left(x_n\right)\right](z)=\sum_{n=-\infty}^{+\infty} \frac{x_n}{z^n}, \quad X(z) \overset{\mathrm{Z}^{-1}}{\mapsto} x=\left(x_n\right)_{-\infty}^{+\infty}, \text{ donde } x_n=\frac{1}{2\pi i}\oint_C X(z) z^{n-1} dz .$$

El cuestionario

Constó de 10 preguntas que se refieren a la comprensión de significados o de la naturaleza de los objetos matemáticos involucrados en la TF y TZ. Aquí presentamos cuatro de las preguntas. Como se señaló antes, una de las dificultades en la comprensión de la fórmula integral de Fourier (1), se debe a que para establecerla se requiere herramienta del análisis matemático avanzado, por lo que resulta importante que el profesor reconozca y explique al alumno que se trata de una deducción totalmente empírica; con la pregunta tres pretendemos averiguar si el profesor hizo una tal explicación o intentó hacer una demostración de (1).

1. Elija las opciones que describan la región de convergencia de una serie de Laurent

$$\sum_{n=-\infty}^{\infty} a_n z^n=\sum_{n=0}^{\infty} a_n z^n+\sum_{n=1}^{\infty} a_{-n} \frac{1}{z^n} \quad .$$

Son los valores de z para los cuales:

a) $\sum_{n=0}^{\infty} a_n z^n$ converge junto con los valores de z donde $\sum_{n=1}^{\infty} a_{-n} \frac{1}{z^n}$ converge.

b) Alguna de las dos series $\sum_{n=0}^{\infty} a_n z^n$ o $\sum_{n=1}^{\infty} a_{-n} \frac{1}{z^n}$ converge.

c) $\sum_{n=0}^{\infty} a_n z^n$ converge, pues la serie $\sum_{n=1}^{\infty} a_{-n} \frac{1}{z^n}$ siempre converge.

d) Ambas series $\sum_{n=0}^{\infty} a_n z^n$ y $\sum_{n=1}^{\infty} a_{-n} \frac{1}{z^n}$ convergen.

e) $\sum_{n=0}^{\infty} a_n z^n$ converge exceptuando los valores de z donde $\sum_{n=1}^{\infty} a_{-n} \frac{1}{z^n}$ diverge.

2. Elija una o varias de las opciones que sean ciertas. Una serie de Fourier es:

a) Cualquier serie de la forma $\sum_{k=0}^{+\infty}\left[X_k \cos(k \tfrac{2\pi}{T} t)+Y_k \operatorname{sen}(k \tfrac{2\pi}{T} t)\right]$.

b) Cualquier suma finita $\frac{a_0}{2}+\sum_{k=1}^{n}\left[a_k\cos(k\,\tfrac{2\pi}{T}t)+b_k\,\mathrm{sen}(k\,\tfrac{2\pi}{T}t)\right]$ o cualquier suma infinita $\frac{a_0}{2}+\sum_{k=1}^{+\infty}\left[a_k\cos(k\,\tfrac{2\pi}{T}t)+b_k\,\mathrm{sen}(k\,\tfrac{2\pi}{T}t)\right]$.

c) Cualquier serie de la forma $\frac{a_0}{2}+\sum_{k=1}^{+\infty}\left[a_k\cos(k\,\tfrac{2\pi}{T_1}t)+b_k\,\mathrm{sen}(k\,\tfrac{2\pi}{T_2}t)\right]$.

d) Cualquier serie de la forma $\frac{a_0}{2}+\sum_{k=1}^{+\infty}\left[a_k\cot(k\,\tfrac{2\pi}{T}t)+b_k\tan(k\,\tfrac{2\pi}{T}t)\right]$.

e) Cualquier serie de la forma $\frac{a_0}{2}+\sum_{k=1}^{+\infty}\left[a_k\cos(k\,\tfrac{2\pi}{T}t)+b_k k\,\mathrm{sen}(\tfrac{2\pi}{T}t)\right]$.

3. La fórmula integral de Fourier suele obtenerse como el siguiente límite:

$$f(t)=\lim_{T\to+\infty}\sum_{-\infty}^{\infty}\frac{1}{T}\left(\int_{-\frac{T}{2}}^{\frac{T}{2}}f(u)e^{-in\omega_0 u}du\right)e^{in\omega_0 t}=\frac{1}{2\pi}\int_{-\infty}^{\infty}\left(\int_{-\infty}^{\infty}f(u)e^{-i\omega u}du\right)e^{i\omega t}d\omega\ .$$

Elija uno de los incisos que corresponda a tu aprendizaje de la formula integral.

a) El profesor nunca hizo tal deducción y sólo estableció la fórmula integral sin explicación.
b) El profesor calculó con rigor matemático tal límite, pero yo nunca lo comprendí.
c) El profesor calculó con rigor matemático tal límite, en ese momento comprendí su explicación, pero ahora no lo recuerdo.
d) El profesor obtuvo el límite, pero comentó que el cálculo que hacía era heurístico por lo tanto no era riguroso matemáticamente.
e) El profesor estableció la formula integral, pero dijo que su demostración se hacía en textos avanzados de Análisis Matemático.

4. Indica cuáles de las siguientes afirmaciones son falsas y cuáles son verdaderas. La transformada bilateral Z:
a) Transforma una función en una función tren de impulsos.
b) Transforma una función tren de impulsos en una función de variable compleja.
c) Es equivalente a la transformada de Fourier pues se deduce de ésta.
d) Transforma una sucesión en una función compleja que en general está definida en lo que se llama una región anular $R<|z|<r$.

Resultados y Conclusiones

Si bien 20 alumnos, que completaron su curso de trasformadas, muestran un aprendizaje instrumental de las TF y TZ, en general ellos no logran una comprensión relacional de los objetos y conceptos involucrados en estas transformadas. Por ejemplo, 15 alumnos no pudieron discriminar la definición de región de convergencia de una serie de Laurent. Tres de los alumnos que erraron eligieron una de las opciones correctas, de las dos que podían elegir, pero lo hicieron en combinación con otras opciones incorrectas.

Respecto a la pregunta 2, solo cuatro estudiantes respondieron correctamente a la pregunta. Los restantes 16 alumnos, aunque fueron capaces de trabajar con las series de Fourier, como lo demostraron en su curso sobre transformadas, no lograron identificarlas de una lista de series trigonométricas similares.

Respecto a la pregunta 3, la cual se refiere a la fórmula de Fourier, tres alumnos indicaron que su profesor les mencionó que la demostración de la fórmula de Fourier se hacía en textos avanzados de análisis matemático y que ahí solo la enunciarían, otros tres dijeron que el profesor indicó que el cálculo que estaban haciendo era heurístico, por lo que carecía de rigor matemático. Seis estudiantes afirmaron que su profesor calculó rigurosamente el límite, pero que ellos o no lo comprendieron o ya lo habían olvidado. Sus respuestas no fueron del todo confiables debido a que ninguno de los textos empleados por los profesores justifican tal límite de forma rigurosa.

En la pregunta 4, que se refiere a la naturaleza matemática de la TZ, siete estudiantes acertaron al responder que era falsa la afirmación del inciso (a), pero respondieron incorrectamente que era verdadera la afirmación falsa del inciso (b), sus respuestas no fueron consistentes. El inciso (c) que se refiere a la afirmación falsa de que TF y TZ son equivalentes, seis estudiantes respondieron que la afirmación era verdadera, ellos conocían la conexión que existe entre TF y TZ, y así fue revelado en la entrevista, pero no tenían claro que estas transformadas no pueden considerarse equivalentes. La afirmación del inciso (d), que es la única verdadera, fue elegida correctamente sólo por cinco estudiantes.

En resumen, podemos decir que los estudiantes no fueron capaces de discriminar, de una lista de enunciados que diferían de manera sutil de un enunciado correcto, el concepto de radio de convergencia de una serie de potencias, región de convergencia de una serie de Laurent, ni fueron capaces de reconocer la forma de una SF de una lista de series trigonométricas. Por otra parte, los estudiantes no tienen claro qué tipo de objeto matemático es el dominio sobre el que opera la TF, la mayoría afirmó que la TF se aplica a funciones periódicas, su confusión proviene del hecho de que la TF se deduce de la SF la cual puede ser calculada para funciones periódicas. Los estudiantes mostraron incomprensión sobre el significado de las integrales impropias de Riemann y de las integrales de contorno para funciones complejas. Finalmente, no es claro para una mayoría de los estudiantes que la TZ transforma una sucesión de números reales en una serie de Laurent compleja, tampoco comprenden el significado de la TZ inversa. Estos resultados revelan que, en el mejor de los casos, los estudiantes aprenden las SF, TF y TZ de manera instrumental pero no logran una comprensión relacional.

LEARNING THE FOURIER TRANSFORM AND THE Z-TRANSFORM: INSTRUMENTAL UNDERSTANDING AND RELATIONAL UNDERSTANDING

The Fourier and Z transforms are important topics in communications and electronics engineering careers. Given the difficulties involved in the mathematics involved in these transformations, we conducted an investigation with students of a Mexican university about their understanding that they achieved once they had completed a course on these transformations. As a theoretical framework, we take Richard Skemp's ideas about instrumental understanding and relational understanding. For the investigation, a questionnaire was used for whose design a concept map was drawn up according to Skemp's ideas and unstructured interviews were conducted to deepen the students' conceptions. The results suggest attending in the classroom the understanding of basic mathematical concepts and objects involved in these transformed

In this study, we investigated one student as she engaged in the exploration of a graph theory problem, the Graceful Tree Conjecture. The study took place in a classroom in the Midwestern United States which contained eighteen students. We report on a descriptive case study of one student, Heidi, as she works her way through different classes of tree graphs and advances through different types of reasoning, justifications, and proving a select class of tree graphs can be labeled gracefully. We found that with repeated experiences, Heidi, was able to advance her level of reasoning and creations of justifications.

Keywords: Problem Solving, Reasoning and Proof, Elementary School Education

The current horizon in mathematics education for elementary school focuses on procedural and conceptual understanding of mathematical content (Bieda, Ji, Drwencke, & Picard, 2013). What would happen if we went against the horizon and instead focused on the mathematical processes of reasoning and proving?

Students engaging in mathematical proof is not characteristically presented until middle school (Lin & Tsia, 2016) or even high school (Stylianides, 2007). Students at the elementary level are typically focused on finding the correct answer but justifying their solutions is not included (Kieran, 2004). Carpenter, Franke, and Levi (2003) have identified three ways students tend to give an argument or mathematical justification: (a) appeal to authority, (b) justification by example, and (c) generalizable argument. A student appealing to authority would give a reason for their answer by stating a rule or procedure their teacher has shared. A justification through example would be where a student makes a case about something through sharing a specific case, such as four times two is eight therefore an even multiplied by an even is always even. For a generalized argument students would give an argument that would be applicable to all cases in the given conjecture.

Carpenter et al. (2003) furthered their team's argument by stating that elementary students do not typically complete generalizable arguments but as they advance in grade level they should be encouraged to develop more generalized arguments and understand how just giving an example restricts their argument. Past researchers (Ball, 1993; Keith, 2006; Lin & Tsai 2016) have documented that elementary students are able to make conjectures and develop justifications. This has been done through students in second and third grade exploring the idea of the sums of even and odd numbers through using blocks and definitions. Many researchers have recommended all elementary students engage in argumentation, proof, and making mathematical justifications in all mathematics content areas (e.g., Ball & Bass, 2003; Carpenter et al., 2003; NCTM 2014; Stylianides, 2007). Bieda, Ji, Drwencke, and Picard (2013) argued students' difficulties with learning to construct formal proofs in geometry high school classes and college level mathematics could be because of the lack of experiences elementary and middle schools students have had with justifying, reasoning and proving. Further, Beida et al. (2013) stated that tasks where elementary students could engage in reasoning and proving is an area of needed research. For this study, we examined a fourth grade student's development in reasoning and proving as she worked through a graph theory problem.

Research Questions

The following questions guided our research study:

1. What ways does a fourth grade student attempt to construct an argument or mathematical justification?
2. How does a fourth grade student progress through repeated opportunities with justifying and proof?

Theoretical Framework

Throughout this study, we wanted students to experience mathematics more similar to how a mathematician might experience it than what they routinely see in a traditional elementary school setting. Thus, we tried to create a community of practice where students had the freedom to understand a mathematical topic through exploration and focused on the topic of reasoning and proving. Because of this, we used the idea of communities of practice (Wenger, 1998) as an overarching theoretical framework for this study and attempted to turn the fourth grade classroom into such an environment.

We used communities of practice as a way to create an experience among the students that would be similar to the ways a mathematician might engage in mathematics. In communities of practice the two major components are practices and identities. This idea develops from the thought that we are "active participants in the *practices* of social communities and constructing *identities* in relation to these communities" (Wenger, 1998, p. 4). The main idea of practice is how we experience the world and create social engagement. There are three components of the relationship between practice and the created community, which are mutual engagement, joint enterprise, and shared repertoire. We attempted to create mutual engagement by allowing the students opportunities to work together; joint enterprise by allowing the students to create a similar goal of finding a solution to the graph theory problem; and shared repertoire by teaching the students new words such as node, edge, conjecture, and the idea of a graceful labeling to use while working in a community of mathematicians. The other main component of communities of practice is identity. According to Wenger (2008), identity is the relationship between the personal and social and thus it allows it to shape a person's belonging in the community.

Methods

In this qualitative study, we investigated fourth grade students while they engaged in the exploration of a graph theory problem, the Graceful Tree Conjecture. The study took place in a classroom containing eighteen students at a private school in the Midwestern United States. All eighteen students participated in the study but because of the length of the paper, we will report on only one student, who we will call Heidi. The students participated in three teaching experiments (Steffe & Thompson, 2000), each lasting 75 minutes. Both of the authors were teacher-researchers in this teaching experiment but not the regular classroom teacher.

During the teaching experiment, the students engaged in parts of the Graceful Tree Conjecture. The used tasks come from a previous research study (O'Dell, 2017). This study looks to extend that research by integrating the ideas of reasoning and proof into a classroom setting.

Graceful Tree Conjecture

The Graceful Tree Conjecture is currently an unsolved problem from graph theory that is accessible to elementary school students. The problem has children explore different types of tree graphs, graphs that are connected with no cycles (see Figure 1). A tree graph must be acyclic which means if you follow along the edges from node to node, you will never cycle back to the same node without retracing an edge. All tree graphs contain one more node than edge.

To create a graceful label for a tree graph, you assign numbers then create a labeling for the edges. For a tree graph of order *m*, every node is labeled distinctly from 1 through m and the edges are then labeled with the absolute value of the difference of the labels on their attached nodes. A tree graph is labeled gracefully if the edges are labeled 1 through *m*-1 distinctly (see Figure 1).

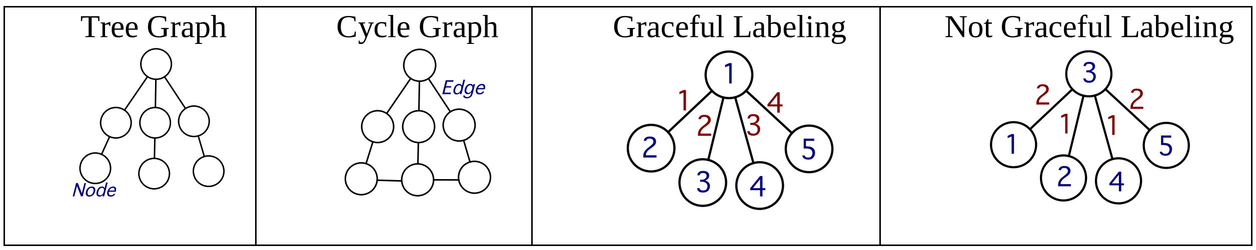

Figure 1: Graceful Tree Concepts

Overview of Teaching Experiment

During the three teaching experiment sessions, students explored different classifications of tree graphs in increasing sophistication (see Figure 2). We tasked students to not just create a graceful labeling for each graph but to find patterns, create justifications, and prove that any graph in the given category could be labeled gracefully. During the exploration of each graph classification, students were given a page that contained the first four distinct tree graphs in a given class, enlarged copies of each of the graphs, and numbered circle and square chips (see Figure 3). The use of the enlarged graphs and chips allowed the students to try multiple configurations without having to erase in hopes of easing frustration.

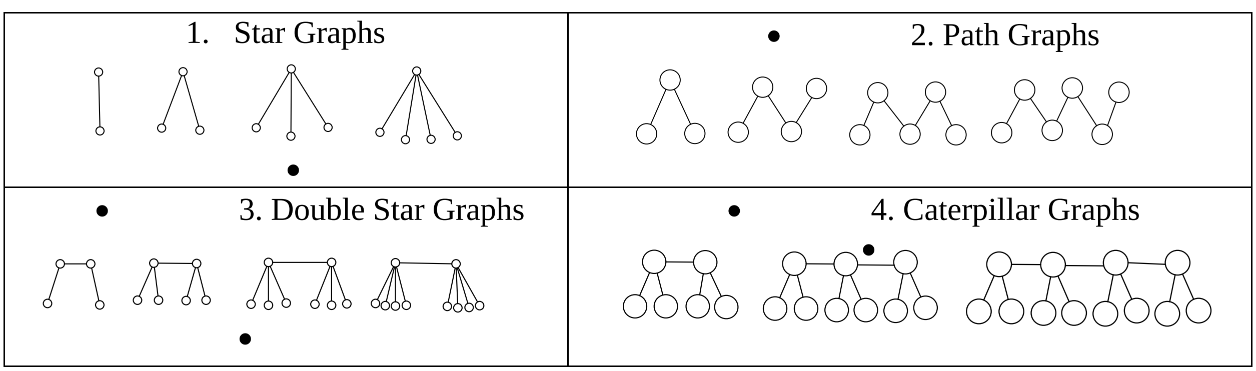

Figure 2: Different Classes of Tree Graphs in Increasing Sophistication

During the first class period students were taught what a conjecture was, each subsequent session started with a reminder that we are looking for a conjecture and what that means. Students were introduced to graph theory and tree graphs, explored graceful labelings, and were

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

tasked to create a graceful labeling of the Star class. Throughout the second class period, students worked to develop a pattern or justification for path graphs. In the third session, students explored and developed justifications for graceful labelings for the group of graphs in the Double Star class and Caterpillar class. At the end of each class, we would have a whole group discussion about the different patterns, justifications, and ideas for proving that a certain class of graphs could be labeled gracefully. For every classification of tree graph students were able to generate at least one generalizable solution. During all three sessions, we encouraged the students to work together, giving them only enough hands-on materials for every two people which meant they would have to work with a partner but record solutions on their own page.

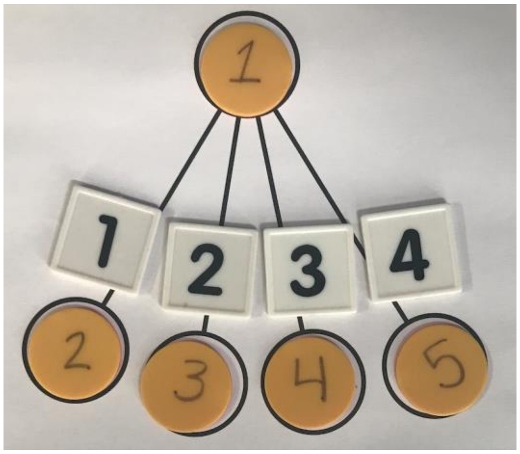

Figure 3: Enlarged Star Graph and Circle and Square Numbered Chips

Results and Discussion

All of the eighteen fourth grade students were able to make progress on each class of tree graphs. They were able to find graceful labelings for the first four distinct graphs in each of the first three classes of tree graphs, Stars, Path, and Double Star Graphs. However, not all of the fourth grade students were able to find patterns and create justifications for each of the graphs. Heidi was selected to be the case study student because she was able to create patterns for all four classes of tree graphs. Many other students were also able to do this for several of the different classes but in the given time period Heidi was the only one to find a pattern for the Caterpillar class. We had to end the session prior to the other students completing this. Heidi was also selected because she sincerely enjoyed the activity and was very willing to share her solutions with the researchers and her classmates during the class discussion period.

Star Graphs

To begin Star Graphs, Heidi quickly worked through labeling the first four distinct graphs in the class (see Figure 2 for the first four distinct graphs). Then she said she did not understand what to do next. We told her to draw and produce the next graph in the Star class by asking her what the next graph would look like. She asked, “Can I draw it?” and we told her yes. Her partner asked if they needed to have six nodes and she responded incorrectly, “You only need five.” She realized her error then changed her answer to needing six nodes. Like the first four graphs, she placed one at the top and put the rest of the numbers in order.

After she drew a graceful labeling for the six noded graph, she asked what to do next. We asked her, “Do you think you could gracefully label any Star graph?” Heidi did not seem to understand the question. We clarified that if there was a Star graph with so many nodes you were not sure how many, could you still label it gracefully. Heidi responded, “Oh.” Again, we clarified, “What if there were thirty nodes?” Heidi stated, “You would put a one at the top and go in a pattern along the bottom.” We asked her to write about it.

To generalize the Star Graphs, Heidi, wrote a description on her page and used her example of a graph with six nodes (see Figure 4). Her description said, “You would put one at the top node and then two, then three and so on depending on how many nodes there are. You label edges by subtracting the number in the nodes also edges labels go in order.”

Heidi was able to find and describe a pattern to label any Star Graph gracefully. In her description of the pattern, she limited herself by drawing a picture of one distinct graph to explain how her pattern worked. She attempted to generalize but this was her first time being pushed to go beyond just developing a solution. However, she did share that she thought all graphs in the Star class could be labeled gracefully following her given pattern.

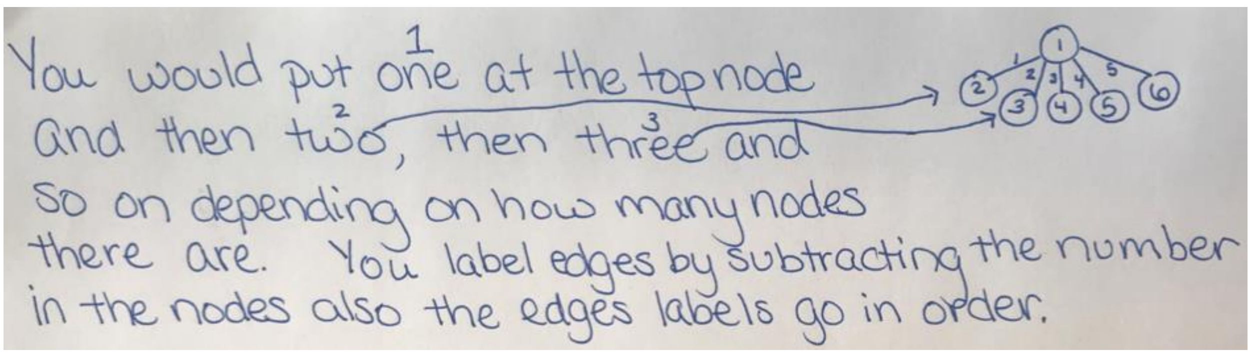

Figure 4: Heidi’s Justification for Star Graphs

Path Graphs

Heidi began working on the Path graphs and labeled the first four distinct graphs in the class. Next, she and her partner talked about what they found. Her partner said that she had the biggest number on top. Heidi said, “No, we put the smallest number on top.” When she was questioned to tell more she said, “The biggest second.” We asked her to write about her pattern. She wrote, “We used one in the first node and then the biggest number in the second node. We also used two in the third node. Then counted down every other node.”

After she finished writing about her pattern, we asked if she would use her pattern to do a Path graph with 50 nodes. She said, “Honestly, yeah.” Heidi went and began drawing and labeling a Path graph where she placed one if the first node, a fifty in the second node, a two in the third node and continued doing she had drawn eleven nodes.

Next, one of the researchers asked her what she would do if she did not know how many nodes. She said, “One would go in the top.” They asked, “What would go next?” She said, “It would be the biggest number.” Next, the researcher asked, “What would go after that?” Heidi looked at her pattern on the other side of her page and said, “Two. And then it kind of depended on…” She stopped talking and looked at her pattern. After several seconds the researcher asked, “Well you had one, the biggest number, two, and what happened with the next number?” Heidi stated, “The second biggest and yeah we did that every time.”

Then Heid went and drew the picture to give a justification, or beginning of a proof, for how she would label any tree graph in the Path class gracefully (see Figure 5). In her justification she completed how she could use her pattern for any Path graph and explained how to label the edges. We saw this as an advancement from her previous explanation of the Star graph where she just described a pattern and referred to one example picture. In this case, Heidi gave a complete justification or what we would consider a proof for a fourth grade student.

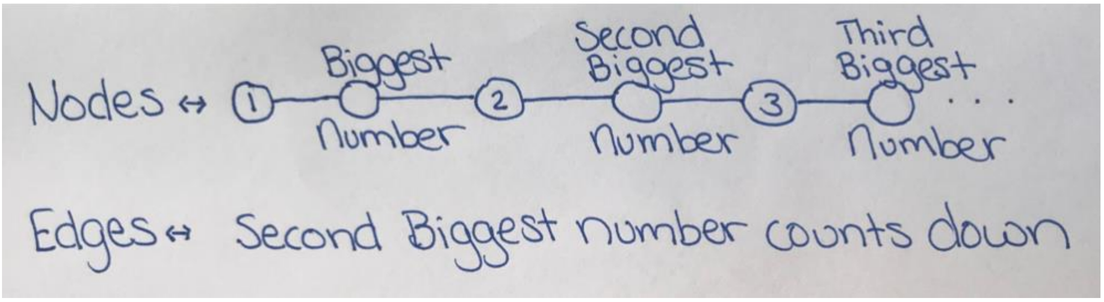

Figure 5: Heidi's Justification for Path Graphs

Double Star Graphs

Heidi began working on Double Star Graphs during the third session. Her partner from the previous two days was absent so she decided to work by herself. After gracefully labeling the first four distinct graphs, she began to write about her pattern. However, on this graph she went back to the idea of using one graph to show her pattern (see Figure 6). She went and wrote how to label the nodes. She wrote "Example Graph." She then wrote "I start the one on the top node. Then take the biggest number and put it below. It goes in a pattern too. From Biggest to smallest."

After she finished, one of the researchers came and she showed them her pattern. The researcher attempted to further the idea with trying to figure out how to label the edges. After a brief discussion they left her with the question of what would the edge that connected the two Stars of the graph might be. Heidi decided that she needed to do a few more graphs to figure it out. She went and drew a Double Star Graph with twelve nodes (see Figure 6). After thinking for a while and looking at her previous graphs in the Double Star class, she furthered this pattern by describing "The top edge is always half of the biggest number. There for whatever the number for the edge is the node is one bigger."

While Heidi was able to find a way to label any graph in the Double Star class she went back to the idea of giving an example graph to explain her pattern. We found this similar to how she labeled her Star Graph and was a slight decline in her advancement of justifications and proofs. However, she did have a more advanced thinking about the graphs than any of her classmates by finding the idea that the edge connecting the two stars of the Double Star Graph was always going to be half of the biggest number and that the node connected to the edge would be one more than half the biggest number.

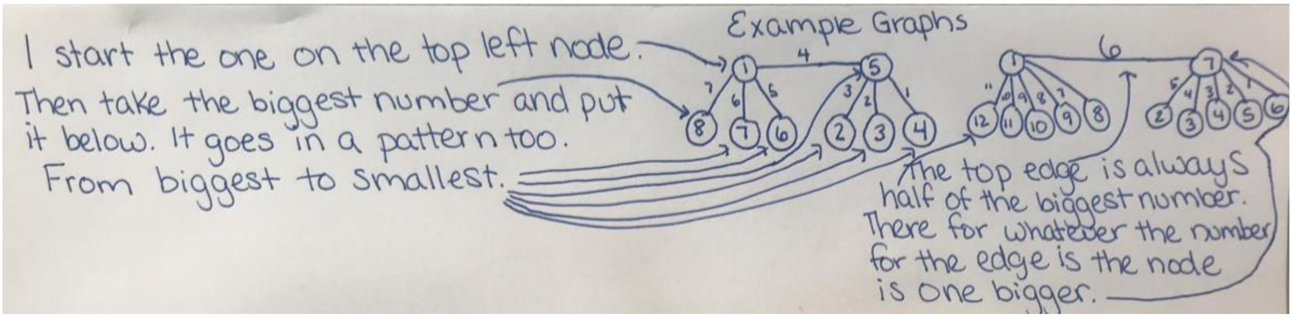

Figure 6: Heidi's Justification for Double Star Graphs

Caterpillar Graphs

Heidi asked if she could start on the next type of graph while her classmates were still finishing the previous graphs during the third session for which she had already completed her pattern. We gave her the Caterpillar Graphs on which to work. She began by completing the graphs with six, nine, and twelve nodes or the first three distinct graphs of Caterpillar class (see Figure 2).

She then drew the next graph in the class, a 15 node graph, and found a graceful labeling. She then went on to write about how she would label any graph in the Caterpillar class. She said, "I always put the one at the top far right node then put the biggest number on the bottom far right node and the second biggest number on the node next to it."

She continued by drawing a picture for how she would label any graph in this type of Caterpillar class (see Figure 7). However, this time she did not do an example of what she wrote as she had previously done for the Star Graph and the Double Star graph; rather, she completed her pattern by drawing a picture where she used the idea of biggest, second biggest, third biggest and so on. To show that her pattern would continue on, she used an ellipsis so show it would continue. She explained this idea as "So on." On this graph, Heidi did not explain how to label the edges but the researcher asked her how she labeled her edges and she verbally said they counted down in order from left to right.

Heidi showed an advancement again in her development on proof and justifications. She was able to complete a pattern and draw how to label any graph in this class similar to how she did for Path graphs.

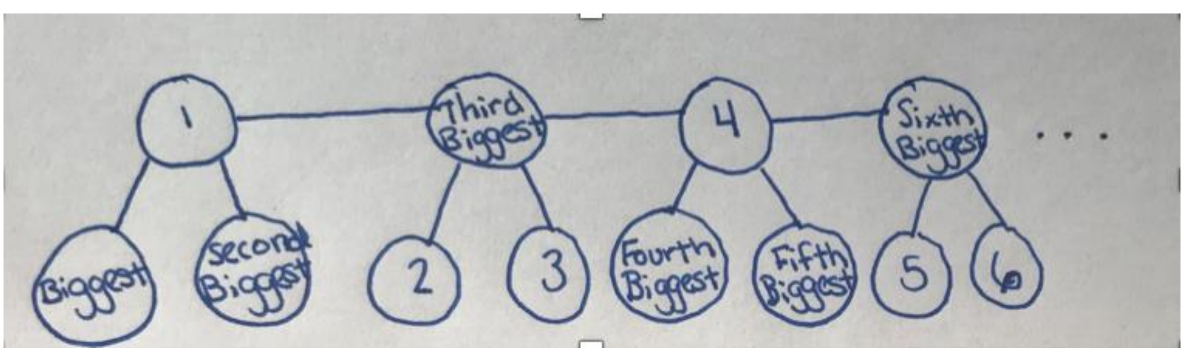

Figure 7: Heidi's Justification for Caterpillar Graphs

Conclusions

Carpenter et al. (2003) stated there are three ways students present a justification or argument, namely: appeal to authority, use an example, or give a generalized argument. We set up the situation so the fourth grade students were not able to appeal to authority because graph theory was not something they had prior knowledge of nor did the classroom teacher. The students tried to present a justification with an example. For Star Graphs, Heidi created an example to explain her pattern. She did this again on Double Star Graphs. However, on Path Graphs and Caterpillar Graphs, Heidi created generalized arguments for each. She even was able to include the ellipsis to show the pattern would continue indefinitely.

As a fourth grade student, Heidi developed through this experience from explaining how a pattern could be labeled through an example and words to creating a generalized argument for graphs in the second type of Caterpillar class. While she did not use the idea of a variable, which would not be common among fourth grade students, she was able to use terminology like the biggest number, second biggest number and so on. Further, on her first attempt at Caterpillar Graphs, she was able to discover that an edge labeling on a graph would be half of the biggest node whereas in previous graphs she only described biggest, second biggest, … numbers. In addition to finding success, Heidi, stated that she enjoyed the challenge of the activity and wondered if we would give her extra graphs to gracefully label.

This study could potentially influence the horizon of teaching because students are not typically given the chance to explore an unsolved graph theory problem in an elementary classroom. Beyond that, they are not typically given a chance to reason through an experience where they have to provide justification or proof. With the case of Heidi, she developed a more in depth understanding of what it meant to prove something with four opportunities. These types of experiences are important because students have the belief they should be able to finish a mathematics problem in five minutes or less (Schoenfeld, 1992) and we need students to understand that any good problem solving will take much longer than five minutes! Further research is needed in this area of discovery; what could happen if we went against the current horizon and shifted our expectations as a community of mathematics learners from a focus on conceptual and procedural understanding to a focus on proving, reasoning, and providing justifications for work?

IMPLEMENTACIÓN DE UNA ESTRATEGIA DE APRENDIZAJE FUNDAMENTADA EN UN SISTEMA DE GEOMETRÍA DINÁMICA

Daniel Ortiz-May
Cinvestav-IPN
daniel.ortiz@cinvestav.mx

Daniel Aguilar-Magallón
Cinvestav-IPN
aguilarm@cinvestav.mx

Se presentan los resultados de implementar una propuesta de aprendizaje enfocada en la resolución de problemas de variación con el uso de un Sistema de Geometría Dinámica (SGD). Los participantes del estudio fueron estudiantes de último semestre de bachillerato. En particular, interesó documentar cómo algunas 'affordances' del SGD permitieron a los participantes desarrollar e implementar ciertos recursos y heurísticas de resolución de problemas. Los resultados muestran que affordances como el arrastre de objetos, la medición de atributos y la generación y visualización de lugares geométricos fueron importantes, en primera instancia, para resolver problemas de variación con argumentos empíricos y visuales y, en segunda instancia, para formular conjeturas y presentar argumentos algebraicos.

Keywords: Resolución de Problemas, Cálculo, Tecnología, Educación Media Superior

1. Introducción

Un concepto fundamental en el marco de la resolución de problemas es el de heurística. Para Schoenfeld (1985): "las heurísticas son las reglas de oro para resolver problemas efectivamente. Son estrategias básicas para lograr progresos en problemas no familiares o difíciles" (p. 44). Polya (1965) ofrece una amplia lista de heurísticas, algunos ejemplos son: realizar analogías (considerar problemas similares o relacionados), descomponer y recomponer el problema (relajar las condiciones del problema), dibujar una figura o esquema, razonar el problema en forma regresiva, buscar objetivos particulares, obtener el resultado de diferentes maneras, entre otras. Aguilar-Magallón y Poveda (2017) argumentan que el uso de un SGD ofrece acercamientos que motivan diferentes episodios de resolución de problemas que involucran aspectos relacionados con la visualización, exploración y validación de conjeturas además de la generalización y exploración de resultados. ¿Cómo influye e impacta un SGD en el uso de heurísticas para resolver problemas? Esta pregunta es importante porque el SGD ofrece herramientas particulares y funcionalidades (*affordances*) que determinan los procesos de acción y respuesta que puede implementar el estudiante (Mackrell y Bokhove, 2017). En esta misma dirección, Leung (2011) menciona que las affordances que ofrece el SGD juegan un papel importante en el aprendizaje de las matemáticas:

> En el proceso de aprender cómo utilizar herramientas en una tarea matemática, los aprendices gradualmente construyen ideas matemáticas que son moldeadas por el empleo de las herramientas y que dan lugar a conceptos expresables en términos de la herramienta (p. 326).

Para este estudio resultó importante documentar los resultados de implementar una estrategia de aprendizaje diseñada alrededor de ciertos recursos y heurísticas de resolución de problemas mediadas por algunas affordances que ofrece el SGD. Estos resultados se describen en términos de estrategias que mostraron los participantes durante el proceso de resolver problemas de variación. En este sentido la pregunta de investigación que guio el estudio es: ¿Qué estrategias y formas de razonamiento exhiben estudiantes de bachillerato al resolver problemas de variación en un ambiente de aprendizaje basado en la resolución de problemas y uso de un SGD?

2. Marco Conceptual

Al emplear un SGD en como herramienta de aprendizaje en escenarios de resolución de problemas se simplifica la ejecución de heurísticas tales como el análisis de casos particulares y la observación de familias de objetos que cumplen ciertas características (Santos-Trigo y Aguilar-Magallón, 2018); además, un SGD constituye una herramienta útil para desarrollar ideas conceptuales relacionadas con la variación (Leung, 2008). En este sentido, el software y el individuo tienen una relación dinámica que ofrece permisibilidades y restricciones; por un lado, se conciben y abordan fenómenos matemáticos de maneras particulares que moldean el aprendizaje y, por otro, el uso del software delimita y enfoca la atención de los individuos hacia elementos matemáticos específicos (Calder y Murphy, 2018). Estas permisibilidades y restricciones se denominarán en este trabajo como *affordances*. El arrastre, por ejemplo, es una affordance que distingue los SGD y conforma una herramienta esencial que permite a los usuarios percibir la dependencia lógica, en términos del contexto matemático, a través del movimiento de objetos que es producido por el movimiento de otros objetos; esto requiere que la información perceptual sea interpretada en relaciones de condicionalidad. (Baccaglini-Frank y Mariotti, 2010).

Al respecto, Aguilar-Magallón (2018) propone una estrategia de resolución de problemas de variación dentro de un SGD llamada análisis dinámico de relaciones (ADR) basada en el arrastre de objetos y la generación de conjeturas matemáticas de condicionalidad. Esta estrategia es la conjunción de algunas heurísticas de resolución de problemas como relajar las condiciones del problema, analizar casos particulares y extremos, analizar y visualizar patrones e invariantes (Santos-Trigo y Reyes-Martinez, 2018) y affordances del SGD como el arrastre de objetos, medición de atributos de figuras, creación de puntos dinámicos y visualización de lugares geométricos. La estrategia ADR se describe principalmente en tres fases: I) *Representación*, en la cual se construye un modelo dinámico de la situación problemática; II) *Exploración*, en donde se identifican los atributos variables que se desean analizar en términos de puntos dinámicos que los relacionan; III) *Solución empírica*, en donde se visualiza la solución al problema de variación por medio del lugar geométrico del punto dinámico creado en la fase de exploración. La naturaleza ejecutable de las representaciones en un SGD dota de movimiento o variación a los objetos matemáticos que usualmente son estáticos en el papel, de modo que introduce nuevas epistemologías que afectan los enfoques de resolución de problemas de los estudiantes y por ende su proceso de aprendizaje de las matemáticas (Santos-Trigo y Moreno-Armella, 2016).

Así, el objetivo de la propuesta de aprendizaje fue que el participante se apropiara de la estrategia ADR como herramienta para resolver problemas de variación.

3. Metodología

La propuesta se implementó con un grupo de 22 estudiantes de bachillerato entre 17 y 18 años, como parte de un taller de Cálculo durante 5 semanas con dos sesiones por semana. Éstas se desarrollaron en aulas de cómputo, donde cada estudiante contaba con una computadora con el SGD (GeoGebra) instalado. Cada sesión estuvo guiada por la resolución de uno o varios problemas que los investigadores planteaban. Los participantes contaban con un momento inicial para trabajar individualmente o en grupos, posteriormente se realizaba una discusión plenaria acerca de las diversas formas de abordar el problema, en la cual los estudiantes exponían frente al grupo sus acercamientos y explicaciones. Finalmente, los investigadores cerraban la sesión con una síntesis. La propuesta se estructuró en tres etapas principales: una etapa de introducción al SGD, una de instrucción de la estrategia ADR y la tercera etapa, de implementación de la estrategia ADR. Las sesiones agrupadas por etapas se resumen en la Tabla 1.

Tabla 1: Organización general de la propuesta de aprendizaje

Etapa	Sesiones	Descripción
Introducción	1-3	Presentación de los aspectos básicos del SGD mediante actividades de argumentación.
Instrucción	4-6	Empleo de las Affordances del SGD para la generación de la estrategia ADR.
Implementación	7-10	Uso de la estrategia ADR para la resolución de problemas de optimización

Los datos del estudio se obtuvieron del trabajo de los estudiantes a través de sus archivos de GeoGebra, producciones textuales y videograbaciones de las sesiones. Los investigadores analizaron el trabajo de las sesiones y, para los fines de este documento, se seleccionaron episodios representativos de cada etapa, en los que se ejemplifican los procesos e ideas que las caracterizan. En la etapa de introducción, el problema representativo consistió en construir un triángulo rectángulo cuya hipotenusa fuera un segmento dado; en la etapa de instrucción, se presenta el problema de encontrar las medidas de un triángulo rectángulo inscrito en una circunferencia dada cuya área sea máxima y en la etapa de implementación, encontrar las medidas de un rectángulo inscrito en un triángulo rectángulo cuya área sea máxima.

4. Implementación y resultados

En esta sección se presentan los episodios representativos de cada etapa de la propuesta. Se destacan los procesos cognitivos que las affordances del SGD favorecieron para la consolidación de la estrategia ADR como una herramienta para resolver problemas de optimización.

Etapa de introducción. Se presentaron a los estudiantes aspectos elementales del funcionamiento de GeoGebra (trazo de puntos, segmentos y círculos) que sirvieron para la construcción de objetos geométricos de mayor complejidad: punto medio de un segmento, mediatriz de un segmento, un triángulo isósceles, un triángulo rectángulo y un cuadrado. Las discusiones se orientaron, principalmente, a la validación de las construcciones de los estudiantes, quienes no estaban habituados a este tipo de tareas. En la Tabla 2 se muestra uno de los problemas abordados en esta etapa con una solución presentada por uno de los estudiantes. En un principio las soluciones al problema planteado estuvieron basadas en aproximaciones, pues los participantes construyeron triángulos ABD (con D móvil sobre el plano) que visualmente parecían rectángulos, sin embargo, al mover cualquier vértice este no conservaba las propiedades de un triángulo rectángulo. Esta necesidad por obtener un modelo dinámico robusto (que conserve las propiedades estructurales de un triángulo rectángulo sin depender de los puntos móviles de la configuración) fue resaltada por los investigadores. Gracias a esta discusión, los participantes pudieron encontrar modelos robustos como el mostrado en la Tabla 2.

Tabla 2: Problema representativo de la Etapa de Introducción

Problema planteado	Aproximación dinámica

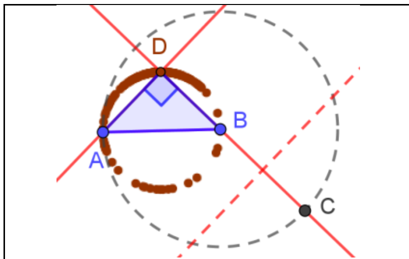
<table>
<tr>
<td>



Dado un segmento cualquiera AB, trazar un triángulo rectángulo que tenga por hipotenusa *AB*
</td>
<td>
Recursos y estrategias: arrastre de puntos, mediatriz, paralelismo.
Solución: Se traza la circunferencia de radio AB con centro en B; se coloca un punto móvil C en la circunferencia. Se traza la mediatriz de BC y la recta paralela a la mediatriz, que pasa por A. Luego, desde B se traza una recta que es perpendicular a la recta que pasa por A. El punto D es entonces la intersección de dos rectas que son perpendiculares, obteniendo así el triángulo rectángulo ABD.
Extensión: ¿Cómo se comporta el punto D cuando el punto móvil C se mueve a lo largo de la circunferencia? Con la traza se nota que D describe una circunferencia de diámetro AB.
</td>
</tr>
</table>

A partir de un análisis retrospectivo de la solución, se observa la implementación de una estrategia de generalización importante: con ayuda de la circunferencia con centro en B y el punto móvil C sobre ella se generó una familia infinita de rectas BC. Un fenómeno interesante que se observa en este acercamiento es que el trazo de la mediatriz no era necesario, sin embargo, es posible que el estudiante sintiera la necesidad u obligación de utilizar a la mediatriz, que había sido un recurso abordado en actividades anteriores.

Dado que el movimiento del punto *D* depende del movimiento del punto *C*, se planteó a los estudiantes utilizar la herramienta *trazo* de GeoGebra para estudiar la trayectoria descrita por *D*. Los participantes conjeturaron que la trayectoria seguida por el punto D era una circunferencia que pasa por *A* y cuyo centro es el punto medio *E* de la hipotenusa *AB* del triángulo (ver Figura 1). En este momento, la actividad se centró en demostrar dicha conjetura. Gracias a la herramienta de medición los participantes observaron que la longitud de los segmentos ED y EB eran iguales y constantes (argumento empírico). El investigador presentó un argumento geométrico basado en el rectángulo *BDAF* y la propiedad de que sus diagonales son congruentes y se intersecan en su punto medio.

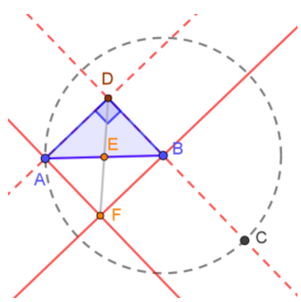


Figura 1: El punto *D* siempre está a la misma distancia del punto *E*.

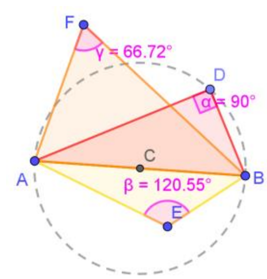

Figura 2: ¿Existe un triángulo rectángulo de hipotenusa *AB* cuyo tercer vértice no esté en la circunferencia de diámetro *AB*?

Esto quiere decir que existe una infinidad de triángulos rectángulos cuya hipotenusa es *AB*, sin embargo, el tercer vértice de todos ellos siempre está sobre la circunferencia de diámetro *AB.* De este modo, se planteó a los estudiantes la pregunta inversa: ¿es posible encontrar un triángulo rectángulo de hipotenusa *AB* cuyo tercer vértice **no** esté sobre la circunferencia que tiene por diámetro *AB?* En la Figura 2 se ejemplifica el tipo de exploraciones que los estudiantes realizaron con ayuda de la medición para conjeturar que no es posible: trazaron triángulos con base *AB* y cuyo tercer vértice estuviera dentro o fuera del círculo con centro en *C*. Gracias a esta exploración concluyeron que el ángulo en dicho vértice es obtuso (si está dentro del círculo) o agudo (si está fuera del círculo). De aquí se concluyó que un triángulo *ABC* es rectángulo con hipotenusa *AB* solo cuando *C* se encuentra sobre la circunferencia cuyo diámetro está sobre *AB.*

Cabe destacar que en esta etapa no solo se introdujo a los estudiantes al uso del SGD, sino que también se promovieron razonamientos propios de la resolución de problemas como lo son el análisis y validación de conjeturas.

La mezcla de aspectos tecnológicos y de contenido de esta etapa se observa en el empleo de estrategias de solución mediadas por elementos de la herramienta como la medición y el arrastre de puntos.

Etapa de instrucción. En esta etapa, es necesario que los estudiantes estén familiarizados con el SGD y con las nociones de función y variación. Una pieza clave en la estrategia ADR consiste en construir un punto dinámico relacional cuyas coordenadas corresponden a dos magnitudes variables dentro del modelo dinámico (longitudes de segmentos, medidas de ángulos, áreas, perímetros, etc.). La variación de las magnitudes depende del arrastre de un punto inicial en el modelo dinámico; si el punto inicial se mueve por una trayectoria bien definida (recta, circunferencia, cónica) es posible trazar el lugar geométrico del punto dinámico relacional. En la Tabla 3 se muestra el problema trabajado en la sexta sesión, el cual servirá como ejemplo del tipo de ideas trabajadas en esta etapa.

Tabla 3: Problema representativo de la Etapa de Instrucción

Problema Planteado	Aproximación dinámica
 Analizar los atributos de un triángulo inscrito en un semicírculo.	**Recursos clave:** Triángulo inscrito en un semicírculo, área de un triángulo, lugar geométrico, movimiento controlado, comando de abscisa de Geogebra. **Fase de representación:** Para obtener una configuración dinámica, se traza una circunferencia de radio *AB* y un triángulo con base igual al diámetro *CB* cuyo tercer vértice móvil *D* se mueve sobre la circunferencia. **Fase de exploración**: Definir el punto dinámico *E* cuya abscisa es la misma que la del punto *D* y su ordenada es el área del triángulo *BDC*. El lugar geométrico que describe *E* cuando *D* se mueve es una cónica. En este caso, se ha decidido explorar el comportamiento del área del triángulo. **Fase de solución:** Cuando *D* se coloque sobre el Eje *Y* se alcanza el punto máximo sobre la curva.

Se retomó la construcción del triángulo rectángulo y se empleó como un punto de partida para iniciar un análisis variacional que los investigadores plantearon de manera abierta al grupo: ¿qué atributos de la figura varían y pueden ser estudiados? La primera propuesta fue explorar el área del triángulo en función de la abscisa del punto *D.* En este caso, el punto *D* funge como punto inicial, y su trayectoria de movimiento está bien definida (dentro de una circunferencia). Así, los estudiantes definieron el punto dinámico relacional *E=(x(D), t1)* con ayuda de la barra de entrada de GeoGebra, donde *x(D)* es el comando que calcula el valor de la abscisa del punto *D* y *t1* es el valor numérico del área del triángulo *CBD* (Tabla 3). Empleando la herramienta de lugar geométrico, los participantes trazaron la trayectoria descrita por el punto *E* a medida que *D* se mueve, obteniendo la mitad de una elipse. Los participantes conjeturaron que cuando *D* se coloca *directamente sobre* el punto *A,* se obtiene un triángulo cuya área es máxima y, visualmente, notaron que para cualquier otra posición de *D* el triángulo tenía un área menor. Posteriormente, se les solicitó a los estudiantes trabajar en parejas, o individualmente, en proponer y estudiar otras relaciones y analizar si en ellas existen máximos (o mínimos); algunas de las propuestas fueron:

- La longitud de alguno de los catetos en función de la abscisa del punto *D*.
- El área del triángulo, en función de la altura del triángulo.
- El perímetro del triángulo, en función de la abscisa del punto *D*.

En este reporte, solo se presentará el análisis de un estudiante acerca del primer punto. En la Figura 3 el punto dinámico relacional *E* tiene por coordenadas *(x(D), b)*, donde *b* es la longitud del lado *AD*. El lugar geométrico que describe *E* a medida que *D* se mueve permite observar que *D* puede aproximarse a *B* tanto como se desee, incrementando arbitrariamente la longitud de *AD*, sin embargo, si esos dos puntos coinciden, no se genera un triángulo.

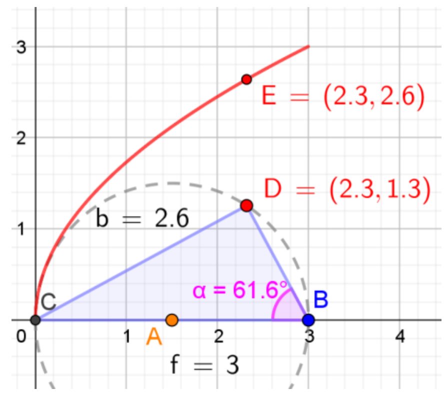

Figura 3: Relación dinámica entre la abscisa del punto *D* y el cateto *b*

Como una exploración adicional, el estudiante identifica la relación *sen*(α)=|*AB*|/|*BC*| Por lo que genera otro punto dinámico relacional *F* que tiene por coordenadas *(x(D), e)*, en donde *e*=*f*·*sen*(α) y *f* es la hipotenusa del triángulo. El estudiante comprueba que su razonamiento es correcto ya que al definir ese punto, *E* y *F* siempre están superpuestos al mover el punto *D*, e incluso cuando el diámetro de la circunferencia inicial incrementa. La producción de este estudiante exhibe la manera en que los objetos observados en el SGD constituyen una plataforma que favorece la abstracción de las variables. Es decir, aunque solo puedan percibirse instancias particulares (por ejemplo, en la Figura 3 |*CB*|=*3*), es posible concebir que las medidas estáticas que observan en la pantalla representan magnitudes que pueden variar libremente. Este estudiante no emplea el valor particular de *AB* para establecer la relación trigonométrica del cateto, aunque *AB* se mantenga constante cuando *D* se mueve, sino que introduce el *nombre* que el SGD asigna a la hipotenusa, pues es consciente de que todos los elementos de la construcción pueden variar.

Etapa de implementación. La estrategia ADR es una potente herramienta para comprender e interpretar problemas de optimización en contextos geométricos. En la sesión 10 se planteó el problema de encontrar las medidas (lados y área) de un rectángulo con área máxima inscrito en un triángulo rectángulo, tal que dos de los lados del rectángulo estén sobre los lados del triángulo (ver Tabla 4).

Tabla 4: Problema representativo de la Etapa de Implementación

Problema planteado	Aproximación dinámica

<table>
<tr>
<td>Encontrar las medidas de un rectángulo inscrito en un triángulo rectángulo cuyos catetos miden m y n tal que su área es máxima.</td>
<td>Recursos clave: Perpendicularidad, área de un triángulo, área de rectángulos, movimiento controlado, lugar geométrico
Fase de representación: Se traza el triángulo ABC cualquiera, con catetos sobre los ejes. Se construye un punto D móvil sobre la hipotenusa y se trazan las perpendiculares hacia cada eje. El rectángulo BEDF cumple las condiciones iniciales.
Fase de exploración: El punto dinámico G relaciona la posición de D sobre la hipotenusa y el área del rectángulo correspondiente. El lugar geométrico de G cuando D se mueve es una parábola.
Solución empírica: Si D es el punto medio de la hipotenusa, G se ubica en el vértice de la parábola. Los lados del rectángulo BEDF miden la mitad de los catetos del triángulo ABC.</td>
</tr>
</table>

En el proceso de construir una configuración dinámica, debe considerarse que las dimensiones del triángulo y las del rectángulo varían, es decir, se presentan dos formas de variación. Distinguir entre ambas formas de variación es fundamental para la implementación apropiada del ADR. Si bien el problema es general, algunos estudiantes comenzaron analizando el caso particular cuando el triángulo rectángulo dado es isósceles (ver Figura 4). El punto *D* es móvil sobre AB y el punto dinámico G tiene por coordenadas el lado AD (la abscisa) y el área del rectángulo (la ordenada). El lugar geométrico descrito por *G* parece ser una parábola.

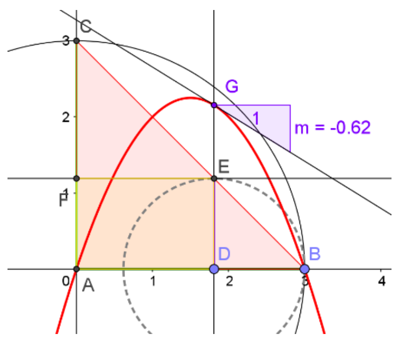

Figura 4: Configuración dinámica del problema del rectángulo inscrito

De manera empírica, la estudiante concluye que cuando el rectángulo es un cuadrado, se alcanza el área máxima y que los lados del cuadrado miden la mitad de los catetos del triángulo. Para apoyar esta idea, la estudiante se da la tarea de explorar el comportamiento de las rectas tangentes a la curva descrita por el movimiento de *G*. Geogebra no admite ciertas acciones sobre los lugares geométricos, de modo que encontrar la ecuación que describe la curva se convierte en una tarea impuesta por la necesidad de interactuar con ella. Su proceso es como sigue:

> Estudiante: Sabemos que para sacar el área de un rectángulo utilizamos base por altura, por lo tanto, en este caso usé la fórmula de $S=x(a–x)$ tomando en cuenta que x es el segmento *AD* la cual tomaríamos como base y $a–x$ es el segmento *DE*. Para justificar esto se hizo una circunferencia de radio *DB* y vemos que la altura es igual al radio del círculo, *DE* y *DB* son iguales.

Cabe destacar que la estudiante es consciente que la gráfica de la ecuación que encuentra y el lugar geométrico descrito por *G* deben mantenerse superpuestas al variar el *AB*, de modo que emplea la variable *a* en la expresión, la cual representa la medida general de los catetos del triángulo. Una vez concluido el caso particular, se procede a verificar si en el caso general la solución se mantiene. Puesto que conseguir una expresión analítica de la función área en el caso general demanda mayor esfuerzo, los estudiantes no consiguieron ofrecer argumentos algebraicos para la solución general, sin embargo, fueron capaces de afirmar que el rectángulo inscrito de mayor área siempre posee un medio del área que el triángulo rectángulo dado y que sus lados miden la mitad de los catetos del triángulo.

Aunque el objetivo de la propuesta nunca fue el de emplear el método analítico tradicional por el cual se resuelven los problemas de optimización (criterio de la primera derivada), el SGD dota de cierta materialidad a los conceptos de variable que podría fungir como una forma de dar sentido a los procesos analíticos por la necesidad de interactuar con ella. En la Figura 4 se muestra una exploración adicional, en la que los estudiantes observan el comportamiento de la pendiente de una recta tangente a la curva en *G*, y a media que se aproxima al vértice, la pendiente tiende a cero. Esto representa un ejemplo del tipo de oportunidades y acercamientos que el empleo del SGD ofrece para ayudar a los estudiantes a interpretar y comprender conceptos esenciales del cálculo.

5. Conclusiones

Parte esencial del trabajo en la propuesta de aprendizaje fue la de introducir elementos pedagógicos en la estrategia ADR. Para conseguir que los estudiantes se apropien del ADR como una heurística en la resolución de problemas, fue necesario crear un campo propicio de trabajo en el que las ideas matemáticas fundamentales fueran desarrolladas junto con la tecnología, de modo que la estructuración de la propuesta en etapas jugó un papel importante. Cada etapa estuvo marcada por la consecución de objetivos necesarios, que contribuyeron a la implementación del ADR. En la primera etapa, se trabajó con tareas de construcción orientadas a prácticas argumentativas, apoyadas en las affordances del SGD: los estudiantes comprobaban sus resultados con ayuda de la medición de segmentos y ángulos, o verificando que sus construcciones se mantuvieran coherentes ante el arrastre de los puntos involucrados; En la etapa de instrucción, fue clave el papel de la parametrización de lugares geométricos en el trabajo de los estudiantes, pues estos procesos fungieron como antesala a la producción de argumentos geométricos y algebraicos. El uso del SGD probó ser de gran ayuda en la abstracción de variables por parte de los estudiantes, ya que estas eran representadas por segmentos cuya variación podía ser percibida de manera concreta. Finalmente, en la tercera etapa, los estudiantes fueron capaces de integrar recursos geométricos y visuales para la construcción de configuraciones dinámicas como representaciones de un problema y, a partir de los elementos ofrecidos por el SGD, obtener conjeturas de las soluciones de problemas de optimización.

6. Agradecimientos

Se agradece el apoyo recibido del proyecto SEP-Cinvestav-12 durante el desarrollo de esta investigación.

IMPLEMENTATION OF A LEARNING STRATEGY BASED ON A DYNAMIC GEOMETRY SYSTEM

We present the results of the implementation of a set of instructional activities that focused on solving variation problems with the use of a Dynamic Geometry System (DGS). The study was conducted with high school students in their calculus course. Particularly, we were interested in documenting how some affordances of the DGS allowed the participants to develop certain problem-solving resources and heuristics. Results show that affordances such as dragging objects orderly, measuring objects and tracing some objects loci were important, at first instance, in the process of solving variation problems with visual arguments and, secondly, for the formulation of conjectures and presentation of algebraic arguments.

CHARACTERIZING EVOLUTION OF MATHEMATICAL MODELS

Jennifer A. Czocher
Texas State University
Czocher.1@txstate.edu

Hamilton Hardison
Texas State University
HHardison@txstate.edu

Formulating a mathematical model is a dynamic process, and attending to changes in students' models as they engage in modeling tasks is critical for informing pedagogical interventions. In this report, we coordinate constructs from literature on mathematical modeling, quantitative and covariational reasoning, and semiotics to characterize changes in mathematical models. We illustrate the application of these constructs using data from an undergraduate solving a modeling task.

Keywords: Modeling, Using representations

Mathematical modeling remains an important skill for K–20 students (Bliss et al., 2016; CCSSM, 2010), and relatively little is known about how to prepare teachers to interact with a student-modeling task dynamic. This is partly because the field has yet to bridge task-centered analyses common to research with teacher-centered "tips" on what to notice in students' work, because it is not clear what to direct teachers to focus on as students model. A cognitive view of modeling (Kaiser, 2017) can be leveraged to provide just such a link. A detailed exploration of how a mathematical model evolves with an eye toward identifying pivotal moments in students' reasoning that could be used for teacher education and teacher intervention has yet to be undertaken. In particular, it would be useful to teachers and teacher educators to know when, how, and with what level of scaffolding to intervene in a student's modeling process, since the best results from teaching with a modeling approach are obtained when students work out their own solutions (Kaiser, 2017). To make progress in this area, it is first necessary to address the methodological problem of articulating criteria for determining whether, and the extent to which, a student's model has changed. In this methodological paper, we will use micro-analytic techniques to document the changes that a student introduces to his model and network a set of theoretical constructs for explaining those changes.

Theoretical Perspectives

The target construct in this exploratory work is *model evolution*, specifically, revisions that a student might make to his/her model during mathematical modeling. A priori, there are several related theories and attendant constructs that might serve to articulate and trace changes to a model (elaborated below) that offer partial explanations of how individuals' models evolve. The Networking Theories Group (2014) proposed strategies like combining, coordinating, integrating locally, and synthesizing, for conducting parallel analysis of empirical phenomenon. Combining and coordinating involve generating "deeper insights into an empirical phenomenon" (p. 120). Integrating and synthesizing involve development of new theory by building on a small number of already-stable theoretical approaches. Here, we foreground our efforts coordinating theories of symbolic forms, multiple representations, and quantitative reasoning. We use one undergraduate's work on a modeling task to facilitate the theory-building. The end result is a method for using observable indicators to trace the evolution of a model. We then apply the method to identify and characterize significant conceptual hurdles experienced by the student, along semiotic and cognitive (Greca & Moreira, 2001) dimensions.

The mathematical modelling process is often conceptualized as an iterative cycle. One approach to studying individuals' modeling activity is to examine what are termed *modeling competencies* (Kaiser, 2017; Maaß, 2006). This approach is cognitive in nature and addresses how students come to understand a real problem and choose mathematical representations for it as they work on challenging tasks, which encourage accounting for various constraints. These competencies are *not* meant to suggest student abilities, but rather describe *phases* of modeling in a way that opens the process to observation and analysis. Phases include formulating a problem to solve (identifying aspects or characteristics that need to be modeled), systematizing (selecting relevant entities and relationships, identifying variables, making assumptions, or estimating parameters), mathematizing (representing entities and relationships in mathematical notation), analyzing (using mathematical techniques to arrive at mathematical conclusions), validating (evaluating the model and establishing its scope), and communicating (sharing conclusions obtained from its use) (Blomhöj & Jensen, 2003; Blum & Leiß, 2007). Student decisions made during each phase contribute to the dynamic evolution of the model. The systematizing and mathematizing phases can be viewed as model construction whereas validating and verifying can be viewed as a reflective monitoring process (Czocher, 2018). Empirically, the phases do not proceed linearly (Czocher, 2016) and the process draws on a complex interplay of mathematical, nonmathematical, and perhaps even scholastic knowledge (Stillman, 2000). Throughout these phases, the model can be refined, modified, or entirely rejected (and replaced) as it evolves to meet the modeler's problem-solving needs. In the next sections, we lay out additional relevant theories that offer insight into ways models could change.

Greca and Moreira (2001) argued that comprehension of a topic in physics is tantamount to being able to predict phenomena without needing to reference mathematical formalism. They distinguish among physical models, mathematical models, and mental models, while also maintaining that an integration of all three is necessary for building understanding. In their elaboration, "a *physical theory* is a representational system in which two sets of signs coexist: the mathematical signs and the linguistic ones" (p. 107). Physical theories are not direct presentations of observations of phenomena or objects; instead, statements of physical theories are about simplified and idealized physical systems, which they term *physical models*. The role of mathematics, then, is to formalize the theory as statements without semantic content. They characterize the *mathematical model* as a "deductively articulated axiomatic system, which can express the statements of the theory in terms of equations" (p. 108), but also acknowledge that the term may also extend to the mathematical theory the syntactic structure is derived from. *Mental models*, then, are internal and idiosyncratic representations of phenomena, which contrast physical and mathematical models which are socially mediated. Finally, they posit "families" of distinct mental models that serve as explanations for phenomena. For example, explaining a physical phenomenon like motion as interactions of forces rather than as a consequence of a linear, causal agent. Greca and Moreira's (2001) demarcation and explanation of interaction among mental, physical, and mathematical models is compatible with a competency view of mathematical modeling, even extending from physics education to modeling other phenomena of interest. We note some changes in vocabulary. We use *mathematical representation* to refer to an outward expression of an individual's mathematical model (Greca and Moreira's "mathematical model"). *Mathematical model* refers to the attendant conceptual system. Empirically, only the mathematical representations are observable, though changes in these may indicate shifts in students' perceptions of the relevant mathematical or physical concepts.

We take two further positions from mathematics education. First, we hold that mathematical models can be expressed in other conventional forms, besides equations (e.g., tables, graphs, words, etc. (Hitt & S., 2014)). Second, the modeling cycles that are common descriptions of students' mathematical modeling activity tend to conceptualize the modeling process as deriving mathematical expressions and variables from the physical problem. In contrast, Greca and Moreira (2001)asserted that variables in equations have meanings only *after* the they are interpreted through a physical model. From our own experience, we suggest that there may not be a general rule regarding whether the mathematical model or the physical model come first when addressing the kinds of modeling problems that are found in educational research. However, the point is tangent to two other useful theories: Sherin's (2001) elaboration of how individuals use mathematical models as templates to adapt to the problem at hand and Thompson's (2011) theory of quantitative reasoning.

A priori, mathematizing a situation would involve generating mathematical models and assigning semantic meanings drawn from physical models of physical theories. Identifying quantities and describing how they vary is just such a link. Thompson's (2011) theory of quantitative reasoning offers relevant insights. First, Thompson asserts that quantities are mental constructs, not characteristics of objects in the world. It immediately follows that a *quantification process* is carried out by an individual in order to conceive of quantities and that the process is non-trivial. Quantification is taken to mean "the process of conceptualizing an object and an attribute of it so that the attribute has a unit of measure, and the attribute's measure entails a proportional relationship (linear, bilinear, or multi-linear) with its unit" (p. 37). One can then also imagine an object, an attribute, and a measure in such a way that the value of the measure takes on different values at different moments. Observing a phenomenon and conceptualizing that there are quantities and that they can vary (or may be constant) is foundational to formulating physical models and articulating physical theories. These mental acts may become quite familiar or nearly automatic if one has much experience in the context. For example, quantities like distance and velocity may be more readily available for high school students than torque, electrical current, or GDP.

Quantitative reasoning entails conceiving of quantities and relationships among quantities. Thus, deriving a mathematical model entails quantitative reasoning. However, conceiving of covarying quantities is a non-trivial mental act. Thompson (2011) explains that covariational reasoning involves conceiving of invariant relationships among quantities whose values may vary independently. The difficulty lies in imagining how a situation can change, the quantities conceived from it can change, but that a relationship among them stays the same. In deterministic language, mathematical modeling entails discovering the invariant relationships that govern the quantities involved. Coordinating quantities and attending to relationships among quantities, variant or invariant, is *covariational reasoning* (Carlson, et al., 2002). It involves identifying ways to combine quantities through operations and trace their changes, rates of changes, and intensities of changes whether they are directly measurable or not (e.g., Johnson, 2015). Relationships can be identified through observation, a priori reasoning, or through knowledge of principles rooted in physical theory. When these relationships are expressed externally in mathematical notation, they become the mathematical representation of a physical model. The mathematical representation brings with it the relevant mathematical model (mathematical concepts, objects, and structures) and the physical meanings of its constituents (attributes, measurements, quantities). Thus, the theory of covariation in conjunction with theory of quantification elaborates an important aspect of how physical models are formalized into mathematical models.

At its core, a mathematical model presents a system of signs used to stand in for a physical system. Naturally, a theory of modeling should attend to semiotic processes that imbue meaning to the signs and to how (perhaps multiple) systems of signs are coordinated. Following Kehle and Lester's (2003) application of Piercian semiotics to mathematical modeling, we view as a process of unification among a sign, a referent (the object the sign stands for), and an interpretant. The interpretant has a dual role; it is the individual's reaction to the sign and object and simultaneously defines the sign/object pairing through the individual's reaction. Generally, interpretants can be actions, emotions, thoughts, or ideas. An interpretant is the fundamental unit of inference between an object and a sign and it is subjective and idiosyncratic.

Sherin's (2001) theory of symbolic forms, which explains how meaning is read from equations, can be construed an extended example of semiosis. A symbolic form consists of a template and a conceptual schema (the idea to be expressed in the equation). For example, _ + _ = _ expresses a "parts-of-a-whole" relationship. The blanks can be filled with a single symbol or a group of symbols representing quantities or combinations of quantities (perhaps related via other symbolic forms). Familiarity with symbolic forms helps individuals "know" to use certain operators (e.g., + or ×) and to know where to place the symbols of quantities in an equation.

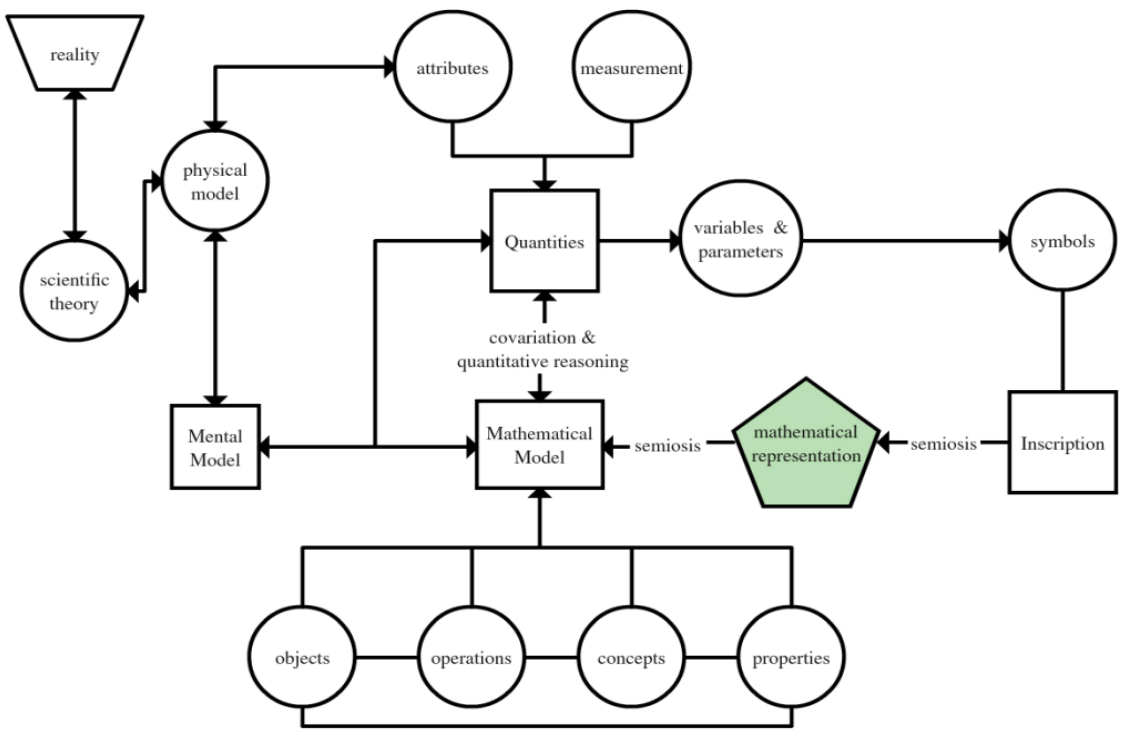

Figure 11: Networking of Major Theoretical Constructs (rectangles), Components (circles), and Mental Processes (arrows) to Hypothesize Sites for Change in How Physical Meaning is Projected onto Mathematical Symbols.

These theories operate at different grain sizes, were developed among different populations, and have different scopes. They are also asymmetrical in terms robustness. However, each layer of theory suggests a dimension of evolution and offers nuance to describe changes in a model at varying grain sizes. The networked theories are shown in Figure 11.We suggest that attending to the aforementioned constructs may produce a more comprehensive and nuanced account of how a student's mathematical model evolves.

Methods

To illustrate the coordination of constructs outlined above, we draw on data generated from a larger project examining instances of students' validating activity as they solved modeling, application, and word problems. Participants ranged from 6th grade to undergraduates. Here, we focus on Merik, an engineering major who had completed Calculus III (vectors) at a large southern university, and his work on The Monkey Problem. Merik's work was purposefully selected to explore the plausibility of the networked theory and articulate criteria for identifying changes in a model because (a) he was exceptionally verbal, (b) he often explained his own reasoning without prompting, and (c) he used multiple approaches to solve the problem.

> ***The Monkey Problem***: *A wildlife veterinarian is trying to hit a monkey on the tree with a tranquillizing dart. The monkey and the veterinarian can change their positions. Create scenarios where the veterinarian aims the tranquilizing dart to shoot the monkey. (And later: create models to represent the situation).*

The networked theory predicts that evolution of Merik's model might proceed along external (symbolic) or internal (meaning-making) dimensions. Thus we conducted three parallel analyses that could highlight opportunities to observe the representation or its meaning changing. The first coded Merik's work according to a modeling competencies framework (Blum & Leiß, 2007; Czocher, 2016) to document the phases of modeling, specifically *validating* activity since it is hypothesized to precipitate changes to the model. The second documented the various representations Merik used to capture and express his reasoning mathematically. The third sought evidence of shifts in meanings of the representations.

To analyze representations, we acknowledged that "what we ultimately observe are the external components (representations), but these cannot be disengaged from the conceptual systems" (Lesh & Doerr, 2003, p. 213). We introduce the term *inscription* to mean writing without implying anything about the inscription serving as a sign. We use the term *representation* to imply that the inscription serves as a sign for Merik. These theoretical commitments necessitated that methodologically we search for overt changes to inscriptions as indicators of changes to the model and separately search for evidence of changes to the cognitively-generated meanings for those inscriptions. To trace changes to representations, we first documented changes to inscriptions by attending to their spatial and temporal organization on Merik's paper. In the first case, we judged his model to have changed if either (1) the system of signs comprising by the representation changed (i.e., the type of representation changed, introducing a symbolic equation after working with a graph) or (2) a new inscription was created in a different location on the page. Each new mathematical representation was called a *parent*. We judged Merik's model to have changed through considering whether Merik's attention switched to another parent and whether there were substantive changes to the parent. To identify substantive changes, we considered (a) whether there was evidence to infer that information or meaning was distributed to the representation or removed from it, (b) whether Merik modified an inscription, or (c) whether Merik modified an inscription in a way suggestive of transporting meaning to or from another parent. We considered these alterations to a parent representation as a *child*. Children amending the same parent were called *siblings*. We recorded the *first time* an inscription was introduced and briefly annotated the nature of the change.

For example, Merik's first inscription appeared at time 0:51 (**Figure 12**). We labeled his *tree representation* as Parent 1 and this first version as Child 1A. At time 2:10, Merik added inscriptions x, θ, y producing Child 1B. Merik's talk indicated that these symbols were signs standing for the quantities *distance between veterinarian to the tree*, *distance from monkey to the ground*, and *angle formed by the veterinarian aiming his dart gun at the monkey*, respectively. His talk about 1A yielded evidence of both an implicit physical theory (kinematics) and an implicit mathematical model (right triangle geometry). The modification of the inscription from 1A to 1B signals introduction of quantities. At 2:38, Merik inscribed a new parent (#2), capturing his ideas that the dart, due to gravity, would not travel along a linear path but rather a parabolic one. The change, combined with his talk, and in addition to introducing gravity explicitly as a quantity, indicated that his mental model and physical model had shifted, necessitating a new mathematical model and mathematical representation. The symbolic form used in Representation 2A was _ - _ . It combined velocity and gravity. Notably absent are an explicit reference to time as a variable (though implicitly it was present in his talk as a quantity) and dimensional analysis. At time 4:25, Merik returned to Representation 1C, substituting in specific numbers for *x*, *y*, and *h* (with *h* standing for "hypotenuse"). We infer these symbols were parameters for Merik that could be fixed momentarily and changed from scenario to scenario.

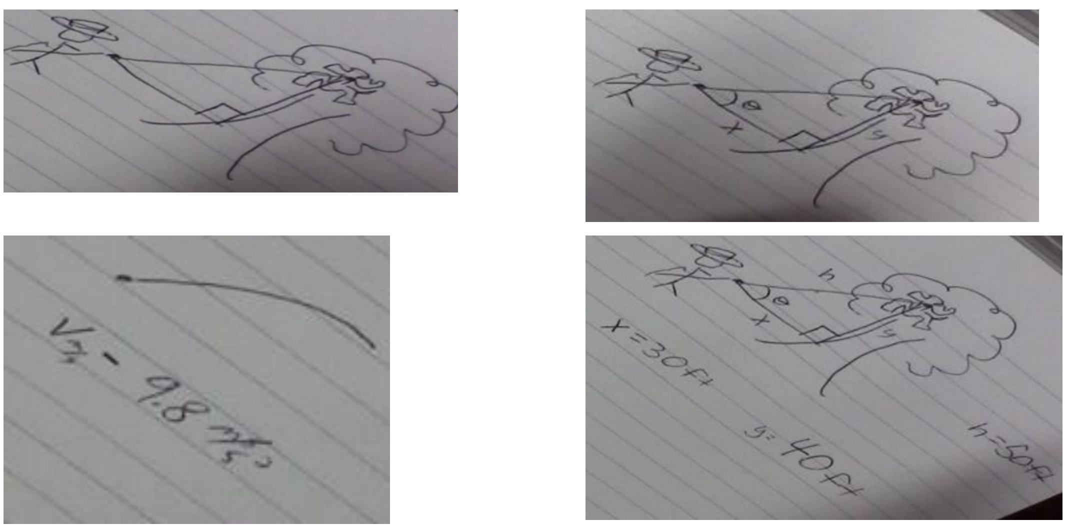

Figure 12: Merik's Representations
Clockwise from top left: Representations 1A, 1B, 1C, 2A

To help us visualize the evolution of Merik's representations, we plotted the parent and child representations over time by recording each time it could be inferred that Merik's attention was on a given sibling (Figure 13). The parent and sibling tracking system allowed us to resolve methodological issues distinguishing representations and models from one another. We next sought shifts in mental, physical, and mathematical models, and quantitative reasoning.

Results

Seventy-four total explicit switches in attention and modifications were identified belonging to 11 distinct parent representations (comprising 22 temporally distinct siblings). The introduction of new parent representations signaled either that Merik was refining existing ways of thinking or to introducing new approaches (see Figure 13 for evolution over time). Of the 31 instances of validating identified using techniques from Czocher (2016), only 10 co-occurred with a shift in (any aspect of) the model, suggesting that most adjustments were not consequences of validating. We share three examples of model evolution in detail.

One

At time 9:45, Merik introduced Representation 4A: $f(x) = Ax^2 + Bx + C$, a standard form quadratic equation because he asserted that it would trace the motion of the dart. At his time, he had already introduced x as distance between the veterinarian and the base of the tree holding the monkey. However, he treated the equation as a symbolic form combining quantities for initial position (*C*) and gravity (*A*), evidenced by his substitutions (representation was "$= -10x^2 + Bx + 0$"). He set $f(x)$ = 0 and solved for B obtaining $B = \frac{94}{3}$ and finally representation 4C, $f(x) = \frac{94}{3}x - 10x^2$. His attention shifted back to Representation 1 and he created 1D by inscribing a parabolic arc to connect the veterinarian and the monkey, leaving the hypotenuse of the triangle in place. Throughout this excerpt we infer that Merik was attempting to describe a spatial parabola, yet the substitutions in his symbolic form suggested a temporal component he did not explicitly attend to. By this we mean that his physical model included a trace of the path of the dart which can be described as a parabola. However, his mental model, which helped him to interpret the meaning of the symbolic form included a temporal component to which he did not explicitly attend. Thus, from our perspective, the meanings ascribed to the representations did not align; however, Merik initially indicated no misalignment due to his certainty that the situation could be represented with a quadratic form. It was not until 15:34 that Merik acknowledged that time would play a role in the quadratic equation, noting that "So yeah, um, x would be time, which means I couldn't use, yeah plugging in these [gestures to x=30 and y=40 in representation 1C] did nothing cause this equation is based on time." This analysis foregrounds the importance of explicit quantitative referents for variables when symbolic forms are used to generate mathematical models and that covariational reasoning was largely absent.

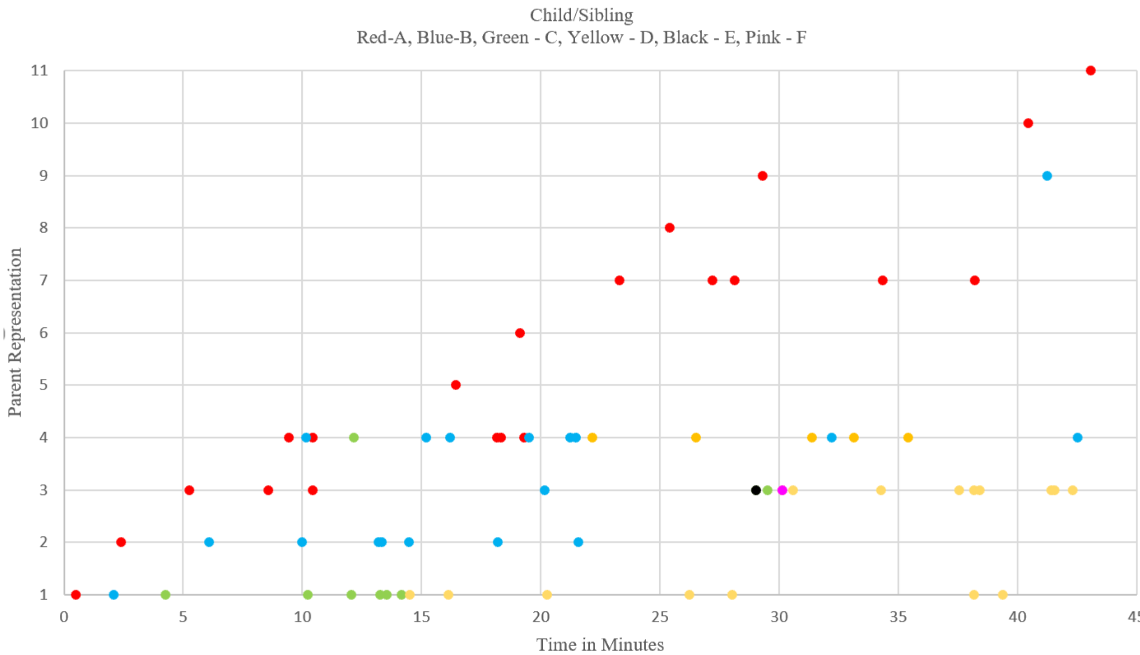

Figure 13: Evolution of Merik's Representations

Two

At 16:45, Merik introduced an analogical problem situation. He described trying to swim across a river with a current. He explained that the situation “applies the same with gravity because of the flow of the river going this way is just your rate of gravity working downwards, but your motion is that way.” Introduction of a sketch of the river (Figure 14) is indicative of abductive reasoning (a type of semiotic inference). The shift leverages a different physical model to support his mental model of how the motion of the dart could be modeled, but still using kinematics as a physical theory.

Three

At 27:18, Merik summarized a difficulty that had emerged in treating the path of the dart as a parabola: he could not use right-triangle trigonometry to determine the launch angle. He acknowledged that it shouldn’t matter that the path was curved. The interviewer intervened with the intention of suggesting an additional mathematical model: angle between tangent vectors. She asked “Can you think of a way that you might be able to find an angle measure between two curves? Have you ever studied anything like that?” She asked him to draw to curves in an xy-plane. He said, “I guess a straight line can be a curve,” and produced representation 3E (**Figure 14**). Merik realized, from a mathematical representation that did not overtly have meaning connected to the monkey problem that he could use tangent lines to curves (via derivatives) to find the angle subtended by the two curves in question. He concluded, “that’s the direction…at that exact instant which means that’s where it’s aimed. So if you do it from the point that leaves the barrel that’s the way…”. Later, at 29:30, he introduced representation 9A, a version of the law of cosines, to express θ. He also confirmed that θ would be a function of x, progressively attaching more information (in the forms of quantities, relations, and dependencies) to his representation. This analysis demonstrates that a shift in mathematical model co-occurred with a static physical theory (kinematics) and static mental mod

el (projectile follows an arc).

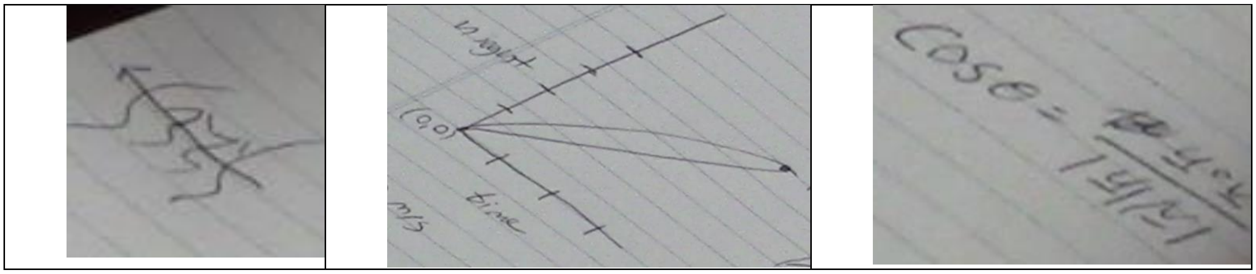

Figure 14: Representations 5A (river), 3E (coordinate axes), and 9A (law of cosines)

Our analysis exemplifies the complexity and richness of mathematical modeling when accounting for the attendant cognitive acts. We have networked theories to hypothesize and then demonstrated empirically several dimensions along which a model can change, including the adding or taking away from the inscriptions themselves, shifting attention among representations, introducing or removing quantities (attributes and how they are measured), semiotic processes (ascribing or shifting meaning of an inscription), mathematical models (including concepts, objects, operations, or procedures), physical models, and mental models. Thus, we demonstrated the plausibility of integrating the networked theory to explain the evolution of a mathematical model by tying together theories of modeling, quantitative reasoning, covariational reasoning, and semiotics.

Shifts in the ever-evolving model are important to identify because they co-occur with the critical competencies of mathematical modeling and are junctures where new ideas can be introduced and developed. We hold that sensemaking and monitoring are ongoing throughout mathematical modeling, noting that tracing representations is only partially predictive of shifts in the model. It will be important to also trace shifts evident in the students' speech that do not co-occur with changes in inscriptions. Though the Monkey Problem did not call for it (Merik worked solely within kinematics), we can easily imagine student-task interactions where a shift in physical theory is called for. We further identified at least two sites for facilitator intervention: one that was used successfully (supporting Merik in finding a mathematical model that would allow him to completely determine an angle) and one that was missed by the interviewer (the mis-alignment between a spatial and temporal parabola). Finally, we posit that the richness of structures is created and maintained through quantitative reasoning. We recommend that future research explore a parallel analysis that would trace quantification as the evolutionary thread rather than representations.

We address the question: How can a student's conceptual transition, from attending only to singleton units (1s) given in multiplicative situations to distinguishing composite units made of such 1s, be explained? We analyze a case study of one fourth grader (Adam, a pseudonym) during the course of a video recorded cognitive interview. Adam's case provides a glimpse into this process, as he proceeded from solving a prompt-less version of the multiplicative situation to two versions that gave gradually more explicit hints for those two types of units. We postulate an inferred process in which Adam reflected on the relationships between his counting actions (of cubes and towers) and the effect of those actions being different numbers pertaining to different units. We discuss the theoretical importance of explaining this transition and its practical implication of understanding whole number multiplication (e.g., array).

Keywords: Reasoning and Proof, Learning Trajectories, Number Concepts and Operations

In this case study of a fourth-grade student named Adam (pseudonym), we addressed the question: *How can a student's conceptual transition, from attending only to singleton units (1s) given in multiplicative situations to distinguishing composite units made of such 1s, be explained?* Our study is situated within and contributes to the body of research focusing on students' units coordination as a conceptual lens to explain multiplicative reasoning (Steffe, 1992; Norton et al., 2015; Ulrich, 2016). These researchers demonstrated that, to reason multiplicatively, a student needs to coordinate and simultaneously operate on at least two qualitatively distinct types of units: singletons (1s) and composite units comprised of such 1s. Our study further elaborates on this stance in two important ways: (a) pointing to the conceptual prerequisite distinguishing between 1s and composite units plays in then also coordinating them multiplicatively and (b) explaining the conceptual process involved in arriving at this distinction.

Explaining this conceptual transition can contribute to understanding challenges students face when taught multiplication. A student may try to solve an archetypical multiplicative situation consisting of several equal-size groups, such as: How many cubes do you need to build 6 towers, each made of 3 cubes? To solve this problem, the student would need to understand two types of different units are involved: single cubes (1s) and towers comprised of three such cubes each (composite units). This distinction seems necessary also in cases where the units are presented as an array (e.g., 6 rows by 3 columns) with a total of eighteen 1s (e.g., dots). In this case, the student would need to unpack the organization of 18 items into rows and columns as a highly compact form in which she needs to coordinate two different units.

Theoretical and Conceptual Framework

Our framework for this study draws on Piaget's (1985) concept of assimilation, which stresses a learner can only make sense of some information by using available (assimilatory) conceptions. For example, upon reading the problem situation above, a student who is yet to distinguish 1s from composite units may literally see both given numbers (6 and 3) while only "taking in" the number of single cubes (3). Assimilation is thus the starting point for any transition to a new conception, which Piaget (1985) and von Glasersfeld (1995) explained by the mental process of reflective abstraction. Simon et al. (2004) elaborated on this process, in a mechanism they termed *Reflection on Activity-Effect Relationships* (Ref*AER). In a nutshell, Ref*AER consists of four mental steps: 1) setting a goal in the problem situation, 2) calling up and initiating an activity sequence to attain that goal, 3) determining if the effects of the activity match the goal, and if not 4) adjusting the activity sequence as needed. In our example, a student may come to link her or his mental actions (e.g., counting 1s) with the effects of those actions (e.g., noticing that the count of cubes resulted in "3" whereas the count of towers resulted in "6"). Tzur & Simon (2004) further distinguished two stages of mathematical conceptual learning based on the extent to which a learner's new conceptions depends on some prompting or can be independently and spontaneously called up and used by the learner. The scope of this study led us to focus the data analysis on Adam's transition to a prompt-dependent form of distinguishing 1s from composite units

As we noted above, the conceptual transformation on which we focus in this study is rooted in the explanation of multiplicative reasoning in terms of units coordination. Of the six multiplicative schemes that Tzur et al. (2013) identified, our study focuses on the first, called *Multiplicative Double Counting* (mDC). Units coordination that characterizes mDC involves the distribution of items of one composite unit (e.g., three 1s) into the items of another composite unit (e.g., six equal-size units, such as towers made up of 3 cubes each). This coordination of two types of units is essential not only for developing multiplicative reasoning but also fractional reasoning (Norton et al., 2015; Hackenberg, 2013; Steffe & Olive, 2010; Hackenberg & Tillema, 2009). By addressing an initial phase in the conceptual transition from not distinguishing between composite units and 1s that constitute them to ably doing so, this study can help explain how this conceptual basis for coordinating both types of units may come about.

Methods

Setting and Participants

This is a case study focused on examining a conceptual transition – a phenomenon requiring in-depth analysis of the participant's meanings (Stake, 1995) while solving mathematical word problems. A fourth grader (Adam, pseudonym), from a school in a large US city, participated in a cognitive interview to assess his assimilatory scheme for mDC. The school he attended reported a percentage of English Language Learners at 54.2% and students receiving free or reduced lunch at 84.9%.

We chose Adam as a case because of three key reasons. First, he exemplifies the conceptual transition at hand. Second, he is a fluent reader whose mathematical abilities did not seem rooted in difficulties to comprehend the questions. Third, he solved the additive screener problem (see next section) by doubling 7+7=14, then adding 1 more to obtain the correct answer of 15. This solution indicated to us Adam capably distinguished and used composite units and 1s to assimilate and solve additive problem situations. Combined, these three reasons provide a basis for analyzing a transition to a unit distinction required to assimilate (make sense) and solve multiplicative situations involving 1s and composite units.

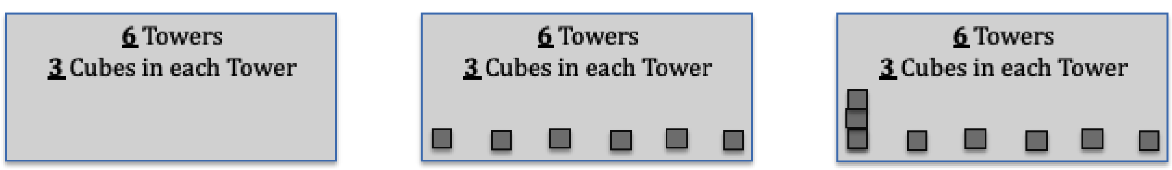
Problem Situations Adam Solved

Our team developed and validated the 5-item assessment, used during the cognitive interview, as a measure of students' mDC scheme (Johnson, et al., 2018). The first item of the measurement, intended as an additive screener question, is followed by four items to measure mDC reasoning. All four mDC items are expressed as word problems and include diagrams to illustrate the given units. Table 1 presents the additive screener and the mDC item (Problem 3 with its four sub-questions) we used in this study of Adam's case. It should be noted that, prior to solving any of those items, Adam literally built a tower of 7 cubes, and then correctly pointed to a diagram of such a tower that was included in the assessment.

Like all four mDC items, Problem 3 begins with a prompt-less version consisting of 4 questions (Figure 1a). Once the child attempts solving that version, the interviewer moves to the next version, which gives a first hint (showing there are 6 composite units) followed by the same four questions (Figure 1b). Finally, the interviewer moves to the third version, which includes a more explicit hint (showing the 6 composite units and the three 1s that comprise the first of them) followed by the same four questions (Figure c). This sequencing of assessment items – progressing from prompt-less to gradually more explicit hints – draws on Tzur's (2007) notion of fine grain assessment.

Table 1: mDC Measurement Word Problems

#	Word Problem
1	For breakfast Ana ate 8 grapes. For lunch, Ana ate 7 grapes. How many grapes did Ana eat in all? Ana ate _______ grapes in all.
3	The picture to the right shows a box. Alex put **6** towers in the box. Alex made each tower with **3** cubes. The numbers on the picture show this. How many **cubes in all** did Alex use to make **6** towers? (fill in the blank): ______



1a: Prompt-less version **1b: First-hint version** **1c: Second-hint version**

Figures 1a, 1b, and 1c: Diagrams Provided Along with Problem 3

Cognitive Interview

The third author of this paper conducted the cognitive interview with Adam. This cognitive interview was one of 40 similar interviews that constituted the last phase of the validation process of the 5-item measure. Accordingly, it required of the interviewer to give no additional support (or probing) beyond what is presented in the written assessment. The protocol for this interview involved first asking Adam if he would like to read the problems on his own or be read to by the researcher. Adam proudly opted for the former. Then, the researcher presented, one at a time, the single page on which each Problem version with its sub-questions is given. Adam read the problem situation and then the sub-questions out loud, while solving each of those questions as he thought proper without any further assistance from the researcher.

Data Collection and Analysis

The cognitive interview was video-recorded and stored along with Adam's written work for later analysis. Three team members (the PI and two graduate research assistants) individually analyzed the video, while taking extensive notes and identifying key moments they would then use to analyze the data. They met to discuss their notes, identified agreed upon key moments, and then then first author (graduate assistant) transcribed those video segments. After scrutinizing the video and transcriptions line-by-line, we chose Problem 3 for the analysis presented in this paper, as it provides the most compelling evidence of Adam's conceptual transition from not distinguishing to distinguishing between 1s and composite units within a multiplicative situation.

Results

We provide evidence of Adam's transformation of his available conceptions that led him to distinguish between single units (1s) and composite units given in a problem situation involving multiplicative relationships. We first analyze data and offer inferences of plausible conceptual sources of his initial inability to solve a task that provided no hints. Then, we articulate how his work on versions of the problem situation that included hints indicates a transformation in his reasoning. We demonstrate his novel distinction between 1s and composite units, which is a conceptual prerequisite for properly operating on both to solve multiplicative problem situations.

We begin with Adam's work on the prompt-less version of Problem #3, which asked to find the total number of cubes (1s) when given 6 towers (number of composite units) each comprised of 3 cubes (unit rate). Excerpt 1 shows Adam's work on the prompt-less version (see Figure 1 above). He read the problem out loud and began answering each sub-question.

Excerpt 1. Prompt-less questions of Problem 3.

A: (Reads the problem aloud, and rather quickly) "The picture to the right shows a box. Alex puts 6 towers in the box. Alex made each tower with 3 cubes. The numbers on the picture show this." (Here, he looks at the box for 2 seconds, then moves on to reading Question 1: "How many towers …?" and incorrectly writes "3". Then, he reads Question 2 silently: "How many cubes per tower …?" and correctly writes "3.")

R: You wanna read that [Question 3] out loud?

A: (Reads Question 3 silently twice: "How many cubes in all?" He looks around and shakes his head) I don't get this.

R: Okay, you can write I don't know, IDK; that's fine.

A: (Looks back and re-reads Question 3 silently, looks up while thinking how to solve it.)

R: Take your time.

A: (Writes, "I don't know," then reads Question 4 silently: "How many cubes are in 2 towers?" He quickly and incorrectly writes "3.")

R: Good? [This question meant, 'Are you good to move on to the next problem?']

A: (Nods, "Yes.")

Data in Excerpt 1 indicate Adam's assimilation of this prompt-less problem situation did not include distinction among different units. To each of the questions, he essentially responded with "3." Whereas this number is a correct answer to the unit rate, it is incorrect when answering the number of composite units (6 towers), the total of 1s (18 cubes), and even the total of 1s in just two towers (6 cubes). We infer from those answers that he could think of the 1s given in the problem (3 cubes per tower), while not yet distinguishing the composite units as six individual items, let alone as six items composed of three 1s each. We thus consider Adam's initial response to Question 3 ("I don't know"), about the total of 1s in all six towers to be genuine. Along with his independent effort to re-read this question twice, the data support our claim that he assimilated the entire problem into a conception that is yet to *distinguish composite units within a multiplicative situation*. We emphasize multiplicative situation, as Adam seemed capable of assimilating composite units in his solution to the additive, screener problem (doubling 7+7 to answer 8+7).

Having completed all four questions in the prompt-less version of Problem 3, Adam continued to its next part, which provides the first hint – a diagram showing the bottom cube of each tower (Figure 2). Aside from this hint, he would then have to answer the same four questions. While Adam's was noticeably slower in his reading of this version than his reading of the prompt-less version, he answered the first two questions the same (incorrect) way. He then also began solving Question 3 similarly. Yet, Excerpt 2 shows that a first perturbation seemed to occur as he further thought of the total of cubes in all 6 towers of 3 cubes each.

Excerpt 2. First-prompt questions.

A: (Reads the problem aloud, noticeably slower pace, touching each word with his pen as he reads it.) "The picture to the right shows a box. Alex put 6 towers in the box. You can see the bottom cube of each ..."

R: (interrupts his reading to orient attention to the hint) Do you see them [the bottom cubes]?

A: (Looks at the diagram, touches one of the cubes with his pen to indicate he does, then continues reading to the end of the problem.) "… 6 towers in the box. You can see the bottom cube of each tower. Alex made each tower of 3 cubes. The numbers on the picture show this."

R: So, can you answer this one?

A: Yah (Reads Question 1 silently. Then, he rereads the given problem situation, and incorrectly writes "3" for number of towers. He then reads Question 2 silently and, similarly to his prompt-less response, correctly writes "3" for the number of cubes in each tower. He moves to reading Question 3 silently (twice), then talk to R as if having an "aha" moment): Wait; so the towers are made of 6? There's 6?

R: (Not confirming Adam's realization directly, but instead restates Question 3) So, "How many cubes **in all** did Alex use to make 6 towers?" You can read it again, or look at the picture, what are the towers and the cubes there. The question is how many cubes **in all** Alex used to make 6 towers.

A: (Writes, incorrectly, "0," then also answers Question 4 incorrectly with "12" cubes as the total in only 2 towers of 3 cubes each.)

Data in Excerpt 2 further support our claim that, while solving the first two versions of Problem 3, Adam's assimilatory conception was yet to include a distinction between units of 1 and other units composed of 1s. In spite of explicitly pointing to the diagram presenting the six bottom cubes of each tower, he still incorrectly responded ("3") to the first three questions. Importantly, an event that could become a turning point in his transition occurred when, upon slowly rereading Question 3, he indicated for the first time a recognition of another numerical quantity that constitutes the problem situation ("Wait; so the towers are made of 6? There's 6?").

This recognition seemed supported by his (a) action following the hint (pointing to the six cubes in the diagram), (b) slower reading of all parts of Problem 3, and (c) rereading of Question 3.

The importance of this perturbing experience, seemingly an "aha" moment for Adam, is that he independently identified the other given number, which he overlooked (did not assimilate) in the previous attempts. His answers to Question 3 and Question 4 were still incorrect. However, his solution to the following, last part of Problem 3, which includes a second, more explicit hint, suggests this realization would contribute to his novel recognition and distinction of the other number as a salient feature of the problem situation.

The final part of Problem 3 included a diagram that shows the bottom cube for all 6 towers as well as all 3 cubes that compose the first tower on the left (Figure 3). The purpose of this hint is to provide a student with a more explicit opportunity to assimilate the two types of units that constitute the problem situation. Excerpt 3 presents Adam's first transition to reasoning with both unit types.

Excerpt 3. Second-prompt questions.

A: (Reads the problem situation aloud in slow pace, touching each word with his pen as he reads it.) "The picture to the right shows a box. Alex put 6 towers in the box. You can see the bottom cube of each tower and all 3 cubes of a tower." (He looks at the diagram, tapping the words about the two different types of units involved (in the box) as he reads them to himself. He then moves on to read Question 1 silently, looks back at the diagram, and *correctly writes "6"* in the blank for the number of towers Alex put in the box. He then reads Question 2 aloud while immediately and correctly answering it) "Alex made each tower with 3." (He writes the answer in the blank and moves to Question 3). "How many cubes did Alex use to make 6 towers?" (He looks at the diagram, makes a circle in the air above the completed tower showing 3 cubes, makes another circle in the air above the next cube that is the basis of the second tower, looks to R, makes circles in the air above the other cubes while likely counting them to six, rereads the question silently, looks up to think more about the question, and finally writes "IDK" for I don't know.)

R: That's okay [confirming IDK as a response].

A: (Reads question 4 silently, looks at that diagram again, and *correctly writes the answer "6"* for the number of cubes in just two towers of 3 cubes each.)

Data in Excerpt 3 indicate the two key aspects of our claim: in Adam's work on the version with a second hint, he was (a) finally able to distinguish between the two units while (b) not yet coordinating them multiplicatively when asked about all cubes (1s) in the six towers (composite units) made of 3 cubes each (unit rate). The first aspect is evidenced in correctly answering Question 1 by identifying the 6 towers (composite units) and in correctly answering Question 2 by identifying the 3 cubes (single units) that composed one tower. We inferred from these two correct answers that Adam has begun a transition to a conception that involves the 1s in each composite unit and the composite units made of those 1s as two distinct types of units.

Having just distinguished the two unit types, operating on both to account for all 1s in six composite units seemed beyond Adam's evolving conceptualization (writing "IDK"). On the other hand, operating on both in Question 4 became possible by this conceptualization. We infer he could then consider the first two towers he might build, each with 3 cubes, similarly to how he used 7+7 when solving the additive screener problem.

Adam's progression through all parts of Problem 3 indicates his transition from inability to an initial ability of distinguishing units of 1 from composite units. We postulate that this transition was initially supported by his reflection on the activity of counting the six cubes in the diagram (Figure 2) provided as the first hint that seemed to enable his "aha" moment. This transition seemed further supported by Adam's reflection on the effects of his explicit actions of counting when studying the problem situation with the second hint. Using two distinct actions of circling above the relevant units, he produced two different effects: counting to three cubes in the first tower and counting to six cubes representing the bottom cube of each tower.

That this transition is not trivial can be emphasized in the sequence of his solutions. Before being prompted, Adam seemed to overlook the multiple units "given" in the problem situation – he seemed capable of identifying only one unit (3), which he used throughout his answers for that problem. Once Adam was given the first hint, he experienced a perturbation that could set in motion his distinction between the units involved in the problem. However, this distinction was yet to be made explicit. Thus, he was still not able to operate correctly with both unit types. With the second hint, Adam's unit distinction had taken on the transformation needed to solve the multiplicative situation. Correctly identifying both units – 6 towers/composite units and 3 cubes in each tower/single units – opened the way to also coordinating them at least when solving Question 4 that dealt with only two towers. His distinction seemed too rudimentary for also coordinating the two types of units when the task involved more than two composite units.

Discussion

We see two key contributions of this study. For research and theory building, it demonstrates how a student engaging in solving mDC problem situations with gradual hints can advance from having no distinction of units to beginning to distinguish between composite units and singletons (1s). That is, the study provides a lens through which to understand the prerequisite role that distinguishing those two types of units serves in advancing to multiplicative operations on such units. Simply put, before operating multiplicatively on two different types of units one must explicitly distinguish them. Moreover, the study goes beyond noting these two, before-and-after conceptual markers (Tzur, 2019), to articulating a mental process involved in the transition from the former (no distinction) to the latter ("seeing" composite units apart from the 1s of which they are comprised). Specifically, we pointed out to Adam's reflection on the effects of his counting activities as a plausible way this transition might have come about (Simon et al., 2004). We do not claim every student would make this critical transition in the same way. However, we believe this study provides a sensible explanation of it. In Adam's case, the role this distinction of units played in his operation on both types of units was manifested in his correct solution to Question 4 (6 cubes in 2 towers of 3 cubes each) of the second-hint version of the problem situation.

For practice, our study demonstrates the importance of developing a way of distinguishing and operating on those two types of units as a basis for learning to meaningfully use arrays as a representation of think whole number multiplication. Adam's case of distinguishing the two units that constitute such arrays can inform teachers about ways their students' may reason is such instances. Students who are yet to make such a distinction would likely reason about such arrays as constituted of all 1s (single items). Such students may hear and assimilate "rows" and "columns" similarly to how Adam read and assimilated the two units given in the prompt-less situation, namely, as 1s. Adam's case also illustrates how students may be able to identify and distinguish between 1s and composite units when they are prompted. Importantly, his case also demonstrates how the students may be able to distinguish between 1s and composite units while not yet being able to operate on those units multiplicatively. We contend that arrays would represent multiplication meaning for students only when they can both make this distinction explicit (as Adam began to do) and operate on the units beyond doubling (as he was yet to do). This information about how the students assimilate and interpret word problems provides a teacher with a conceptual basis to determine where they could go next (i.e., goals for the students' learning) and what activities could be designed to promote the intended advance. Specifically, for students like Adam the goal would be to support their conceptual ability to independently and explicitly distinguish among the units (prompt-less). For students who accomplished such a conceptual ability – the goal would be to promote their multiplicative operations with/on those units.

A QUANTITATIVE REASONING PERSPECTIVE ON STUDENTS' UNDERSTANDING OF DIFFERENTIALS: AN EXPLORATORY STUDY

Thembinkosi P. Mkhatshwa
Miami University
mkhatstp@miamioh.edu

This paper extends work in the area of quantitative reasoning at the undergraduate level. Task-based interviews were used to examine six high-performing students' reasoning about an application problem that involves differentials, and what their reasoning about the problem revealed about their understanding of differentials. Analysis of verbal responses and work written by the students while solving the problem revealed that a majority of the students were successful in solving the problem. However, three students confused differentials with derivatives. Furthermore, findings of this study suggest that the opportunity to learn about differentials during classroom instruction in the United States is either absent or minimal.

Keywords: Differentials, Quantitative reasoning, Problem solving, Calculus education.

Differentials have numerous important applications in the sciences, especially in physics and engineering (Artigue, Menigaux, & Viennot, 1990; Hu & Rebello, 2013). However, there have been relatively few studies that have examined students' understanding of differentials. Findings of a comprehensive review of literature on students' understanding of various topics in college calculus by Speer and Kung (2016) indicate that there is a dearth of research on students' reasoning about differentials. Of the few studies involving differentials, Hu and Rebello (2013) found, among other things, that when solving physics problems involving integrals, students do not see differentials as representing physical quantities but rather as abstract mathematical symbols. Artigue et al. (1990) reported on high-performing students who confused differentials with limits in a mathematics context. Similar results were reported by Orton (1983). Amos and Heckler (2015) found that students confused differentials with derivatives in a physics context. López-Gay, Sáez, and Torregrosa (2015) found that a majority of the 298 university students in their study had "a quasi-exclusive conception of the differential as an infinitesimal increment" (p. 591). While these studies have provided beneficial information about students' thinking about differentials, there is still much to be explored about how students set up and solve application problems in calculus that involve differentials, which is the motivation for this study. Thus, to build on these studies, we intend to explicitly examine students' understanding of key steps involved in the process of solving application problems that involve differentials.

Theoretical Perspective

This study draws on the theory of quantitative reasoning (Thompson, 1993; Thompson, 1994b; Thompson, 2011). Quantitative reasoning is the analysis of a situation in terms of the quantities and relationships among the quantities involved in the situation (Thompson, 1993). Quantitative reasoning, as used in this study, refers to how students thought about units of quantities, how they used algebraic equations to represent relationships between quantities, how they created formulas for the unknown quantity (i.e., the unknown differential) in the task they were given, how they evaluated these formulas to determine the numeric value for the unknown quantity, and how they created and used diagrams in their solution to the task. Thompson (2011) described three tenets (a quantity, a quantitative operation, and quantification) that are central to the theory of quantitative reasoning. A quantity is a measurable attribute of an object. Examples of quantities (i.e., measurable attributes) in this study include the radius and the volume of the sphere referred to in the task that appears in the methods section. In this task, the sphere is the object.

A quantitative operation is the process of creating a new quantity from other quantities (Thompson, 1994b). The task used in this study provided an opportunity for students to create a new quantity, the unknown differential, through the process of differentiation. Solving this task successfully requires students to find a model (algebraic formula) that relates the quantities in the task. In this task, an appropriate model would be the formula for the volume of a sphere, i.e., $V = \frac{4}{3}\pi r^3$ where V is the volume of the sphere and r is the radius of the sphere. Differentiating this model with respect to r (to get $dV = 4\pi r^2 dr$) would lead to the creation of two new quantities, namely the differentials dV (the unknown differential) and dr. Quantification is the process of assigning numerical values to quantities (Thompson, 1994d). Evaluating dV at the values of r and dr given in the task would lead to the determination of a numerical value for the quantity dV. Our study was guided by the following research question: How can we interpret the theory of quantitative reasoning in the context of students solving application problems that involve differentials? In this paper, the terms "application problem" and "task" are used interchangeably to mean the same thing.

Methods

This qualitative study used task-based interviews (Goldin, 2000) with six students. The interviews lasted for about 30 minutes, on average, and contained three tasks. In this paper, we report on how the students reasoned quantitatively about one of the tasks, adapted from Stewart (2016):

> The radius of a sphere was measured and found to be 10cm with a possible error in measurement of at most 0.05 cm. Use differentials to estimate the maximum error in using this value of the radius to calculate the volume of the sphere?

The students worked through the task while the interviewer asked clarifying questions about their work. After the student concluded their work on the task, the interviewer asked the following questions about the task and the content of their solutions: (a) Have you seen a problem like this before? (b) What did you do to solve the problem? (c) What does your answer tell you? (d) What are the units for the quantity you found? (e) What does each quantity throughout your solution mean? All the students acknowledged having seen or solved a similar task.

Setting, Participants, and Data Collection

The study participants were six high-performing undergraduate students (pseudonyms Brian, Caleb, Jacob, Laura, Lenny, and Mike) who were enrolled in two sections of a traditional calculus I course in the fall semester of 2017. At the time of the study, three students (Caleb, Lenny, and Mike) were engineering majors, Brian was a mathematics education major, Jacob was a business major, and Laura's major was undecided. Only one student (Caleb) had taken a high school calculus course prior to participating in this study. Four students (Brian, Caleb, Jacob, and Laura) were freshman, one student (Lenny) was a sophomore, and another student

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

(Mike) was a junior. The cumulative grade point averages (GPAs) of the six students had a mean of 3.61 on a 4.0 scale.

Data for the study consisted of transcriptions of video-recordings of task-based interviews and work written by the six students during each task-based interview session. In addition, because of the scarcity of research on students' learning of differentials, we created and administered a two-question survey to help gather data that would provide an insight on the teaching of differentials in the United States. Of the 23 surveys we sent to colleagues in different Mathematics departments across the nation, 10 surveys were completed and returned. The surveys covered the following questions:

- Are differentials an optional or mandatory topic for calculus I instructors in your department?
- If you answered mandatory to the preceding question, roughly how may instructional days and/or hours are devoted to teaching differentials?

Data Analysis

Data analysis was done in three stages. In the first stage, we read through each interview transcript and coded instances where students: (1) reasoned about the units of each quantity they used in their solution to the task, (2) mathematized (Freudenthal, 1993) the task, (3) performed quantitative operations (i.e., created formulas for the unknown quantity (differential) through the process of differentiation, (4) engaged in quantification (i.e., determined numeric values for the unknown quantity), and (5) reasoned about the usefulness, or lack thereof, of diagrams they created and used in their solutions to the task. In the second stage of the analysis, we looked for patterns in each of the codes identified in the first stage of the analysis. These patterns included trends in the students' understandings, or difficulties they had in connection with each of the codes identified in the first stage. The common understandings or difficulties in students' reasoning found in the second stage of our analysis provided answers to our research question. In the third stage, we tallied the number of survey respondents who indicated that teaching of differentials in Calculus I is mandatory in their department. We also noted the amount of instructional time (i.e., lecture periods) spent on teaching differentials in these departments. In addition, we tallied the number of survey respondents who indicated that teaching differentials is optional in their department.

Results

Analysis of students' written work and verbal responses to the problem posed in the task revealed that nearly all the students took a similar approach when solving the task. In general, the approach taken by the students consisted of the following sequence of steps:

1. Orienting to the task (e.g., reading problem statement aloud/silently, underlining key words, writing/underlining given quantities, and identifying the unknown quantity).
2. Drawing a diagram (i.e., visual representation of the quantities in the task).
3. Mathematizing: using algebraic symbols to represent quantities, and finding a function that relates the quantities in the task (i.e., the equation for the volume of a sphere, $V =$

$\frac{4}{3}\pi r^3$, where the variable V represents the volume of the sphere and the variable r represents the radius of the sphere).

4. Performing quantitative operations: Differentiating the equation determined in step 3. with respect to r to get $dV = 4\pi r^2 dr$.
5. Engaging in quantification: Evaluating the unknown quantity (i.e., the differential dV) at the given values of r and dr.

Table 1 summarizes students' performance in each of the above-listed steps. The "✓" symbol means that a student correctly carried out the indicated step, the "x" symbol means that a student incorrectly carried out the indicated step, and the "-" symbol means that a student did not do the indicated step.

Table 1: Summary of Results

	1.	2.	3.	4.	5.
Caleb	✓	-	✓	✓	✓
Jacob	✓	-	✓	✓	✓
Mike	✓	✓	✓	✓	✓
Brian	✓	✓	✓	✓	✓
Lenny	✓	-	x	✓	x
Laura	✓	✓	✓	-	-

We remark that in addition to reading the task silently, one student (Laura) underlined keywords (e.g., volume), given quantities such as the possible error in the measurement of the radius, and the statement about the unknown quantity (i.e., the estimated maximum error in calculating the volume of the sphere) while orienting herself to the task. Three students (Laura, Mike, and Brian) each drew a circular diagram they stated was a "picture of the sphere" mentioned in the task. However, none of the students found the diagrams to be useful in solving the task. For example, when asked if creating a diagram was helpful in solving the task, Mike commented, "it wasn't necessary, but I just like to do it." We further remark that three students (Jacob, Lenny, and Mike) assigned the units of cm^3 to the quantity dV/dr suggesting that they confused the quantity of volume (an "amount" quantity) with the rate of change of volume (a "rate" quantity). Three students (Mike, Brain, and Jacob) used "derivative" symbolic notation to represent at least one differential in their solutions, suggesting that they confused differentials with derivatives. Analysis of the survey responses indicated that teaching differentials is optional at four of the 10 responding departments, and only half a lecture period is spent on differentials at three other departments. Three colleagues reported that about two lecture periods are devoted to the teaching of differentials in their departments. The majority of the survey participants were affiliated with at least an R2 institution based on the Carnegie Classification of Institutions of Higher Education at the time of the study.

Discussion and Conclusions

An important finding of this study is that a majority of the six students were successful in solving the problem. Three students confused differentials with derivatives. Similar results were reported by Amos and Heckler (2015) in a physics context. Three students confused an "amount" quantity (volume) with a "rate" quantity (the rate of change of volume). Students' tendency to confuse “amount” and “rate” quantities is well documented in the research literature (cf., Mkhatshwa & Doerr, 2018; Prince et al., 2012; Rasmussen & Marrongelle, 2006). To some extent, the survey results seem to suggest that differentials are either not taught at all or that when they are taught, calculus instructors do not cover this topic in depth. Much work remains to be done with regard to students’ reasoning about differentials, and the opportunities they have to learn about this topic through classroom instruction in the United States.

MEETING THE COGNITIVE DEMANDS OF PROOF BY INDUCTION: THE CASE OF BEN

Anderson Norton
Virginia Tech
norton3@vt.edu

Rachel Arnold
Virginia Tech
rlongley@vt.edu

Applying mathematical induction within a proof induces high cognitive demand. To investigate this demand, we developed a theoretical framework that integrates action-object theory within a model of working memory. We applied the framework in analyzing interviews with students enrolled in a proofs course. Here, we report results from a student named Ben. We examine ways that holding logical implication as an object offloads working memory so that students, like Ben, can attend to other components of proof by induction.

Keywords: Reasoning and Proof, Undergraduate-level Mathematics

In the Principle of Mathematical Induction, the inductive implication $P(k) \rightarrow P(k+1)$ can be treated as an inductive step, $P(k+1)$, from the inductive assumption, $P(k)$; or, as an invariant relationship between $P(k)$ and $P(k+1)$ for any k (Dubinsky, 1986). This distinction relates closely to Piaget's (1970) definitions of mathematical actions and objects from which Dubinsky (1991) developed APOS theory. Within that framework, Dubinsky (1991) hypothesized that success in proof by induction depends on a student holding logical implication as a mathematical object—"the encapsulation of the process of implication" (p. 111). We adopt a re-framed version of Dubinsky's hypothesis. Namely, we hypothesize that holding logical implication as a mathematical object reduces the cognitive demand of proof by induction, enabling one to attend to other aspects of the proof, such as quantification and domain-specific knowledge.

Working Memory and the Cognitive Demands of Proof by Induction

To deal with the challenging aspects of understanding the inductive implication, Avital and Libeskind (1978) suggested that teachers focus students' attention on how particular cases follow from prior cases. By looking across several cases, students might reflect on the structure of the implication and generalize that the relationship holds between $P(k)$ and $P(k+1)$ for any arbitrary k. Harel (2002) elaborated on this instructional approach and labeled it "quasi-induction."

Reasoning by quasi-induction, a student might show that $P(1)$ is true and that $P(1) \rightarrow P(2)$, $P(2) \rightarrow P(3)$, $P(3) \rightarrow P(4)$, and so on. This leads to the plausible conclusion that $P(n-1) \rightarrow P(n)$. However, the conceptual jump from quasi-induction to formal proof by induction is larger than it may seem. Harel (2002) asserts that this cognitive gap is substantial; he refers to formal proof by induction as an abstraction of quasi-induction. Our framework characterizes this gap as the distinction between the conceptual view of logical implication as an action versus as a mathematical object.

In addition to challenges imposed by the inductive implication, researchers have identified a few other factors that affect student success in proof by induction (e.g., Ernst, 1984). These factors include the importance of the base case, the role of (hidden) quantifiers, and domain-specific knowledge for the conjecture. Shipman (2016) noted that students' mistreatment of quantifiers often leads to the erroneous proof of a "for all" statement by example.

Our framework addresses the limitations of working memory relative to the cognitive demand of tasks (Baddeley & Hitch, 1974; Pascual-Leone, 1970). Existing literature informs us of task factors in proof by induction that place demands on working memory. We contend that the construction of logical implication as an object lowers the cognitive demand of such a task by enabling the student to assimilate the logical implication as a single object, rather than two separate components joined through action. This lowered demand would free up cognitive resources so that the student might attend to other factors, such as quantification.

Working memory relies on a frontoparietal network that includes the prefrontal cortex and the parietal cortex (Harding, Yucel, Marrison, Pantelis, & Breakspear, 2015; Sauseng, Klimesch, Schabus, Doppelmayr, 2005). Specifically, the central executive, which distributes task demands, relies heavily on neural activity in the dorsolateral prefrontal cortex and calls upon cognitive units with neural substrates in the parietal lobe. Figure 1 illustrates this functioning.

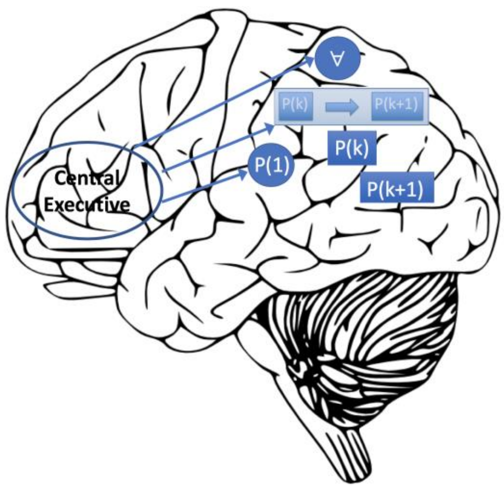

Figure 1: Theoretical Role of Working Memory During Inductive Proving

Research in educational neuroscience indicates a general frontal-to-parietal shift as students develop mathematically. Older and more experienced students rely more on parietal activity when compared to their younger, more novice peers solving the same tasks (Cantlon, Brannon, Carter, & Pelphrey, 2006). Our model accounts for this shift by positing that, over time, sequencing existing cognitive units in working memory can induce the construction of new cognitive units so that fewer units are required to solve the same task. In particular, cognitive units for the inductive assumption, $P(k)$, and the inductive step, $P(k+1)$, might be reorganized into the single inductive implication unit, $P(k) \rightarrow P(k+1)$, as depicted in Figure 1.

Methods

To elicit students' understandings of logical implication and components of mathematical induction, Norton conducted clinical interviews with students from a proofs course taught by the Arnold. A research assistant visited Arnold's class at the beginning of the 2016 fall semester to describe the study and recruit participants. Three students volunteered and were invited to participate. Norton conducted a pair of interviews with each of the participants—one before Arnold's instruction on mathematical induction and one after. All interviews were video-recorded and lasted about 45 minutes.

Interview tasks consisted of three types: logical implication (Type A), components of mathematical induction (Type B), and formal proof by induction (Type C). Table 1 shows tasks, from the pre-interview—the focus of our analysis. More specifically, we focus on pre-interview responses from a high-performing student named Ben.

Table 1: Sample Tasks (adapted from Norton & Arnold, 2017)

Task Type	Tasks
A. Logical Implication	Suppose the statement is true: "If two topological spaces are homeomorphic, their homology groups are isomorphic." Evaluate whether the following statements are true, false, or uncertain. a) [converse] b) [contrapositive] c) [negation]
B. Components of Mathematical Induction	Suppose *P(n)* is a statement about a positive integer *n*, and we want to prove the claim that *P(n)* is true for all positive integers *n*. For each scenario, decide whether the given information is enough. c) *P(1)* is true; there is an integer $k \geq 1$ such that *P(k)* implies *P(k+1)*. d) *P(1)* is true; for all integers $k \geq 1$, *P(k)* implies *P(k+1)*.
C. Formal Proof by Induction	Prove the following claim: For every positive integer *n*, $2 + 2^2 + 2^3 + \ldots + 2^n = 2^{n+1} - 2$.

Results

We use Ben's responses to Type A tasks as evidence that logical implication had emerged as an object upon which Ben could operate. For instance, when Ben was given the converse to the statement shown in Table 1, he responded, "I want to say 'uncertain' because I can separate the [original] statement into *P* and *Q*… and the second one tries to reverse that into a *Q* and *P*, which I'm not certain would be true in all cases." Ben seemingly conceived of the original statement as something he could separate into constituent parts, reverse, re-constitute, and then compare back to the original as a totality.

Across tasks, we consistently saw Ben break down implications, manipulate their parts, re-combine them, and compare the result to other implications, as totalities. Such activity indicates that he could treat implications as objects to operate upon (e.g., reverse or negate) and compare. However, the time and effort, along with his appeal to truth tables learned in class, suggest that this treatment of logical implication was a recently emerging development.

Ben's responses to Type B tasks indicate how he coordinates the components of mathematical induction independent of mathematical content. At first, Ben thought scenario c provided enough information to conclude that *P(n)* would hold for all positive integers. He justified his conclusion as follows: "Since it includes 1, you can say *P(1)* implies *P(1+1)*… so *P(2)*, and then you can say the same thing, that *P(2)* implies *P(3)*… and you can just continue along that path for all positive integers." Note that Ben's reasoning fits Harel's (2002) description of quasi-induction. Ben stated that he had never completed a proof like that before, and that "the *k* and *k+1* made me think of some kind of like sequence of numbers just going up." In attending to this case-by-case application of induction, Ben overlooked the existential quantifier. The quantifier's significance remained hidden to Ben until he saw scenario d (which has the structure of mathematical induction) and compared it back to scenario c.

Task C is an inductive proof in a domain-specific context. Ben worked on the task quietly for about four minutes, writing down equations. When asked what he was thinking, he said:

> …my first instinct is to look for some sort of pattern. I did $2 + 2^2 + 2^3$, and that gave me 14, which was 2 minus, then, 2^4, which would be the next term. So, I tried that for 2 plus all the way up to 2^n…and I get some value. And if it works the same as for all of the other values before it in the sequence, then I should be able to add 2 to that to get 2^{n+1}.

Ben used smaller-valued cases to test the statement and to find a pattern. When Norton asked him about his approach, Ben shifted his treatment of these cases to fit the role of a base case. "I guess I might show that, for smaller values, this is true, where you can move the 2 over to where you get, say, $2+2^2+2^3 = 2^4-1$ and then show the pattern holds for other values you add into it." Ben clarified that he wanted to add new terms to the sum to show that the equation would still hold. This approach of "incrementing the exponent by 1," is quasi-inductive.

The limitation of quasi-inductive reasoning became clear when Norton asked, "when does that stop?" and Ben responded, "um, that's a good question." Transitioning from quasi-induction to formal induction would require Ben to generalize the inductive implication to an arbitrary positive integer k, not just specific integers like $k=3$. Instead, Ben focused on the proposition itself, "I think that if you can show that it holds true for small cases and then make it more general by throwing in the n, saying you can go on as far as you want to and this will still be true. But I'm not sure exactly how to express that in proof form." After a few minutes of trying, Ben concluded, "I'm still not sure how you could show that it works for some arbitrary number."

In Harel's (2002) terms, Ben now had an *intellectual need* for formal induction, but his reasoning was presently limited to quasi-induction. So, Norton drew Ben's attention to the Task B scenarios in which Ben seemed to understand inductive arguments. After looking at the scenarios at length, Ben responded, "I'm thinking about the ones where $P(k)$ implies $P(k+1)$ and if you can get some sort of sequence where you can start throwing in values of k, or in this case, n." Here, Ben shifts his focus from $P(n)$ itself to the inductive implication $P(k) \rightarrow P(k+1)$. However, Ben was still unsure how k might first appear when working from specific cases.

Ben tried to translate Task C into the form of Task B scenario d. He was successful in proving the base case; however, he was not able to formalize the inductive implication. Rather than formulating a general inductive implication, he attempted to identify $P(k+1)$ for specific values of k, "So, the next term would be $2+2^2 = 2^3 - 2$." He summarized his goal as follows: "continue the sequence for who knows how many terms and it will still be as true as when you had $P(1)$." Ben's reasoning remained quasi-inductive, at least in this particular domain.

Discussion

For Ben, logical implication was emerging as an object that he could transform and apply in various ways. We saw him apply the inductive implication to arguments about the truth of a proposition, P(n). However, his arguments became problematic as he attended to additional components of proof by induction, including two of those identified in prior research: quantifiers (Shipman, 2016) and domain knowledge (Dubinsky, 1991). Ben could account for both components individually with some cognitive effort, but never simultaneously.

The cognitive effort Ben demonstrated could be instrumental in his development of inductive reasoning. Avital and Libeskind (1978) suggested that quasi-induction could prove fruitful in that development, but Harel (2002) noted a cognitive gap, which Ben exemplified, between quasi-induction and formal induction that would require an abstraction. That abstraction could manifest itself as the objectification of logical implication, which was newly emerging for Ben. Tasks that engage students like Ben in sequencing and coordinating various components of mathematical induction, with the support of figurative material (e.g., written equations), might induce the kind of frontal-to-parietal shift that would further encapsulate logical implication together with its quantification, allowing for flexible application of induction across domains.

OPPORTUNITIES FOR GENERALIZING WITHIN PRE-SERVICE SECONDARY TEACHERS' SYMBOLIZATION OF COMBINATORIAL TASKS

Lori Burch	Weverton Ataide Pinheiro	Erik Tillema
Indiana University	Indiana University	Indiana University
ljburch@iu.edu	wpinheir@iu.edu	etillema@iu.edu

This paper reports on an interview study conducted with four pre-service secondary teachers (PSSTs) for the purpose of understanding how symbolizing sets of outcomes supports opportunities for generalizing in the context of solving combinatorial problems. This paper examines opportunities for generalizing based on differences in symbolization as well as differences in PSSTs' conceptualization of seemingly identical symbols.

Keywords: Algebra and Algebraic Thinking, Cognition, Design Experiments

Introduction with Supporting Literature

The act of generalizing is central to mathematical reasoning because it is a primary vehicle for the construction of new mathematical knowledge (Amit & Klass-Tsirulnikov, 2005; Lannin, 2005; Sriraman, 2003). As a result, "developing children's generalizations is one of the principal purposes of school instruction (Davydov, 1972/1990, p. 10)." Current mathematics curricula and standards reflect this principal purpose (e.g., Hirsch, et. al., 2007; Lappan, et. al., 2006), and State and National standards focus on generalization (e.g., Council of Chief State School Officers, 2010; Indiana Academic Standards for Mathematics, 2014).

Researchers studying combinatorics have identified symbolizing sets of outcomes as helpful for students to produce all possible outcomes (English, 1991, 1993; Nunes & Bryant, 1996); avoid, correct, and explain common counting errors (Lockwood, 2014); and establish when two ways of reasoning are isomorphic (Maher, Powell, & Uptegrove, 2010). Researchers investigating combinatorial reasoning have not yet explicitly examined how symbolizing sets of outcomes could support students' opportunities for generalizing. Two reasons such an exploration is of interest in combinatorics are: (a) it is common for students to symbolize sets of outcomes for the same problem in different ways; and (b) it is common for students to symbolize sets of outcomes in ways that look identical, but their symbols have different meanings.

Given these observations, the purpose of this paper is to examine differences in the way pre-service secondary teachers (PSSTs)–who were student-participants in a teaching experiment–symbolized sets of outcomes in their solution of combinatorics problems and to identify how these differences afforded and constrained their opportunities for generalizing. The following research questions guide this paper:

1. What different opportunities for generalizing are available to PSSTs when they symbolize sets of outcomes for the same problem in different ways?
2. What different opportunities for generalizing are available to PSSTs when they symbolize sets of outcomes in the same way but conceive of the symbols differently?

Theoretical Perspectives

We use the term *symbolizing sets of outcomes* to include the creation of graphic items (or the use of other figurative material) in the context of a student implementing her schemes (cf. Von Glasersfeld, 1995). We include in our definition items that are conventional ways of symbolizing a set of outcomes like a written or verbal list, a tree diagram, an array, or an empty slot as well as non-conventional ways of symbolizing sets of outcomes like a drawing, tally marks, curved lines, or a demonstration with concrete materials. We follow Ellis (2007) in differentiating between generalizing actions and reflection generalizations. For the purposes of this paper, we consider symbolizing sets of outcomes to be a generalizing action, which is an action that precedes and may support a formal statement of generalization. Therefore, we focus on differences in the way PSSTs symbolized sets of outcomes and how such differences afforded or constrained opportunities for statements of generalization. We do this even in situations where students may not explicitly make formal statements of generalization.

Methods and Methodology

The data for this study was collected using teaching experiment methodology (Confrey & LaChance, 2000; Steffe & Thompson, 2000). The research team consisted of one university faculty member and six graduate students in mathematics education. Participants in the study were four PSSTs who were concurrently enrolled in their second mathematics methods course at a Midwestern university during the fall of 2018.

Participants were paired for interview purposes, with each pair participating in 13 teaching episodes. Teaching episodes were conducted weekly, lasted 60-90 minutes, and were recorded with three cameras. Two cameras recorded the written work of each PSST, and a third captured the interaction between the teacher-researcher and the PSSTs. The goal of the first 9 teaching episodes was to help the PSSTs see combinatorial structure in common algebraic identities, with an aim at helping them gain a progressively more general understanding of the relationship between common algebraic identities and combinatorial structure (Tillema & Gatza, 2016; Tillema & Gatza, 2017). The remaining 4 episodes focused on how the PSSTs could use their work to teach a lesson sequence during their student teaching.

Data analysis included the first and second author independently watching video segments from each of the four participants to analyze how symbolizing sets of outcomes afforded or constrained opportunities for generalizing. The first and second author then discussed their interpretations of these video segments until they reached a common interpretation. These interpretations were then shared with the third author and again discussed until there was a common interpretation. The example in this paper focuses on opportunities for generalizing based on PSSTs' symbolizing sets of outcomes in a combinatorial situation where they were making meaning for the term $10x^3y^2$ in the expansion of $(x + y)^5$. We choose this example because the ten arrangements of three x's and 2 y's was not obvious to the PSSTs who had not yet developed a systematic way to count arrangements for middle terms in the identity (i.e., $10x^3y^2$, $10x^2y^3$).

Results and Discussion

In this paper, we provide one example of how symbolizing a set of outcomes affords different opportunities for generalizing. This case highlights differences in the ways Olive and Aaron symbolized sets of outcomes. We will provide additional examples across the four PSSTs during the presentation.

During the ninth teaching episode, Olive and Aaron generated a list related to the algebraic identity $(A + B)^5 = 1A^5 + 5A^4B + 10A^3B^2 + 10A^2B^3 + 5AB^4 + 1B^5$. At this point in the study, Olive and Aaron had established: (a) that A and B were variables representing the number of possible options in a binary situation; (b) that each term on the right-hand side of the equivalence represented 5 selections of either variable A or variable B; and (c) that the coefficients represented the number of ways they could position the As or Bs in 5 slots (e.g., the number of

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

different ways to position 3 *A*s and 2 *B*s for the term A^3B^2). They, however, did not have a systematic way to count the arrangements of *A*s and *B*s for the middle terms of the identity (i.e., A^3B^2 and A^2B^3). The teacher-researcher pressed both PSSTs to show the different ways to arrange 3 *A*s and 2 *B*s.

For the A^3B^2-term, Olive focused on the variable appearing fewer times, i.e. *B* (Figure 1).

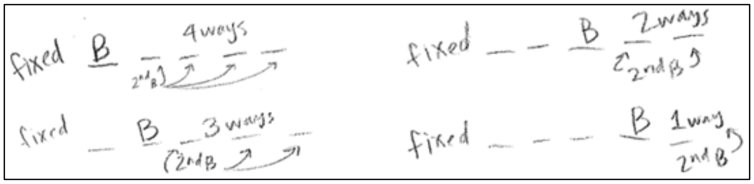

Figure 1: Olive's representation of the 10 variations of A^3B^2.

Olive's way of symbolizing the set of outcomes communicated a systematic organization, and so the teacher-researcher asked Aaron to make a conjecture regarding Olive's thinking.

> She fixed her *B*s and then rotated where the other [second] *B* could be. Because you only have two *B*s. She fixed [a *B*] in the first position and then moved [the fixed *B*] to the second position. But you know that you can't have another B back in the first position because you already counted that for the first one. And then you keep working your way down, rotating over the fixed *B* and counting the other ways, knowing the others behind the fixed *B* were already counted.

Olive agreed that Aaron had adequately explained her method. Without prompting, Olive symbolized her set of outcomes as 4 + 3 + 2 + 1 = 10. After accurately explaining Olive's list, the teacher-researcher asked Aaron to explain his own (Table 1, left).

Table 1: Aaron symbolizing outcomes

Aaron's original list of outcomes:			Aaron's list emphasizing his thinking:		
xxxyy xxyxy xxyyx	xyxxy xyxyx xyyxx	yxxxy yxxyx yxyxx yyxxx	xxxyy xxyxy xxyyx	xyxxy xyxyx xyyxx	yxxxy yxxyx yxyxx yyxxx

Aaron explained that he focused on placing three *x*'s for the outcomes in the first column. He fixed two *x*'s in the first two positions and then rotated the third *x* through the remaining three positions (i.e., either position 3 or 4 or 5) (Table 1, right). In the second column, he repeated this process by fixing *x* in the first and third positions while rotating the third *x* through the remaining two positions. Aaron then fixed *x*'s in the first and fourth positions, placing the third *x* in the last position. Realizing he had exhausted possible arrangements with *x* in the first position, Aaron considered arrangements with *y* in the first position. At this point, Aaron's thinking changed *from* placing *x* in three out of five positions *to* placing *y* in two out of five positions. Aaron stated "the *y*'s are easier to explain. I fixed the first *y* and started the other at the outside and just worked its way in."

Although Aaron interpreted Olive's method before explaining his own, he did not seem to alter his explanation based on new insight provided by Olive's method. We make this inference based on Aaron's reaction to (a) Olive's re-voicing of his thinking and (b) Olive subsequently explaining how she could see her own structure in Aaron's list. During Olive's explanation, Aaron gestured between the two lists (i.e., Olive's and his own) as if attempting to confirm the connection Olive suggested.

Based on Aaron's thinking, the total number of outcomes in his list could be symbolized as (3 + 2 + 1) + 4, where (3 + 2 + 1) represents arrangements when the *x* positions were foregrounded and 4 represents the foregrounding of the *y* positions. However, Aaron did not numerically symbolize his set of outcomes in either way; he simply wrote that there were 10 ways. Writing 10, taken together with Aaron's statement that "the *y*'s are easier to explain", indicates that this mixed method of listing constrained his ability to easily symbolize a structure that he could subsequently generalize with algebraic notation.

Response to Research Question 1

Olive and Aaron worked on the same task; however, they symbolized the set of outcomes differently. Olive's method *explicitly* demonstrated a process, but left the individual outcomes *implied*. The explicit nature of Olive's listing method allowed Aaron to accurately infer the process she used and enabled Olive to independently translate her method into the sum 4 + 3 + 2 + 1 ways to produce the A^3B^2-term. Aaron, on the other hand, listed individual outcomes *explicitly*, switching processes part way through. When Aaron used numerical symbols for his solution he did not use them to show the structure of his reasoning; this is in part because he switched the process for generating outcomes as he created his list. We see these distinctions as affording differences in opportunities to generalize. Olive's explanation suggested she could project how she would reason in new cases whereas Aaron's explanation suggested he would have difficulty projecting his reasoning onto new cases. We took the PSSTs' ability (or inability) to provide explanations that could be applied to new cases as a key indicator of opportunity to generalize.

Response to Research Question 2

Aaron generated his final four outcomes using a new strategy. Aaron could have continued to focus on the position of the *x*'s after exhausting outcomes with *x* in the first position. With this method, Aaron's list (Figure 2) could be symbolized as (3 + 2 + 1) + (2 + 1) + (1)–i.e., as a sum of sums–with the partial sum (2 + 1) symbolizing the number of outcomes with the first *x* fixed in the second position, and the final partial sum (1) as symbolizing the number of outcomes with the first *x* fixed in the third position.

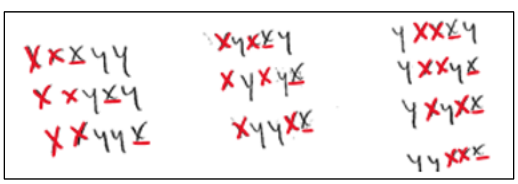

Figure 2: Aaron's list

We see other students, who produce the same list as Aaron but conceive of their list as a sum of sums by persisting with focus on *x*'s, as afforded greater opportunity to generalize.

Our data illustrates both that *different ways* of symbolizing sets of outcomes offer different opportunities to generalize and that different meanings for the *same way* of symbolizing a set of outcomes offers different opportunities to generalize. These findings support the conclusion that careful attention both to the way students symbolize sets of outcomes as well as to the meaning students have for the outcomes they have symbolized is crucial for teachers interested in supporting generalization in the domain of combinatorics.

EARLY CHUNKY AND SMOOTH IMAGES OF CHANGE IN THE DURATIONAL REASONING OF TWO SECOND GRADERS

Amy Smith
University of Colorado, Denver
amy.L2.smith@ucdenver.edu

Children's daily experiences create the foundation for their development of psychological time—the time of memories (Piaget, 1969). How children reason about this time has not been studied in math education, therefore it is unknown how these conceptions influence children's ability to understand and quantify time. Building from Castillo-Garsow and colleagues' (2012, 2013) chunky and smooth images of change, this study compares how two second graders' reason about time through reflection on their experiences. Semi-structured interviews found that the two demographically similar participants reflected on their lived experiences in very different ways to explain what time is and how to account for it.

Keywords: Elementary School Education, Informal Education, Problem Solving, Reasoning and Proof

Children are exposed to time concepts both formally and informally from a young age. A parent telling their child to "hold on a second" (Evans, 2004) or a family's weekly schedule (Lareau, 2011) are examples of informal time experiences. The intuitive perceptions children gain from experiences such as these establish their early conceptions about time (Piaget, 1969). Through reflection on these experiences, children develop foundational conceptions about what time is and how it can be quantified.

The present research explores the way two second graders explain time as they reflect on their durational experiences (i.e., the length of everyday activities). Utilizing research from Castillo-Garsow and colleagues' (2012, 2013) the cases demonstrate early indications of chunky and smooth reasoning.

Theoretical and Conceptual Framework

Piaget (1971) posited three types of knowledge: physical, social, and logico-mathematical. Physical knowledge is the attributes of objects that can be understood through observation, such as knowing that clocks have numbers. It is purely about the objects, rather than the understandings the individual imparts on the objects. Social knowledge, like physical, exists outside of the individual; however, social knowledge is constructed by people, such as structured start times for daily events like school or a sports practice. Because human constructs are cultural, social knowledge varies from place to place and is a crucial consideration when discussing how children's daily experiences found their understanding of time.

Logico-mathematical knowledge, unlike physical or social, exists only within the mind of the individual. It is the mental relationships constructed through reflection on experiences. When a child is able to recognize that they can cause shorter durations (time intervals) by making their actions quicker, she is reasoning with logico-mathematical knowledge.

Temporal Constructs

Piaget (1969) identified numerous constructs that are coordinated through durational reasoning. Specifically, he indicated that the operationalization of psychological time requires the coordination of two systems: succession of events and colligation of duration.

Succession. Succession is the order in which events occur. Piaget (1969) described duration as a function of succession, in that shorter durations result from quicker successions (and vice versa). So, for example, if two children race to a playground, the child who ran faster will necessarily get to the playground first, precisely because she took less time to get there. The succession of being first before second is the result of the shorter duration.

Colligation. Colligation is the organization of successive durations. It is the means through which "duration acquires a structure" (Piaget, 1969, p. 159). The seriation of durations is inherently successive given the chronology of events. For example, the time taken to fill a jug with water results from the successive partial durations of the flow of water—from empty to full—into the overall duration of "filling up."

Duration. Duration is the intervals of *and* between events. These intervals are naturally successive, operationally colligated, and can be quantified. The notion of the durations of psychological time returns to the earlier considerations of succession—a child's perception of the sequence of events as they actually occurred and how these events are reconstructed in the child's memory. Because perception influences understanding, psychological time is a test of how a child operationalizes the colligation of successive durational memories.

Images of Change

Castillo-Garsow (as cited by Thompson, 2012) "suggested, to operate with change happening in conceptual time, one must extract time from change, so that change happens in relation to time as opposed to happening because of passing time" (p. 11). A child who reasons intuitively about time sees change happening *because* of passing time, for example the bottles filled because time passed but more time passed for one bottle than the other. One who has operationalized time understands change in relation to time, so time passed while the bottles filled, but one filled faster *so* it took less time. Castillo-Garsow and colleagues (2012, 2013) defined two ways to reason about the covariation of time and action: chunky and smooth images of change.

Chunky images of change. When reasoning with chunky images of change, a learner considers only the discrete, countable moments of an event (Castillo-Garsow, 2012). Relating to Piaget's (1969) description of duration, it is acknowledging the intervals between events, but not of the events themselves. For example, when traveling 65 miles per hour, the 65 is the conclusion of the hour because the miles traveled are a result of the hour that passed (Castillo-Garsow, 2012, p. 9). The time passed as a result of the activity.

Smooth images of change. Conversely, when a learner imagines change in progress (Castillo-Garsow, 2012) she is reasoning with smooth images of change. From the previous example, traveling 65 miles per hour is not the result of the time or speed but is instead the continuous relationship between the two. A smooth image of change requires that the learner not only recognizes the start and end of a duration, but also understands that while the duration between is constant, the action(s) that fill the duration can impact the overall duration.

Methodology

The following cases (Yin, 2003) present two children from the same grade of similar demographics and a similar level of mathematical achievement; however, the reasoning expressed during interviews showed two different ways of reasoning about time.

Participants and Procedure

Taylor and Ellis (pseudonyms) are both second-grade, white males of similar backgrounds, from a large suburban city in the western United States. Each come from a two-parent household, with the ability to provide many extracurricular experiences. The two live in the same neighborhood and have been friends since kindergarten. The only difference between them, demographically, is that Taylor is an only child and Ellis has a younger brother. On paper, the two boys appear very similar.

Each participant was video recorded in an individual, semi-structured interview intended to explore how the child understood time (e.g., What is time?), determined various durations (e.g., What is something that takes you a short time to do?), and quantified common experiences (e.g., How long does it take you to brush your teeth?). After every question, the child was asked why or how he knew or came to his answer. It was in this explaining that Ellis and Taylor differed, and a connection was made to Castillo-Garsow and colleagues' (2012, 2013) images of change. These interview were transcribed in their entirety for analysis.

Data Selection and Analysis

With the focus on images of change, each transcript was read thoroughly, and excerpts were pulled that highlighted Taylor and Ellis's reasoning about time through the lens of chunky and smooth images of change. Using a constant comparison analysis (Glaser & Strauss, 1967), each chosen excerpt was narrowed into smaller sections, usually by sentences or sentence fragment and codes were counted for frequency of use by each child, to allow for a cross-case comparison.

Themes were identified correlating with Castillo-Garsow and colleagues' (2012, 2013) chunky and smooth images of change, such as time as distinct points, time as a continuous flow, and time as influenced by action. A Keywords-In-Context analysis (Fielding & Lee, 1998) was performed within each theme, looking specifically at how each child explained their durational experiences. Then, a componential analysis (Spradley, 1979) was performed to more precisely compare the distinctions between the reasoning presented by Ellis and Taylor.

Findings

Ellis: A Case of Chunky Images of Change

From early in the interview, Ellis related time to the units in which it is measured. From his initial definition of time, it became clear that Ellis's reasoning about time as a quantity—that being a thing that can be measured (Thompson, 1994)—was focused not on the duration of the passing time, but rather the beginning and end, the completed chunks (Castillo-Garsow, 2012).

Author (A): What is time?
Ellis (E): time is like, say it's like 5 o'clock..like maybe you have to do something at 5 and then you're done at like say 6:30
A: so if you start something at 5 and end at 6:30, where is the time in there?
E: it's the 5 o'clock and the 6:30
A: so the start and the end?
E: yah, the start and the end

Ellis explained time as only measured units, specifically the start and the end, but gave no indication of the continuous flow between these units as part of the duration. Later in the interview, Ellis demonstrated an understanding of seconds being a consistent passing beat; however, when he had to coordinate his actions with this passing time, his reasoning centered on the individual chunks of time passing rather than the overall flow of the duration.

A: if you walked that same path, and you wanted it to take less time, what could you do?
E: you can do like this (takes huge steps across the rooms as he says with each step) 1, 2, 3

A: so you could take bigger steps?
E: yah, bigger steps but it would take the same amount of time because, like, if you were walking (re-demonstrates taking smaller steps as he counts with every other step) 1, 2, 3 and when you're walking like this (walks again) and you're like (takes huge steps as he says with each step) 1, 2, 3, you're just taking longer leaps instead of shorter leaps
A: so shorter leaps and longer leaps can take the same amount of time, but what if you wanted to make the *time* shorter?
E: shorter(?)
A: how could you make it take less time to walk?
E: take less time to walk(?)

Ellis's focus is heavily on the numerical counting of the steps as a proxy for the duration they fill. These steps indicate a chunky image of change, as there is no consideration for the time during or between the steps.

Taylor: A Case of Smooth Images of Change

From the beginning of the interview, Taylor reasoned about time differently than Ellis.

Author (A): what is time?
Taylor (T):…um, time is, like what you're doing—time can be in days, months, years, seconds, minutes, hours—and time is what you're doing, um, when you pick to do it
A: you said time is what you're doing, later you said it is when, so is it what you do or when?
T: it's both

Taylor mentioned units of time measurement as examples of what time can "be in," however, he attended to both the action and when the action occurs. The qualitative nature of this response demonstrates a more abstract reasoning about time as a quantity. Taylor expanded upon this abstraction of time when asked how he could measure time.

A: how long does it take you to brush your teeth?
T: 2 minutes
A: how do you know?
T: because most people said brush your teeth for 2 minutes or 1 minute because the happy birthday song can usually take you 1 minute—or 30 seconds
A: okay, so you talked about the happy birthday song
T: singing it twice, and so I don't get cavities I say two long names

While not explicitly stating it, the last sentence "so I don't get cavities I say two long names" seemed to indicate that Taylor understands the inverse relationship between his actions and the length of a duration. By saying *two long* names, the duration of his teeth brushing increases, causing him to not get cavities. Taylor seemed to be accounting for time as being changeable through the progress of his action (Castillo-Garsow, 2012); the duration of his teeth brushing was defined not by a set start and stop moment, but through the continuous passing of his actions.

Discussion and Implications

While the reasoning presented by the participants was not intended as covariational, as Castillo-Garsow (2012) had designed these images of change, Piaget (1969) asserted that the understanding of time requires the coordination duration via movement through space, which necessitates a covariational relationship. Ellis and Taylor drew from their lived experiences to explain what time was and how it can be measured; however, their explanations differed greatly in *both* what time was *and* how it can be measured. I suggest that the reason these two seemingly similar children reason so differently about time lies in early construction of chunky and smooth images of change (Castillo-Garsow, 2012; Castillo-Garsow, Johnson, & Moore, 2013).

GROUP PRESENTATIONS AS A SITE FOR COLLECTIVE MODELING ACTIVITY

Corey Brady
Vanderbilt University
corey.brady@vanderbilt.edu

Hyunyi Jung
Marquette University
hyunyi.jung@marquette.edu

We approach student presentations of solutions to modeling tasks as occasions for whole-class reflection on the rich conceptual work that small-group teams have done in parallel. Analyzing and interpreting these interactions can offer insights into how a classroom group negotiates a shared sense of what they have learned and what they collectively view as "newsworthy" across groups from their recent (and ongoing) model-building. We describe analytical tools to interpret a classroom's work during presentations, and we illustrate their use in a single case. This work offers a foothold for design-based research to harness presentations to improve learning, drive instructional decisions, and illuminate modeling processes at both individual and group levels.

Keywords: Modeling; Problem solving; Communication

Orchestrating presentations and the surrounding discussions can be critical in classroom practice (Ball, 1993; Lampert, 2001), where it can be challenging to avoid a simple "show and tell" pattern (Stein, Engle, Smith, & Hughes, 2008; 2015). In the context of rich modeling problems, we framed group presentations as a scene of second-order, shared mathematical modeling. That is, we viewed interactions around presentations as reflecting the class's shared effort to make sense of what they have learned and to identify continued uncertainty or disagreement. To proceed analytically, we developed a scheme for coding presentations along three *dimensions*, characterizing utterances in terms of (a) how they referred to phases of modeling, (b) how they enacted rhetorical stances, and (c) how they contributed to whole-group-level modeling (e.g., building toward consensus or strengthening a sense of multiplicity in the class's solutions). We present this scheme in Brady & Jung (2019). Here, we focus on a single case, analyzing a class discussion that provoked reflection and shared modeling. We present this case to demonstrate how our coding scheme functions to capture dynamics that reframe presentations as shared modeling opportunities. A single case cannot show changes over time in a class's practices, but it illustrates our method, the dimensions, and connections among them.

Literature Review: In Search of a Group-Level Model of Modeling

Mathematical modeling processes involve the development and refinement of purposeful *models* that describe or provide insight into real-world problem-solving situations (e.g., COMAP & SIAM, 2016; Kaiser & Stender, 2013; Lesh, English, Sevis, & Riggs, 2013; Lesh, Yoon, & Zawojewski, 2007). Lesh, Hoover, Hole, Kelly and Post (2000) defined a *model* as a system used to describe another system. Thus, a *mathematical model* is a system that consists of mathematical elements (e.g., numbers and variables); relationships among the elements (e.g., equivalence relationships); operations and representations that describe how the elements interact (e.g., graphs, symbols, equations); and patterns or rules that show how it can describe another system (Lesh et al., 2000). Developing a mathematical model in the face of a situation, or *mathematizing* reality, involves organizing, quantifying, and/or coordinatizing a real-world situation (Lesh et al., 2007). To characterize students' *presentations* of modeling we consider: (a) features of modeling they refer to; (b) discourse moves they enact; and (c) emergent structure across presentations.

A significant strand in the international research on mathematical modeling has articulated modeling as a cycle with phases (see, Blum, 2015). "Modeling competencies" (Kaiser, 2007; and cf Niss, 2003) are under debate, with a broadly shared caveat that such competencies are not isolated skills, but develop together (e.g., Blum, 2015; Zbiek & Conner, 2006). For example, Galbraith and Stillman (2006) endorse a generally regular image of the modeling cycle, but they show that students can experience barriers in moving from any phase to the next. On the other hand, Borromeo Ferri (2007) found that the work sequence for individual students could be quite idiosyncratic and non-linear, departing from any canonical cycle. In our study of *presentations*, we conjectured that struggles or insights characteristic of model cycle phases (and transitions) might be milestones for groups, but that these might occur in any order.

Our conjectures were also supported by research (a) at the small group level, and (b) on learners' meta-cognitive reflections on their modeling. Czocher (2016) visualized patterns exhibited by *groups* in modeling phases and the transitions between them. She found diversity and non-linearity similar to Borromeo Ferri (2007), but these patterns could be understood in terms of groups' *styles* of problem solving. Research on metacognition by Magiera and Zawojewski (2011) building on work by Wilson and Clarke (e.g., 2004) used students' talk in stimulated-recall interviews about Model-Eliciting Activities or MEAs (Lesh et al, 2000).

As we worked to understand modeling at the whole-class level during presentations we foregrounded *constructivist* and *situated* perspectives on knowing and learning (e.g., Beth & Piaget, 1966; Lesh & Lehrer, 2003) attending particularly to how the specific conditions or framing could affect students' behavior. This led us to begin inductively from cases and focus on characterizing emergent structures of agreed-upon and disputed features of models.

Methods

We present data collected during a two-week summer camp on mathematical modeling for Grade 6-8 students and led by the second author and a mathematics teacher. Twenty-one middle school students (ten females and nine racially diverse students) from five schools participated. On the first day of the camp, the group as a whole constructed norms on interacting with other students (e.g., listen to your classmates, respect others' ideas). Throughout the summer camp, students worked in teams and presented their ideas and solutions to modeling problems to the whole class. The case we present here involved the *Counting Caribou* problem (Lesh & English, n.d.). Students were given aerial photographs of caribou herds and asked to develop a procedure for estimating their numbers. Their "client" was the Alaska Department of Fish and Game. Features of the two sample photographs added to the problem's complexity: (a) there were too many caribou in each photo to count easily; (b) the density of populations differed within and across the photos; (c) some caribous' bodies extended beyond the edge of the photos.

Our analysis focuses on student discourse around six small groups' solutions to this problem, which occurred in a 24-minute exchange at the end of the sixth day of the camp. We selected this case as it was also fundamental in generating our larger codebook for describing references to *modeling phases* and students' *discourse moves* in presentations (see Brady & Jung, 2019).

Findings: Patterns in Discourse across Mathematical Modeling Presentations

We analyzed the class's presentations and discussions of their solutions focusing on understanding moments where questions from the audience provoked shared reflection. The six groups' presentations were very diverse, yet patterns emerged across all of our dimensions. In terms of *modeling phases*, we used the following descriptors:

- **Understand the problem**. Return to the problem statement (including text, tables, or figures) to clarify what constitutes a solution for the Client.
- **Construct / structure**. Frame the problem situation and solution criteria to address them with mathematical tools. Choose a way of looking at the problem.
- **Patch**. Adapt the model in process, responding to "unruly" features of the problem situation that emerge as the initial model is applied.
- **Work mathematically**. Do (or explain) arithmetic or algebraic manipulations.
- **Validate**. Consider the reasonableness of the answer or process. Check extreme or special cases; check assumptions/validity of the mathematical procedures used.
- **Interpret**. Explain the answer as referring back to the context of the problem.

We found that presenters emphasized the Construct/Structure and Work Mathematically phases. In contrast, questioners emphasized the Understand the Problem and Patch phases. This complementarity struck us. We then asked whether we could characterize *forms* of question that had high leverage for raising new ideas. We found questioner contributions of "Seeking Explanations" and "Inquiring about Omitted Features" forms often provoked presenters to introduce novel features of their models, which had been unstated. In particular, unique aspects of the presenters' work did not always show up until students in the audience asked questions of these kinds. We felt that this might be a feature of interactions around presentations that could be supported or learned. In our case, the first instance of this came in the questions for Group 1: Hope, Tim, and Kevin (all proper names are pseudonyms). Their presentation had introduced several key ideas, but many important themes that later arose in the discussion as a whole had not yet emerged. The audience's questions quickly led three of these to surface:

01 Uri: So, I really liked that yours was really exact, but it was also pretty easy and simple. I also have a question. What did you do with the overlapping caribou? Like the ones that are half on the page and...
02 Hope (presenter 1): Oh, those ones we connected.... If it was half a body, we found another half body we would smush it together to make one.
03 Teacher: Any other comments or questions?
04 Irene: Why did you decide to do it in the most crowded...count the ones in the most crowded area?
05 Hope (presenter 1): Well, we kind of like.... All three of us, we counted different areas, so one of them counted up to like 110 or so, some of them counted like to 95 or so. We kind of just rounded them to 100.
06 Tim (presenter 2): Yeah.
07 Uri: So how did you account for.... Like the second one, how did you account for...the instance where there was like none of them...Like the second picture... It's just like...
08 Kevin (presenter 3): We eliminated those squares so I could get an accurate estimate.

The class's questions prompted Group 1 to elaborate on aspects of their modeling that they had left out of their presentation. They also served to identify issues in the public forum that any future presenters should attend to. As such, they represented bids to contribute to an emergent, shared *specification for an adequate solution*. Uri's question surfaced a "patch" that Group 1 had devised as they applied the procedure they had described simply as, "We counted the caribou in one section." Irene called into question the logic of choosing a highly populated grid cell (rather than using a "medium" cell, which emerged with later groups and became a 'standard'). Here, Hope's answer was not fully responsive: instead, she used the question as an occasion to elaborate the counting strategy beyond what Group 1 had presented. (In their solutions, they sampled three *different* crowded grid cells and took a rough average of caribou counts across these.) Finally, Uri's question led Kevin to mention a feature that came to be shared across many groups' presentations: "patching" the grid approach for Herd 2 by removing the number of empty or very sparsely populated grid cells from the count used in the calculation.

These question contributions were coded in our *discourse-moves* dimension as "Inquiring about omitted features of the problem or solution process" (Uri's questions) and "Seeking explanations for aspects of the modeling process" (Irene's question). We find it interesting that the questioning session here operated in collaboration with the presentation to articulate complementary aspects of Group 1's solution and to raise features of the problem and solution that would highlight the diversity of later groups' modeling work and feed consensus and debate.

A more extensive account of our data analysis describes how the sequence of presentations led to the emergence of a shared *solution specification* and a shared *"skeleton" model* at the class level. That is, the class came to agree on what would count as a solution for the Client and also on some key components of good approaches. Without this class-level discussion—constituted across contributions by presenters and questioners—the solution specification and the structural similarities among groups' approaches might have remained implicit. In contrast, this class appeared aware that a shared model had indeed emerged by the end of the presentation sequence. Group 5 began by saying, "Okay. So our method was essentially the same as basically everybody else's method." And Group 6 repeated a similar pronouncement, twice: at the start ("Okay, so we pretty much did the same procedure as everyone else") and after describing a unique aspect of their work ("…and then we did the exact same thing like everybody else").

Discussion and Conclusion

We have explored presentations as occasions where a whole class can identify common ground across their work and identify "newsworthy" elements of each others' approaches. This lens allowed us to ask questions about how the class converted a small-group modeling activity into a second-order modeling experience at the whole-class level. We used a case from our larger study to illustrate the phenomena we are focusing on and to demonstrate our approach.

Reflecting on generalizability, we expect that similar conceptual issues and challenges would face any classroom engaged in processing its small-group work on a rich modeling activity, but that there would be variation in the specific results. This variation might be used to characterize aspects of "expert" group-level modeling practices and/or to guide instructional decision-making. With this in mind, we intend our approach to illuminate the texture of whole-class modeling work, rather than to categorize it neatly or uni-dimensionally. In particular, we expect different phases of modeling to be highlighted in different classrooms or for different activities. For instance, Counting Caribou is a Model Eliciting Activity, or MEA (Lesh et al, 2000), but it places a relatively low emphasis on the details of the client's situation, relative to other MEAs. This might in part account for a relatively low occurrence of Understand the Problem, Interpret, and Validate codes in our *model-phase* dimension.

Having groups present their solutions to the whole class can be critiqued on the basis of the value of the use of time. In fact, Lesh (2010) proposes an alternative approach, modeled on conference Poster Sessions, to allow groups to be exposed to and critically assess alternative solutions. However, our analysis suggests it is possible for a class to engage in collective modeling at the whole-class level, and this may be an instructionally useful experience. Our larger study and future work in applying and interpreting the coding approach presented here promise to offer insights into collective modeling during presentations, and to suggest instructional interventions that could support students in formulating and recognizing high-leverage discourse moves that drive collective modeling processes.

STUDENTS' VIEW AND UTILIZATION OF PROFESSORS' FEEDBACK WHEN REVISING THEIR PROOF

Nurul Schraeder
West Virginia University
nuwahyuni@mix.wvu.edu

David Miller
West Virginia University
millerd@math.wvu.edu

Feedback on proofs is an important tool that can help students to learn from their proof writing errors. We studied how students view written feedback by having students revise some of their proofs from introduction-to-proof class. We discovered four main findings: 1) students tend to skip reading the feedback when they performed well, 2) students prefer clear, detailed, and descriptive feedback, 3) feedback is not always about fixing students' errors, but it can indirectly influence how they think and reason through future proofs, and 4) doing revisions improves students' understanding. The findings from this study could have an important impact on what type of feedback a professor gives based on their purpose (giving less-detailed feedback so that students can revise their work or giving more-detailed feedback so that students can clearly see what mistakes they made) and how students perceive that feedback.

Keywords: Reasoning and Proof, Feedback on Proofs, Assessment of Proofs, Proof Revision

It is well documented that undergraduate students have difficulty writing proofs (Weber, 2001; Moore, 1994; Sowder & Harel, 1998) and that proof-writing is a primary competence that mathematicians want students to learn in upper-level mathematics classes (Weber, 2004, Zorn, 2015). To help students learn during their proof writing, professors provide feedback on students' proofs during grading with the goal that students will use the feedback to improve their proof writing (Byrne, Hanusch, Moore, & Fukawa-Connelly, 2018; Moore, 2016; Miller, Infante, & Weber, 2018). It is important to investigate professors' feedback on students' proofs because feedback can have a greater impact on students' understanding and writing of mathematical proofs than other instructional practices (Black & William, 1998; Henderson, Yerushalmi, Kuo, Heller & Heller, 2004, Hattie & Timperley, 2007).

Byrne et al. (2018) found to some extent that students may use the feedback on their proofs, but their uses were more rudimentary (quickly reviewing feedback, reviewing feedback before exams, making mental notes when reviewing the feedback). One of the reasons for students' non-use of professors' feedback may be that they are not required to address the feedback or revise their proofs. We see that revisions as a way for students to review and reevaluate their proof productions. While we would argue that feedback can aid students' proof-writing skills and comprehension, we do not know much about the effectiveness of professors' feedback on students' proofs. The goal of this study was to answer the following research questions: 1) how do students utilize feedback during revision and 2) in what ways does the feedback help students revise their proofs and improve their proof comprehension.

Theoretical Framework for This Research

Lyster and Ranta (1997) created a classification of written feedback into six categories, i.e., (1) Explicit correction, (2) Recast, (3) Clarification, (4) Metalinguistic Clues, (5) Elicitation, and (6) Repetition. The study was on French language learning in immersion setting which involved subject-matter lessons and French language arts lessons at the primary level. They found that teachers had a tendency to use the *recast* form of feedback. However, they also found that *recast* is the least effective type of feedback at eliciting correction where the most effective ones were *elicitation* followed by *metalinguistic clues.*

In another study, Byrne et al. (2018) handed three marked proofs with feedback from a professor to each of eight students. They used Lyster and Ranta's (1997) classifications to categorize the feedback. They found that the feedback that was classified as *explicit correction* or *recast* to be the most effective in eliciting the change. The results from Byrne et al. (2018) were in contrast to Lyster and Ranta's (1997) finding where *recast* resulted in uptake only 31% of the time and *explicit correction* about 50% of the time. Byrne et al. (2018) also found that professor comments classified as *clarification* and *elicitation* were the ones that students struggled to understand. In addition, Moore (2016) found that professors have a noticeable variation in how they grade students' proofs and that they provide a lot of feedback that is not always associated with the grade they assigned.

Methodology

Participants

Seven students in an introduction-to-proof class at a large state university in the United States agreed to participate in this study during the Fall 2018 semester. All participants had completed at least the second semester of Calculus. We anonymized the data by referring to the first interviewed student as S1, the second as S2, and so on, and assigned a feminine pronoun for each student.

Material and Procedure

Each participant met with the first author and was videotaped and audiotaped for the first phase of the interview that asked participants general open-ended questions about their views and use of feedback on proofs. For the second phase, we selected four participants (S1 through S4) for further interviews with the first author to discuss their interpretations of the feedback on their graded proofs. These proofs were taken from homework and exams that were selected based the number of feedback and one that the participant had struggled to write a complete proof. The participants were then asked to revise their proof and articulate their thoughts as they revised their proof. We repeated this process for 2 to 3 proofs for each student, totaling 11 participant interviews.

All participants' revision work was recorded on a LiveScribe notebook and backed up using video and audio recordings. After the participants finished working on the revisions, we asked them to describe their approach to revising their proof to get their overall thoughts on their revision work. Once the interview was completed, the first author rewrote the revised proof to anonymize the participants' written proofs and names, and then asked the professor of the course (second author) to provide feedback and regrade the proofs. The interviewer asked the students for another revision only if the revision submitted received a grade of 70% or lower. In the case that the participant needed to revise their proof again, the first author only asked them to revise their proof to see if they would use the feedback. This was followed by asking the participants to describe their approach to revising their proof again.

Analysis

All interviews were transcribed. The authors engaged in thematic analysis (Braun & Clarke, 2006) in the following way. First, both authors individually read over all the data while identifying and highlighting passages that might be of theoretical interest concerning feedback. Both authors met to discuss and compare their findings and developed a list of phenomena for further investigation. Next, each author reread the transcripts again, searching for further participant comments related to each phenomena of interest; we then put this excerpt into a file of comments related to that phenomenon. Through this process, we developed criteria and descriptions of these themes. Finally, the authors individually went back through the data one last time to identify passages that would satisfy the criteria for each of these themes.

This study is different from Byrne et al. (2018) since the participants in our study were reading and writing proofs on mathematical topics that they were working on during the semester, while participants in Byrne et al. (2018) study were not chosen from a specific class and were not reading and writing their own proofs. Also, the comments were written by the professor who was teaching the course, unlike in Byrne et al. (2018), where the feedback wasn't provided by the participants' professor. We believe that these differences are significant to our research due to two reasons. We knew exactly what the feedback meant without having to make assumptions since the professor who gave the feedback was involved in the analysis. Secondly, by having the students read feedback from their own proofs, we can see students' abilities in interpreting comments related to their own proof-writing and proof-comprehension abilities. This will give us a better insight into how students deal with feedback and their perspective toward feedback when revising their proofs.

Results

Reading or Not Reading Feedback Based on Proof Performance

The first important finding was that many participants disregarded the feedback whenever they were satisfied with their performance, regardless of the feedback. For example, S5 remarked "I guess when I got a hundred on it (a proof), I might not read it (the feedback) because I figured I did well" and S1 commented that "if I get like a high enough grade, I'll probably just like brush it (the feedback) off", but did mentioned that she may look at the feedback later. This was reiterated by S4 that "if I've got a lot of papers back and my grade is pretty good and there are other papers that need more attention I'll ignore the feedback on the better ones". Hence the performance can be an indicator on how much students utilize feedback.

Students' View of Professors' Feedback

Most participants claimed that professors give feedback to help them as they learn about mathematical proof. For instance, S3 made the following comment on why professors give feedback, "mostly probably to guide the students into thinking the correct way about how to approach the problem and how to I guess think about the process of solving proof". Therefore, students understood the overarching reasons why professors give feedback.

We also found that the typical feedback that was more favorable to participants were the ones that are clear, descriptive, and detailed. This confirms the result of Amrhein and Nassaji (2010) where they found that students prefer written feedback that requires less of their effort to correct. However, providing extensive detailed feedback can be time consuming and not very thought-provoking. Weber made a point mentioned in Byrne et al. (2018) that "the most important ideas that professors want to convey to students are ways of thinking and proof-writing habits and techniques" (p. 250). However, even though S2 preferred detailed feedback, she somehow understood that "good feedback tells you what you did wrong and usually has a hint of how you could improve it [...] because if it is more detailed, if it's spelling it out for us, we're not as likely to think about it as much."

The interviews with students show that such feedback is most likely considered to be unclear feedback. As a result, we see a gap between what students and teachers prefer on written feedback. On one hand, we see that since students are the recipients of feedback and we need their judgement on the type of feedback that resonates with them. On the other hand, students also may not always recognize the benefit of the feedback when the intention of the professors is not communicated.

Students' Utilization of Professors' Feedback

The interviews confirmed that most students value feedback as something that helps them to improve. But in practice, they would very rarely take the time to revise their proofs based on the feedback they were given, let alone when they received high scores on their proofs. The students see feedback as something that they just need to read, keep in mind, and learn from it.

The revision process gave us a better insight on how students utilize feedback. It is fairly obvious that the revision process forces students to read the feedback (see next finding), but we also found that feedback may have an indirect impact. The feedback can address their general approach, but not give them feedback to address proof specific issues. For instance, S2 made the following remark on one of the comments that she received, *"*It helps me to show a, how the way I was thinking about doing proofs in general was wrong but it doesn't specifically help me to redo this proof", when we asked her if a particular feedback helped her on her proof revision. On the other hand, the feedback can be clear to students but still not sufficient for them to correct their mistakes during revision. For instance, S1 understood the meaning of all the comments and the errors she made but she still could not revise her proof. She claimed "I understand what I did wrong but I still don't understand like how the proof would come together [...] because if he told me like where to start, where should have I started, then I would be able to blow through it [the proof]".

This suggests that, having a clear feedback itself is not enough to enable students to correct their proof errors. It suggested that when they were far from having a good proof, they need some direct feedback to guide them. However, a further investigation is needed to see the effectiveness of direct feedback since we do not have much data supporting this argument.

Revising Improves Students' Use of the Feedback and Their Proof Understanding

The fourth important finding is that students receive much more benefit from the feedback than just reading the feedback during the revision stage. To illustrate this, we note that after S3 was done with her revision work, she said, "I realized what I did properly wasn't 100% correct but I didn't really understand why until I really sat down and looked at what the reasoning for me getting it wrong.*"* Furthermore**,** S2 remarked *"*it [revising her proof] helps reinforce the concepts, it helps reinforce the feedback and it's a more effective form of studying than just looking at old homework actually not only redoing it but having consequences behind redoing it." Thus, a student will not likely utilize the feedback unless they need to revise their proof. From our data, we see that when the students revised their proof, they read the feedback, work to comprehend what the feedback is addressing and use the feedback to guide their revision work.

Conclusion

Reading feedback itself is not enough to be able to correct most mistakes; one needs to comprehend the feedback to learn from it. Having the students revise their proofs results in learning from the feedback. Even though the feedback that a professor gives on a proof is not very clear at first sight, students can improve their proof with work on comprehending the feedback and correcting their errors. We observed that this is a very effective way to utilize feedback and also a way to help students to better understand how to rewrite their proof.

Giving feedback itself is not an easy task. Students with different skill levels will need different types of feedback. For example, a student who has a weaker background will not likely understand very brief feedback and therefore they need more detailed feedback. But this is probably not to be the case for an advanced student. Satisfying the feedback preference for every student is also very unlikely to be achieved. These results suggest that the professors might need to regularly remind students that when they give feedback, they are providing ways of thinking to students and want students to learn from the feedback, even when they do not deduct points for proof writing errors. The professors do this to make the feedback as meaningful and thought-provoking as possible.

USO DE EXCEL PARA LA MODELACIÓN DE UNA ACTIVIDAD DE CRECIMIENTO POBLACIONAL

Verónica Vargas-Alejo
Universidad de Guadalajara
veronica.vargas@academicos.udg.mx

Luis E. Montero-Moguel
Universidad de Guadalajara
montero_hk@yahoo.com.mx

En este estudio se muestran los modelos que estudiantes de carreras de administración y contabilidad construyeron al realizar una actividad cercana a la vida real, con el uso de Excel. Se analizan las representaciones y las ideas exhibidas por los alumnos cuando usaron el software. La metodología fue cualitativa. El marco teórico fue la Perspectiva de Modelos y Modelación. Los resultados muestran que el uso de la herramienta permitió explorar de manera dinámica conceptos matemáticos como: covariación, tasa de cambio y función exponencial. Los estudiantes formularon conjeturas, argumentos, explicaciones y justificaciones.

Keywords: Modelación matemática, Resolución de problemas, Tecnología.

Las funciones son objetos matemáticos cuya comprensión requiere de conocimiento de conceptos como variación, tasa de cambio, dominio, rango, función inversa (logarítmica), entre otros; su aprendizaje está relacionado con el desarrollo de un razonamiento covariacional (Carlson, Jacobs, Coe, Larsen, & Hsu, 2002). De acuerdo con investigaciones basadas en la Perspectiva de Modelos y Modelación [PMM] (Lesh & Doerr, 2003), la resolución de situaciones cercanas a la vida real, puede apoyar la comprensión de conceptos matemáticos como función exponencial (Ärlebäck, Doerr, & O'Neil, 2013).

En esta ponencia se presentan resultados obtenidos al implementar una actividad, diseñada con base en un Crecimiento poblacional (CP) y asociada a la función exponencial. Se analiza el potencial de la actividad en términos de las habilidades y los conceptos matemáticos que los estudiantes revelaron y desarrollaron. Se responden las preguntas de investigación siguientes: 1) ¿qué modelos construyeron los estudiantes de carreras de contabilidad y administración para resolver esta actividad CP? Es decir, 2) ¿qué representaciones, conjeturas, creencias, argumentos y conocimiento matemático utilizaron? 3) ¿cómo apoyó Excel la construcción, modificación y extensión del conocimiento? Se utilizaron los seis principios de diseño de las Actividades Provocadoras de Modelos [MEA por sus siglas en inglés: Model Eliciting Activities] (Lesh, Cramer, Doerr, Post, & Zawojewski, 2003) para analizar el potencial de la actividad CP.

Es importante mencionar que el profesor que diseñó e implementó la actividad CP forma parte de un proyecto mexicano de investigación multi-nivel (Doerr & Lesh, 2003), centrado en la PMM. Este profesor participó en un proceso de formación de doce sesiones, de dos horas cada una, donde el profesor, apoyado por investigadores, a) observó la implementación de la MEA del Problema del avión de papel (Lesh & Doerr, 2003; Universidad de Minnesota, 2008), b) discutió los resultados con investigadores, c) implementó la MEA del Hotel (adaptada de Aliprantis & Carmona, 2003), c) diseñó la actividad CP aquí presentada, y d) preparó e implementó la actividad. En este documento, por falta de espacio, sólo se describen los resultados de la implementación.

Marco Teórico

Aprender matemáticas es un proceso de desarrollo de sistemas conceptuales, que cambian de manera continua, se modifican, extienden y refinan a partir de las interacciones del estudiante con su entorno (los profesores y compañeros) y al resolver problemas (Lesh, 2010). Para desarrollar sistemas conceptuales la PMM (Doerr, 2016) propone estructurar experiencias para que el alumno exprese, analice, pruebe, revise y refine sus formas de pensamiento durante el proceso de diseño de herramientas conceptuales podersoas que incorporen construcciones matemáticas significativas (Sriraman & Lesh, 2006). La PMM sugiere el uso de Actividades Provocadoras de Modelos (MEA) en el aula para promover que el alumno manipule, comparta, modifique y reutilice herramientas conceptuales, para construir, describir, explicar, manipular, predecir o controlar sistemas matemáticamente significativos (Lesh & Doerr, 2003). Interesa que los estudiantes logren desarrollar procesos de matematización; es decir, cuantificar, dimensionar, coordinar, categorizar, simbolizar algebraicamente y sistematizar objetos, relaciones, acciones, patrones y regularidades relevantes (Lesh & Doerr, 2003). Lo importante, por lo tanto, es el proceso de construcción de modelos, más que el modelo mismo ya que interesa que el estudiante desarrolle habilidades y conocimiento matemático.

La PMM propone diseñar MEA’s a través del uso de seis principios (Lesh et al., 2003, p. 43): de significado de personal (Principio de la realidad), de construcción del modelo, de autoevaluación, de externalización del modelo (Principio de la documentación del modelo), del prototipo simple y de generalización del modelo. Estos principios fueron usados para el diseño de la actividad CP y el análisis de los datos recolectados, ya que interesaba desarrollar habilidades y conocimiento matemático en los estudiantes. La tecnología jugó un papel importante por su potencial para la construcción de representaciones.

Metodología

Los participantes en este estudio fueron un grupo de un cinco alumnos (adultos inmersos en el campo laboral con edades entre 24 y 34 años) que estaban cursando la materia de Matemáticas aplicadas a los negocios en el primer cuatrimestre de la Licenciatura en Administración y Licenciatura en Contabilidad. La sesión se llevó a cabo en un aula de cómputo. El Equipo 1 se conformó por tres alumnos (S1, S2, S3) y el Equipo 2 por dos alumnos (S4, S5). S1, S2 y S5 eran estudiantes de administración y S3 y S4 de contabilidad. El estudiante S1 tenía las mejores calificaciones del grupo, la estudiante S4 tenía las más bajas calificaciones y participaba poco en el aula; además, S4 trabajaba como vendedora de seguros en horas extraclase.

Santiago Vázquez, alumno egresado de la carrera de administración de nuestro campus UVM GDL SUR, está haciendo su Maestría en Desarrollo Local y Territorio. Su profesor le solicitó que elabore una carta dirigida a la Secretaría de infraestructura vial sobre el crecimiento poblacional de la zona metropolitana de Guadalajara, para que sea tomada en cuenta en los próximos proyectos de infraestructura vial.

Santiago investigó y encontró que en el año 2018 la población de la zona metropolitana de Guadalajara llegó a 4.299 millones y que el promedio de crecimiento es de un 1.7% anual.

Para que la carta tenga el impacto necesario en la Secretaría, Santiago necesita enviar un procedimiento que permita conocer cuál sería la población en los años 2020, 2022, 2024, 2030, 2040, 2041, 2100, expresar si la variación es constante y saber en qué año habrán 6 millones de habitantes, 7.560 millones, 8.232 millones y para qué año la población se duplicará respecto a la del año 2018.

Ayúdale a Santiago a redactar la carta. Describe el procedimiento de tal manera que pueda ser útil para describir el crecimiento poblacional de cualquier otra ciudad o del mundo.

Figura 1: Situación problema de la Actividad CP

La actividad CP, denominada Crecimiento poblacional en la zona metropolitana, estaba compuesta por tres páginas, las dos primeras contenían la actividad de calentamiento diseñada con base en la problemática del incremento de tránsito vehicular como consecuencia del crecimiento poblacional de la zona metropolitana de Guadalajara. La tercera página (Figura 1) contenía el problema, el cual podía resolverse mediante procedimientos de tipo: tabular (recursivo), tabular (relación funcional), gráfico y algebraico. Los datos fueron extraídos de fuentes gubernamentales (Gutiérrez-Pulido et al, 2011).

La actividad CP se implementó en un periodo de tres horas y media en un aula de cómputo, en dos sesiones. Las fases fueron: 1) individual y luego grupal para la lectura del artículo de periódico, 2) individual, equipo y grupal para la resolución del problema y 3) individual para resolver un ejercicio tipo libro de texto. El papel del docente fue como observador y facilitador. Los criterios de análisis utilizados para describir y analizar los modelos elaborados por los estudiantes en Excel y el potencial de la actividad fueron los seis principios para el diseño de APM.

Resultados y discusión de resultados

Se analiza el potencial de la actividad CP en términos del desarrollo de conocimiento, creencias y habilidades matemáticas.

Principio de significado personal

La lectura individual de la nota periodística permitió que los estudiantes se familiarizan con el contexto y se sintieran motivados para resolver la actividad. Mencionaron su preocupación y reflexión sobre el crecimiento poblacional de su ciudad y la influencia de este fenómeno en los problemas de vialidad de la zona metropolitana de Guadalajara.

Principios de construcción, externalización y documentación de modelos

Modelos iniciales. El equipo 1 elaboró su procedimiento en la hoja electrónica de cálculo. Los integrantes del equipo 2 realizaron primero operaciones en su cuaderno con apoyo de la calculadora; posteriormente, trabajaron en la hoja electrónica de Excel y construyeron dos representaciones: una tabular y una gráfica.

Covariación y tasa de cambio en el modelo del equipo 1. En la tabla elaborada por el equipo 1 los estudiantes detectaron que la población (P) variaba, es decir, era diferente cada año e identificaron cómo variaba. Detectaron un patrón de comportamiento, y escribieron una fórmula recursiva para P. La conjetura de S1 y S3 fue que el crecimiento poblacional era lineal y la tasa (1.7) era constante, No reconocieron la relación exponencial.

Covariación y tasa de cambio en el modelo del equipo 2. El equipo 2, al igual que el equipo 1, tuvo dificultades iniciales para identificar si la tasa de cambio era constante o no. La conjetura de S5 fue que el crecimiento era lineal y la tasa era constante (1.7). Sin embargo, S4, después de realizar un par de operaciones, detectó que la variación no era constante y que debían realizar un procedimiento similar al que hacía de manera cotidiana en su trabajo, como vendedora de seguros. El equipo 2 escribió una relación recursiva. A diferencia del equipo 1, sintetizó todas las operaciones. Es decir, utilizó la población del año dado (actual) para determinar la del próximo año, y obtuvo el crecimiento anual de la población. Este equipo tuvo menos dificultades para identificar el comportamiento exponencial. Aunque S1 (del equipo 1) escuchó a S4 mencionar que la variación no era constante, no la tomó en cuenta; lo anterior, debido a la creencia de que S4 era la compañera de más bajo desempeño en su clase de matemáticas.

Función inversa. Ambos equipos tuvieron dificultades para identificar en qué año habría 6, 7.560 y 8.232 millones de habitantes. Pero, pudieron estimar posibles respuestas a partir las tablas de datos construidas en la hoja electrónica.

El modelo final de los equipos. En la discusión grupal de modelos cada equipo leyó su carta, la cual describía los procedimientos realizados. Cuando el equipo 2 presentó la gráfica, S1 dijo en voz alta: "es cierto, el crecimiento no es constante". Tal como se menciona en la literatura de investigación (Lesh & Yoon, 2004), los estudiantes refinaron su pensamiento sobre el problema. Los estudiantes modificaron el primer modelo lineal y construyeron un modelo de crecimiento exponencial.

El uso de Excel permitió a los integrantes de ambos equipos organizar la información dada en el problema y escribir en lenguaje de la hoja electrónica una relación entre las cantidades, la cual (al ser *arrastrada*) posibilitó analizar cómo variaban las cantidades. En la literatura de investigación (Friedlander, 1999) se considera que la relación recursiva está lejana de apoyar la construcción de una representación algebraica de la covariación. Sin embargo, de acuerdo con el NCTM (2000) es importante que en el salón de clases surja la definición iterativa o recursiva para la función y debe ser comparada con $P(n)$ para ayudar a los alumnos a ver las ventajas y limitaciones de ambas. Esto fue retomado más tarde por el docente.

Principio del prototipo simple y de generalización del modelo

S4 (integrante del equipo 2) identificó que el modelo construido era útil para resolver problemas con otro tipo de contexto. No así los demás estudiantes.

Extensión del conocimiento de los estudiantes con apoyo dirigido por el docente

Después de la discusión grupal, el docente, con base en los modelos construidos, promovió la generalización y escritura de la representación algebraica $P(n) = 4.299(1.017)^n$ para alentar la discusión de los estudiantes en términos de la covariación y uso de la función inversa. En una sesión posterior el profesor propuso la resolución de un problema enunciado en forma verbal, de interés compuesto, del tipo de libro de texto. Los alumnos resolvieron sin dificultades el problema y explicaron al docente el comportamiento de crecimiento exponencial que involucraba, es decir, lograron utilizar su conocimiento para describir una situación problemática en otro contexto.

Conclusiones

Con respecto a las preguntas de investigación planteadas inicialmente, se puede mencionar lo siguiente. El uso de Excel para la elaboración de modelos con representaciones tabulares para resolver el problema permitió a los estudiantes concentrarse en el proceso de revisar cómo variaban las cantidades, al *arrastrar* la fórmula recursiva construida con lenguaje de la hoja electrónica. El uso de la representación gráfica posibilitó que en la discusión grupal los integrantes del equipo 1 modificaran sus conjeturas respecto al comportamiento lineal, e identificaran el comportamiento exponencial. Si bien es cierto, los estudiantes no construyeron una relación algebraica para $P(t)$, pero identificaron la relación recursiva en el lenguaje de la hoja electrónica, la cual les permitió contestar varias de las preguntas planteadas y, además, comprender la situación. El apoyo del profesor fue fundamental para construir y dar sentido a la relación algebraica.

La resolución de la actividad CP, posibilitó que los estudiantes construyeran varios modelos, los manipularan, compartieran y predijeran el comportamiento de la situación. Expresaron sus ideas sobre la variación y tasa de cambio, las analizaron y revisaron; observaron patrones, relaciones y regularidades, es decir, los estudiantes desarrollaron habilidades y conocimiento matemático, lo cual es importante en el aprendizaje de las matemáticas. Un aspecto que no se trabajó en el aula fue la exploración del carácter dinámico de los modelos al cambiar las cantidades iniciales y la tasa de cambio para generar familias de problemas, queda pendiente propiciar y analizar estas acciones en posteriores estudios.

USING EXCEL FOR THE MODELING OF A POPULATION GROWTH ACTIVITY

In this study we show the models that students of administration and accounting careers built when performing an activity close to the real life, with the use of Excel. The representations and ideas exhibited by the students when they used the software are analyzed. The methodology was qualitative. The theoretical framework was the Models and Modeling Perspective. The results show that the use of the tool allowed the dynamic exploration of mathematical concepts such as: covariation, rate of change and exponential function. The students formulated conjectures, arguments, explanations and justifications.

Keywords: Modeling, Problem solving, Technology.

Functions are mathematical objects whose understanding requires knowledge of concepts such as variation, rate of change, domain, range, inverse function (logarithmic), among others; their learning is related to the development of covariational reasoning (Carlson, Jacobs, Coe, Larsen, & Hsu, 2002). According to research based on the Models and Modeling Perspective [MMP] (Lesh & Doerr, 2003), the resolution of situations close to the real life can support the understanding of mathematical concepts as exponential function (Ärlebäck, Doerr, & O 'Neil, 2013).

In this paper we present results obtained when implementing an activity, based on a population growth (CP), and associated with the exponential function. The potential of the activity is analyzed in terms of the skills and mathematical concepts that the students revealed and developed. The following research questions are answered: 1) What models did the students of the Bachelor of Administration and Bachelor of Accounting build to solve this CP activity? That is, 2) what representations, conjectures, beliefs, arguments and mathematical knowledge did they use? 3) How did Excel support the construction, modification and extension of knowledge? The six principles for developing model eliciting activities (Lesh, Cramer, Doerr, Post, & Zawojewski, 2003) were used to analyze the potential of the CP activity.

It is important to mention that the professor who designed and implemented the CP activity is part of a Mexican multi-tiered research project (Doerr & Lesh, 2003) focused on the MMP. This professor participated in a training process of twelve sessions, of two hours each, where the professor, supported by researchers, a) observed the implementation of the MEA of the Paper Airplane Problem (Lesh & Doerr, 2003, University of Minnesota, 2008), b) discussed the results with researchers, c) implemented the Hotel MEA (adapted from Aliprantis & Carmona, 2003), c) designed the CP activity presented here, and d) implemented the activity. In this document, due to lack of space, only the results of the implementation are described.

Theoretical Framework

Learning mathematics is a process of developing conceptual systems, which change continuously, modify, extend and refine from the student's interactions with their environment (teachers and peers) to solve problems (Lesh, 2010). To develop conceptual systems, the MMP (Doerr, 2016) proposes to structure experiences, so that the students express, analyze, test, revise, and refine their ways of thinking during the process of desiging powerful conceptual tools that embody significant mathematical constructions (Sriraman & Lesh, 2006). The MMP suggests the use of Model Eliciting Activities [MEA] in the classroom to encourage students to manipulate, share, modify and reuse conceptual tools to construct, describe, explain, manipulate, predict or control mathematically significant systems (Lesh & Doerr, 2003). The students manage to develop processes of mathematization; that is, to quantify, dimension, coordinate, categorize, symbolize algebraically and systematize relevant objects, relationships, actions, patterns and regularities (Lesh & Doerr, 2003). The important thing, therefore, is the process of building models, rather than the model itself.

The MMP proposed to design MEAs through the use of six principles of instructional design (Lesh & Doerr, 2003, p. 43): personal meaningfulness (reality principle), model construction, self-evaluation, model externalization (model documentation principle), simple prototype, and model generalization. These principles were used for the design of the CP activity and analysis of the data collected, since our goal was to develop skills and mathematical knowledge in the students. Technology played an important role because of its potential for the construction of representations.

Methodology

The participants in this study were a group of five students (adults immersed in the labor field with ages between 24 and 34 years) who were studying Mathematics applied to business in the first semester of the Bachelor of Administration and Bachelor of Accounting. The session was held in a computer classroom. Team 1 was formed by three students (S1, S2, S3) and Team 2 by two students (S4, S5). S1, S2 and S5 were administration students and S3 and S4 accounting. Student S1 had the best grades in the group and student S4 had the lowest grades and participated little in the classroom; In addition, S4 worked as an insurance saleswoman in extra-class hours.

Santiago Vázquez, a graduate student of the management career of our campus UVM GDL SUR, is doing his Masters in Local Development and Territory. His teacher asked him to prepare a letter addressed to the Department of road infrastructure on the population growth of the metropolitan area of Guadalajara, so that it can be taken into account in the next road infrastructure projects.

Santiago investigated and found that in 2018 the population of the metropolitan area of Guadalajara reached 4,299 million and that the average growth is 1.7% per year.

For the letter to have the necessary impact in the Secretariat, Santiago needs to send a procedure that allows knowing what the population would be in the years 2020, 2022, 2024, 2030, 2040, 2041, 2100, expressing if the variation is constant and knowing in what year there will be 6 million inhabitants, 7,560 million, 8,232 million and for what year the population will double compared from 2018.

Help Santiago write the letter. Describe the procedure in such a way that it can be useful to describe the population growth of any other city or the world.

Figure 1: Problem Situation of the CP Activity

The CP activity, called population growth in the metropolitan area, was composed of three pages, the first two contained the warm-up activity, based on the problem of increased vehicular traffic as a result of population growth in the metropolitan area of Guadalajara. The third page (Figure 1) contained the problem, which could be solved by means of tabular (recursive), tabular (functional relation), graphic and algebraic procedures. The data were extracted from government sources (Gutiérrez-Pulido et al, 2011).

The CP activity was implemented in a period of three and a half hours in a computer classroom, in two sessions. The phases were: 1) individual and group to read the newspaper article, 2) individual, team and group to solve the problem and 3) individual to solve a textbook problem. The role of the teacher was as an observer and facilitator. The six principles for the design of model eliciting activities were the criteria for analyzing and assessing the models elaborated by students with the use of Excel.

Results and Discussion

The potential of CP activity is analyzed in terms of the students' development of knowledge, beliefs, and mathematical abilities.

The Personal Meaningfulness Principle

The individual reading of the newspaper article allowed students to familiarize them with the context and to feel motivated to solve the activity. They mentioned their concern about the population growth of their city and the influence of this phenomenon on the road problems of the metropolitan area of Guadalajara.

The Model Construction, Model Externalization and Model Documentation Principle

Initial models. The team 1 elaborated their procedure in the Spreadsheet. The members of team 2 made first operations in their notebook with the support of the calculator; later, they worked on the Excel Spreadsheet and built a tabular and a graph representation.

Team 1, covariation and rate of change. In the data table prepared by team 1 the students detected that the population (P) varied, that is, it was different each year, and they identified how it varied. They detected a pattern of behavior, and wrote a recursive formula. The conjecture of S1 and S3 was that the population growth was linear and the rate (1.7) was constant. They did not recognize the exponential relationship.

Team 2, covariation and rate of change. Team 2, as team1, had initial difficulties in identifying whether the rate of change was constant or not. The conjecture of S5 was that the growth was linear and the rate was constant (1.7). However, S4, after performing a couple of operations, found that the variation was not constant and that they had to perform a similar procedure to the one they did on a daily basis in their work, as an insurance salesperson. Team 2 wrote a recursive relationship. Unlike team 1, it synthesized all the operations. That is, he used the population of the given year (current) to determine next year's, and obtained the annual growth of the population. This team had less difficulty identifying the exponential behavior. Although S1 (from team 1) heard S4 mention that the variation was not constant, he did not take it into account; this was due to the belief that S4 was the lowest performer in her math class.

Inverse function. Both teams had difficulties to identify in what year there would be 6, 7,560 and 8,232 million inhabitants. But, the team 2 was able to estimate possible answers from the constructed data tables in the Spreadsheet.

The final model of the teams. In the group discussion of models, each team read their letter, which described the procedures performed. When team 2 presented the graph, S1 said aloud: "it's true, growth is not constant". As mentioned in the research literature (Lesh & Yoon, 2004), the students refined their thinking about the problem. The first lineal model became a model of exponential growth.

The use of Excel allowed teams to organize the information given in the problem and write in the Spreadsheet language a relationship between the quantities, which (when being dragged) made it possible to analyze how the quantities varied. In the literature research (Friedlander, 1999) it is considered that the recursive relationship is far from supporting the construction of an algebraic representation of covariation. However, according to the NCTM (2000) it is important that in the classroom the iterative or recursive definition for the function arises and it must be compared with $P(n)$ to help students see the advantages and limitations of both. This was taken up later by the teacher.

Simple Prototype and Model Generalization Principle

S4 (team 2) identified that the exponential model was useful to solve a broader range of situations. Not so the other students.

Extension of Student Knowledge with Teacher-led Support

After the group discussion, the teacher, based on the constructed models, promoted the generalization and writing of the algebraic representation $P(n) = 4.299(1.017)^n$ to encourage the discussion of the students in terms of covariation and use of the inverse function. In a later session the professor proposed the resolution of a textbook compound interest word problem. The students were able to solve the problem; they explained to the teacher the behavior of the exponential growth involved, from which, they managed to use their knowledge to describe a problematic situation in another context.

Conclusions

With respect to the research questions initially raised, the following may be mentioned. The use of Excel for the elaboration of models with tabular representations to solve the problem allowed the students to focus on the process of reviewing how the quantities varied, by dragging the recursive formula constructed with the language of the Spreadsheet. The use of graphic representation enabled the team 1 to modify their conjectures, regarding linear behavior in the group discussion and identify the exponential behavior. While it is true, the students did not build an algebraic relationship for $P\left(t\right)$, but they did identify the recursive relationship in the Spreadsheet language, which allowed them to answer several of the questions posed and, in addition, to understand the situation. The teacher's support was fundamental to build and give meaning to the algebraic relationship.

The resolution of the CP activity allowed the students to construct several models, manipulate them, share and predict the behavior of the situation. They expressed their ideas about variation and rate of change, analyzed and revised them; they observed patterns, relationships and regularities, that is, students developed mathematical skills and knowledge, which is important in learning mathematics. One aspect that was not worked in the classroom was the exploration of the dynamic nature of the models by changing the initial quantities and the rate of change to generate family of problems; it is still necessary to promote and analyze these actions in subsequent studies.

ANALYSIS OF MATHEMATICAL ARGUMENTS IN A 5TH GRADE CLASSROOM

Youngkee Cho
Texas State University
y_c95@txstate.edu

The aim of this study is to provide a new conceptual framework to analyze mathematical arguments using data from a 5th-grade classroom. For the analysis, Toulmin's model of logic and Inglis's distinction between inductive and deductive warrants are employed. A dominant feature of argumentations in this classroom is that taking particular examples is often used to justify universal statements. To evaluate the validity of such arguments, the examples used in the arguments are classified into four categories according their functions: justifier, representative, witness, and conjecturer. The introduction of this new classification allows to more precisely describe the structure of their arguments and re-evaluate their validity.

Keywords: Classroom discourse, Reasoning and proof.

1. Introduction

This study is based on an analysis of one lesson in a 5th grade classroom, exclusively focusing on their mathematical arguments they make during whole-class discussion. The data is a part of the Discussion in Mathematics Classrooms (DIMaC) project (Project PI: J. Bishop). The purpose of this study is two-fold: (1) to find and describe the unique features of arguments of the 5th grade students in one mathematics classroom; and (2) to re-evaluate the force and effectiveness of their arguments by applying Toulmin's layout of logic along with a new specification of 'arguments by example'. There have been various studies of students' mathematical argumentations or arguments, to which Toulmin's layout of logic was applied. (Krumheuer, 1995; Conner et al., 2014; Inglis et al., 2007; Freeman, 2011). This study differs from these previous ones in that it attempts to re-evaluate the validity of relatively younger students' arguments beyond factual descriptions.

The remainder of this paper will proceed as follows. First, in Section 2, the methods I employ in this study are explained. In Section 3, I will share examples of analyses of arguments in the transcripts. Using these examples, we will see that students' invalid arguments from the perspective of the traditional formal logic, can be re-evaluated as valid within Toulmin's framework if we make a proper distinction of their examples in terms of their functions in arguments. In Section 4, the results of the analyses will be described. Finally, in Section 5, I will discuss the implication and potential instructional application of this study.

2. Method

Traditionally, an argument has been analyzed into premises and a conclusion. Toulmin, however, decomposes an argument into six elements: data (D), warrant (W), claim (C), backing (B), rebuttal (R) and qualifier (Q) (Toulmin, 1958). In this new taxonomy of argument, the validity of an argument depends on the backing supporting its warrant. Since the force of backings is determined by the field in which the argument is used, in Toulmin's framework, the validity of an argument becomes relative to the field. One advantage of Toulmin's new model of logic is that it makes a room to re-evaluate the arguments in this transcript as legitimate ones, which the traditional view of logic would ignore or discard simply as invalid.

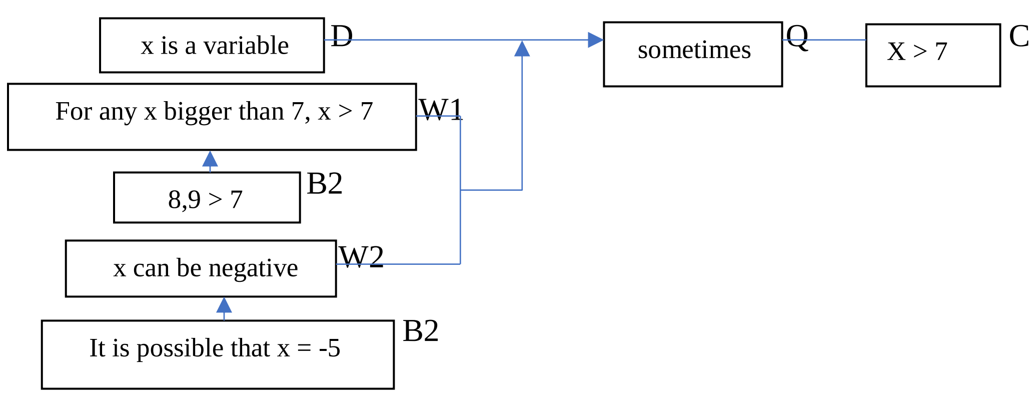
I also adapt Inglis' distinction between inductive and deductive warrants. Inglis defines an inductive warrant as a justification of claim by quantitatively evaluating the claim in one or more specific cases, and a deductive warrant as a form of a formal mathematical warrant, which includes deductions from axioms, algebraic manipulations, or the use of counterexamples. While inductive warrants only reduce uncertainty about the conclusion, Inglis explains, deductive warrants make an argument logically valid (Inglis, 2007). Toulmin and Inglis, however, argue that an inductive warrant paring with its adequate qualifier can make an argument valid as well.

In addition to these tools, I introduce a new classification of examples used in inductive arguments in the transcript. A dominant feature of arguments in the 5th grade classroom in this study is that taking a particular example is often used as means of the justification for universal statements in various ways. For instance, students in the class use a particular number or formula for different purposes. This is illustrated in Table 2. As we will see, this new classification of examples is crucial in evaluating their argumentations in this study

3. Examples of Analysis

Across the entire lesson in the transcript (approximately one hour and twenty minutes), I identified a total of 22 arguments shared during whole-class discussion. Due to its length and the limit of space, I offer only two examples of analyses of arguments. In Argument 1, students are determining whether x > 7 is always, never, or sometimes true. (Note that I am not identifying who [students or teacher] contributes which element of the argument in this analysis; however, in each of the 22 arguments in this lesson students played some role in authoring the argument.)

Argument #1



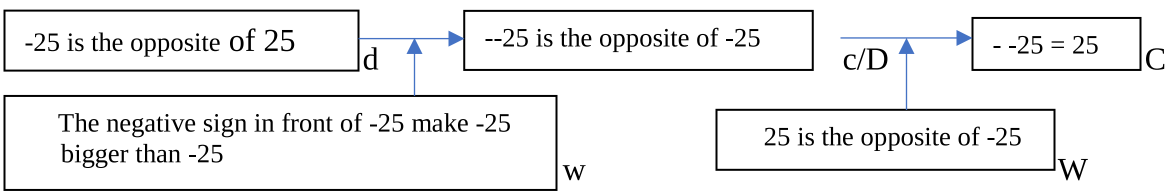
The diagram above illustrates the logical relationship between the statements: The claim C is grounded on the data, D; two warrants, both W1 and W2 support D, each of which is justified by different backings, B1 and B2 respectively; and the qualifier, Q, restricts the applicability of C.

Two things are noteworthy about this argument. First, the whole argument cannot be valid without the qualifier, 'sometimes'; in general, the inductive warrant cannot justify the universal statement without a modal qualifier. Thus, it is an example to show that an inductive warrant paired with an adequate qualifier can justify a universal claim. Second, two inductive backings, B1 and B2 play different roles: While B2 is taken to justify a statement W2, B1 is used only to assure or check the truth of a statement not requiring its justification. According to their different functions, we might call B1 'justifier,' and B2 'witness', respectively.

From a logical point of view, a universal statement cannot be justified by particular instances. However, B2 can justify W2 due to the modality, ‘can’ in W2. W2 can be rewritten as ‘Possibly, x is negative’, and then, B2 can be taken as the evidence for W2. This is another example to show that an inductive warrant or backing can make its argument valid if it is paired with an adequate qualifier. In the case of B1, the context in the transcript clearly indicates that B1 was not intended to justify W1 but just to check the well-known fact which is accepted by all members in the class. It would not be appropriate to require that B1 justify W1 when B1 is not intended to justify W1. Overall, thus, the Argument 1 can be said to be sound even if it contains inductive backings and warrants.

The second example I share comes from a discussion of whether --25 = 25 is always, never, or sometimes true. This argument contains a subargument—the data, warrant, and claim of which is expressed by small letters, d, w, and c, respectively. Note that the claim of the subargument, c, is used as the data of the main argument.

Argument #2



The argument presupposes that the opposite of a number is unique. One important point here is that in d and W, the number, 25 plays different roles. In W, 25 is being used to refer to the number 25. But in d, 25 represents numbers in general. That is, in d, 25 is being treated as an arbitrarily selected number, not as 25 itself. So, we can rewrite d more explicitly as ‘-25 is the opposite of 25 in the virtue of being a number’ or ‘-25 is the opposite of 25 insofar as it is a number.’ Thus, what d really means is that, ‘for any number x, -x is the opposite of x’; even if we substitute 25 with any number, the force of d does not change. In such case, an example is used to represent a group of mathematical objects like numbers. We might call such an example ‘representative.’ Thus, the subargument can be seen as deriving an existential claim, c, from a universal statement, d. Using a particular number as ‘representative’ of a certain group of number is understandable and even justifiable in a circumstance in which students are still learning the concept of variable and only familiar with using concrete numbers.

From these two arguments, we see that examples or instances can play different roles and a proper classification of them may render seemingly invalid arguments valid ones. Another distinguishable function of examples in the students’ arguments is to conjecture the truth of a general statement. Students are sometimes found to use a specific example to determine the truth of a universal statement. For instance, to decide whether a general claim ‘-c > c’ is true, they check the truth of -3 > 3. This ‘conjecturer’ is to be distinguished from ‘justifier’ in that the former is not intended to justify a claim by itself. Thus, as far as it helps or leads students to find a further justification for a universal claim, using it as a warrant for the claim is not problematic.

4. Result

The following are the results and interpretation of the analysis of students and teacher’s arguments in the transcript. Table 1 categorizes the premises used in each argument in this lesson based on (a) whether the argument was inductive or deductive, and (b) whether the premise was used as data, warrant, or backing. Table 1 reveals a general feature of arguments in this 5th grade mathematics classroom. That is, their arguments mostly rely on inductive premises, which function primarily as data and warrants (with few instances of backings). Since the students did not yet fully develop abstract thinking and deductive reasoning, this is understandable. Especially, universal clams and warrants are justified by particular numbers of formula.

Table 1: Inductive vs. Deductive

	Data (36)	Warrant (17)	Backing (1)
Deductive Premises	9	2	0
Inductive premises	27	15	1

In Table 2, I categorize the 42 instances of examples used in arguments based on their function or purpose. The class in this study uses a particular number to (i) represent a certain group of numbers such as negative or positive number, (representative), (ii) confirm the truth of a well-known mathematical fact (witness), (iii) conjecturer whether a statement is true or false for the direction of their further proof (conjecturer), or (iv) directly justify a claim or warrant (justifier). 41 of the 42 examples were used as the premises in the 43 inductive arguments in Table 1. Thus, it can be said that taking an example is the dominant method of argumentations at this stage.

Table 2: Use of Example

Examples	Representative	Witness	Justifier	Conjecturer
42	6	4	31	1

Table 2 shows that the taking an example method is used for different purposes in this classroom. Note that examples are most often used as a representative of some group of numbers. This is because they need to prove a general statement, without the knowledge of deductive reasoning or without knowing how to deal with variables.

Table 3 categorizes the 9 arguments (out of 22 total from this lesson) that use a qualifier by the type of qualifier. Among them, 'sometimes' is most frequently used. We have seen that with the use of 'sometimes', arguments can become valid. Thus, as Inglis points out, with an adequate use of qualifiers, we can preserve the validity of arguments supported by inductive premises.

Table 3: Qualifier

Qualifier	Sometimes	Always	Never
9	5	3	1

5. Conclusion

So far, we have seen the features of arguments in a 5th grade mathematics classroom. One dominant feature of their arguments is that taking an example is a predominant method of justification. We classified such examples into four kinds according to their function in the argument: representation, witness, conjecturer, and justifier. We found that, with that classification, most seemingly invalid substantial arguments in the transcript may, in fact, be valid. We also saw that adopting a qualifier can change the status of an argument.

This study provides a conceptual framework to better understand the nature of mathematical arguments of students who have not yet been exposed to justifying general mathematical statements through deductive reasoning. This framework is expected to allow mathematics educators to develop more suitable instructional strategies to help younger students advance their own valid mathematical argumentations within their current mathematical knowledge.

VISUALIZING PROPORTIONAL REASONING WITH MEASURED QUANTITIES

Reasoning with measured quantities and developing proportional reasoning are crucial and challenging focuses of middle grades mathematics. Research-based guiding principles (NCTM, 2014) include promoting reasoning with quantities as well as using and connecting mathematical representations. We consider six future middle grades teachers and some of the fine-grained reasoning that occurs while they solve a missing-value proportional reasoning task. Future middle grades teachers were able to use a provided visual display along with a unified view of multiplication to create equivalent proportions.

Keywords: Cognition, Problem Solving, Rational Numbers, Using Representations

Visualization can aid engagement with meanings and concepts that are not readily available through symbolic representation (Arcavi, 2003). In addition, Arcavi (2003) noted that visuals can "group together clusters of information that can be apprehended at once" (p. 218) and noted that "visualization at the service of problem solving, may also play a central role to inspire a whole solution, beyond the merely procedural." (p. 224). Proportional reasoning is both a crucial and challenging concept in the middle grades, and its development, or lack thereof, can greatly influence success for students in later mathematics (Beckmann & Izsák, 2015).

The Common Core State Standards (2010) stress the importance of reasoning with fractions as measured quantities in real-world problem contexts. Quantitative operations are not the same as numerical operations and correspondingly, reasoning with quantities is more complex than reasoning with numbers void of context (Thompson, 2011). Middle grades teachers are required to reason multiplicatively using fractional amounts with designated units, and to guide their students in developing the knowledge to operate with quantities. The present study investigates how future middle grades teachers reason with quantities, as well as how a visual display provides affordances or constraints for reasoning.

Theoretical Perspective

We draw upon theoretical and empirical work in quantitative and proportional reasoning to guide our research design and analysis. More specifically, we consider an account of proportional reasoning (Beckman & Izsak, 2015) that uses a quantitative definition of multiplication (see Figure 1) considering equal size groups where the Product amount (P) is comprised of both units of measure for the Multiplicand (N) and the Multiplier (M).

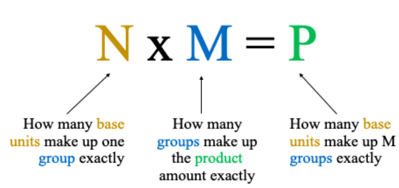

Figure 1: Quantitative Definition of Multiplication: When multiplied together, the multiplier (M) and Multiplicand (N) yield the product P and this can be represented as

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

either MxN=P or NxM=P (Beckmann & Izsák, 2015).

The Multiplicand (N) is the number of base units in exactly one group and can be either a whole number or a fraction. The Multiplier (M) is the number of groups, which can also be fractional. The resulting equation is MxN=P or NxM=P, where either order employed in a consistent fashion provides structure for developing reasoning across situations. For this study, we use NxM=P where the number of base units in each group appears first.

Proportional relationships can be seen within this quantitative view of multiplication when there is invariance with one of the three terms, while the other two terms co-vary. For example, if the multiplicand (N) is fixed, there are always 3 cookies on each plate. In this case the multiplier (M) and product (P) can vary (3 plates yields 9 cookies on all the plates, 5 plates yields 15 cookies on all the plates, etc.). Proportional reasoning is often enacted procedurally by both students and teachers and the focus on numerical solutions to standard missing value problems may attribute to the difficulty students and teachers have when explaining it in context. In order to explain why the typical cross multiplication algorithm works in context, a well-developed recognition of situational attributes and a coordinated understanding of relationships is necessary. Using an equal sized groups view of multiplication allows for a more conceptual understanding of proportionality and can help future teachers understand and explain the “why” of cross-multiplication.

This unified view of multiplication works across situations when working with measured quantities. Quantification considers proportionality, as it is “the process of conceptualizing an object and an attribute of it so that the attribute has a unit of measure, and the attributes measure entails a proportional relationship (linear, bi-linear, or multi-linear) with its unit” (Thompson, 2014, p. 37). Since a measured quantity must be conceptualized, it seems reasonable that using a consistent name for an object, like an apple, might be helpful to reason with it in context. Additionally, the realization that the same attribute of the same object can be measured in different units entails proportional reasoning.

Research Design

We analyzed transcripts from six future middle grades teachers who were interviewed in the fall of 2016 using a thematic analysis approach (Braun & Clarke, 2006). These future teachers (FTs) were enrolled in the first of a two semester sequence of mathematic content courses, the first with a focus on numbers and operations and the second with a focus on algebra. These semi-structured interviews were video recorded, all written work created during the interview was scanned and the interviews were transcribed verbatim. The data for this study is part of a broader study of future teachers’ reasoning about multiplication and division, fractions, and proportional relationships.

This study considers one particular task, the daffodil problem, given to each of the six participants in part of the third interview. The interviews took place near the end of instruction focusing on multiplication and division, but before instruction on ratio and proportional relationships. Each interview was recorded with two video cameras in order to capture both a close-up view of the participant’s work and a broader view including body language, mannerisms and facial expressions (Hall, 2000). Each of the authors watched the interviews, read the interview transcripts and co-created lesson graphs (Seago, 2004), making analytic notes to document our interpretations of the FT’s reasoning.

The daffodil problem was designed to target a sense of invariance, which in this instance can be seen when the multiplicand (N) remains constant. The problem includes two parts, A and B given to the participants separately. The first part is simply a word problem about a gardening company who plants 224 daffodils per acre and asks how many acres are planted at a park where they plant 392 daffodils. The second part asks the participants to use a visual display (see Figure 2) to solve this same problem.

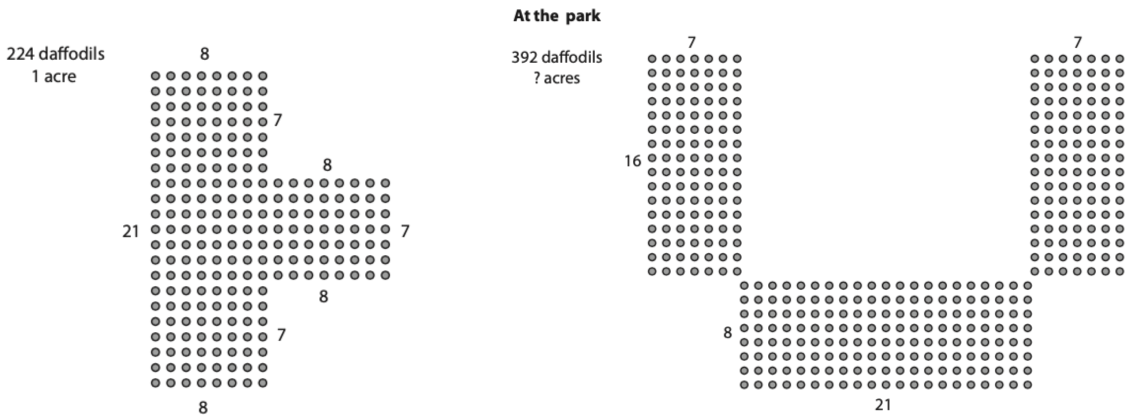

Figure 2: Visual Display for the *Daffodil Problem*, Part B

Results and Significance

We used thematic analysis (Braun & Clarke, 2006) to code the data from the transcripts and identify resulting themes. Our report addresses three themes that our preliminary analysis has identified: quantifying values, selecting base units and identifying equivalence. As we analyzed the transcripts, we use the term “plot” for each of the 7x8 rectangle of 56 daffodils. These are the equal sized groups that allow participants to recognize that the daffodils planted at the park is equivalent to 7/4 acres without carrying out the numerical calculation of 392 ÷ 224.

Overall, the FTs were able to numerically model how to solve part A of the daffodil problem and obtain a correct equation using either division (392 ÷ 224 (3), 392/224 (1)) or cross multiplication (224/1 = 392/x (2)). More of the FTs may have chosen division as opposed to cross-multiplication since they had been exposed to the standard structure of multiplication (NxM=P) in the classroom where division occurs when the multiplier or multiplicand is unknown. Some FTs struggled to explain why their cross multiplication equations worked, one stating “Because I know if you cross-multiply you get an equation… just what I’ve been taught”. All FTs identified this as partitive division where a daffodil is a base unit and an acre is a group. This is consistent with the equation 224*M=392 where the N and P are invariant and the number of groups (M) is unknown.

More interestingly, their reasoning with the visual display showed a range of reasoning and revealed some interesting patterns. Most of the participants began Part B of the daffodil problem by matching like size regions with more of a focus on shape or number. They generally found the whole acre in the park drawing, then determined the value of the “leftover” part, knowing the value is somewhere between one and two. All FTs gave their initial answer in the form of a proper fraction ($1\frac{3}{4}$) which has benefits of being able to see where it falls on the number line. However, it may be this proper form that is stressed in schools that limits their proportional reasoning and the ability to apply the 7:4 ratio to see the 7/4 acres of daffodils that are planted at the park.

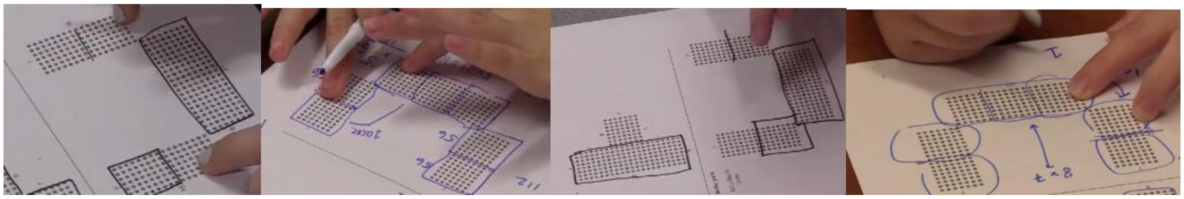

Figure 3: FTs Work Using Plots to Determine Acres

Quantifying an object includes envisioning both an attribute to be measured and a unit of measure. Many of the FTs had difficulty in naming the quantity of a “plot” and this may have impacted their reasoning. Words such as rectangles, blocks, “smallers”, boxes, thingy, and squares were used to identify the ¼ of an acre. Those FTs who identified a name and used it consistently provided more coherent and better coordinated explanations. Additionally, those who identified a number of daffodils (56) for this plot were able to create an equation.

Some of the participants struggled to keep up with the appropriate whole, and two FTs considered the plot to be 1/3 of the whole, as they were using the larger rectangular 8x21 block as the whole instead of this area plus a plot which represents one acre. These FTs self-regulated and found the right relationship, one after receiving a scaffolding question from the interviewer. We consider this to be a constraint of reasoning with the visual display.

Most (5) of the FTs explained the subdivided acre with multiplication by retaining the base units as a daffodil and redefining a group as a plot. However, Molly, who in our opinion had the most coherent explanation and worked flexibly throughout the problem, retained the acre as a group and redefined the base unit as a plot (she consistently called this a square) as opposed to retaining the base unit as a daffodil.

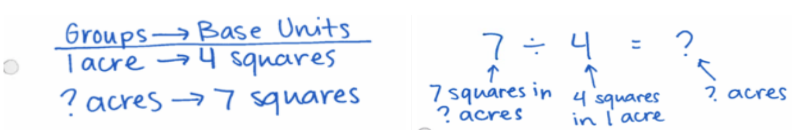

Figure 4: Molly’s s Work Identifying Plots (squares) as Base Units

At times FTs used drawings to come up with relationships, but then did not acknowledge the usefulness of the drawing. For example, Lily was able to use the visual display to see the ratio of plots in an acre to plots in the park as 4:7 but claimed to “use my math rather than these drawings.” Although Lily was unable to produce an equation for part B, which we contribute to her lack of understanding of the measurement attribute, she was able to speak to and represent the equivalence of the relationships (see Figure 5).

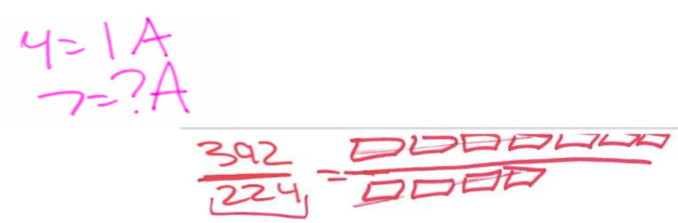

Figure 5: Lily’s s Work Representing Equivalence of Fractions

Conclusion

Research has shown students lack conceptual understanding of proportional reasoning (Keitel, C., & Kilpatrick, J. 2005), and often students and teachers alike will solve missing value proportion problems procedurally applying an algorithm such as cross multiplying. Visual displays can be a useful tool in scaffolding students conceptual understanding, however many practicing teachers are not comfortable using them in instruction (Jacobsen & Izsák, 2015). Our preliminary analysis shows that a provided visual display allows FTs to recognize equal size groups and use this information along with a unified view of multiplication to create an equivalent proportion. The evidence provided here may assist in instilling the need to use representations well beyond the elementary grades.

DIMENSIONS OF STUDENT DOUBTS AND MATHEMATICAL PROBLEM POSING

Priyanka Agarwal
University of California, Irvine
priyanka@uci.edu

The paper reports on student task-based interviews and a teaching experiment on students' mathematical problem posing. The study aims to better understand relationship between students' mathematical doubts and ways in which students craft math problems. Drawing on student small-group interactions and student written-work, the study finds four dimensions of mathematical doubts: pragmatic, empirical, theoretical, and transformational. Definitions, frequencies, and examples of the dimensions of doubts are elaborated. Relationships between the dimensions of doubts and implications for student learning are discussed.

Keywords: Doubts, Problem-posing, Student questions, Mathematical inquiry

Given the importance of mathematical problem-posing for student learning (NCTM, 2000; NRC, 2005), researchers have begun theorizing how to design learning spaces and prepare teachers for problem-posing pedagogy (e.g., Lueng, 2013; Singer, Ellerton, & Cai, 2015). A large part of making progress towards this goal includes seeking clarity of students' epistemic needs (what is it that students are drawn to know and their developing understanding of what can be known and how to know it) and understanding how might students' epistemic needs be related to how students craft math problems. Epistemic needs refer to the feeling of doubt that propels the desire to know and understand something. A doubt is often a feeling of unease, a troubling thought about a situation, a question not yet well-formed, or simply a statement that expresses some kind of uncertainty, wondering, perplexity, or even a conjecture. Thus, I conceptualize problem-posing as student questioning when faced with *doubts* about mathematically obscure situations.

In defining problem posing using the notion of mathematical doubts, I assume that encountering a math doubt is a precondition for student problem posing. This assumption while theoretical in nature is supported by many examples of mathematical work of students and mathematicians in the literature. Dewey (1910) argued that "The origin of thinking is some perplexity, confusion, or doubt" (p. 12) that allows problem finding and reflective inquiry within a socioculturally situated activity. Dillon (1988) referred to student questions that are "expressive of doubt, uncertainty, or perplexity" (p.199) as knowledge seeking tools that allow students to initiate a search for knowing. More recently, Engle & Conant (2002) conceptualized learning as students' efforts to resolve "disciplinary uncertainties". A common theme across these ideas is the recognition that doubts lead to questioning and questioning to new understandings. The notion of mathematical doubts, thus, provides an important lens to investigate the understudied processes of problem-posing. It gives us the leverage to step outside the certainty that so strongly epitomizes the discipline of mathematics and instead investigate the confusions, perplexities, and epistemic needs of students that might engender productive problem-posing.

Using a rich set of data that includes video-recordings, student written work, and interviews; the study asks the following research questions: What types of initial doubts emerge when students explore open unstructured artifacts? What relationship, if any, do the math doubts have with the problems students pose and in what ways do students mathematize their initial doubts to pose meaningful math problems?

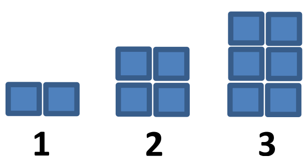
Methods

Research Setting and Data

Data includes task-based paired interviews (Houssart & Evens, 2011) with 64 middle-school students and a teaching experiment in two low-track eighth-grade classes (n=56) in a predominantly working class Latinx neighborhood school. The student interviews were conducted by me. The teaching experiment and the classroom lessons were designed in collaboration with a math teacher. The tasks students worked on during both the interview and the classroom experiment were designed such that students could verbalize their doubts and musings prior to posing a problem. All interviews and classroom interactions were videotaped. Whole-class discussions and 3-4 small-groups in each period were videotaped using flip cameras with an attached table mic. Written work of students was collected to capture their non-verbalized ideas, representations, and conceptual knots.

Tasks

Figure 1 shows the artifact presented to the students during the interview. It consisted of a growth pattern made up of blue blocks placed on a sheet of white paper in the center. Typically, pattern problems (see Parker, 2009; Mathematics Education Collaborative patterning tasks) are used to promote multiplicative thinking, algebraic and functional reasoning and understanding of variables and expressions. Figure 2 shows the border image given to the students during the classroom experiment. It is typically used in a well-known border problem (see Boaler & Humphreys, 2005) as a pre-algebra task to develop knowledge of variables, equivalent expressions, and generalizations. During both the interview and classroom experiment, students were first asked to generate a list of what they notice and wonder about the given artifact or situation. Next they were asked to use their observations and questions from the notice and wonder list to create math problems together with their group-members.



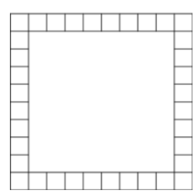


Figure 1

Figure 2

Data Analysis

Data Preparation. 19 video-hours from the interview and 16 video-hours from the classroom along with the written work were analyzed. Prior to the analysis, the data was prepared using Heath, Hindmarsh, & Luff's (2010) three stages: a preliminary review, a substantive review, and an analytic review of the data corpus (see also Erickson, 1985). Content logs cataloguing the participants, time stamps, and a simple description of the students' mathematical activities were created. Specific instances of the phenomenon—student doubts—were found and stored in a separate excel sheet called the *doubt list*. Doubts were any written or verbal statements that reflected a perplexity, query, wondering, or a conjecture. Any statement that reflected student observation of visible or obvious features of the given artifact was not considered a doubt. Doubt list was used to create doubt logs that documented the verbal and nonverbal activities that transpired after the emergence of the initial doubt leading to students posing math problems.

Coding (RQ1). The main purpose of coding the doubt list for both interviews and classroom lessons was to determine if there are any patterns in the data that could more systematically help us understand the nature of students' initial doubts to answer the first research question. The coding generally followed Saldana's (2015) "Four Ductions": deduction, abduction, induction, and retroduction to draw on what we know from the literature about the nature of mathematical thinking and questioning specific to the tasks but also to stay open to the new meanings emergent in the data. I conducted three iterations of coding.

First, I conducted In Vivo coding (Saldana, 2015) that helped gather the mathematical features of the tasks that students focused on and the different ways in which students perceived the given artifact. This, however, did not help shed light on underlying epistemic needs of students, i.e., what students might have desired to know or understand. In the final iteration, I looked at student doubts through the lens of what students might be doing or trying to get at when posing a doubt. Emergent codes included codes such as recalling, generalizing, computing, historical grounding, finding relevance, and asking what-if, why, and how questions. These codes were then thematized into four categories of doubt, which are described in the Findings section. Lastly, I conducted open Process Coding (Saldana, 2015, p.96) to further confirm these themes and to extract the tacit conceptual meanings behind what students were doing or saying.

Processes (RQ2). Using the doubt logs, I selected cases that would distinguish productive problem-posing from the ones that were not productive. Productive defined as problems meaningful enough to allow resolving initial doubts and solutions to which are not immediately apparent. For example, student asking "How many squares?" in the border problem is considered a valid student doubt, but it is not considered a productive problem, since the solution to it can easily be figured by counting. Then, I conducted analyses of small-group interactions for the selected cases to understand the characteristics and the conditions that allowed students to productively mathematize their initial doubts into meaningful math problems.

Findings

Research Question 1

I find four interrelated dimensions of student mathematical doubts: Pragmatic, Empirical, Theoretical, and Transformational.

1. **Pragmatic Doubts.** By raising a pragmatic doubt, students are seeking to understand the purpose, significance, or relevance of the given artifact. A larger question that students appeared to be asking was *What is it for?* Sometimes, rather than questioning its purpose students simply speculated or conjectured it. For example, in the border problem (refer to figure 2), several students in different period and groups said, "It looks like a picture frame", and later used this idea to create a math word problem.
2. **Empirical Doubts.** By raising an empirical doubt, students are seeking to understand specific features and characteristics of the artifact in order to make sense of its non-obvious aspects. A larger question that students appeared to be asking was *What is it?* Once again, many times rather questioning, students conjectured about those empirical features of the artifact. For example, in the pattern problem (refer to figure 1), several

students made conjectured about the relation between case number and the number of cubes in that case: “In each case, the number of the case is multiplied by 2”.

3. **Theoretical Doubts.** By raising a theoretical doubt, students are questioning the facts and characteristics of the artifact as given. Essentially, students were asking: *Why is it the way it is?* Why is it made that way? Resolutions of questions of this nature helped students theorize the reasons behind certain characteristics of the artifact. For example, for the growth pattern several students asked why it only uses blue blocks when the red block as were also available. Students then theorized that blue blocks are to represent even number of cubes while addition of blue blocks can help create another pattern with odd numbers.
4. **Transformational Doubts.** By raising a transformational doubt, students are reaching for new possibilities and transformations of the given artifact. Essentially, students were asking: *What if? How can it be changed?* This dimension of doubt is similar to Brown & Walter’ (2005) what-if-not strategy of formulating new problems. Students were modifying the given properties of the artifact to generate new possibilities.

Research Question 2

Table 1 outlines dimensions, frequencies, and examples of doubts and associated mathematical problem posing. It was found that variation in the frequency of types of doubts students raised depended on the participation structure, the nature of the task and students’ prior familiarity with it, and the ways on which those types of doubts were positioned by the researcher/ teacher vis-à-vis mathematical credence. For instance, the teacher in the classroom in the very beginning explicitly shut down pragmatic and transformational doubts as not worthy of belonging in a math classroom. This influenced students’ diversion towards asking more Analytic and transformative doubts in the classroom as compared to during the interview. Also, it was later found that while students had exposure to growth pattern problems, students had seen the border problem for the first time. This influenced students being able to reach for and imagine new possibilities in the case of the border problem; while for growth pattern problem students asked more familiar and expected questions. Lastly, it was determined that when taken up for problem-posing, each type of doubt had capacity for generating a meaningful math problem as displayed by the given examples in the Table 1.

Table 1: Four Dimensions of Doubts, Frequency, and Associated Math Problem

Types of Doubt	Frequency		Examples—Initial doubts	Examples—Math problems
	Interview	classroom		
Pragmatic (What is it for?)	45%	16%	Can it be used as a picture frame?	How many pictures and of what shape and size can fit in the picture frame?
Empirical (What is it?)	27%	35%	How many border squares are there and how can I tell?	Find the number of border squares in NxN square.
Theoretical (Why is it the way it is?)	22%	13%	Why is the middle empty?	How many ways are there to fit 16 squares or less in the middle?
Transformational	6%	36%	Can they be any another shape?	If they were triangles instead of rectangles: find the relation

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* St Louis, MO: University of Missouri.

(What if? Can it be changed?)				between case# and the area of the triangle (# of blocks)?

Discussion

A nuanced understanding of the dimensions of students' doubts and it's relation with problem-posing disrupts the deficit identity that is associated with struggling students in math. Findings reveal that even the silliest of a doubt is a result of a learner's epistemic need to know something at a certain time in a certain way and holds a potential for productive problem-posing. Findings highlight the power of cultivating students' doubts for problem-posing, student agency, and for restituting marginalized students' claim to knowledge and knowledge producing practices.

Keywords: Reasoning and Proof

Proof is an integral component of knowing, doing, and understanding mathematics (Schoenfeld, 1994), and current policy suggests that K-12 students should engage in reasoning and proof regularly (CCSSI, 2010; NCTM, 2000). A considerable amount of literature suggests students of all ages struggle to create viable mathematical arguments (Stylianides, Bieda, & Morselli, 2016). Because of this, scholars have suggested multiple supports to aid students in becoming more proficient in proof (Nardi & Knuth, 2017). In this paper, we explore two classroom-based interventions for supporting proof and argumentation in K-12 contexts: communal criteria for proof and collective argumentation.

Communal Criteria and Collective Argumentation

Communal criteria for proof refers to negotiating the standards for what counts as proof in a specific mathematical setting (Stylianides & Stylianides, 2009). When students negotiate the standards for proof, it increases their autonomy in the classroom (Yee, Boyle, Ko, Bleiler-Baxter, 2018), and it explicates the standards for their mathematical community. Collective argumentation is a process wherein students create arguments in collaboration with others as opposed to individually. Specifically, our conceptualization aligns with Brown (2017) who developed the key-word format for facilitating collective argumentation. Brown's (2017) key-word format includes six phases: *represent, compare, explain, justify, agree, validate*.

Methods and Findings

Our study took place during the 2018-2019 school year at a private middle school in the Southeast. The participants were 44 eighth-grade students who were enrolled in one of four different Pre-Algebra classes. For the purposes of our study, Author 1 and Author 2 co-taught each of the four class periods for three days of instruction (55-minute class periods) introducing students to communal criteria and collective argumentation. Over the three days of instruction, students worked on three proving tasks in groups of four, and their arguments were coded according to Stylianides and Stylianides (2009) framework. The preliminary results suggest engagement with communal criteria combined with collective argumentation can help students understand that an argument needs to be general to count as a proof. The groups also generally made progress in their ability to create increasingly sophisticated arguments over the three days of instruction. Future analyses will consider qualitative aspects of students' discourse to understand productive forms of engagement with communal criteria and collective argumentation.

FACILITATING THE IMMIGRATION DEBATE WITH STATISTICAL MODELING

Ayse Ozturk

manouchehri.1@osu.edu

This study examined a model of teaching with the intent to empower students to reach statistically sound conclusions and develop a personal perspective of the U.S.–Mexico border context and the hardships immigrants face while trying to cross the southern U.S. border. The following question guided our study: How can we advance students' statistical reasoning through the modeling process when adopting the socio-critical perspective of modeling? Our research is grounded by the socio-critical perspective of statistical modeling (Zapate-Cardona, 2018), which suggests that choosing a context that is not only authentic but also socially significant can aid the development of both statistical reasoning skills and deeper awareness of complex real-world social issues. In adopting this perspective, we set out to support our students in investigating the issue of immigration. Students posed their own statistical questions and collected, summarized, represented, and interpreted statistical data to develop an understanding of the issue of immigration between the United States and Mexico.

A teaching experiment (Steffe & Thompson, 2000) methodology was used to study how a teacher guides students through the modeling process, which consists of formulating questions, collecting data, and representing and interpreting results. The research team included the teacher/researcher and an observer who worked with the students twice a week for 60 minutes for 3 weeks with 19 students between the ages of 16 and 18 years old. Each teaching episode was video-recorded in order to examine what transpired during the course of instruction, to prepare subsequent teaching episodes, as well as in conducting a retrospective analysis of the teaching experiment. An instruction unit was designed with six lessons around the issue of immigration between the United States and Mexico. This unit emerged as a result of student interests within the context of immigration. Our research team set out to design lessons as a reaction to these student-driven discussion. The website *http://humaneborder.info* was utilized to guide students in their statistical investigation. The site offers migration data from 1981 to 2018. Students collected and organized data from the website, presented their data to the class, and made informal inferences to interpret the data's results.

The ongoing data analysis has focused on different processes: (1) the representations students used to summarize, organize, and understand the data; and (2) the use of models to make predictions or draw conclusions. Our study confirmed that students' statistical investigation process, from formulating questions to drawing conclusions from datasets, became meaningful to them as they learned more about the context of the issue of migration over the southern border. Overall, three discussion themes emerged from students' investigations on migrant deaths: (1) the primary cause of death, (2) gender differences in deaths, (3) in what regions the most migrants died. Two aspects of implementation were prominent in supporting students' statistical reasoning: using a website to support the statistical investigation process virtually and numerically offered a means to make assumptions, and generate conclusions; and orchestrating reflective classroom discussions to elicit students' reasoning and sense-making supported the development of shared understanding.

UNDERSTANDING THE GENERALITY REQUIREMENT FOR PROOF ACROSS MULTIPLE DIMENSIONS: THE CASE OF LEXI

Kimberly Conner
University of Northern Iowa
kimberly.conner@uni.edu

Keywords: Reasoning and Proof; Cognition; High School Education

One key component of proof is that they demonstrate the validity of the claim for all cases included in the scope of the statement (generality requirement). Prior studies have described the difficulties secondary students face in recognizing and adhering to the generality requirement, such as becoming convinced of a claim's validity after checking a few examples (e.g., Healy & Hoyles, 2000), not consistently recognizing that a proof demonstrated the statement's validity for all possible cases (e.g., Martin, McCrone, Bower, & Dindyal, 2005), and remaining open to the existence of a counterexample after being presented with a proof (Chazan, 1993). This poster presents an analytical framework for analyzing students' understanding of the generality requirement. I illustrate the framework using a series of arguments produced by Lexi, a ninth grader who participated in a teaching experiment that aimed to introduce proof through developing understanding of the generality and purpose of proof.

I analyzed Lexi's written and verbal work during a series of semi-structured interviews for evidence of her recognition of and adherence to the generality requirement when proving and evaluating geometric and numeric universal claims. Specifically, I a) attended to the explicit and implicit justifications included in her written arguments and used when evaluating provided arguments; b) categorized the purpose of examples used, if any, during the proving process (Ellis et al., 2017); c) identified language used that explicitly referenced the scope of the proof claim or her mathematical statement; and d) noted other aspects of her argument that related to the generality requirement, such as the way she used variables and labeled her self-constructed diagrams during the proving process.

Lexi consistently demonstrated understanding of the generality requirement through her justifications and use of examples, but struggled to reflect this understanding when using variables or labeling diagrams. She routinely included justifications that adhered to the generality requirement within her written arguments, although they tended to be implicit when proving numeric claims (e.g., "Anytime you add two even numbers together, it equals even…"). She also consistently evaluated provided empirical arguments as *not* proofs (e.g., "You can have, like, different examples and it might not prove all of them"). Next, she used examples as a way of gaining initial certainty regarding the validity of the conjecture and to convey a general claim when verbally explaining her arguments (e.g., "So anytime the shape adds up to a multiple of 180, it will tessellate. So like, if it adds up to 720º, that'll tessellate too"). Despite Lexi's prior success in Algebra and understanding of the generality requirement according to the prior criteria, she consistently interpreted variables as placeholders that could be used to generate examples and used variables as placeholders when writing equations in her arguments. She also initially used specific numbers to label her constructed diagram during a proof task, but then revised them to variables after feedback. Viewing Lexi's understanding of the generality requirement across multiple dimensions highlights the complexity of this component of proof and the multiple facets of mathematical arguments it impacts, from the types of justifications used to the way that diagrams are labeled and mathematical relationships are represented.

AN EXPLORATION OF STUDENTS' ABILITIES FOR DETECTING ERRORS IN NON-AUTHENTIC AND ILL-POSED WORD PROBLEMS

Roberto G. Perez-Delgado
FCFM, BUAP, Mexico
rgperezd@gmail.com

Josip Slisko
FCFM, BUAP, Mexico
jslisko@fcfm.buap.mx

Keywords: Problem Solving, Critical Thinking, Textbook Errors

Much has been said about the need to integrate critical thinking into the curricula and classrooms in all levels of education, however, it is still unclear how to do so. Ennis (1996) outlines specific dispositions and abilities that critical thinkers should possess, such as, but not limited to: analyzing arguments, questions, and their validity, identifying possible answers to a question (if there are any), judging the credibility of sources, and seeking alternative sources of information. We propose that the activity of searching for and detecting errors in word problems can help develop critical thinking skills since this entails all of the abilities and dispositions mentioned above. This work discusses the initial results from a study concerning Mexican middle school students' abilities for detecting errors in non-authentic and ill-posed word problems drawn from current approved and published Mexican seventh grade mathematics textbooks.

We conducted a document review of all 17 current government approved and published Mexican seventh grade mathematics textbooks and found multiple non-authentic and ill-posed word problems. Said problems were categorized as follows: a) Word problems with spelling, grammatical, or typographical errors, b) Non-authentic word problems with artificial or unrealistic contexts, and c) Word problems with multiple answers, or insufficient or irrelevant data. We selected two word problems with spelling, grammatical, or typographical errors and two non-authentic word problems and developed two different questionnaires, each containing one non-authentic problem and one problem with spelling, grammatical, or typographical errors. These questionnaires were applied to 79 Mexican students from grades 7-9 and were aimed at investigating if the students were able to detect the errors in the problems and, furthermore, if they could re-write the problems correctly.

We found that there are students that are able to detect errors in ill-posed word problems when they are invited to do so. Roughly half the students in our study were able to detect spelling, grammatical and typographical errors and some of them were also able to re-write the problems correctly. This suggests that these students already possess critical thinking skills that are not currently being trained because educational programs, curricula, textbooks, and classrooms, in general, do not require students to analyze the word problems contained in their textbooks and determine if they are well-posed. The Age of the Captain problem phenomenon (Baruk, 1985) shows that students tend to try to solve word problems without previously analyzing and determining if said problems are well-posed. Our study suggests that this phenomenon may be caused by a lack of training in critical thinking skills, namely, word problem error detection skills. We propose that word problem error detection may help reverse The Age of the Captain problem phenomenon and, furthermore, help break students' notions that textbooks and the word problems contained in them have no errors.

OPTIMIZATION IN A NON-SCHOOL SETTING: A DEVELOPMENTAL APPROACH

Cheryl Eames
SIUE
ceames@siue.edu

Kyle Heckert
SIUE
kyhecke@siue.edu

Keywords: Problem Solving, Calculus

Background and Research Questions

One of the biggest focuses of today's mathematics teacher education is problem-solving, and most real-life mathematics problems are based on some sort of optimization. Pennings showed that his dog could solve a classic optimization problem and thus "knew Calculus" (Pennings, 2003). Kaplan and Otten designed an approach for optimization that guided students into a successful use of different representations of the problem (Kaplan and Otten, 2012). There is a gap in the literature when it comes to problem-solving in a non-school setting. Thus, the purpose of this study is to see how well students of different age levels and abilities handle an optimization problem in a non-classroom situation.

Method

Results reported here are part of a larger thesis study about children's performance and strategies for coping with problems involving optimization in a non-school mathematics setting.

Participants

A sample of 30 participants was recruited for the study: 10 students in each of three age groups: Grades 5 to 8, Grades 9 to 12, and ages 18 to 22.

Procedure

Start and finish cones were placed on opposite sides of a swimming pool. The finish was 44 ft. 6 in. down the pool from the start, and the pool was 34 ft. 2 in. wide. Participants were told to get from start to finish as quickly as possible. This was repeated three times.

Data Sources

Data sources include students' run and swim speeds, calculated beforehand using the average of three timed trials, as well as the pool entry point for each student in each trial.

Analysis

Students' swim and run speeds were used to calculate the optimal point of entry to the pool for each student, and deviations from that optimal point of entry were calculated. Multiple regression and two-proportion z-tests were used to determine how well students at different ages cope with a problem involving optimization in a non-school math setting across three trials.

Results and Conclusions

A multiple regression analysis showed that students' deviation from the optimal path was significantly predicted by the model tested ($R^2 = 0.1788$, $F(6, 83) = 3.01$, $p = 0.01$). It was found that deviation from optimal significantly decreased from Age Group 1 to Age Group 3 ($p = 0.042$) but not from Age Group 1 to Age Group 2 ($p = 0.52$). Deviation from optimal significantly decreased from Trial 1 to Trial 2 ($p = 0.007$), but not from Trial 1 to Trial 3 ($p = 0.074$). Deviation from optimal was not significantly predicted by students' self-reported math ability ($p = 0.234$) or swim ability ($p < 0.727$). A two-tailed, two-proportion z-test showed that this difference was not significant with $z = 0.76$, $p = 0.45$, which suggests that students' propensity to jump into the pool too soon did not change in response to repeated engagement with the task. This finding may be rooted in an intuition that the shortest distance between two points is a straight line (Chiu, 1996) rather than reasoning about their swimming and running rates. Future research should explore why children across age groups exhibit a propensity to jump in too soon, with attention to students' thought processes while solving optimization problems in a non-school setting. If we as teachers understand the order of students' thinking and experiences, we can guide instruction appropriately (Kaplan & Otten, 2012).

Keywords: Reasoning and Proof, Problem Solving, Technology

According to the National Council of Teachers of Mathematics (2014), teachers should provide students opportunities to use technology to reason about mathematics. Pre-service secondary teachers (PSSTs), then, should engage in tasks to develop their own reasoning skills as they develop fluency with mathematical actions technologies. We considered the nature of PSST reasoning in this context and sought to answer the following question: What role does reasoning play in PSSTs' approaches to a dynamic algebra supported exploration problem?

Hendriana, Prahmana, and Hidayat (2018) found that PSSTs utilized novel approaches and ideas only about 10% of the time when reasoning through mathematical tasks. Reasoning in which the reasoner uses a novel (for them) approach, includes arguments for plausibility of approach or solution, and anchors arguments within mathematical properties would be categorized as creative mathematical reasoning (CMR; Lithner, 2008, 2015). In contrast, imitative reasoning (IR; Lithner, 2008) suffices when a task may be solved by recalling a response or applying an known algorithm to a familiar problem type.

To investigate our research question, PSSTs were asked to describe the path traced by the vertex of parabola $f(x) = ax^2 + bx + c$ as parameters a, b, and c were varied independently (Cullen, Hertel, & Nickels, in press). Through the use of dynamic graphing software, one group of four PSSTs engaged in reasoning about several subtasks of the problem while identifying the path of the vertex as a was varied. We focus on the subtask in which the PSSTs tried to determine the slope of a line for their conjectured vertex path.

By analyzing video and video-based transcription of the group's conversation about this subtask, we identified claims and strategy choices that evidenced CMR and IR. We found that, when engaged in IR, PSSTs' collaboration was productive until an obstacle—such as generalizing an expression for slope—halted their progress. When progress was stalled, PSSTs use of CMR allowed the group to change or modify their problem-solving strategy. For example, one PSST stated, "I think we were supposed to define arbitrary points *A* and *B*, say on that line, they are solutions to, these lines or something." Group members then used IR to calculate the slope of a line between two specific points. A group member identified an obstacle preventing successful completion of the task by stating that the calculated slope was "not general enough." A group member then used CMR when suggesting that they try a pair of arbitrary points and test to see if those points led to the desired outcome. The calculation of slope using arbitrary points was novel (in the situation), plausible, and anchored in mathematical properties.

Hendriana et al. (2018) asserted that CMR was associated with perseverance in nonroutine learning tasks. We found that PSSTs used both CMR and IR to complete this nonroutine subtask; in fact, an interplay between both kinds of reasoning propelled them toward a solution.

Keywords: Curriculum, Equity and diversity, Problem-solving, Modeling

Modeling-eliciting activities (MEAs) are thought-revealing tasks that require students to mathematize real-world situations (Lesh & Lehrer, 2003). This poster shares work from a grant-funded project whose goal is to design, field test, implement, and evaluate MEAs that address agricultural life science issues. These unique MEAs encourage a culturally relevant lens on societal issues in students' local communities (i.e., food security, environment, energy, and health). Writing MEAs is a complex endeavor, especially for a novice MEA writer. Working alongside a team member who has expertise in writing and designing MEAs, the lead author engaged in a collaborative self-study to document the iterative process of MEA design, development, and implementation of four MEAs. Self-study is an "intentional and systematic inquiry into one's practice" (Dinkleman, 2003, p. 8). Self-study necessitates constructive criticism of one's practice, which can then be used to refine and enhance one's practice. The purpose of this poster is to convey results from a self-study by a novice MEA author with the aim of adding to scholarly conversations about MEA development. Data sources for this self-study come from journaling, meeting notes, classroom observations, focus groups, artifacts, reflections, and systematic formal reviews by the research team. The lead author used narrative inquiry (Cresswell, 2012) to capture the MEA design, implementation, and reflection process (Liljedahl, Chernoff, & Zazkis, 2007). One finding from the self-study was that the cultural and community components of the MEA must be developed in tandem with those who understand the objective of the task design. A second finding was that MEA writing became easier over time and benefitted from collaboration with diverse partners. An implication of these results is a possible pathway of MEA development that should be further investigated. A second implication from this work is to document how MEA development teams grow as MEA developers.

Toulmin's model of argumentation is a tool for describing and classifying components of students' mathematical arguments. The model is comprised of six components: *claim*, *data*, *warrant*, *qualifier*, *backing*, and *rebuttal* (Martinez & Pedemonte, 2014; Toulmin, 2003). Each mathematical argument is a unique collection of one or more these six elements connected by relational links (Nussbaum, 2011). Erduran, Simon, and Osborne (2004) used Toulmin's Argument Pattern (TAP; Toulmin, 2003) to identify specific data-claim relationships during classroom activities. In this research, we consider how TAP may be used to trace a sequence of reasoning from conjectures to proof, in a dynamic algebra exploration task.

This instrumental case study involved preservice secondary teachers (PSSTs) enrolled in a content course that focused on problem solving with technology. The task required students to explore the path of the vertex of the quadratic function $y=ax^2+bx+c$ when the parameters were varied (Cullen, Hertel, & Nickels, in press). We focused on the collective reasoning of one group of PSSTs, including Joelle and Jared, and used TAP to model the arguments related to their development of a conjecture about the vertex's path when parameter a was varied.

We model the group's collective reasoning using a Path of Argumentation (PoA), which illustrates a chronological sequence of related arguments from conjecture to proof. Figure 1 illustrates how we linked (with arrows) key components from several TAP claim diagrams, related to the group's reasoning about varying parameter a in the general quadratic, to form a PoA. The collective argumentation evolved from observing that the path of the vertex made a line to then searching for a proof to support this conjecture. Joelle's GeoGebra-supported claim of linearity led to Jared's claim (based on using slider manipulation data) about the slope's dependence on b. Joelle's concern about the limits of relying on GeoGebra data, led to Jared's search for a general proof. Data related to a specific argument, informed the proof development.

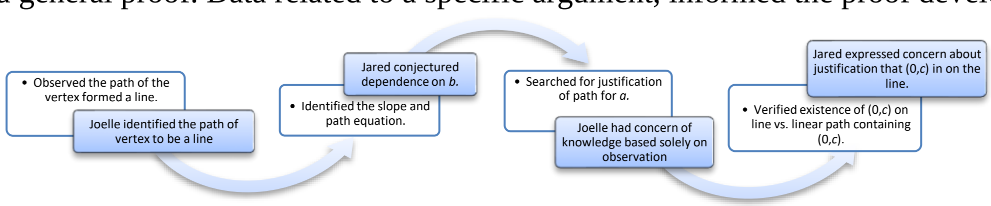

Figure 1: PoA Illustrating Joelle and Jared's Collective Argumentation

We found that the PoA was a valuable way to model PSST's collective argumentation during an extended exploration task, which exposed connections across TAP claim diagrams. Components of reasoning around a single claim appear to guide and influence next steps in an exploration that leads from conjectures to proof, in a dynamic algebra-supported task.

MODELING FOR SOCIAL JUSTICE: A MODEL-ELICITING ACTIVITY ON GERRYMANDERING

Sandy Spitzer
Towson University

Research suggests that for students to develop deep and connected mathematical understandings, they should solve real-world problems in which mathematics is used to model situations and construct solutions (e.g., Pollack, 1969; Lesh & Doerr, 2003). However, for teachers to effectively use mathematical modeling in their classroom, they must develop an understanding of the modeling process and learn to select, modify, and enact modeling tasks. To be prepared to enact modeling in their classrooms, pre-service secondary mathematics teachers (PSTs) need explicit support and education (e.g., Cai et al. 2016). Engaging PSTs in model-eliciting activities (MEAs, or tasks for which the creation and evaluation of a mathematical model is the primary goal) can help them both integrate and apply their mathematics knowledge and prepare to conduct such tasks as teachers (Daher & Shahbari, 2015). Meanwhile, attending to equity and social justice in pre-service mathematics teacher preparation is an urgent concern (e.g., Bartell, 2013; White et al., 2016). Although modeling and attending to equity may seem like disparate skills, the use of MEAs involving social justice contexts can engage pre-service teachers in studying and mathematizing situations to "experience mathematics as an analytical tool to make sense of, critique, and positively transform our world" (Aguirre et al., 2019, p. 8).

The issue of gerrymandering presents a good opportunity for integrating social justice into school mathematics, since it provides an example of authentic mathematics being used to influence public policy. Two actual U.S. Supreme Court cases in 2018 (most notably *Gill v. Whitford*) had significant mathematics content, with much of that math content accessible to K-12 students. Further, since teachers often cite a wish to avoid discussing controversial issues with their students (Simic-Muller, Fernandez, & Felton, 2015), a topic which is facially neutral (like gerrymandering) can be a useful entry point for novice teachers to incorporate social justice issues. All citizens can be concerned about whether or not their vote has an impact; this topic is particularly relevant for high school students who are preparing to vote for the first time.

Although the topic of gerrymandering can address a variety of mathematical topics (including proportions, statistics, etc.), our gerrymandering MEA focuses on the geometry of congressional districts. Many states require legislative districts to be "compact," but there is little agreement about how compactness should be measured. In fact, there are over 30 mathematical models of compactness used by political scientists (Kaufman, King, & Komisarchik, in press). With the goal of engaging PSTs in modeling for social justice, we created an MEA which asked participants to construct their own mathematical measure (i.e., model) of compactness and use their model to identify states which have the most gerrymandered districts. This model-eliciting activity draws on mathematical ideas appropriate for secondary mathematics classrooms, such as area and perimeter, scale, and attributes of shapes. In the activity, PSTs are given data including perimeter and area of congressional districts, as well as printed maps, and challenged to find a

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* St Louis, MO: University of Missouri.

model which can rank districts by compactness. In a pilot implementation, PSTs struggled to conceptualize the geometric nature of compactness and downplayed its importance. They focused instead on issues of fairness in representation, including ideas of proportionality. This MEA thus provides PSTs with an opportunity to not only engage in rich mathematical practices, but also learn about relevant and pressing social justice issues.

HOW TO POSE IT: EMPIRICAL VALIDATION OF A PROBLEM-POSING FRAMEWORK

José N. Contreras
Ball State University
jncontrerasf@bsu.edu

Problem posing is an important mathematical activity. Doing mathematics involves creating problems and investigating their solutions. Thus, learning to pose mathematical problems should be an important educational goal. In fact, professional organizations (e.g., National Council of Teachers of Mathematics, 1989, 2000), mathematicians (e.g., Halmos, 1980, Polya, 1945/1973), and mathematics educators (e.g., Brown & Walter, 1983, 1993; Kilpatrick, 1987; Silver, 1994) call for all students to have experiences posing problems. However, the mathematics research community continues to investigate the different aspects and issues of teaching and learning problem posing (Felmer, Pehkonen, & Kilpatrick, 2016; Silver, 2013; Singer, Ellerton, & Cai, 2013, 2015) with the goal of improving students' problem-posing abilities.

During the poster presentation, the author will display a problem-posing framework with examples of problems posed by him and his students using said framework. The framework includes the following systematic strategies to modify a given problem to pose new problems: reversing, proving, specializing, generalizing, extending, and further extending. These strategies have been very helpful in improving not only his problem-posing abilities, but also those of his students. Most of the problems posed involve geometric situations, but the framework is also useful to pose problems in other areas of mathematics.

I will include classical problems to illustrate the problem-posing strategies. For example, the author will use a version of Varignon problem (Let *E*, *F*, *G*, and *H* be the midpoints of the consecutive sides of a parallelogram *ABCD*. What type of quadrilateral is *EFGH*?), among other problems, to illustrate the usefulness of the problem-posing framework. Examples of problems that are related to this version of the Varignon problem are:

- Problem 1: If E, F, G, and H are the midpoints of the consecutive sides of a rhombus ABCD, prove that EFGH is a rectangle. (Special problem)
- Problem 2: *E*, *F*, *G*, and *H* are the midpoints of a quadrilateral ABCD. If EFGH is a rectangle, what type of quadrilateral is ABCD? (Converse of problem 1)
- Problem 3: If *E*, *F*, *G*, and *H* are the midpoints of the consecutive sides of a quadrilateral *ABCD*. What type of quadrilateral is *EFGH*? (General problem)
- Problem 4: Prove that the medial quadrilateral of a kite is a rectangle. (Extended problem)
- Problem 5: ABC is a triangle. Characterize quadrilateral BDEF where D, E, and F are the midpoints of the sides BC, CA, and AB, respectively. (Extended problem to a triangle, which is a degenerate case of a quadrilateral)
- Problem 6: Prove that the points of intersection of the angle bisectors of the consecutive interior angles of a parallelogram ABCD are the vertices of a rectangle. (Further extended problem)

The author will also provide solutions to problems that are supported by proofs in some cases or conjectures supported by empirical evidence in other cases (such as geometric diagrams created with Dynamic Geometry Software or numerical examples).

Growing interest in "flipped" classrooms has made video lessons an increasingly prominent component of post-secondary mathematics curricula. However, relatively little is known about how students watch and learn from instructional videos. We describe and use an eye-tracking methodology to investigate attentive fidelity—the degree to which students attend to the visual imagery that is the subject of the video narration at each moment in time. Our preliminary study suggests that students' attentive fidelity varies widely, but there was no evidence that this fidelity is connected to students' ability to solve calculus problems.

Keywords: Technology, Calculus, Research Methods

Over the past few decades as educators have sought to develop online courses and incorporate active learning strategies into their classrooms, they have turned to videos as a way to deliver lectures outside of a traditional classroom setting (e.g., Lage, Platt, & Treglia, 2003; McGivney-Burelle, & Xue, 2013; White House, 2013). Flipped classrooms have been used to support problem-based learning (e.g., Tawfik & Lilly, 2015) and interactive engagement (e.g., Maciejewski, 2015), and interest in using a flipped classroom instructional format in post-secondary mathematics teaching has grown (e.g., Maxson & Szaniszlo, 2015).

Despite the enthusiasm for using video lectures, relatively little is known about how students engage in the video-watching process, what they learn from watching videos, and how their actions while watching the videos might be connected to learning. Most studies of flipped classrooms have failed to distinguish in-classroom learning from out-of-classroom learning (e.g., Anderson & Brennan, 2015; Schroeder, Micgiveny-Burelle, & Xue, 2015). Weinberg and Thomas (2018) found that students displayed a wide range of ways of interpreting mathematics video lectures and called for researchers to closely examine students' video-watching activity.

The goal of this study is to begin to investigate what students attend to as they watch video lessons. In particular, we will describe a methodology for investigating students' *attentive fidelity*—whether students attend to imagery that corresponds to what instructors would identify as showing the focus of the video at each moment in time. In addition, we will present results from a preliminary study on students' attentive fidelity and learning from calculus videos.

Theoretical Background

One way of investigating students' attentive behavior—that is, the sequence of objects and images in the world that students pay attention to—is to record their eye movements as they engage in activity. Eye-tracking has been widely used in educational research, specifically to examine the ways students interpret curricular resources and, increasingly, to study students' mathematical thinking (e.g., Andrá et al., 2015; Inglis & Alcock, 2012; Lee & Wu, 2018; Mock, Huber, Klein & Moeller, 2016; Ögren, Nyström & Jarodzka, 2017). Eye-tracking offers a substantial advantage over self-reporting methods, which are constrained by students' limited ability to accurately reconstruct and reliably communicate their thinking in the moment.

When people interact with visual stimuli, they make a sequence of *fixations* in which their foveal vision (i.e., the center of the field of vision) is focused on a particular point for roughly 200 to 500ms (Hyönä, 2010). These fixations are connected by *saccades*, which move the foveal vision to new locations without processing information. Fixations may indicate cognitive attention (Andrá et al., 2015), difficulty extracting information (Jacob & Karn, 2003), mental calculation (Hartmann, Mast, & Fischer, 2015), or bored staring.

The *eye-mind hypothesis* (Just & Carpenter, 1980; Rayner, 2009) proposes that there is a positive relationship between what a person looks at and what they attend to. Researchers typically assume that eye movements correspond to cognitive operations (Obersteiner & Tumpek, 2016). However, Holmqvist et al. (2011) noted that it is possible for a person to be thinking about something other than what their eyes are fixated upon. From a slightly different perspective, Abrahamson and Bakker (2016) proposed that eye movements are *part of* the individual's cognitive processes rather than reflecting separate mental processes.

Methods and Methodology

The participants in the study were students enrolled in a first-semester calculus class at either a mid-sized comprehensive college or a large state university. All students in the sections were invited to participate and 13 volunteered to participate in (up to) eight interviews (all reported student names are pseudonyms). Each interview was conducted prior to the calculus topic being discussed in class. For this report, we chose a video about Riemann sums because it involved both procedural and conceptual aspects—that is, it was designed to support students' understanding of how to construct a Riemann sum and how to interpret its computation.

In the interview session, the students were first asked to solve several problems about Riemann sums using a think-out-loud protocol; the interviewer asked follow-up questions to probe their thinking. Then, the students watched a video about Riemann sums and solved several problems that were similar to the pre-video questions.

Participants' eye-movements were recorded with a Tobii X2-60 eye tracker mounted below a 22" LCD monitor. The eye-tracker captured the on-screen coordinate of each participant's fixation at a rate of 60 Hz; we called each time at which coordinates were captured a *moment*. At the beginning of each interview, the eye tracker was calibrated with a 9-point display. The participants viewed the screen without a head restriction from approximately 2 feet away, which corresponded with roughly 0.5-degree accuracy (Tobiipro, 2019).

To identify whether students attended to areas of the screen that correspond to what instructors would identify as the primary foci of each moment of the video, we created one or more rectangular *areas of interest* (AOIs) on frames of the video. We defined two types of AOIs: A *primary AOI* was meant to capture whether or not a student was focusing on the area of the screen that was conveying new knowledge or visual aids for the narration. These included:

- Areas that contained numbers or shapes to which the narrator of the video was referring
- Areas that contained text that the narrator was reading
- Areas that contained deictic animations (e.g., arrows, boxes, or circles being drawn)
- Areas that contained other active animations that illustrated a mathematical concept

A *secondary AOI* was meant to capture areas that were directly related to—or important for understanding—the primary AOI, but were not the immediate object of the narrator's focus. For example, Figure 1 shows a frame from the video with one primary (in red) and two secondary AOIs (in yellow and blue). At this moment, the narrator reads "At 90 km dust accumulates at a rate of 6 mg per km," highlighted by the primary AOI. This speech refers to the numbers 90 and 6 and the units in the table, so these were included in Secondary AOIs because they added relevant contextual information to help understand the subject of the Primary AOI.

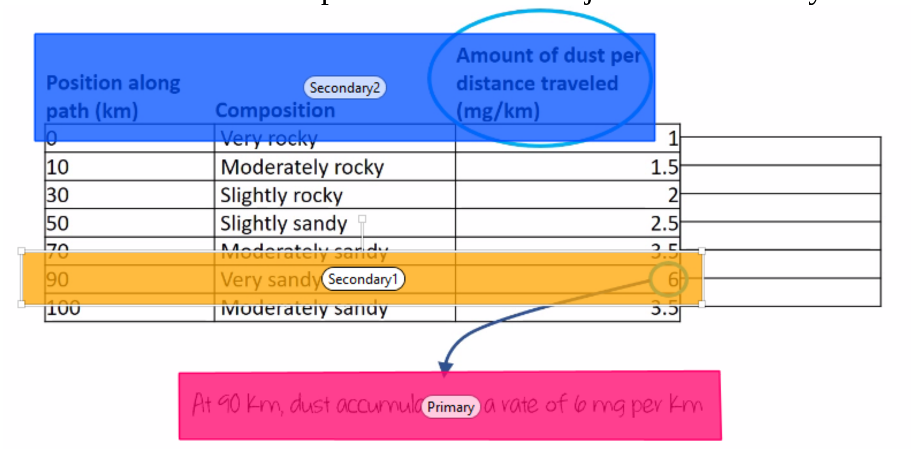

Figure 15: A Frame from the Video Showing One Primary and Two Secondary AOIs

Primary AOIs were defined for each section of the video that described mathematical concepts, but not for sections that introduced the context for the video (dust accumulating on a Mars rover). Secondary AOIs were defined whenever applicable. In order to account for the lack of perfect accuracy in the eye-tracking recording, we created each AOI with roughly a quarter inch border around the intended on-screen imagery. We measured attentive fidelity by determining whether a student's fixation was contained in one of the defined AOIs. The eye-tracker also reported information about whether it was able to locate a fixation anywhere on the screen in each moment, indicating whether or not the participant was looking at the screen.

Results

The video that the participants watched included approximately 12,500 moments in which at least one AOI was defined. Due to hardware or calibration errors, two students had a large percentage of moments (61% and 73%) in which the eye tracker was unable to detect the eye location. Concerns about accuracy led us to remove these two students' data from the study.

Table 1 shows the percent of moments for which the location of each participant's fixation was in an AOI along with whether the participant provided a correct answer to the pre- and post-video questions. The mean for the Primary AOIs was 37% (SD = 10.1%), for Secondary AOIs was 7% (SD=3.4%), and for all AOIs combined was 44% (SD=12.3%). There was substantial variation between the total percentages, with a minimum value of 22% and a maximum of 61%. There was also considerable variation in each participant's split between Primary and Secondary AOIs; for example, 45% of Camila's fixations were in Primary AOIs and only 7% were in Secondary AOIs, while Beth had much closer percentages—34% Primary and 13% Secondary.

There appears to be no relationship between whether a student had a high percentage of fixations on a Primary or Secondary AOI and their performance on the post-video questions. Of the students who got a higher percentage of post-video questions correct than pre-video questions (*n*=6), their total percent of fixations in an AOI was between 22% and 52% with a mean of 40%; the students whose performance decreased (*n*=3) had a mean of 47%.

Table 2: Summary of Results

	Percent of Moments with a Fixation on an AOI			Pre/Post-Video Question Correctness		
Participant	Primary	Secondary	Total	Pre-	Post- Q1	Post- Q2
Alec	20%	2%	22%	Incorrect	Incorrect	Correct
Beth	34%	13%	46%	Incorrect	Correct	N/A
Caleb	50%	11%	61%	Incorrect	Incorrect	Incorrect
Camila	45%	7%	52%	Incorrect	N/A	Correct
Elouise	32%	3%	36%	Incorrect	Correct	Correct
Joaquin	23%	7%	30%	Incorrect	Incorrect	Incorrect
Kayla	43%	10%	52%	Correct	Correct	Correct
Nina	44%	7%	51%	Correct	N/A	Correct
Rory	26%	4%	30%	Incorrect	Correct	Incorrect
Tristan	44%	9%	52%	Incorrect	Correct	Correct
Ursula	41%	9%	50%	Correct	Incorrect	Incorrect

Discussion

In this study we described a new methodology using eye-tracking technology for investigating attentive fidelity—whether students attend to imagery in calculus videos that corresponds to what instructors might identify as the primary foci of the videos. This involved identifying areas of interest throughout the video and measuring students' eye fixations to determine the percent of fixations that were inside these AOIs. If we accept the eye-mind hypothesis, then these percentages indicate the percent of time students were paying attention to these areas of the screen or, similarly, the degree to which this imagery played a role in the students' thinking about the concepts described in the video. Given the nature of the video—in which the Primary AOIs were constantly changing—we believe that it is unlikely that students would be thinking about the Primary AOIs if their fixations were on another part of the screen.

Our preliminary data suggest that students display a wide range of attentive fidelity and that they frequently attend to areas of the screen other than those we believe are most germane to the concepts being described in the video at any given moment. This might suggest that creators of videos need to be careful to incorporate elements that might help direct students' attention to desired areas of the screen. Conversely, it might be the case that there is no way to ensure that students will attend to particular imagery.

Our sample data do not suggest that there is a connection between attentive fidelity and change in performance from pre- to post-video questions. However, with the "coarse" nature of this measure (one pre-video question and two post-video questions) and small sample size, such an inconclusive result is not surprising.

We believe that the construct of attentive fidelity could be a useful tool for analyzing and understanding students' behavior and cognition as they watch instructional videos. Expanding the data corpus to include more videos, more students, and more detailed measures of learning would provide the foundation for generating a new, detailed perspective on student learning.

In this paper, we explore students' understandings of functions in abstract algebra. We analyzed students' general conceptions of function and how this understanding was or was not unified with their understanding of particular functions in abstract algebra. We conducted a series of six task-based interviews with undergraduate students from two United States institutions. From these sessions, we analyzed key elements of students' function concept image including metaphors, representations, and evoked example space. We then looked across their activity related to homomorphisms to see the degree of coherence, attention to the homomorphism as a class of function, and the degree to which the students saw functions in abstract algebra as the same or different than functions from prior courses. We found that students demonstrated a variety of levels of function understanding and varying profiles ranging from non-unified to completely unified understanding of function across abstract algebra and earlier contexts.

Keywords: Undergraduate-level Mathematics

Function is one of the core concepts that serves to connect the mathematics curriculum from early algebra through advanced mathematics. The role and importance of function is ubiquitous as documented by mathematics education researchers across varying levels and content in mathematics (e.g., Oehrtman, Carlson, & Thompson, 2008). Furthermore, function has been documented to be quite complex and often poorly realized by students (e.g., Dubinsky & Wilson, 2013). While we know that students struggle with functions at the secondary and early college levels, it is an open question whether limited or incomplete views of functions persist through advanced mathematics contexts including courses like abstract algebra. As such, we report on a study aimed to explore the degree to which undergraduate abstract algebra students demonstrate a coherent understanding of function, and the degree to which their understanding of function plays a role in their activity related to abstract structures found in this subject area. We address the following research questions:

1. What are students' concept images of functions at the end of an abstract algebra course?
2. How is students' general function understanding connected to their understanding and activity related to functions in abstract algebra?

Literature Review

Early research on function understanding established that students and teachers have a wide range of definitions for functions including a normative correspondence definition and more limited definitions such as a function as a rule (e.g., Vinner, 1983; Vinner & Dreyfus, 1989). As Thompson (1994) articulated, even at the undergraduate level, a function is often thought of as

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

"two written expressions separated by an equal sign" (p. 24). The focus on a written symbolic rule obscures important aspects of function such as the need for well-definedness (a challenging property for students, Even, 1993). Students often opt for a symbolic rule even when other representations would be advantageous (Knuth, 2000), struggle to move between various representations (Akkoç & Tall, 2002; Schwarz, Dreyfus, & Bruckheimer, 1990), and may not see alternate representations, such as tables, as functions at all (Clement, 2001). A coherent view of function requires both attention and understanding of important attributes, and the successful integration of representations. Additionally, metaphors serve an important role where functions may be understood as machines, collections of objects with directional links (e.g., Lackoff and Núñez, 2000), or as traveling and transforming (Zandieh, Ellis, & Rasmussen, 2017). Furthermore a function may be understood as a process going from domain to codomain or an object that can be acted on itself (e.g., Breidenbach, Dubinsky, Hawks, & Nichols, 1992; Dubinsky and Wilson, 2013; Sfard, 1991).

At the abstract algebra level, research has focused on students' understanding of particular function types: isomorphisms and homomorphisms. For example, Leron, et. al (1995) identified the group, the function, and the existential quantifier as three connected areas needed to understand isomorphism. Students in Leron, et. al's (1995) study often compared groups using a concrete set of checks (such as looking at order of elements) rather than focusing on the critical aspect of the function map itself. In terms of function components, Rupnow's (2017) preliminary work demonstrated that students continue to use function metaphors (often inflexibly) when engaging in homomorphism. In general, the research in abstract algebra education raises the testable conjecture that students' function understanding may play an important role in how they engage with more complex functions in the setting of advanced mathematics.

Theoretical Orientation

In this study, we leverage two constructs to address our research questions: *concept image* (Vinner, 1983) and *unified notion of a concept* (Zandieh et al., 2016). A concept image contains all of a students' cognitive structures related to a particular concept including their personal definition, metaphors, representations, and examples. These components may or may not be coherent and aligned. Zandieh at al. (2016) furthered concept image to include ideas of unification across varying contexts, that is, the degree to which students understand "various constructs of a concept as examples of the same phenomenon" (p. 24). We extend this notion to the abstract algebra setting where students may or may not see particular types of maps such as homomorphisms as belonging to the larger category of function. We also expand unified notion of a concept to differentiate between explicit and implicit coordination. That is: (1) a student may be explicitly aware that a particular construct is a type of function, (2) a student may not explicitly address this requirement but implicitly evoke function concept image components in this new setting, or (3) not demonstrate any coordination across the contexts. Additionally, we also incorporate analytic tools to parse aspects of concept image including metaphor, representations, examples, and properties.

Methods

Data Collection

We provided written surveys to four undergraduate-level abstract algebra classes across two large, public universities in the United States. The survey included prompts about definitions, examples, and representations of functions. Then the second portion included prompts related to homomorphisms and kernels. For example:

> **Task 5:** Is ϕ: **Z** → **Z**: $\phi(x)=x+1$ a homomorphism? Why or why not?
> **Task 9:** Let $i=\sqrt{1}$. Consider the homomorphism $\phi(n)=i^n$, that maps **Z** under addition to the set H={i, -i, 1, -1}(a subgroup of **C** under multiplication). What is the kernel of this homomorphism?

After the completion of the survey, six students agreed to participate in follow-up interviews. These interviews lasted between 1 and 1.5 hours and consisted of three types of prompts: (1) elaborate thinking on original survey items, (2) new tasks related to functions and homomorphisms, and (3) reflections on functions in abstract algebra. The interviews were semi-structured. Each interview was audio-recorded and transcribed for analysis.

Data Analysis

When analyzing for students' conceptions of function, student responses were analyzed in terms of the properties that students attended to, metaphors (Zandieh et al. 2017) and representations (Melhuish, 2015) and Mesa, 2004) used, the students' evoked example space for functions and non-functions, and the similarities and differences that the students identified between functions in abstract algebra and in K-12. When analyzing for how students' general understanding of functions may be connected to their understanding of functions in abstract algebra, evidence of explicit awareness of homomorphism as a function, the role that functions played when engaging with tasks related to homomorphism, and the consistency of the students' use of metaphors, representations, and process/object treatment of function were analyzed. All parts of the interviews were analyzed independently by at least two researchers with disagreements resolved through discussion. We created profiles for the six cases based on: their concept image of function and their unification of the general function and homomorphism.

Results

For the scope of these results, we focus on two divergent cases. We note that these cases provided particularly contrasting images. A more thorough treatment of the cases can be found in Melhuish, Lew, Hicks, and Kandasamy (2019).

Case 1: Student D. Fragmented Concept Image and No Unified Function Understanding

Student D understood function as being necessarily tied to an explicit equation. Her function definition was: "equation that will do some kind of operation to an input to get an output." She introduced the idea of a vertical and horizontal line test, but could not determine which was necessary or how these tests may link to what a function is. Her evoked examples were limited to traditional symbolic equations such as $y=x^2$. Her definition for homomorphism then did not include any explicit reference to homomorphism being a function. Rather she wrote down the property: "$\phi(x)\phi(y)= \phi(xy)$". She further responded, "ϕ is what encompasses all of it." We deem Student D's function integration as an *empty symbol* approach. Student D was not able to identify that ϕ was a function without extensive prompting. Further, this lack of function conception persisted into her abstract algebra activity. She explained that $\phi(x)=x+1$ from ***Z*** to ***Z*** is not a homomorphism:

> If you were to apply the homomorphism property, you can't get ... I mean, the left and the right won't equal each other when you apply ϕ to both sides. That's kind of how I interpreted it. Because $\phi(x+1)$ isn't going to equal $\phi(x)$.

Student D manipulated $\phi(x)=x+1$ as an equation (applying something to "both sides") rather than treating this a function where inputs are mapped to that value summed with one. Further, Student D evidenced a limited understanding of function mappings that appeared to interfere with her success on standard abstract algebra prompts. For example, when determining the kernel of a non-injective homomorphism, Student D identified only one element of the pre-image rather than the full set of elements that map to the identity. Such treatment reflects a need for concrete referents and likely an action conception of functions that does not allow for the consideration of multiple elements at a time.

Case 2: Student C. Robust Concept Image and Unified Function Understanding

Student C provides a contrasting case. She was flexible in her understanding of function, and her personal definition for function was coordinated with other aspects of her function understanding. Student C attended to both well-definedness and everywhere-definedness in her definition of function. She also had a rich example space including functions from both secondary and abstract algebra and a variety of representations. Her definition of homomorphism, found in Figure 2, explicates that homomorphism is a function with particular properties. She expanded informally, "[the homomorphism] takes that bunch of things and it maps it to a… bunch of things. But it preserves certain things. So, if you can switch up order, you can still switch up order afterwards. So, commutativity." In contrast to Student C, the mapping element was a primary component of Student D's understanding of homomorphism.

She was then able to leverage this understanding to successfully engage in a number of abstract algebra tasks. In Task 5, Student C leveraged the identity preservation property to address that $x+1$ was not a homomorphism:

> So, if you take ϕ of ... I said here, but it's really $\phi(0)$. Zero is the identity element in the integers. So, and then you say well that's 0+1, that's gonna give you 1, not 0, which is the identity element in the integers. So the identity doesn't map to itself. So, because- that's not gonna be a homomorphism.

Notice the integration of mapping metaphor language as she considers where the identity element maps. Her more robust understanding of function also appeared to play a supportive role in various activities. For example, when identifying the kernel, Student C explained:

> So some element of **Z** that takes i to that power and gives us out 1, which would be the identity element for H. Because i^1 is gonna give us i. i^2 is gonna give us - i, so on. So in order for i to be taken to a certain power and give us 1, it needs to be a multiple of 4.

She was comfortable attending to a multi-element pre-image via holistically considering the homomorphism at as a process.

Discussion

Across our interviews, we found (1) students at the end of an abstract algebra course demonstrated a variety of levels of function understanding, (2) students had varying levels of integrating functions from this setting into their larger function understanding. We shared Student D and Student C to illustrate the extremes of these aspects. Without a strong function understanding or unified view of function, Student D struggled to approach nearly all of the abstract algebra tasks. Student C relied on robust conceptions of function and implicit and explicit leveraging of function understanding when engaged in the abstract algebra tasks.

The results of this study have implications for learning and teaching abstract algebra. First, this study suggest that students may still have incomplete understanding of function even after having completed a course in abstract algebra. Second, students' understanding of function may support or constrain their success in abstract algebra tasks. Instructors may want to explicitly attend to students' understanding of function as they study the specific types of function in abstract algebra. Furthermore, we suggest that researchers, of even advanced mathematics students, be attentive to how the complexities of function may interact and account for student activity and understanding in these settings.

EXAMINING THE EFFECT OF INSTRUCTION IN THE CONCEPTUAL UNDERSTANDING OF FUNCTIONS IN PRE-CALCULUS STUDENTS

Keshab Raj Adhikari

Duane Graysay
Syracuse University
dtgraysa@syr.edu

Understanding of the function concept is essential for students' success in calculus and in STEM-oriented careers. This brief report shares a small part of findings examining relationships between the teaching of inverse functions in a classroom and students' learning of the concept as displayed in their response to the Function Concept Inventory (O'Shea et al., 2016).

Keywords: Precalculus, Undergraduate-level Mathematics

Proficiency in quantitative reasoning skills is a critical skill necessary to meet the requirements of employment in STEM disciplines (Golfin, 2005). Thus, there has been a growing emphasis on STEM-oriented education in high school and college (Rowan-Kenyon et al., 2012). To enter and develop careers in the STEM disciplines students need to do well in calculus in college. Therefore, college-level calculus has become an essential course for students. But many high school graduates enter college without the understanding or skill needed for college calculus (Carlson et al., 2002; Oehrtman, Carlson, and Thompson, 2008; Monk, 1992; Thompson,1994) and are therefore required to take precalculus courses as a prerequisite. Such courses have the objective of building conceptual and procedural foundations in mathematics which are essential for supporting students' success in calculus (Kilpatrick et al., 2001).

Students are more prepared for college calculus when they have strong conceptual understandings of functions and skills in algebraic competencies associated with functions. This includes cognitive abilities to coordinate two or more related quantities that change together in a functional situation so that students can model realistic problems in their calculus classes (Monk, 1992; Thompson, 1994). Therefore, the extent to which precalculus courses support the study of calculus is related to the extent to which such courses are effective at supporting students' conceptual understanding and procedural fluency (Carlson et al., 2002).

Precalculus courses are often not successful at helping students develop the understandings and skills that support success in calculus (e.g., Carlson et al., 2002). However, it is not clear how features of instruction relate to students' learning in such courses. We investigate this relationship by assessing students' learning of the function concept and by relating that learning to instruction. We investigate the following questions:

1. How do students' understandings of the function concept change over the duration of their enrollment in a precalculus course?
2. How do changes in students' understandings of the function concept relate to the teaching that occurs in their precalculus course?

Related Literature

Mathematics educators and researchers (e.g., Carlson,1998; Thompson,1994) have sought to describe fundamental aspects of understanding the function concept. To understand the concept, students must be able to distinguish between two perspectives on the nature of function: the

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

notion of function as a *correspondence* and the notion of function as a *covariation.* The correspondence perspective defines a function as a correspondence between two non-empty sets that assigns to every element in the first set exactly one element in the second set (Confrey & Smith, 1994; Vinner & Dreyfus, 1989). The correspondence approach to function is essentially a top-down approach in which a teacher or text provides a rule of association and students are supposed to acquire procedural competence for dealing with such formulas (Confrey & Smith, 1994). The pedagogy adopted by this approach emphasizes students' procedural competencies for establishing correspondence between input and output variables (Brumfiel, 1980).

In contrast, the covariational perspective is characterized by students' understanding of links between two simultaneously varying quantities, with a sustained image of both the quantities in one's mind (Saldanha and Thompson, 1998). Carlson et al. (2002) defined covariational reasoning as "the cognitive activities involved in coordinating two varying quantities while attending to the ways in which they change in relation to each other" (p. 354). Although it is difficult to teach the concept of covariation to students, Confrey and Smith (1994) express that covariational reasoning is a powerful tool for students to succeed in calculus and higher-level mathematics courses.

Drawing on existing literature on the function concept, O'Shea et al. (2016) outlined a framework of six elements of conceptual understanding of function. These elements are based on students' abilities to identify key properties of the function concept. O'Shea et al. (2016) argued that the framework can be implemented to design instructional strategies for conceptual learning of function as well as to assess students' structural understanding of the function concept in the action- process-object continuum. O'Shea's framework consists of six elements: 1) the ability to distinguish between functions and equations; 2) the ability to recognize and relate different representations of functions and use them interchangeably; 3) the ability to classify relationships as functions or not functions; 4) the ability to have a working familiarity with properties of functions such as one-one/many-one, increasing/decreasing, linearity, composition, inverses; 5) the ability to use functions in context, modelling and interpreting; 6) the ability to engage with covariational reasoning. O'Shea et al. (2016) used this framework of functional understanding to construct and validate a Function Concept Inventory (FCI) consisting of 12 items designed to elicit students' abilities identified by the six elements of the framework.

Research Design and Methodology

Participants were recruited from among all students enrolled in precalculus during a single semester at a midsized private research university in the northeastern United States, along with their respective instructors, including recitation leaders. From among instructors who consented to participate, Guilia (all names in this report are pseudonyms) and the students in her class were selected as participants, in part because Guilia had taught the course for several semesters and was relatively practiced and experienced with the content of the course.

The FCI was administered to students as a pretest and posttest at both ends of a six-week observational period. The corresponding author observed six episodes of Guilia's classroom teaching during the semester, interviewed Guilia about her teaching and her perspective about the precalculus course, conducted three clinical interviews with selected students (Jim, Ryan, and Dikardo, selected because they had completed both pretest and posttest and had consistent attendance habits), and gathered all worksheets that Guilia used during the semester. Data for this study consisted of students' responses in the pretest, posttest, and clinical interviews, transcripts of classroom observations, an interview with Guilia, and Guilia's worksheets.

Pretest-posttest differences in students' responses for each of the multiple-choice items in the FCI were taken as evidence of student learning. Some of the items in the FCI required students to write their responses. For the explanatory items (i.e. item #2, and #7) students' descriptions were compared in an attempt to identify how the students' understanding changed during the semester.

O'Shea et al.'s (2016) six elements of functional understanding were used to code transcripts of classroom observations and clinical interviews for instructional activities with the capacity to support each of the six elements. Findings regarding instruction were then compared to findings regarding student learning to describe how instruction and learning did (or did not) appear to be related.

Findings

For the purposes of brief report, we have selected to describe findings related to a subpart of element 4 of O'Shea's inventory, namely, a working familiarity with the concept of inverse. First, we discuss changes in students' learning about inverse as displayed by their responses to item #7 of the FCI, then we describe how the notion of inverse function was introduced in the classroom instruction.

Finding 1: Students' Learning of the Function Concept Was Limited

Item 7 of the FCI assessed students' understanding of inverse functions (see Figure 2). Regarding students' learning of the concept of inverse functions was concerned, the students' responses to item 7 in the pretest and posttest were similar.

Problem 7. Look at the graphs in (i) and (ii) below.

a) The claim is that Graph (ii) represents a function which is the inverse of the function represented by graph (i). Explain what this means and state whether you think the claim is true. b) Look at the other graph given below and draw, on the same axes, a graph to represent its inverse if you think there is an inverse. Explain clearly why you think there is an inverse or not an inverse.

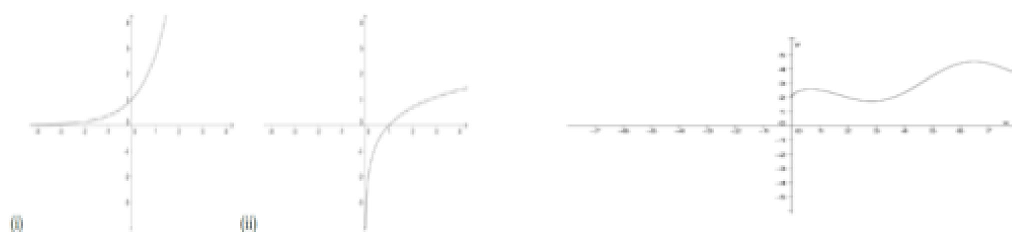

Figure 1: Item 7 from the Function Concept Inventory (O'Shea et al., 2016)

Four students in their pre-test rejected the claim in part (a). Of the ten students who accepted the claim, two described the inverse as a reflection on y = x; the remaining eight students used terms like opposite, positive-negative, reverse concavity, or negative slope to explain the meaning of inverse. 8 students did not respond to part (b). The 6 students who responded either drew an additional graph that was either reflection on the line y = x (the same two students who interpreted it as such in part(a)); on the x-axis; or about the origin.

Similarly, in the post-test two students chose not to respond to item 7. 8 students responded for part (a) but did not respond to part (b) and 4 students responded for both parts. Two of the students rejected the claim for part (a); the other 10 responded positively. The two students who had, in pretest, interpreted the graph of the inverse of a function to be the reflection of the graph in y = x reiterated that interpretation. The remaining 10 students who had responded for item #7 continued to interpret the inverse graph as a reflection on x-axis, y-axis, or both axes and the diagram that they drew for part (b) were not consistent with their interpretations in part (a).

Finding 2: Teaching Engaged Students with Activities Around the Notion of Inverse Function

Guilia's classroom teaching and her classroom materials included attention to the concept of function. In one of the observations, Guilia prompted students to do a graphing activity involving $y = 10^x$ and $y = \log x$:

> Guilia: So, do activity #3, draw the graph of $y = 10^x$ and $y = \log x$ yon the same grid and compare the two graphs. You can use the graphing calculator if you need.

After students completed the task, Guilia led the discussion comparing the two graphs and establishing the inverse relationship of the two functions. Then she asked students to do the following task:

> Guilia: Now, I would like you to investigate the relationship between y = ln x and y = e^x just like we did for log x and 10^x in activity #4. And see whether we can make similar observations.

Guilia used students' work from activity #3 and #4 to lead a discussion about the inverse nature of the pairs of functions in the activities, emphasizing the reverse concavity of inverse functions and how, in each pair of functions, the graph of one is the reflection image of the other across the line y = x. One of the worksheets that Guilia used in class also shows that, besides exploring the graphical nature of the inverse functions, Guilia and her students also examined the algebraic nature of inverses (Figure 1).

Inverse Function Notation

- If we want to emphasize that g is the inverse of f, we call it f^{-1} (read "f-inverse"). To express the fact that the population of birds, P, is a function of time, t, we write $p = f(t)$
- To express the fact that the time t is also determined by P, so that t is a function of P, we write $t = f^{-1}(P)$

Example 1: The cricket function, which gives temperature, T, in terms of chirp rate, R, is T = f(R) = ¼ · R + 40. Find a formula for the inverse function, R = f^{-1}(T).

Recall: The functions f and f^{-1} are called inverses because they "undo" each other when composed: $f\left(f^{-1}(x)\right) = f^{-1}\left(f(x)\right) = x$

Exercise 9: Find the inverse(s) of the following functions:

a) $y = x^3 + 3.$
b) $y = 2x + 8.$

Figure 2: Excerpt from In-class Handout on Inverse Function Notation

Finding 3: Instruction Does Not Necessarily Translate into Learning

Students had limited recollection of instruction related to the concept of inverse. Of the three students who participated in the clinical interview, Jim said he did not remember the topic being discussed in the class. Ryan (who was one of the students who correctly responded part (a) of item #7 in both the tests) said his answers were based on learning from a course he did in high school. Dikardo said that he vaguely remembered the topic being discussed in class but was not sure about the answers to item #7.

Conclusions

It is not clear from our data how substantial the attention to the notion of inverse was in Guilia's instruction. However, posttest results show that, in spite of at least two lessons explicitly designed to engage students with the notion of inverse, student learning in this area was limited. This is a concern, particularly given that students reported limited recollection of engaging in the course activities related to inverse. These findings are consistent with the idea that effective instruction requires ongoing, repeated opportunities for students to engage with core aspects of the function concept in order to develop the understandings that are deemed essential to their future success in mathematics.

FRAMEWORK TO ANALYZE AND PROMOTE THE DEVELOPMENT OF FUNCTIONAL REASONING IN HIGH-SCHOOL STUDENTS

César Briseño Miranda
CINVESTAV-IPN, México
cbriseno@cinvestav.mx

Ernesto Sánchez Sánchez
CINVESTAV-IPN, México
esanchez@cinvestav.mx

The research this report belongs to aims at exploring the functional reasoning of high-school students from a covariation approach and proposing a framework to describe and predict the students' responses to modeling tasks in Dynamic Geometrical Situations. Items were designed for the students to build/construct the corresponding function guided by questions that allowed for the analysis of covariation. The results are shown in a framework consisting of five components, which describe the student's response patterns based on the examples of each component. The framework will provide a basis for the design of tasks involving learning and evaluation of the concept of function for high-school students. It can be an instrument to analyze the students' covariational and functional reasoning.

Keywords: Algebra and Algebraic Thinking, Geometry and Geometrical and Spatial Thinking, High School Education, Modeling.

Introduction

Mathematicians and mathematics educators share the conviction that the concept of function is one of the most powerful and useful notions within Mathematics because of its integrating role and the multiple applications inside and outside this discipline. However, they also know that learning the concept is often slow and fragmented and gives rise to false conceptions. Therefore, understanding how students appropriate the concept of function has been of great interest to several researchers in mathematics education. In addition, the research has become increasingly diverse about functions, exploring learning at all educational levels, covering different theoretical and methodological frameworks (Carraher & Schliemann, 2007; Kieran, 2004; Kieran, 2007; Thompson & Carlson, 2017). Furthermore, in the field of mathematics education there is a lack of consensus regarding which aspects of function to highlight in their introduction to mathematics classes. The function can be characterized in several ways; for example: a rule of correspondence, ordered pairs, a curve in a cartesian plane, or as a covariation of quantities. This research focuses on the first and last characterizations.

Carlson, Jacobs, Coe., Larsen, and Hsu (2002) address the study of functions from a covariational approach and propose a framework "for describing the mental actions involved in applying covariational reasoning when interpreting and representing dynamic function events". Such framework is designed to provide an account of college students' covariational reasoning in order to develop the concept of function to be used in the courses on differential and integral calculus. However, it is convenient to develop and examine how high-school students adopt covariational reasoning without even considering aspects of the Calculus course such as slopes and derivatives. For that reason, the aim of this work is similar to that of Carlson et al. (2002) but in a lower educational level: based on empirical observations and knowledge of literature on mathematics education regarding algebraic reasoning, we seek to propose an initial framework to analyze, predict, and nurture the development of reasoning with and about the concept of function from a covariational approach by high-school students.

Conceptual Framework

This work has been formulated based on an approach of the research on *Grounded Theory* (Glaser & Strauss, 1967/2008; Birks & Mills, 2014), which recommends not to adhere to any pre-established theory but to generate knowledge and build a local and humble theory based on data. This does not mean to address the object without any thought whatsoever, which is impossible, but that we are simply not expecting the reality observed to confirm a theory. Furthermore, we do not assume that a theory chosen in advance will explain the reasonings underlying in the students' responses. This work seeks to understand the students' reasoning from their productions and the patterns of their responses to the questions proposed. Still, some concepts are key to our exposition.

We will restrict the *concept of function*, with a pedagogical objective, to the covariation between two variables that can be represented with one algebraic expression. It is understood that in its more general and precise conception, the concept of function can be constructed based on this expression. Carlson et al. (2002, p. 354) define "covariational reasoning to be the cognitive activities involved in coordinating two varying quantities while attending to the ways in which they change in relation to each other". In our case, we focus our attention on situations in which quantities vary continuously, particularly when a variable is associated to the displacement of a point on a line segment and the other, to the area of a geometric figure. *Dynamic Geometry Situations* (DGS) are geometric constructions that change in a predictable way when a point moves along a curve. An important trait of DGS is that the characteristics of the construction reveal the *mechanism that explains the covariation*, which is understood as a structure that allows for deducing, based on knowledge of the context, the rule of correspondence between the variables. In several dynamic situations, the *mechanism explaining the covariation* is not transparent (for instance, think on the phenomenon of free-falling bodies); still, in the DGSs proposed, only some geometric knowledge is enough to deduce such mechanism.

Method

The participants of the study were sixteen high-school students grouped in eight couples and enrolled in a first Calculus course. Four problem-activities based on different DGSs with progressive difficulty were carried out. Several written questions were formulated in each problem-activity, so that the students could model the situation with the algebraic expression of a function. The research was designed in two phases, each one consisting of nine sessions lasting two hours: (i) The first phase consisted in activities to model each situation using only paper-and-pencil; (ii) the second phase consisted in using GeoGebra to study the models obtained in the first part; students had to introduce the models [rule of correspondence] in the software to obtain and study the graphs. Additionally, parameters of the situations (e.g., length of the initial segment) were changed so that the students extracted conclusions on the family of functions. In this paper, we provide information on the students' reasonings collected during the first activity (first phase of this research); that is, during the paper-and-pencil phase, without using GeoGebra. The authors are working on a more comprehensive report including the second part.

The first DGS administered to the students is:

The following figure (see Figure 1.a) shows the segment $\overline{AB}$ whose length is 10 units. Place a point Q on segment $\overline{AB}$. Draw the square AQCD; the length of each of its sides is segment

$\overline{AQ}$. *Then, draw square QBEF; the length of each of its sides is segment* $\overline{QB}$.

Based on the construction of polygon ABEFCD (see Figure 1.b; not visible for the students), students are asked: (1) find the area of polygon *ABEFCD* for a defined position of point Q; (2) determine on what the value of the area of the polygon depends; (3) identify which variables are involved when point Q is displaced on segment $\overline{AB}$ and determine whether the area of the polygon is constant when point P (Q before) is displaced on segment $\overline{AB}$; (4) find the algebraic expression that allows for the calculation of the area of polygon *ABEFCD* with respect to any point P; and (5) outline the graph of the previous expression.

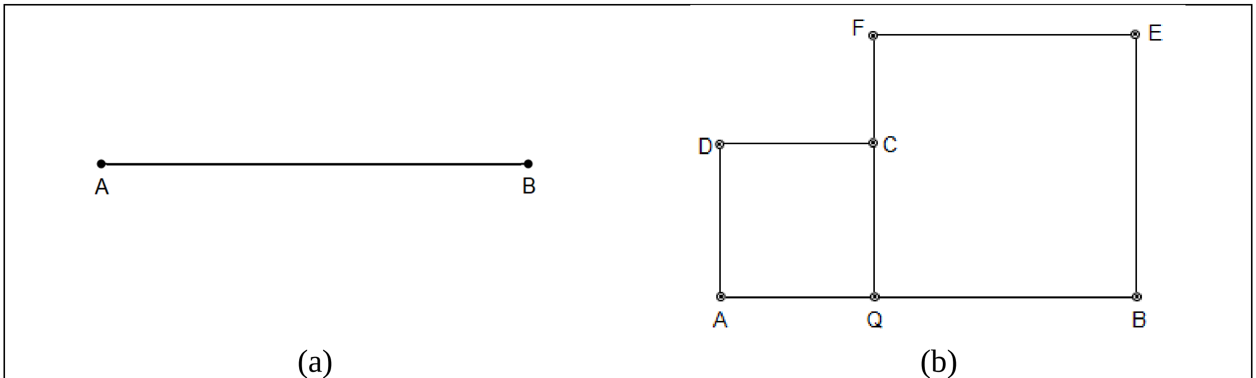

Figure 1: GDS. (a) Initial Segment, (b) Geometric Construction Integrating the GDS

To analyze the data, we considered the principles and procedures of the *Grounded Theory* (Glaser and Strauss, 1967/2008; Birks and Mills, 2011), which is a general methodology of research in social sciences (Holton, 2008) whose objective is to create local theories from data and not logical deductions or other theories previously established. The data analyzed are those responses to the questions formulated and written by the students on their worksheets. These were transcribed into electronic files for handling and were coded, comparing responses between them and grouping those responses when similar characteristics were identified. Through this process, we determined the categories that constitute the proposed framework.

Results

The students' responses to the questions in the item were grouped according to one of the components of the framework described in Table 1.

Table 1: Initial Framework of Covariational Reasoning.

Component	*Description*
I. Ignorance of covariation	The dynamic situation is analyzed statically (fixing a position); then, calculations are made with constant quantities or literals conceived as general numbers.
II. Consideration of covariation	The dynamic aspect of the situation is verbalized, describing how the change of an object (point, quantity, or variable) produces a change in another one (figure, length, area, or volume).
III. Previous analysis of covariation	Dependent and independent variables are identified and the mechanism explaining the covariation is described. Additionally, the range of the

	each variable is recognized.
IV. Representation of covariation	The rule of correspondence is symbolically represented. Representations go from those using geometric notation to those written purely in algebraic notation.
V. Consequences of covariation	From the first representation of the proposed function, other representations, as tabular and graphic, are expressed. Variation ranges are determined, and maximum or minimum values are anticipated.

Figure 2 synthesizes the components that constitute the initial framework of covariational reasoning, which are intertwined, since each level is a consequence of the upper one.

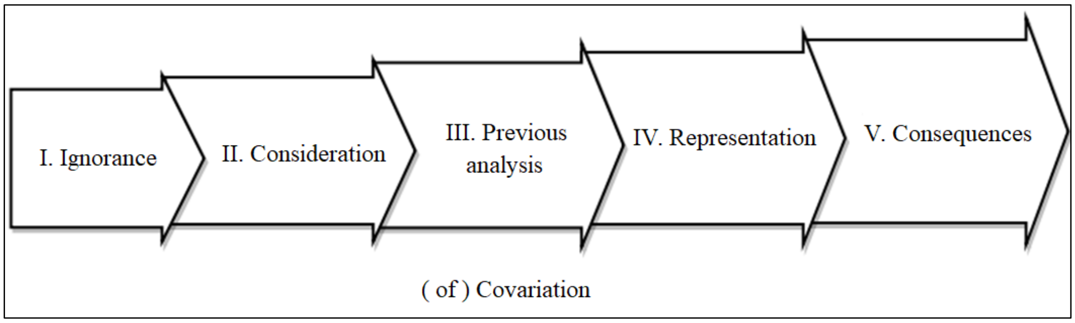

Figure 2: Identified Categories in the Initial Framework of covariational Reasoning

Below are the results obtained from the first task based on the described components:

I. Ignorance of Covariation

A dynamic situation can be and is often modeled fixating it in a certain moment to analyze its structure. Ignoring the covariation means carrying out an analysis of the structure of the situation at a given moment. This is often the first step of a strategy to model such situations.

In the first question after describing the situation, the students are asked to write the area of geometric configuration obtained for a position of a point Q on the segment $\overline{AB}$. All the couples provide a response ignoring covariation, either because they use a constant value for the independent variable or because they do not suggest displacing or changing the initial point Q, although they propose a general expression using symbols of segments or literals.

On the one hand, two couples based their response on the assignation of a numerical value to segment $\overline{AQ}$ and then calculated the requested area based on the outline of the corresponding configuration. For instance, a team assigns $\overline{AQ}$= 3.414634146 and then $\overline{QB}$= 6.585365854, operates with these numbers, and correctly obtains *Area of ABEFCD* = 55.026. Although this procedure includes the data and reflects the understanding of the mechanism explaining covariation, the result leaves no trace of such understanding. On the other hand, two couples use segment notation to express the area of the polygon, but one is not expressed as equation and none of the couples include the data [$\overline{AB}$=10 and $\overline{AB} = \overline{AQ} + \overline{QB}$]. For example, one of the couples writes: $\overline{DA} \cdot \overline{AQ} + \overline{FQ} \cdot \overline{QB}$. Finally, four couples write general expressions; still, none included the data in the equation. As an example, the following response represents these four teams: $A = \overline{AQ}^2 + \overline{QB}^2$. It must be noted that, in this phase, segment expressions are used as general numbers; that is, they express a fixed but undetermined number.

The quality of the responses in this category depends on two aspects: (i) the notation used,

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

better if symbolic and not only arithmetic, and (ii) the addition of problem data to the expression, keeping only the dependent and independent variables, laying the ground to transit towards the algebraic expression.

II. Consideration of Covariation

This category includes the manifestations in which students recognize that the situation is dynamic, alluding to the notion of variable. They can express the idea of covariation in discrete terms; for example, "for values different from $\overline{AQ}$ we obtain different polygons or different area values". They can also implicitly express the continuity of the relation: "When point Q is displaced on the segment $\overline{AB}$, the polygon or the area changes." Question 3, part of the battery of questions asked, promoted the consideration of covariation between point Q and the area of the polygon: *(3) If point Q is displaced on line segment $\overline{AB}$, is the area of the polygon constant?*

For example, a team stated that when "point Q is displaced on the segment $\overline{AB}$, the area grows without being constant and while a square grows, so does its area." Another team states the area is not constant and argue that "when Q is in the center [in the middle of line segment $\overline{AB}$], the area of the polygons is equal. When Q is at the center, that is the smallest area we will get from both polygons. If Q goes from A to the center of $\overline{AB}$, the area decreases and if it goes from the center to B, it increases." Other teams are more explicit. In the following case, the students make a description that does not refer to the area of the polygon, but to the areas of the squares forming the polygon: "If P (previously Q) is in the midpoint of $\overline{AB}$, the areas will be equivalent. If $\overline{AP} > \overline{PB}$, then the area goes from a maximum to a minimum value and after this constant it will grow equally on the opposite side until it reaches its maximum height." The students in this team try to describe covariation observing the changes in the squares forming the polygon. The most developed answers are those that describe the way in which the whole area of the polygon changes. Still, there are others describing covariation by observing the movement of the polygon and not its area.

III. Previous Analysis of Covariation

The fundamental elements of covariation are independent and dependent variables, rule of correspondence, and ranges of both variables. When students identify some or all these elements, we consider they have made a prior analysis of covariation.

The questions *(2) What does the value of the area depend on?* and *(3) Which variables intervene when point P is displaced on line segment $\overline{AB}$?*, foster that students to refer to the variables. It must be noted that, in their responses, no pair of students refers to both variables ($x = \overline{AP}$ and $a = area\ de\ ABEFCD$). Three teams associate the independent variable with the position of point P; for example, one says: "The only variable is P because the two internal segments depend on the position of P." Four teams mention the segment $\overline{AP}$ and a fourth one identifies the magnitude of the segment "*P=distance traveled on* $\overline{AP}$". No team refers to any variable as "*x*". Additionally, students seem to have interpreted the term variable as independent variable and thus the analysis of covariation is partial in all cases.

We must emphasize that the students' responses do not entirely deviate from the context. A majority considers the independent variable as a position or line segment, instead of thinking about it as a quantity associated to the position of the point albeit different from it. However, the most advanced students use letter "*p*" as a quantity that varies and not as a point; no one uses variables "*x*" and "*y*".

IV. Representation of Covariation

An important objective while modeling *Dynamic Geometry Situations* is achieved when the corresponding algebraic expression is obtained. The activities described in the previous components are mere aids of, and subsumed in, the (algebraic) representation activity of covariation. A student who move forward adequately in the activities of the previous components has a good chance of writing the corresponding representation and provide it with a sense related to its dynamic aspect.

The representation activity is promoted with the question *(4) Find the algebraic expression that allows for the calculation of the area with respect to any point P*. All the students propose a representation, and we have identified the group of representations according to the notation used: Geometric, Mixed, and Algebraic, as well as the integration of $\overline{AB} = 10$ and $\overline{AB} = \overline{AP} + \overline{PB}$.

In their representations, most of the teams keep traits of the geometric context in which the problem is formulated. The response $a = \overline{AP}^2 + \overline{AB}^2$ is completely geometric; in such expression, we have conjectured that letter "*a*" is used as a tag and not as a variable (remember that in the section "Analysis of covariation" no student identified the "*area*" as a variable). Additionally, the representation does not include the two data mentioned. Three teams used mixed notation; that is, they combined Geometric and Algebraic notations. For example, a team writes $f(p) = p^2 + (\overline{AB} - p)^2$, but does not include $\overline{AB} = 10$. Finally, two teams use Algebraic notation, although they do not use conventional letters: $p^2 + (10 - p)^2 = a$.

Interestingly, two teams spontaneously provided an algebraic expression that nonetheless alluded the context by using variables "*p*" and "*a*" instead of "*x*" and "*y*". The reluctance to separate the expression from the context is greater in the teams using Geometric or Mixed notation; they tend to overlook the inclusion of the data to the expression. Surely, additional activities are necessary for students to be willing to regard the algebraic expression independently from the context. In the present studies, the activities carried out later using GeoGebra allowed the students to produce expressions using algebraic notation for GDS models. However, paper-and-pencil activities were also convenient for students to reflect on some of the consequences of their representations.

V. Consequences of Covariation

The modeling process consists of representing a situation to study its properties and consequences. Then, the aim is not only to represent covariation but also obtain consequences from it, one of which is (the immediate although not simple) graphic representation that, in turn, allows to obtain more consequences. Other approaches on the concept of function focus on the occurrence of a situation or a data set, then the graph and its interpretation (Leinhart, Zaslavky & Stein, 1990). A consequence in this case would be obtaining the algebraic expression. Even though this approach is fruitful, the one we propose in this work is better adapted to the objectives of an algebra course considering later pre-calculus or calculus courses.

To help students express the consequences of covariation, they were asked: *(5) Outline the graph of the symbolic expression previously obtained.* Figure 3 shows three types of graphs found among the students' responses. A team outlines a graph including two line segments joined at a vertex (see Figure 3.a). The graph did not consider the algebraic expression and was directly derived from a direct (but inadequate) qualitative interpretation of the situation. Another team provided a graph showing a curve segment (see Figure 3.b); still, there is no apparent relation between the written equation and the table built. Five teams provide an acceptable outline of the graph, building the table, plotting the points, and then interpolating the curve (see Figure 3.c).

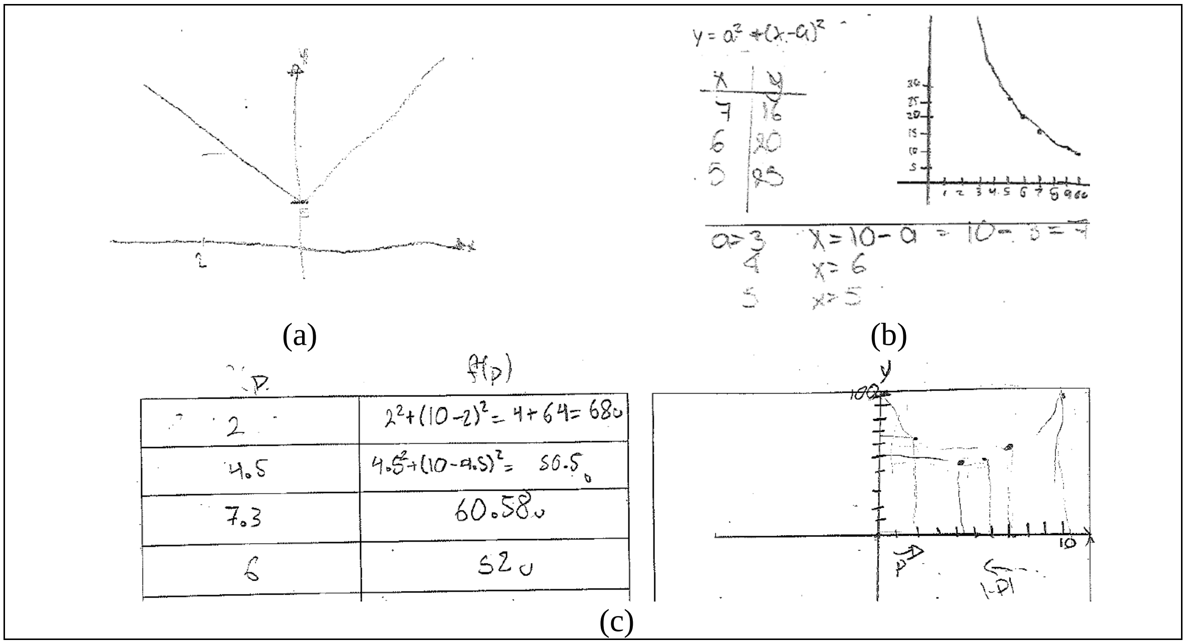

Figure 3: Consequences of Covariation

Conclusions

Once the students have reached a basic level at handling algebra (use of an unknown and formulation of equations to solve problems in static situations), they can model dynamic geometric situations. Therefore, they can progress to building the concept of function, at least in its conception as covariation of quantities. In this research, we characterized different types of actions students take in the process of algebraically modeling a dynamic situation in which they can easily deduce the rule of correspondence from the *mechanism that explains the covariation* [polygon *ABEFCD*]. This methodological decision of reducing the mathematical difficulty with the intention to allow students derive the rule of correspondence highlighted some of the natural and adequate dispositions of the students and reveal their difficulties for using algebra to model dynamic situations. For instance, the notion of displacing the point and coordinating it with what occurs in the polygon naturally leads to the use of symbols as variables. Contrastingly, it seems students have difficulties representing the function independently from the geometric context from which it arises. The approach we propose is part of a teaching experiments in whose development GeoGebra was used. This also explains the aim towards constructing the algebraic expression given that this software can be used to introduce the algebraic expression and obtain the corresponding graph on screen. The analysis and result of this stage is not part of this report; however, we can anticipate it was useful to consolidate the interpretation of the graph of the function and the correct actions and reasoning made in the stage here reported.

SEEING EXPONENTIAL FUNCTIONS DESPITE REPRESENTATIONAL FLUENCY IN A QUANTITATIVELY RICH QUADRATIC FUNCTION TASK

Nigar Altindis
Syracuse University
naltindi@syr.edu

Nicole L. Fonger
Syracuse University
nfonger@syr.edu

In this study we explored how preservice teachers' (PTs) demonstrated representational fluency and functional thinking in approaching quadratic function tasks within a realizable task context. Participants were secondary school mathematics PTs in their final semester. We employed a multi-case study method with task-based interviews to deeply explore PTs problem-solving activity. The findings showed representational fluency pushed learners to switch back and forward between covariational and correspondence reasoning.

Keywords: Representational Fluency, Covariation and Correspondence Reasoning

Rationale and Research Aim

This research aims to respond to an enduring challenge of supporting secondary mathematics preservice teachers (PTs) in learning about conceptually-oriented approaches to teaching functions. Creating, connecting, translating between, and making meaning of multiple representations, or representational fluency (Fonger, 2019), is an important aspect of PTs' pedagogical content knowledge (Dreher, Kuntze, & Lerman, 2016). Indeed, creating and interpreting representations are "important cognitive processes that lead students to develop robust mathematical understandings" (Huntley, Marcus, Kahan, & Miller, 2007, p. 117). A prevelent notion in math education is that "using multiple representations" supports students' conceptual understanding of mathematics (e.g., NCTM 2014). However, a representational fluency lens on conceptual understanding is by itself insufficient (Fonger, 2019; Lobato, 2013). Indeed, a growing body of work demonstrates that students make sense of functions by reasoning with both covariational and correspondence approaches (Carlson et al., 2002; Confrey & Smith,1994, 1995; Lobato et al., 2012; Thompson & Carlson, 2017). In one study, PTs' covariational reasoning fostered their understanding of the relationship between multiple representations (Moore et al., 2013). Moore et al found "students engaged in covariational reasoning to make sense of and conceive invariant relationships among multiple representations" (p. 472). Moore and colleagues identified a relationship between students' covariational reasoning and their interpretation of multiple representations. The generalizability of this finding to other contexts remains an important area of inquiry.

In this study we investigate PTs conceptual approaches to quadratic function tasks by networking two lenses: representational fluency and functional thinking. We aim to contribute to an understanding of relationships between PTs functional thinking and representational fluency in solving problems in a quantitatively rich context. We ask: RQ1. How do PTs use and connect representations to reason about quadratic functions?; and RQ2. What relationships are observed between PTs representational fluency and functional thinking?

Theoretical Framework and Background Literature

From our stance, a person (e.g., PT) is viewed as active in their meaning-making processes through the activities of creating and interpreting invariant features among representations. We draw on Fonger's (2019) articulation of meaningfulness in representational fluency as an analytic tool to discern the nature of students' problem-solving approaches with multiple representations.

Functional thinking includes students' abilities to generalize and represent functional relationships (Stephens, Fonger, Strachota, Isler, Blanton, Knuth, Gardiner, 2017; Kaput, 2008). Correspondnece, covariation, and recursive are three ways of reasoning about functions (Confrey & Smith, 1991; Thompson & Carlson, 2017); we focus on the first two in this report. From a *correspondence* perspective, students determine output or dependent values (of the range) as related to input values (of the domain) and may identify a symbolic equation between dependent and independent values. From a *covariation* perspective, students reason about relationships of change across two or more quantities (e.g., change in *x* and change in *y*) "describing how one quantity varies in relation to another" (Confrey, & Smith, 1995, p.79). We adopt this framing across symbolic, graphic, numeric, and diagram representations.

Methodology

Data Sources and Mode of Inquiry

Participants of this study were five secondary PTs, in their second semester of a two-semester methods sequence at a private university in the U.S. The authors conducted a 60-minute audio-recorded semi-structured task-based interview (Goldin, 2000) with each PT. Given space constraints and commitment to deeper understanding of participants' thinking, this study reports on only one participant as a case study (Stake, 1995), Eve,who selected task C (Figure 1a). We prompted PTs to think aloud, clarifying meanings of their activity.

Data Analysis Techniques

In this study, we employed an analytic framework for representational fluency (Fonger, 2019), in particular lesser meaningfulness to characterize PTs' discursive activity in creating, interpreting, and connecting multiple representations, and a priori descriptions of students' functional thinking (cf. Stephens et al., 2017) (RQ1). Lesser meaningfulness includes: *pre-structural understanding*; creating and interpreting one representation with unsophisticated thinking; and *multi-structural understanding*; creating or connecting multiple representations with unsophisticated thinking. This framework allowed us to identify relationships between PTs' representational activity and their ways of thinking about function (RQ2) in rounds of coding.

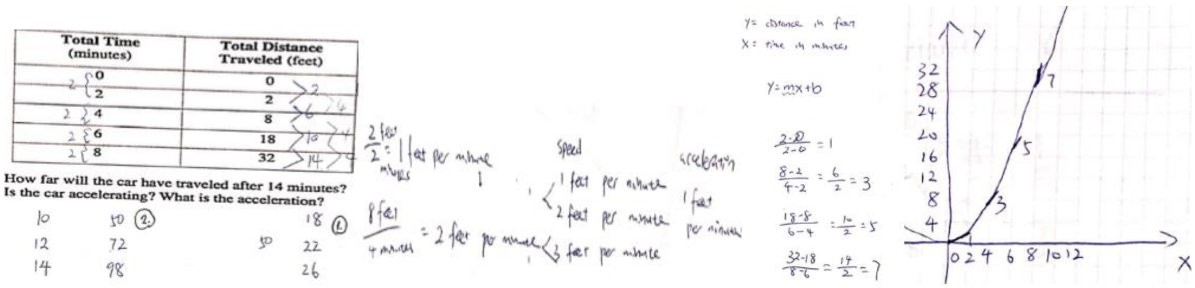
Results

Eve used multiple strategies; covariational reasoning on a table and graph, and correspondence reasoning to create generalized symbolic equation. We discuss each in turn.

Strategy 1: Eve's Covariational and Corresponding Reasoning with a Table

Eve had strong covariational reasoning; to find how far the car traveled after 14 minutes, she extended the table in Task C (Fig. 1a) by finding that the change in the distance was 2, 6, 10, 14, and 18, and the change in the time was 2 for each time interval (see Fig. 1a). While she was extending the table, she recorded both change in the distance and the change in the time as coordinated pairs of quantities. Eve placed her right hand on time and the left hand on the distance column on the table at the same time to represent the covariation across columns. While positioning her hands, she said "So, I see that when the time increased by two every time, the total distance also increased." Eve's covariational reasoning helped support her use of the tabular representation in making sense of this task and finding the distance the car travelled in 14 minutes. To determine if the car was accelerating, Eve employed a corresponence approach by calculating ratios of time and distance, then calculated change in those quantities:

> "I do two feet divided by two minutes [fig. a]. And then I do the same for four minutes. So, I get two feet per minute and then I get three feet per minute. So, I compare the speed between one per minute, two per minute and three per minute. And then I realized that each time the speed is changing by one foot per minute. So, I think the acceleration is just going to be one foot per minute."



(a) (b)

Figure 1: Eve's Quantitative Reasoning with Multiple Representations on the "Car Task"

Also shown in Fig. 1a, Eve divided the total distances and total time for each of: 2 ft/2 min.=1ft/min, 8 ft/4 min.=2ft/min.; 18 ft./6 min.=3ft/min., correspondence reasoning. From these ratios, Eve noted that the speed of the toy car increased by 1 ft/min and concluded that acceleration was 1 ft/min by looking change in total distance over time for each interval. She attended to change in speed, not noticing the time intervals between the computed speeds were 2 minutes each. She seemed to either assume that acceleration is a change in speed or had assumed that the time between the calculated speeds was 1 minute, not recognizing acceleration is a change in speed per unit of time. Thus, while Eve was able to identify patterns by extending and interpreting the table (covariation), and computing ratios of distance and time (correspondence); she had little confidence in distinguishing between average speed, instantaneous speed, and acceleration across the table and verbal representation types, *multi-structural* fluency.

Strategy 2: Eve's Correspondence Reasoning to Create a Symbolic Representation

When asked to solve the task in another way, Eve used a correspondence approach; she investigated a relationship between input (time) and output (distance) variables. Eve labeled y as distance in feet and x as time in minutes, then attempted to find out whether the change in y (distance) divided by change in x (minutes) was constant. She wrote $y = mx + b$ and said:

> "So, if I make y to be the distance and then x to be the time in minutes… So, the speed, the velocity would be my slope because I think that would be m, x plus b. So, if I wanted to find the slope, I can do 2 feet divides by 2 minutes [writes (2-0)/ (2-0) =1], like two, I think that would be exponential. If I do eight minus two [writes (8-2)/ (4-2)], it would be six over two. Which would be [3]. Yeah. Because it's accelerating. So, the slope will not be the same"

Shown in Figure 1b, Eve calculated the "slopes" as 1, 3, 5, and 7, using feet and minutes as units when she was referring to distance and time, realizing the slope was not constant. She reasoned that the slope was increasing, and the relationship between time and distance was exponential. She looked for an exponential equation to model speed even though she noticed initial value is zero, she did not change her claim of exponential growth. She said: "If I try to find the exponential function, it has the form like y equal to initial times the rate of change to a time interval. So, the initial, which would be zero... It does not make sense because if I have zero everything will give me zero." Although Eve saw that the initial value was zero, she did not change her reasoning about exponential growth and wrote $y = \textit{initial value}(\textit{rate of change})^{\textit{time}}$.

Eve expressed an understanding of the meaning of slope and tangent line, quantifying the slope as the speed of the car in a graph. Eve used *correspondence* reasoning to look at the relationship between time and distance, and to find an equation to model the car's speed. She reasoned that the slope would be speed, and from reasoning about ratios of change (*covariation*) she divided the distance by each time interval to calculate the speed. Hence, Eve connected a tabular representation to a symbolic one, without a complete portrayal of the formula. So, we consider Eve' s reasoning as *multi-structural*.

Strategy 3: Eve's Covariational Reasoning with a Graph

In a third strategy, Eve decided to create a graph. Eve labelled y-axis as distance and x-axis as time, and as she plotted the points. After connecting the points on the graph, Eve interpreted the graph as an exponential (Fig 1b). When asked why, she said: "this is going very fast. The speed. So, it's slowly at the beginning, like a small, more flat line, and then the line keeps getting steeper." Eve's visualization of faster speed in a graph was the line getting steeper, so if it increased quickly, then it must be exponential. Eve represented the slopes 1, 3, 5, and 7 for time intervals 0-2, 2-4, 4-6, and 6-8 on the graph, then realized that the function was a concave up curve, *covariational* reasoning. She correctly created a graph that matched the data in the table yet insisted on an interpretation of the function as exponential, *multi-structural* fluency.

In order to observe Eve's ability to connect representations, we asked Eve to represent the change in distance (which she identified as 4 in the table, see Fig. 1b) in the graph. She said, "So the difference is increasing by four each time [referring the change of change in distance in the table, see Fig. 1a], but how does it relate the graph, I do not know.". Although Eve's reasoning showed she was finding average rate of rate of change as constant, she did not recognize the function as quadratic. She also identified this rate as the slope and showed the slopes as tangent lines on the graph. Eve was able to interpret the graph and see "the car is accelerating, 'cause when you see the graph it is going up very fast." However, she could not reason how much the car would accelerate and the distance it would travel after 14 min.

Overall, Eve reasoned that the relationship between time and distance as exponential in graphical and tabular representations. Her interpretation was that the function must be an exponential; she used graphical representation to argue for her interpretation, noting that the graph did not have a constant slope for each time interval (and thus could not be linear), and that it had a non-negative domain for the time variable. Eve's reasoning about rate of quadratic function on a table was clearer than on a graph. As Eve did, greater sophistication in representational fluency supported her to draw connections between covariational and correspondence reasoning.

Discussion and Conclusion

This study contributes to knowledge about how representational fluency and functional thinking may interact in a symbiotic relationship, shedding light on PTs meaningful learning of functions with multiple representations. For instance, Eve's correspondence and covariational approach to tabular representation made the acceleration visible in solving the task. Moreover, interpreting, creating and connecting multiple representations pushed Eve to switch back and forward within covariational and correspondence reasoning. Hence similar to Moore et al.'s (2013) study, PTs' representational fluency is grounded in covariational reasoning. The connection learners make between covariational and correspondence reasoning through representational fluency might develop sophisticated understanding of function concept. Supporting PTs' fluency and functional thinking is a viable approach for teacher education focused on conceptually-oriented approaches to learning. Future research is needed to support PTs understanding of the nature of function families as grounded in rich quantitative tasks.

The paper examines sociomathematical norms in a Precalculus course at a four-year public university. The data were collected through a set of instructional activities designed to breach students' expectations about what constitutes an acceptable mathematical solution by exposing them to alternative solution methods. This paper describes one such activity in detail and reports on the nature of a sociomathematical norm that was revealed by the activity: Students characterized an acceptable solution as one that followed procedures modeled by the instructor, while solutions which used other valid mathematical approaches were considered incorrect by the students.

Keywords: Post-Secondary Education, Instructional Activities and Practices

Background / Purpose

Incoming college students who are low-achieving in mathematics are often placed in developmental or remedial mathematics courses such as College Algebra or Precalculus. Research over recent decades describes various shortcomings of such mathematics courses (Stage & Kloosterman, 1991; Hagedorn, 1999; Boyer et al., 2007; Lagerlof & Seltzer, 2009; Bahr, 2013), such as an overemphasis on exposure to remedial content, which often does not require students to change the mathematical practices and habits that contributed towards their need for remediation (Carlson et al., 2010; Goudas & Boylan, 2013). In addition, students, especially those with poor mathematics skills, often prefer a dependent learning style with a procedural focus towards mastering algorithms. Consequently, some researchers have suggested that attempts to improve developmental courses should consider the nature of students' mathematical engagement, focusing on developing students' argumentation skills and reasoning strategies (Chiaravalloti, 2009; Partanen & Kaasila, 2014). This, in turn, requires establishing productive socimathematical norms in the class. These norms help shape how students interact with mathematics, including how they interpret and solve mathematical problems (Voigt, 1995) as well as how students reason and justify their reasoning (Inglis & Mejia-Ramos, 2009). Negotiating sociomathematical norms can help teachers guide students' inquiry and convey how to productively participate in class. This can help focus students' engagement on developing reasoning skills necessary to be successful in future mathematics courses.

As part of a larger study that seeks to characterize students' mathematical engagement in a Precalculus class at a four-year public university, this paper reports on the analysis of sociomathematical norms that developed in such a class. Specifically, we examine the following research question: What characterizes the sociomathematical norm of what constitutes an acceptable mathematical solution in a post-secondary Precalculus class?

Framework

The Emergent Perspective and Norms

This research adopts the view that social and psychological perspectives are essential to characterizing classroom activity, which aligns with the emergent perspective (Cobb & Yackel, 1996). One key social construct in the emergent perspective is *norms*, which characterize mutually established and regulated activity or behavior amongst a collective (Cobb et al., 2001). In a class, norms are not pre-made rules for students to follow but are rather developed through continual student and teacher interaction, either explicitly or implicitly. Even though teachers typically initiate the negotiation of norms, norms are usually based on mutual expectations that are formed as both students and teachers interact with one another (Yackel et al., 2000). *Sociomathematical norms* are specific to mathematical aspects of students' activity (Yackel & Cobb, 1996; Kazemi & Stipek, 2008/2009). One sociomathematical norm of particular importance to this research is: what constitutes an acceptable solution. Research shows that effectively negotiating this norm can help develop a culture to support effective student participation in mathematical discussions (Partanen & Kaasila, 2014).

Methods

Data collection focused on one post-secondary Precalculus class of twelve students, taught by Ethan (all names used are pseudonyms), a first-year graduate student with prior teaching experience. The class largely consisted of students taking the class for the second time, as they did not earn a sufficient grade the previous semester to advance to Calculus 1, and non-traditional students, such as those returning to school or those involved with the armed services.

Typically, norms are widely abided through unconscious acceptance, which can make them difficult to study (Braswell, 2014). To elicit information about social norms, Garfinkel (1967) introduced the methodology of breaching experiments, in which a researcher attempts to violate conjectured social norms. This study appropriates this idea by utilizing a breaching experiment in the form of an instructional activity for students, which was designed to uncover the sustained sociomathematial norms in the class on what constitutes an acceptable mathematical solution.

Students worked on in groups of three or four. Each activity comprised three phases. The first phase asked students to solve a mathematics problem on the content recently covered in class. This phase allowed for the capture of typical mathematical practices pursued by the students. The second phase asked students to cooperatively formulate a grading key by distributing six points in any way they agreed upon. Students were told that they had to explain their point allotment and that they could change it later on if desired.

The last phase of the activity, which is the focus of this paper, asked students to use their grading key to evaluate sample solutions. This phase attempted to disrupt students’ expectations by presenting alternative methods or including mistakes that violate hypothesized normative mathematical conventions established in class. Phases two and three of the activity provided information about the nature of the sociomathematical norm of what constitutes an acceptable mathematical solution.

Data Collection and Analysis

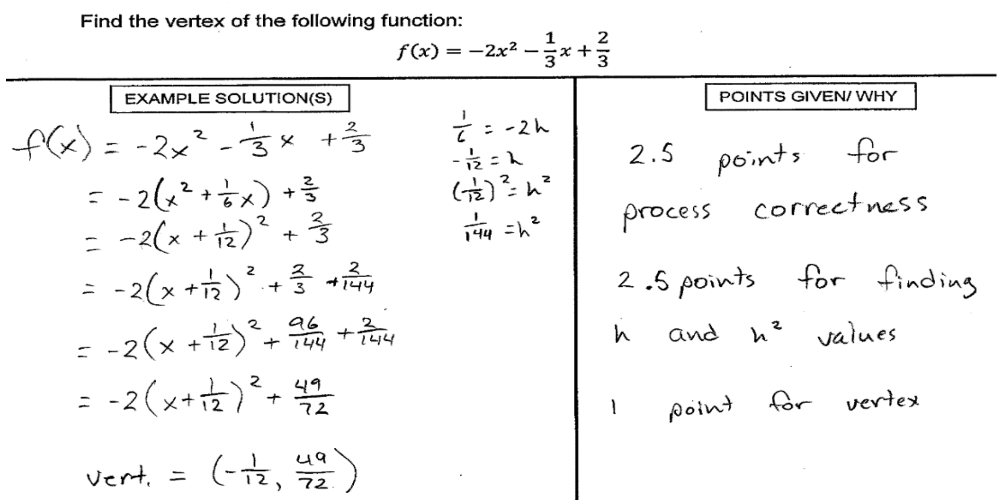
Two groups were video-recorded using 360° cameras. We coded students' activity and conversations during all stages of the activity with consideration to other collected data, including their solutions, grading rubrics, and the grading of sample solution work, to look for evidence of the sociomathematical norm of what constitutes an acceptable mathematical solution. The following results focus on the activity of a group consisting of Darryl, John, Noah, and Sean, which were similar to the other group recorded.

Results

The mathematical topic for this activity was to find the vertex of a parabola. The instructor introduced the activity to the students and described its purpose as an opportunity to explore "different ways to do things … cool ways to solve problems." He stressed that the methods he taught were not "the only way or the best way even" to find the vertex of a parabola.

Phase 1 and 2: Solving the Problem and Creating a Grading Key

Figure 1, below, shows the group's solution and their scoring rubric for assessing the sample work. This solution followed a method referred to as *completing the square,* which was previously modeled by the instructor. The group's rubric depicted their value for completing the square, as most points were rewarded for adhering to this process. This suggests that the group values the process more than the answer. Since the class was not accustomed to exploring different approaches, it is unsurprising that their rubric focuses on the approach that they are acquainted with.



Find the vertex of the following function:

$$f(x) = -2x^2 - \frac{1}{3}x + \frac{2}{3}$$

EXAMPLE SOLUTION(S)	POINTS GIVEN/ WHY
$f(x) = -2x^2 - \frac{1}{3}x + \frac{2}{3}$ $= -2(x^2 + \frac{1}{6}x) + \frac{2}{3}$ $= -2(x + \frac{1}{12})^2 + \frac{2}{3}$ $= -2(x + \frac{1}{12})^2 + \frac{2}{3} + \frac{2}{144}$ $= -2(x + \frac{1}{12})^2 + \frac{96}{144} + \frac{2}{144}$ $= -2(x + \frac{1}{12})^2 + \frac{49}{72}$ vert. $= (-\frac{1}{12}, \frac{49}{72})$ $\frac{1}{6} = -2h$ $-\frac{1}{12} = h$ $(\frac{1}{12})^2 = h^2$ $\frac{1}{144} = h^2$	2.5 points for process correctness 2.5 points for finding h and h^2 values 1 point for vertex

Figure 1: The Group's Solution and Grading Key

Phase 3: Evaluating a Sample Solution

One sample solution, by the fictional student "Frodo," represented a non-standard but valid approach to the problem that only provides the y-coordinate of the vertex (Figure 2). This deliberate flaw was included to determine if students would take exception to how the solution was expressed, as Ethan had emphasized that a vertex was a point with two coordinates.

What was most interesting about students' treatment of this solution, was how the group members fixated on determining the degree to which Frodo followed the procedure that was familiar to them. They were highly critical of Frodo's approach, and were keen to address how the solution deviated from theirs instead of trying to understand it, as the next comment shows:

> John: They're not going to get any other points for it. They don't even have h's in here. So there's 2.5. They don't even have, this isn't the same form to use with h, they don't even have any h's in sight, they completely skipped the h's. So minus 2.5 for that.

The group's reaction provided information about the sociomathematical norm of what constitutes an acceptable solution: an acceptable solution needs to follow the procedures learned in class.

Besides faulting Frodo for not following the "correct procedure," the group further criticized his solution for lacking logic. This was especially surprising considering that Frodo arrived at the same y-coordinate as the group; Darryl attributed this to Frodo being "super lucky."

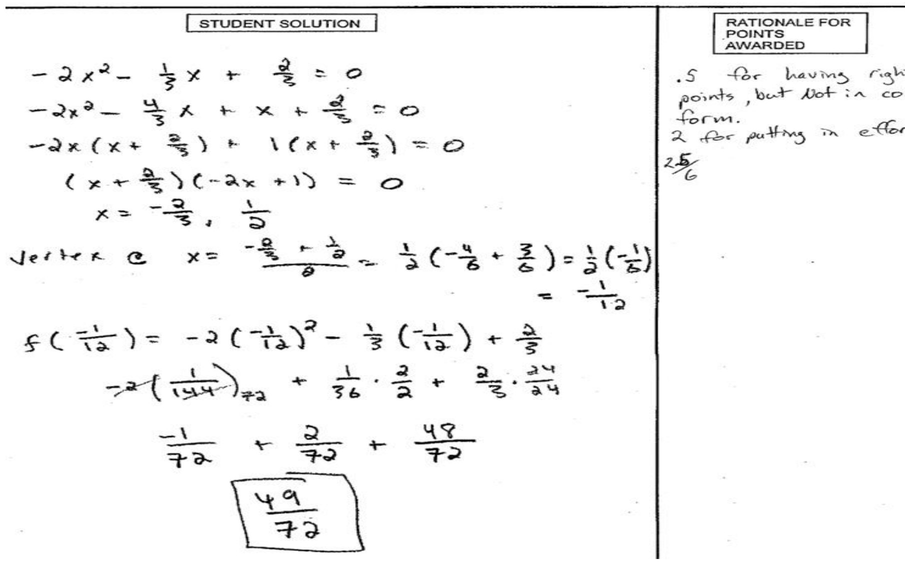


Figure 2: Frodo's Solution and the Group's Grading Rationale

Discussion

One result from this study, that acceptable solutions must represent methods learned in class, displays Ethan's pedagogical approach of having students focus on repeating procedures. Without allowing for investigation into different approaches, Ethan implicitly conveyed to students that the objective of his lessons was for them to learn to reproduce the procedures he modelled. This may have inculcated inflexibility in students to other solution methods, which can be seen by the dismissal of unfamiliar methods as incorrect. This is unfortunate considering one of the goals of developmental mathematics classes is to help students develop flexible reasoning skills needed for subsequent mathematics courses instead of merely having students repeat fixed procedures.

It is important to note that Ethan's instruction did not reflect his own teaching philosophy. He faced several constraints, such as needing to coordinate with other instructors and covering a wide curriculum, which hindered his ability to teach as he wanted. This struggle depicts the usefulness of activities, such as the one described above, that promote student reasoning and flexibility in performing procedures yet still advance the content coverage of the curriculum.

The pedagogical value of this activity was that it allowed Ethan to explicitly negotiate sociomathematical norms to promote more productive mathematical engagement. For example, Ethan began to explicitly dissociate between valid mathematical reasoning and following a procedure, something he noticed the students were conflating during the activity. Because of this, in the following activities, Ethan's students spent increasingly more time investigating the reasoning behind different approaches. These efforts presented opportunities for students to practice drawing on their own intellectual resources.

In addition to identifying sociomathematical norms revealed during breaching instructional activities, this paper is part of a larger project that identifies how sociological constructs develop over the course of a semester. Analyzing multiple breaching instructional activities has allowed us to begin investigating how, for example, the sociomathematical norm of what constitutes an acceptable solution evolved and how this influences students' engagement. Other sociological constructs studied are social norms and communal mathematics practices, which also help characterize students' engagement in the classroom.

We report on results from 20 one-hour task-based interviews with 10 students enrolled in first-term calculus. Each student participated in two interviews. The first interview included tasks designed to assess students' ways of reasoning about fractions in static measurement scenarios (which did not involve varying quantities) and the second interview included tasks designed to assess students' reasoning about scenarios involving quantities that co-vary. We discuss relationships between the ways students coordinated units in static situations and the ways students reasoned about co-varying quantities. The results contribute to the field's understanding of the development of covariational reasoning and the role of constructing three-levels-of-units coordinating structures.

Keywords: Units Coordination, Covariation, Measurement, Calculus Students

Introduction

Steffe's (2017) plenary for PME-NA described children's coordination of units as foundational for their construction of rational number and measurement concepts. How might differences in units coordination relate to differences in older students' reasoning? This paper reports on our exploration of associations between introductory calculus students' ways of coordinating units and their covariational reasoning.

Theoretical Background and Purpose

We believe individuals learn by organizing their experiences to fit within or to extend their existing mental *schemes* (von Glasersfeld, 1995). Schemes are researchers' constructs serving to describe their observations of others' reasoning. A scheme consists of three parts: recognition of a situation, operations (mental actions), and an expected result (von Glasersfeld, 1995). An example is the *iterative fraction scheme* (Steffe & Olive, 2010). A student who has constructed an iterative fraction scheme understands the size of an improper fraction as the result of *partitioning* and *iterating* the size of '1'. For example, they understand 9/4 as 9 copies of 1/4 of 1. If their iterative fraction scheme were *reversible*, the student also understands the amount of 1 to be the result of partitioning and iterating the size of an improper fraction: 1 is 4 copies of 1/9 of 9/4.

In general, reversible schemes are those for which the result of one sequence of mental operations is recognized as a situation for a reversed sequence of operations. Only reversible schemes may become *interiorized,* which allows the recognition of a situation and an expected result of mental activity to be experienced as synchronous. Interiorization allows the results of schemes to become part of more complex logico-mathematical *structures* (Piaget, 1970).

A units coordinating *structure* defines and regulates relationships between transformed units as possible, logically necessary, and reversible (Boyce & Norton, 2017). For example, a student with an interiorized iterative fraction scheme anticipates that there will be iteration of the amount determined by partitioning before actually carrying out the partitioning. This requires assimilation with a units coordinating structure relating the three *levels* of units (e.g., four 1/4 units within one and nine 1/4 units within 9/4, see Figure 1).

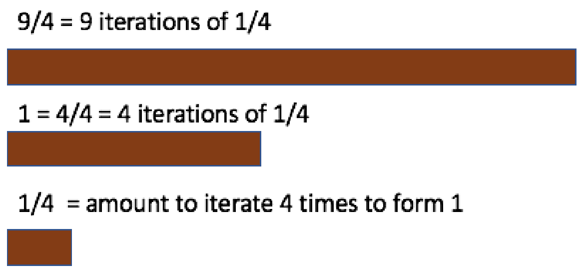

Figure 1: Example of the Form of a Three-level Units Coordinating Structure for 9/4

As part of constructing a three-level units coordinating structure, students learn to coordinate three levels of units *in activity*, which means they "build" an ephemeral third level of units as part of their way of reasoning (Ulrich, 2015). For example, a student who assimilates the task of forming the size of 9/4 given the size of '1' with a two-level structure for coordinating fractional units might form the correct size by *recursively partitioning* the 9/4 into 2 wholes plus 1 part that is one-fourth of a whole, without anticipating that the one-fourth part is one-ninth the size of 9/4 (Steffe & Olive, 2010). Through the activity of partitioning the 9/4 into 1 + 1 + ¼, they may identify the nine one-fourths.

Students who coordinate three levels of fractional units in activity can be successful at school mathematics and persist into college STEM majors (Boyce & Wyld, 2017; Byerley, 2019), although research suggests affordances for students with three levels of fractional units interiorized include abilities to reason flexibly about linear algebraic equations involving unknown values (Hackenberg & Lee, 2015). Such connections between units coordination and algebraic reasoning may explain some differences in students' success in calculus (Grabhorn, Boyce, & Byerley, 2018). In this report we focus on a different connection: relationships between calculus students' units coordination and their *covariational reasoning* (Thompson & Carlson, 2017, p. 440, see Figure 2).

Saldanha and Thompson (1998) described reasoning about covariation as "someone holding in mind a sustained image of two quantities' values (magnitudes) simultaneously. It entails coupling the two quantities, so that, in one's understanding, a multiplicative object is formed of the two" (p. 299). A multiplicative object is different from a units coordinating structure in that iteration is not necessarily involved in forming a multiplicative object. The connection to levels of units is the notion of *simultaneity*. Holding in mind an image of two magnitudes as single conceptual entity requires assimilation with a structure of two or more levels. One level involves individual quantities' magnitudes (Thompson, Carlson, Byerley, & Hatfield, 2014), and a second level is the coupling of the two magnitudes. The focus of our investigation is identifying and testing relationships between students' levels of units and their maintaining of multiplicative objects as they are reasoning about quantities that covary.

We theorize that students who assimilate with one level of units can link two quantities' magnitudes, but the act of reasoning about *changes* to either value necessitates a de-coupling—a destruction of the link and lack of a sustained image of simultaneity. We thus expect that students coordinating only two levels of units in activity are limited to pre-coordination of values (or no coordination)(See Table 1).

Smooth continuous covariation	The person envisions increases or decreases (hereafter, changes) in one quantity's or variable's value (hereafter, variable) as happening simultaneously with changes in another variable's value, and the person envisions both variables varying smoothly and continuously
Chunky continuous covariation	The person envisions changes in one variable's value as happening simultaneously with changes in another variable's value, and they envision both variables varying with chunky continuous variation.
Coordination of values	The person coordinates the values of one variable (x) with values of another variable (y) with the anticipation of creating a discrete collection of pairs (x, y).
Gross coordination of values	The person forms a gross image of quantities' values varying together, such as "this quantity increases while that quantity decreases." The person does not envision that individual values of quantities go together. Instead, the person envisions a loose, nonmultiplicative link between the overall changes in two quantities' values.
Pre-coordination of values	The person envisions two variables' values varying, but asynchronously—one variable changes, then the second variable changes, then the first, and so on. The person does not anticipate creating pairs of values as multiplicative objects.
No coordination	The person has no image of variables varying together. The person focuses on one or another variable's variation with no coordination of values.

Figure 2: Levels of Covariational Reasoning (Thompson & Carlson, 2017, p. 440)

Table 1: Theorized Relationships Between Levels of Units and Covariational Reasoning

Levels of Units Interiorized	Levels of Covariational Reasoning Available to Construct
3	Smooth continuous or chunky continuous covariation
2	Coordination of values or gross coordination of values
1	Precoordination of values or no coordination

We theorize that students who assimilate with two levels of units and coordinate three levels of units in activity can reason with either "coordination of values" or "gross coordination of values". Coordination of values involves anticipating the repeating of the mental actions of coupling two quantities' magnitudes to form a sequence of multiplicative objects representing a correspondence without reasoning about the changes in values. Gross coordination of values involves reasoning about the effects of changes to constituent quantities' magnitudes, but these are limited to reasoning about dichotomous changes—one quantity increasing/decreasing and another quantity increasing/decreasing—without coordinating these changes with particular magnitudes of either quantity. Thus in these two levels of covariational reasoning, there is a structural coordination of two values, but not three.

We theorize that the two higher levels of covariational reasoning, in which coordination of values and coordination of changes *are* integrated (smooth continuous covariation and chunky continuous covariation), are each in the purview of students who have interiorized three levels of units. Our purpose is to report on how conjectured relationships held up in clinical interviews of students' levels of units interiorized and levels of covariational reasoning.

Methods

In Fall 2018 the research team conducted one-on-one task-based clinical interviews (Clement, 2000) with 23 students currently enrolled in Calculus I at one of two public universities in the United States, to assess their units coordinating structures and schemes for reasoning with fractions as measures. For example, one task presented a rectangular bar labeled as 7/3, and the student was tasked to create a bar that represented the size of '1'; another task was for students to create a ruler depicting two fictional measures of distance, given that one measurement unit was 5/9 as long as the other. Each interview took approximately one hour, and participants were selected based on convenience. The interviewer's role was to clarify instructions and request elaboration of a student's reasoning, following the approach described in (Byerley, Boyce, Grabhorn, & Tyburski, 2019)

We recruited these 23 students to participate in a follow-up (one hour) interview to assess their covariational reasoning. Ten of the students participated in a follow-up interview, taking place within three weeks of their initial interview. There were three tasks used for assessing covariational reasoning, and we focus on responses to just the first task in the Results. This task (see Figure 3) is a modification of a task in which students reason about the height and volume of liquid in a jug as the liquid evaporates (Frank, 2018; Paoletti & Moore, 2017; Stalvey & Vidakovic, 2015). The other two tasks were modifications of tasks in which students reason about relationships between a bouncing balls displacement from rest, total distance travelled, and elapsed time (Thompson, 2016, p. 451), and a task in which students reason about a ladder sliding down a wall (Carlson et al., 2002, p. 371)

	Imagine this jug has been completely filled with water. It is then left indoors in a sunny window and left untouched until all the water has evaporated. Describe how the height of the water in the jug would change as the volume of the water in the jug decreases. Sketch a graph that gives the height of the liquid in the jug as a function of the volume of the water in the jug. Describe the rate at which the height of the water is changing with respect to volume.

Figure 3: Reverse Bottle Problem Task

Both sets of interviews were video-recorded. Each of the video-recordings was viewed by at least two members of the research team, who independently coded (Corbin & Strauss, 2014) the students' levels of units and levels of covariational reasoning and documented video-evidence to support their assertions. We subsequently met as a team to discuss the outcomes and reconcile our coding, revisiting videos for which there was uncertainty or disagreement. Finally, we revisited our descriptions of students' covariational reasoning for common themes in students' ways of responding to the tasks.

Results

Each of the students we interviewed were assessed as either having three levels of units interiorized or coordinating three levels of units in activity. We had expected that the students who had interiorized three levels of units would be able to reason at the levels of Chunky continuous covariation or Smooth continuous covariation, while the students coordinating three levels of units in activity would be limited to Gross coordination of values or Coordination of values. The overall results aligned with these expectations, except that several students who had interiorized three levels of units did not exhibit continuous covariational reasoning. We elaborate on interviews with five students, indicated by shading in Table 2, to exemplify the similarities and differences of students' reasoning.

Table 2: Levels of Units and Levels of Covariational Reasoning

Pseudonym	Levels of Units Interiorized	Highest Level of Covariational Reasoning
Amber	2	Gross coordination of values
Shawna	2	Gross coordination of values
Jessica	3	Gross coordination of values
Marisa	3	Gross coordination of values
Jacob	3	Coordination of values
Maude	3	Coordination of values
Rebecca	3	Coordination of values
Emily	3	Chunky continuous covariation
George	3	Smooth continuous covariation
Jack	3	Smooth continuous covariation

Amber's Reasoning (Two levels of units, Gross coordination of values)

On the Reverse Bottle Problem Task, Amber's initial graph indicated she was attending to the evaporation of the water, as she plotted her graph from right to left (starting with the point (10, 10), see Figure 4) and described that "the volume of the water would decrease as it evaporates and the height of that would also be decreasing." The interviewer asked how a linear segment of her graph represented the relationship between height and volume, and she first suggested that they were "directly proportional". The interviewer asked whether the volume of water would be the same for two different "cross-sections" of equal height (two regions directly below the top cylindrical portion). Amber decided they were not the same but said, "I don't know how I would draw that… I think I could draw that on a volume to time graph, but just comparing the volume to the height, that one's kind of hard to be able to draw."

Shawna's Reasoning (Two levels of units, Gross coordination of values)

In contrast, Shawna's graph did not indicate reasoning about time, and her graph was plotted from left to right. Like Amber, Shawna's reasoning was focused on three intervals. She explained that "as our height goes up, our volume increases, and once our height hits about the 2/3 mark our volume has a sharp increase because it is getting wider here. Then the volume decreases, because it is getting smaller at the top, so it goes back up like that." Shawna's first graph showed that the total volume in the jug is monotonically increasing. Her second graph (see Figure 4) of the same relationship shows that the volume increases and then decreases and she appeared to mean "cross sectional volume" when she said volume. She struggled to speak precisely about the quantities she was considering. She also tended to speak about one quantity at a time without reference to the other quantity, which we associate with a sequential, rather than simultaneous, coupling of the quantities. For example, she said, "The rate of the change would be increasing and then once we hit the widest part I think it would be decreasing."

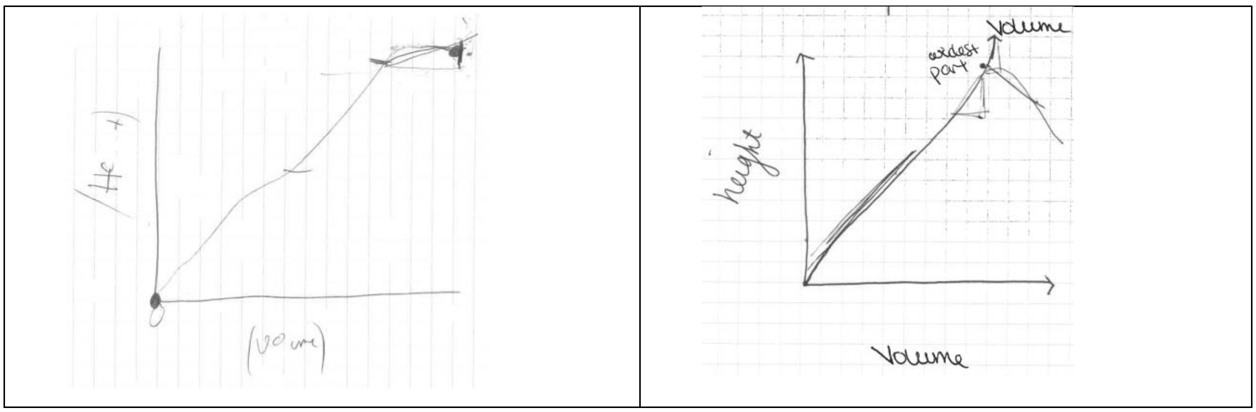

Figure 4: Amber's (left) and Shawna's (right) Graphs on the Reverse Bottle Problem Task

Marisa's Reasoning (Three Levels of Units, Gross Coordination of Values)

On the Reverse Bottle Problem Task, Marisa's responses were similar to Amber's, in that she verbalized both the height and the volume decreasing. As she was preparing to sketch a graph, she labeled the origin, the horizontal axis as volume and the vertical axis as height. She drew arrows parallel to these axes, stating "As x decreases, y decreases" before creating a concave up graph (see Figure 5). These labels and language suggest she was reasoning at the level of gross coordination of values and that values on her x-axis decreased from left to right.

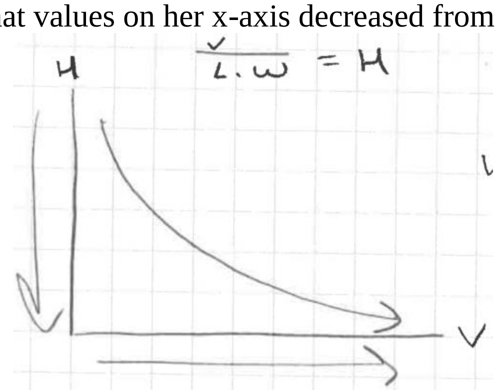

Figure 5: Marisa's Initial Graph on the Reverse Bottle Problem Task

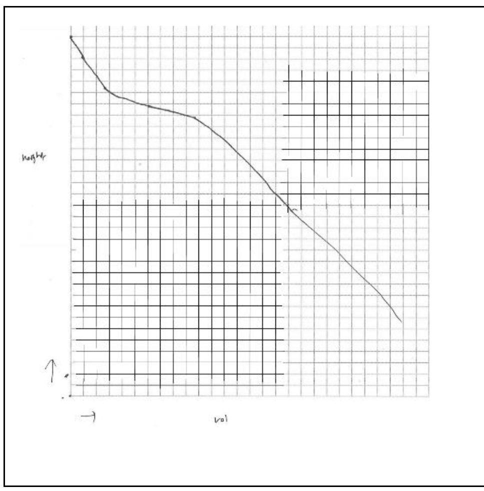
Marisa explained that in her graph, she was attempting to represent her understanding of the meniscus (that water curves up near the walls of a container). After the interviewer clarified that they would measure the height of the water at lowest point of the meniscus, Marisa claimed the relationship between height and volume would be linear. “Every time the volume decreases, the height decreases, by a rate of 3…It’s like a ratio of 3:1, the ratio of volume to height.” Marisa estimated this ratio by noting that the bottle was taller than it was wide so the “height and volume are both decreasing but volume is decreasing at a faster rate”. She did not attend to the varying width of the bottle until pressed. When pressed she did attempt to compare changes in height and volume but found it difficult to create a graph that reflected her ideas.

Jacob’s Reasoning (Three levels of units, Coordination of values)

Jacob’s initial graph attended to three regions from left to right: a linear section of the graph corresponding with the neck of the bottle, the section “becoming wider,” followed by the section with “steady decrease” (see Figure 6). Jacob had partially disentangled time from the situation, in that he represented a relationship between height and volume (not time), but he represented a “decreasing” slope to correspond with the evaporation of water. After the interviewer asked Jacob what the uppermost point on his first graph represented, Jacob decided that since the volume was not zero at the maximum height, he should re-create his graph.

Jacob maintained reasoning about *decreasing* volume and height, suggesting “the start of time is [at the point in the upper right of his graph]” and “the end of your time is [at the bottom left]. His creation of his revised graph is evidence that he had constructed a multiplicative object relating the height of water and the volume of water in the container, coordinating values of height with values of the width of the container (associated with volume). When asked to justify the rates of change depicted in his graph, Jacob correctly explained that the same amount of water would take up less height in the wider portions of the container than at the neck. But when he was asked to justify the concave down portion of his graph, his maintained reasoning about time was problematic. He claimed the rate of change is negative because “both height and volume” are decreasing, and he did not express reasoning about “chunks” of height (or volume) outside of the neck except to compare to the neck.



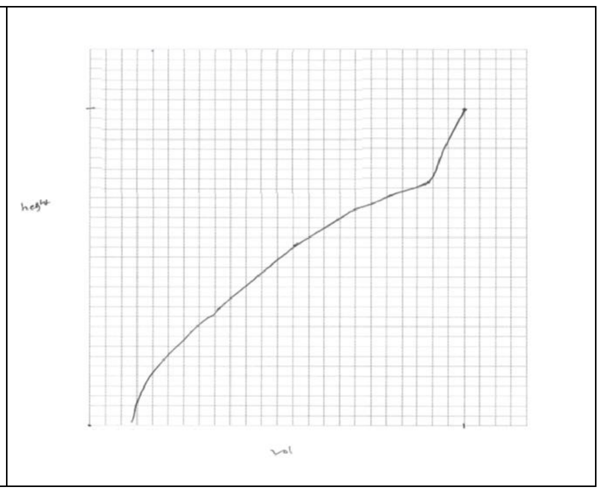


Figure 6: Jacob’s Initial (left) and Revised (right) Graphs of Height-Volume Relationship

George's Reasoning (Three levels of units, Smooth continuous covariation)

George's immediate reaction to the first task prompt was "as volume decreases, the height is also going to decrease. I don't think they are going to be linear." George indicated awareness of the directionality in the change in height and volume with respect to time (their *decrease*). However, in his subsequent activity, he focused completely on the quantities of height and volume and discussed relationships between their increases. He marked units of height on the container (see Figure 7) and represented height on the horizontal axis. To create his graph, he started by explaining that "[the point (1,1)] is specifying a volume unit, it doesn't matter what. At height two, [the region of the container from height 1 to height 2] takes more volume, so it's not going to be [at point (2,2)], it's going to be a little higher". The graph depicted in Figure 7 depicts his intermediate corrections of the right-most portion of his graph, which culminated in him representing and stating that "it should curve, and then go straight at some rate" past the height of 5.

After the interviewer prompted George to revisit the prompt, George explained that he "was just thinking of height versus volume, [he] wasn't thinking of filling or evaporating". He went on to explain that the graph could represent filling or evaporating, stating "I could read this backwards and say the same thing." He explicitly expressed reasoning with smooth continuous covariation, stating "it doesn't have to be between 0 and 1, or 1 and 2, or 2 and 3, the volume keeps increasing over every other unit. Over any equivalent chunk of height, the volume is going to be bigger than any of the previous chunks of height below it. As height goes up, the volume increase is more than the height increase".

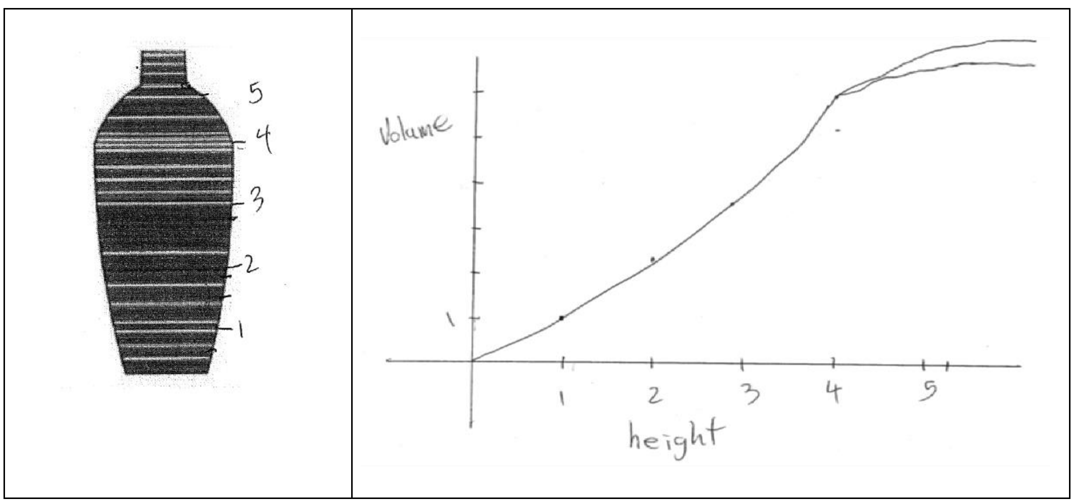

Figure 7: George's Approach to Representing the Covariation of Height and Volume

Conclusion and Discussion

Our anticipation of the relationship between students' structures for coordinating units and their ability to reason with multiplicative objects was affirmed in the sense that neither of the students who had interiorized fewer than three levels of units reasoned at the level of coordination of values or above. However, there were students who had interiorized three levels of units who did not reason above the level of gross coordination of values. Those students were able to form a multiplicative object involving static quantities, as they were able to assimilate with a (unit of (units) of units) structure in which three numerosities are coupled pairwise, but they were unable to maintain links between pairs of quantities' magnitudes associated with dynamic events.

Students with a high level of covariational reasoning were able to do the following without conflating quantities: (1) form a simultaneous coupling of changing quantities *de-coupled from time* and (2) form a simultaneous coupling of *changes* in values that is de-coupled from particular values themselves. Of the students who had interiorized three levels of units; those reasoning with continuous covariational reasoning were able to both (1) and (2); the students who reasoned with coordination of values did one or the other, and the students who reasoned with gross coordination did neither. These results add to our field's understanding of how and why students' construction of three level units coordinating structures is necessary, but insufficient, for continuous covariational reasoning.

CONTEXTUALIZED INSTRUCTION AS A MOTIVATIONAL INTERVENTION IN COLLEGE CALCULUS

Enes Akbuga
University of Michigan
akbuga@umich.edu

Taylor Acee
Texas State University
aceet@txstate.edu

The purpose of this study is to measure the impact of an intervention on student performance expectations, utility-value, and interest in college calculus courses. Six calculus sections were selected for this study, and three were randomly assigned to take the intervention. Students in the three intervention sections completed calculus tasks that were contextualized to various STEM disciplines. The results indicated that the impact of the intervention on student motivation was not statistically significant. However, student motivation significantly changed over time. Future directions about such interventions is discussed.

Keywords: Undergraduate-level Mathematics; Calculus; Student Motivation; Integrated STEM

Calculus students often ask, "why are we learning this?" Students might not see the value or the connections between course material and their lives (Wulf, 2007; Brophy, 1999). If students are not given the opportunity to see this connection, they might become disengaged, and therefore lack the motivation and develop negative attitudes to study the subject (Clarke & Roche, 2017; Harackiewicz, Tibbetts, Canning, & Hyde, 2014).

Eccles et al. (1983) have developed an Expectancy-value model of achievement-related choices, which includes utility-value as an essential motivational variable. They defined utility-value as "how well a task relates to current and upcoming goals." Aligned with this theory, researchers designed relevance interventions to attempt to modify student motivation (Acee, Weinstein, Hoang, & Flaggs, 2018). For instance, Puruhito et al. (2011) designed an intervention using video segments to increase student motivation in college calculus. Other studies developed writing interventions to help students see the relevancy of psychology course-material (Hulleman, Godes, Hendricks, & Harackiewicz, 2010; Hulleman, & Harackiewicz, 2009; Durik & Harackiewicz, 2007). Other relevance interventions have focused on modifying course content to increase the chances that students find it. For instance, Walkington (2013) developed a context personalization intervention to customize mathematics instruction to secondary school students. Cordova and Lepper (1996) found that contextualization substantially increased student motivation in elementary schools. Overall, relatedly, the purpose of this study is to develop contextualized instruction in college calculus courses and examine its effects on motivation.

Conceptual Framework

Expectancy-value theory (1983) was the primary conceptual framework of this study, which posits that students' subjective task values and expectations of success are major proximal determinants of students' achievement-related choices and motivated behaviors. Accordingly, interest, utility-value, and performance expectations were considered as components of student motivation and chosen as outcomes for this investigation.

The intervention for this study was the implementation of contextualized calculus tasks with science, technology, and engineering applications into an introductory calculus course. The following research questions were investigated: (1) How do the contextualized calculus tasks impact utility-value, interest, and performance expectations in college calculus? (2) How do students' utility-value, interest, and performance expectations change throughout a semester in college calculus?

Modes of Inquiry

Participants

This study took place at a southwestern university in Fall 2017. At this institution, calculus is being taught in the mathematics department and is required for most STEM majors. Participants were enrolled in this introductory calculus course. Eighty-one students responded to both Survey 1 and Survey 3, and 66 students responded to all the three surveys. This data was used for the analysis. The majority of students were male and either White or Hispanic.

Research Design and Procedures

This study followed a quasi-experimental research design. The participants were enrolled in three courses taught by different instructors, each having two lab sections taught by respective teaching assistants (TA). Each lab section was randomly assigned to intervention and comparison conditions (three intervention and comparison lab sections). Therefore, each instructor had both intervention and comparison lab sections, and this helped counterbalance course instructor effects.

The intervention sections were given the contextualized tasks, and the comparison sections were given their regular calculus tasks (typical exercise problems in a textbook). The author coordinated with all the TA's to make sure the comparison groups did not get contextualized tasks. The researcher implemented the tasks in all sections twice during the semester (see Figure 1).

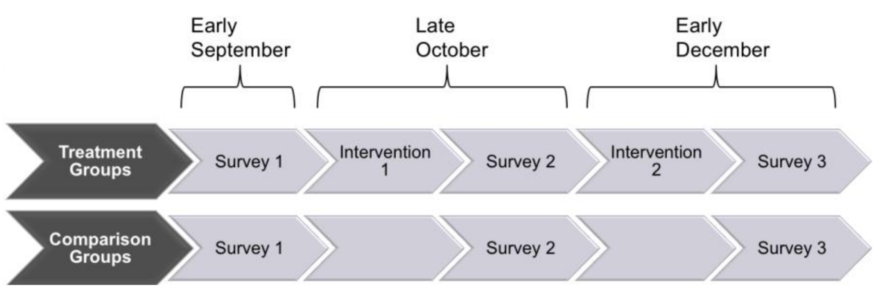

Figure 1: Timeline of the Data Collection

The students were given clear directions about the work on the tasks, and their performance was not graded. Meanwhile, the students in the comparison groups only worked on typical calculus problems with their TA's like any other day.

The data only came from the survey, and the researcher administered the surveys three times (the same survey) throughout the semester. Survey 1 was administered in the second week of the semester to measure scores. Survey 2 was administered around late October since this was the time the first contextualized tasks (Intervention 1) were given. Survey 3 was administered in early December, before the last intervention (Intervention 2) session and final exams.

Intervention

The intervention was comprised of three contextualized calculus tasks with applications to science, technology, and engineering disciplines. The first two tasks were administered to students concerned computer science, and physics (Intervention 1), and the third task concerned engineering (Intervention 2). The tasks required students to practice their calculus knowledge in the contexts of different fields. These tasks were developed as part of a more extensive collaboration of STEM professors at the institution where this study took place, and students were likely to have some of these professors in their future courses.

Instruments

A survey was used in this study to measure motivation—performance expectations, utility-value, and interest, which included twelve *Likert* items. The utility-value (three items) and interest items (six items) were adapted from Hulleman et al. (2010). The performance expectation items (three items) were adapted from Pintrich, Smith, Duncan, and Mckeachie, (1991). *Cronbach's alpha* reliability coefficients for each scale were strong (greater than .90). Exploratory factor analysis was run on the pretest items (Survey 1) to validate the dimensionality and factor loadings. *Principal axis factoring* and *oblique* rotation was used to reduce the data and allow factors to correlate. The items had high loadings on their respective factors and no problematic cross-loadings.

Results

Linear-mixed effects modeling and repeated measure analysis was used to investigate motivation. As an outcome variable for each of the models, the difference in scores of performance expectations, utility-value, and interest was considered.

Effects of Intervention

The first model was run to determine the impact of the intervention on student motivation by considering the instructor as a random effect. Results showed that the effect of the intervention on student motivation, although positive in some cases, was not significant.

Effects of Time and Intervention

Three models—performance expectations, utility-value, and interest were presented for the effects of time and intervention. Time was considered as a variable for analysis as the second research question investigates the change in motivation over time. Results showed that (Table 1) time was a significant factor for change in student performance expectations (p=.03, *eta*=.05). The student expectations keep decreasing for both groups over time (Figure 2).

Table 1: The Main and Interaction Effects of Time and Intervention on Expectations.

	Source	Type III Sum of Squares	df	Mean Square	F	Sig.
time	Sphericity Assumed	4.568	2	2.284	3.609	**.030**
	Greenhouse-Geisser	4.568	1.799	2.540	3.609	**.035**

Note: N=66, participants responded to all surveys.

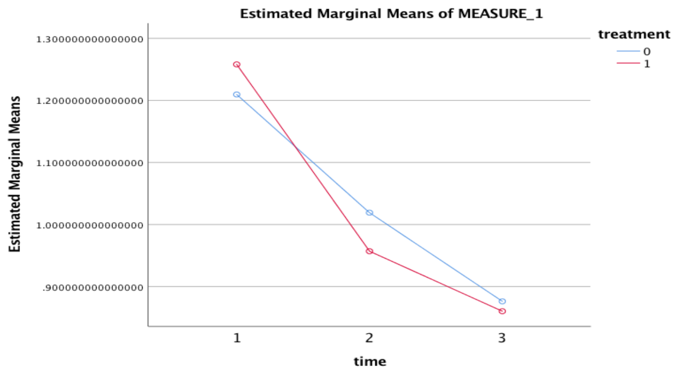

Figure 2: Change in Student Performance Expectations Over Time

When looking at utility-value scores, the impact of time itself, the interaction of time and intervention, and the change in utility-value in between the surveys were not significant. When interest scores examined (Table 2), the impact of time on student interest was significant (*p*=0.04, *eta*=.049.

Table 2: The Main and Interaction Effects of Time and Intervention on Interest

Source		Type III Sum of Squares	df	Mean Square	F	Sig.
time	Sphericity Assumed	3.498	2	1.749	3.275	**.041**
	Greenhouse-Geisser	3.498	1.915	1.826	3.275	**.043**

Note: N=66, participants responded to all surveys.

Discussion

We believe that the research community could benefit from learning about motivation interventions. Our efforts focused on measuring the extent to which contextualized instruction influenced student motivation. The first author implemented these tasks with the expectation that they would make a motivational change towards calculus.

The results showed that the intervention was not significant on student performance expectations, utility-value, and interest overall. Time itself was a significant impact on student expectations, but the interaction of time and intervention was not significant throughout the semester. This result aligns with the national study of calculus courses (Bressoud, Mesa, & Rasmussen, 2015) where they found that composite student attitude (confidence, enjoyment, and desire to persist) in calculus decreased at the end of the semester. This general tendency in calculus courses in the U.S. might explain the students' low-performance expectancy measures in this study.

One unique aspect of this study was the idea of implementing contextualized calculus tasks that were explicitly developed by potential future instructors of students in computer science, physics, and engineering fields. Although the result is consistent with Elliott et al. (2001), where the interdisciplinary approach did not show any significant effect on students, it was different from Marrongelle (2004) where they found that providing interdisciplinary tasks helped students to make connections between calculus and physics.

The study has limitations, but it should be considered as a first step towards designing such contextual instruction as relevancy intervention in college calculus courses. First, the results may not be generalized or extended to populations beyond the group of students that participated. Although the assignment of intervention and comparison was conducted at random, instructors and students were not. Second, the survey that was adapted did not undergo an in-depth validation study. Although the items that were used in the survey were based on previously validated instruments and tested for internal reliability and dimensionality in other settings, it may be limited to calculus usage. Third, the tasks were only validated concerning their content by the authors of the tasks and the researcher. Hence, they may only be appropriate for students at the institution where this study took place.

SELF-EFFICACY FOR SELF-REGULATORY BEHAVIORS AND STUDENT ACHIEVEMENT IN AN UNDERGRADUATE CALCULUS COURSE

Kari Jurgenson
Iowa State University

Jeffrey Rokkum
Iowa State University
rokkum@iastate.edu

Amanda Baker
Iowa State University
ambaker@iastate.edu

Heather Bolles
Iowa State University
hbolles@iastat.edu

This study investigated if students' self-efficacy for self-regulation of learning in an undergraduate Calculus I course predicts student achievement and their successful completion of the course. Results indicated that students' self-efficacy for self-regulated learning did significantly predict their achievement in the course. Also, greater self-efficacy for self-regulation was associated with an increased likelihood of passing. The results highlight the importance of educators to teach students self-regulatory skills and build students' confidence in their ability to regulate their own learning.

Keywords: Calculus, Undergraduate-Level Mathematics, Post-Secondary Education

The growing emphasis on preparing future STEM professionals highlights the importance of supporting students' achievement in STEM courses. Thus, university faculty members are interested in ways to support students' academic success, especially first-year students (Kisantas, Winsler, & Huie, 2008) who are learning to adjust to college life. To learn and succeed in college courses, students need to self-regulate their learning (Cohen, 2012) which refers to the "degree to which students are metacognitively, motivationally, and behaviorally active participants in their own learning process" (Zimmerman, 1989, p. 329). Self-regulated learners control their cognition, motivation, emotions, and actions to enhance their own learning process (Pintrich, 2004) by using strategies such as setting goals and progress monitoring (Cohen, 2012).

The National Council for Teachers of Mathematics (2000) advocates that students be active participants in solving mathematical tasks. This active participation involves learning strategies that support self-regulation. However, simply knowing self-regulatory strategies is not enough to ensure their effective use; students also must believe that they can use them effectively, known as self-efficacy for self-regulated learning (SRL) (Usher & Pajares, 2008). Self-efficacy for SRL influences the academic success of children, adolescents, and adults (Bandura, 1986; Klassen, 2010; Zimmerman, 1998, 2002). Self-efficacy for self-regulation raises academic goals, the standards for quality work, and beliefs in one's ability to succeed academically after controlling for instructional level, previous academic performance, and relevant aptitude (Zimmerman & Bandura, 1994; Zimmerman, Bandura, & Martinez-Pons, 1992). Similar to previous studies, we controlled for students' prior knowledge, as measured by the Calculus Concept Inventory at the beginning of the semester in our analyses.

Although many studies investigate students' SRL, relatively few studies investigate students' *self-efficacy for* SRL. Among these studies, we are unaware of any that situate this research in a college mathematics course. The purpose of this study is to examine how students' self-efficacy for SRL in an undergraduate Calculus I course impacts student achievement and their successful completion of the course. The following research questions guided this study.

1. Does self-efficacy for self-regulated learning at the start of the semester predict end of course grades among undergraduate students enrolled in Calculus I, controlling for gender, race, and prior Calculus knowledge?
2. Does self-efficacy for self-regulated learning at the start of the semester predict the likelihood of passing Calculus I, controlling for gender, race, and prior Calculus knowledge?
3. Is there a difference in students' self-efficacy for self-regulation of learning when they begin Calculus I between students who passed the course, students who failed and course, and students who dropped/withdrew from the course?

Theoretical Framework

Students' confidence and beliefs about their ability to self-regulate their learning are key factors in whether they employ self-regulatory strategies (Zimmerman & Cleary, 2006). Thus, one's self-efficacy for SRL is an important predictor of the person's use of self-regulatory skills and strategies (Bandura, Barbaranelli, Caprara, & Pastorelli, 1996, 2001; Bandura, Caprara, Barbaranelli, Gerbino, & Pastorelli, 2003; Bong, 2001; Zimmerman & Bandura, 1994; Zimmerman, Bandura, & Martinez-Pons, 1992) and is related to motivation and achievement in a variety of academic areas and levels of schooling (Bandura, 1997; Pajares, 2007). This emphasizes the difference between having self-regulatory skills and using them regularly. A belief in one's self-efficacy for SRL will support the consistent application of self-regulatory skills even in the face of difficulties, stressors, and distractions (Caprara et al., 2008).

Methods

Participants and Procedure

Within the first two weeks of the semester, students enrolled in a Calculus I course at a large, Midwestern public university (1,758 students) were invited to participate in a survey measuring their attitudes and expectations toward Calculus; 34.3% (n = 606) responded. Of those who responded, 499 students completed all the self-efficacy for self-regulation items on the survey, for a completion rate of 28.4%. Consistent with enrollment patterns for the course, the majority of the students in the sample were in their first year of college (79.4%, n = 396) and were enrolled in a major within the College of Engineering (72.5%, n = 362) at the start of the study. The next most common majors of participants were Computer Science (7.0%, n = 35), Undeclared (4.0%, n = 20), and Biochemistry (2.6%, n = 13). Of the 488 participants who answered the question about their gender, 76.2% were male. Of the 474 participants who reported their race, 81% were white, 6% Asian, 7% Hispanic, and 6% Arabic/Middle-Eastern, Black, Native American, Hawaiian/Pacific Islander, and multiethnic. Of the 492 participants who answered the question about their prior calculus experiences in high school, 39.4% reported that they had not taken calculus in high school. Informed consent was received from all participants.

Materials

Self-efficacy for self-regulation. The scale for measuring self-efficacy of SRL was designed by two of the authors of this paper following the recommendations put forward by Bandura (2006). A total of 7 tasks were specified which represented skills demonstrating their ability to manage their own learning process in Calculus (self-efficacy for SRL in mathematics), and respondents were asked about their confidence for each skill. The skills inquired about represent the abilities of the students to learn mathematics on their own. All items began with the stem "How confident are you in your ability to" and was followed by statements for each item including "learn how to solve a problem by watching my professor solve it," "use the resources available to me (e.g., textbook, online videos, office hours) to learn new material outside of class," and "seek help from my professor and/or teaching assistants when I need it." The responses options to these Likert-scale items ranged from 1 (not at all confident) to 6 (completely confident). A mean score of the respondents' answers to these questions was then created to create one self-efficacy for SRL score which was used in the analyses.

End of course grades. End-of-course letter grades for the Calculus I course were received from the University Registrar for all participants which were then converted to a traditional grade point average scale ranging from 0 - 4.0. To answer the second and third research question, three groups of students were formed: (a) students who earned a passing grade (grade of C- or higher), (b) students who did not earn a passing grade (grade of D+ or lower), and (c) students who formally withdrew or dropped the course.

Covariates. The covariates included in this study are the Calculus Concept Inventory (CCI) developed by Epstein (2006; 2007), gender, and race. Participants completed the CCI, a test of conceptual understanding of basic principles of Calculus, at the beginning of the semester and was used to assess students prior Calculus knowledge and understanding. Information on gender and race was received directly from the University Registrar.

Results

To answer the first research question, we used linear regression to see if we could predict the students' end of course grade from their self-efficacy for self-regulated learning scores (Table 1). Students who dropped or withdrew from the course were excluded from this analysis. The regression model statistically significantly predicted end of course grades, $F(4, 407) = 32.99$, $p < .001$, adj. $R^2 = .245$, and conceptual understanding of calculus, self-efficacy for SRL, gender, and race explained 23.7% of the variance in end of semester course grades. The students' self-efficacy for SRL at the start of the semester significantly predicted their end of semester Calculus I grade, $b = .245$, $t(407) = 5.62$, $p < .001$, as did their conceptual understanding of Calculus, $b = .396$, $t(407) = 8.82$, $p < .001$. Students' gender also significantly predicted their end of semester Calculus I grade, $b = 0.163$, $t\ (407) = 3.656$, $p < 0.001$.

Table 1: Results of Regression Analyses Predicting End of Course Grades From Their Self-Efficacy

	t	*p*	B	F	*df*	*p*	Adj. R^2
Overall Model				32.99	4, 407	<.001	.237
Constant	-0.144	.886					
Gender	3.656	<.001	.163				
Race	-1.881	.061	-.082				
CCI	8.821	<.001	.396				
Efficacy	5.616	<.001	.245				

For the second research question, a logistic regression was used to ascertain the effects of gender, ethnicity, the students' conceptual understanding of calculus, and their self-efficacy for SRL on the likelihood that participants pass or fail their Calculus I class (Table 2). Students who dropped or withdrew from the course were excluded from this analysis. The logistic regression model was statistically significant, $\chi^2(4) = 55.419$, $p < .001$. The model explained 22.7%

(Nagelkerke R^2) of the variance in pass/fail rate and correctly classified 80.5% of cases. Greater self-efficacy for SRL was associated with an increased likelihood of passing just like a higher conceptual understanding of calculus was associated with an increased likelihood of passing.

Table 2: Results of Logistic Regression Analyses of the Likelihood to Pass Calculus I

	B	S.E.	Wald	*p*
Gender	.673	.377	3.190	.074
Race	-.081	.121	.449	.503
CCI	.289	.055	27.445	<.001
Efficacy	.805	.212	14.447	<.001
Constant	-4.048	1.128	12.883	<.001

For the third research question, an ANOVA was performed to test if there were differences between the students who dropped or withdrew from the course, those who failed, and those who passed at the start of the semester for their self-efficacy for SRL (Table 3). Self-efficacy for SRL was statistically different between different the three groups, $F(2, 496) = 17.710$, $p < .001$. Scheffe post hoc analysis revealed a significant difference in the self-efficacy for SRL scores between students who passed the course (N = 380, $M = 4.79$, $SD = 0.65$) and both the students that dropped out of or withdrew from the course (N = 55, $M = 4.34$, $SD = 0.70$, $p < .001$) those who failed the course (N = 64, $M = 4.38$, $SD = 0.87$, $p < .001$). There was no significant difference between the students who dropped/withdrew from the course and those who failed.

Table 3: Analysis of Variance of Self-Efficacy in Self-Regulation and Completion of Calculus I

	SS	*df*	*MS*	*F*	*p*
Between Groups	16.826	2	8.413	17.710	<.001
Within Groups	235.626	496	.475		
Total	252.452	598			

Discussion

This study found that self-efficacy for SRL significantly predicts students' end of semester grade in Calculus I and greater confidence in one's ability to regulate his/her learning is associated with a greater likelihood they pass Calculus I are consistent with previous research suggesting that confidence in SRL contributed to students' academic achievement (Bandura, 1986; Caprara et al., 2008; Zimmerman, 2002). The third result indicates that students who passed Calculus I had more confidence in regulating their own learning at the beginning of the course than those who did not pass or chose to drop/withdraw from the course. We suggest that future research investigates what distinguishes students who pass Calculus I from other students in the course who may be struggling. This would help instructors focus on increasing students' self-efficacy for self-regulatory skills. K-12 educators may want to focus on teaching SRL to equip students for college mathematics. Similarly, college instructors may want to support students' confidence in SRL in Calculus courses. These findings are important for educators teaching freshman-dominated mathematics courses, such as Calculus I, as they must prepare their students to study effectively on their own and encourage their confidence in doing so.

RE-HUMANIZING ASSESSMENTS IN UNIVERSITY CALCULUS II COURSES

Kelly MacArthur
University of Utah
macarthur@math.utah.edu

Conceptual Perspective

Recent work aiming to heighten equity in math education has focused on "rehumanizing mathematics" (Gutiérrez, 2018). One way to interpret this is as a call to action in implementing humane teaching and testing practices in the math classroom in order to better serve students. One high leverage way to enact this change is to focus on assessment, given the high-stakes nature of grades in college calculus courses.

Research Question & Design

In this study, I explore the question: How does a rehumanizing-math approach to assessment in large calculus 2 classes impact exam scores, student learning and students' attitudes toward calculus?

I changed the structure of all four exams, without altering the content, in two university calculus 2 courses, with about 165 students total. My goal was to decrease anxiety on exams, increase confidence and build community in the class. To work toward achieving that goal, I included a group discussion piece of each exam. To investigate the impact, I examined exam grades, final course grades, attitudinal survey data, and focus group data. As a control group, I compared data from the changed course with roughly the same number of students from a semester prior to the implemented changes.

Data Analysis & Results

The grade averages and standard deviation on the first exam were about the same for the control group and the comparison group. However, from the second exam on, the grade averages for the comparison group were significantly higher than for the control group, while the standard deviations decreased dramatically. By the final exam, the test average for the comparison group was 91% compared to 82.5% for the control group, with standard deviations of 9.6% and 16.5% respectively.

For the survey and focus group data, qualitative analysis identified several emerging themes, including: (a) less anxiety and higher confidence experienced during exams and (b) a community feeling in the classroom, in the rehumanized classroom. Furthermore, data highlighted student views on the importance of rehumanizing math. For instance, when asked what does rehumanizing math mean, one student wrote: "I think teachers/educators can re-humanize math by *making better learning environments* in class, and by *learning how to connect better with people*." (italics added)

Significance

My findings illustrate that this new exam structure helped create precisely the type of classroom where students felt a sense of belonging. I answered the theoretical call to rehumanize the classroom by boots-on-the-ground changes in assessments that produced positive, promising results. This structure engendered a kind, humane classroom, where students flourished doing mathematics.

COMPOSING THE COMPOSITE FUNCTIONS: EXAMINING STUDENTS' MEANINGS FOR FUNCTION COMPOSITION

Kristin M. Frank
Towson University
kfrank@towson.edu

Rachael M. Talbert
Towson University
rtalbe1@students.towson.edu

Keywords: Algebra and Algebraic Thinking, High School Education, Curriculum Analysis

Piaget (2001) distinguishes between students' actions and the products, or consequences, of those actions in order to characterize the nature of the learner's reasoning. For example, in the context of function composition one can engage in the action of stringing together two functions, f and g, so that the output of the of the function g is taken as the input of the function f. This activity highlights the two-step nature of composing two functions. The product of these actions can be conceptualized as the composite function h, where h(x) = f(g(x)).

While much of the function composition literature focuses on the difficulties students have engaging in function composition tasks (e.g., Bowling, 2009; Engelke, Oehrtman, and Carlson, 2005; Jojo, 2011), in this study we sought to understand the extent to which students' meanings for function composition were limited to thinking about the activity of stringing together two functions as opposed to thinking about the product of those actions, the composite function. In this poster we present preliminary results of a textbook analysis and clinical interviews with undergraduate students.

The first phase of this study consisted of a textbook analysis of 8 textbook (Algebra 2 (n=2), Precalculus (n=3), and Calculus (n=3)). The research team classified the meanings of function composition supported by the examples and homework problems in the book. During the first round of open coding (Strauss and Corbin, 1990) we noticed that while all presentation types (e.g., graphs, tables, and algebraic rules) were used in each book, 25% of the problems focused on students' ability to create the rule for $f \circ g$ given the algebraic rules for f and g and another 28% asked students to determine the value of $(f \circ g)(a)$ given representations of f and g. In other words, the textbook problems focused on the activity of composing two functions.

In the second phase of the study we asked 70 university calculus students to complete a written instrument consisting of six function composition tasks. Preliminary results reveal that calculus students experience little difficulty composing two functions but are less likely to conceptualize the product of their activity as a composite function. For example, after producing the algebraic rule for s(x) = f(g(x)), 65% of students evaluated s(2) by first computing g(2) and then f(g(2)). These students did not use the function rule they constructed for s to evaluate s(2). Interviews with these students reveal that these students did not conceptualize the composite function as a single mapping from x to f(g(x)) and thus did not anticipate that the function s could be defined by a single function rule. Additionally all students experienced difficulty when asked to graph $f \circ g$ given the graphs of f and g with 81% leaving the question blank with some noting they "do not remember how to combine graphs" and others stating the task was impossible because you need to know the algebraic rule for both g and f in order to determine f(g(x)).

Preliminary results reveal that it is nontrivial for students to construct the composite function from their activity composing two functions. We anticipate that students' focus on compositing functions and their limited engagement with the composite function likely impact their understanding of the chain rule and implicit differentiation although further research is needed to verify this conjecture.

THE REALITY OF COMMON GRADING: ONE ASPECT OF A CALCULUS I COORDINATION EFFORT

As Rasmussen and Ellis (2015) report there is tremendous variation in who is teaching calculus at any given university including tenure track faculty, other full time faculty, and part time adjuncts. As a result, there is variation in the content being taught. And, it seems likely, that an "A" means something different in each section. Thus, in Fall 2018 our mathematics department decided to coordinate Calculus 1 across all twelve sections. We used Rasmussen and Ellis's finding - successful calculus programs at PhD-granting universities had a well-established system for coordinating Calculus I that included a common syllabus, pacing, homework, midterms, and final exams - to inform our university's coordination efforts.

Our coordination included common midterms and common rubrics for grading each exam. The three midterms (limits, derivative rules, applications of derivatives) were co-developed by the twelve full-time faculty members teaching calculus 1 in Fall 2018. The rubrics, on the other hand, were developed by the course-coordinators. After the first exam, the coordinators asked the twelve faculty members to participate in a mock grading where each faculty member would grade the same exam using the assigned rubric. The exam used for the mock grading was developed by a course coordinator based on common student misconceptions documented in the literature as well as her own students' work on the exam.

Ten of the twelve faculty members participated in the mock grading. Faculty grades for the exact same exam ranged from a 53 to an 85. Framed differently, depending on the section that student was enrolled in, the student's work could have earned him/her anywhere from an F to a B on the same exam. In this poster we share the breakdown of the instructors' grades by exam question and focus on aspects of the question and rubric that might have contributed to the range of grades produced by the faculty.

In addition to producing a quantitative metric for comparing instructors' grading practices, this mock grading activity encouraged the mathematics faculty to engage in conversations about students' learning and assessment. While these conversations are often typical amongst mathematics education faculty, the mathematicians involved in the study commented that this was a novel, and enlightening, experience for them. For example, faculty realized that some faculty grade by individual item so that the student's score is the sum of the points they earn on each question. Other faculty believe that the student's score should reflect his/her understanding of the material. Thus, one faculty was perturbed that the student seemed to exhibit "B- level understanding but the grade would be about 65". In addition to reflecting this particular instructor's beliefs about grading, this comment revealed a discrepancy between the midterm/rubric and the instructor's belief about what B level understandings of calculus entail. In the poster we highlight other instructors' beliefs about grading that emerged during this study.

Finally, we conclude by sharing what we learned about creating common rubrics both their importance in the coordinated calculus experience as well as the challenges in designing exams and rubrics that appropriately assess students' mathematical understandings.

STUDENTS' EVOKED CONCEPT IMAGES OF QUOTIENT RINGS

Valentin A. B. Küchle
Michigan State University
kuechlev@msu.edu

Keywords: Advanced Mathematical Thinking, Undergraduate-Level Mathematics

Over 70% of mathematics majors at U.S. universities are required to take a course in abstract algebra (Blair, Kirkman, & Maxwell, 2018). In fact, between 2014 and 2016, abstract algebra was the most offered upper-division course, running at least biennially, in U.S. mathematics departments (Blair et al., 2018). Although the content covered in abstract algebra courses may vary from institution to institution, the Mathematical Association of America's (MAA) Committee on the Undergraduate Program in Mathematics (CUPM) has published sample syllabi outlining a number of prototypical abstract algebra courses (Isaacs, Bahls, Judson, Pollatsek, & White, 2015). In all of these syllabi, the concepts of quotient groups or rings are present.

Although students' difficulties with quotient groups have been well-documented over the last 30 years (e.g., Asiala, Dubinsky, Mathews, Morics, & Oktaç, 1997; Dubinsky, Dautermann, Leron, & Zazkis, 1994; Larsen & Lockwood, 2013), the study of students' understanding of ring theory—including quotient rings—has been little researched (Cook, 2018). I seek to contribute by reporting on students' evoked concept images (Tall & Vinner, 1981) of quotient rings, as well as the preceding concepts of rings, subrings, ideals, and cosets to answer the question: What are students' evoked concept images of rings, subrings, ideals, cosets, and quotient rings?

In January 2019, task-based interviews were conducted with six students who had completed their first course in abstract algebra, covering ring theory, in Fall 2018 at a large Midwestern public university. Students were granted access to their notes, a compiled set of definitions from their textbook, as well as their textbook to mitigate against memory loss due to the 3-week winter holidays. The interviews were recorded with a Livescribe pen and transcribed.

The task-based interviews are in the process of being coded using a two-cycle coding approach. The first cycle of coding is done using provisional coding (Miles & Huberman, 1994, p. 58) which begins with the researcher "creating a provisional 'start list' of codes prior to fieldwork" (p. 58). My starting list builds on the literature about students' learning of group theory in the expectation that many similarities will exist. To account for differences, I am also building up codes inductively to account for ring-specific findings. All ideas are pulled together in my second cycle of coding, pattern coding, which "identifies an emergent theme, configuration, or explanation" (Miles & Huberman, 1994, p. 69). Pattern Coding allows me to condense my data into manageable units while finding themes and explanations in my data that my previous codes may not have picked up on. Thus, I hope to end up with categories of students' evoked concept images of rings, subrings, cosets, ideals, and quotient rings.

I anticipate that this study will mirror some of the findings from the literature on students' understanding of group theory. For instance, I expect that: (a) students may struggle with the coset notation, (b) confusion around binary operations of rings, subrings, and quotient rings will arise, and (c) that context-dependency of understanding remains an issue. On the other hand, I expect some findings unique to ring theory as students are faced with two binary operations instead of just one. More specifically, I expect that the switch from normal groups to ideals (as the objects by which students "quotient") will pose a challenge to students.

AN INTERNATIONAL STUDY OF PROSPECTIVE SECONDARY TEACHERS' NOTICING OF STUDENT THINKING

Kristin Lesseig
Washington State University

Gregory Hine
University of Notre Dame Australia

Professional noticing of student thinking is considered a useful construct to investigate instructional decisions and activity made by teachers to support learning. This paper highlights the findings from one component of a multi-university (United States & Australia) research project focused on improving pre-service secondary mathematics teachers' (PSMTs) abilities to notice student thinking. The pre-post video component was specifically designed to document PSMTs' abilities to attend, interpret, and respond to student thinking. Results indicate that despite an improvement in ability to attend to and interpret student thinking, there was relatively no improvement in PSMTs' responding scores. This finding, which contradicts Monson et al.'s (2019) study, raises important questions about context and potential intervening factors to which researchers should attend when designing and implementing noticing interventions.

Keywords: Preservice teacher education, Instructional activities and practices, Teacher knowledge.

Introduction

In light of decades of research on how students learn mathematics (e.g., NRC, 2001), a more active vision of mathematics teaching, one that foregrounds student understanding and fosters student participation in the learning process, has emerged (NCTM, 2014). Teaching that uses student thinking as the basis for instructional decision-making, also known as responsive teaching, places significant demands on the teacher. Specifically, teachers need to attend to the substance of student ideas, recognize the disciplinary import of these ideas, and make intentional decisions about how to pursue those ideas (Robertson, Adkins, Levin, & Richards, 2016).

Skills such as interpreting and assessing the mathematical potential in student contributions, necessary prerequisites to responsive teaching, are especially difficult for prospective secondary mathematics teachers (PSMTs). PSMTs are understandably at a very different place than practicing teachers along the continuum of learning to teach (Feiman-Nemser, 2012) and often have had very limited opportunities to analyze student work in their teacher preparation programs (Jenset, Klette, & Hammerness, 2018; Simpson & Haltiwanger, 2017). However, research has demonstrated that PSMTs' abilities to attend to, interpret, and respond to student thinking can be developed through intentional, structured opportunities to engage in this work.

To that end, we sought to replicate a successful intervention, an Interview Module designed for secondary methods courses in the United States (Monson, Krupa, Lesseig & Casey, 2019), in an Australian context. The Australian context was deemed appropriate for two reasons: first, the topic of quadratics (the content central to the Interview Module) is taught to similar-aged students in both Australia and the United States; and second, the teacher education programs at the researchers' universities have similar structures and goals. Before detailing our research study, we briefly review the theoretical underpinnings of professional noticing of student thinking—the competency this intervention is designed to assess and develop—and discuss related empirical research. In this review, we highlight the goals and successes of intervention studies as well as the challenges revealed in research with PSMTs.

Theoretical Perspectives and Related Research

Noticing has proven to be a useful construct to investigate instructional moves and decisions teachers make in relation to student thinking (Schack, Fischer, & Wilhelm, 2017; Sherin, Jacobs, & Philipp, 2011). Teacher noticing builds on Goodwin's (1994) definition of professional vision as "socially organized ways of seeing and understanding events that are answerable to the distinctive interests of a particular social group" (p. 606). Subsequently, teachers' professional vision, or noticing, refers to the ways in which teachers are attuned to 'notice' significant events in a teaching situation and engage in principled reasoning when interpreting and reacting to those events (Sherin et al., 2011). With roots in both cognitive and situative perspectives, the construct of teacher noticing has potential to bridge the research divide between teacher dispositions and teaching performance (Scheiner, 2016). In particular, noticing research, focused on situation-specific skills of perception, interpretation, and decision-making, helps reveal complex interactions among teacher knowledge and actions (Sánchez-Matamoros, Fernández, & Llinares, 2018; Thomas, Jong, Fisher, & Schack, 2017).

Our work is situated in a particular aspect of noticing referred to as *professional noticing of student thinking* (Jacobs, Lamb, & Philipp, 2010). Professional noticing of student thinking [hereafter professional noticing] consists of three interrelated practices of (1) *attending* to the mathematics evidenced in student work (writing, verbal communication, or actions); (2) *interpreting* what students understand and/or do not understand based on their mathematical work; and (3) *deciding* how to respond in light of this interpretation.

While the characteristics of expert noticing are still evolving, there is some agreement on the nature of noticing necessary for responsive teaching. In particular, researchers have highlighted the importance of attending to salient mathematical details in a student's approach as well as the ability to connect those details to key mathematical understandings (Jacobs et al., 2010; Sánchez-Matamoros et al., 2018). On the contrary, more novice noticing is characterized by general statements, descriptions, or evaluations that are not tied to specific evidence from students (Jacobs et al., 2010; Mason, 2011). Research has demonstrated that professional noticing can be enhanced through collaborative, structured opportunities to interact with students' mathematical thinking through video (Ding & Domínquez, 2015; Schack et al., 2013), one-on-one student interviews (Monson et al., 2019; Fernandez, 2012) or samples of students' written work (Simpson & Haltiwanger, 2017; Son, 2013). While the majority of intervention studies report positive gains in the noticing abilities of prospective teachers, the results also reveal inconsistent improvements and highlight the complex interaction of noticing with other factors (e.g., teacher knowledge, the mathematical content of the task).

For example, prospective teachers have difficulty distinguishing between procedural and conceptual errors (Ding & Domínquez, 2015) or recognizing evidence of conceptual understanding (Bartell et al., 2013). Studies by Son (2013) and Son and Sinclair (2010) document difficulties prospective teachers had responding to students when conceptual errors were present, with most offering procedural explanations and other teacher-centered responses that did not aim to advance conceptual understanding. Content knowledge was insufficient. This was also evident in Son and Crespo's (2009) study in which PSMTs who were able to unpack the mathematics behind a student's non-traditional approach (i.e. those with strong content knowledge) were actually more likely to offer teacher-centered responses than their peers. In sum, studies consistently demonstrate that responding is the most difficult component of noticing to develop. The one exception is Monson and colleagues' (2019) study in which activities explicitly targeting PSMTs' ability to respond were added to an existing Interview Module.

Purpose of the Research

In this paper we present findings from a multi-university research project focused on improving PSMTs' abilities to notice student thinking within the context of secondary mathematics teaching and learning. The pre-post video component, on which this paper reports, was designed to specifically document PSMTs' abilities to attend, interpret and responding to student thinking. The overarching research question guiding the study was: *What, if any, improvements in attending to, interpreting, and responding to student thinking do PSMTs' demonstrate after completing the Interview Module?*

Research Design

The research is based on an Interview Module, which was developed by one of the authors and colleagues and has been used within the United States to demonstrate gains in PSMTs' noticing abilities. The Interview Module is comprised of a pre-post video assessment, prescribed readings, a one-on-one interview with a secondary student, and a sequence of responding assignments involving analysis of student work samples (Monson et al., 2019).

Participants and Context

Data for this paper come from the pre-post video assessment given to PSMTs enrolled in secondary mathematics teacher preparation programs in two countries. Nine PSMTs completed the assessment, with 6 PSMTs enrolled at one Australian university and 3 PSMTs at one university in the United States. The Australian participants were in their first or second year of their preparation program. Two of the US participants were in their second year of an undergraduate preparation program, though one was returning to university after working in a math-related field. The third had earned a BS in mathematics from a different university and was in her first semester of a 15-month Masters in Teaching program.

Pre-post video assessment. The researchers collected pre-post assessment data, which were based on PSMTs' written responses to short videos shown prior to and upon completion of the full Interview Module. These videos show a Mathematics Teacher Educator (MTE) conducting a task-based interview with a secondary student. In each video, the student is asked to solve two quadratic equations (one resulting in one real solution, the other with two imaginary solutions) which mirrors the student interview PSMTs conducted that focused on solving linear equations. The problems and prompts given to the student are provided in Table 1.

Table 1: Pre-post Video Assessment Problems and Prompts

Question 1:	Solve for x: $x^2-4x+4=0$
Probe:	Could you solve that another way?
Question 2:	Solve for x: $x^2-2x+3=0$
Probe:	Could you solve that another way?

After watching the pre- and post-videos, the PSMTs were asked to independently respond in writing to three prompts, each corresponding to one component in the noticing framework: (1) What do you notice? (Attending) (2) How would you describe what this student understands? (Interpreting) and (3) Describe some ways you might respond to this student and explain why you chose those responses (Responding).

Analysis and Coding

Both researchers used a coding scheme adapted from the module developers (Krupa, Huey, Lesseig, Casey & Monson, 2017), and independently coded PSMTs' ability to attend to, interpret, and respond to student thinking on the pre- and post-assessments. Each question was coded as demonstrating either no evidence (0), limited ability (1), or emerging ability (2). Initially, each researcher coded responses (pre- & post-) from three participants before meeting virtually to discuss any discrepancies in coding. After resolving all coding differences and reaching consensus, the researchers coded the responses from the remaining six participants before meeting virtually again to agree on a consensus score for each response. Reliability in coding was enhanced by the creation and maintenance of an operative codebook with examples and non-examples of responses at each level (Miles, Huberman, & Saldaña, 2013), and any discrepancy was discussed in reference to the codebook until consensus was reached.

Findings

The pre-post video assessment data provided the researchers with an opportunity to look for growth in PSMTs' attending, interpreting and responding skills. While in the larger study these data were compared with other components of the Interview Module, this paper outlines changes in PSMTs' skills as evidenced in the video assessment only. The scores from pre-post video assessment data are presented in Table 2 (all participant names are pseudonyms). The scores represent the following: 0 = No evidence, 1 = Limited Ability, 2 = Emerging Ability. Tables 3, 4 and 5 outline verbatim participant responses according to *attending*, *interpreting* and *responding* skills, respectively, together with the video phase (pre-/post-) and the consensus score (0, 1, 2) given to the response by the researchers. While not necessarily meant as exemplars, these responses have been included to indicate a qualitative range and illustrate our coding levels.

Table 2: Pre-post Video Scores for Attending, Interpreting and Responding

	Attending		Interpreting		Responding	
	Pre	Post	Pre	Post	Pre	Post
Andi (US)	2	2	2	2	2	2
Brook (US)	1	2	1	1	2	2
Rachel (US)	1	2	1	2	2	2
Benedict (AUS)	0	2	0	1	0	1
Georgia (AUS)	1	1	1	1	0	0
Jai (AUS)	1	2	1	2	1	1
Emmeline (AUS)	1	2	2	2	2	2
Steven (AUS)	0	1	0	0	1	0*
Owen (AUS)	1	2	1	2	1	2

Key: * = score decreased from pre- to post; score with gray shading (e.g. 2) = increased; no shading = no change.

Changes in PSMTs' Noticing in Pre-Post Video Assessment

Attending. With the exception of two participants (Andi & Georgia, who remained at the *limited ability* level for pre- and post-), all participants improved their pre-video attending score by at least 1 point in the post-video assessment. Participant Benedict demonstrated the greatest growth in the attending component, scoring at the *no evidence* level in the pre-video assessment and *emerging ability* in the post-video assessment. Benedict attended to the student's affective dispositions in the pre-video assessment (see Table 3), yet documented in detail a number of mathematical terms used by the student in the post-video assessment (e.g., "...knew of two ways to solve a quadratic, factor and formula. Showed/said her understanding of graphing").

Table 3: Examples of Participants' Attending Responses

Participant	Response
Benedict (Pre-video, 0)	Girl always waited slightly to get confirmation about her process when she was uncertain; tried to logically solve it and talked through the process.
Georgia (Post-video, 1)	The student was checking that her factorization was correct. [She] simplified the answer as much as possible without a calculator. The student could think about other ways to answer the question.
Brook (Post-video, 2)	The student correctly factored and solved the first problem. She was also able to sketch a general graph of the equation. Moreover, she realized graphing was an alternative method of solving the equation when asked for another method. The second equation she factored, but in checking herself realized her factoring was not correct. She knew she needed to use the quadratic formula to solve the equation. However, she could not graph the equation. Additionally, the interviewer prompted her to correct a negative sign.

Interpreting. Five of nine participants demonstrated growth in the interpreting component, with the remaining four participants maintaining the same score from pre-video to post-video assessments. Only two participants scored at the *emerging ability* level during the pre-video stage, with this number increasing to five after the post-video assessment. In the pre-video assessment, Rachel only wrote a list of things the student did incorrectly, (e.g. "...the student cancelled a 2 wrong from Problem 3 and she didn't know how to simplify or solve for a negative square root...", scoring a 1 for this response. Rachel's post-video interpreting response was scored as a 2 due to the list of correct and incorrect things the student did, coupled with various statements about what the student understands supported with evidence, (e.g. "...she knows the graphs for parabolas with real solutions, but she needs some help with understanding imaginary solutions and their graphs").

Table 4: Examples of Participants' Interpreting Responses

Participant	Response
Steven (Pre-video, 0)	Jumps straight into the first question. Understood how to solve the 1st question but got the graph wrong when asked what it was (sic) looked like.
Brook (Post-video, 1)	She has a very good grasp of the material. When graphing the first problem, she states the graph would contain two zeros. However, when she sketches the graph, she draws it correctly with only one zero. She solved the 2nd problem correctly using the quadratic equation. She seemed to understand how to graph it but was not immediately able to estimate $2\pm\sqrt{2}$ to pick values for the x-axis.
Emmeline (Pre-video, 2)	Understands factors of factorisation. Perfect square (notion of x^2 and $\sqrt{x}$). Can solve for x, understands inverse relationship of operations. Has an understanding that different method(s) can be used. Knows the quadratic formula. Understands $\sqrt{-x}$, that it isn't possible, therefore that 'no solutions' are possible.

Responding. Eight of nine participants either improved or maintained their pre-video responding score in the post-video assessment (Steven's score decreased by 1 point). Four participants scored at the *emerging ability* level during the pre-video stage, with this number increasing to five on the post-video assessment. To illustrate, Owen scored a 1 in the pre-video assessment after providing a limited rationale of how he intended to respond to the student, (e.g. "Would encourage her to understand a visual representation of the graphs. Might suggest that she considers what's the best approach at the beginning, in case there are short-cuts"). The post-video response from Owen was:

> Can you explain to me your working in solving/using the QF? (help her find the mistake). Is your QF correct? (Direct her to mistake if she doesn't find herself). What does the root of a negative number give you? (Must give understanding as to why it's special).

This response was scored as a 2 by both researchers, as they felt Owen anchored his response and rationale, which he included in parenthesis, to his observations of the student's error in working with the quadratic formula and the result of obtaining a negative discriminant.

Table 4: Examples of Participants' Responding Responses

Participant	Response
Georgia (Pre-video, 0)	Directive questioning -- open questioning to allow her to explain her thought process (e.g., rather than to assume her thought process)?
Jai (Post-video, 1)	I would ask her to check her work to avoid follow-through errors...ask her why she thinks eq. 1 has 2 roots. Might explain why she draws a y-int @ 2.
Andi (Pre-video, 2)	Show her some problems regarding reducing fractions with addition on the top to remind her of why reducing too early gives incorrect answers. To help her graph and aid her in understanding how the first graph looks, I would have her plot points from 0 to 4 to help her visualize the graph. I would also have her plot out points for the graphs x^2=y and $\sqrt{x}$=y to help her understand where she got the idea for her first graph from.

Discussion

As demonstrated in Table 1, the largest improvements in professional noticing were evidenced in PSMTs' ability to attend to student thinking, with seven of nine PSMTs scoring at the *emerging level* on the post-video assessment. Further analysis revealed that while PSMTs mainly attended to mathematical aspects in both the pre- and post-video assessments, they did so with even greater focus after the intervention. Five of nine PSMTs made comments about the interviewer and/or student disposition in the pre-assessment. In particular, PSMTs noted that the 'teacher' did not correct or tell the student if she was correct; but instead prompted her with questions. In the post-video assessment there were no comments about interviewer actions and only one comment that the student in this second video was "quite confident". These promising findings from Australia add to the US literature confirming that noticing skills can be developed through targeted interventions.

Despite improvement in both attending and interpreting, there was relatively no improvement in PSMTs' responding scores. This result is understandable in the US case, given that all three participants received scores of 2 on the pre-video assessment. However, the lack of improvement in scores for the Australian participants is in stark contrast to Monson et al.'s (2019) study in which participants showed the greatest gains in responding. In this regard, the findings from the Australian cohort more closely align with results from an earlier implementation of the Interview Module (Krupa et al., 2017), which prompted the addition of the responding assignments. In that initial study, with 36 PSMTs across three US universities, 38% of participants showed gains in attending, 25% gained in interpreting, but there was no notable change in responding after the intervention. While we are naturally hesitant to draw too many inferences based on the limited sample, we wonder about contextual factors that may have played a role. For example, in the US case, the three participants were the only students enrolled in the methods course, and as a result received more targeted instruction and feedback during the in-class responding assignment. In contrast, 39 PSMTs were enrolled in the course in Australia and thus may have relied more on their peer-group and received less 'expert' feedback when crafting responses to the student work presented. Another possible intervening factor, also potentially related to the disparate class sizes, is the fact that on both the pre- and post-video assessments, the US participants simply wrote more when addressing all three of the prompts. Finally, we wonder whether the in-class responding component of the module was sufficiently outlined in the Interview Module materials to support implementation by an MTE from outside the group. In other words, the different instructors may have enacted parts of the assignment very differently. Given that a key purpose of this study was to investigate the transferability of the Interview Module to a new context, this explanation is a cause for concern that warrants further investigation.

Finally, we note that although there were no significant changes in responding scores (due in part to the ceiling effect with the US participants), we did see qualitative differences in the ways PSMTs chose to respond. Most apparent was the shift toward more student-centered responses. On the pre-video assessment 4 PSMT responses were coded as teacher-centered (2 from the US participants), 3 were coded as student-centered, and 2 as mixed. In contrast there were no responses on the post-video assessment that were coded as strictly teacher-centered, with responses more focused on eliciting additional student thinking or building the student's understanding rather than providing further instruction. For example, there was a shift in language from "I would *show her*…" or "I would *go over* quadratic graphs and what they look like" to "*I would ask* the student…"

This finding is consistent with previous work in which "leaving room for student thinking" was the characteristic PSMTs were best able to meet when crafting responses on the take-home assignment associated with the responding components that were added to the Interview Module (Casey, Lesseig Monson & Krupa, 2018). We speculate that this aspect–allowing students to do their own thinking, rather than jumping in to 'tell'–is not only highly supported throughout the module (e.g., in the course readings as well as the in-class responding assignment), but also is less reliant on subject matter, or pedagogical content knowledge. Son and Crespo's (2009) study with elementary preservice teacher provides some support for this claim.

Limitations

In addition to the limitations alluded to above (e.g., small number of participants, differences in US and Australia class size) the study is subject to methodological limitations that plague noticing research more generally. Specifically, we acknowledge that there may well be differences between what is attended to explicitly versus implicitly (Scheiner, 2016). We accounted for this to some degree by encouraging students to take notes while watching the video, prior to addressing the first prompt. These notes were collected and included in our analysis and scoring. Second, video of a clinical interview (the format employed in the pre-post assessment) provides limited access to information pertinent to the teaching and learning episode (e.g., students' prior experiences or attitude toward mathematics, specific learning goals or associated curricular materials). Without this full context, PSMTs are left to "fill in the gaps", often relying on their own experiences with this topic as high school students. This not only impedes the situational awareness of the PSMTs, but also our abilities as researchers to infer meaning from PSMTs' responses (Nickerson et al., 2017). In future work, we intend to attend more carefully to PSMTs' background experiences and explore potential relationships among PSMTs' knowledge, skills, and dispositions; we encourage other researchers to do the same.

A TRANSFORMATIVE LEARNING EXPERIENCE FOR THE CONCEPT OF FUNCTION

Functions form a central part of the U.S. mathematics curriculum. A large body of research shows that students at all levels, including preservice secondary mathematics teachers, have difficulties with defining function as a correspondence between two sets with a univalence condition. Those difficulties include privileging algebraic representations and reductive interpretations of the univalence condition in the form of the vertical line test. In our research study, 47 pre-service mathematics teachers provided definitions of function, engaged with an interactive applet that had a non-standard representation of function. The interaction with the applet was effective in initiating a series of dilemmas in their conception of function that resulted in the majority of the participants transforming and/or refining their conception of function.

Keywords: Teacher Education - Preservice, Teacher Knowledge, Technology

Introduction

The concept of function is considered to be one of the most important underlying and unifying concepts of mathematics (e.g., Leinhardt, Zaslavsky, & Stein, 1990; Thompson & Carlson, 2017). Students work with functions from the very earliest grades in pattern exploration, through high school with a formal treatment of functions as arbitrary mappings between sets. There is an extensive body of research on students' understanding of function (e.g., Carlson et al., 2003; Cooney et al., 2010; Dubinsky & Harel, 1992; Even, 1990; 1993, Oehrtman et al., 2008) and much of that research reports that learners (including preservice mathematics teachers) have considerable difficulty identifying functions and in distinguishing them from non-functions. With the emphasis on function in school mathematics, preservice secondary mathematics teachers (PSMTs) must have robust conceptions of function to plan to support their students' understanding. Based on years of research on students and teachers flawed, limited conceptions of function, and on transformation theory (Mezirow, 2000; Taylor, 2007), we designed a task, utilizing advanced digital technology, to meet this need. The purpose of this study is to examine ways in which the task elicited and transformed PSMTs' conceptions of function.

Literature Review and Relationship to Research

Defining Function

In Thompson & Carlson's (2017) discussion of the evolution of the definition of function, they describe how a variation and covariation conception of function came to be replaced, owing to the emerging dominance of a set theoretic conception of variable as used in group theory and other areas, by a correspondence conception of function. This definition "solved problems that arose for mathematicians, [but that] introducing it in school mathematics made it nearly impossible for school students to see any intellectual need for it" (p.422). This abstract correspondence definition is often referred to as the Dirichlet-Bourbaki definition of function and states that a function is a correspondence between arbitrary sets satisfying a univalence condition i.e. each element in the domain corresponds to exactly one element in the codomain.

Thompson and Carlson (2017), citing Cooney and Wilson (1993), as well as drawing on their own review of 17 U.S. Precalculus textbooks, note that a correspondence definition of function is used exclusively in all of these textbooks. Therefore, while we expect that most students (and PSMTs) who have attended U.S. schools to have experience with a definition involving a correspondence between two sets with constraints on the mapping of individual elements (the univalence condition), Even (1993) notes that many students retain a "protypic" (p.96) concept of functions as linear relationships and "many expect graphs of functions to be "reasonable" and functions to be representable by a formula." (p. 96).

Teachers' Understandings of the Function Concept

In addition to content knowledge of functions, mathematics teachers require Mathematical Knowledge for Teaching (Ball, Hill, & Bass, 2005) of functions i.e. teachers should be aware of various representations of functions, many examples of functions and non-functions, and known areas of challenge for students when learning functions. However, teachers' understanding of function, at the content level, is similar to that of school and college students (Bannister, 2014; Even, 1990, 1993; Wilson, 1994). In particular, practicing teachers and PSMTs tend to privilege algebraic representations of functions and emphasize properties of graphs (e.g., vertical line test) in their descriptions of functions and non-functions (Even, 1990, 1993; Wilson, 1994). They also exhibit a limited repertoire of representations on which to draw in helping students understand functions (Bannister, 2014; Hatisaru & Erbas, 2017).

Crucially, teachers' understanding of function has been shown to impact the pedagogical choices they make during instruction. In a study of 152 PSMTs, Even (1993) found they could not justify the need for univalence and did not know why it was important to distinguish between functions and non-functions. Owing to this lack of content knowledge, the PSMTs' MKT was constrained and they limited the exposure of their students to various function representations and emphasized procedures such as the vertical line test in identifying functions.

Learning in Technology-rich Environments

A considerable body of research supports the idea that advanced digital technologies can support learning in general (Tamim et al., 2011) and mathematics concepts in particular (Drijvers et al., 2010; Olive et al., 2010.). Drijvers (2015) argues that "the criterion for appropriate design is that it enhances the co-emergence of technical mastery to use the digital technology for solving mathematical tasks, and the genesis of mental schemes that include the conceptual understanding of the mathematics at stake." (p.15). For example, a good design to allow students to engage with the concept of function will allow the user to experience different kinds of functions and non-functions with enough data to differentiate between the two.

Theoretical Framework

Transformation Theory

Given the preponderance of evidence in the literature that the conception of function of PSMTs is often underdeveloped, our goal was to design a learning experience that problematized those conceptions, required PSMTs to reflect on them, and, ideally, resulted in refinement of their conception. Given that PSMTs come to their methods courses as adults and with a wealth of previous experiences related to the function concept, we turned to an adult learning theory, namely Mezirow's (2000) transformation theory. Transformation theory is an adult learning theory that is consistent with constructivist assumptions and expands on those assumptions by acknowledging the broad predispositions an adult might have toward a concept based on prior experiences, and the role these dispositions play in their meaning making (Mezirow, 2000).

Mezirow (2009) describes four forms of learning at the heart of transformation theory: elaborating existing meaning schemes, creating new meaning schemes, transforming meaning schemes, and transforming meaning perspectives. According to Mezirow (2009), learning by transforming existing meaning schemes and perspectives often begins with a stimulus, a *disorienting dilemma*, which requires one to question their current meaning schemes. However, experiencing a disorienting dilemma alone is not enough to effect a transformation and learning will only occur through critical reflection (Merriam, 2004; Mezirow, 2000; Taylor, 2007).

Sfard (1991) distinguishes between a *concept*, a mathematical idea in its "official form" (p. 3) and a *conception*, "the whole cluster internal representations and associations evoked by a concept" (p. 3). A *concept* is the generally accepted structure of mathematics that has been culturally developed and shared formally among mathematicians for centuries (Pehkonen & Pietila, 2003) whereas a *conception* is a learner's individual, often, incomplete understanding of the concept. In Sfard's definition of conception we see the connection between knowledge and the affective aspects of meaning schemes as defined by Mezirow (2000). Conceptions, then, are the personal side of a concept, one's individual experiences, beliefs, attitudes, and emotions that result in personal definitions, examples, and non-examples of concepts.

Therefore, we aimed to design a learning experience for PSMTs that would trigger a disorienting dilemma related to their conceptions of function and non-function and require critical reflection in the expectation that a transformation of meaning scheme occurs.

A Transformative Learning Experience for the Concept of Function

Given the promise of cognitive roots (Tall et al., 2000) such as a function machine, we set out to design a machine-based experience using representations that were unfamiliar for PSMTs as a stimulus for examining their meaning schemes of function. The applet we designed, built on the metaphor of a vending machine, contained no numerical or algebraic expressions. Our intention was to put PSMTs in a context in which they would not be able to automatically rely on an algebraic, and often procedural, conceptions of functions (e.g., use of the vertical line test).

The Vending Machine applet (https://ggbm.at/X3Cn7npQ) consists of four pages; each with two to six vending machines and asks the user to identify each vending machine as a function or non-function. The machines each consist of four buttons (Red Cola, Diet Blue, Silver Mist, and Green Dew). When a button is pressed it produces none, one, or more than one of the different colored cans which may, or may not, correspond to the color of the button pressed.

Which One is a Function? (pgs. 1 - 3)			
A	Red → Red Blue → Blue Silver → Silver Green → Green	B	Red → Red Blue → Blue Silver → Silver Green → Random
C	Red → Blue Blue → Silver Silver → Green Green → Red	D	Red → Random Pair Blue → Blue Silver → Silver Green → Green
E	Red → Red Blue → Blue & Random Silver → Silver Green → Green	F	Red → Red Blue → Silver Silver → Silver Green → Green

Which Ones Could be Functions? (pg. 4)			
G	All Random	H	Red → Green Blue → Green Silver → Green Green → Green
I	Red → 2 Silvers Blue → Green Silver → Red Green → Blue	J	Red → Red Blue → Blue Silver → No Can Green → Green
K	Red → Red Blue → Blue Silver → Silver Green → Red & Green	L	Red → Red Blue → Red Silver → Silver Green → Silver

Figure 1: Description of Each Machine in the Applet

By removing numeric and algebraic representations, the applet could allow PSMTs to attend to input/outputs and their relationship. We intentionally designed to trigger dilemmas related to known issues from the literature e.g. researchers have shown that students as well as teachers exhibit difficulties identifying constant functions as functions (e.g., Carlson, 1998; Rasmussen, 2000); thus, there is a machine that acts as a constant function, i.e. every button produces the same color can. The purpose of this study is to determine the extent to which we were successful in designing for transformative learning (Mezirow, 2000; Taylor, 2007) related to the function definition. Specifically, we aim to answer the following research question:

> To what extent did PSMTs experience disorienting dilemmas when engaging with the vending machine applet and in what ways did PSMTs' conceptions of function transform as a result of personal critical reflection in the context of the vending machine task?

Methods

Participants and Data Sources

Participants in this study are 47 PSMTs enrolled in a secondary mathematics methods course at four different U.S. universities, ranging from five to 18 PSMTs per university. The PSMTs were all undergraduate mathematics and/or mathematics education majors working toward a secondary mathematics teaching license. The individual degree programs all required at least 36 hours of mathematics, and the PSMTs had all completed at least Calculus II at the time of the study. Every PSMT in the four methods courses took part in the study (N = 55). However, there were some PSMTs that did not have complete data sets (e.g., video had no sound, missing artifacts), these participants were removed, leaving 47 PSMTs in this particular study.

Data for this study consists of all of the PSMTs' work related to the Vending Machine task. During a class the PSMTs completed the task individually and then the class came together for a whole class discussion. Data is focused on PSMTs individual work on the task and includes both written work and video recorded screen captures of their engagement with the applet. Specifically, we collected PSMTs' written pre- and post-definitions of function and their written responses to the Vending Machine task worksheet. In addition, each PSMT captured a screencast of their work on the Vending Machine task as they followed a "think-aloud" protocol while working on the task.

Analysis of Applet Engagement Descriptions

We created a document for each PSMT which consisted of their pre- and post-definitions and a detailed description of the video-recorded screencast. These descriptions included a chronological record of PSMTs' engagement with the applet and verbatim transcriptions of PSMTs' expressed thoughts related to their work. The participant descriptions were uploaded to Atlas.ti and coded for evidence of the occurrence of disorienting dilemmas, triggers for those dilemmas, articulated conceptions of function that were challenged by those triggers, and transformations of meaning schemes related to conceptions.

Dilemmas were identified based on PSMTs' verbal utterances and interactions with the applet. For example, verbal utterances such as, "Ok these are two cans but they seem to be the same. Does it have to be one can of coke, or two cans can still be one output? I don't know. Let's see what others are" were coded as a dilemma. Each dilemma was then assigned a trigger code. Each dilemma was either resolved or not resolved in the PSMTs' utterances. Those that were resolved were coded as having a change in meaning scheme. Trigger codes included both a priori triggers and emergent triggers. Given the personal nature of conceptions of function, we could only code for those that were articulated explicitly in writing or spoken on the screencast. All of the quotations coded for function conception were then open coded to identify themes (Creswell, 2014). Themes for the articulated conceptions of function are shown were: (i) Functions must be/don't have to be continuous; (ii) Functions can/can't be many-to-one; (iii) Functions must map elements in the domain to elements in a defined codomain; and (iv) Functions must be one to one (with or without correct meaning of one to one).

Findings

In our findings we discuss the dilemmas triggered through engagement with the applet, the conceptions of function which were problematized, and the ways in which PSMTs' conceptions of function were transformed as a result of engaging with the Vending Machine Task.

Triggering Disorienting Dilemmas and Transforming Conceptions

From our analysis of the 47 PSMTs' screencast descriptions, we identified a total of 158 dilemmas (i.e. a little over 3 per PSMT on average), with approximately 91% (43 PSMTs) articulating at least one dilemma while engaging with the applet. The machines that triggered these dilemmas were those that produced two cans or no can as an output, those for which different inputs produced the same output, or those for which the color of the can (output) did not match the button pressed (input). Of the 158 articulated dilemmas, 124 resulted in a transformation in a PSMTs' conception of function, where transformation is defined, per our theoretical framework as any one of: elaborating existing meaning schemes, creating new meaning schemes, transforming meaning schemes, and transforming meaning perspectives. The transformations we report on below, i.e. the resolved dilemmas, were mainly "elaborating existing meaning schemes" although there were some instances of "transforming meaning schemes." The three most commonly transformed conception themes were: elements of the codomain, many-to-one, and continuous function. For the sake of brevity, only the first of these will be discussed in this paper.

Conceptions of Elements in the Codomain

The most common conception of function that was triggered was that of PSMTs considering (or not) possible ways of defining the codomain, with 41 of the 47 PSMTs (87%) articulating such a dilemma. We intentionally did not state what elements made up the domain, codomain, and range for the machines in the applet. The machines that produced two cans as an output (D, E, I, K) and no can as an output (J) were designed with the hope that engagement with the machines would trigger a dilemma for the PSMTs and elicit such considerations.

When encountering Machines D, E, I, K, and J, PSMTs typically articulated their dilemma by questioning whether or not no can or two cans could be outputs. For example, PSMT 2's response to Silver Mist not producing an output on Machine J, "Oh, the Silver Mist has no output. [Presses Silver Mist button many times.] That's not broken, right? So, is that ok, that Silver Mist doesn't have an output?" and PSMT 6's response to two cans as an output on Machine K, "Red is red, blue is blue, silver is silver, and green is [red and green cans appear]. That is definitely not a function, because you can't have two. I guess you could have two outputs (sigh) this is very difficult." Additionally, some PSMTs went beyond just verbalizing a dilemma to explicitly discussing the possible output values. One example that typifies how PSMTs explicitly discussed defining the possible codomain elements follows,

> Ok these are two cans, but they seem to be the same. That's an interesting question… That's interesting what we define as output. Does it have to be one can of coke or two cans can still be one output? (PSMT 3, on Machine I).

All of these PSMTs clearly articulated a dilemma related to their conception of types of elements that could possibly be in the codomain.

The first machine where these dilemmas occurred was on Machine D (Red Cola → random pair), and while 20 PSMTs articulated a dilemma on this machine, only 6 resulted in a transformed conception of function. This result can be attributed to the fact that making sense of the two can output was not required to classify the machine as a function or non-function due to the randomness of the output. For example, after deciding that the machine was not a function because of the random nature of the outputs PSMT 23 stated, "And, I'm still hung up on this two can thing, but I really don't know why. And I haven't been able to work through it yet. So, maybe I can explore some more and get back to that."

Most transformations of conceptions of functions related to defining elements of the codomain occurred on Machines I, J, and K (17, 20, and 18 respectively). As PSMTs articulated their transforming conceptions related to the nature of the codomain they either focused on the consistency of the outputs, examples of representations of functions they were familiar with, or their personal definition of function.

Consistency of outputs. Most PSMTs (23 out of 41) who articulated transformed conceptions with respect to codomain attended to consistency as they worked to make sense of what they observed as outputs on Machines I, J, and K. For example, as PSMT 7 engaged with Machine I they explained,

> Ok, now I'm having second thoughts about these two sodas. And like, would Green Dew have two different arrows? So, I guess it depends on how you see your output values. Are the output values just a red soda, green soda, blue soda, silver soda? Or can they be different combinations of those? So, going off of the assumption that it's going off the same output every time, then it's a function. But since it's giving you two different drinks, is it still? Hmm, I'm questioning all my thoughts now. I guess it would depend on how you classify your outputs, so if like getting two different drinks is OK, but as long as it happens every single time that you put this input in then I think it would be OK.

In this example PSMT 7 is considering elements that might be in the codomain, going beyond noting elements of the range that have been observed with the machines so far. PSMT 7 makes the point that whether or not this is a function, depends on how the codomain is defined, ultimately deciding that if it was defined to include pairs of cans then Machine I could be a function because the result of clicking on the Red Cola button is consistently two silver cans. Similar reasoning is evident in the following explanation of Machine J by PSMT 30:

> That's not broken, right? So, is that ok, that silver mist doesn't have an output? … I think its ok, because it's the same output. If it gave us something one time, then I wouldn't be ok with that. So, even though silver doesn't give you anything, by giving you nothing, it is consistently giving you nothing.

In each of these responses, the PSMTs articulated transformed conceptions of the codomain, specifically an elaborated conception that included two cans or no cans as elements. This transformation is a result of considering the importance of consistency in the relationship between input and output elements. Furthermore, all of the PSMTs that attended to consistency when deliberating about how to resolve their dilemma transformed their conception of codomain to include both two and no cans.

Using examples of familiar functions. Other PSMTs worked through dilemmas in which their conceptions of the nature of codomain were challenged by drawing upon examples of familiar representations of function. This is evident in PSMT 34's work on Machine I,

> This one is the most questionable one that I'm the least certain on. We will say that is not a function. I don't know how that would really work on a graph. How that could be expressed as a graph? I think that would basically be saying if I put in a one I would get two 2s out of that. Which is not possible.

PSMT 34 could not imagine how two cans might be represented on a graph, resulting in a transformed conception of codomain in this context that did not include elements other than single cans. PSMT 11 used similar reasoning on Machine J (no can),

> Silver doesn't give me anything. What? … I don't know, it's just the fact that it doesn't give me one out, if that's the reason why I don't think it's a function or…even like a linear basic function. If you put something into it, you have to come out with something. There's got to be some number there. Okay, okay, because you have to have an output.

In this example, the PSMT is trying to imagine the situation as a known function, even a "linear basic function" but is not able to do so. After declaring they cannot think of a function that behaves this way, the PSMT goes further to state that an input must have an output to go with it.

When PSMTs drew on familiar representations to make sense of a dilemma regarding issues with the codomain, they used the familiar representations to determine if a machine was a function or non-function. This resulted in a changed understanding of the codomain in this non-algebraic context by drawing on possible codomains from algebraic contexts.

Drawing on personal definition of function. Drawing upon one's personal definition was also common for the PSMTs when they were thinking about elements of the range and codomain. Consider PSMT 20's explanation of Machine I,

> Immediately that red button is giving you two different cans. Which is not… They are both silvers, but I take that as still two different values even if they're the same value which you can't have. Yeah two different cans we can't have two cans off of one… two ys off one x. Then it's not a function. Although if they are the same can… nah I still think that's not.

Similarly, PSMT 35 working on Machine J said,

> The problem is the silver, because it since it doesn't give you anything. It's like having an x that doesn't go to a y. And, one of the rules of functions is that every x needs a y but not every y has to have an x. So, because silver doesn't give you a can, this makes it not a function.

Both of these examples are evidence of PSMTs transforming their conceptions of codomain. In the latter case, in such a way that the empty set is not included based on their conceptions of the univalence requirement of the definition of function.

Discussion

The purpose of the design of the Vending Machine applet and this study was to elicit PSMTs' many conceptions of functions and attempt to challenge and transform any less robust conceptions to more robust conceptions of functions. The fact that PSMTs exhibited many conceptions and difficulties consistent with research literature on understanding of function suggest that the applet design was effective in this regard. Furthermore, there is evidence in the totality of the data collected that engaging with the Vending Machine applet resulted in most PSMTs reconsidering and refining their conceptions of function in a positive direction.

To enable and facilitate this change we drew on transformation theory (Mezirow, 2000), and Drijvers's (2015) notion of the importance of didactical possibilities in the design of advanced digital technology applications, to guide the creation of an applet to trigger dilemmas that address common conceptions from the literature on distinguishing functions and non-functions. The use of advanced digital technology, allowed us to create a task with which the PSMTs could interact independently and which, with immediate feedback allowed them to formulate conjectures and test those conjectures without having to wait for a class discussion or intervention from an instructor. At the beginning of the task PSMTs articulated conceptions of function that we expected based on the literature. For example, the PSMTs articulated disorienting dilemmas related to their conceptions of univalence (e.g., Even, 1993; Vinner & Dreyfus, 1989), many to one (e.g., Carlson, 1998; Rasmussen, 2000), and continuity (Bezuidenhout, 2001; Tall & Vinner, 1981). With the exception of continuity, we designed the applet to trigger dilemmas related to each of these conceptions. One of the persistent problems noted in the literature is over privileging of algebraic representations (Even, 1990, 1993; Wilson, 1994), putting PSMTs in the context of the vending machines appears to have mitigated this problem.

The ways in which the PSMTs engaged with the applet provided considerable insight into their conceptions of functions and the ways in which they were both challenged and transformed. Given that 43 out of 47 (91%) PSMTs articulated a dilemma related to at least one of the triggers we designed for, we know that we leveraged advanced digital technology to create an opportunity for transformations of conceptions to occur. Furthermore, 41 of the 47 PSMTs (87%) experienced a dilemma related to their conceptions of codomain and the result that 76%

(31 out of those 41) were able to articulate the impact of the definition of domain and codomain on the way the machines would be classified, is significant. Overall, the vending machine task was successful in triggering dilemmas, eliciting critical reflection, and supporting PSMTs in transforming their conceptions of function.

Conclusion

It is crucial that PSMTs have a solid understanding of function, know variations in the definition of function, develop the ability to translate among different representations of functions, and know when to use each definition based on context (Bannister, 2014; Hatisaru & Erbas, 2017). This specialized content knowledge is needed to understand and plan for the diverse student conceptions they will encounter during instruction. While there is a vast literature base on the limited conceptions of functions PSMTs often develop through high school and undergraduate mathematics, little is known about how to transform them after years of building on them in algebraic contexts. The results of this study indicate that by removing PSMTs from familiar function contexts and designing to trigger dilemmas based on conceptions identified in the literature, we can transform PSMTs' conceptions of function in a positive direction.

Functions form a central part of the U.S. mathematics curriculum especially at the high school level. There is a considerable body of research showing that students at all levels, including preservice secondary mathematics teachers, have difficulties with the definition of function as a correspondence between two sets with a univalence condition. Those difficulties include privileging algebraic representations and reductive interpretations of the univalence condition in the form of the vertical line test. In our research study, 47 pre-service mathematics teachers provided definitions of function, engaged with an interactive applet that had a non-standard representation of function, and then provided revised definitions of function. The results of the study show a measurable increase in the participants level of abstraction in their definitions, and an increase in their attention to the univalence condition.

Keywords: Teacher Education - Preservice, Teacher Knowledge, Technology

Introduction

The concept of function is considered to be one of the most important underlying and unifying concepts of mathematics (e.g., Leinhardt, Zaslavsky, & Stein, 1990; Thompson & Carlson, 2017). Students are provided experiences with functions from the very earliest grades, usually pattern exploration, up to and through high school with a formal treatment of functions as arbitrary mappings between sets. Indeed, in the Common Core State Standards for Mathematics the study of function is given its own domain in grades 9-12 (National Governors Association for Best Practices & Council of Chief State School Officers, 2010).

There is an extensive body of research on students' understanding of function (e.g., Carlson et al., 2003; Cooney et al., 2010; Dubinsky & Harel, 1992; Even, 1990; 1993, Oehrtman et al., 2008) and much of that research reports that learners (secondary, post-secondary as well as pre-service and in-service teachers) have considerable difficulty identifying functions and in distinguishing them from non-functions.

Given the emphasis on function in school mathematics, it is important to consider preservice secondary mathematics teachers' (PSMTs) conceptions of function. Since PSMTs must possess robust conceptions of function so they can plan for supporting the development of their future students' function understandings. As such, mathematics teacher educators need to identify methods for eliciting and transforming PSMTs' conceptions of function to meet these needs. The decades of research outlining the details of both students' and teachers' flawed and limited conceptions of function provide grounding for thinking about how to support PSMTs' further conception development. Coupling this vast literature and transformation theory (Mezirow, 2000; Taylor, 2007), a specifically adult constructivist learning theory, we designed a task utilizing advanced digital technology to meet this need. The purpose of this study is to examine the ways in which this task elicited and transformed PSMTs' personal definitions of function. In doing so we aim to add to the knowledge base of designing learning experiences for PSMTs that problematize and support transformation of important mathematical conceptions.

Literature Review and Relationship to Research

Defining Function

In Thompson & Carlson's (2017) discussion of the evolution of the definition of function in the history of mathematics, they describe how a variation and covariation conception of function came to be replaced, owing to the emerging dominance of a set theoretic conception of variable as used in group theory and other areas, by a correspondence conception of function that "solved problems that arose for mathematicians, [but that] introducing it in school mathematics made it nearly impossible for school students to see any intellectual need for it" (p.422). This abstract correspondence definition is often referred to as the Dirichlet-Bourbaki definition of function and states that a function is a correspondence between arbitrary sets satisfying a univalence condition i.e. each element in the domain corresponds to exactly one element in the codomain.

Thompson and Carlson (2017), citing Cooney and Wilson (1993), as well as drawing on their own review of 17 U.S. Precalculus textbooks, note that a correspondence definition of function is used exclusively in all of these textbooks. Therefore, while we expect that most students (and PSMTs) who have attended U.S. schools to have experience with a definition involving a correspondence (or mapping) between two sets with constraints on the mapping of individual elements (the univalence condition), Even (1993) notes that many students retain a "protypic" (p.96) concept of functions as linear relationships and "many expect graphs of functions to be "reasonable" and functions to be representable by a formula." (p. 96).

Teachers' Understandings of the Function Concept

In addition to content knowledge of functions, mathematics teachers require Mathematical Knowledge for Teaching (MKT) (Ball, Hill, & Bass, 2005) of functions in order to be effective, i.e. teachers should be aware of various representations of functions, many examples of functions and non-functions, and known areas of challenge for students when learning functions. However, the situation regarding teachers' understanding of function, at the content level, is quite similar to that of school and college students (Bannister, 2014; Even, 1990, 1993; Wilson, 1994). In particular, similar to students, practicing teachers and PSMTs tend to privilege algebraic representations of functions and emphasise properties of graphs (e.g., vertical line test) in their descriptions of functions and non-functions (Even, 1990, 1993; Wilson, 1994). They also exhibit a limited repertoire of representations on which to draw in helping students understand functions (Bannister, 2014; Hatisaru & Erbas, 2017).

Crucially, teachers' understanding of function has been shown to impact the pedagogical choices they make during instruction. In a study of 152 PSMTs, Even (1993) found they could not justify the need for univalence and did not know why it was important to distinguish between functions and non-functions. Owing to this lack of content knowledge, the PSMTs' MKT was constrained and they limited the exposure of their students to various function representations and emphasised procedures such as the vertical line test in identifying functions.

Learning in Technology-rich Environments

The importance of advanced digital technologies in mathematics education is now well established. Major stakeholders such as The National Council of Teachers of Mathematics (NCTM) have asserted that "It is essential that teachers and students have regular access to technologies that support and advance mathematical sense making, reasoning, problem solving, and communication" (NCTM, 2015, p.1). A considerable body of research supports the idea that advanced digital technologies can support learning in general (Tamim et al., 2011) and mathematics concepts in particular (Drijvers et al., 2010; Olive et al., 2010.)

In explaining the importance of design Drijvers (2015) argues that "the criterion for appropriate design is that it enhances the co-emergence of technical mastery to use the digital technology for solving mathematical tasks, and the genesis of mental schemes that include the conceptual understanding of the mathematics at stake." (p.15). For example, a good design to allow students to engage with the concept of function will allow the user to experience different kinds of functions and non-functions with enough data to differentiate between the two.

Theoretical Framework

Transformation Theory

Given the preponderance of evidence in the literature that the conception of function of PSMTs is often underdeveloped, our goal was to design a learning experience that problematized those conceptions, required PSMTs to reflect on them, and, ideally, resulted in further development and refinement of their conception as articulated in their personal definition (i.e., learning). Given that PSMTs come to their methods courses as adults and with a wealth of previous experiences related to the function concept, we turned to an adult learning theory, namely Mezirow's (2000) transformation theory. Transformation theory is an adult learning theory that is consistent with constructivist assumptions and expands on those assumptions by acknowledging the broad predispositions an adult might have toward a concept based on prior experiences, and the role these dispositions play in their meaning making (Mezirow, 2000).

Mezirow (2009) describes four forms of learning at the heart of transformation theory: elaborating existing meaning schemes, creating new meaning schemes, transforming meaning schemes, and transforming meaning perspectives. According to Mezirow (2009), learning by transforming existing meaning schemes and perspectives often begins with a stimulus, a *disorienting dilemma*, which requires one to question their current meaning schemes. However, experiencing a disorienting dilemma alone is not enough to effect a transformation and learning will only occur through critical reflection (Merriam, 2004; Mezirow, 2000; Taylor, 2007).

A Transformative Learning Experience for the Concept of Function

There is a significant research base that recognizes that PSMTs often have conceptions of function that are inconsistent with the concept itself (e.g., Bakar & Tall, 1991; Breidenbach, et al., 1992; Carlson, 1998; Carlson & Oehrtman, 2005; Rasmussen, 2000; Vinner & Dreyfus, 1989). Given that PSMTs will be responsible for teaching others about function, it is important to try to address this concern through carefully designed learning experiences.

The idea of a *cognitive root* was introduced by Tall et al. (2000) as an "anchoring concept which the learner finds easy to comprehend, yet forms a basis on which a theory may be built" as they were developing a cognitive approach to calculus (Tall et al., 2000, p.497). As an example of a cognitive root for function concepts, Tall et al. suggest the use of a *function machine* (sometimes referred to as a function box). The machine metaphor Tall and colleagues describe is typically a "guess my rule" activity which is algebraic in nature. Studies using function machines were promising but some students still struggled with connecting different representations and determining what is and is not a function (e.g. McGowen et al., 2000).

Given the promise of cognitive roots we set out to design a machine-based experience using representations that were unfamiliar for PSMTs as a stimulus for examining their meaning schemes of function. The applet we designed, built on the metaphor of a vending machine, contained no numerical or algebraic expressions. Our intention was to put PSMTs in a context in which they would not be able to automatically rely on an algebraic, and often procedural, conceptions of functions (e.g., use of the vertical line test).

The Vending Machine applet (https://ggbm.at/X3Cn7npQ) consists of four pages; each with two to six vending machines and asks the user to identify each vending machine as a function or non-function (Figure 1). The machines each consist of four buttons (Red Cola, Diet Blue, Silver Mist, and Green Dew). When a button is pressed it produces none, one, or more than one of the different colored cans which may, or may not, correspond to the color of the button pressed.

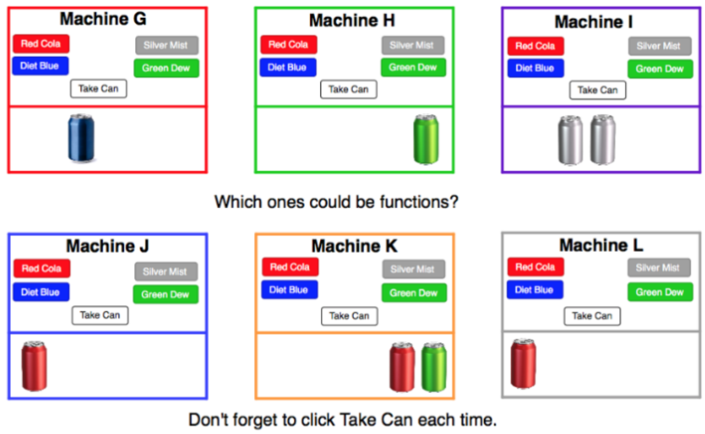

Figure 1: Vending Machine Applet

By removing numeric and algebraic representations, the applet could allow PSMTs to attend to the nature of input and outputs and the relationship between them. We intentionally designed to trigger dilemmas related to known issues from the literature e.g. researchers have shown that students as well as teachers exhibit difficulties identifying constant functions as functions (e.g., Carlson, 1998; Rasmussen, 2000); thus, there is a machine that acts as a constant function, i.e. every button produces the same color can. The purpose of this study is to determine the extent to which we were successful in designing for transformative learning (Mezirow, 2000; Taylor, 2007) related to the function definition. Our research question was:

> In what ways did PSMTs' personal definitions of function transform as a result of engaging with the vending machine task?

Methods

Participants and Data Sources

The participants in this study are 47 PSMTs enrolled in a secondary mathematics methods course at four different U.S. universities, ranging from five to 18 PSMTs at each university. The PSMTs were all undergraduate mathematics and/or mathematics education majors working toward earning their secondary mathematics teaching license. The individual degree programs all required at least 36 hours of mathematics, and these students had all successfully completed at least a second level calculus course at the time of the study. Every PSMT in the four methods courses took part in the study (N = 55). However, there were some PSMTs that did not have complete data sets these participants were removed, leaving 47 PSMTs in this particular study.

Data for this study consists of all of the PSMTs' work related to the Vending Machine task. This current paper represents a subset of a larger project and he subset of data relevant to this paper is written pre- and post-definitions of function on the Vending Machine task worksheet.

Analysis of Pre- and Post-definitions.

Pre- and post-definitions were entered into a spreadsheet for analysis. They were then coded using a codebook which was developed in a previous study and for which reliability was established (Author et al., 2018). All 94 definitions (47 pre and 47 post) were double-coded by two of the four authors using this codebook. To ensure reliability, coding was done in subsets of the data corpus, and coders compared codes, discussed, and resolved discrepancies (DeCuir-Gunby, Marshall, & McCulloch, 2011).

Similarly to Vinner and Dreyfus (1989), each definition was coded in terms of 1) accuracy, 2) focus, and 3) attention to output. In terms of *accuracy*, each definition was assigned a code of correct, incorrect, or close to correct. Key elements of a correct definition were 1) the definition was not limited to a specific type of function (e.g. linear or quadratic), or to a particular representation (e.g., equation), and 2) the definition addressed the idea that functions map each input to one and only one output, i.e., the univalence condition. Definitions coded as close to correct included those that indicated each input has one and only one output, but were not classified as correct because they were not general enough (e.g., the definition limited a function to a particular representation, such as an equation).

In terms of *focus*, each definition was coded regarding whether the definition indicated a function was a relationship (or mapping), an object, or neither. We referred to this set of codes as *focus*, as they indicated how the students "saw" function. We note that our use of the term *object* differs from its meaning in the APOS framework (Asiala et. al., 1996). In general, if a student identified a function with a representation or representations (e.g., "a function is an equation…"), then the definition was assigned a code of object. If the definition referred to a function as a relationship or mapping between variables or sets, it was coded as relationship. Finally, some definitions did not identify a function as an object or a relationship, but simply described some property of a function, e.g., "a function passes the vertical line test," then the definition was coded as neither. Although this code was intended to be mutually exclusive, there were a few definitions that identified a function as both a relationship and an object.

Finally, definitions were coded according to whether or not they *attended to output*. In order for a definition to be coded as attending to output, the definition needed to note something special or unique about the output. For example, "an equation with an input and an output" would not be considered as attending to output, while "an equation where each input has exactly one output" would. In addition, any definition which included mention of the vertical line test was coded as attending to output.

After coding was completed, results for each code were summarized and analyzed for patterns and themes that provided insight to transformations of students' conceptions related to the definition of function.

Results

PSMTs' Personal Definitions of Function

Given the applet design goal of disrupting students' meaning schemes for the concept of function, we noted how many students changed their definition from pre to post (students were given the option of not changing their definition from to pre to post as well). The number and percentage of definitions that were classified as correct, close to correct, or incorrect, pre- and post- engagement with the applet are shown in Table 1.

Table 1: Accuracy of Function Pre- and Post-Definitions

	Correct n (%)	Close to Correct n (%)	Incorrect (n (%)
Pre	4 (8.5%)	9 (19.1%)	34 (72.4%)
Post	7 (14.9%)	18 (38.3%)	22 (46.8%)

While 36 of the 47 PSMTs made a change to their definition, in many cases the post-definition did not change in terms of accuracy. Of those 36 that revised their definitions, 15 PSMTs improved the accuracy of their definition from pre to post, one PSMT's definition degenerated, and the rest of the definitions did not change with respect to accuracy. All 15 PSMTs whose definition improved started with incorrect definitions; three improved to a correct definition, and the other 12 moved from incorrect to close to correct. An example of a change for incorrect to correct is PSMT 17 who changed from "A function describes a relationship between 2 variable where the value of one variable determines the value of the other variable. A function must pass the vertical line test" to "A function describes a relationship between the domain and the range where for each input, or each value in the domain, there is only one corresponding output, or value in the range." With the PSMT noting "I changed this definition so that it focused on the number of outputs." An example of a change from incorrect to close to correct is PSMT 30 who went from "Function: an identity with more than one variable" to "A function is an equation that for every input (usually x) there is one output (usually y). It ceases being a function when multiple outputs exist for one input." The one PSMT whose definition declined with regard to accuracy went from close to correct to incorrect.

In terms of focus, the frequencies and percentage of definitions classified as relationship, object, both, or neither is depicted in Table 2. The notable result and very important with respect to focus is that while *object* was the most common code for the pre-definitions, *relationship* was the most common code for the post-definitions. This change corresponds both with the improvement in accuracy noted above.

Table 2: Focus of Function Pre- and Post-Definitions

Focus	Relationship n (%)	Object n (%)	Neither (n (%)	Both (n (%)
Pre	17 (36%)	19 (40%)	7 (15%)	4 (9%)
Post	20 (43%)	15 (32%)	9 (19%)	3 (6%)

Finally, the classification of attention to output had the most drastic change from pre- to post-definition. 60% (n= 28) attended to the output in their pre-definition and 89% (n= 42) attended to the output in their post definition. All of the 28 PSMTs who attended to output in their pre-definition continued to do so in their post-definition, and 14 of those who did not attend to the output in their pre-definition did so in their post-definition. Examples of PSMTs paying changing to pay attention to output are PSMT 12 who changed from "An expression involving more than one variable," to "An expression involving more than one variable. For each input there is only one output" and PSMT 29 who moved from "A relationship that maps inputs and outputs and has some combination of variables and constants to "A relationship that maps every input to one output consistently."

Overall the number of PSMTs who experienced a shift in accuracy of their personal definition, and who attended to output in their post-definition, and did not in their pre-definition indicates engagement with the applet resulted in transformations of their articulated conceptions of the definition function.

Discussion

The purpose of the design of the Vending Machine applet and this study was to elicit PSMTs' personal definitions of functions and attempt to challenge and transform those definitions. The PSMTs exhibited many difficulties consistent with research literature on understanding of function suggesting that the applet design was effective in this regard. Furthermore, there is evidence that engaging with the vending machine applet resulted in most PSMTs reconsidering and refining their personal definitions of function in a positive direction.

Unsurprisingly, PSMTs' struggled to articulate a complete definition of function, with much focus on objects rather than relationships or mappings as has been shown in previous research (e.g., Breidenbach et al., 1992; Carlson, 1998; Even, 1993). As future teachers of the function concept, perhaps the most concerning issue in PSMTs' articulated definition, prior to engagement with the applet, was that 59% did not attend to the univalence requirement. However, as a result of engaging with the Vending Machine applet 89% attended to the univalence requirement in their post-definitions.

To enable and facilitate this change we drew on transformation theory (Mezirow, 2000), and Drijvers's (2015) notion of the importance of didactical possibilities in the design of advanced digital technology applications, to guide the creation of an applet to trigger dilemmas that address common conceptions from the literature on distinguishing functions and non-functions. The use of advanced digital technology, allowed us to create a task with which the PSMTs could interact independently and which, with the immediate feedback of the machine outputs allowed them to formulate conjectures as they worked and test those conjectures without having to wait for a class discussion or intervention from an instructor. Our use of function machine, in the form of vending machines, as a cognitive root (Tall et al., 2000) proved to be accessible and meaningful for the PSMTs. One of the persistent problems noted in the literature is privileging algebraic representations (Even, 1990, 1993; Wilson, 1994) and putting PSMTs in the context of the vending machines appears to have mitigated this problem.

Conclusion

It is crucial that PSMTs have a solid understanding of function, know variations in the definition of function, develop the ability to translate among different representations of functions, and know when to use each definition based on context. This specialized content knowledge is needed to understand and plan for the diverse student conceptions they will encounter during instruction related to functions. While there is a vast literature base on the limited conceptions of functions PSMTs often develop through high school and undergraduate mathematics, little is known about how to transform them after years of building on them in algebraic contexts. The results of this study indicate that by removing PSMTs from familiar function contexts and designing to trigger dilemmas based on conceptions identified in the literature, we can transform PSMTs' personal definitions of function in a positive direction.

The results of this study suggest that coupling the research base in mathematics education with transformation theory to guide the design of learning experiences for PSMTs is promising, particularly in a technology-rich environment. Transformation theory values and leverages the wide-range of mathematical experiences of PSMTs, combining this with what research has revealed about learners' conceptions of a particular mathematical concept provides mathematics teacher educators a framework upon which to design such experiences. Given these findings, we hope that mathematics teacher educators will consider the use of transformative theory when designing learning experiences for PSMTs and inservice teachers.

PRESERVICE TEACHERS' USE OF NOTICING PRACTICES TO EVALUATE TECHNOLOGICAL RESOURCES

Sheunghyun Yeo
University of Missouri
syhw6@mail.missouri.edu

Corey Webel
University of Missouri
webelcm@missouri.edu

This study examines how elementary preservice teachers notice children's mathematical thinking and how this noticing influences the evaluation of technological resources. In particular, we explore the aspects of thinking to which preservice teachers attend and how they interpret evidence about children's thinking when using the Spatial-Temporal Math (ST Math) program. Data collection included a group survey administered after an initial exploration of a set of ST Math activities, screencast recordings during which children used and talked about the program, and a reflective writing assignment. The findings of this study show how preservice teachers used their noticing skills (attending and interpreting) in their evaluations of the tool, in some cases prompting them to shift their evaluation on the basis of student thinking.

Keywords: Teacher Education-Preservice, Technology, Instructional Activities and Practices

Introduction

Professional noticing (Jacobs, Lamb, & Philipp, 2010) is an important instructional practice, essential for supporting and extending students' mathematical thinking by focusing on in-the-moment decisions as well as on students' mathematical understanding. Recent studies have connected noticing to the use of technology, including technology evaluation (Smith, Shin, Kim, &, Zawodniak, 2018), technology-mediated teacher noticing (Walkoe, Wilkerson, & Elby, 2017), and developing noticing through the creation of animated teaching episodes (de Araujo et al., 2015). For example, Smith and his colleagues (2018) articulated a technological framework for the evaluation of technological tools by having preservice teachers (PSTs) engage with and reflect on the qualities of the tools. In this study, we build on this work by exploring 1) how PSTs notice the mathematical thinking of students as they engage with a particular tool, and 2) how this noticing influences their evaluation of the tool.

The technological resource we investigated was "Spatial-Temporal Mathematics" or ST Math, a game-based instructional software. We selected ST Math primarily because it was a tool that had been adopted by the district in which most of the PSTs in the program were placed for their junior-year field experience. District policy was that elementary students were to spend 90 minutes each week using ST Math. As a central focus of the mathematics methods course was noticing and responding to student thinking, we wanted to know how PSTs would use these skills in the context of the ST Math program.

ST Math is designed to use multiple dynamic representations of quantities and other mathematical objects to develop students' construction of mental images ahead in space and time (Peterson et al., 2004). In a previous analysis of student's engagement with ST Math, Yeo (2018) found that various ST Math activities ranged widely in their support for the development of mathematical concepts, with some activities providing strong connections to concepts and others requiring only surface level engagement.

This study shifts the focus from student thinking to PST noticing, exploring how novices make sense of student actions and speech when they are engaged with ST Math software. In particular, this study seeks to examine the following questions: (1) To what aspects of children's thinking do PSTs attend when the children are engaged in the ST Math activities, and how do the PSTs interpret evidence about this thinking? (2) How do PSTs draw on their noticing of children's thinking when evaluating the ST Math activities?

Theoretical Background

Teachers are aware of aspects of students' work in the classroom and they use this awareness to make pedagogical decisions (Goodwin, 1994). Awareness and sense-making of student's work have been described as *intentional noticing* (Mason, 2002) and were later expanded to include instructional responses and referred to as *professional noticing* (Jacobs et al., 2010). Professional noticing consists of three components: *attending* to student's mathematical ideas, *interpreting* their understanding, and *deciding how to respond* to their understanding. Studies have shown that PSTs can learn and develop these noticing skills through the support of teacher educators (Sherin & van Es, 2005), and that there are patterns in how PSTs apply the components (e.g., Wieman & Webel, 2019). The noticing framework has been extended to serve as a basis for a set of specific teaching moves (Jacobs & Empson, 2016), with the justification that one cannot act on information that one does not perceive. This idea is echoed in the establishment of "Elicit and use evidence of student thinking" as one of eight central teaching practice endorsed by the National Council of Teachers of Mathematics (2014). Noticing has also recently been extended to the evaluation of technological tools, such as interactive dynamic geometry activities (Smith et al., 2018). Previous studies have shown that teachers tend to evaluate online resources and activities positively with little consideration of mathematical or pedagogical features, but instead attended to surface level characteristic, such as whether students would be familiar with the problem types or if the activities had a game-like interface (e.g., Webel, Krupa, & McManus, 2015). In this study, we focus on how PSTs attend to and interpret children's thinking in the use of technological resources.

Methodology

The participants of this study were 21 elementary PSTs enrolled in a methods course at a Midwest university. Most participants were in their third year of a four-year program. The primary emphasis of the course was to understand how children's mathematical thinking develops in the domain of number and operations (Carpenter et al., 2014) and to develop the core teaching practices of eliciting and responding to children's thinking (Jacobs & Empson, 2016). Additionally, the PSTs engaged in daily one-to-one interactions with an assigned student in 3rd, 4th, or 5th grade (a "Math Buddy") during the whole semester.

In a series of course assignments, PSTs were first asked to explore a specified set of ST Math activities in small groups and respond to some reflection prompts. Then they later asked their Math Buddies, who were familiar with ST Math, to engage the same activities. PSTs were asked to elicit the child's thinking about the mathematics in the same tasks, and then finally to write a reflection paper about this experience. Three ST Math tasks (Figure 1) were chosen: *Pie Monster* (subtraction), *How Many Petals?* (place value), and *Building Expressions* (multiplication and division). These were selected to ensure that all of the children could engage in a developmentally appropriate task, and because, based on our previous engagement with ST Math, we believed they represented a range of opportunities for children to develop conceptual understanding. Specifically, the *Pie Monster* task involves whole number subtraction with various structures, such as start-unknown, change-unknown, and result-unknown (Carpenter et al., 2014) including three types of direct modeled representations. The screen (see Figure 1- left) uses two red-circles to represent the change (subtrahend), seven orange-circles to represent the start (minuend), and the white circles in the Monster's belly to represent the result (difference). When choosing the number of the white circles, JiJi (penguin character) attempts to cross the screen. If a provided answer is correct, the boxes are burnt by the Monster's fire and Jiji can cross the screen. If not, JiJi would go back to the starting place and one trial would be lost. The *How many petals?* task involves two-digit and three-digit place value concepts with the representations of petals (ones), flowers (tens), and a bunch of flowers (hundreds). Each tap on the 'ten' section on the screen (Figure 1-middle) collects ten petals, and so on for each place value. If the the 'ones' section has more individual petals than ten, a flower would be automatically made of the ten petals. Ten tens will automatically transform into a bunch of flowers (hundreds). The *Building Expressions* task involves the relationship between multiplication and division (e.g., 24 ÷ 4 = 6, 4 × 6= 24). A number of green dots must be selected according to the first number of a given number expression and the user decides how to drag the slider to partition the set of dots into the number of pink segments as designated by the second number. The quotient is the number of dots corresponding to each segment.

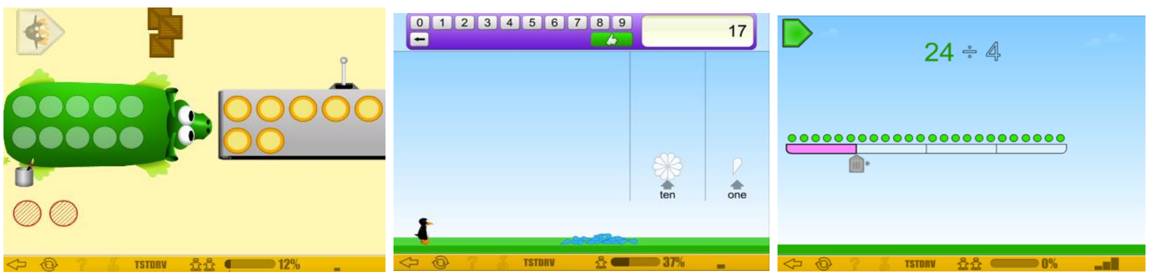

Figure 1: *Pie Monster* (left), *How Many Petals?* (middle), and *Building Expression* (right)

The data collected consisted of three parts: 1) "responses from the exploratory activity," in which groups of PSTs described, for each ST Math task, what mathematical ideas they believed the task was targeting, whether the task provided a "good opportunity" to learn those ideas, and what questions they would ask children to better understand their thinking while engaging in the task; 2) "screencasts" recorded while working with the Math Buddies, which captured manipulations on a tablet device and verbal explanations in real time; and 3) an individual reflection paper in which PSTs described the children's strategies, compared the strategies to how the children solved story problems, and gave an evaluation of each activity.

To address RQ1, PSTs' initial responses regarding the ST Math activities were categorized into *attending* and *interpreting*, and then additional data from reflection papers were coded similarly (see Table 1 for specific codes). In this analysis, we did not include the codes for *deciding how to respond* to focus on PSTs' evaluation of technological resources through the process of attending and interpreting. The screencasting data were reviewed to redefine and modify this coding scheme. Then, we examined responses from the exploratory activity to characterize each PST's initial evaluation of the ST Math activities. To address RQ2, this baseline was compared to their final reflection paper submitted after actually interacting with students. We noted whether the PSTs' evaluation of the ST Math activities changed, and how their noticing of student thinking appeared to influence their evaluation (or not).

Table 1: Noticing Coding Scheme in Exploratory and Reflective Phases

	Attending	Interpreting
Exploratory Phase	-Instructions -Visual representations -Manipulation -Mathematics concepts -Strategies	-Using sense-making to solve tasks -Potential mathematical concepts -Making a connection between representation and concept -Requirement of prior knowledge
Reflective Phase [additional codes]	-Task structures -Learning goals -Verbal explanations -Semiotic actions -Gamified features -Situated context	-Progression of problem-solving strategies -Solving tasks with given representations -Sequence of the tasks

Findings

In this section, we present our analyses of PST's attending to and interpreting children's mathematical thinking in the context of their ST Math explorations, focusing primarily on the *Pie Monster* task. We then discuss PST's noticing positive and negative features of ST Math in relation to potential learning opportunities for children, focusing primarily on the *How many Petals?* and *Building Expressions* tasks.

Attending to Children's Thinking

Attending refers to focusing on "noteworthy aspects of complex situations" (Jacobs et al., 2010, p. 172). PSTs understandably tended to pay more attention to student thinking when reflecting on their interactions with their Math Buddies, but they also showed evidence of noticing when reflecting on their own exploration of the ST Math tasks. That is, they anticipated how students would think about and solve the tasks, commenting on the instructions, the visual representations, ways the environment could be manipulated, the mathematical concepts in the tasks, and strategies students might use. For example, Group A attended to the instructions of the Pie Monster task (Figure 2), which represents whole number subtraction with various number choices.

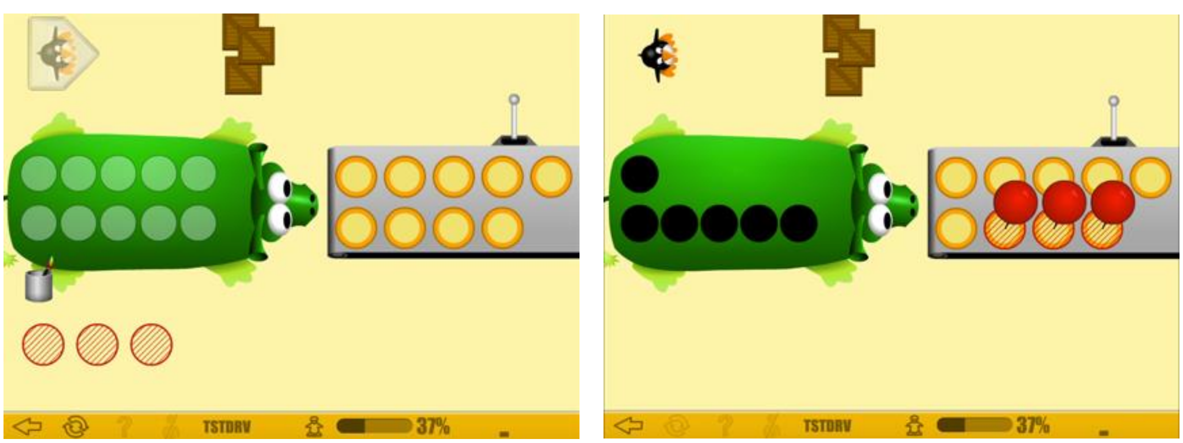

Figure 2: Problem Solving of the Pie Monster Task

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

This group noticed that the activity did not provide any instructions about how to play the game (this is a central design feature of ST Math). This unique feature of ST Math could lead to confusion about how to start and what they are supposed to do: "I feel like the game is simple but the instructions are not there and it can take them a while to figure out what numbers they need to subtract".

The initial attending pattern was expanded through one-to-one interaction with their student. PSTs attended to task structures, learning goals, verbal explanations, semiotic actions, gamified features, and situated context. For example, PST B reflected on her student's understanding of task structures:

> Something I noticed while asking him about the game is that...when the game changed from a result unknown problem to a change unknown problem, he recognized that shift in mathematical concepts.

Since there are various levels in one task, students should be engaged in multiple problem structures with a similar context. PST B attended to this transitioning of tasks and the mathematical structure of the Pie Monster task.

Interpreting Children's Thinking

Interpreting includes reasoning about children's strategies and comprehending their understanding based on details (Jacobs et al., 2010). PSTs' initial interpretations focused on how children might make sense of the tasks, what mathematical concepts they might engage with, how they might make a connection between a concept and the ST Math representation, and what prior knowledge might be required. For example, Group C anticipated a possible way to use sense-making when students solve the Pie Monster task: "Some kids might know how to visually play the game but not understand that they are actually doing subtraction." This group of PSTs anticipated that students might use the visual representations to solve the task without understanding the embedded mathematical concepts (e.g., subtraction).

In the reflection paper, PSTs' interpretations of student thinking included descriptions of how students solved the tasks, how they engaged with different representations, and how the sequence of the tasks impacted students' approaches. For example, PST D noticed the progression of her Math Buddy's strategies. The students used a guess-and-check strategy at first, but this strategy had changed to a counting strategy over time:

> She was beginning to use other strategies that weren't simply guess-and-check, such as counting on. She counted the red circles, then found that amount in the yellow circles. She then counted the yellow circles that were left to find the answer.

PSTs articulated how students' solutions to the ST Math tasks, including their actions and explanations, revealed evidence about their understandings.

PSTs' Evaluations of ST Math

Our data revealed that PSTs' evaluations of the ST Math activities were, in some cases, more negative after engaging in them with students. In other cases, they were more positive, and in the other cases, the evaluations appeared similar.

Increased negative evaluations. Seven PSTs had a positive evaluation based on their initial explorations, but during their interactions with children they began to question whether some features were likely to foster mathematical thinking relevant to targeted concepts. For example, PST E was positive about the potential of the How many Petals? task to develop place value concepts (Figure 3). The major mathematical idea in this task is to recognize 10 petals are the same as 1 flower and 10 flowers are the same as a bunch of flowers.

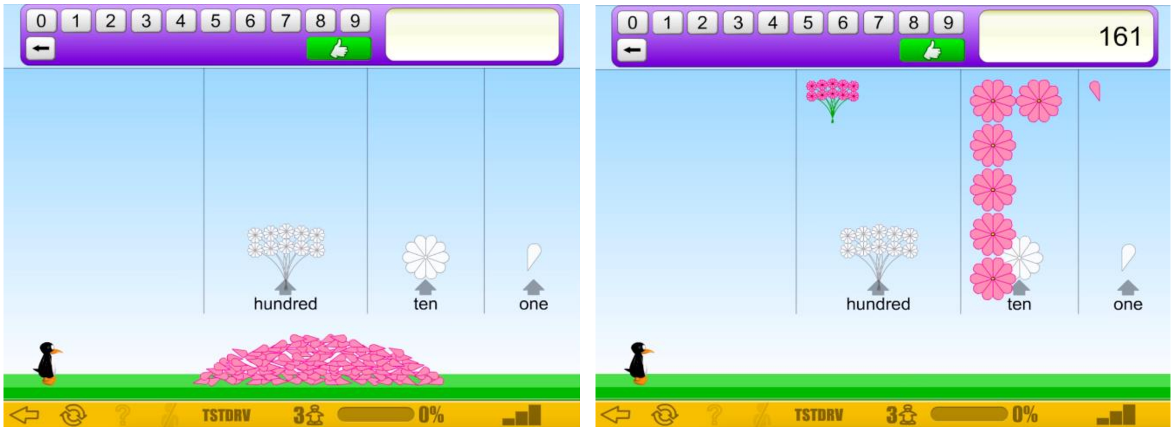

Figure 3: Problem Solving of the How many Petals? Task

PST E believed that the task could provide an opportunity to learn place value concepts (e.g., hundreds, tens, ones): “I think that the students can learn that they need 10 petals to make a flower and that they need to know how many flowers they have.” However, he noticed that his student was able to get the right answers by just tapping the columns repeatedly, and did not demonstrate an understanding of the relationship between different places.

> *PST E*: [Before solving the second problem] So on this one you explain all your thinking out loud and how you do it. So, what’s the first thing you do?
> *Math Buddy [MB]*: So, like if there is a big pile you press tens. These are all tens. And then or if you have not enough tens press ones.
> ...
> *PST E*: [At the third problem] Basically you just keep pressing tens until you run out.
> *MB*: Yeah.
> ...
> *PST E*: [At the final problem] What are you learning on this game you play? So, what do you learn when you do this?
> *MB*: I don’t really know.

Even though the student completed the task successfully, he was not sure what he was learning from the ST Math activity. PST E noticed this lack of understanding of the mathematical concept:

> My understanding is that my buddy just counts the petals and that’s it. You can even hear him clicking on the tablet screen rapidly to get rid of as many petals as you can. To me, there isn’t much learning going on during this game, other than being able to identify where the hundreds, tens, and one’s value is.

Initially, PST E believed that tapping the counting button could help develop an understanding of the relationship between ones, tens, and hundreds. However, when working with his Math Buddy, he noticed that the student was able to mindlessly tap the button until the solution was represented as a number of bunches, individual flowers, and petals. This made him evaluate the ST Math activity negatively ("isn't much learning going on").

Increased positive evaluations. Two PSTs had the opposite shift from a negative evaluation of ST Math to somewhat more positive evaluation, though these were sometimes the result of relatively sophisticated reasoning. For example, PST F initially criticized the *How many Petals?* task, anticipating that students might not use mathematical thinking: "The kids do not really have to do much thinking; they just need to memorize the different flowers." However, after she saw her Math Buddy demonstrate strong understanding in her explanation for why certain ones go in the tens column and others in the ones column, her evaluation was more positive:

> This leads me to believe that she was thinking mathematically rather than just playing the game without thought… I think that she does better at ST math because it is easier for her to visualize, as she uses direct modeling as her primary strategy for solving problems… I do not think ST Math should be discounted, it seems to be a big help for students to refresh on previously learned material.

PST F modified her evaluation of ST Math, focusing on its potential to "refresh on previously learned material." Indeed, the child appeared to be bringing her understanding of place value concepts to the task rather than developing it through the activity. The PST noticed this, and remained negative about its potential to "help students learn new material." Though the PST's evaluation is somewhat softened, we argue that the response shows a fairly sophisticated evaluation that includes some skepticism despite the child's "success."

Consistently negative. Our analysis showed three PSTs remaining consistent in their evaluations of ST Math. For example, PST G initially expressed the concern that her Math Buddy might use only an unsophisticated "counting by ones" strategy, "Because they can always count single units within the 10 petals, so as long as they can count by 1's they can finish the levels." When working with her Math Buddy, however, PST G noticed that the student focused on getting a right answer only without considering other strategies: "She seemed to just pick up patterns of how to pick out the correct answers and numbers to move to the next problem…. I do not believe that there is any strategy of solving the problem besides counting."

PST G was also worried about her student's misconceptions since it was possible to get the correct answers without understanding the base 10 structure of the petals representation: "It also may give students the impression that they understand the content just because they are able to find the pattern of the game and fill in the rest of the answers."

Consistently positive. Only one PST was included in this category. This PST kept evaluating ST Math positively. For example, she expected her Math Buddy to understand and use the relationship between multiplication and division embedded in the given pictorial model (e.g., dots, boxes) in the Building Expressions task (Figure 4). She initially appreciated the potential of the tasks, writing, "Students get to see a visual representation of every step of the multiplication and division process, furthering their understanding."

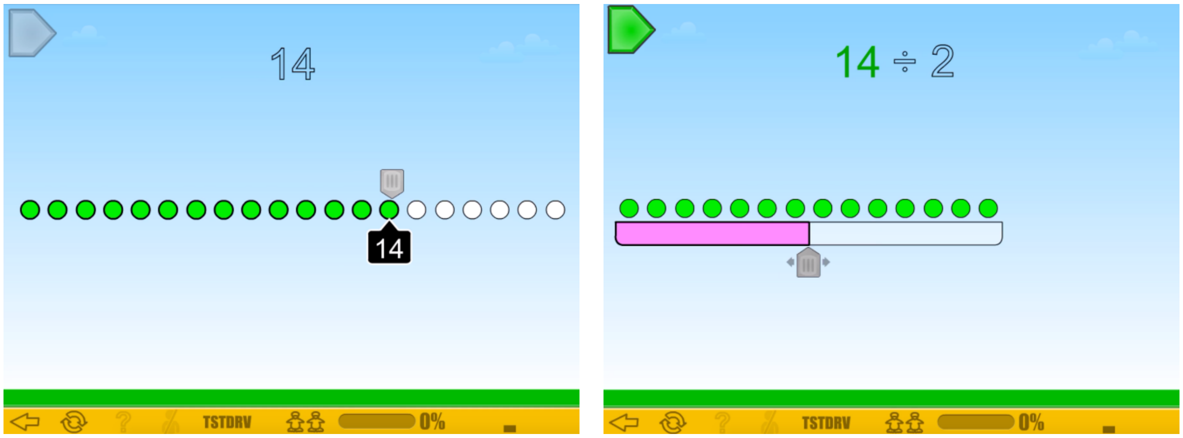

Figure 4: Problem Solving of the Building Expression Task

During the interview, PST H noticed her Math Buddy expressing more of his understanding with ST Math tasks, and eventually concluded that ST Math could provide good opportunities for children to engage in mathematical concepts and thinking: “When working with my Math Buddy I realized that ST Math reveals more about his thinking and understanding than story problems…This allows him to focus on showing his understanding of multiplication and division, or any other concept he is working on, instead of focusing on the words in a word problem.” Perhaps because her Math Buddy was an emerging English Language Learner, the PST interpreted his work in ST Math as evidence that the visual representation could support his mathematical understanding better than story problems.

Discussion

In this study, our data show PSTs’ attending to and interpreting student thinking during the use of ST Math tasks. Furthermore, we saw evidence of PSTs’ drawing on their noticing of student thinking in their evaluations of the ST Math tool, in some cases coming to different conclusions from their original evaluations, prior to working with students (e.g., PSTs E and G). Often, these conclusions were based not just on whether children were able to complete the tasks and answer with correct answers, but rather how they were thinking about the mathematical ideas embedded in the tasks (Dick & Hollebrands, 2011; Pea, 1985). This raises the possibility that developing noticing skill, in general, might help PSTs be better consumers of technology, especially if they are asked to evaluate tools while simultaneously attending to student thinking.

Notably, many PSTs were positive about the *Building Expression* task after the exploratory activity, explaining that the task seemed accessible and helpful in developing the concept with broken-down visual models. However, most changed their evaluation after engaging with students and seeing them struggle to make sense of the connection between the symbolic and quantitative representations. One possible implication is that interactions with real children, with whom PSTs have relationships, can stimulate critical reflection on the value of learning experiences, including those involving new technologies.

We illustrated PSTs’ attending and interpreting using example of ST Math tasks. These data extend earlier studies (e.g., Smith et al., 2018) to use field experiences in elementary schools for the development of technological noticing skills. We were encouraged to see several PSTs take a critical perspective on the use of technological resources based on their noticing of children’s mathematical thinking. We believe that starting with a tool (ST Math) that preservice teachers see in their placement classes increases the relevancy of the activity, and helps us better understand how noticing children's thinking influences their evaluations. We also realize the limitation of this single case would not represent all technological resource and need further studies to investigate the impact of different types of tools.

janewton@purdue.edu

Although research and policy documents provide recommendations to inform secondary mathematics teacher preparation, no single study has addressed the "big ideas" of courses in multiple programs and how those big ideas may be interpreted through the lens of recent research and policy documents. To answer this need, we focused on big ideas and course objectives from three courses (i.e., Linear Algebra, Secondary Mathematics Methods, and Teaching in a Diversity Society) taught in four secondary mathematics programs. Major themes emerged related to mathematical content, pedagogy, and issues of equity. We describe findings related to big ideas, course objectives, and their connections to recommendations from current policy documents. Such integration contributes to promoting dialogue related to the preparation of mathematics teachers and informing teacher educators.

Keywords: Preservice Teacher Education, Linear Algebra, Equity

Given the challenges that future mathematics teachers will face in supporting their students for successful learning, preservice teachers (PSTs) must be guided by quality instruction to meet these challenges (Association of Mathematics Teacher Educators [AMTE], 2017). Extant research has addressed aspects of knowledge that teachers need to develop related to both content and pedagogy (e.g., Ball, Thames, & Phelps, 2008; Fuson, Kalchman, & Bransford, 2005). Specifically, teachers need preparation that "covers knowledge of mathematics, of how students learn mathematics, and of mathematical pedagogy that is aligned with recommendations of professional societies" (National Research Council [NRC], 2010, p. 123). Recent policy documents have been written by mathematicians, mathematics educators, and teacher educators to focus on: (a) how secondary mathematics teachers should be prepared (e.g., National Council of Teachers of Mathematics [NCTM], 2014; AMTE, 2017), (b) how mathematics should be taught---to future teachers or any undergraduates (e.g., Mathematical Association of America [MAA], 2018; NCTM, 2014), and (c) how university instructors should address issues of equity and access to mathematics, and communicate these issues to future teachers (e.g., AMTE, 2017; MAA, 2018; NCTM, 2000; 2014). Little is known about how such recommendations are incorporated into programs of study in mathematics for teachers (NRC, 2010). Although these policy recommendations inform secondary mathematics teacher preparation, no single study has addressed the "big ideas" of courses in multiple secondary teacher preparation programs and how these big ideas are interpreted through the lenses of recent research reports and policy documents (e.g., AMTE, 2017; Ball et al., 2008; Fuson et al., 2005; MAA, 2018). This paper utilizes data from a larger study that administered a national survey and conducted case studies to describe opportunities that secondary mathematics preparation programs provided for PSTs to learn about mathematical content, teaching practices, and issues of equity. In this study, we examined three courses required at four universities (i.e., 12 courses) to address the following question: *How do course goals and big ideas of courses in secondary mathematics teacher education programs emphasize areas related to content and teaching practices necessary for future mathematics teachers as recommended by policy documents?*

Relevant Literature

The teaching and learning of mathematics for K-16 students has been studied extensively, leading to detailed conceptualizations and descriptions of essential mathematics content and student experiences. To develop our framework for this study, we examined several national policy documents (e.g., AMTE, 2017; MAA, 2018; NCTM, 2000; 2014).

The authors of MAA's (2018) *Instructional Practices Guide* argued that "professional associations in the mathematical sciences along with state and national funding agencies are supporting efforts to radically transform the undergraduate education experience" (p. vii). The guide provided overviews and vignettes of effective mathematics teaching practices for undergraduate mathematics faculty. The introductory manifesto argued that mathematics instruction should incorporate experiences that allow access to rich and deep mathematics for all students, which requires ongoing change and attention to classroom, assessment, and task design practices.

The standards described in AMTE (2017) inform the preparation of preservice mathematics teachers, including "clearly articulated expectations for what well-prepared beginning mathematics teachers need to know and be able to upon completion of a certification or licensing program and the recommended characteristics for programs to support teachers' development" (p. xii). AMTE built on existing research (e.g., Ball & Forzani, 2011; Hill, Rowan, & Ball, 2005; Shulman, 1986) and policy documents (e.g., NCTM, 2000; NCTM, 2014). For example, AMTE (2017) stated that learning to teach mathematics requires deep understanding of the content they will teach, knowledge of how students reason about mathematics, knowledge of instructional approaches that support students' mathematical learning, and awareness of the societal context in which the content is used in students' everyday life. Similarly, several researchers proposed the importance of knowledge related to mathematical content, student thinking, and instructional approaches (Ball et al., 2008; Hill et al., 2005; Shulman, 1986), as well as the societal context in which mathematics is taught (Turner, Celedón-Pattichis, Marshall, & Tennison, 2009).

Teaching for access and equity is emphasized by researchers and professional organizations, including AMTE (2017), MAA (2018), and NCTM (2000). AMTE, for example, highlighted the importance of equity as the first of five foundational assumptions about mathematics teacher preparation, stating "Although equity, diversity, and social justice issues need to be specifically addressed as standards, they must also be embedded within *all* the standards…we believe that equity must be both addressed in its own right and embedded within every standard" (p. 1). Similarly, NCTM (2000) emphasized equity as the first "principle," highlighting the critical importance of ensuring *all* students have access to mathematics programs that provides quality instruction. MAA (2018) also emphasized inequities existing in our society, encouraging instructors to provide mathematics instruction that increases access to all students. While these standards provide recommendations for mathematics educators to shape their courses, little is known about how these recommendations are enacted in specific mathematics, mathematics education, and general education courses in secondary mathematics teacher education programs.

Method

As part of a larger study, we conducted a series of interviews in secondary mathematics teacher education programs at four universities: Great Lakes University (GLU), Midwestern Research University (MRU), Midwestern Urban University (MUU), and Southeastern Research University (SRU); the institutions were chosen based on the diverse nature of their student populations, the types of communities in which they were situated, and the departmental homes of their secondary mathematics education programs. At each university, the research team selected approximately ten required courses in the secondary mathematics teacher education program based on the likelihood that each course would offer students opportunities to learn algebra content and/or to learn to teach algebra; courses included mathematics, mathematics education, mathematics for teachers, and general education courses. For the purpose of this paper, we examined one Linear Algebra course, one Secondary Mathematics Methods course, and one General Education course related to teaching in a diversity society required at each university.

For each course, we collected a syllabus and interviewed an instructor. We asked each instructor, "What are the goals or big ideas of this course?" For mathematics content courses, we asked a follow-up question, "Do you do anything specific in this course to help prepare future mathematics teachers?" We analyzed course goals and big ideas as reported in the interview and written in corresponding course syllabi under "Course Objectives" or "Course Goals." To clarify statements from the big ideas question and course objectives, at times we examined other elements of a course syllabus or responses to follow-up questions.

To answer our research question, multiple policy documents (e.g., AMTE, 2017; MAA, 2018; NCTM, 2000; 2014) were reviewed by the three authors. We also examined instructor responses from interview transcripts and text from corresponding syllabi, noting emergent themes that were common and different across the courses (Creswell, 2007). We focused on emergent themes that related to recommendations in policy documents. We compared themes to summarize similarities and differences between course objectives in syllabi and instructor responses to interview questions. After writing a summary of responses, we iteratively reviewed their original responses, considering what they reported through the lens of selected policy documents.

Findings

We present findings from each course type in this section: linear algebra, secondary mathematics methods, and teaching in a diverse society. We compare similarities and differences between reported big ideas and course objectives, through the lens of policy documents.

Linear Algebra

The four Linear Algebra instructors understandably described their big ideas, their goals for Linear Algebra, in similar ways. For example, instructors reported focusing on: moving from or between concrete mathematical situations and abstractions (MRU, SRU); studying systems of linear equations and their solutions (GLU, MUU, SRU); eigenvectors, eigenvalues, and eigenspaces (GLU, MUU, SRU); computational applications (MRU, SRU); and learning ideas that are needed in other areas of mathematics and other disciplines (GLU, MUU, SRU). In this section, we describe how the four Linear Algebra instructors reported their intended classroom practices, assessment practices, and course (and task) design practices.

Three of the instructors (GLU, MUU, and SRU) described their modeling of teaching strategies that they believed teachers might notice and use in their own teaching. The GLU instructor explained that in his department, the culture is that mathematicians and mathematics education specialists work well together so he incorporated teaching strategies to be consistent with experiences in pedagogy courses. The MUU and SRU instructors felt their teaching strategies would implicitly support future teachers. Instructors' responses revealed intended instructional practices.

MAA (2018) described several strategies to support access to mathematics for all students through classroom practices. We focused on the use of groupwork, supporting productive struggle, and supporting critical thinking and reasoning. MAA strongly recommended use of small groups as a strategy for collaborative learning. In his syllabus, the GLU instructor urged students to work together on homework. He reported using groupwork extensively in the course, saying that students worked in small groups on activities to consolidate ideas, foreshadow ideas, or discover concepts. MAA described practical tips for supporting productive struggle, practice that is essential in mathematics. In alignment with these goals, the MUU instructor described his structure of class sessions as "lively," with spontaneous discussions of student questions and struggles: “going through the challenges that they also went through and showing how they have overcome that.” MAA described strategies for “responding to student contributions in the classroom,” especially “creating a safe space for incorrect answers” and “focusing on reasoning” (pp. 5-6). The SRU instructor described that he pushed all of his students to explain their reasoning with a focus on explanations, proofs, counter-examples, and holding students accountable for addressing the why rather than just stating facts.

MAA (2018) recommended using multiple forms of assessment, including formative assessment cycles and summative assessment when appropriate. In their syllabi, instructors described their assessments as including: three exams and a final exam (all), weekly homework (GLU, MRU, SRU), weekly quizzes (GLU, MRU, MUU), and computer lab activities (GLU). Although neither assigned points for student journaling, the MUU and GLU instructors reported that they encouraged students to write mathematical journals. The MUU instructor’s syllabus did not indicate his expectation for writing journals; however, he reported that, in the beginning weeks of the course, he frequently told students when certain ideas from their homework or class notes should be written in their journals. After several weeks, he said he would stop pointing out these ideas, expecting students to take ownership of their needs for the journals. The GLU instructor gave a clear description of expectations for mathematical communication and his expectation for students to keep “a well-organized record of all your study notes and completed problems for future reference.”

Providing clear learning goals to students is recommended as a course design practice in MAA (2018). In his syllabus, the MUU instructor listed clear learning goals for students that included attention to content and process; for example, “Be able to apply some technology...to facilitate problem solving.” Regarding task design, MAA drew on Stein et al. (1996) to recommend that students have opportunities to engage in high-level tasks that allow multiple solution strategies: “there is not a predictable, well-researched approach or pathway explicitly suggested by task instructions” (p. 31). MAA also drew on Boaler (2015) to recommend that instructors open tasks to provide open learning spaces using several strategies, including “open the task up to multiple methods, pathways and representations” (p. 40). The GLU instructor reported that he modeled valuing mathematical processes and encouraged students to recognize the potential for alternative, and equally valid, solutions or approaches.

Secondary Mathematics Methods

The four secondary mathematics courses share commonalities and differences in their big ideas. Common features of these courses included the practices of planning and implementing mathematical lessons, analyzing students’ mathematical thinking, and exploring instructional materials. While three courses (GLU, MUU, SRU) focused more on pedagogical content (e.g., learning to assess student learning or identify appropriate questions), the MRU course centered around the reconstruction of school mathematics (e.g., ratios and proportional reasoning, integers) to envision how PSTs would communicate mathematically with their students. In this section, we describe how these secondary mathematics methods instructors provided opportunities for PSTs to develop knowledge and practices.

Most secondary mathematics courses involved field experience components that required the design and implementation of lesson plans. AMTE (2017) recommended that effective secondary preparation programs provide PSTs with multiple opportunities to learn to teach through clinical experiences with coherent, developmentally appropriate contents. The GLU instructor, for example, mentioned a big idea addressing this recommendation: “We spend a great deal of the semester focusing on this cycle [teaching-learning cycle]… you start developing plans…then you implement the plans and then the cycle goes around.” Similarly, the SRU instructor emphasized planning and implementing mathematical lessons as a big idea. PSTs in her course had the opportunity to learn about facilitating classroom discourse and using appropriate instructional strategies in the field, while they concurrently took a methods course in which they discussed and reflected on relevant readings. Learning about teaching through the design of instruction addresses the knowledge of content and teaching (Ball et al., 2008), one of the domains of mathematical knowledge for teaching. In selecting and implementing tasks for teaching, orchestrating effective classroom discussions is essential. PSTs pose purposeful questions to probe students’ mathematical ideas and make mathematical structures visible (NCTM, 2014).

While PSTs designed, implemented, and reflected on their lessons, instructors intended that PSTs develop their understanding of student thinking. Anticipating what students are likely to think about mathematics is relevant to knowledge of content and students (Ball & Forzani, 2011; Ball et al., 2008; Shulman, 1986). AMTE (2017) recommended that well-prepared PSTs are committed to deepening their knowledge of students’ mathematical skills and dispositions. The GLU instructor addressed this need: “As you are talking to the student [during implementing your lesson plan], what information did you gather, what did it tell you about, and then what support did you need to provide as a result of that?” Similarly, the MUU instructor provided PSTs with the opportunity to interview a middle or high school student to ascertain the student’s beliefs about mathematics and knowledge of a particular mathematical topic. PSTs were to develop a series of questions and performance-based tasks that they would pose to the student during the interview. In a writing report, PSTs would describe the student’s mathematical knowledge and beliefs based on their analysis of data gathered during the interview.

All instructors incorporated opportunities for PSTs to explore a variety of instructional materials. AMTE (2017)’s standards address this opportunity that well-prepared preservice teachers analyze and discuss curriculum and standards documents. Knowing about appropriate instructional materials and their characteristics is an essential teacher knowledge to be developed (Ball et al., 2008; Hill et al., 2005). The GLU secondary mathematics methods instructor included a goal that addressed this knowledge: “to acquaint the teacher assistant with available instructional resource materials such as curricula, professional journals, and relevant research.” The MUU instructor also described a specific activity PSTs engaged in during the semester, in which they explored and critiqued textbooks. She said, “I have them look at materials [the traditional course sequence versus integrated math courses] and evaluate them, and that’s the subject of again, usually a class discussion about what they think the opportunities are that are afforded by these textbooks, versus traditional textbooks, the challenges of teaching math in this way.” PSTs in her course then observed the way integrated math curricula were being taught and evaluated the implementations of the curricular.

While all four courses emphasized PSTs' development of pedagogical content knowledge, a course offered by MRU emphasized PSTs' development of specific mathematical contents for teaching. AMTE (2017) stated that learning to teach mathematics requires "a central focus on mathematics" (p. 2) and flexible knowledge of school mathematics. The MRU secondary methods course was the only course among the four in which developing specific school mathematical concepts was a course objective. The syllabus highlighted: "The mathematical topics that we will examine are ratios and proportional reasoning,...and quadratic relationships and factoring. These are BIG ideas in middle school and early high school mathematics, and they are important for reasoning algebraically." PSTs in this course were asked to keep a three-ring binder of problems exemplifying these topics. The instructor stated in her syllabus, "One of your greatest assets in understanding students' mathematical thinking is understanding and deepening your own mathematical thinking." PSTs generated mathematical conversations with each other, reflected on their own mathematical knowledge around these mathematical concepts, and used their mathematical knowledge to design problem sequences for students. They submitted the binder of problems to receive feedback and points for thoroughness, organization, explanations and analysis of targeted problems, quality of problem sequence and discussion, and mathematical correctness.

Teaching in a Diverse Society

Each of the four SMTE programs under review required a course related to diversity; the title of this course varied across program, however to protect anonymity, we gave all courses the generic title: Teaching in a Diverse Society (TDS). What was common across these courses was that they were general education courses, taught by female instructors who were not associated with mathematics or mathematics education; therefore, the curriculum was not subject-specific and students from multiple education disciplines enrolled simultaneously. Several themes emerged from TDS course big ideas and objectives provided by the instructors.

First, the instructors emphasized their attention in the course to highlighting the vast number of ways in which diversity is present in the United States; all instructors highlighted multiple aspects of diversity. For example, when the SRU TDS instructor was asked about the big ideas of the course, she said "we talk about race and ethnicity; we talk about class, gender and sexual identity, exceptionality, like special needs students. We talk about language, geography, religion. And really, my goal at the end is that students would…be ready to teach in a diverse environment." No one aspect of diversity was mentioned in all four TDS courses; however, race, culture, ethnicity, religion, sexual orientation, ability, and language were each mentioned in three of the four courses. The second theme emphasized across the TDS courses was the idea that schools are situated in historical, socio-political, and geographic contexts. For example, the MUU instructor emphasized the local context, including "Understand the impact of family and community in the learning experiences of English language learners in the classroom" as a course outcome. Taking a more national approach to context, the GLU instructor stressed the importance of PSTs' "understanding how their work in the classroom and in the schools is a part of democratic practice in the United States."

The third and most prevalent theme highlighted across the TDS courses was the impact of diversity (theme 1) and historical, socio-political, and geographic contexts (theme 2) on educational opportunities in particular schools and for particular learners. TDS instructors highlighted strategies they used to attempt to mitigate these effects. For example, the MUU instructor discussed opportunities that she offered for PSTs to engage in investigating students' school experiences, including reading and discussing articles such as *Nothing to Do: The Impact* *of Poverty on Pupil's Learning Identities* (Muschamp, Bullock, Ridge & Wikeley, 2009) and *Barbie Against Superman: Gender Stereotypes and Gender Equity in the Classroom* (Aksu, 2005). In addition, the PSTs analyzed U.S. federal laws developed to ensure all students access to education (e.g., Individuals with Disabilities Education Act [IDEA], McKinney-Vento Act [protects the rights of homeless children]).

Several TDS instructors also mentioned critical reflection as an important activity for PSTs in developing dispositions and skills for teaching diverse learners; the MRU instructor made this focus on reflection explicit in her syllabus: "We will explore various realms of diversity…As part of that exploration we will engage in significant reflection, written and oral, personal and collective, challenging our assumptions, and questioning our beliefs." Similarly the GLU course was described as: "grounded in the idea that an essential aspect of good teaching is having the time and space to reflect upon the kinds of issues that impact your pedagogy and instruction."

The attention to the impact of diversity and contextual factors on educational opportunities reported by TDS instructors is well supported by professional mathematics and mathematics education organizations, including AMTE, MAA, and NCTM. In fact, attention to historical inequities in mathematical learning opportunities is highlighted front and center in NCTM (2000) as the first "principle," in AMTE (2017) as "Assumption #1," and in the Manifesto of MAA (2018). NCTM (2000) expressed concerns about pervasive low expectations and tracking practices, and less challenging mathematics curriculum for "students who live in poverty, students who are not native speakers of English, students with disabilities, females, and many nonwhite students" (p. 13). They highlight engaging curriculum, use of technology, enhanced assessment practices, and increased attention to mathematics processes (beyond memorization and symbolic manipulation) as possible mitigators to increase equity in mathematics classrooms.

AMTE (2017) took a similarly strong stance toward the need for teacher education programs' commitment to preparing teachers who have the skills and dispositions to teach all learners: "Assumption #1: Ensuring the success of each and every learner requires a deep, integrated focus on equity in every program that prepare teachers of mathematics" (p. 1). The authors repeatedly emphasized the disparate opportunities resulting from historic discrimination and sociopolitical factors, and stressed the importance of preparing teachers who are advocates for their students with these disparities in mind: "Well-prepared beginning teachers embrace and build on students' current mathematical ideas and on students' ways of knowing and learning…They also attend to developing students' identities and agency so that students can see mathematics as components of their cultures and see themselves in the mathematics" (p. 13). The authors recommend opportunities for PSTs to critically analyze current mathematics education systems, challenge deficit views about student learning, recognize the key roles that identity and power play in mathematics education, and spend time in community settings to learn from and about students, families, and communities.

MAA (2018) continued this call for first, recognition that these systemic inequities exist, and second, action to change the status quo: "Inequity exists in many facets of our society, including within the teaching and learning of mathematics...We owe it to our discipline, to ourselves, and to society to disseminate mathematical knowledge in ways that increase individuals' access to the opportunities that come with mathematical understanding" (p. vii). The authors describe the statistical disparities of underrepresented populations among both mathematicians and university students in mathematics departments, and encourage instructors to beware of implicit and explicit messages being sent to students about who "belongs" in mathematics.

Discussion & Implications

Although recent policy documents provided recommendations about how secondary mathematics should be prepared to learn about mathematics, mathematics teaching, and equity issues in mathematics teaching and learning (AMTE, 2017; MAA 2018; NCTM 2000; 2014), little is known about how such recommendations are integrated into mathematics teacher education programs (NRC, 2010). To promote dialogue related to the preparation of secondary mathematics teachers, this study highlighted ways in which course goals and big ideas in secondary mathematics teacher education programs emphasized areas related to mathematics learning, teaching, and issues of equity and access as recommended by policy documents.

Across all course types, we noticed that many policy and research recommendations were addressed, both explicitly and implicitly. In fact, many of the "big ideas" reported with closely related to these recommendations. For example: The GLU Linear Algebra instructor pointed to the strong mathematics-mathematics education community in his department as leading him to experiment with multiple teaching strategies that he hoped would align with his students' future teaching needs. The MRU secondary mathematics methods course centered around the reconstruction of school mathematics, such as proportional reasoning and integers, to address PSTs' development of big mathematical ideas for teaching. The MUU TDS instructor provided opportunities for PSTs to engage with their students' families and communities.

In this study, we confirmed that, although the four universities required similar versions of these three courses (i.e., Linear Algebra, Secondary Mathematics Methods, and Teaching in a Diverse Society), the courses were also unique. Therefore, the experiences of PSTs across these programs will be different, likely as a result of many factors, including geography, program emphases, and priorities of the course instructor.

This study is intended both to build on existing research (e.g., Ball et al., 2008; Fuson et al., 2005; Hill et al., 2005; Turner et al., 2009) and policy documents about mathematics teacher preparation (e.g., AMTE, 2017; MAA, 2018; NCTM, 2000) and to encourage researchers to explore areas that are less well investigated. We acknowledge that creating programs that are coherent across multiple departments and disciplines is often a challenge. We wonder what creating a culture of communication among the dozens of faculty who support future teachers at each university would look like. We wonder how such a culture could naturally build coherence by discussions asking: What are the big ideas of our program? What are the fundamental ideas we want threaded throughout the program? How do we ensure that students have multiple opportunities to encounter these ideas, building on each other, through the program?

From the findings of this study, next steps would include an investigation of how big ideas play out in written curriculum (e.g., textbooks, course materials, other resources) and enacted curriculum (e.g., classroom instruction) as well as an investigation of how PSTs perceive the opportunities provided throughout their secondary mathematics teacher education programs. What would be the benefits of an in-depth exploration of each of our programs? How would such a conversation get started? How would it be sustained? For example, from a stance of equity, how might TDS instructors interact with mathematics and methods instructors to stimulate conversation about opportunities for discipline-specific, equity-related experiences?

Integration between course goals and policy documents contributes to promoting dialogue related to the preparation of secondary mathematics teachers. Our study presented here, connecting big ideas of multiple courses with recommendations from research and recent policy documents, promises to inform teacher educators, especially those who are new mathematics teacher educators in the field. Future work analyzing our larger data will provide insights into how other areas of recommendations from policy documents play out in practice; this current work is an initial step to illustrate big ideas of required courses commonly offered by the four case study universities.

CASES OF LEARNING TO RESPOND TO ERRORS THROUGH APPROXIMATIONS OF LEADING WHOLE-CLASS DISCUSSIONS

Erin E. Baldinger
University of Minnesota
eebaldinger@umn.edu

Matthew P. Campbell
West Virginia University
mpcampbell@mail.wvu.edu

The emerging use of approximations of practice in teacher education calls for ways to document teacher candidates' (TCs') skill from their enactments and to determine how TCs' skill develops through such pedagogies. We highlight two cases of secondary mathematics TC development, connecting analyses of two types of approximations—coached rehearsals and scripting tasks—with a focus on the practice of responding to errors in whole-class discussion. Each case illustrates a distinct example of TC development. This work contributes to the research on pedagogies of practice in teacher education by offering approaches for understanding TC practice and development through multiple data sources.

Keywords: Teacher Education-Preservice; Instructional Activities and Practices

The use of approximations of practice (Grossman et al., 2009) in teacher education offers a promising way for teacher candidates (TCs) to develop skill with key aspects of the work of teaching. There exists the need to document TCs' skill from their enactments and to identify the way in which TCs' skill develops through such designs (Janssen, Grossman, & Westbroek, 2015; Shaughnessy, Boerst, & Farmer, 2019). In this paper, we connect analyses of two types of approximations—coached rehearsals and scripting tasks—to investigate the relationships between learning opportunities and evidence of learning captured across time. We use two cases to illustrate what can be learned about TC development through these multiple data sources.

Literature Overview

Leading whole-class discussions is complex work. It includes eliciting, responding to, and building upon student contributions in ways that move the discussion toward mathematical goals (Boerst, Sleep, Ball, & Bass, 2011; Leatham, Peterson, Stockero, & Van Zoest, 2015; Sleep, 2012). While errors—contributions that are incomplete, imprecise, or not yet correct—are key to students' learning process (Brodie, 2014), they are often positioned negatively when teachers quickly correct them or avoid them entirely (Bray, 2011; Santagata, 2005; Tulis, 2013). This can potentially remove opportunities for students to make sense of errors. During whole-class discussion, teachers must also balance the needs of the student who contributed the error with the needs of the rest of the class, who may or may not share that student's conception. For these reasons, we focus on this practice in our work investigating TC learning.

Coached rehearsals, an approximation of practice, can afford opportunities for TCs to develop a vision of ambitious and equitable practice; understandings of students and content; dispositions regarding students, content, and teaching; and a repertoire of practices and tools (Ghousseini & Herbst, 2016). In this approximation, one TC takes on the role of teacher while other TCs take on the role of the students, and the teacher educator provides in-the-moment coaching (Kazemi, Franke, & Lampert, 2009). TCs engage in the interactive work of teaching, such as making sense of and responding to student reasoning during discussion. TCs' enactments during approximations of practice also provide a lens for teacher educators and researchers to assess TCs' developing skill and their coordination of approaches and goals.

We also use "scripting tasks" as an approximation that puts TCs in a position to make sense of and respond to student reasoning. In designing these tasks, we draw on research around scripting classroom interactions (Crespo, Oslund, & Parks, 2011; Zazkis, 2017). TCs are presented with a classroom scenario and then demonstrate, through written dialogue, how they might continue the discussion. These dialogues represent, in part, TCs' imagined response to a particular student contribution. They also represent TCs' sense of how students might contribute further, giving insight into TCs' view of what is reasonable or desirable in a classroom episode.

Perspective on Teacher Learning

Hammerness and colleagues (2005) assert that teachers must be supported in learning communities and enabled to develop tools and practices, vision and dispositions, and understandings. This framework guides our research on TC learning through approximations. Tools and practices encompass a sense of when, where, why, and how to do the work of teaching. Vision represents teachers' sense of where they are going and what is possible in teaching, which are connected to dispositions, which relate to commitments toward professional growth and inquiry into practice. Understandings represent a teacher's deep knowledge of their subject and how to make it accessible to others, including knowledge of how students learn and develop particular ideas. Taking this perspective, we ask the following research question: What forms of TC learning are evident through their work with multiple approximations of practice? In particular, we focus on evidence of TCs' practices and vision as they develop over time.

Methods

Our work is the product of an ongoing, multi-year collaboration situated in secondary mathematics methods courses at two large, public research institutions. At "Institution A", TCs are enrolled in the methods course as part of a yearlong post-baccalaureate licensure program. TCs from "Institution B" are enrolled in a shared methods course across multiple programs. At both sites, TCs completed the scripting task (Baldinger, Campbell, & Graif, 2018a) twice: early in the methods course ("Initial") and then again near the end of the course ("Follow-up"). The scripting scenario we highlight in this paper depicts whole-class discussion around a sorting task (Baldinger, Campbell, & Graif, accepted), where students are asked to sort shapes into examples and non-examples of polygons. The scenario concludes with a student, "Jessie," contributing an error. TCs are prompted to assume the role of the teacher and write a dialogue of how the conversation would continue. TCs also write a rationale for how they constructed their dialogues.

In between the two implementations of the scripting task, TCs participated in coached rehearsals of a sorting IA (Baldinger, Selling, & Virmani, 2016) focused on defining linear functions. For all rehearsing TCs, the mathematical focus and the sets of cards to be used were provided by the teacher educator, with common materials used across sites. In order to ensure that these rehearsals include opportunities for responding to errors, we used "planted errors" (Baldinger, Campbell, & Graif, 2018b). Non-rehearsing TCs contributed these instances of student thinking during the rehearsal, enabling the teacher educator to stay in the role of coach while providing more authentic student voice to the rehearsal. After a set of rehearsals, TCs completed reflections, in part through video annotation, which serve as additional data.

For this paper, we zoom in on the experiences of two TCs, one from each site, purposively sampled to represent the range of TC learning that might be visible through these different approximations of practice. We selected TCs who rehearsed one of the sorting IAs. From Institution A, we highlight the experience of Greg (all names are pseudonyms). Greg was often quiet during class discussions, and showed off his engaging personality during interactions with students. In his sorting IA, students were asked to sort graphical representations into examples and non-examples of linear functions. The planted error involved a student asserting that the graph of a vertical line ($x = 2$) was a linear function because it looked like a straight line.

From Institution B, we highlight the experience of Travis. He regularly exhibited thoughtfulness about the work of teaching in his contributions in the class. In Travis's sorting IA rehearsal, students were asked to sort tabular representations into examples and non-examples of linear functions. The planted error involved a student looking only at the change in the y-values in a table and concluding that the table did not represent a linear function because the change in y was not constant. However, the change in x-values was also not constant, and looking at the changes in x- and y-values together would reveal that the table did have constant slope.

Using the themes developed through our analysis of data from the larger study, we looked holistically across the data in each case for evidence of learning related to each aspect of framework for learning to teach (Hammerness et al., 2005). We considered features of each approximation such as the types of teaching moves used, the representations of student voice, and the way in which each TC attended to the mathematics. We investigated vision and dispositions through exploring TC reflections on their own practice. In presenting these findings, we aim to develop a picture of each case not for the sake of comparing the two cases, but rather to illustrate the range of learning captured across these different approximations of practice.

Findings

In this section we share the cases of Greg and Travis to provide two distinct images of TC learning, and two instances of how that learning can be documented through coordinated analysis across two distinct approximations of practice.

Trying New Practices, Changing Vision: Greg

Scripting task. Greg demonstrated some notable differences in his two responses to the scripting task polygon scenario (see Table 1). In the Initial dialogue, Greg first calls students' attention to the "extra line" in Shape J. This starts a series of funneling questions to get Jessie to quickly correct how shape J is sorted. In contrast, the opening move in the Follow-up dialogue asks for additional arguments in support of classifying shape J as a polygon.

Table 1: Greg's Initial and Follow-up Dialogues

Initial Dialogue		Follow-up Dialogue	
Teacher:	well what about this extra line here? Does it make a difference?	Teacher:	Who can tell me another reason why shape J is a polygon?
Jessie:	Idk, maybe	Student:	Like Rosalia said, all of the sides are straight.
Teacher:	What does it mean to be a square?		
Jessie:	All sides are equal length and opposite sides are parallel	Teacher:	Who can tell me why shape J might not be a polygon?
Teacher:	So does this fit the definition of a square?	Student:	There is that line in the middle so it is not really a square.
Jessie:	No, that line isn't parallel to anything	Teacher:	Can someone expand on what _____ just said?
Teacher:	So what can we say about it being	Student:	Well that segment has one end not

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

	a polygon?	meeting any other sides.
Jessie:	that it is not because that line only connects to that one edge and the other lines have to [*sic*] edges	

The Initial dialogue includes only conversation between the teacher and Jessie, making no effort to incorporate other students. In the Follow-up dialogue, though the students are not named, it is possible that up to three different students participate in these few turns of talk. Another interesting feature of the Follow-up dialogue is how it concludes without any move to lead students toward a conclusion. It feels much more like a snippet of a longer conversation, as opposed to the Initial dialogue, which feels in some ways like a completed conversation.

Greg's thinking about why he constructed the dialogues in this way also changed (see Table 2). At first, he intended to draw on the definition of a square in order to correct the sort and move the discussion forward. In contrast, on seeing this scenario for the second time, Greg focused much more on engaging other students. Though he acknowledged Jessie had incorrectly sorted shape J, correcting that error was no longer the focus of his dialogue.

Table 2: Greg's Initial and Follow-up Rationales

Initial Rationale	Follow-up Rationale
The student is having a misunderstanding to what a square is, so I believe it is important for them to re-think what a square is and modify what they are saying about Shape J. From there it might be easier for the students to recognize whether it is a polygon or not.	Well I would want other students to think about why it is possible for J to be a polygon, but then I would also want other students to explain why they think it is not a polygon. Although it is not a polygon I want students to be thinking about both reasonings.

Greg pointed out many of these differences himself. In reflecting on how his response to the scenario changed, he wrote, "My questioning is much different, I tried to expand more one the original ideas rather than going straight to finding the 'right' solution." Greg did not see his Initial responses when he wrote this, but his recollection is strikingly accurate. The shifts in his dialogues and rationale, along with this final reflection, suggest changes in Greg's practices related to responding to errors, as well as his vision for dealing with errors.

Rehearsal. Evidence of Greg's changing practices and vision of responding to errors is clear in his rehearsal. Greg was the second of three TCs to rehearse the sorting IA. The rehearsal included discussion of five cards: two easy-to-sort examples of a linear function, two easy-to-sort non-examples, and one boundary case. The planted error was the first card contributed. Greg responded to the error by experimenting with orienting moves: "It's a straight line. Alright, you are correct, it is a straight line. Does anyone agree with this? Who agrees with this?" After one student agreed, Greg said, "Alright, does anyone disagree with this?" Several students contributed some disagreements, and Greg restated and recorded their reasoning. He then checked back in with the group that originally contributed the error:

Teacher: Okay, interesting. So, going back to your group, what do you think about this? Does your opinion change?

Student: It doesn't because my idea of what a linear function was, was a straight line. And even thought that line is up and down, it is definitely straight, there's no curves.

Teacher: Sounds good. Alright, we'll leave that here for now. We can come back to it.

Greg experimented with a tabling move, allowing the disagreement among the class to go unresolved for the moment as he moved the discussion on to additional cards.

Greg's approach to responding to student thinking was relatively similar for the contributions without errors. He continued to experiment with orienting moves, seeking agreement and disagreement from students. He recorded student thinking and received feedback from the teacher educator about his practice. Later, students discussed the graph of a step function. Some argued that the step function was not a line, and the teacher educator inserted disagreement, saying that the step function had constant slope, and thus represented a linear function. Through this conversation, Greg helped the class discuss the vertical line test as a way to determine whether or not a graph represented a function, and that led to the following conversation:

Teacher: Can someone give me a reason that they disagree that it needs to pass the vertical line test in order to be a linear function?
Student 1: Yeah, because of Graph D [the vertical line graph] that we were talking about earlier. For that one to be a function.
Student 2: But it's not a linear function.
Teacher: But it's a nonlinear function?
Student 2: But it says it's a linear function.
Student 1: Oh yeah, we left it in a gray area. Bah. Alright.
Teacher: Going back to [Graph D], do we all agree that it needs to pass the vertical line test in order to be a linear function? [Some students nodding] Unless someone's going to disagree? Give voice to that? [Pause] So if we come back to this [Graph D], does it pass the vertical line test?

This exchange shows how Greg was able to revisit the planted error while keeping the focus on student thinking. Many of Greg's moves in the rehearsal are consistent with his Follow-up dialogue. Following the rehearsal, Greg reflected that he "learned better ways to facilitate discussions by using better questions." He felt that "The timeouts were quite helpful, as I was able to stop the lesson and go back and fix what I did wrong." This illustrates Greg's intentional work on questioning and his changing vision about how to best respond to errors in the moment.

Complexity in What Gets "Taken Up" from Rehearsals and Coaching: Travis

Scripting task. Travis uses similar moves in both dialogues, but they are used in seemingly more productive ways over time (see Table 3). For example, the Follow-up dialogue starts with an orienting move instead of a question probing Jessie's reasoning. Also, the third line of each dialogue elicits agreement (or disagreement), yet the move in the Follow-up dialogue is not focused only on Jessie's contribution. These changes show shifts in approaching the error—from something to be targeted to something that is part of a broader conversation.

Table 3: Travis's Initial and Follow-up Dialogues

Initial Dialogue		Follow-up Dialogue	
Teacher:	What is your reasoning for determining that Shape J is a square?	Teacher:	Rosalia, can you re-state what Jessie was trying to say about Shape J?
Jessie:	Well it has 4 straight sides of equal	Rosalia:	I think Jessie said that Shape J is a

	length that are connected.		polygon because it is a square.
Teacher:	Does anyone else agree with Jessie, that Shape J is a square, and therefore a polygon?	Teacher:	Alright, does anyone agree or disagree that Shapes Q and J are polygons because they are squares?
Melinda:	I disagree that it is a square and a polygon.	Student:	I don't think Shape J is a square. A square only has 4 sides that are straight lines. That shape has 5 straight lines.
Teacher:	And why do you believe that?		
Melinda:	Well it looks like a square with an extra line inside of it, and that line isn't connected to another line on both sides. So it isn't a square or a polygon.	Teacher:	What do you think about what student said about this shape not being a polygon because it isn't a square?
Teacher:	Could you say in different words why you think it is not a polygon?	Jessie:	If we are looking at the shape as a whole, then it would make sense that it isn't a square. If you ignore that diagonal line, we have a square, but I don't think we can do that after hearing that explanation.
Melinda:	The figure has a side that is not connected to two other sides. (Teacher records this reasoning on the board)		

Another difference is the way the error gets resolved. In the Initial dialogue, since only Melinda's idea is recorded, it suggests that the error has been corrected without any input from Jessie. Alternatively, in the Follow-up dialogue, the teacher checks back in with Jessie after another student contributed a disagreement. While Jessie appears to become convinced with this new information, we see how Travis is considering ways to involve Jessie in that work.

We can connect these observations to Travis's rationales (see Table 4). His Initial rationale was focused on probing Jessie's thinking and eliciting other students' ideas. The rationale also confirms the inference that the last moves were an effort to highlight correct ideas about polygons. The Follow-up rationale details the deliberate decisions being made to use moves that clarify the ideas being discussed, to elicit agreement or disagreement (though without singling out a particular idea), and to go back to Jessie as part of resolving the error in-the-moment.

Table 4: Travis's Initial and Follow-up Rationales

Initial Rationale	Follow-up Rationale
It is always useful to allow students to explain their reasoning out loud. It helps this practice explaining their thoughts in mathematical terms as well as giving other students opportunities to engage with each others' [*sic*] thoughts. Then the teacher asked for another student's opinion to give another student a chance to either restate what has already been discussed or to give a different opinion/thought process on the situation. The teacher asked questions to help the student try to dive deeper into why she did not think it was a polygon and therefore getting more information out	I think it is important to have crucial parts of the discussion be re-stated so that everyone is clear about what we are discussing specifically. I also thought it was better to ask the class to agree or disagree with both shapes Q and J so that it did not seem as if the teacher was singling out one of the cards, giving a cue to the students that the point made about the card was probably wrong. After a correct description was given about the card, it is important to go back to the student who had an incomplete conception about the card to ensure that they understand

there to help students understand the requirements/definition of a polygon.	where their mistake was and why the card can be sorted as a non-example.

Based on his recollection of his Initial response, Travis noted that his focus on “coming back to the original student who made the statement with an incomplete conception” was a change. He “tried to focus the discussion on the goal more than I did the first time,” which might explain the Post-dialogue correcting the error. These shifts suggest changes in Travis’s practices and vision, and also provide insight into what does not seem to change in the dialogue alone.

Rehearsal. Making sense of Travis’s development is supported by considering his rehearsal. Travis was the third of three TCs to rehearse the sorting IA. His rehearsal included discussion of four cards: two easy-to-sort examples of a linear function and two easy-to-sort non-examples. The planted error (Table D) was the first non-example shared and was revisited later by another student. Travis elicited more reasoning about Table D from the student, recorded ideas, and confirmed that he was representing the idea accurately—all moves consistent with his Pre-dialogue. Travis then elicited other non-examples, implicitly tabling the conversation about the planted error. This move was consistent with how he initially responded to all cards.

Travis’s intention to move on was challenged by other students wanting to disagree. After asking for additional non-examples, he allowed a student to comment on Table D. After the student shared a lengthy contribution, Travis turned to the teacher educator and said:

Teacher: Okay, so I guess now this would be - what I’d like to talk about now is sort of the difficulty to get closer down to the definition of it. But I don’t know if I want to talk about that yet.

Coach: Then yeah, I think that’s a sound decision. So, one thing you could have done with [Student] wanting to comment, is you could have tabled that and known to go to [Student] whenever there is an opportunity to raise any questions or disagreements or whatever. But prior to that it seemed that you were willing to move on to the next card. So that’s great.

In his reflection on this moment, Travis expressed wanting to respond to the error in a way that did not make it, “seem as if I single [*sic*] out the one person who makes an incorrect statement with an incomplete conception.” This may explain the tabling move, and also highlights the way Travis negotiated valuing students’ ideas while pursuing the goal. In reflecting on the second contribution about Table D, Travis noted that the student, “made an important distinction here where he began to discuss the how the *x*-values are changing relative to the *y*-values,” but that he got “lost” in the student’s ideas.

This example speaks to the power of considering multiple data sources. Looking only at the rehearsal, we might claim Travis was experimenting with tabling moves as a response to errors. From the scripting tasks, we might claim that Travis did not “learn about” tabling moves and wants to correct errors relatively quickly. Together, we see that Travis’s takeaway seems to be a negotiation of valuing student contributions while also making progress toward goals.

The rehearsal also helps explain Travis’s attention to checking back in with the student who contributed the error. Once students shared reasoning about Table D as an example of a linear function, the teacher educator reminded Travis to check back in with the student who originally initially contributed Table D. Travis later turned to that student:

Teacher: [Student 1], how would you use these change in *y*'s versus these change in *x*'s to show that this is an example?
Student 1: So, I get that the *y*'s and *x*'s are both changing at different rates, but I don't understand like how they're connected. So, like, I get that the *x*'s aren't constantly changing by 1 and the *y*'s aren't, but how does that make it—I still don't understand how that would make it an example.

Travis elicited an explanation from another student about the specific relationship of the changes in *x* and *y* and recorded those ideas. He then checked back in with the original student:

Teacher: [Student 1], does what [Student 2] was discussing there, does that make more sense about how we're relating the change in *y*'s to the changes in *x*?
Student 1: Yeah, I think I get it now, because you have to divide the change in *y* by the change in *x* to find what the slope is. And when you actually do it, it gives you 6 every time. I think I get it now.

Checking in with original student in the Follow-up dialogue had roots in Travis's rehearsal. Reflecting on this moment of his rehearsal, Travis noted that he, "made it a priority to come back to [Student 1] to ensure that he had understood what his errors in thinking were." The check in move helped realize two key aspects of Travis's vision—valuing students' contributions and making progress toward a mathematical goal. Even though the student was not initially convinced, the student was eventually able to articulate the correct idea, which is consistent with Travis's Follow-up dialogue. Looking across these approximations enables us to make more meaningful claims about TC learning and what experiences contributed to that learning.

Discussion & Conclusion

Through this work, we respond to the need to document TCs' skill from their enactments through approximations of practice and how to identify the way in which TCs' skill develops through such designs (Janssen et al., 2015; Shaughnessy et al., 2019). Through our analysis of two TCs' engagement with multiple approximations of practice, we highlight characterizations of skill and a more nuanced understanding of TC development across approximations. The cases of Greg and Travis illustrate different manifestations of skill and development that contribute to sensemaking of TCs' work through approximations—both in-the-moment and over time.

Greg's developing practices, made evident through differences in his dialogues, had direct connections to the moves he experimented with during his rehearsal. While these practices were continually developing throughout the rehearsal, their use in response to errors seemed to shape his vision of how discussions around errors could unfold without the need for immediate resolution. Travis also demonstrated through his dialogues how his practice of using orienting moves continued to develop as he refined the purpose for using these practices. Travis's rehearsal provided opportunities to experiment with moves and experience discussions around errors that play out in novel ways. While this contributed to his developing vision that included a valuing of students' ideas, that was being negotiated with a developing focus on how discussions are moving toward a goal. This resulted in Travis's focus on involving students who contribute ideas in the continued discussion of that idea (particularly involving resolving errors).

A main takeaway from these two cases is how the variety of data sources—across multiple approximations and time—offer a more complete picture of TCs' developing practice and the way a vision of teaching informs that practice. These cases highlight how looking at only one approximation or only at TCs' enactment would result in an incomplete picture. We see this work contributing to the field of research on pedagogies of practice in teacher education by offering approaches for understanding TC practice and development through multiple data sources. While we have focused our work on supporting TCs around the practice of responding to errors in whole-class discussion, we see these findings as having implications for the broader body of work and a focus on other focal practices.

This research report describes a study that explored the intersections of professional noticing of children's mathematical thinking (PN), pedagogical content knowledge (PCK), and affective domains with preservice elementary teachers (PSETs). An instructional module on professional noticing, as defined by Jacobs, Lamb, and Philipp (2010), included three components: attending, interpreting, and deciding, was implemented with 170 PSETs. A comparison group of 121 PSETs were enrolled in mathematics methods courses but the PN module was not implemented. PSETs who participated in the module showed significant positive growth in attending, interpreting, and attitudes toward mathematics. While there was no significant change in dispositions toward teaching mathematics, a decrease was observed in PSET deciding and pedagogical content knowledge. However, findings showed promising connections among the constructs.

Keywords: Teacher Knowledge; Affect, Emotion, Beliefs, and Attitudes; Preservice Teachers

Introduction and Objectives

Research on teacher noticing has been prominent in the field of mathematics education over the past decade (Schack, Fisher, & Wilhelm, 2017; Sherin, Jacobs, & Philipp, 2011; Stahnke, Schueler, & Roesken-Winter, 2016). Much of this work has used proximal measures of teaching practices to examine teacher noticing. In addition to teacher noticing, mathematics education research has established strong connections between teacher knowledge and teaching practices (Kunter, Klusmann, Baumert, Richter, Voss, & Hachfeld, 2013). While affect (e.g. attitudes and beliefs) has also been studied extensively in the field, there have been fewer links made between affect and teaching practices in mathematics (Philipp, 2007; Schoenfeld, 2015; Swars, Smith, Smith, Carothers, & Myers, 2018). However, there is a dearth of literature that connects the constructs of teacher noticing, pedagogical content knowledge, and affect in mathematics among preservice teachers. As Philipp (2007) states, "Researchers studying teachers' knowledge, beliefs, and affect related to mathematics teaching and learning are still trying to tease out the relationships among these constructs and to determine how teachers' knowledge, belief, and affect relate to their teaching" (p. 257). In this study, we attempt to examine such intersecting constructs that have the potential to influence teaching practices. Specifically, we explored professional noticing, a specific branch of teacher noticing, with the following research questions:

1. *To what extent can the implementation of a PN module influence PSET professional noticing skills, pedagogical content knowledge, and affect toward teaching mathematics?*

2. *In what ways do PSET professional noticing skills relate to their pedagogical content knowledge and affect toward teaching mathematics?*

Theoretical Framework

Professional Noticing of Children's Mathematical Thinking

Professional noticing of children's mathematical thinking (PN) is a specific branch of teacher noticing defined by Jacobs, Lamb, and Philipp (2010) as the amalgam of three components, attending, interpreting and deciding. Jacobs et al.'s definition of PN is widely referenced in the mathematics education community. It is frequently shortened to PN often leading to confusion with the more general term, teacher noticing (Sherin, Jacobs, & Philipp, 2011), which usually includes only the attending and interpreting components. Schack, Fisher, Thomas, Eisenhardt, Tassell, & Yoder (2013) demonstrated that PN can be developed in preservice teachers with improved responses to prompts related to attending, interpreting, and deciding over the course of a mathematics methods course embedded with specific instruction on PN. Additionally, Fisher, Schack, Thomas, Jong, Eisenhardt, Tassell, & Yoder (2014) previously explored connections between PN and preservice teachers' attitudes toward mathematics. Using the Attitudes Toward Mathematics Inventory (ATMI) developed by Tapia and Marsh (2004) and adapted for preservice teachers by Schackow (2005), Fisher et al. (2014) found significant change from pre to post assessment on three of the four factors of the ATMI. There was, however, no significant correlation found between ATMI factors and PN. This study extends that work by engaging preservice teachers in more complex teaching situations and examining the interactions of pre-service teacher PN with affect, as measured by two domains of the Mathematics Experiences and Conceptions Survey (MECS) (Jong & Hodges, 2015), and pedagogical content knowledge, as measured by selected items of the TEDS-M (Brese & Tatto, 2012).

Pedagogical Content Knowledge

Pedagogical content knowledge refers to that knowledge about content that is specifically needed to teach the content. Shulman (1986) drew upon Ong's 1958 observation that the medieval university made no distinction between content and pedagogy. Shifts in teacher preparation that emphasized pedagogy over content led Shulman to examine the need for content/subject knowledge in one's pedagogical approach. He defines pedagogical content knowledge as "the ways of representing and formulating the subject that make it comprehensible to others" (p. 9). Teachers with strong pedagogical content knowledge also are knowledgeable of the potential misconceptions (Shulman, 1986) and speed bumps students will encounter in their learning, preparing instructional environments that allow students to grapple with the content, and ultimately overcome the speed bump. Pedagogical content knowledge has been the subject of much research over the past three decades (Ball, Thames, & Phelps, 2008; Hill et al., 2008; Depaepe, Verschaffel, & Kelchtermans, 2013) following on the premise that Shulman presented his theory as a heuristic method for studying the types and processes of knowledge needed by teachers. Ball, Thames, and Phelps (2008) attempted to refine Shulman's knowledge types, including pedagogical content knowledge, but acknowledged that further research was needed to bring clarification to the definition.

Depaepe et al. (2013) performed a systematic review of research on pedagogical content knowledge in mathematics education seeking to determine how PCK is conceptualized and investigated in empirical studies. The results demonstrated much alignment in researchers' definitions with Shulman's but there were also variations that drew upon other conceptualizations of pedagogical content knowledge (Ball et al., 2008; Hill et al., 2008).

Depaepe et al.'s (2013) conclusions illustrate that some researchers study a cognitive conceptualization of PCK, one in which PCK is within the mind of the teacher and often assessed through a test, and others study a situated conceptualization of PCK, which is related to "knowing-to act", one of Mason and Spence's (1999) four types of knowing.

Affect in Mathematics Education

Affect is used as a broad term that most commonly includes attitudes and dispositions, and are also closely linked to beliefs and self-efficacy, which vary in where they fall along the spectrum from emotion to cognition (Philipp, 2007). Schoenfeld (2015) points out the complexities of understanding affect in different contexts and while asserting that underlying beliefs influence practices, he also states that actions are what ultimately matter. He also urges researchers to examine changes in affective factors over time as he notes that since it takes years to develop beliefs and practices, then one would expect the same for substantive changes accompanied by support over time. Although there are affordances and drawback to various methods that examine affect in mathematics teaching, scholars agree that beliefs and attitudes matter (Aguirre & Speer, 1999; Jacobson & Kilpatrick, 2015; Wilkins, 2008).

Connections: Professional Noticing, Pedagogical Content Knowledge, and Affect

Thomas, Jong, Fisher, & Schack (2017) examined potential theoretical connections between two frameworks: mathematical knowledge for teaching and PN of children's mathematical thinking. They theorized that the skills of PN mediate mathematical knowledge for teaching and teacher responsiveness to children's mathematics. They developed a hypothesized trajectory of effective PN skills as an outcome of a well-developed MKT and responsiveness to student thinking and this research will continue to investigate these relationships. Similarly, Stahnke et al (2016) argue that such "skills display the missing link between mathematics teachers' dispositions (professional knowledge, affective motivational features) and their performance (observable behavior)" (p. 24). They are essentially making a case that PN skills have the potential to bridge affect, pedagogical content knowledge (referred to as "professional knowledge"), and teaching practices. Swars et al. (2018) recently conducted a study on the preparation of elementary mathematics specialists. They examined connections among pedagogical beliefs, teaching self-efficacy beliefs, specialized content knowledge, and observed teaching practices at the end of the program. The only significant relationship they found was between pedagogical beliefs and teaching self-efficacy; however, it might have been partly due to the self-reported nature of the instruments. Newton, Leonard, Evans, and Eastburn (2012) examined preservice teachers' self-efficacy, pedagogical content knowledge, and outcome expectancy before and after a mathematics methods course. Results from their study showed a consistent moderate positive correlation between self-efficacy and pedagogical content knowledge, but no relationship with outcome expectancy.

Methodology

Participants and Context

Participants were preservice elementary teachers enrolled in mathematics methods courses during one of five semesters at five universities (two urban, three rural) in the south-central United States. Treatment group PSETs (N = 170) participated in a module designed by the researchers to develop PN in the context of early algebraic thinking in a whole class setting. The *Examining Essential Expressions in Algebra* (E^3A) module included three 60-minute sessions focused on PN skills through the content of early algebraic reasoning and used complex video vignettes from whole class instruction in elementary mathematics classrooms to prompt discussion about the three components of PN: attending, interpreting, and deciding. Comparison group participants (*N* = 126) completed their mathematics methods course "business as usual".

Data Collection

Participants completed pre and post assessments consisting of three instruments, although not all participants completed all assessments, thus the varying *N*s. PN was assessed using a video-based assessment (*N* = 268). Affect was measured using the MECS (*N* = 149). We focused on the MECS' two-subscales of attitudes and dispositions to capture affect (Philipp, 2007). Additionally, preservice teachers responded to selected TEDS-M items (*N* = 196) chosen for their relation to pedagogical content knowledge in that some items represented student (mis)conception and required participants to identify such and discuss how they might respond instructionally. Selected TEDS-M items also matched the module's algebraic thinking content.

Video-based assessment. We assessed preservice teacher PN through a video clip of an authentic classroom in which children are engaging in the meaning of the equal sign in a whole group setting. The teacher has presented a number sentence, 10+10=__+5 asking the children to determine what number to put in the blank to make the number sentence true. The full class setting requires preservice teachers to attend to multiple understandings as displayed by the various children's responses in close temporal proximity to each other, make sense of the responses, and make an instructional decision based on the responses. The assessment prompts are aligned with the three components of PN in the order of deciding, attending, and interpreting: 1) *Pretend that you are the classroom teacher. What might you do next? Provide a rationale.*, 2) *What mathematical thinking and actions did you observe?*, and 3) *What did you learn about the children's mathematical thinking that influenced your decision in question 1?*. We intentionally prompted participants to decide first in an attempt to capture their in-the-moment thinking, more closely. PSET responses were scored by research team members on a four-point scale using decision trees programmed in JavaScript for automated scoring (see Schack, Dueber, Jong, Thomas, & Fisher, 2019 for details).

Mathematics Experiences and Conceptions Surveys (MECS). MECS is a set of instruments consisting primarily of six-point Likert-scale items (ranging from *strongly agree* to *strongly disagree*) designed to measure various affective factors related to teaching mathematics, such as attitudes, beliefs, dispositions, and self-efficacy over time (Jong & Hodges, 2015). MECS utilized the Philipp (2007) definitions of attitudes as "manners of acting, feeling, or thinking… Attitudes, like emotions, may involve positive or negative feelings. …Attitudes are more cognitive than emotions, but less cognitive than beliefs" (p. 259). It was also informed by his broader description of affect as "a disposition or tendency or an emotion or feeling attached to an idea or object", the main distinction between attitudes and dispositions being a feeling versus a tendency that might be more directly linked to an action. The two subscales used in the study were attitudes (MECSA) and dispositions (MECSD) toward mathematics. MECSA consists of six items, such as: "Mathematics is one of my favorite subjects." and "I look forward to teaching mathematics." MECSD consists of 10 items, such as "I plan to engage students in mathematics discussions." and "I plan to encourage students to share their thinking."

Teacher Education and Development Study in Mathematics (TEDS-M). TEDS-M was a study, funded by the International Association for the Evaluation of Educational Achievement, that examined how preservice teachers were prepared to teach mathematics at both the elementary and secondary levels in teacher education programs across 17 countries (Brese & Tatto, 2012). A major aim of TEDS-M was to capture preservice teachers' knowledge about mathematics. To assess pedagogical content knowledge in our study, we used a subset of eight

TEDS-M released items from the number and algebra content domains. Responses were then scored according to the TEDS-M scoring guide with varying scores of 0-2 based on the problem. Three open-response questions were added to the eight items to assist the researchers in further understanding PSETs' thinking. We did this by simply asking, "Please explain your response." We had specifically selected items within the number and algebra content domains because the TEDS-M post-test was administered immediately after the E^3A module was implemented in an attempt to capture PCK that was closely related to the content goals.

Data Analysis

Psychometric properties (e.g. model fit, factor analyses) of the aforementioned instruments were completed using WINSTEPS (Linacre, 2018) to inform subsequent analyses. Preliminary analyses of MECS' affect subscales indicated that the attitudes and dispositions scales were the most reliable, given the sample size. A Rasch rating scale model was used to examine reliability and model fit of the scales. Both subscales (at both pre and post) had reliability estimates ranging from 0.70 to 0.88. Principal components analysis of the residuals from the Rasch model also indicated strong unidimensionality for both scales, but a few items had poor fit according to INFIT and OUTFIT (Bond & Fox, 2007) and thus were eliminated from the analyses. Preliminary analyses of the TEDS-M items revealed excellent item fit according to INFIT and OUTFIT; however, the TEDS-M showed poor reliability (0.65 for pre and 0.55 for post) due to the limited number of items. This low reliability can reduce power in univariate significance testing such as *t* tests (Kanyongo, Brook, Kyei-Blankson, & Gocmen, 2007), and make the results of multivariable statistical analyses such as multiple regression untrustworthy (Cole & Preacher, 2014). Thus, we present findings including TEDS-M scores with a great deal of caution. While there are major limitations of the claims we can make with the TEDS-M due to the low reliability, we thought it would be beneficial to present results as a way of being transparent.

As PN video-based assessment scores are not interval level data, Wilcoxon signed rank tests were performed to determine whether PN scores significantly changed from the pre to the post assessment. As TEDS-M, MECSA, and MECSD scores are interval level data, a mixed design ANOVA was conducted on pre and post data for these scales to explore changes given the treatment effect and repeated measures aspects of the design. In the event of a significant interaction term, indicating a greater score change for the treatment group than the control group, a paired *t* test was performed to provide a significance test and Cohen's *d* effect size for the score change of the treatment group.

Next, in order to determine whether variables other than the treatment condition contributed to post-test scores, a multiple regression model was employed for each outcome of interest in which all measured variables (e.g. sum scores for TEDS-M and MECS factors) at pre-test were used as predictors. Models were tested with and without interaction terms (e.g., PreAttending × Treatment), but none of the interaction terms had significant regression coefficients and these interaction models did not explain significantly more of the variability in the outcome than the main effects models. Therefore, only main effects models are reported. As not all measures were completed by all participants, missing data were handled using full information maximum likelihood, an approach which utilizes all available data and makes fewer assumptions about the nature of missingness than listwise or pairwise deletion techniques (Enders, 2010).

Because of the way measurement error attenuates correlations, measurement error in the predictors of a multiple regression model can change the strength and pattern of effects. On the other hand, measurement error in the outcomes of a multiple regression model attenuate the strength of effects. Therefore, correcting for measurement error can give a more accurate description of the true underlying relationships (Cole & Preacher, 2014). Due to substantial measurement error in the TEDS-M data, we performed a sensitivity analysis in which results using observed variables were compared to results using a single indicator latent variable (SILV; Hayduk, 1987) technique for correcting for measurement error in the MECSA, MECSD, and TEDS-M variables.

Results

Changes in Constructs

Table 1 provides average pre and post scores of the various constructs examined among PSETs from both the comparison group and those who participated in the E^3A module. For the PN component scores of the treatment group, Wilcoxon signed-rank tests indicated that significant positive changes were observed in attending (Z = -3.219, *p* = .001) and interpreting (Z = -3.961, *p* < .001), but not in deciding (Z = -.384, *p* = .701). Furthermore, since scores for all three components decreased for the comparison group, there is evidence to suggest that the treatment was effective in the areas of attending and interpreting; however, the deciding component warrants further investigation.

Table 1: Descriptive Statistics

	Treatment		Comparison	
	Pre	Post	Pre	Post
	M (*SD*)	*M* (*SD*)	*M* (*SD*)	*M* (*SD*)
Attending	1.03 (0.98)	1.34 (0.92)	0.96 (1.01)	0.83 (0.92)
Interpreting	0.77 (1.11)	1.22 (1.11)	0.88 (1.09)	0.66 (0.94)
Deciding	1.36 (0.81)	1.34 (0.88)	1.55 (0.98)	1.45 (0.99)
MECSA	21.85 (7.55)	24.09 (6.20)	22.73 (7.05)	22.49 (6.31)
MECSD	43.64 (3.95)	44.27 (3.35)	44.73 (2.91)	43.48 (4.47)
TEDSM	9.70 (2.75)	9.45 (2.13)	10.67 (2.33)	9.41 (2.05)

The mixed-effect ANOVAs of the TEDS-M and MECS results are reported in Table 2. On the left half of the table are the results of omnibus tests of interactions; all three interactions are significant, indicating that treatment group scores improved relative to control group scores. The results of post-hoc paired t tests on the treatment group can be found on the right half of Table 2. Affect, consisting of the MECS scales, yielded a significant positive change in attitudes (MECSA), and a non-significant positive change in dispositions (MECSD). Pedagogical Content Knowledge (PCK) included scores from the TEDS-M, in which average scores were lower, but not significantly lower than pre-treatment scores. Note that scores for MECSD and TEDS-M exhibited a treatment effect according to the ANOVA interaction term, but no significant improvement in scores for the treatment group. The significance of the treatment effect was therefore at least partially due to score decreases in the control group.

Table 2: Mixed-Design ANOVA and Post Hoc Tests

	Omnibus test of interaction effect				Treatment group paired *t* test				
	F	df	*p*	$\widehat{\eta_p^2}$	Diff.	t	df	*p*	*d*

MECSA	11.38	1, 146	.001	0.072	2.235	6.172	114	<.001	0.296
MECSD	6.322	1, 146	.013	0.042	0.635	1.762	114	.081	0.161
TEDSM	6.124	1, 162	.014	0.036	-0.254	-1.271	117	.206	0.092

Note. Cohen's d computed using pre-score standard deviation

Connections Among Constructs

Results of observed multiple regression models for all outcome variables are presented in Table 3. When the same models were estimated including SILV corrections for measurement error, all statistical decisions about significance were retained. Furthermore, parameter bias was slight except for the coefficients for the TEDS-M predictor, which were all smaller in the observed model than the SILV model. Accordingly, only the results of the more conservative observed model are reported and interpreted. All models had a significant R^2, however, for the TEDSM and MECSD variables, the only significant predictor was the pre-score of the same variable. The E^3A module, or treatment condition, was seen to be a significant positive predictor of Post-Attending (PostATT), Post-Interpreting (PostINT), and PostMECSA, consistent with earlier reporting of changes in constructs. Furthermore, PreINT significantly predicted PostATT, while PreTEDSM significantly predicted PostDEC. Also, PreMECSD significantly predicted PostMECSA.

Table 3: Standardized Regression Coefficients for Observed Analysis

	Outcome					
	PostATT	PostINT	PostDEC	PostTEDSM	PostMECSA	PostMECSD
	β	β	β	β	β	β
Treatment	.27***	.29***	-.00	.05	.21***	.15
PreATT	.27***	.01	.06	.01	.00	-.09
PreINT	.16**	.35***	-.01	-.06	.05	-.04
PreDEC	-.00	.06	.06	.01	.03	-.07
PreTEDSM	.15	.06	.24*	.58***	.02	.11
PreMECSA	-.05	-.04	.15	.11	.86***	-.01
PreMECSD	-.09	.03	.02	.03	.11*	.46***
R^2	.21***	.21***	.11*	.27***	.77***	.25***

Note. The coefficient for the treatment variable only standardizes the outcome, in order to provide a standardized difference between the two treatment and control groups while controlling for the other predictors. *p < .05. **p < .01. ***p < .001.

Discussion

In this study we endeavored to study the connections of PN, with PCK and affect. Multiple regression analyses confirmed ANOVA results, indicating that participation in the E^3A module was a significant positive predictor of PSETs' attending, interpreting, and affect. In regard to the connections among constructs, we found that pre-interpreting significantly predicted post-attitudes, demonstrating a connection between PN and affect. Pre-dispositions significantly predicted post-attitudes, which makes sense but needs to be further investigated. In addition, pre-PCK significantly predicted post-deciding. While tenuous, this shows a connection between PN and PCK. This was an interesting finding, given that significant differences were not observed from pre to post in either deciding or PCK. Post scores of every component skill, except deciding, were significantly predicted by the pre-score of that component skill. It is also worth noting that results yielded no connections between PCK and affect.

The interaction of PN, pedagogical content knowledge, and affect offers the opportunity to examine the conceptualization of each construct. Our results indicate that connections between PN and affect in mathematics teaching can be detected in a brief period. While it makes sense that dispositions might serve to predict attitudes as related constructs, it is less clear why interpreting might serve as a predictor for attitudes. We suspect that PSETs who have a stronger grasp on interpreting children's mathematical thinking at the onset might be more enthused about teaching mathematics. If the TEDS-M instrument were more reliable, we would be able to say with more confidence that pre-PCK influenced post-deciding. However, both resulted in lower scores and it might be the case that the regression analysis picked up on similar slopes.

We are aware that there are limitations in the context and the instruments of this study. The context is limited by the short duration of the treatment embedded in a semester-long mathematics methods course. While significant changes for the treatment group were realized, this may have been associated with the course in which the treatment was embedded and not the treatment alone. The use of the comparison data is useful in debunking this particular limitation, we recognize that all instructors used in the study teach in diverse ways. The TEDS-M instrument is limited by the reliability due to the low number of items selected. The limitations of the TEDS-M also underscore the need for an instrument that is more reliable in assessing PCK and/or MKT of preservice teachers. Fisher, Thomas, Schack, Jong, & Tassel (2018) previously attempted to assess preservice teachers using the LMT (Hill, Schilling, & Ball, 2004), however, because this assessment was designed for inservice teachers, our results were limited. Given these limitations, we believe reporting these results is important for the advancement of research exploring the interaction of these constructs: PN, affect, and PCK. Our results indicate there are connections amongst the three constructs though not clearly among all three constructs and not among all components of the various constructs. Though limited, this is an encouraging step in the research that should be further explored with an improved assessment instrument for PCK and potentially better measurement strategies for PN.

As noted previously, the literature illustrates that many researchers are exploring such connections. Mired within this research are multiple challenges, not the least of which is the invisible nature of what occurs in a teacher's head. Jacobs, Sherin, and Philipp (2013) referred to teacher noticing as "the hidden skill of teaching" (p. 723). One might argue that affect and PCK are similarly hidden.

An additional challenge to researchers is in sorting through the language used to describe the various constructs. Questions arise. What is simply a language difference and what constitutes a different construct? In what ways is PN alike or different from the situated conceptualization of PCK (Depaepe et al., 2013)? In what ways is PN alike or different from the integrative perspective of teacher knowledge conceptualized by Gess-Newsome (1999) as the integration of subject matter, pedagogy, and context? Thomas et al. (2017) found connections in the theoretical space between PN and MKT. "[W]e contend that one productive lens for considering the practical outcomes of professional noticing is from the perspective of responsiveness. In this instance, responsiveness may be considered a broad manifestation of the coordinated component skills of professional noticing. . .[and] effective professional noticing occurs at the intersection of developed MKT and a high level of responsiveness to the mathematical activities of students" (pp. 13-14).

Ultimately, the goal is to support teachers to enact responsive teaching that benefits the learning of the students. To be responsive, teachers must constantly use converse and diverse thinking. Attending to an individual student's mathematical response requires converse, or very focused seeing (Broudy, 1984; Polanyi, 1966), that considers that specific student's response and the specific mathematics of the moment. However, the teacher must also think diversely of the needs of the whole class of students as well as the mathematics of the moment in context of a larger mathematical concept.

Are these descriptions of teacher practice describing the same or different constructs? Is it that many attempted to understand teacher thinking and practice from different perspectives, using different language? Does it benefit research on teacher preparation to study essentially the same construct under different names? If constructs are different paths to the same end, understanding "the hidden skill [or skills] of teaching" (Jacobs et al., 2013, p. 723), research such as this, that attempts to find the intersections is crucial to deepening our understanding of effective teacher thinking and with that, how to better prepare teachers.

LEARNING TO TEACH MATHEMATICS FOR SOCIAL JUSTICE: HELPING PRESERVICE TEACHERS CONNECT CRITICAL TOPICS TO STANDARDS

Marrielle Myers
Kennesaw State University
mmyers22@kennesaw.edu

This study examines how preservice teachers select standards, plan tasks, and develop a full lesson plan focused on a social justice context. While traditional studies of this topic involve scholars examining completed lesson plans, this study is unique in that audio data was recorded to capture the types of discussions preservice teachers engaged in while completing social justice lesson plans. Findings indicated that PSTs used keywords to map standards onto elements of the social justice context, that they vacillated between selecting a standard and developing an appropriate task, and that they treated the social justice context as a fixed scenario. I will share examples along with implications for how mathematics teacher educators can better support PSTs as they navigate this complex process.

Keywords: Equity, Diversity, Instructional activities and practices, Teacher knowledge

Introduction

Teaching mathematics for social justice (TMfSJ) is a complex process that involves the coordination of "fair and equitable teaching practices, high expectations for all students, access to rich, rigorous, and relevant mathematics, and strong family/community relationships to promote positive mathematics learning and achievement" (National Council of Supervisors of Mathematics and TODOS, 2016). In this paper, I present findings based on a semester-long project with preservice teachers (PSTs) focused on the Flint water crisis. I begin this paper with an overview of research on teaching mathematics for social justice. Next, I describe the context of the study, the participants, and articulate key elements of the data sources. I then provide excerpts from transcript data that illuminate how PSTs negotiated the complexities of planning mathematics lessons focused on social justice. After identifying themes that emerged in the data, I conclude by discussing the implications of the findings.

Background

While teaching mathematics for social justice is not a new concept in mathematics education, understanding how preservice teachers come to enact this pedagogy is still relatively new to the field. Previous work around this topic has examined PSTs beliefs about teaching injustices or controversial issues (Simic-Miller, Fernandes, & Felton-Koestler, 2015). Gonzalez (2012) articulates four components of TMfSJ. These components include students having access to rigorous mathematics, that mathematics is re-centered on issues related to historically marginalized students, that mathematics is used to critique society, and that we use the knowledge generated from the previous three constructs to advocate for change (Gonzalez, 2012). For PSTs to engage in this type of pedagogy, Felton-Koestler (2017) states that PSTs must experience mathematics for social justice as a learner, see examples of what this could look like in practice, and reflect on their own beliefs about mathematics. Much of the extant literature around TMfSJ calls attention to the fact that PSTs need explicit exposure to examples of these lessons and opportunities to plan lessons for themselves as they will not likely find social justice lessons in their school curriculum (Leonard & Evans, 2012).

Bartell (2013) described secondary teachers' attempts to teach mathematics for social justice. In this study, in-service teachers enrolled in a graduate course designed, implemented, and revised a mathematics lesson that had social justice goals (Bartell, 2013, p. 136). Findings from this study indicated that teachers had varying definitions of what it meant to teach mathematics for social justice ranging from awareness, to cultural exposure, to student empowerment. Another finding from this study was that participants felt tensions between "mathematical goals and social justice goals" while planning (Bartell, 2013, p. 141). I have replicated these findings in my work in that many of the topics elementary PSTs selected when planning a social justice lesson related to their own goals for the lesson (e.g., wanting to expose their students to world issues) as opposed to addressing students' needs (Myers, 2017). PSTs also planned lessons that focused on current events or chose less critical topics (e.g., discussing pet adoption instead of racial issues involved in the adoption of children) because of their belief that young students could not handle this type of mathematics, for example (Myers, 2017).

While previous research has demonstrated that PSTs can design lessons focused on social justice topics, it is unclear how they negotiate the tension between mathematical goals and social justice goals in their lesson planning activities. Further, much of this work has focused on analyzing survey data about PSTs beliefs or examining completed lesson/unit plans (Leonard & Evans, 2012). This study makes a unique contribution to the field in that the focus is on exploring the conversations that PSTs engaged in while planning social justice lessons. After a discussion of the theoretical framework and methods, I will share themes that emerged from the analysis along with sample text from transcripts of the PSTs lesson planning sessions.

Theoretical Framework

This study is grounded in Gutstein's (2003 and 2006) framework for teaching mathematics for social justice. The goal was for PSTs to unpack the Flint water crisis and think about how mathematics could be used as a tool for elementary students to engage with and act upon this injustice. In essences, how could we use mathematics to *read* the Flint Water Crisis? Gutstein (2003) defines *reading the world with mathematics* to mean:

> [Using] mathematics to understand relations of power, resource inequities, and disparate opportunities between different social groups and to understand explicit discrimination based on race, class, gender, language, and other differences. Further, it means to dissect and deconstruct media and other forms of representation and to use mathematics to examine these various phenomena both in one's immediate life and in the broader social world and to identify relationships and make connections between them. (p. 45)

To help students engage in *reading* the Flint water crisis, I provided PSTs with articles, links, and hashtags to read and follow before our discussion. I intentionally selected multiple forms of media (e.g., print media, blogs, social media) as well as publications from different political backgrounds (e.g., CNN, Fox News, and The Root) so that PSTs could see this crisis from multiple lenses and begin to think about how to negotiate various viewpoints.

Another essential framework for this study was the Culturally Responsive Mathematics Teaching (CRMT) Lesson Analysis Tool. This tool was developed as a part of the TEACH-MATH project and was intended to support teachers in critical analysis of how they plan and implement lessons (Drake et al., 2015). Because previous literature highlights challenges PSTs face with maintaining the mathematical goals of the lesson, it was critical to select a framework that explicitly draws the user's attention to mathematical goals of a lesson as well as sociopolitical goals. Additionally, one "critique" of TMfSJ is there "where is the math" question. This framework contains elements of "good mathematics teaching" (e.g., open tasks and discourse) as well as critical components of reading the world with mathematics. This tool is composed of six categories including cognitive demand, depth of knowledge and student understanding, mathematical discourse, power and participation, academic language support for ELLs, and cultural/community-based funds of knowledge (Drake et al., 2015). Each of the six categories is further delineated by a five-point rubric where level one articulates a less sophisticated or appropriate approach to the category and level five represents an ideal demonstration of the construct.

Methods

Context

I conducted this study in a semester-long mathematics methods course. Students were simultaneously enrolled in literacy, science, and social studies methods courses and followed a cohort model. In addition to taking four methods courses, all students completed a 200-hour field requirement during the semester where they were expected to progress from completing structured observations, to one-on-one interviews, to small group activities, and ultimately teach a whole-class lesson.

As the PSTs worked on this lesson planning activity, they had a variety of resources to use while planning. They had electronic access to the state standards, the departmental lesson plan template, documents that listed mathematical supports and scaffolds for ELL students, as well as articles about the Flint water crisis. One graphic that the students were particularly drawn to is shown below:

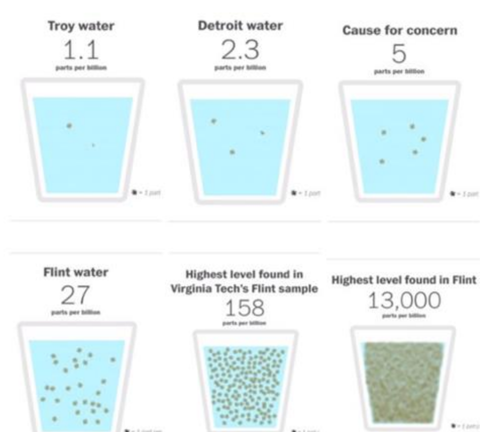

Figure 1: Michigan Water Level Contaminations. Reprinted from "We had to make some cuts": Flint water catastrophe a matter of business, by D. Johnson, Retrieved from http://www.occupy.com/article/we-had-make-some-cuts-flint-water-catastrophe-matter-business#sthash.o2xFPb6m.dpbs. Copyright 2016.

Participants

Seventeen PSTs participated in this study. Of these participants, five identified as African-American, seven identified as White, one as Hawaiian, two identified as Hispanic, one as

Jamaican, and the final student identified as Vietnamese. Three of the PSTs students were bilingual (they learned English as a second language) and all of the students identified as female. The racial makeup of this class was atypical in comparison to other sections of the course offered that semester and the overall demographics of the department.

The students worked in grade-level teams according to the grade level they were placed in for their field experience. There were five groups in the class. Three groups of PSTs worked on first-grade lesson plans, one group worked on a second-grade lesson plan, and the final group worked on a third-grade lesson. In this paper, I will share the results of one subgroup of this study that was made up of three PSTs. Two of the three PSTs in this subgroup identified as White. The third identified as African-American.

Data Sources and Analysis

Data sources for this study included small group lesson plans and audio recordings of lesson planning sessions. The lesson plan template asked candidates to: identify a GA standard; state the problem to be solved (based on the Flint water crisis); identify tools needed; identify polysemous words, cognates, and other vocabulary demands; pose probing questions to ask students; articulate differentiation strategies; as well as create summative and formative assessments. I used this lesson plan template because it is a required template for the department. In the first part of this project, candidates were given three hours in class to work on their group lesson plans.

Both ongoing and retrospective data analysis were used. Data were coded using open coding (Merriam, 2009). After broad themes were identified, I looked for examples of each of the six categories from the CRMT lesson planning tool. Although the tool can be used to "rate" each category of the lesson plan, I will not provide ratings as the focus of this study is to explore the complexities of PSTs conversations as opposed to the final result of what was produced on the lesson plan.

Findings

For this paper, I am going to discuss the data from one of the first-grade groups. A few themes emerged in the analysis. In the subsequent sections, I will discuss each of these themes in greater detail and offer examples from the transcripts and lesson plans to illuminate the case.

Standards vs. Tasks

At the start of the semester, I engaged the class in a discussion around the elementary mathematics standards for the state. We also engaged in a discussion about some of the way's standards are used, and expectations school administrators typically have for how teachers implement standards-based instruction. This is a critical conversation to have with PSTs because in my previous work, I have found that there is significant push back given that mentor teachers believe that TMfSJ falls outside of the standards. Therefore, helping PSTs understand that this potential pushback is coming can help them be proactive about justifying their lessons and the resulting tasks. Additionally, negotiating standards and TMfSJ is an integral part of the political work of mathematics teaching.

As the PSTs continued reviewing the state standards, they would select multiple standards to work with. They would then develop a task aligned with that standard. This process was not linear however, and it appeared that PSTs vacillated between choosing a standard and developing a task. There were a few examples of this in the data:

Student C: So, I guess they could count the number of things in the cup [see Figure 1 above] and then write it out. Could we maybe have them count to understand place value? Like maybe ten particles in a cup equals the Flint water.
Student A: I see where you're trying to go there
Student B: You're trying to use place value
Student A: I'm trying to put that into words
Student C: Have them think of like…
Student A: Have them use the particles like blocks…like base-10 blocks
Student C: Yes…have them understand that…
Student A: I don't know how we would convert all that though
Student B: You would convert it just like you would anything else. You would have one particle [referring to the particles in the cups pictured above]…Instead of trying to like come up with or find something that fits in more complex ones, we can work with what we have. Because we know we can do households affected…like with number of people. Cause you can find that easily…you count…you know what I mean?
Student A: So, should we do word problems?
Student B: Yeah…work with what you can do…no trying to re-invent the wheel.
Student A: Right…so that would be like use addition and subtraction within 20 to solve word problems that involve situations of adding to, taking from, putting together, taking apart, and comparing with unknown

When this clip begins, the PSTs had planned to create a task based on representing and interpreting data. After the PSTs had some difficulty translating this into a task, one of the group members suggested a standard that focused on place value. From there, the PSTs begin to discuss how they could get students to count and graph the particles of water in Figure 1. Another student then suggested that the conversions (particularly the two cups that are represented with decimal numbers) will be too difficult and that the task should include discrete values only. This data highlights that PSTs were trying to coordinate the standard they selected, a possible task, and the cognitive demand of the proposed task. The conversation then shifted to creating a word problem, which is a different standard. This pushed one of the PSTs to now select a standard that addresses solving word problems within 20.

PSTs looked at other research they had done on Flint, and this conversation continued until they settled on a standard and a task:

Student A: I think I would go with the one that has addition and subtraction so that we could do like…you know…x amount of homes had this many or this many homes got infected, how many homes were left uninfected?
Student B: Say that again…
Student A: If you started with the number of homes that were uninfected and then gave them the number of homes that got infected, how many homes were left uninfected
Student B: So, you could say there were this many homes in Flint…50 homes in Flint…20 of them got affected with lead poising due to unclean water. How many more homes have yet to be affected? Thirty. Ok …let's go with that.

Standards as Keywords

Like the previous example highlights, unpacking standards is a complicated task. Initially, some PSTs assumed that they would teach one standard per day until all grade-level standards had been exhausted. As students entered methods courses and started field placements, they were exposed to how standards must be unpacked and that each standard is comprised of smaller learning goals. As PSTs attempted to unpack the standards in this study, they pulled keywords from the standards and tried to map keywords from the standard onto elements of the social justice context. In the following example, you will see that the words *represent* and *interpret* were selected to frame a possible task for students.

Student A: Let's use organize, represent, and interpret data up to three categories
Student B: Represent…you can compare the lead in the water to the amount of people that ended up sick…that can be *represented* on a chart…data…at this rate…you can use one city [referring to Figure 1 above]…you can like *interpret* the data…like if they keep on using this water source and you look at the ratio between the people getting sick and how in a year or two years how much more people would end up getting sick.

Data seemed like a natural first step for PSTs to consider when planning this lesson. One PST continued looking at the standards as the rest of the group was working and noticed that, "It looks like represent and interpret data is under every standard though." The PSTs decided that this standard was too broad and that they should look for something more specific than *representing* and *interpreting*.

Planned Supports vs. Standards vs. The Task

It seemed that the PSTs had settled on a standard and created a word problem that aligned with that standard. The discussion then shifted to what types of tools they would use to support students in developing rich mathematics. Much of their conversation here centered on category two of the CRMT Lesson Planning tool in that the PSTs grappled with what they could provide students with so that students could show their learning. The challenge that emerged here is that as the PSTs tried to engage in this discussion, they found that their planned supports were not necessarily aligned to the standard they selected or the word problem they created.

Student A: Ok…so what tools will we use?
Student B: Modeling? It has one for model with mathematics and it has use appropriate tools.
Student A: Under tools?
Student B: But I'm thinking tools can be rulers, graph paper…
Student A: I want to say like…manipulatives…because yeah, those dots…I think they're just called counters
Student B: So, is graph paper not a tool?
Student A: So, are we going to have them create graphs? Because that is not part of the standard.
Student B: I thought you was comparin' …it could be.
Student A: I feel like you would show them the graph to say 'hey this is what's happening here and this is what's happening here'
Student C: What exactly are we doing?

Student B: The water pollution vs. the people getting sick. Basically, the water pollution vs. the people going to the hospital. I guess I don't know how you'd compare that in one city. That would be hard the hard thing. Ehhhh…I don't know.
Student A: Uhhh…not yet. Well we have the math part…so maybe we can at least… I'm confused
Student B: What are we doing? Let's start with that
Student A: They're gonna do word problems. So, they're not…
Student B: But you can show word problems though…you know what I'm saying?
Student A: So, they can draw it out and use graph paper…so I can definitely see it to be used there. I put down manipulatives and by manipulatives I put i.e. counters. I put down graph paper.
Student B: What did you put next to the manipulatives? You could use white boards? I'm thinking too much into it.

As you see here, the conversation about manipulatives caused the PSTs to question the standard they had selected as well as the goals of the task. To help reconcile this difficulty, the PSTs engaged in a discussion about what mathematical tools were, what tools were necessary for students to solve a story problem, and additional layers about the Flint Water Crisis. As I stated earlier in this analysis, planning lessons related to data seemed like a "safe space" for PSTs to develop tasks. The notion of comparing and representing data re-emerged in this discussion, although it was not related to the word problem the PSTs previously decided on.

Is the Context Fixed?

Recall that a component of teaching mathematics for social justice is that mathematics be used to examine a socio-political context. Moreover, this examination is not solely to better understand the setting but also to create an avenue for advocacy. A key learning that emerged from this study is that although we spent a significant amount of time unpacking the water crisis, once PSTs started planning the lesson, Flint went from being a dynamic sociopolitical context to a fixed context. This was further confounded as PSTs went back and forth about the type of task they wanted to create. At one point, they planned to use existing data to graph. Later in the discussion, they considered the idea that this problem may not be fixed and they wanted to project the type of damage that could occur if the necessary changes to infrastructure did not happen. The PSTs then settled on creating a word problem that used Flint as a context (e.g., infected homes versus homes that are not infected).

As they continued working on the lesson plan, further dialogue emerged around the mathematical goals and the social justice goals for the lesson. The exchange below provides additional insight into this:

Student A: So, one goal should be make sense of problems and persevere in solving them?
Student B: Where are you finding this?
Student A: I am on the GA standards website. I think another goal should be for them to understand the severity of the water crisis since that's what we're…
Student B: But you can't say understand…umm…I remember one teacher saying that when you set goals for students you can't say things like they're going to understand…You can say make them aware
Student C: So, make the students aware of the severity of the water crisis

These examples illuminate different conceptions of a social justice context. For instance, if PSTs treat the context as something static (e.g., a word problem to be solved or fixed data points to graph), the actual goals of TMfSJ may never be realized because no action emerges from these types of tasks. The discussions that we engaged in when unpacking Flint as a class did not carry into the lesson planning discussions. As this last set of data from the transcript reveals, PSTs sought to raise awareness about Flint without an additional step of advocacy or effecting change.

Implications

This study adds to the extant literature in the field by providing details about the types of challenges PSTs negotiate while planning lessons focused on TMfSJ. Although scholars typically analyze completed lesson plans, studying the lesson plan along with the dialogue from the transcripts, provides us with new insights. First, given the complexity of TMfSJ, PSTs can benefit from sustained opportunities to engage in some of these categories independently (e.g., unpacking standards and socio-political contexts) before attempting to create a full lesson plan. For example, if PSTs do not know how to fully deconstruct a socio-political context and see the historical underpinnings of it, Flint and other social injustices will be reduced to a simple context for a problem just like shopping in a store or playing video games. As presented, the PSTs discussions in this portion of the study aligned with level three of category 6b in the CRMT-TM Lesson Analysis Tool. This highlights that while PSTs did plan for opportunities to analyze a socio-political context, they did not intend for students to engage in discussions about how the mathematics could be used to change or transform the problem (levels four and five of category 6b).

Categories one and two of the CRM-TM Lesson Analysis Tool address the cognitive demand in the lesson as well as the opportunities to develop students' depth of knowledge. During this study, it was clear that PSTs own content knowledge directly impacted their ability to plan lessons aligned with level five in each of these categories. For example, the word problem that this group settled on did not provide opportunities for "complex mathematical thinking, [utilizing] multiple representations…or complex understanding" (TEACH-MATH, 2012). Therefore, PSTs need ongoing development of their mathematics understanding as they plan lessons. As I highlighted above, PSTs abandoned one potential task because they did not think they could do the necessary numerical conversions.

Another overall finding from this work is the balance between learning to develop such a complex skill compared to PSTs trying to meet doing a “good job” with this activity (although it was not graded). PSTs were very concerned about demonstrating everything that was required for the assignment and wanted to be sure they were getting it right. PSTs seemed to think that there was one “preferred task” that they should pick to work towards developing a standard. Therefore, there were many times during the conversation that the PSTs wanted to quickly decide on what to fill in for the lesson plan template to satisfy the professor. Mathematics teacher educators must be explicit that the purpose of these assignments is for PSTs to navigate this complex process in a safe space free from assessment.

GRADE THREE STUDENT'S SOLUTION STRATEGY ON A MULTIPLICATION TASK: PRESERVICE TEACHERS' NOTICING AND REFLECTION ANALYSIS

Amy Roehrig
Illinois State University
aeroehr@ilstu.edu

In this study, I looked at the type of noticing through reflections written by preservice teachers (PSTs) after viewing a video of a grade three student's multiplication solution strategy. The task presented to the grade three student was also completed by the PSTs prior to viewing the video. PSTs were provided with a prompt to complete a reflection concerning the video. Results show that the use of video observations and reflection prompts in conjunction with content lesson produced reflections that were focused on analysis of student strategies and thinking.

Keywords: Problem Solving, Teacher Education-Preservice, Instructional activities and practices

Observations are an integral part of teacher education programs, for they provide a way for preservice teachers (PSTs) to experience a classroom before they have their own (Star & Strickland, 2008). But what PSTs garner from the experience is often different than the intended goal set forth by the teacher educator (Mason, 2008, 2011). The purpose of this paper is to report on the type of noticing made by PSTs using video observations, reflection prompts, and teaching mathematical content in conjunction with the observation.

Introduction/Background

A person's previous experience and beliefs influence what they notice (Beswick & Muir, 2013; Mason, 2011). This knowledge is an issue when PSTs are required to observe classrooms and students as part of their teacher education program. When PSTs observe and reflect on their experiences, they tend to focus on events of the classroom in chronological order, with a large focus on classroom teachers' classroom management of students (Beswick & Muir, 2013; Star & Strickland, 2008; van Es & Sherin, 2002). The noticed event depends mostly on a person's "own experiences of teaching and learning…all influenced by their experiences of the subject and how it is taught and learned" (Beswick & Muir, 2013, p. 29).

A growing field of research in education centers around what teachers notice that non-educators may fail to notice (Roller, 2016). Teachers go through the day being aware and noticing multiple aspects of student learning and understanding. When people "are not attuned or sensitized to" (Mason, 2011, p. 35) something, their attention can be drawn elsewhere. This seems to be the case when teacher educators require PSTs to observe classrooms, teachers, and students. When PSTs are not cognizant of what they should be observing, they often focus on teacher classroom management actions and classroom environment, whereas experienced teachers notice more about student learning (Star & Strickland, 2008).

To better focus PSTs' observations and noticing, several researchers have incorporated videos into their education courses (e.g., Ineson, Voutsina, Fielding, Barber, & Rowland, 2015; Mason, 2008; Roller, 2016). Researchers found that the use of video for observations attuned PSTs to fine details in the classroom setting and navigate the complexity of teaching and learning (Mason, 2011). Roller (2016) allowed PSTs to "re-watch and reflect using various lenses or questions to help tease apart what was effective and not" (p. 480). The purpose of using video for observations was to give PSTs a moment outside of teaching to break down and analyze decisions that occurred during a teaching episode and the effect on student learning (Mason, 2008, 2011; Roller, 2016; van Es & Sherin, 2002).

Another method that researchers have used for focusing PSTs during observations is providing prompts or specific learning goals for the video observation (Beswick & Muir, 2013; McDuffie et al., 2014; Phillip et al., 2007; Star & Strickland, 2008). Phillip et al. (2007) found that giving PSTs the opportunity to analyze student understanding of mathematics before being tasked with teaching students allows PSTs to make connections linking what they “are learning about teaching with what they already know about students’ mathematical understanding” (p. 443). Likewise, Beswick and Muir (2013) found that when PSTs were given prompts prior to viewing a video, they were able to better identify students’ learning.

Lastly, the task of writing reflections about video viewing exercises enables PSTs “to recognize the specific features of problems to which experts know to attend” (van Es & Sherin, 2002, p. 576). Analyzing what is noticed is just as important as the action of noticing. This analysis through written reflection allows PSTs to develop skills in interpretation of student learning and actions that can then be used to inform pedagogical decisions (van Es & Sherin, 2002). McDuffie et al. (2014) found that by providing support such as through prompts and class discussion, PSTs were able to “notice a range of student resources and to analyze how and why these resources enhance learning” (p. 267).

Methods

Participants

Participants were 22 elementary PSTs at a Midwest university, enrolled in a 16-week mathematics content course focused on algebra and geometry. Nine student reflections were selected based on their adherence to the reflection protocol and evidence that they viewed the student video.

Data Collection

A multiplication task was assigned to the PSTs to examine their understanding of non-traditional multiplication solution strategies for finding the total number of mailboxes in a 23 x 29 array. The same task was presented to a grade three student in a one-on-one interview. PSTs were shown the grade three student video interview. A class discussion followed the initial viewing and PSTs were given access to the video and a reflection prompt.

Data Analysis

The constant comparative method of data analysis was used inbuilding a framework for coding data. To enable the development of a coding schema, Corbin and Strauss’ (2015) three phases of coding—open, axial, and selective were used. Data analysis begun using open coding, statements that focused on how PSTs viewed the learning of the student and beliefs about the level of student understanding were selected. Axial coding followed, wherein the extracted statements were grouped according to the focus of the statements (i.e., PST centered, student centered, or a comparison statement). A second survey of the reflections produced more statements of interest using the three focus categories. To finish analysis, selective coding was done, in which the final schema was constructed.

Relations among the statements within and between the three categories were identified and new coding categories were created which led to a two-part coding schema: (1) focus of statement; (2) description statement. Through the process of open coding a total of 88 statements of interest were found and categorized.

Results

The purpose of this research was to determine the types of reflection PSTs provide using video, prompts, and content knowledge. Of the 88 statements, 35% were focused on PSTs' strategies or self, 45% were focused on the student's strategy, and 19% were focused on comparison between the PST and student. The following sections will illustrate results for each of the seven descriptive categories.

Error/Strategy Analysis

Thirty-one percent of the statements were focused on a student made error or an analysis of the student strategy and many of the statements were focused on the student. Only one statement was comparing the PST's strategy to the student's strategy.

Expected Strategy

Statements concerning the student using an expected strategy included only two of the 88 statements. None of the statements focused solely on the student, but instead focused on the PST or was a comparison statement. The comparison statement discussed how the student's method was similar to the PST's strategy.

Unexpected Strategy

Many of the statements categorized as *unexpected strategy*, focused on the PSTs being surprised or interested that a student would use a similar strategy to their own. This is evident in 12 out of 14 statements being focused on the PST. Two statements that were focused on the student were elaborated on the student's explanation of why certain steps were necessary or used.

Insight into Standards

There were few statements focused on insights into mathematical standards because the PSTs' experience with state standards was not a course focal point. Only five of the 88 statements contained language that could be interpreted as centering on standards or a point in learning expectations. For example, one PST wrote, "he started to learn the algorithmic way, but it was interesting to see how he still used the horizontal way" (PST 8).

Insight into Video Viewing

Though viewing the video of a grade three student was part of the reflection process, very few PSTs focused on the video and its specific usefulness in observation or reflection. Of the five statements concerning viewing the video, three were focused on the PST. The theme of the statements fixated on future teaching positions or the degree to which mathematics education has changed since they were elementary school students.

PST Learning/Insight

When PSTs' statements focused on their own learning and insight into multiplication, it was often written as a comparison between theirs and the student's strategy. There was a total of 19 statements, 13 of which focused on the comparison of strategies. PSTs did not provide insight into analyzing the difference between the strategies, instead they focused on what they did compared to the student.

Student Strategy

Statements focusing on the student's strategy but not analysis of the strategy comprised of 17% of the total statements of interest. As expected, many of these statements restated the step-by-step procedure or comment on method done by the student. For example, one PST stated, "he [the student] was able to find his answers fairly quickly in his head" (PST 9).

Connections

When PSTs' reflections were focused on themselves, they were more likely to comment on the student's unexpected strategy or the use of video observations. For example, referencing the use of video observation, a PST commented, "…this video proved how much math has changed since I was in school" (PST 3). When referencing an unexpected strategy from the student, a PST stated, "I did not really know what types of steps or methods a third grader may use to solve these [problems]" (PST 8).

If the reflection statements focused on the student, the PSTs were more likely to be reflecting on the specifics of the student's strategy or attempting to analyze an error or strategy used by the student. One PST wrote, "he was spilling any thoughts he had onto the paper" (PST 1) and "he went for 2 sections of 20x10" (PST 1), when referencing the student's strategy. To analyze an error or strategy, PSTs' commented on the confusion the student had when he was attempting to use the distributive property. For instance, "he would break them [mailboxes] down and then add, but sometimes got confused on how to break them down" (PST 1).

Lastly, PSTs were more likely to discuss their insights into their own learning when they were making comparison statements between theirs and the student's strategy. For example, one PSTs reflected on the beliefs the student has concerning mistakes, "…Grant corrected his mistake and even laughed at his misstep. I oftentimes forget to let myself make those mistakes and laugh when I do" (PST 7).

Discussion

In this study, analysis of PSTs' reflections of a grade three student's solution strategies through video observation in conjunction with mathematical content knowledge was done. My goal was to document the types of reflection statements given in response to a video observation.

It was found that the PSTs' noticing was focused on student learning, possibly due to the alignment of content knowledge and reflection. The experience the PSTs garnered from completing the task themselves enabled them to focus on strategies the student used. Such as, PST 3 stated that they "were surprised that he [Grant] was able to multiply horizontally so easily" when the PST had a difficult time multiplying mimicking his strategy. PSTs were able to analyze and compare the student's work to their own. For instance, PST 9 recognized that Grant "knew the skeleton of the distributive property, but still needs to develop his understanding because he erroneously distributed (9x10)x3 instead of (10x9) + (10x3)." The PST then continued by describing their own use of the distributive property.

These results are like the findings of Roller (2016), who found that PSTs were positively affected by the experience of viewing the video. Both McDuffie et al. (2014) and Mason (2011) found that by providing a focus prior to the observation the participants were more attentive to the observation goals. By providing a prompt, the PSTs were able to focus their noticing when viewing the video. This was evident in the procurement of 88 statements within the nine one-page reflections. Additionally, the wording of the prompt directed PSTs to focus on error analysis, unexpected strategy, and comparison of their strategy to the student's strategy, which was showed by the 31%, 16%, and 22% of the total statements, respectively.

A limiting factor in this study was low number of reflections used to create a coding scheme; therefore, future research is necessary to support the framework. The prompt provided to the PSTs was limiting in focus, further research needs to be conducted on the level of specificity needed in a prompt to produce higher quality PSTs' reflections. This study provided additional insight into the use of video when engaging PSTs in student observations and adds to the growing research on methods to aid in PST noticing practices. Lastly, further research is needed to determine whether an increase in the number of focused reflection statements transfers to better quality observations.

COUNTING, LAYERS, AND FORMULAS: PSTS' RESPONSES TO STUDENTS' VOLUME MISCONCEPTIONS

Dae S. Hong
University of Iowa
dae-hong@uiowa.edu

Cristina Runnalls
Cal Poly Pomona
ccrunnalls@cpp.edu

The purpose of this study was to explore how elementary pre-service teachers responded to students' hypothetical misconceptions about volume measurement. We carried out both pre-assessments and follow-up interviews with 17 pre-service teachers, with tasks focused on both volume content knowledge and hypothetical student responses to volume tasks. Preliminary findings indicated a preference towards show-and-tell responses, often with a focus correct or incorrect use of the volume formula. While PSTs were frequently able to correctly identify students' learning challenges with regards to volume, they experienced difficulty in addressing those challenges in meaningful ways. Recommendations for supporting pre-service teachers in teacher education programs are discussed.

Keywords: Geometry and Geometrical and Spatial Thinking, Measurement, Teacher Knowledge

In *Principles to Action*, the National Council of Teachers of Mathematics [NCTM] (2014) presented eight highly effective practices for teaching mathematics. One important practice promotes specifically the need to elicit and use evidence of student thinking during teaching. Teachers are required to make in-the-moment decisions when responding to students, using questions to build productive discussions, and interpreting students' thinking in ways that help shape further instruction (NCTM, 2014).

In the present report, we attend to these ideas in the topic of volume measurement. Findings from national and international assessments indicate that American students tend to perform poorly in the measurement domain compared to other mathematical domains (e.g. Mullis, Martin, Foy, & Hooper, 2016). There are many potential reasons for students' learning difficulties in volume measurement, such as development or conceptual difficulties, as well as inadequate curricular coverage. One significant factor in students' learning is the role of teachers' knowledge about volume measurement, especially as it affects lesson design and implementation. The purpose of this study was to explore types of knowledge that PSTs possess with regards to volume measurement, and the ways they use this knowledge in response to hypothetical student work in volume.

Related Literature

Understanding Volume Measurement

To understand volume measurement conceptually requires coordinating several ideas, such as: filling three-dimensional space with same-sized units, counting same-sized units, an iterating layer structure, and linking layer structure to the volume formula (Battista, 2004; Sarama & Clements, 2009; Vasilyeva et al., 2013). While these ideas are fundamentally important in other measurement topics such as length and area, the addition of a third dimension for volume makes them significantly more challenging. When working with same-sized units and volume, students may count only cubes visible on the faces, sometimes double-counting (Battista & Clements, 1996), or may struggle to "see" the structure of layered cubes in three-dimensional space

(Battista, 2004). Unfortunately, without these ideas, students tend to use the volume formula for a rectangular prism, $l \times w \times h$, without knowing why or how it works (Vasilyeva et al., 2013).

Different Types of Teachers' Knowledge

As suggested by the NCTM practices guide and others, teachers need many different types of knowledge to plan and teach effective lessons. For volume measurement, some of the knowledge required may include understanding and linking ideas of space-filling with same-sized units with ideas of iterated layer structure, and knowing and responding to students' well-known challenges in volume measurement (Battista & Clements, 1996; Vasilyeva et al., 2013).

To explore our PSTs' developing knowledge about volume, we employed analysis of their responses to hypothetical student work. Examining PSTs' responses to hypothetical students' errors or invented strategies has been an effective tool in previous studies, where it has been used to explore PSTs' knowledge regarding multiplication (Maher & Muir, 2013), subtraction (Son, 2016a), and ratio and proportion (Son, 2013), among others. Teachers can elicit and use evidence of student thinking if they are able to respond to students' misconceptions, and build on these to have productive mathematical discussions. To explore the mathematical knowledge of our PSTs, as well as to better understand the knowledge necessary for effective teaching of volume measurement, the present study analyzed PSTs' responses to volume tasks and hypothetical student responses to those tasks. Through our analysis, we were interested in exploring types of knowledge that PSTs need to design and develop effective volume measurement lessons. We also hoped that the results of this analysis could help identify areas requiring additional support in teacher education, especially with regards to volume measurement.

Methods

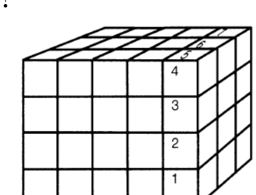
This study took place in a large Midwestern university. The first author taught a 15-week geometry and measurement content course for elementary education majors, designed to address K-8 geometry and measurement topics. A total of 17 participants from the class volunteered for the study. All participants were female, reflecting the overall makeup of the course. There were a wide range of mathematical backgrounds, with highest previous reported mathematics courses ranging from other college mathematics (41%) up to Calculus (41%).

Data Collection

Data collection began immediately before the measurement unit of the course, and continued throughout the length of the unit. A written pre-assessment was first used to examine students' content knowledge and initial responses to hypothetical students' strategies. The pre-assessment consisted of six tasks focused on volume measurement, adapted from previous studies (Battista, 2004; Battista & Clements, 1996; Vasilyeva et al., 2013). Follow-up semi-structured interview explored the same tasks more in-depth. We report on PSTs' written responses and interviews for two of the tasks, both shown in Figure 1

1. The following is a student's response to a volume question.
   a) Do you agree with this response? Why or why not?
   b) Why do you think the student answered that way?
   c) If you don't agree, how could you help the student with the question?

T: How many cubes does it take to build this prism?
S: There are seven layers, so it will be 105 cubes.



2. The following is a student's response to a volume question.
   a) Do you agree with this response? Why or why not?
   b) Why do you think the student answered that way?
   c) If you don't agree, how could you help the student with the question?

T: How many cubes does it take to build this prism?
S: There are ten cubes in the front, and six on the right side, and eight in the back corner. So it should take 24 cubes to build it.
T: So what's the volume of the shape?
S: Length times width times height… so 30.

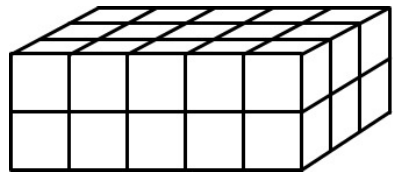


Figure 1: Pre-Assessment Tasks

Data Analysis

We analyzed Tasks 1 and 2 with a focus on participants' assessment of student thinking and use of pedagogical strategies. Our analytical framework for Tasks 1 and 2 was adapted from (Son, 2013), who developed a framework for analyzing PSTs' responses across several studies. The analytic framework served to examine several facets of responding to student errors, including the focus of instruction, form of address, and pedagogical actions. Categories and subcategories used are outlined in Table 1.

Table 1: Analytic Framework for Pedagogical Strategies

Aspect	Categories
Mathematical/instructional focus	Conceptual, procedural
Form of address	Show-and-tell, give-and-ask
Pedagogical action(s)	Re-explain volume concepts, suggest visual cognitive conflict, probe student thinking, recommend partitions, etc.

Mathematical/instructional focus was coded as either procedural, conceptual, or both, with double-coding if a participant elaborated upon strategies that involved both conceptual and procedural suggestions in their answer. Procedural responses focused primarily on use of the formula or correct answers, while conceptual responses attempted to use fundamental ideas of volume to make sense of the task. Form of address was introduced by Son and Sinclair (2010), and was coded as either show-and-tell or give-and-ask. Show-and-tell responses were primarily teacher-centered responses that provided solutions or explanations, typically using words such as *show*, *explain to*, or *demonstrate* (Son, 2016b). Give-and-ask responses were often student-centered, and asked the student to provide explanation for their work. These responses included words such *give*, *ask for*, *suggest*, or *look at* (Son, 2013). Finally, pedagogical actions were specific to the tasks, and including coding for the ways PSTs' responded to the mathematical content of the student response. These actions included revisiting the volume formula, pointing out double-counted layers, and other similar actions.

Results

Written Responses

For Task 1, responses to this student were focused on procedure, and often involved re-explaining the concept of volume through use of the formula. The most common response noted that the student had incorrectly counted cubes, with a focus on double-counting. This response indicated that our PSTs were able to diagnose the student's primary challenge, a good foundation for addressing that challenge. However, only four PSTs went on to mention addressing layer structure for their pedagogical suggestions. This showed that PSTs might not have connected the importance of understanding layer structure to the student's misconception, with over half of participants instead reminding students of the formula for volume to solve the task.

Task 2 was interesting because the hypothetical student did not provide the correct answer initially, but was able to still correctly apply the volume formula. Responses to Task 2 did not show the same reliance on procedural responses as before. The most frequent responses noted that the student was correct, with little elaboration. The most frequent pedagogical suggestion involved introducing the use of manipulatives to *show* or *tell* the student how to count cubes. However, is interesting to note that many PSTs who thought the student was correct did not attempt to provide any pedagogical suggestions, despite evidence of confusion in the transcript. These PSTs may have believed that arriving at the correct answer once was enough to not to explore student's thinking further, and hints at the fact that several of the PSTs in our study viewed using formula correctly as synonymous with understanding volume.

Interview Responses

For Task 1, although approximately half of our PSTs recommended using manipulatives to explore volume measurement, only one PST requested that the student explain his/her thinking. Seven PSTs noted that they might tell or teach the student more about the topic, with many referring to reviewing the volume formula. Additionally, only two PSTs mentioned that they would address or re-explain 3D or layer structure. It appeared that many PSTs were not aware that understanding of layer structure was critical to the task.

For Task 2, unlike their written responses, more PSTs provided pedagogical suggestions, including recommending the use of manipulatives, or an explanation of structure. However, only two PSTs requested the student to explain his/her thinking. These responses show that it is likely PSTs may feel the need to provide further instructions to students, preferring to "tell" or "explain" volume concepts rather than using students' thinking to guide discussion.

Discussion and Conclusions

Our initial analysis shows that encouraging PSTs to not only correctly identify students' learning challenges, but also move towards strategies of addressing them at a conceptual level is a pivotal step towards supporting PSTs in future implementation of effective volume lessons. Our findings also highlight the importance of reminding PSTs that providing mathematically correct answers is not synonymous with conceptual understanding. Continually assessing students' thinking, even after arriving at a correct answer, remains an important and critical instructional practice key to implementing effective lessons. Our preliminary findings also indicate several recommendations for teacher educators. First, although it is natural to think that using the formula might be an easier way to solve volume problems, PSTs need opportunities to understand and explore layer structure and space-filling ideas. Once they are familiar with layer structure and space-filling with same-sized units, they will be more likely to recognize the relationships between these ideas and well-known learning challenges in volume measurement. Since our PSTs were early in their teacher education, it is expected that they lean towards more “show and tell” strategies, especially with a focus on the formula. However, it is important for PSTs to have opportunities to develop familiarity with give-and-ask strategies as well.

PROSPECTIVE ELEMENTARY SCHOOL MATHEMATICS TEACHERS' PERSPECTIVES OF CHANGES IN THEIR IDENTITY THROUGH A STEM COURSE

Olive Chapman
University of Calgary
chapman@ucalgary.ca

Dianne Dodsworth
University of Calgary
ddodswor@ucalgary.ca

Research has indicated that there is a strong relationship between teachers' identity and their teaching. This suggests the importance to support prospective teachers' development of identities oriented to teaching mathematics from a reform perspective. This study investigates prospective elementary school mathematics teachers' perspectives of changes to their professional identities resulting from their participation in a Science, Technology, Engineering, Mathematics [STEM] education course that incorporated multiple perspectives of STEM education. Data collected through interviews were analyzed qualitatively based on the theoretical perspectives of identity and STEM education. Preliminary findings indicate shifts to their identity based on their view of mathematics, doing mathematics, teaching mathematics, and themselves as becoming teachers of mathematics. This was influenced mainly by one unit of activities of the STEM course.

Keywords: Affect, emotion, beliefs and attitude; Instructional activities and practices

Recent studies on prospective mathematics teachers [PTs] have addressed different issues in relation to their identity including: how they understand teaching and themselves as mathematics teachers (Neumayer DePiper 2012); the development of their identity as they transitioned from prospective to practicing teachers (Jong, 2016); how they positioned themselves in field experience contexts (Mosvold & Bjuland 2016); and how their identity progressed from mathematics methods coursework to field experience (Hodges & Hodge 2017). Some studies focused on change in identity or identity development resulting from PTs' participation in mathematics education courses, mathematics course for PTs, or field experience activities. For example, Heffernan (2016) investigated change in PTs' mathematical identities during a mathematics course for education majors; Kaasila, Hannula and Laine (2012) compared the identity talk of five PTs at the beginning and end of a mathematics education course to identify their interpretative repertoires; and Akkoç and Yeşildere-İmre (2017) investigated the contextual nature of professional identities of three PTs prior to and after participating in field experience activities. The results of such studies provide evidence of the importance to understand and impact PTs' professional identity to enhance their learning in becoming mathematics teachers.

In general, research has indicated that there is an important relationship between teachers' identity, particularly, their beliefs or conceptions of mathematics and mathematics pedagogy, and their teaching of it. However, as Ponte and Chapman (2016) discussed, there are few studies that deal explicitly with PTs' identity and more attention is needed on how to support its development. This paper reports on an ongoing study that contributes to this area of research. The larger study is investigating the impact of a Science, Technology, Engineering, Mathematics [STEM] education course in a teacher education program on elementary school PTs' identity related to mathematics education. The research question addressed here is: what are the PTs' perspectives of how they changed in their thinking (e.g., beliefs/conceptions) associated with their identity about mathematics and its teaching and learning and what aspects of the STEM course supported these shifts?

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

Theoretical Perspectives

The key theoretical constructs framing the study are identity, STEM education, and inquiry-based learning.

Identity

While identity has become an important construct in researching the teacher and in teacher education, it is a complex construct that has been conceptualized in different ways in studies in education (Beauchamp & Thomas 2009; Beijaard, Meijer & Verloop 2004) and more generally (Gee 2001; Wenger 1998). Identity includes our experiences and knowledge, our perceptions of ourselves, others' perceptions of us, and our perceptions of others' perceptions of us (Wenger, 1998). It is also viewed as beliefs, commitments, and intentions adjusted to a particular community (Lave & Wenger 1991), the constellation of attributes, beliefs, values, motives and experiences that people use to define themselves in their professional capacity (Schein, 1978), and the roles, values and norms of the professional group (Berger & Luckmann1966). These perspectives can be used to study different aspects of teachers' identity; however, in this paper, the focus is on their professional identity, which is important because it is a key way that individuals assign meaning to themselves, and it shapes work attitudes, affect and behavior (Siebert & Siebert, 2005). It includes professional attributes, beliefs, values, motives and experiences they use to define themselves as teachers (Schein 1978). In this study, the PTs' professional identity is considered to include their views, beliefs, conceptions, or what they value about mathematics and its learning/teaching and about themselves as the mathematics teachers they want to become. Their perspectives of their identity consist of their views or beliefs based on their explanations of their thinking and experiences in the STEM course.

STEM Education

In the last decade, STEM education has received increased attention as concerns grow about preparing students for a changing global economy and workforce needs. As Bybee (2013) points out, the overall purpose of STEM education is to further develop a STEM literate society. However, STEM education could have different meanings depending on if it is viewed, for example, as an acronym for the four separate disciplines or as interdisciplinary or intradisciplinary that cuts across the boundaries of these disciplines. Bybee also noted that the "purpose of STEM education is to develop the content and practices that characterize the respective STEM disciplines" (p. 4). Thus, for example, a course in mathematics that includes connections to real-world situations to develop deep understanding of mathematics, or a course in which "students are required to demonstrate their understanding of STEM disciplines in a work-based, contextual environment" (Kennedy & Odell, 2013), or a course on robotics in which students are expected to innovate and invent with no explicit focus on developing mathematics or science concepts can all be considered to be STEM courses. The section of the STEM course in this study was a hybrid of these perspectives, structured around three units that focused on mathematics, robotics, and the engineering design process.

Inquiry-based Learning

An inquiry-based learning perspective framed the STEM course. Inquiry-based learning places emphasis on the learners with their understanding as the central focus. "[It is] about asking questions and seeking answers, recognizing problems and seeking solutions: wondering, imagining, exploring, investigating, discussing, reasoning and looking critically at what we find out" Jaworski (2015, p. 30). Students are engaged individually and collaboratively in inquiry tasks to "foster [their] construction of their knowledge through inquiry, exploring, and finding their own path to solution" (Maaß & Artigue 2013, p. 782).

Research Methods

This study, which is in progress, is based on one section of the STEM course offered in Fall 2018 and taught by the second author of the paper. Participants are elementary school PTs in the first semester of their two-year Bachelor of Education program at a Canadian University. They had no post-secondary mathematics and no mathematics education courses prior to the STEM course. They are representative of PTs who disliked mathematics and took the course because it was required for their program. Based on ethics requirement, we are allowed to recruit them after the course ends and final grades are confirmed by the university.

The STEM Course

The course is scheduled for two 90 minutes classes each week for 11 weeks. The learning outcomes for students include*:* (1) Develop a foundational understanding of the nature of discourse in STEM disciplines as related to teaching and learning; (2) Understand and appreciate how the engineering design process can contribute to teaching and learning mathematics and science; (3) Design learning environments in STEM; and (4) Identify concepts and make explicit the connections across disciplines. Key activities of the section of the course being studied were:

Activity (1): Conduct a *concept study* of elementary school mathematics concepts (e.g., whole number multiplication) over 4 weeks. This included exploring alternative meanings, representations, instantiations of concepts; identifying concepts within genuine/rich/authentic contextual tasks; and making connections within and across mathematics concepts. Problem solving/modeling also played an important role. For example, students, in groups, had to identify a real-world scenario (e.g., local forest fire with plans to reforest) and decide on an authentic problem to solve (e.g., how long to reforest a park).

Activity (2): Create a real-world challenge task of their choice and design, build and program a robot to complete the task over four weeks. This included understanding and applying the engineering design process.

Activity (3): Apply the engineering design process to design a STEM inquiry unit for teaching and unpack the mathematics and science concepts contained within it that students will learn.

Data Sources and Analysis

Data for the study consist of interviews, students' course assignments, and instructor's notes during the course. We base this paper on the first four PTs we interviewed before the due date of the proposal. We also focus only on the interviews to offer a sample of the participants' perspectives of changes to their identities in becoming teachers of mathematics. Each participant was interviewed for about an hour. The semi-structured interview included eliciting their thinking about their school experience learning mathematics, pre- and post-STEM course beliefs and feelings about mathematics and doing mathematics, learning in the STEM course, shifts in understanding of mathematics and its teaching and learning, and aspects of the STEM course that contributed to these shifts. All interviews were audio-recorded and transcribed.

Analysis was guided by the research question and theoretical perspectives of identity and STEM education. Using open coding (Corbin & Strauss, 1990), the transcripts were scrutinized to highlight statements that indicated the participants' perspectives of changes in their thinking about mathematics and its teaching and learning and their experience in the STEM course that contributed to these changes. This included coding their pre- and post-course beliefs and feelings about mathematics, doing mathematics and teaching and learning mathematics and aspects of the STEM activities identified as supporting changes in their thinking. The coded information was summarized for each participant and compared for similarities and differences in their thinking/identity. The findings reported here are examples of common shifts in their thinking.

Results

These preliminary findings are a preview of changes to the PTs' identity and of specific aspects of the STEM course they considered to be effective in helping them to achieve these changes to value mathematics differently from the way they experienced it as learners and want to teach it. In particular, there were shifts in their identity based on how they viewed mathematics and doing mathematics, teaching mathematics, and themselves as becoming teachers of mathematics. Examples of these shifts follow.

For their pre-course view of mathematics, all the PTs emphasized that mathematics was about numbers and applying numbers. Consistent with this, for them, doing mathematics meant developing numeracy and working on computations and repetitive worksheets. The main shift in their post-course view of mathematics was extending it to include mathematics as problem solving, connections and reasoning.

Their pre-course view of teaching focused on teacher-directed approaches which were "very un-engaging" for students. Their post-course view shifted to a more student-centered perspective, which included: "engaging students in multiple ways to solve a problem" and "logic of math" (i.e., mathematical reasoning); "offering opportunity for success for all;" seeing "potential to facilitate success for all;" "making it [math] more visible and authentic to students;" and "making it relevant to life of student."

Their pre-course view of *self* as teacher was connected to "terror" of doing and teaching mathematics. Their post-course view shifted to having "increase in confidence" to teach mathematics, being "less intimidating," having more "courage to explore math," and being "grateful to be empowered."

The PTs' perspective of course influence on these shifts included: (1) what they learned; for example, "STEM gives the context for math," "hands-on, real-world math problem and problem solving," "multiple problems from real-world situation," "problem posing," "many ways to understand math," "multiple ways to solve problems" and (2) collaboration; i.e., "group work."

While course Activities 2 and 3 described above had potential to enhance the PTs' math-related identity, the four participants did not refer to them and focused mainly on Activity 1, that explicitly addressed mathematics concepts and problem solving, as the key influence on the changes in their identity. For example, the engineering design process has similarities to problem solving and modelling, but without explicit support to consider these similarities these PTs seemed to not associate this process with mathematics and any impact on their mathematical identity. They also drew on the mathematics they already "knew" in unpacking mathematics concepts in the STEM tasks, suggesting no new learning of mathematics for teaching and shifts in identity. Thus, while the inquiry-oriented approach allowed them to be innovative in designing STEM tasks, their initial identity seemed to play a role in limiting the type of shifts they were able to achieve in their thinking and identity.

Conclusion

Our preliminary results, offered with caution, suggest that elementary school PTs could experience meaningful shifts in their identity for teaching mathematics in an inquiry-based, STEM education course with a component that explicitly deals with mathematics. However, further work is needed to explore the relationship between other components/perspectives of a STEM course (such as activities 2 and 3) and PTs' learning that can result in shifts in their identity development to become teachers who can meaningfully engage students in learning mathematics. We intend to consider this as we complete the larger study and make changes to the course to further investigate and understand this relationship.

FRACTION-WITHIN-FRACTION: PROSPECTIVE TEACHERS' PERSPECTIVE ON SYMBOLS AND MEANING

Ofer Marmur	Xiaoheng Yan	Rina Zazkis
Simon Fraser University	Simon Fraser University	Simon Fraser University
omarmur@sfu.ca	xkyan@sfu.ca	zazkis@sfu.ca

We explore prospective elementary-school teachers' attempts to provide signs and symbols with mathematical meaning. The data comprises responses to a task inquiring about the existence of numbers between 1/6 and 1/7, in which the participants were asked to compose a hypothetical dialog between a teacher and students addressing this issue. We focus our analysis on three representative cases exhibiting difficulties in assigning meaning to "6½" when it appears in the numerator or denominator of a fraction representation. These difficulties are examined by utilizing the theoretical lens of "semiotic representation", and explained via the meaning associated with different representations of fractions.

Keywords: Teacher Knowledge; Number Concepts and Operations; Rational Numbers

Among the many difficulties associated with the learning of fractions, we focus on difficulties related to the multiple representations of fractions (e.g., Čadež & Kolar, 2018), and inquire into how learners attempt to provide unexplained signs and symbols with mathematical meaning. We present a case where $\frac{1}{6½}$ and/or $\frac{6.5}{42}$ were proposed as solutions by prospective elementary-school teachers, and examine the teachers' difficulties in accepting the symbolic suggestion as a legitimate solution endowed with meaning.

Theoretical framework

We rely on the notion of *semiotic representation* (Duval, 2006), which suggests that mathematical objects can be accessed only through signs. These signs are not the mathematical objects themselves, but merely representations of mathematical objects, which can be represented in different semiotic systems, also called registers. Regarding fractions, different models are linked to a range of semiotic representations. For example, the same fraction can be represented in a verbal register (three-quarters), symbolic register (¾), and visual register ().

According to Duval (2006), a mathematical activity consists of two types of *transformations* of semiotic representations: treatments and conversions. *Treatments* are transformations of representations within the same semiotic register, while *conversions* are transformations of representations between different registers. For example, a transformation between $\frac{3}{4}$ and $\frac{6}{8}$ is a treatment within the fractional register; and a transformation between $\frac{3}{4}$ and 0.75 is a conversion between the fractional and decimal registers. Duval pointed out that conversions between registers are more complex than treatments, and are accordingly a significant source of learners' difficulties. We use these constructs to address the following research question: *How do semiotic representations of fractions play a role in prospective elementary-school teachers' consideration of the appearance of a non-whole number in the numerator or denominator?*

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

Method

The participants were 33 prospective elementary-school teachers enrolled in their last term of an undergraduate program towards a teacher certification. During the course the participants were given several scripting tasks, which included a beginning of a hypothetical classroom dialogue between a teacher and students that the participants needed to extend in a way they found mathematically and pedagogically fit (e.g., Brown, 2018; Marmur & Zazkis, 2018).

Teacher:	Could you give me a number between 6 and 7?
Anna:	We don't have any numbers between 6 and 7!
Maya:	That's not true! $6\frac{1}{2}$ is a number between 6 and 7.
Anna:	Ah, right. I forgot about fractions.
Emily:	Teacher, is there a number between any two numbers?
Teacher:	Good question. What do you think?
Emily:	Hmm, I don't know.
Maya:	I don't think so. There are no numbers between $\frac{1}{6}$ and $\frac{1}{7}$.
Teacher:	…

Figure 1: Prompt for the Scripting Task

The scripting task we discuss here (see Figure 1) presented two pseudo-successive fractions, $\frac{1}{6}$ and $\frac{1}{7}$, and included a student-character claim that there are no numbers in-between. In addition to extending the dialog, the participants were asked to provide complementary commentaries, including a diagnosis of potential sources of error and a description of their own understanding of the mathematics involved. In the design of the prompt, we chose two fractions whose denominators were successive natural numbers, as such fractions are often perceived incorrectly as successive numbers with no numbers in-between (e.g., Vamvakoussi & Vosniadou, 2004). For analyzing the data, we first used inductive content analysis to identify emerging themes in the participants' responses. Subsequently we used directed content analysis (Hsieh & Shannon, 2005) to explain the rejection of solutions in which six and a half appeared in the numerator or denominator, while concentrating on different representations of fractions.

Findings

We focus on three representative cases that illustrate three kinds of obstacles in accepting the six-and-a-half suggestion, based on the provided meaning to its semiotic representation.

Symbolic Representation of Fractions: The Case of Adam

Adam's assignment demonstrated a rather sophisticated mathematical understanding, as it was one of only four assignments that explained how infinitely many numbers between 1/7 and 1/6 could be found. Nonetheless, his script opened with a student-character wondering whether 1/6.5 could be a solution, a suggestion that was immediately rejected by the teacher-character:

Teacher: As we can see, the numbers 1/6 and 1/7 go here and here (Points to exactly where these two numbers fit in on a number line). Now Emily, do you think that there are any numbers that are between 1/6 and 1/7?

Emily: There must be, because there is a gap between these two numbers in our number line, but what could they be? 1/6.5?

Teacher: It cannot be 1/6.5 because a fraction is already a decimal, so we cannot have a number that is 1/6.5. Any other ideas?

In the above excerpt, the teacher not only instantly rejects 1/6.5 as an optional answer, but also provides a perceived reason: “a fraction is already a decimal, so we cannot have a number that is 1/6.5”. Clearly the suggestion is rejected on the basis of representation: 6.5 is not an accepted representation for a denominator. This type of reasoning was also found in additional scripts that proposed an answer with 6.5 in the numerical expression. These responses pointed towards a rejection of 1/6.5 based on the mixture of fractional and decimal representations, revealing a fraction image in which the numerator and denominator must be whole numbers.

Interestingly, later in Adam’s script the student-characters suggested 2/13 as a solution, which is equivalent to the rejected 1/6.5. Nonetheless, neither in the continuation of the script nor in Adam’s mathematical commentary, was 2/13 connected to 1/6.5. Shedding light on this matter, we return to the teacher-character’s statement, “we cannot have a *number* that is 1/6.5”, and suggest that the option of 1/6.5 was rejected not only as a possible answer, but also as a perceivable number. Accordingly, while 1/6.5 can be written as a string of symbols on the page (“1”, “/”, “6”, “.”, “5”), this semiotic representation may not be associated with any numerical meaning for the scriptwriter. In this regard, we suggest that no connection between 2/13 and 1/6.5 was made, as the representation of the latter was not interpreted in the “number register”.

Visual Representation of Fractions: The Case of Sarah

Sarah’s script included many visual representations of fractions aimed at exemplifying the meaning of fractions and equivalent fractions. Attempting to create a visual representation was also the way by which the characters in Sarah’s script tried to make sense of 1/6.5:

Emily: Well, you know, Maya seems to make some sense, when I see the number 1/6 and 1/7, 6 is before 7 and you can’t have make a 1/6.5.

Anna: Yeah, 1/6.5 sounds weird... If I try to draw it, it looks weird:  Wait... I just drew 1 part of 6.5, so it is possible? Oh man, now I’m super confused. My drawing doesn’t make any sense.

We interpret the picture above as an attempt to draw six and a half squares in a row – the six squares on the left, and the last “half square” (rectangle where one side was halved) on the right. Additionally, the most left square is colored in, indicating what we interpret as the “1 part of 6.5”. We suggest that this visual representation provides a sophisticated attempt at making visual sense of 1/6.5, employing a *set model* of fractions, rather than the common *area model* involving pizzas and pies. Interestingly, later in the script, Sarah demonstrated an understanding of the set model, by creating a visual representation of 4/12 as 4 squares out of a total of 12 squares. Nonetheless, this model was rejected when applied to the suggested representation of 1/6.5.

We suggest that the common part-whole fraction-image may be so overpowering to learners, that even when demonstrating part-set understanding, they can only make sense of it as long as the numbers involved are whole. In this regard, we note Sarah’s attempts to make a conversion between different representational registers of fractions, that is between a visual part-whole register and a visual part-set register. Nonetheless, even when producing a suitable visual representation for 1/6.5 in the part-set register, we observe Sarah’s *cognitive impossibility of dissociating* (Duval, 2006) the fraction object and its ingrained visual part-whole representation.

Permissible Operations on Fractions: The Case of Eve

Eve's script included a suggested solution of $\frac{6.5}{42}$, although also here we found a student-character claiming: "I don't think we can have a fraction as a numerator". Similar to Adam's case, the student-characters reached an equivalent solution 13/84, though no connection to 6.5/42 was made. However, as opposed to Adam's case, we suggest that the issue here is not whether "6½ over 42" is a *number* according to the scriptwriter, but whether it is recognized as a *fraction*. When examining Eve's script, we noted that 6/42, 6.5/42, and 7/42 were written together in a row, though only 6/42 and 7/42 were *operated on* as fractions (to reach 12/84 and 14/84), illustrated by small "×2" writings present only next to these two fractions.

Additionally, in the accompanying commentary to the script, Eve suggested 1/6½ as another solution and provided her personal mathematical understanding: "I also knew 6 ½ was between 6 and 7 so inverse 6 ½ and turned it into a fraction: $1 \div 6½ = 1 \div \frac{13}{2} = 1 \times \frac{2}{13} = \frac{2}{13}$." While this calculation is correct, we argue that not only is the expansion of the numerator and denominator by 2 a quicker method to reach the final answer (i.e., $\frac{1}{6.5} = \frac{1\times2}{6.5\times2} = \frac{2}{13}$), but also that the mathematical symbols Eve uses reveal how the numbers are mathematically regarded by her. Rather than representing "inverse 6 ½" in fractional form as $\frac{\text{number}}{\text{number}}$, it is represented with a division symbol "÷" as "$\text{number} \div \text{number}$"; and subsequently operated on in accord with the rules of fraction division. We argue that in order to treat 1/6½ as a fraction, it should be recognized in the "fraction register". If it is not recognized as such – it is treated in the "number" register. It is clear Eve recognizes "1/6½" as a number between 1/7 and 1/6, as evident from her comment above. However, in Eve's own words, the symbolic manipulations are taken so that "inverse 6 ½" could be "*turned* into a fraction". Thus, as mathematical operations are associated with specific registers (Duval, 2006), not being able to regard 1/6½ in both "number" and "fraction" registers, narrows the range of permissible operations on this mathematical object.

Discussion

In the education literature it is well-known that the choice of a symbolic representation can play a crucial role in learners' understanding of a mathematical object. This is also evident in the case presented herein, as the data pointed towards the representation of fractions as an underlying source of explanation for the participants' unwillingness to accept their *own* 6.5-suggestions. Rather, the "odd" fraction representations, whether in symbolic or visual form, seemed to have shaped the assigning of meaning to the suggested mathematical object. In particular, the prospective teachers either: (a) dismissed the proposed answer as an actual number; or (b) struggled to make conversions between different representation registers of fractions; or (c) operated on the object according to division rules rather than fraction rules. Whereas the last option limited the range of permissible operations on the suggested object, the first two options resulted in the full rejection of the six-and-a-half numerical expression.

The overreliance of prospective teachers on the part-whole representation of fractions has been evident in the responses of almost all the participants in the current study. In Duval's (2006) terminology, we suggest it might be a cognitive impossibility of dissociating fractions from this early introduced representation, that is at the core of the difficulty with accepting fractions involving 6.5 as a semiotic representation endowed with meaning. We also note that the language used by many of the scriptwriters to describe their solutions, suggested that the *existence* of fractions between 1/6 and 1/7 depended on the symbolic representation enabling whole-numbers-in-between; as for example illustrated in the following statement: “There is no fraction that can fit between 6/42 and 7/42 but it looks like there could be a 13 that would fit between 12/84 and 14/84.” To conclude with practical implications, we note that in the literature we could not find sufficient attention to the *set model* of fractions (see Sarah’s case). We suggest that further attention to the set model not only could provide learners a way to endow semiotic representations of fractions-within-fractions (such as 1/6.5) with approachable meaning, but could also expand the ways by which they can operate on fractions.

THE GROWTH OF PRESERVICE SECONDARY MATHEMATICS TEACHERS' TECHNOLOGICAL CONTENT KNOWLEDGE DURING INSTRUMENTAL GENESIS

Xiangquan Yao
Pennsylvania State University
xzy73@psu.edu

Relying on the theory of instrumented activity, this study examined the development of PSMTs' technological content knowledge when solving mathematically rich problems with GSP. Preliminary findings from the study were shared to highlight the dynamic interactions between technological and mathematical knowledge.

Keywords: Technology; Teacher Knowledge

The ubiquity of technology offers mathematics teacher educators opportunities and challenges to enhance the ways in which prospective teacher learn about mathematics and mathematics pedagogy. Serval organizations have highlighted the importance of preparing teachers to teach students mathematics using appropriate technology (e.g., NCTM, 2014; AMTE, 2017). Mishra and Koehler's (2006) framework of Technology, Pedagogy, and Content Knowledge (TPACK) offered a useful way to conceptualize what knowledge preservice teachers need to integrate technology into teaching practices but left the specifics of what lies in each circle to disciplinary researchers. Bowers and Stephens (2011) noted that technological content knowledge (TCK) had received less research attention than other domains of knowledge for teaching mathematics. This study aimed to address this gap and was guided by one research question: How preservice secondary mathematics teachers (PSMTs) develop their technological content knowledge when working with Geometer's Sketchpad (GSP) to solve mathematically rich problems? Following Bowers and Stephens (2011), this study defines technological content knowledge as knowledge of using technology to explore mathematical relations.

Theoretical Framework

Theory of instrumented activity (Verillon & Rabardel, 1995) served as a conceptual framework for this study. Based on a neo-Vygotskian approach, this theory considers situations in which an instrument is used to measure actions between a subject and an object. It differentiates between an *artifact* and an *instrument*. An artifact is merely a bare tool, which is available to the user and has the potential to support a certain kind of activity, but which might be a meaningless object if the user does not know what tasks the tool can support in which ways. The subject does not initially consider an artifact to be an instrument (Artigue, 2002). The user needs to develop an understanding of the affordances and constraints of an artifact and to establish a relationship with the artifact. An artifact becomes an instrument when the user is aware of how the artifact can extend one's capacities for accomplishing a given task and has developed means of using the tool for a specific purpose. Therefore, an instrument consists of both an artifact and the associated mental schemes that the user develops to use the artifact for accomplishing specific tasks. Instrumental genesis describes the process of developing an instrument from the interaction between a subject and an artifact.

Instrumentation and instrumentalization describe a bilateral relationship between the artifact and the user established within instrumental genesis. *Instrumentation* describes processes oriented toward the learner him/herself, in which the learner's mathematical activity and the corresponding emergent conception of mathematics are influenced by the affordances and constraints of a tool. In contrast, i*nstrumentalization* refers to processes directed toward the artifact, in which the learner enriches the artifact's properties acquired momentarily or durably. Through instrumentation, utilization schemes are developed, which are subsequently transformed into techniques for dealing with the task at hand. Utilization schemes are defined as significant and coherent mental schemes aimed to resolve a specific type of task with the use of an instrument (Drijvers, 2013). *Techniques* (a set of procedures used to solve a determined type of problem) are the observable counterpart of the invisible mental schemes. The two dialectical relationships (i.e., artifact and instrument; instrumentation and instrumentalization) are at the heart of the theory of instrumented activity (Figure 1).

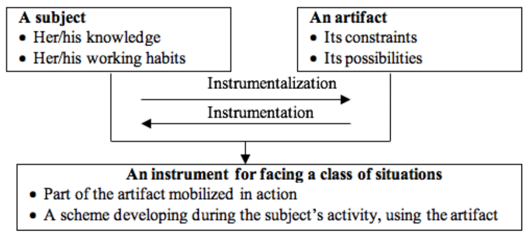

Figure 1: A Representation of an Instrumental Genesis (Trouche, 2018)

Methodology

To investigate the development of technological content knowledge, one-on-one constructivist teaching experiment (Steffe & Thompson, 2000) methodology was utilized. At its core, the teaching experiment is a "conceptual tool that researchers use in the organization of their activities. It is primarily an exploratory tool… it involves experimentation with the ways and means of influencing students' mathematical knowledge (Steffe & Thompson, 2000, p. 273). One of the primary functions of constructivist teaching experiment is the construction and testing of hypothesis regarding human thinking. Such was the case for this study. When planning for the teaching experiment, I considered various types of tasks in order to study instrumental genesis in different scenarios. Some tasks demanded participants to construct GSP sketches, while other tasks invited participants to explore with existing GSP sketches. In some cases solving the problem might only demand the development of a new mathematical idea or new use of GSP, while in other cases new mathematical idea and novel use of GSP were both essential for successful problem solving. Figure 2 presents sample tasks used in the teaching experiment.

The participants of this study were three junior undergraduate students enrolled in a secondary mathematics teacher education program. Chen majored in both mathematics and mathematics education, and Jan and Joe majored in mathematics education. Prior to the study, all the participants have taken courses in calculus, linear algebra, discrete mathematics, abstract algebra, real analysis, and algebra for teachers. None of them had taken an undergraduate course in geometry. While participating in the study, all the participants were enrolled in a course that focused on teaching mathematics in technology-intensive environments, where they learned to use various mathematics-specific technologies (TI-Nspire, GeoGebra, GSP, and Fathom). However, since GSP had not yet been introduced in that course when the study began, and none of the participants had any exposure to it before, the researcher introduced GSP and its basic

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

tools (e.g., "construct", "transform", and "measure" commands) to each participant and provided them time to play with it and get conformable with the dynamic environment.

Each participant participated in 8 teaching sessions, each of which lasted approximately 2 hours. Screen-recording was used to capture the participant's interaction with GSP. Interaction between each participant and the teacher-researcher was video-recorded. GSP files the participants produced in each session were saved. The verbatim transcripts of the recordings were annotated to include snapshots of GSP screen content and non-verbal actions. Instances of instrumental genesis were then identified. An event was identified as an instance of instrumental genesis if a new technique of GSP usage was observed or new mathematical idea was developed through the use of GSP. Each instance was analyzed based on the following categories: techniques used in the activity, prior mathematical knowledge activated in the activity, mathematical ideas newly developed in the activity, cognitive obstacles manifested in the activity, and interaction between the student and teacher-researcher. These categories allowed the researcher to identify techniques and utilization schemes participants developed when working with GSP to solve mathematical problems. The utilization schemes and techniques provide a window to examine the dynamic interactions between instrumentalization and instrumentation and growth of technological content knowledge.

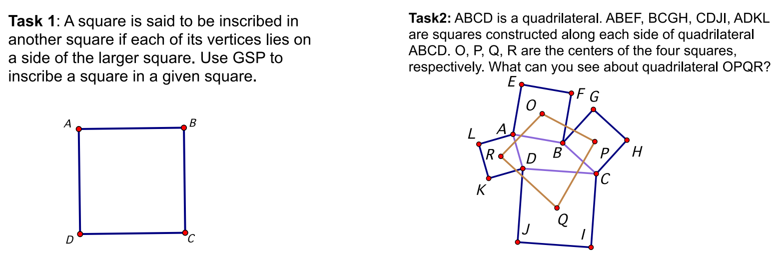

Figure 2: Sample Tasks in the Teaching Experiment

Result and Discussion

Data analysis is still ongoing. This section presents two participants' work on inscribing a square inside a given square to illustrate dynamic interaction between technological and mathematical knowledge and paths PSMTs took in developing technological content knowledge.

The Case of Joe

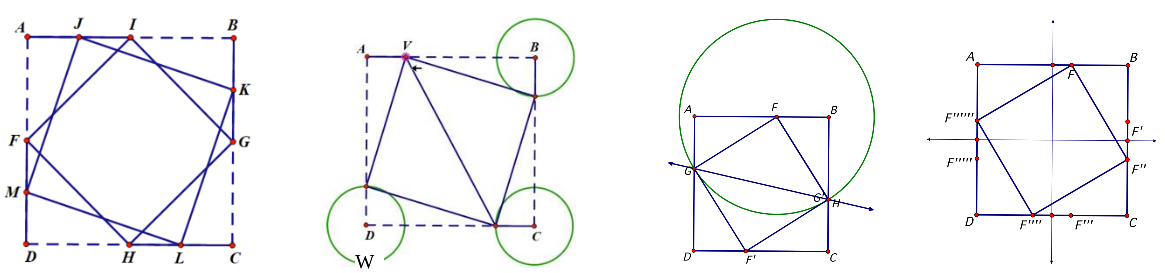
Joe approached the problem by finding midpoints of the four sides of the given square and then connecting the midpoints to form an inscribed square. Joe relied on the Pythagorean theorem to justify why the sides of the inscribed shape were congruent and used the 45°-45°-90° triangle at each corner to explain why angles of the inscribed figure were 90°. In response to the request to find another inscribed square, Joe constructed "midpoints of the midpoints" of sides of the given square and connected the four "midpoints" to form another inscribed square (see Figure 3a). Again, Joe relied on the Pythagorean theorem to justify the congruency of the four sides of the inscribed figure, but was only able to use measurement to verify the angle measures of the inscribed square. Joe then stated that there were infinite many inscribed squares as he could keep finding "midpoints of the midpoints" and thus J could be anywhere on $\overline{AB}$. He also observed m$\overline{AJ} \cong m\overline{BK}$ and the four triangles were congruent by the side-angle-side theorem.

The researcher then pointed out to Joe that he would not be able to drag the vertices of each inscribed squares constructed in his way and challenged him to inscribe a square such that he could change its size by dragging its vertex. The researcher invited Joe to consider the observations he just made about the diagram. Joe knew he would need four congruent triangles at the four corners, but did not know how to obtain them. He put a point V on $\overline{AB}$ and another point W on $\overline{AD}$ and was wondering how to make $\overline{AV}$ and $\overline{DW}$ congruent. The researcher then asked Joe whether he thought about the circle tool and pointed out that there are two ways to construct a circle in GSP ("circle by center + radius" and "circle by center + point." Joe then constructed three circles at each corner of the square by using “circle by center + radius” tool and found the other three vertices of the inscribed square (Figure 3b).

The Case of Chen

Similar to Joe, Chen created an inscribed square by connecting midpoints of the four sides of the given square. When asked whether that was the only inscribed square, Chen picked a point F on side $\overline{AB}$, drew a segment from F to $\overline{AD}$, and rotated the segment 90° around F. By dragging F and G, Chen observed “for every point on AB, it looks there is only one orientation of this angle that would allow having equal length hitting both $\overline{AD}$ and $\overline{BC}$." Based on this observation, Chen constructed a circle with F as the center and FG as the radius. He thought point H was another vertex of the inscribed square. However, when starting to move F, he realized the circle did not always intersect with $\overline{BC}$ and the two segments were not always perpendicular. He dragged F and G to make G' and H coincide. Chen then reflected $\overline{FG}$ and $\overline{FG'}$ across $\overleftrightarrow{GG'}$ to create an inscribed square (see Figure 3c). He seemed to be aware that his square would not pass the dragging test because he picked the point on $\overline{BC}$ visually. The researcher asked Chen what he noticed about the triangle at each corner. Chen stated that they were congruent.

The researcher challenged Chen to make a draggable inscribed square. After a long pause, Chen stated he was thinking of rotating ΔAFG about B for 90°because that would probably give him $\Delta BG'F$. After deleting previous work, Chen did the following: rotated F 90° around B, reflected F' across the line connecting the midpoints of $\overline{AD}$ and $\overline{BC}$ to get F'', rotated F'' 90° about C to get F''', reflected F''' across the line connecting midpoints of $\overline{AB}$ and $\overline{DC}$, rotated F'''' 90° around D to get F''''', and reflected F''''' across the line connecting midpoints of $\overline{AD}$ and $\overline{BC}$ to get F''''''. He claimed the figure $FF''F''''F''''''$ is a square (see Figure 3d). When asked why he decided to carry out a rotation followed by a reflection on each side of the given square, Chen said he was really thinking of rotating the entire ΔAFG, although he only cared about recreating $\overline{AF}$ on each side of the square. The researcher asked Chen if he could simplify his construction steps. Chen was not able to reduce his construction steps.



(a) (b) (c) (d)

Figure 3: Joe’s and Chen’s Approaches to Inscribe a Square

Although both Joe and Chen successfully inscribed a dynamic square, they relied on different mathematical and technological knowledge to obtain the desired configuration and seemed to gain different technological content knowledge. Joe’s initial approached relied on the “midpoint” tool, which allowed him to create multiple inscribed squares and developed a dynamic mental image about the inscribed squares. Relying on this mental image, he used the "circle by center +radius" tool to inscribe a dynamic square inside the given square. In contrast, Chen seemed to rely on geometric transformations frequently. He first used 90° rotation and dragging to create the desired configuration that started a square. Based on the knowledge developed from this non-draggable configuration, he used a series of composition of rotation and reflection to create a dynamic square inside the given square. His problem-solving actions revealed that transformation tools became his technique for creating congruent geometric objects.

The two cases revealed a pattern that describes a relationship between instrumental genesis and the growth of geometric knowledge. This cyclic pattern is as follows: Use particular GSP tools to obtain a static or non-constructible geometric configuration, observe new geometric properties or relationships from this configuration, and use this newly developed knowledge to guide GSP usage and create a more dynamic configuration or an alternative method for constructing a dynamic configuration. It highlights the interactions among learner, mathematical tasks, technological tools, and teacher and creates a dynamic space within which new mathematics knowledge and meaningful ways of using technology emerge.

MATHEMATICAL MODELING EXPERIENCES: NARRATIVES FROM A PRESERVICE TEACHER AND AN INSTRUCTOR

Sarah Brand
Marquette University
sarah.brand@marquette.edu

Hyunyi Jung
Marquette University
hyunyi.jung@marquette.edu

Regardless of the benefits of engaging in mathematical modeling, few preservice teachers (PTs) have experienced mathematical modeling firsthand. This study offers an example of how to make sense of the interaction between the teaching and learning of mathematical modeling by examining a teacher educator's decision making, her analysis of 36 PTs' learning, and an in-depth narrative from a PT. Findings show the value of engaging with structurally relevant mathematical modeling tasks and considering social issues via mathematical modeling, resulting in task designs which aim to deepen students' understanding of society and mathematics.

Keywords: Mathematical Modeling; Preservice Teacher Education

The benefits of engaging with mathematical modeling (i.e., the process of using mathematics to provide insight into real-world situations) have been presented by numerous research studies (Consortium for Mathematics and Its Applications & Society for Industrial and Applied Mathematics [COMAP & SIAM], 2016). Students develop reasoning abilities, entrepreneurial thinking, conceptual understanding, and procedural fluency when they engage with mathematical modeling (e.g., Blum & Niss, 1991; Lesh, Hoover, Hole, Kelly, & Post, 2000; Zbiek & Conner, 2006). However, despite the advantages of learning mathematical modeling, many teachers have limited experience with learning and teaching the related content and processes (e.g., Burkhardt, 2006; COMAP & SIAM, 2016). The inclusion of mathematical modeling in preservice teachers' (PTs') learning has been recommended so that they may be prepared to engage their future students with authentic problem-solving experiences (Association of Mathematics Teacher Educators, 2017); still, few PTs have experienced mathematical modeling firsthand. Research remains to be done about mathematical modeling learning opportunities provided to PTs, especially on the purpose of such learning opportunities and how learners respond to them. This study offers an example of how to make sense of the interaction between the teaching and learning of mathematical modeling by examining a teacher educator's curricular intentions and her PTs' responses to tasks designed around those intentions. The focus here is on the teacher educator (second author)'s decision-making, her analysis of PTs' learning, and a more in-depth narrative from one of her PTs (first author). Specifically, the research questions are "How does a teacher educator make decisions about implementing mathematical modeling to preservice teachers?" "How do PTs respond to the implementations of mathematical modeling tasks?" and "How does a PT reflect on and narrate specific aspects of the implementation?"

Methods

36 PTs enrolled in three sections of a problem-solving mathematics course taught by the second author (Jung) at a Midwestern university in the U.S. Thirteen teams of PTs solved, designed, and revised mathematical modeling tasks in this course. Specifically, the PTs solved relevant mathematical modeling tasks, including Model-Eliciting Activities (MEAs), which are known to showcase the nature and usefulness of mathematics while developing valuable

everyday skills (Lesh et al., 2000). PTs also reflected on their own learning and relevant literature related to mathematical modeling (e.g., English, Fox, & Watters, 2005). They then collaboratively designed mathematical modeling tasks and revised them based on peer feedback. The course resulted in the following data sources: (a) audio-recordings of individual interviews focusing on PTs' learning of mathematical modeling; (b) 26 team solutions for two mathematical tasks (13 solutions for each task); (c) 25 mathematical modeling tasks designed by PT teams; (d) and PTs' individual reflections on their learning.

Data analysis involved two phases. During the first phase, Jung and her colleagues analyzed data sources collected from 36 PTs and found the overall learning opportunities related to mathematical modeling (Jung & Magiera, 2018). This analysis was used to describe Jung's analyses of the 36 PTs' learning opportunities. The second phase focused on the learning experiences of the first author (Brand). Among the 36 PTs, Brand was uniquely interested in multitiered teaching experiments (Lesh & Kelly, 2000) and the analysis of her learning of mathematical modeling. Brand's products included her team's written solutions to two MEAs, two written mathematical modeling problems designed by her team, and seven individual journal reflections that documented her learning of mathematical modeling. Upon dissecting her solutions to tasks, Brand noted themes embedded within her processes of developing mathematical constructs as she solved or designed mathematical modeling problems. Then, analyzing her reflections, Brand focused on what she learned from each activity and documented evidence of changes revealed from each journal reflection (Strauss & Corbin, 1998). The following section outlines the overall learning experiences of 36 PTs as intended and analyzed by Jung, followed by Brand's narratives of her own learning.

Results

PTs as Problem Solvers

Jung's intention and initial analysis of student work. To engage PTs with mathematical modeling as learners, Jung first selected the Fun on the Field MEA (Chamberlin, 2000), which required PTs to split 15 individuals into three equal teams for a school's field day. To sort the students, four categories of data were provided: each individual's 100-meter dash time, 800-meter run time, high jump height, and whether they passed a fitness test. When she analyzed PTs' initial work on this MEA, Jung found that only five out of 13 teams demonstrated a sophisticated sorting method that considered all four categories of data. Jung asked each team to review other teams' work and provide peer feedback (West, Williams, & Williams, 2013). She then provided the Volleyball MEA as a follow-up activity because it was mathematically connected to the Fun on the Field MEA but required more complex thinking about large datasets. By way of explication, the Volleyball MEA engaged PTs to split 18 individuals into three equal teams for a volleyball summer camp. Compared to the Fun on the Field MEA, the Volleyball MEA required a more involved usage of ranking systems and quantification processes, as it supplied additional data sets, including qualitative data (e.g., coach's comments). Jung's anlysis of PTs' work on the Volleyball MEA revealed that most teams (12 out of the 13 teams) considered all the data sets and used ranking methods to represent their sorting system.

Brand: My narrative. As my partner and I began solving the Fun on the Field MEA, I proposed using a point system which assigned points to individuals' results based on predetermined intervals for each category, excluding the fitness test results. My partner, however, expressed a concern that my procedure failed to differentiate between individuals whose results fell in the same point interval. Suggesting we rank individuals within each category, my partner encouraged me to consider both our avenues for solution. As we continued, my partner and I wanted to ensure that our solution strategy utilized all the data provided. Thus, we needed to determine how to include the participants' fitness test scores. Initially, we chose to assign 1 point to individuals who passed the test and 0 points to those who did not. Upon review, though, we recognized two flaws with this plan. For one, according to our ranking system, a lower score indicated a more athletically inclined individual. Receiving additional points for passing a fitness test would increase that individual's score, making them appear less physically adept than he or she was. To fix this, we quickly decided to add 0 points to an individual's score for passing the test. For our second concern, I was apprehensive about how uninfluential the fitness test results were on the subjects' final scores. I recommended that we add 5 points to the scores of those who failed, while still adding 0 points to the scores of those who passed. My partner agreed that this would generate an appropriate effect on the subjects' final scores.

Overall, my learning from this MEA included growth in my recognition and application of justifiable strategies, open-mindedness to others' skillsets, and receptivity to revisions. I also grasped that mathematical modeling allows for students to continuously revise their models until a desirable outcome is reached. Resultingly, when my partner and I completed the Volleyball MEA, we paid close attention to our peers' feedback and strategies from the Fun on the Field MEA. Having two opportunities to engage in similar MEAs encouraged my peers and me to develop more evolved mathematical reasoning skills and problem-solving strategies.

PTs as Designers: First Task

Jung's intention and initial analysis of student work. Jung later incorporated a problem-posing activity in her course. She also provided PTs opportunities to revise their tasks based on peer feedback, followed by instructor feedback. Her analysis of 36 PTs' invented tasks revealed improvements from the initial tasks to the revised tasks. Most PTs refined their tasks to make them more realistic and mathematically sound. Specifically, they developed diverse mathematical modeling tasks, including contexts such as Christmas tree decorating, a dream vacation plan, and designing a park.

Brand: My narrative. When designing my first modeling task, I frequently evaluated my group's problem to ensure it met the mathematical modeling problem criteria discussed in class and required students to (a) make assumptions about and predict a realistic context; (b) create and verify mathematical models; and (c) provide complex solutions beyond numerical results. Because my group was anxious about meeting these standards in our first original MEA, we chose to create a task which elicited strategies we had applied when solving previous MEAs. The result was an MEA, titled "Ms. Penny's Classroom," similar in mathematical structure to the Fun on the Field and Volleyball MEAs. Specifically, the task required students to split 15 students into three groups of equal academic caliber for a group project.

Despite the similarities between our problem and those we had solved in class, a new strategy could emerge from this problem: using qualitative data as a tool for revision. My team recognized that quantifying comments on students' behavior (e.g., "well-behaved and a great student") was not entirely feasible. We instead chose to use that dataset as a mechanism to adjust our initial groupings. Creating a new MEA thus broadened my supply of problem-solving strategies. Additionally, I developed an understanding of mathematical modeling as an enriching instructional experience because of its relevance to students' realities.

PTs as Designers: Second Task

Jung's intention and initial analysis of student work. Although the contexts of the first tasks that PTs developed were relevant to target students of their choices (e.g., Christmas tree, academic grouping), Jung wanted PTs to consider critical aspects of the real world. She believed it to be crucial that PTs encourage students to critically interpret the world using mathematics (Gutstein & Peterson, 2005). PTs were asked to share unfair or unjust experiences their future students may face in their lives or world. With these experiences in mind, PTs collaboratively developed a mathematical modeling task with a critical context.

Brand: My narrative. My partner and I wished to create a problem which did not ask students to group individuals or items, as we felt we had exhausted this type of context. After much consideration, we recalled the garbage pollution in our city and chose to focus our task on a solution for widespread littering. We also wanted to involve spacial concepts in our problem through the use of a map. Our problem "Preventing Litter in the City" emerged, involving data reasoning strategies we'd encountered in previous MEAs. Further, a new strategy, which we dubbed "grouping," became necessary for my team to both teach and solve our problem. For example, I chose to group two trash cans with every recycling bin in my solution. I also wanted the task to demonstrate my own beliefs that since we should involve "students in social and political conflicts…we should ensure that the implications in our math problems allow this" [Reflection 6]. To do so, I incorporated my students' city of residence in the problem, thereby encouraging them to take action within their own community. Ultimately, by creating this task, I learned the importance of choosing justice-oriented contexts for mathematical modeling tasks. I saw how teaching mathematics can be more engaging, interdisciplinary, and useful for developing students' knowledge of social justice.

Conclusion

Through the reflective processes, the authors illustrated practical and research knowledge that influenced the decisions a teacher educator and a PT made throughout mathematical modeling problem-solving and problem-posing experiences. As Diefes-Dux and Capobianco (2008) proposed, reflection supports a better understanding of the complex, interrelated sets of situations that teaching and learning requires. When this line of thinking is organized and connected, it often leads to new knowledge or action (Diefes-Dux & Capobianco, 2008).

The reflective nature of this self-study contributes to mathematics education in three ways. First, this-self study describes both the instructor's intentions for and analyses of 36 PTs' mathematical modeling experiences, as well as one PT's narrative of her learning. The perspectives from both the instructor and PT provide evidence of learning and changes in action, which would remain uncaptured were only one of these lenses considered. The results show that each participant was an active decision maker (Mundry, Britton, Raizen, & Loucks-Horsley, 2000), acting in different, evolving directions (Lesh & Kelly, 2000). Second, both the instructor's and PT's reflections reveal the value of engaging with structurally relevant mathematical modeling tasks (Ärlebäck, Doerr, & O'Neil, 2013; Doerr, 2016). The PTs used more sophisticated ways of data reasoning, including the analysis of qualitative data, when they engaged with two related mathematical modeling tasks. Brand's narrative detailed decisions she made when solving and posing mathematical modeling problems, ultimately contributing to a better understanding of her process of engaging with complex mathematical modeling activities. Last, the study details the rationales of how a PT created mathematical modeling tasks regarding societal issues. PTs were encouraged to design tasks that aimed to deepen students' understanding of society. Such results around mathematical modeling problem-posing activities extend findings from previous studies about PTs' problem-posing activities focusing on word problems (Tichà & Hošpesovà, 2010) or other modeling problems (Paolucci & Wessels, 2007).

As Brand narrated, choosing socially-aware contexts for a mathematical modeling problem enabled her to see the value of mathematics as a tool for broadening problem solvers' knowledge of the world.

The field of mathematics teacher education has been moving collectively towards a common goal of preparing preservice mathematics teachers to teach with technology, which is explicated in the Association of Mathematics Teacher Educators' (2017) Standards for Preparing Teachers of Mathematics*. In this paper we present findings from a national survey of accredited university secondary mathematics teacher education program. The purpose of the study is to describe the current state of the ways in which programs are preparing preservice teachers to teach secondary mathematics with technology.*

Keywords: Technology, Policy, Teacher Education

Since the release of the *National Educational Technology Standards for Teachers* (International Society for Technology in Education, 2000), the field of mathematics teacher education has worked to develop common goals about how secondary mathematics teachers should be prepared to teach mathematics with technology. Recently these goals were articulated in the Association of Mathematics Teacher Educators' [AMTE] (2017) *Standards for Preparing Teachers of Mathematics*, which stated that "well-prepared beginning teachers of mathematics are proficient with tools and technology designed to support mathematical reasoning and sense making, both in doing mathematics themselves and in supporting student learning of mathematics" (p. 11). These standards call for prospective secondary mathematics teachers (PSMTs) to be proficient in using digital tools to solve mathematics problems, to "enhance or illuminate mathematical and statistical concepts," to "explore mathematical and statistical ideas and to build conceptual understanding of these," and know when such tools "enhance teaching and learning, recognizing both the insights to be gained and possible limitations of such tools" (p. 12). Although these goals have now been articulated and disseminated, relatively little is known about the ways program faculty have designed courses to meet these goals.

Given the complex nature of teaching with technology, it is evident that teacher preparation programs need to focus on supporting PSMTs' learning to effectively integrate technology in mathematics classrooms. Although standards exist that purport this importance, there are many ways in which teacher education programs might choose to meet this need. In 2003, Kersaint, Horton, Stohl, and Garofalo reported that 21% of mathematics teacher educators in the U.S. who responded to their survey taught a course focused on technology. A few years later, Leatham (2006) reported that 29% of mathematics teacher educators had courses at their U.S.-based institutions that focused specifically on the teaching of mathematics with technology. However, simply identifying whether or not a course focused on teaching mathematics with technology is offered may be misleading. Secondary mathematics education programs might incorporate teaching mathematics with technology into methods courses, content courses, or even general educational technology courses (Kersaint et al., 2003; Leatham, 2008). Of course, the scope and nature of such integration could vary drastically across programs.

While the extant literature does have suggestions for the design of courses in which learning to teach with technology is a goal (Lee & Hollebrands, 2008; Leatham, 2008), the research on how that is actually being done is limited and largely out of date. In an aim to provide an update of where we are as a field we conducted a nationwide survey of U.S. secondary mathematics teacher education programs. In this paper we answer the following questions: 1) In what types of courses are PSMTs being prepared to teach mathematics with technology? and 2) What reasons do programs give for why they do not have a course specifically focused on learning to teach mathematics with technology?

Methods

We employed survey methodology (Groves et al., 2009) and mixed methods analysis. The survey was designed to elicit descriptive information (using both closed and open-ended questions) about courses designed specifically to address learning to teach mathematics with technology. For example, after identifying whether or not a mathematics specific technology course (typically referred to as a technology, pedagogy, content [TPC] course) is offered within a program, the remaining questions targeted the structure of the course(s) in which teaching with technology is incorporated, course learning objectives, different types of technology utilized and frequency of use, and types of learning activities included. In this brief report we focus on survey items related to the structure of courses.

We identified all accredited university secondary mathematics teacher preparation programs in the U.S. by visiting the department of public instruction website for all 50 states. Once a list was procured, we visited each university website to verify that the university had an undergraduate secondary mathematics teacher preparation program and, if so, to identify a potential contact person. This search resulted in a list of 956 accredited programs. The survey was sent to all 956 universities along with two reminder emails, if necessary. The response rate was 30%, well above that of previous studies focused on this topic (Kersaint et al., 2003; Leatham, 2006). The sample represents a broad cross-section of universities from 49 of the 50 states.

Descriptive statistics were used to describe the various courses in which programs address preparing PSMTs to teach mathematics with technology and to discern overall patterns and differences between programs with dedicated technology courses and those that do not. In addition, we open coded responses to a question posed to non-TPC programs, “A number of institutions offer a course dedicated to teaching mathematics with technology. What are some of the reasons why you do not offer such a course?” to identify themes related to decisions about not offering a technology-specific course.

Findings and Discussion

Of the 290 programs that responded, 71 (25%) reported that they offer a designated TPC course (referred to as TPC programs going forward), 214 (74%) indicated they do not have a designated course, but instead integrate technology across other courses (referred to as non-TPC programs going forward), and two (<1%) reported that technology preparation is not included in their program. It is encouraging that, with the exception of these two programs, the remaining programs (n=288) represented in this study provide a number of opportunities for PSMTs to learn about teaching and learning mathematics with technology. The 25% of programs that currently offer a TPC course is practically the same proportion from a decade ago (29% according to Leatham, 2006). In the remainder of this brief report we focus on the types of courses in which goals related to preparing PSMTs to teaching mathematics with technology are intentionally integrated when a TPC course is not offered and the reasons programs give for why they do not offer a TPC course.

Types of Courses in Which Teaching Mathematics with Technology is Integrated

Of the 214 non-TPC programs, 158 (74%) reported the titles of courses in which they integrate technology. Of those 158 programs, 64 (41% noted they integrate technology in one course, 44 (29%) across two courses, and 50 (32%) across three or more courses. Typically, the courses identified were mathematics methods courses (143 of the 302 courses reported, 47%). However, 83 (53%) were mathematics or statistics content courses, 51 (33%) were general education methods courses, and seven (4%) were field experience courses (e.g., student teaching). For the 41% of programs that indicated they integrate technology in only one course, that one course is typically a mathematics education methods course (70%), with the second most common course type being a general education course (19%). Looking across the number of courses in which technology is integrated, 21 programs (13%) indicated technology was integrated into only mathematics and statistics content courses and 15 programs (10%) indicated technology was integrated into only general education courses.

It is notable that 23% of the non-TPC programs are not integrating technology into a mathematics education course. Given the complexity of integrating technology into mathematics pedagogy, this separation from mathematics specific methods is concerning. In addition, 29% of programs are integrating technology in only a single mathematics methods course. While integrating in a mathematics specific methods course does suggest attention to pedagogical considerations, integration into a single course suggests minimal time is being allocated to this very complex practice in these programs.

Reasons for Intentionally Integrated Courses Instead of TPC Courses

Programs that indicated they did not offer a TPC course (*n*=214) were asked why they did not offer one; 136 (63%) of these programs provided an explanation as to why. The most common reasons for choosing to integrate across courses rather than offering a TPC course were program limitations such as credit limits (35%) and program size (24%). In addition, it is notable that 4% indicated there was no faculty expertise to design or teach a TPC course. One respondent wrote “We currently do not have instructor expertise to design coursework around teaching math with technology.” Thus, it appears that many non-TPC programs do not offer TPC courses because of programmatic constraints rather than purposeful choice.

Table 1: Reasons for Intentionally Integrated Courses Instead of TPC Courses

Reason	Percentage
Program credit limits don’t allow adding another course	35
Low program enrollment	24
Sufficient Attention in other courses	21
Believe integrating across is more impactful	9
Lack of faculty expertise	4
Not required by state/accreditation agencies	4
Faculty does not believe in using technology	2
No faculty consensus on need of such course	2

Although one in five (21%) of the non-TPC programs suggested that program decisions about integrating teaching with technology across methods courses was intentional due to sufficient attention in other courses, their responses make one wonder about the validity of those statements. For example, one respondent explained, “There is the sense that something like technology is best integrated across other courses (I tend to agree with that to some extent), though I cannot say we do a very good job of it.” Another wrote, “Because we incorporate technology across required mathematics courses.” In contrast, some respondents (9%) noted that their intentional integration was done because they believed integration was more impactful than offering a TPC course. For example, one respondent wrote, “To have a course dedicated to technology alone flies in the face of expecting students to use technology at any time in any course in which the technology is deemed appropriate.” The most concerning responses were those that indicated intentional integration was chosen because the faculty does not believe in using technology. This belief was expressed by 4% of the respondents through statements like “I do not believe technology is a vehicle for discovering mathematical principles” and “Because it is not an effective way to teach math.”

Conclusion

Although every program is working within their local constraints to make decisions about how to best address the goals set out by AMTE with respect to preparing PSMTs to teach mathematics with technology, some of the reasons provided for not including a TPC course give rise to issues that should be important to the field. For example, 8% of responding programs indicated they do not have faculty expertise to develop such a course. If we consider that the sample represented in the study likely favors the use of technology in mathematics education, it is highly possible that there are many more programs for which there is not adequate faculty expertise related to learning and teaching mathematics with technology. There are some projects currently underway (e.g., Enhancing Statistics Teacher Education with E-Modules [ESTEEM], Preparing to Teach Mathematics with Technology – Examining Student Practices [PTMT-ESP]) aimed to address faculty expertise with respect to preparing PSMTs to teach with technology, finding ways to ensure these faculty are aware of existing projects and their materials should be a priority.

Preparing PSMTs to teach mathematics with technology remains an area of emphasis in our national standards (AMTE, 2017; NCTM, 2012) and an area where, across our programs, we have yet to converge on a common understanding of the most effective ways to meet our goals. We hope that this paper provides fodder for conversation as we collectively work to prepare all teachers to productively incorporate technology in the teaching of mathematics.

SUPPORTING PROSPECTIVE TEACHERS' DEVELOPMENT OF RELEVANT AND AUTHENTIC MATHEMATICS STORIES

Eryn M. Stehr
Georgia Southern University
estehr@georgiasouthern.edu

Lindsay M. Keazer
Sacred Heart University
keazerl@sacredheart.edu

Supporting prospective elementary teachers (PTs) to develop mathematics problems with contexts that reflect their students' lives is a challenge that remains to be explored. We began this work by conducting collaborative action research to explore PTs' development of mathematics problems that were relevant and authentic to PTs' own lives. We engaged in iterative cycles of action research by asking PTs to write mathematics stories, followed by our review and discussion of the themes we saw and sharing selected examples with PTs during class discussions. Findings after three cycles of data collection suggest that PTs' mathematics contexts became more story-like and personally authentic, and the authors (mathematics teacher educators) developed a clearer understanding of their goals for supporting PTs' development.

Keywords: Culturally Relevant Pedagogy, Instructional Activities and Practices

Scholars of equity in mathematics education have established that teaching mathematics is not a neutral enterprise, and that teachers' choices of mathematical problems convey messages to students about what issues mathematics is useful for addressing (e.g., Felton, 2010; Gutiérrez, 2007; Gutstein & Peterson, 2013). How teachers learn to identify mathematics problem contexts that mirror students' diverse lives and experiences is not yet fully understood. As mathematics teacher educators, we (the authors) realized that our students (elementary prospective teachers) may not yet have sufficient experiences working with children to connect mathematics to children's cultures beyond superficial ways. Thus, this collaborative action research focused on supporting prospective teachers (PTs) in telling mathematical stories that reflected their own lives and cultures, as a first step towards developing the ability to see relevant mathematics in the world around them and eventually connect mathematics to their future students' cultures.

We began the project from a shared value for supporting the development of PTs' decision-making and creativity about how to contextualize mathematics learning opportunities in meaningful ways. We asked the guiding question: How can we support PTs in telling mathematical stories that are relevant and authentic to their lives, homes, and communities?

We engaged in iterative cycles of action research by asking PTs to write mathematics stories, followed by our review and discussion of the themes we saw. Then we presented examples to PTs during class discussion and prompted them to continue to search for mathematics contexts within their lives. While we each engaged in independent analysis of our own PTs' data, a second and integral part of our professional learning opportunity was collaborative action research (Capobianco & Feldman, 2006): discussing our noticings and wonderings through phone calls and emails as our distinct goals and strategies emerged.

Literature Review

Mathematical problems communicate messages about what is normal in our world and what issues mathematics is useful for addressing (Felton, 2010), and teachers' choices of mathematics problems influence the messages communicated. Some teachers have difficulty developing contexts that connect to students' experiences (Rubel, 2017), or risk making connections to students' cultures in superficial ways (Author blinded).

We see culturally relevant contexts as an important way to connect to students' lives and experiences (Ladson-Billings, 1994). Developing relevant mathematics contexts reveals the power and potential of mathematics as a tool to understand students' culture, community, or the broader world (e.g., Gutiérrez, 2007, Gutstein & Peterson, 2013).

Developing authentic mathematics problem contexts--particularly contexts that are authentic to students--was another idea that motivated our work. We align our definition of authentic contexts with that of the youth-centered perspective described by Buxton (2006), who outlined three perspectives of authentic contexts based on a review of science education research literature. The youth-centered perspective is "grounded in useful truths for solving students' real problems" (Brickhouse, 2001, cited in Buxton, 2006, p. 698). Aligned with this definition, we wanted PTs to develop their ability to identify real problems existing in their own lives that mathematics would be useful for understanding and solving.

As we considered ways to support PTs in developing mathematics problems with culturally relevant and authentic contexts, Radakovic, Jagger, and Jao's (2018) account of PTs writing mathematical poetry inspired us to provide PTs an opportunity to write their lives into mathematics stories. We hoped this open-ended task would encourage their creativity and hone their ability to see mathematics problems that were real within their worlds.

Method

We engaged in a model of collaborative action research (Capobianco & Feldman, 2006), collaborating around a common goal while allowing our voices, philosophies, and teaching methods to remain distinct. Carr and Kemmis (1986) conceptualized teacher action research as a self-critical inquiry into one's practice with the goal of improving and developing a better understanding of practice. Teacher action research enables us, as teacher educators, to study our own practice through cycles of action and reflection (Reason & Bradbury, 2008). Collaboration strengthens opportunities beyond those of individual action research (Capobianco & Feldman, 2006), as teacher researchers support each other in the refinement of their individual inquiries while serving as "critical friends" (Kemmis & McTaggert, 1988).

We conducted action research working with K-8 PTs in two distinct contexts: Eryn's project is situated in a number and operations content course, and Lindsay's project is situated in an elementary mathematics methods course. Eryn's PTs have not yet been accepted into the teacher education program. Her course is the first mathematics-for-teachers course they experience. Over the semester, she hoped to support her PTs to notice mathematics relevant to the course as well as authentic to their lives. Lindsay's PTs are seniors in an elementary mathematics methods course during the semester prior to student teaching. She hoped to help PTs learn to better recognize the mathematics already embedded in their lives and in the local community and write mathematics problems that captured this.

Data Collection and Analysis

Two types of data were collected: data from PTs' mathematics stories and data on instructors' actions and reflections. PT data was collected through PTs' mathematics stories written as classwork, transcribed by the instructors into Excel. Instructor data was collected through email discussions, meeting notes, and researcher journals (writing brief ten-minute reflections after meetings or class sessions). We met for discussion and exchanged emails throughout the semester, before and after each writing prompt was given to PTs.

Data collection spanned 6 weeks as we engaged in three cycles of action research, collecting PTs' mathematics stories in weeks 1, 3, and 5. We conducted interim analysis of the data during the week between each data collection cycle. This consisted of repeated reviews of the data, noticing categories and themes in an informal grounded theory approach (Creswell, 2007). As part of our collaborative action research, we then discussed with each other the themes we were noticing in our data. We each selected individual PT responses that stood out to us and discussed how these responses were distinct from the themes we saw in others. The process of identifying themes and distinct examples within PTs' responses allowed us to better understand differences and clarify our goals for the next steps of our action research. This analysis informed our implementation of a class discussion of PTs' stories the following week: we each shared selected PT responses during class discussion and asked PTs what they noticed about different examples. Then PTs were given the prompt again the following week. A later, second round of analysis occurred after all data was collected, following a more formal approach to grounded theory (Creswell, 2007).

Findings

We present findings regarding PTs' mathematics stories and our learning as mathematics teacher educators, contextualized by describing the actions taken by each instructor in their course. Because the courses and instructors were different, course activities were tailored to the course and the action research strategies that emerged were also distinct.

Author Eryn

During week 1, I asked PTs to write a response to: "Word problems in the classroom are not always realistic. Thinking about the math in this course, write one example of math you have noticed in your home, your life, or your community." To connect this prompt to our mathematics course content, I prompted PTs to incorporate mathematics concepts from the course as they searched for mathematics contexts reflecting their lives. After reviewing responses, I noticed that PTs' mathematics contexts felt impersonal and lacked detail or context. This observation triggered my learning and made me aware that I wanted to push PTs to make their descriptions more story-like, and also to consider how to make them authentic: to solve real mathematics problems that they saw in their lives (Buxton, 2006). After categorizing PTs' responses, I shared a series of selected responses with them in a week 2 discussion. Examples ranged from impersonal stories or stories with minimal description to a detailed story about a PT's interaction with her younger brother around dividing pepperonis evenly between pizzas in a Lunchables.

In week 3, I revised the prompt to emphasize the need for developing story-like contexts, changing the word *realistic* to *authentic*, and prompting for a detailed math story instead of one example. I also shared my own example of a mathematical story from my life. I discussed how situations authentic to one person, are not necessarily authentic to another. After reviewing PTs' week 3 responses, I noticed that many PTs followed a structure and context similar to my story. This noticing helped me refine my goals: to support PTs in developing an ability to recognize new ways that mathematics might be used as a tool to investigate the world around them and problems interesting to them, rather than using my example as a template. As part of my analysis of PTs' responses, I made notes of responses that demonstrated this use of mathematics.

Accordingly, during week 4 I shared selected examples of PTs' mathematics stories that better illustrated my goal of using mathematics to explore their own curiosities in their lives. I also shared the story of students learning fraction operations while studying a problem of concern for them: school overcrowding (Turner & Font Strawhun, 2007). I revised the prompt in week 5 to emphasize using mathematics to "help you make sense of or critically examine situations in your home, life, or community." Many responses seemed to describe ways PTs had used mathematics to make sense of situations in their lives. It seemed that the more personal mathematical stories were written to be more complex and less solveable than a typical mathematics story problem.

Author Lindsay

As part of my mathematics methods course, PTs had the opportunity to read several articles related to relevant mathematics contexts and teaching mathematics for social justice (e.g., Felton, 2010; Turner & Font Strawhun, 2007). At each data collection I gave PTs the prompt: "Word problems in the classroom are not always realistic or connected to peoples' experiences. Let's look for ways to bring in math from our own culture. What math have you noticed in your home, your life, or your community?"

When I reviewed my first set of responses during week 2, I was initially disappointed to see that many PTs' responses felt like generic lists of mathematics contexts that may have been told to them during their socialization into school mathematics (e.g., money, time, cooking), and that sounded akin to typical story problems found in traditional textbooks. In contrast, a few PTs' responses stood out as examples that illustrated mathematics embedded in their personal experiences or uniquely connected to their community. This clarified my understanding of my goals, as these personal mathematics stories (as we began to call them) signified the development of a PT's ability to self-identify connections between their lives and mathematics. Identifying instances of mathematics in their lives seemed quite different from regurgitating mathematics contexts that they had learned from their past school mathematics experiences. In the class discussion the following week, I provided a series of selected responses and asked PTs to comment on what differences they noticed across them. I provided several list-like responses on the first slide, followed by four PT examples that were contextualized in a personal and story-like way. PTs noticed the more story-like nature of the examples that I highlighted and began to emulate that in subsequent data collection opportunities.

After completing the second and third rounds of data collection and continuing to facilitate class discussions around selected examples of PTs' mathematics stories, I saw shifts occurring in PTs' responses. Their responses became noticeably lengthier and developed more personal and story-like qualities. While PTs had developed their story-like descriptions of mathematical contexts, however, I realized that they had not yet given the contexts specific enough quantities to make them into mathematical tasks. This seemed to be a direct reflection on what I had brought their attention to during class discussions, and what I had not yet emphasized. This provided me with a next-steps goal for my action research in the future.

Discussion

The process of conducting collaborative action research around a common goal allowed us to reflect together on our learning as mathematics teacher educators, through the process of developing PTs' lenses to "see" mathematics in the world around them and to tell mathematical stories that reflected relevant and authentic experiences of their own. Our mathematics teacher educator learning as a result of this research centered on three key themes: a) refining our understanding of what relevant and authentic mathematical stories looked like by identifying developing evidence in PTs' work, b) recognizing PTs' desire to simply follow prescriptive instructions rather than hone their creativity, and c) identifying the power of our actions and expressed values on influencing PTs' responses. The repeated action of presenting PTs' with examples of their peers' mathematics stories seemed to accomplish multiple purposes: to value the PT's contribution, as well as provide positive peer pressure by providing new illustrations of the ways that mathematics could be connected to life in authentic and personally relevant ways. These themes will be unpacked in detail during the presentation.

PROSPECTIVE TEACHERS' COLLECTIVE KNOWLEDGE: SOLVING INTEGER MISSING SUBTRAHEND PROBLEMS

Nicole M. Wessman-Enzinger
George Fox University
nenzinger@georgefox.edu

Laura Bofferding
Purdue University
LBofferd@purdue.edu

We present the collective knowledge used by fifteen prospective teachers' as they solved two integer subtraction open number sentences, with a missing subtrahend, during think-aloud interviews. The results indicate that prospective teachers have a rich, collective bank of strategies for integer subtraction. Their reasoning can be leveraged to explain the procedures they are often characterized as using in literature and that they also used in this study.

Keywords: Teacher Education-Preservice; Number Concepts and Operations; Cognition

"Subtracting a negative is like adding a positive, which I don't really get why." —Karey

Based on responses from PTs, such as in the opening quote by Karey (pseudonym), prospective teachers (PTs) are often characterized as having poor content knowledge. PTs' low or procedural performance leads to calls for more content courses and increased use of tests for certification. However, considering their collective thinking and providing PTs the opportunity to talk about (and share) their thinking presents an encouraging view. This approach challenges the expectation that prospective teachers need to have mastered all content, in this case integer operations, and positions teachers as lifelong learners who have a rich network of collective knowledge to draw on.

Moving Toward a Community of Practice Mentality

Historically, teachers in the United States have worked in relative isolation compared to cooperative countries, such as Japan (Wong, Brittan, & Ganser, 2005). In line with an individualistic point of view, many descriptions of teacher knowledge in the United States paint a grim view of teachers having more procedural knowledge and less conceptual knowledge of mathematics (e.g., Lui & Bonner, 2016; Ma, 1999). However, given the renewed focus on learning communities (Darling-Hammond & McLaughlin, 2011), research—against a new horizon—on teacher knowledge might benefit from a shift away from focusing on teachers as isolated beings to teachers as being part of a community of practice (Lave & Wenger, 1991; Wenger, 1998; Wenger-Trayner & Wenger-Trayner, 2015) where teachers are considered resources for each other. From this perspective, analyzing a community's collective knowledge takes the forefront.

Strategies for Integer Subtraction

Integer subtraction is notoriously famed for the use of rules and procedures in nonsense-making ways (Bishop, Lamb, Philipp, Whitacre, & Schappelle, 2018; Piaget, 1948), and PTs often use procedures with integer operations (Bofferding & Richardson, 2013; Kajander & Holm, 2013; Steiner, 2009). However, PTs are capable of reasoning in ways about integer subtraction beyond rules. In addition to procedures and recall of facts for integer addition and subtraction, PTs may draw on strategies that use translation for integer subtraction (Bofferding & Wessman-Enzinger, 2018). Their strategies for translation may include counting, referents to zero, movements with distance, and subitizing distance. PTs may also use other strategies like analogies, where they compare integer addition and subtraction to whole number addition and subtraction. Or, PTs may use counterbalance strategies where they make use of the magnitudes of numbers, trying to "balance" numbers by using additive inverses (Bofferding & Wessman-Enzinger, 2018). Although we have insight into the types of strategies that PTs may use to solve result missing problems (e.g., -3 – 2 = ☐), we know little about the collection of strategies that PTs may produce for part missing problem types (e.g., -3 – ☐ = -5). Furthermore, we need insight into PTs' collective reasoning for different open number sentence types to better understand how to support PTs and how to position them as resources for each other. Therefore, we investigate the following research question: What is the collective knowledge of PTs as they solve integer missing subtrahend problems?

Methods and Analysis

Fifteen PTs (eight secondary, seven elementary) participated in think-aloud interviews (Ericsson, 2006; Ericsson & Simon, 1993). They all had taken some mathematics coursework in the mathematics department prior to participating. Part of the individual think-aloud interviews included solving a series of integer addition and subtraction open number sentences (i.e., ☐ + 1 = -2; ☐ – -7 = 15). We coded each of the open number sentences for the strategies used. Although interviews were conducted individually, we examined the types of strategies generated collectively for understanding collective knowledge. The results presented here focus on the richness of their collective reasoning for the two integer subtraction open number sentences, -2 – ☐ = 4 and -5 – ☐ = 0, where the subtrahend is missing.

Results

Collective Strategies for -2 – ☐ = 4

Overall, the PTs drew on two main strategies for solving this problem, which could be broken down into a few variants, and three (analogy, counterbalance, procedures or recall) supporting strategies (see Table 1).

Algebraic manipulation. The first main strategy was using algebraic rules to solve for the box. Collectively, PTs demonstrated flexibility in manipulating the problem as they initially added a box to both sides, added a positive two to both sides, or subtracted a negative two from both sides. When moving the box to the right side (-2 = 4 + ☐), one PT then subtracted four from each side to get -2 – 4 = ☐. In order to solve the problem, the PT changed it to -2 + -4 = -6. One PT who initially added two to both sides got -☐ = 6. She then multiplied both sides by negative one in order to make the box positive. Finally, a PT who subtracted negative two from each side ended up with -☐= 4 – -2. She continued, "Four minus negative two is the same as four plus two, so negative box equals four plus two, which equals six. So negative box equals six."

Translation. The second main strategy was using translation, either by using zero as a reference point or by counting each individual space between -2 and 4. Interestingly, this strategy provides a conceptual way for solving the right side of the equation when solving -☐ = 4 – -2, a step in solving the problem algebraically when subtracting -2 from both sides. One PT explained why reasoning about the numbers in relation to zero made sense:

> Negative two is on the other side of zero on the number line, and I was trying to get to four, and I was subtracting. So I knew I was going to have to add to move to the right. And so, minus times a minus, I knew I needed a negative number here [in the box] to move in that direction.

Additional reasoning. Beyond using procedural rules, PTs sometimes used additional strategies, often together with algebraic manipulation or translation. For example, one PT referenced a counterbalance conceptual model (hills and holes) and used an analogy to a related positive number problem after adding the box to both sides and subtracting four from both sides (☐ = -2 – 4): "Again, we have a hole of negative two and we are subtracting four more units. So two plus four is six, but because we are going in the hole, that is a negative six."

Table 1: Collective Knowledge and Connections for -2 – ☐ = 4

Algebraic Manipulation	Translation	Additional Reasoning
-2 – ☐ = 4 → -2 = ☐ + 4 → -2 – 4 = ☐ → ☐ = -6 -2 – ☐ = 4 → -2 = ☐ + 4 → ☐ = -2 + -4 → ☐ = -6 -2 – ☐ = 4 → -☐ = 6 → ☐ = -6	Distance from -2 to 4	-2 = hole of 2 units; subtract 4 more units (dig a deeper hole); -6 = hole of 6 units
PTs exhibited flexibility in procedures used. These procedures could be connected to translation strategies. Further, their manipulations of adding 2 or subtracting -2 from both sides could be used to explore different ways of making zero (i.e., additive inverses and subtracting from self).	This strategy provides a conceptual way for solving the right side of the equation when solving -☐ = 4 – -2, a step in solving the problem algebraically when subtracting -2 from both sides.	This strategy provides a conceptual way for solving the left side of the equation when solving -2 – 4 = ☐, the resulting equation when adding the Box to both sides and subtracting four from both sides.

Collective Strategies for -5 – ☐ = 0

Unlike for the previous problem, PTs relied heavily on analogies for this problem with less focus on algebraic manipulations (see Table 2).

Analogy. PTs constructed analogies as the main strategy for this problem. The PTs compared -5 – ☐ to 5 – 5 or other subtraction problems. For example, one PT explained, "Negative eight minus negative eight equals zero, um, I would put negative five in there just again, the quantity minus itself is zero."

Translation. As with the previous problem, PTs counted each space or moved in chunks when using translation for this problem. Two PTs used zero as a referent, stating, "To get negative five to be zero, I would have to add five to get that point." An additional PT explicitly referenced the distance between -5 and 0 as adding 5. Both of these PTs thought additively about -5 – ☐ first and adjusted their reasoning. Another PT used counting:

> I wanted to reach zero, I could do like one, two, three, four, err, it really should be negative

> four, negative three, negative two, negative one, zero. And so these ones are three, negative two, negative one, and that was one, two, three, four, five. And so this one would be five.

This PT wavered between +5 and -5, but ultimately decided on -5.

Algebraic manipulation. One PT used algebraic procedures and solved -5 – ☐ = 0 by replacing the box with an X. Then, the PT added 5 to both sides, changing the open number sentence to -X = 5. The PT multiplied -X = 5 by -1 and determined the solution to be X = -5.

Procedure. The most common procedure that PTs used for solving this problem involved recognizing -5 – -5 is equivalent to -5 + 5. Although many of the PTs used a procedure for solving -5 – ☐ = 0, three of the PTs paired their procedures with other strategies, like translation or analogy.

Table 2: Collective Knowledge and Connections for -5 – ☐ = 0

Analogy	Translation	Algebraic & Procedure
Compare to 5 – 5, -8 – -8, or x – x.	Distance from -5 to 0 is 5.	-5 – -5 = -5 + 5 -5 – x = 0 → -x = 5 → x = -5
Comparing -5 – box to 5 – 5 is a strategy that children often use. PTs made reference to any quantity minus the same quantity (i.e., x – x), which is a form of algebraic reasoning. This type of reasoning could be compared and connected to the other problem -2 – ☐ = 4.	This type of contribution aligns to visual representation of a number line well, which is different from the other strategies. These strategies provide opportunities to about what -5 - -5 looks like on a number line.	The procedures that the PTs used can be compared to the distance strategies they created. The distance models they created matched -5 + 5 = 0 well.

Discussion

The PTs' collective reasoning portrays a rich perspective of the types of knowledge that PTs bring to their classrooms about integer reasoning. The PTs collective reasoning illustrates potential for conceptual understanding (i.e., translation, analogy) to build to procedural fluency (i.e., algebraic manipulation). As mathematics teacher educators and researchers, our work includes facilitating opportunities for making connections among the PTs' reasoning and making the collective knowledge accessible to all students. Beyond that, we need to help PTs use each other as a resource and help them create spaces where they can build on the group's knowledge.

Critical pedagogies offer potential to think about how to incorporate use of collective knowledge. Complex instruction, for example, is based on a teaching-learning perspective where all students are necessary for the thinking and learning of the class (Featherstone, Crespo, Jilk, Oslund, Parks, & Wood, 2011). When using complex instruction "the teacher structures the assignment so that all the children must participate in the intellectual work of problem solving" (Featherstone et al., 2011, p. 4). Building on the research around students' integer thinking and this research on PTs' integer thinking, we could design complex instruction tasks that draw on this collective knowledge. Although developing an instructional task is outside the purpose of the work described in this research brief, we aim to describe the thinking of PTs as intellectual work and hope that describing their thinking will provide a lens into how to support instruction with PTs in the future.

ENGAGING PROSPECTIVE ELEMENTARY TEACHERS IN STANDARDS FOR MATHEMATICAL PRACTICE WITHIN CONTENT COURSES FOR TEACHERS

Brooke Max
Purdue University
bmax@purdue.edu

Rachael M. Welder
Texas A & M University
rachael@rachaelwelder.com

Since prospective elementary teachers (PTs) in the US will be expected to engage students in mathematics via the Common Core Standards for Mathematical Practice (SMPs), national teacher preparation standards are calling for PTs to have opportunities to engage in these practices during their development of mathematical knowledge for teaching (e.g., AMTE's Standards for Preparing Teachers of Mathematics, 2018). This report investigates the intended curriculum of 82 mathematics content courses for teachers for such opportunities. Findings suggest that most instructors of these courses intend to engage PTs in several of the SMPs, mostly by offering them opportunities to experience learning through lessons planned with the SMPs in mind. However, substantial variance was noticed in the frequency and depth of which the individual SMPs were reported or found evidenced in sample tasks. Implications to follow.

Keywords: Teacher education – preservice, Instructional activities and practices, Standards

Common Core State Standards of Mathematics (CCSS-M, National Governors Association Center for Best Practices and the Council of Chief State School Officers [NGA & CCSSO], 2010) offer standards for K-12 students in terms of mathematical content and practices. The Standards for Mathematical Practice (SMPs) bring attention to the processes and practices that have been recommended by US national organizations for K-12 students (e.g., National Council of Teachers of Mathematics (NCTM) *Process Standards*, 2000; National Research Council *Strands of Mathematical Proficiency*, 2001). The CCSS-M, including the SMPs, are currently adopted by 41 states (NGA & CCSSO, 2019) and included in national recommendations for the preparation of prospective elementary teachers (PTs) (e.g., Association of Mathematics Teacher Educators *Standards for Preparing Teachers of Mathematics*, 2018; Conference Board of Mathematical Sciences (CBMS) *Mathematical Education of Teachers II*, 2012). Because of the increased attention being given to the SMPs in terms of teacher preparation, we investigated the intended curriculum of mathematical content courses for opportunities they afford prospective elementary teachers (PTs) to engage with the SMPs during their development of mathematical knowledge. By gaining insight into the ways in which Mathematics Teacher Educators (MTEs) are affording PTs such opportunities, our community can consider ways of replicating and enhancing this work.

Methods

Data Collection

A subset of data from a larger study on the mathematical content preparation of elementary teachers was analyzed to address the question, "In what ways are PTs being afforded opportunities to engage with CCSS-M SMPs in content courses for PTs?" The data for the larger study (see Max, 2018) was collected through an online survey that was sent to MTEs across the US through the use of various large-scale listservs and social media outlets (e.g., the AMTE email and affiliate list, the STaR listserv, the AERA SIG-RME Facebook page). The survey asked MTEs who are involved in the mathematical preparation of elementary teachers about their educational and professional backgrounds, the teacher preparation programs in which they are involved, and any content courses they teach that are specifically designed for PTs.

For each content course, participants were asked to select all of the SMPs they intentionally address in their courses and to provide general information about the ways in which the SMPs are addressed (by selecting from a list of potential options, including an option to select “other” and explain). They were also asked to identify the SMP that receives the *most* attention in each course and to describe an example of a way in which PTs are engaged in that particular practice. Open-ended responses to this prompt will be referred to as *SMP descriptions* and considered to be *explicit* ways in which MTEs are engaging PTs with SMPs.

Participants were also asked to upload or describe an activity, assessment, or reading related to the content domain (CBMS, 2012) that receives the most attention in each class. While respondents were not asked to consider the SMPs in regard to their content examples, their responses to this prompt were analyzed through the lens of the SMPs to identify ways in which MTEs might be engaging PTs in SMPs throughout tasks focused on content development. This collection of written responses and uploaded materials will be referred to as *content examples* and considered to be *implicit* ways in which MTEs are engaging PTs in SMPs. For more detailed information on survey construction and data collection, please see Max (2018).

Participants

The online survey was completed by 44 MTEs who have experience teaching content courses for PTs and will serve as the sample for this study. This sample represents MTEs from 41 different US universities across 19 states. Thirty-nine (89%) of the MTEs reported having some affiliation within a department of mathematics: 28 (72%) of these MTEs belong solely to a mathematics department, while 11 (28%) have joint affiliations with a department of education. The remaining five MTEs (11%) work solely in departments of education. The participants reported a mean of 10.7 years of experience teaching at the post-secondary level. Thirty-three (75%) MTEs reported prior experience as a K-12 teacher, with a mean of 4.5 years of teaching experience. Ten (30%) MTEs had taught at the elementary level, nineteen (58%) at the middle level, and twenty-five (76%) at the secondary level, with twenty-two (66%) having taught at more than one of these levels.

The respondents reported a mean university program requirement of 2.1 content courses for PTs, worth a mean of 6.7 total credit hours, with 84% of these courses being housed in departments of mathematics. These courses are reportedly being taught by faculty 91% of the time, with staff (17%), graduate students (16%), and adjunct faculty (7%) teaching these courses much less frequently. MTEs also reported over 50% of these courses tending to be taken by first-year college students, with only 22% likely to be enrolled by juniors or seniors. Lastly, all but one of the respondents reported research as being a component of their current position, with 38 (88%) of MTEs conducting research in the area of mathematics education, 3 (7%) in mathematics, and 2 (5%) in a non-math related field.

Analysis

Descriptive statistics and content analysis were used to investigate the collected data looking for evidence of opportunities for PTs to engage in the SMPs in content courses. Using protocol coding (Saldaña, 2016), all SMP descriptions and content examples were coded according to each of the SMPs considered to be addressed. This was done by identifying opportunities that aligned with the actions explicated in the detailed SMP descriptors offered in the CCSS-M standards document (NGA & CCSSO, 2010). For example, for SMP3: Argumentation, the coders looked for opportunities for PTs to "construct viable arguments and critique the reasoning of others…make conjectures… use counterexamples… justify their conclusions, communicate them to others…explain what it [a flaw in an argument] is" (pp. 6-7). Although the participants were asked to discuss activities pertaining to the SMP and content domain that receive the *most* attention in each course, the coding served to identify any and all SMPs that PTs were invited to engage in throughout the activities described. This coding scheme was used because SMPs are interconnected and at times unable to be separated from one another. For example, one respondent described how they address SMP1: Problem-Solving in a task related to finding the volume and surface area of three-dimensional objects. Since this task involved PTs using Geo-Solids, it was also coded as addressing SMP5: Tools. Each of the SMP descriptions and content examples were independently coded by two researchers. The coders cross-checked their work to find an initial 75% agreement; all disagreements were discussed until consensus was achieved.

Results

The 44 participating MTEs provided information for a total of 82 content courses for PTs that they were either teaching or have previously taught. Below, we report findings on our analysis of the ways in which PTs are being provided opportunities to engage in SMPs in these 82 courses. First, we will discuss *explicit* attention given to SMPs found in the intended curriculum of content courses through analyzing SMP selection data and coded SMP descriptions. Afterwards, we will discuss *implicit* attention identified through analyzing coded content examples).

MTEs selected one or more SMPs as being intentionally addressed in 74 (90%) of the reported 82 content courses (n = 74). See Table 1 for the number of courses for which each SMP was selected. For 55 (74%) of the 74 courses that address at least one SMP, MTEs selected a most-addressed SMP (n = 55). Table 1 also shows the number of times each SMP was selected as being the most-addressed SMP for a course. However, we acknowledge that asking participants to choose a single most-addressed SMP may have presented a challenge. For example, one respondent indicated, "Each of them [SMPs] is addressed regularly. It is difficult to say which is addressed the most." In fact, MTEs stated that all SMPs received regular and/or equal attention in 4 of the 55 courses. In these cases, we recorded all 8 SMPs as having been selected (thus the total in the "Most Addressed" column is greater than 55).

Table 1: Attention to SMPs

	Explicit Attention			Implicit Attention
SMP Name	Intentionally Addressed (n = 74)	Most Addressed (n = 55)	Indicated by a SMP Description (n = 39)	Indicated by a Content Example (n = 57)
1. Problem Solving SMP	64	17	21	40
2. Reasoning SMP	63	6	4	10
3. Argumentation SMP	62	30	20	13
4. Modeling SMP	56	9	1	9
5. Tools SMP	62	7	5	26
6. Precision SMP	59	5	4	8

7. Structure SMP	60	8	2	23
8. Regularity MP	54	6	0	6

Information regarding the ways in which SMPs are being explicitly addressed was provided for 69 (93%) of the 74 courses. When asked to select from a list of potential options, respondents reported that 88% (61) of their courses offer PTs the opportunity to experience learning through lessons planned with the SMPs in mind. The remaining provided options, having PTs read the SMPs, facilitating lessons using the SMPs, and creating lesson plans that reference SMPs, were selected for 32 (46%), 16 (23%), and 5 (7%) courses, respectively. Respondents described “other ways” they address the SMPs for 9 (13%) courses, with open-ended responses including “discussion of how these standards play out in class lessons,” “reflecting on their use in lessons in class,” and having a “poster of SMPs on [a] wall in [the] classroom.” Additionally, written SMP descriptions were provided for 39 (53%) of the 74 courses (n = 39). Table 1 presents the results of our coding showing the number of times each SMP was identified as being evidenced within a SMP description.

Content examples were provided by MTEs for 68 (83%) of the 82 content courses on which they reported, including 48 written descriptions of content activities and 20 uploaded activities/tasks. However, only 57 (84%) of the content examples provided enough information for the coders to identify one or more SMPs (n = 57). Table 1 provides the number of times each SMP was coded as being implicitly evidenced within one of these 57 content examples.

Discussion and Conclusion

MTEs reported that all SMPs are being addressed in the vast majority of their content courses for PTs with little variance among the individual SMPs (each being addressed in 73%-86% of the courses). However, when opportunities for explicit and implicit attention were further analyzed, the attention being given to individual SMPs showed greater variation. SMP1: Problem Solving and SMP3: Argumentation were selected much more often as being the most addressed SMP, and consequently showed up the most in the SMP descriptions (for task samples and discussion on the ways in which SMP3 occurred within content examples, see Max & Welder, accepted). These findings are consistent with the national attention these practices have received (e.g., NCTM, 1980, 2000). However, they were only somewhat consistent with the SMPs identified in the content examples, as the use of SMP5: Tools and SMP 7: Structure were noted much more frequently than SMP3: Argumentation. In fact, these two SMPs organically emerged in nearly half of all content examples. On the other hand, our results suggest that it could be beneficial for MTEs to consider additional ways to engage PTs in SMP8: Regularity, SMP4: Modeling, and SMP6: Precision. MTEs identified these three SMPs as receiving attention in the fewest of their courses and they were found to occur the least in the content examples they provided. We encourage MTEs to reflect upon their practice and the ways in which they can afford PTs meaningful opportunities to develop these less-evident SMPs in content courses, as they may not be occurring as organically as others (such as SMP1: Problem Solving). We also encourage MTEs to identify ways in which they are attending to SMPs, perhaps in ways of which they are not aware, so they can connect such occurrences to the SMP language for PTs.

We note that the findings of this work are based on MTEs’ intended curriculum and hypothesize that more (and perhaps more explicit) attention to SMPs could be identified through observing activities being enacted with PTs. Additional research in this direction could be useful in supporting MTEs in finding ways to foster PTs’ working understanding of the SMPs. By helping PTs become more aware of the valuable role each SMP can play in the development of mathematical content knowledge, we may be able to better prepare elementary teachers for engaging their future students in such practices.

EMERGING SOCIAL AND SOCIO-MATHEMATICAL NORMS DURING TECHNOLOGY-ENHANCED LESSONS

Tuğçe Kozaklı-Ülger

Marmara University
hakkoc@marmara.edu.tr

This study aims to explore the way in which social and socio-mathematical norms endorsed by pre-service mathematics teachers change as they move from traditional lessons to technology-enhanced lessons. Two pre-service mathematics teachers participated in this case study. Each participant's four lessons (a total of eight lessons) were video-recorded. Two of each pre-service teacher's lessons were technology-enhanced. Participants were also interviewed after their lessons. The findings indicated that participants constituted new norms and changed some of their endorsed norms during technology-enhanced lessons. Emerging norms were concerned with certain aspects such as justification of mathematical rules and collaboration.

Keywords: Emergent perspective, Social norms, Socio-mathematical norms, Technology-enhanced lessons

Introduction

As teachers move from traditional lessons to technology-enhanced lessons, they also change the nature of classroom interaction such as roles, behaviors and communication (Monaghan, 2001). Rather than reducing the role of the teacher, teaching with technology requires new roles such as choosing available tools, supporting students' participation and constituting new classroom norms (Gardiner, 2002). Therefore, there is a need for investigating teachers' choices, behaviors and norms constituted in technology-enhanced learning environments (Drijvers, 2012). It is also vital to focus on norms endorsed by pre-service teachers since they will be responsible for "creating an intellectual environment where serious mathematical thinking is the norm" (NCTM, 2000, p. 18). Considering this need, the aim of this study is to investigate how social and socio-mathematical norms endorsed by pre-service mathematics teachers change as they move from traditional lessons to technology-enhanced lessons.

Theoretical Framework

This study will explore the social aspects of this new environment, namely social norms and socio-mathematical norms, which are based on Yackel and Cobb's (1996) emergent perspective. Focusing on the individuals and classroom community, emergent perspective explores the development of norms. Norms will be investigated in a comparative manner by exploring them both in traditional and technology-enhanced lessons.

A norm in teaching and learning process is based on expectations and obligations established through interaction between students and teachers (Yackel, Rasmussen & King, 2000; Roy, Safi, Tobias and Dixon, 2014)). It is not only an individual notion, but also a collective construct. Social norms are concerned with aspects of classroom interaction which become normative (Yackel et al., 2000). Whether it is a traditional or reform-oriented classroom culture, social norms are operative for that particular class. For example, an expectation established in a classroom in the way that students should challenge others' thinking and justify their own interpretations is a social norm (Bowers, Cobb & McClain, 1999). The term "socio-mathematical norm" is distinguished from general social norms and refers to normative aspects of mathematical discussions which are specific to mathematical activities (Yackel, 2000). For example, a standard constituted by student-teacher through interaction to evaluate an argument as mathematically sophisticated is a socio-mathematical norm (Bowers et al., 1999). This study will explore how social and socio-mathematical norms change with the existence and use of technological tools in mathematics lessons.

Methodology

A case study was conducted to investigate the way in which social and socio-mathematical norms' changes in technology-enhanced lessons. Participants are two pre-service mathematics teachers (both female) enrolled in a teacher preparation program in a state university in Bursa, Turkey. Participants taught lessons in partnership schools in high school classes with around thirty students during the "Teaching Practice" course. Data collection instruments were observation and semi-structured interview. Since classroom culture might affect norms in a classroom, each pre-service teacher' lessons were observed in the same class, respectively. Participants were also interviewed to better understand their constituted norms. They were asked to explain how they planned to integrate technology into their lessons and compare their technology-enhanced lessons to their traditional lessons. The first author of this paper observed four lessons of each participant: the last two lessons were technology-enhanced. Video recording of all lessons were transcribed and analyzed to investigate differentiation of norms in traditional lessons and technology-enhanced lessons.

Findings

This section presents the way in which pre-service teachers' endorsed norms change as they integrate technological tools into their lessons.

Table 1: Burcu's and Gizem's Endorsed Norms

</table>

	justifications of mathematical rules/statements. (SMN) (Hershkowitz and Schwartz, 1999)	Students make verifications of mathematical rules/statements. (SMN)

The analysis of data indicated various norms some of which were also reported in other studies (see Table 1). The table indicates that participants' endorsed norms have changed in certain aspects such as collaboration, justification or verification of mathematical rules, and relational understanding as they integrated technology into their lessons.We will illustrate this change by focusing on a detailed account of one of the participants, namely Gizem.

Gizem used Geogebra software during her lesson on basic elements of triangles and area of a triangle. She projected Geoegebra drawings on the smart-board and students in groups made drawings using Geogebra which were installed in their tablets. Gizem endorsed the socio-mathematical norm "Students make verifications of mathematical rules/statements" which was also reported by Hershkowitz and Schwartz (1999) and Williams (2010). In her technology-enhanced lesson, rote learning gave way to mathematical verification using the software. This is illustrated in the following excerpt in the context of equilateral triangles:

> Gizem: We have an equilateral triangle but we don't know its height. Let's draw a perpendicular line here onto the triangle and find area of it using the angles. Height from the point "A" to the side "a" divides the side into two equal parts. a/2. The angle A is divided into two, 30 and 30. Side against the angle of 30 is a/2, and then side against the angle of 60 degrees is $\sqrt{3}$, isn't it? Then the area is $a^2\sqrt{3}/4$. Is this valid for the areas of all equilateral triangles?
> Student: At the end, isn't it a formula?
> Student: We find all of them with the formula. Is it gonna be different according to lengths?
> Gizem: We all should be convinced of the validity of this formula. Therefore, let's draw an equilateral triangle using Geogebra and examine the validity of the formula.
> Student: What is the length of the side?
> Gizem: Each group can start with a different length. What do you think?

As can be seen from the excerpt above, Gizem introduced the socio-mathematical norm "Students make verifications of mathematical rules/statements" by emphasizing that they (herself and her students) should be convinced of validity of rules. After giving basic concepts and properties, Gizem moved to Geogebra and use it for verification (See the screen shot on the left in Figure 1). Working in groups, students were involved in this verification process using the software on their tablets.

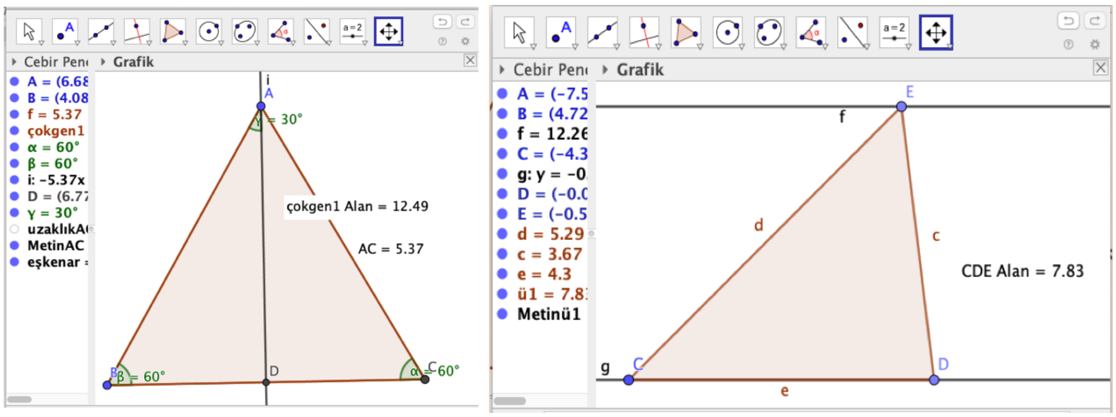

Figure 1: Gizem's Geogebra Constructions During Her Lessons

Another finding was related to the social norm "Students work individually to find solutions to problems" which was replaced by another social norm "Students collaborate to find solutions to problems" in Gizem's technology-enhanced lesson. Although, she did not rely on mathematical software throughout the whole lesson, she encouraged collaboration among students during the whole process. Working in groups in technology-enhanced lessons was negotiated between students and the pre-service teacher and this norm was sustained for other lessons. Students who worked in groups not only focused on solving the problem, but more importantly, examined different solutions and reasons behind them. This situation points out the socio-mathematical norm "Working in groups, students examine the "reasons" behind mathematical solutions/expressions". This norm revealed itself during a discussion on how the area changes when the peak of the triangular area between the two parallel lines varies. Using Geogebra, Gizem constructed a triangle between two parallel lines and moved the upper vertex horizontally and asked her students whether the area remained constant and why. This way, the pre-service teacher helped her students to discover this relationship and reasons behind it working in groups. The socio-mathematical norm "Working in groups, students examine the 'reasons' behind mathematical solutions/expressions" was introduced by the pre-service teacher and negotiated between her and her students without any difficulty. In addition, observational data indicated that Gizem sustained the socio-mathematical norm "Students reach mathematical solutions using the given rules to them" in all her four lessons. She particularly asked for rules and formulas and made this clear for her students. As this norm was sustained, on the one hand, reasons behind these became the focus of discussion in her technology-enhanced lessons.

Discussion

This study explored how social and socio-mathematical norms endorsed by two pre-service mathematics teachers changed as they started to integrate technology into their lessons. By observing participants' traditional and technology-enhanced lessons at the same time, not only pre-existing norms were specified but also emergence of new norms was observed in technology-enhanced lessons. Data also indicated that some of the norms effaced themselves.

One of the remarkable findings is the emergence of new norms with the existence of technological resources in the classroom. Among those norms, one particular norm continued to be introduced and sustained throughout technology-enhanced lessons: Students make verification and justifications of mathematical rules/statements. Considering the fact that pre-service teachers did not give importance to verification and justifications in their traditional lessons, their emphasis on verification and justification in their technology-enhanced lessons became crucial. The emphasis on verification and justification might be due to dragging feature of the dynamic geometry software they used which provides opportunities to verify and justify geometrical theorems and properties. Another remarkable change in norms was concerned with collaboration among students to examine the "reasons". After this norm was introduced, they started to question "why" and "how" mathematical solutions/expressions worked and privileged reasoning.

To the extent that classroom norms constrain and enable learning, it is possible for teachers to estimate which norms they might wish to foster (Yackel, 2000). A new environment can generate new classroom norms (Tabach, Hershkowitz & Dreyfus, 2013). Therefore, teachers and pre-service teachers should be provided guidance. Teacher education programs should monitor pre-service teachers' development with regard to their endorsed norms for successful technology integration and develop an awareness of social and socio-mathematical norms.

We describe an experience within mathematics teacher preparation that engages pre-service teachers of mathematics (PMTs) in Making and design practices that we hypothesized would inform their conceptual, curricular, and pedagogical thinking. With a focus on the design of new tools that can generate new possibilities for mathematics teaching and learning, this Learning by Design experience has PMTs exploring at the intersection of content, pedagogy, and Making. We describe the forms of knowledge brought to bear on their experiences through a case study analysis of one pair of PMTs' Making experience. As the advancement of these forms of knowledge is essential to effective mathematics teaching, these findings suggest the promise of a Making experience within mathematics teacher preparation.

Keywords: Instructional Activities and Practices, Teacher Knowledge, Technology

Objectives

Preservice elementary teachers have been characterized as coming to teacher preparation with limited conceptions of mathematics (AMTE, 2013) and a model of mathematics teaching that largely appeals to rules and procedures (Ball, 1990; Ma, 1999; Thompson, 1984). Unfortunately, this model is not consistent with a pedagogy that supports learning mathematics with understanding. Consequently, prospective elementary teachers' preparation must include opportunities that challenge their current models of mathematics teaching and learning. In this proposal, we present one such opportunity that is centered in the activity of *Making*. We draw on Halverson and Sheridan's (2014) conception of Making as *designing, building and innovating with tools and materials to solve practical problems*. We present a novel *Making-oriented experience* within mathematics teacher preparation that tasks prospective mathematics teachers (PMTs) with designing, fabricating, and evaluating new manipulatives (Post, 1981) to promote learners' mathematical thinking and reasoning. In seeking to determine what this experience might offer prospective elementary teachers as they prepare for the work of mathematics teaching, this project addresses the following question: *What forms of knowledge can be brought to bear on prospective elementary teachers' design work as they Make new manipulatives to support the teaching and learning of mathematics?*

Theoretical Framework

Our theoretical framing is organized around the learning theories of *constructivism* and *constructionism*. These theories recognize that knowledge is actively constructed by a learner, with constructionism adding the dimension that the knowledge be constructed during the process of making a shareable object (Harel & Papert, 1991). We drew from the rich scholarship devoted to teacher knowledge to characterize what forms of knowledge might actually be brought to bear on PMTs' design work (Ball, 1990; Borko & Livingston, 1989, 1990; Cochran, DeRuiter, & King, 1993; Hill, Ball, & Schilling, 2008; Koehler & Mishra, 2009; Mishra & Koehler, 2006; Shulman, 1986). In particular, we took a *Learning by Design* approach (Koehler & Mishra, 2005;

Koehler, Mishra, Hershey, & Peruski, 2004) to leveraging and potentially advancing this knowledge. Learning by design involves the PMTs in the activity of *designing*, or the purposeful imagining, planning, and intending that precedes and interacts with Making. This approach calls upon PMTs to "actively engage in inquiry, research and design" so that they can make "tangible, meaningful artifacts" that represent "the end products of the learning process" (Koehler and Mishra, 2005; p. 135). This approach provides an opportunity to consider the interplay between the evolving artifact and the application of teacher knowledge domains in the artifact's development. The premise for learning by design honors the proposition that it is productive to develop teacher knowledge within a context that recognizes the interactions and connections among these constituent domains of knowledge.

The artifact that a PMT makes, and the design decisions that go into the Making, provide a rich source of data for understanding these knowledge domains if we consider the artifact and its creation from the perspective of designing for mathematical abstraction (Pratt & Noss, 2010). In the case of manipulatives, the designer aims to embed a concept in its design so that it can be made available to the learner for abstraction through their sensorimotor manipulation of the object (Kamii & Housman, 2000; Piaget, 1970; Vygotsky, 1978). This is the task we set for the PMTs in this project: to design a manipulative that is hypothesized to support learners' abstractions of a mathematical concept from concrete tools. Pratt & Noss's case study (2010) offers a proof of concept that learning by design provides a venue for characterizing the interplay between a participant's beliefs and knowledge domains as they are invoked during the design process.

Methods

The study took place in a specialized mathematics content course for prospective elementary teachers. Twenty-six participating students comprised twenty-one groups. The PMTs were given the following task: "The purpose of this project is for you to 3D design and print a new physical tool (or "manipulative") that can be used in teaching a mathematical idea. The design of this tool and a corresponding task will reflect a) your knowledge of what it means to do mathematics and how we learn with physical tools, b) your knowledge of elementary-level mathematics content, and c) your perspective on pedagogy and curriculum in mathematics education." This project had three written components, which comprise the corpus of research data: 1) an "Idea Assignment" that describes a group's initial thoughts about a manipulative they want to work on, 2) a "Project Rationale," which is an account of how their design reflects an understanding of what mathematics is and how learning happens, and 3) a "Final Paper" that describes the purpose of the manipulative, the corresponding tasks that were created, and the group's findings from an intended user's manipulative-mediated engagement with those tasks.

Data analysis proceeded in two phases. In Phase I (more fully reported in Greenstein & Seventko, 2017), three researchers analyzed the PMTs' written work and generated codes (Corbin & Strauss, 2008) that identify forms of knowledge in the PMTs' written work, with initial codes derived from the mathematics knowledge for teaching literature. Intercoder reliability on the codes was calculated at .82. This analysis provided a promising foundation for delving more deeply into the PMTs' written work in order to understand how the knowledge we identified was brought to bear in their Maker projects.

In Phase 2, we took a case study approach (Yin, 2009) with purposeful sampling (Patton, 2002) to identify and select design cases whose reflections bear evidence of *mathematical richness*. In these cases, PMTs articulate and express multiple layers of mathematical detail in describing mathematics content, student thinking, or the use of technology during the project. This sampling technique purposefully mirrors the knowledge frameworks so that we could describe the PMTs' constituent forms of knowledge as reflected in their written work. Crafting narratives of the PMTs' design experiences involved a process of moving between the Phase 1 codes and the PMTs' reflections to intuit the data and weave narratives that illuminate the knowledge brought to bear on the PMTs' design activity. Harnessing the case study's virtue for evoking "images of the possible," (Shulman, 2004; p. 147), we present our narrative for Casey and Mia and their tool called *Minute Minis* (see Fig. 1 for digital design).

Results

We viewed the PMTs' written reflections as containing instances of the knowledge they brought to bear in their design work. For Casey and Mia, our analysis identified various dimensions of mathematical knowing in teaching, such as knowledge of mathematical content, pedagogical content knowledge (PCK), curricular knowledge, and knowledge of how learning works in interaction with manipulatives.

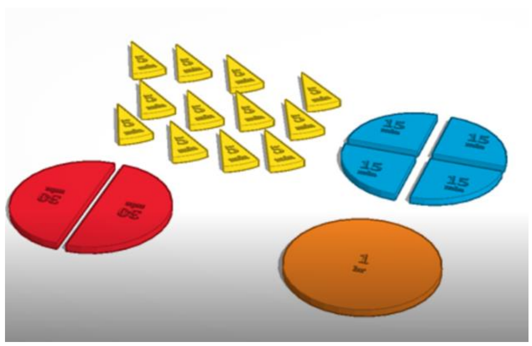

Figure 1: Minute Minis

Casey and Mia were inspired to design a manipulative that could help children reason about the abstract concept of time. In their initial design rationale, they hypothesize about breaking through the ordinarily obscure nature of time to make it more accessible to learners:

> The main goal of this project is to give a concrete representation of the relationship between hours and minutes. Using manipulatives is especially important when exploring new concepts, and sense (sic) time is a very abstract concept, it is especially pertinent that students have something concrete to work with. With these manipulatives, students will be better able to solve addition, subtraction, multiplication and division problems relating to time.

Making such a tool for the shared purpose of learning and teaching was initially and genuinely influenced by questions Casey had about how children were thinking of time in the classroom where she was doing her student teaching:

> Currently, most of the 2nd graders in my class can tell time to the nearest half hour, yet I am unsure of how they know how to do this. Is it just because they know that when the minute hand is pointing at the 6 I say _:30 and when it's pointing at the 12 I say _:00? Or do they have a more (sic) deeper understanding of time and how a clock works?

These considerations reflect how Casey's PCK (wondering about students' current conceptions of the topic of time) inform her design. Over the course of the project, these questions develop into other strands of knowledge that she and Mia use to investigate these issues. That is, the Making of Minute Minis was driven by a desire to transform potentially limited conceptions of time from memorized models into deeper mathematical meanings. Drawing upon other aspects of PCK and of mathematical and curricular knowledge, Casey and Mia take an existing design of fraction circles and use concepts from geometry to amend it for their objectives:

> [We] will be using the same concept of fraction circles, yet instead of labeling them with a fraction, they will be labeled with minutes. For instance, a whole circle will be labeled "1 hour," while two half circles will be labeled "30 minutes." [We] will also have [fraction] circles for 15 and 5 minutes. (see Fig. 1)

One of their key design issues focused on being able to "visually illustrate the concept of minutes as fractions of an hour." Additionally, the circular shape was important to them in ensuring "that students would be able to use the Minute Minis directly on the face of a clock. This would aid [students] in exploring the relationship between where the minute hand is pointing and the number of minutes past the hour." Such a design component was seen as essential in supporting student inquiry of the fractional ideas embedded in the tool so that the child could assemble the fractional pieces to compute time.

We continue to see PCK emerge in Casey and Mia's reflections about tasks teachers can pose to students using their tool. They describe teachers familiarizing students with their tools by asking questions like, "How many 30 minute pieces make an hour? How many 5?" Then they go on to consider and describe how a child might use their tool to investigate how many hours it takes to do four homework assignments each of which takes 45 minutes to finish:

> one 30 minute piece and a 15 minute piece to show 45 minutes, then replicating this 3 other times to show 4 × 45. A child might then notice that they can make 2 wholes – hours in this case – using 4 of the 30 minute pieces and 1 whole/hour using the four 15 minute pieces, leading them to an answer of 3 hours.

Concluding Discussion

We hypothesized that an iterative design experience centered on the task of Making and evaluating a physical manipulative for learning mathematics would provide our PMTs an opportunity to leverage and deepen their understandings (Schön, 1992) of mathematics content, curriculum, and pedagogy. Accordingly, we introduced a pedagogically genuine and authentically open-ended task into a Making context, inviting the interplay between the iterative design of a shareable artifact and the application of teacher knowledge in the artifact's development. Casey and Mia, a pair of PMTs who participated in that experience, shared reflections that illustrate their design in development, and leveraged their knowledge of fractions and area to help mediate a bridge between the abstract and concrete representations of time. By supplementing the traditional focus of instruction about time with a concrete representation that facilitates conceptual connections between a clock face and its underlying area properties, Casey and Mia were able to draw on this knowledge to articulate the mathematical richness underlying this manipulative and its possible uses by a child.

As researchers exploring how design experiences might catalyze new possibilities for pedagogical and curricular change, we positioned PMTs as knowledgeable designers of instruction in a space of technological possibilities. As PMTs assumed the multi-faceted role of teachers designing with technology, they created powerful and innovative tools, and their work demonstrated a rich and mature repertoire of knowledge domains that we are not typically afforded opportunities to see (AMTE, 2013). We propose that the identification and advancement of this knowledge, which is essential to effective mathematics teaching, suggest the promise of a Making experience within mathematics teacher preparation. Future research seeks to illuminate the particular features of the configured world (Holland, Lachicotte Jr., Skinner, & Cain, 1998) of the design environment that contributed to these outcomes, and to assess the impact of the experience on PMTs' identities (Sfard & Prusak, 2005) as designers of mathematical instruction.

This study examines the development of preservice teachers' (PSTs) understanding of student resources that support productive struggle and promote equity in a semester-long mathematics content course through video analysis. Our qualitative study examines 39 PSTs in two sections of a mathematical content course for prospective elementary teachers. Findings suggest that PSTs could identify a variety of resources leveraged by teachers and students who engaged in productive struggle, such as translanguaging, peer interactions, and mathematical thinking. Our study also examines the role that instructor feedback plays in the development of resource noticing in PSTs.

Keywords: Instructional activities and practices; Equity and Diversity; Teacher Education-Preservice; Teacher knowledge

Teacher noticing of children's thinking has been recognized as an important skill in classroom teaching (e.g. Jacobs, Lamb, Philipp, 2010; Schack, Fisher, et al, 2013). Research has further extended the focus of noticing to how teachers can support students' understanding, particularly as children are struggling to make sense of mathematics (Hiebert & Grouws, 2007; Warshauer, 2015). The support of productive struggle is among the teaching practices that can promote students' conceptual understanding of mathematics (NCTM, 2014). By productive struggle, we mean when "students expend effort in order to make sense of mathematics, to figure out something that is not immediately apparent" (Hiebert & Grouws, 2007, p. 387). While research suggests that productive struggle is an important component of learning mathematics (Warshauer, 2015; Hiebert & Wearne, 2003), supporting productive struggle in the classroom remains a challenge for teachers to implement (NCTM, 2014). Mathematics content and methods courses can provide an ideal setting for introducing these effective teaching practices to preservice teachers (PSTs) as they engage in their own sense-making of the mathematics (Warshauer, 2015; Roth McDuffie et al., 2014).

Prior studies, including ours, examined how support of productive struggle can be introduced and developed in a mathematics content course for PSTs (Warshauer, et al., 2017). Similar to Turner and colleagues' (2012) findings, we observed PSTs, whose interpretations about the mathematics of the struggle were underdeveloped and not based on the students' mathematical thinking. Their focus on student behavior, participation and/or environmental features were what Mason (2008) called a "fragmented awareness" between the culture/community in the classroom and students' mathematical thinking. There is a need to develop PSTs' noticing of productive struggle concurrently with PSTs' noticing for equity (Erickson, 2011). Elementary teachers need to be prepared to teach in diverse classrooms and simultaneously leverage children's mathematical thinking and their cultural funds of knowledge (Turner & Drake, 2016). Prior research on teacher noticing of equity suggests that teachers who notice equitably perceive mathematical and interpersonal activity inextricably linked and notice individual student participation (van Es et al., 2017; Hand, 2012; Turner et al., 2012, Wager, 2014).

In our current study, we focused on introducing PSTs to how teachers draw upon and leverage resources and knowledge bases to support and empower students' mathematical understanding and productive struggle in inclusive settings (Lynch, Hunt, & Lewis, 2018). Using video clips of classroom interactions between teachers and students, we focused PSTs attention to the resources teachers use to support students in productive struggle. By resources we refer to students' funds of knowledge including mathematical, cultural, community, family, linguistic, interests and classroom peers (Roth McDuffie et al., 2014). Supports to develop the skills of noticing and support of productive struggle were introduced to the PSTs using the Productive Struggle Framework (Warshauer, 2015). We further hypothesized that feedback to the PSTs may provide them additional support to their noticing of students' struggles and the resources teachers capitalize upon in subsequent classroom interactions (Roth McDuffie et al., 2014).

Our research questions for this study are:

1. What resources do PSTs notice are made available in a classroom where students are engaged in productive struggle?
2. How do PSTs connect the resources they notice to supporting students' productive struggle?
3. What is the role of instructor feedback on PSTs development of noticing productive struggle and the resources that support productive struggle?

Methodology

This study was conducted in 2017 over a 14-week period at a public, four-year, Hispanic Serving Institution located in a rural area in the western United States. There were 39 participants enrolled in one of two sections of their final mathematics content course for elementary PSTs, taught by the same instructor. The PSTs completed three productive struggle writing assignments (WA). Each WA allowed the PSTs to reflect on a video episode of student struggles that occurred in a classroom setting and that was supported productively by the teacher. The PSTs were to connect the mathematical content of the video to what they were learning in class, examine teacher responses to the observed student struggles, consider what resources the teacher used to support the students, and decide how productive the struggle was for the student(s). For each WA, the instructor gave feedback to each PST about each component listed above. In this preliminary report, we report results from the analysis of PSTs' noticing of resources from WA2 to WA3.

We coded the two WAs using qualitative content analysis (Hsieh & Shannon, 2005). The WAs were coded inductively to identify themes and compare the PSTs' responses to the expert codes that the four researchers had agreed upon were present in the videos. A sample of the codes were re-analyzed by all researchers to ensure inter-rater reliability. Additionally, we analyzed whether the PSTs went beyond the baseline of listing the resources to describing the connections and/or relationship between or among the resources, the student struggle, and the teacher and student moves. Our coding scheme was an adaptation of van Es' (2011) "Framework for learning to notice", ranging from Level 1 (listing resources and general impressions) to Level 4 (interpretations of relationships between or among the resources, teacher moves, students' thinking, and the mathematical struggle). Furthermore, we analyzed whether the PSTs perceived the use of the resource they noticed as a positive, negative, or neutral. Lastly, we analyzed whether there was a change or no change in PSTs' noticing of resources from the WA2 to WA3 and inductively coded the different groups' feedback from the instructor.

Findings

We report preliminary findings for our research questions. Table 1 includes the type of responses that we noted in the respective WAs and the frequency in which they occurred. We found that 72% PSTs discussed at least one resource they noticed at a Level 3 analysis (awareness with focused noticing on resources with evidence and a discussion on how the resources were used in the interactions) or a Level 4 analysis (analyzing the connections and/or relationship between or among the resources, the mathematical struggle, and the teacher and student moves). Of the 29 PSTs who noticed translanguaging (García, et al., 2017), only 9 of the PSTs had a Level 4 analysis and discussed how translanguaging was a tool that allowed students to convey their mathematical thinking and productively engage in different mathematical struggles. 20 PSTs described the use of translanguaging as a positive resource and only 1 PST had a deficit interpretation of the use of translanguaging in a mathematics classroom. The other 8 PSTs provided neutral descriptions of the translanguaging resource and did not elaborate on the impact translanguaging had on the mathematical struggle.

Table 1: Examples of PST Responses in Writing Assignment 2 and 3

Type of Response	Frequency of Noticing (WA2)	(WA3)	Examples in WA2	Examples in WA3
Peer Interactions	27	31	Group discussion Shouting out ideas Class voting	Classroom community Students compare thinking Group work
Communication	5		Using casual language Thumbs up voting	
Manipulatives	9		Using fingers for subtraction Counting on fingers	
Visual	19	7	Use of white board Visual record of student ideas	Writing on white board
Mathematical Knowledge	20	23	Previous knowledge Knowledge of division Math experiences	Use previous knowledge Knowledge of addition
Experiences	10		Field trip experience	

Translanguaging	29		Spanish to build community Switches between English and Spanish
Use of Examples	8		Additional examples
Non-Resource Teaching Practice	6	Teacher as a mediator Teacher questioning	

The instructor gave individual feedback for WA2 by highlighting the key points the students made and wrote questions and comments, if further interpretations and analysis was needed. The instructor also included a rubric with a score for how well the student addressed resources and the connection to mathematical struggle. 8 PSTs provided Level 1 or 2 description of the resources they noticed in WA2 but improved to a Level 3 or 4 interpretation in WA3. The feedback provided to these PSTs was of the following form: "You noticed a resource was peer interaction. How did the teacher use peer interactions in the struggle to make it productive?" (S1). There were 6 PSTs who provided Level 1 or 2 descriptions in both WAs. PSTs in this category received feedback such as: "You mentioned one resource, the students' knowledge, but did not provide evidence from the transcript or relate it to the students' struggles." (S2). 18 PSTs discussed the resources they noticed at a Level 3 or 4 in both WAs and 6 PSTs' noticing of resources declined from WA2 to WA3. Both groups did receive feedback stating, "You did a good job identifying the different resources and how they were linked and supported the mathematical struggled." (S3). Further analysis is ongoing to determine how and what type of feedback contributes to PSTs noticing of resources to support students' mathematical understanding.

Conclusion

Our findings indicate that PSTs in a content course were able to notice a wide range of resources leveraged by teachers and students who engage in productive struggle. In addition, the PSTs show evidence of developing the skills to analyze the relationships between the resources, teaching moves, students' mathematical thinking, and engagement in productive struggle. The predominant resource that PSTs noticed and discussed at the highest level of interpretations was peer interactions. Consistent with Roth McDuffie and colleagues' (2014) findings, most of the PSTs tended to interpret the resource of students' home languages in a classroom at a lower level. What the PSTs noticed and the level of interpretations provided may be connected to the PSTs' experiences in mathematics classroom. For instance, the mathematics content course leveraged many of the resources, such as peer interactions and mathematical knowledge to support the PSTs themselves as they engaged in productive struggle. Therefore, these were common resources that all the PSTs saw incorporated into a mathematics classroom. However, the integration of students' home languages in a classroom was not a common experience for all the PSTs. The majority of PSTs who did notice translanguaging as resource were bilingual themselves and a subset of those PSTs entering or applying to the multiple subject, bilingual authorization program. This could also explain why the PSTs who did notice this resource, described the use of translanguaging as an empowering resource and believed that allowing students to use their full language repertoire was a way to leverage the students' linguistic wealth and make the mathematical content accessible.

USING LESSON PLAY TO ASSESS PEDAGOGICAL UNDERSTANDINGS IN AN ONLINE MATHEMATICS METHODS COURSE

Diana L. Moss
Utah State University
diana.moss@usu.edu

Dov Zazkis
Arizona State University
dzazkis@asu.edu

This report describes the preliminary results of a study that aims to acquire new insights about using lesson plays for examining prospective teachers' pedagogical understandings in an online mathematics methods course. In a lesson play, prospective teachers imagine that they are teachers and are interacting with a group of students about a mathematical problem. They write a script between a teacher and the students and provide commentary. Pre-post lesson plays allowed us to chronicle the influence of the activities in the methods course on prospective teachers images of teacher-student interactions. We intend to refine the pre-post lesson play method so that other instructors of prospective teachers can more effectively implement this method in their courses.

Keywords: Instructional Activities and Practices, Teacher Knowledge, Assessment and Evaluation

Mathematics methods courses are intended to deepen prospective teachers' (PTs) knowledge of teaching and learning mathematics. This includes improving PTs' interactions with students through probing students' thinking, valuing students' explanations, and encouraging deeper understanding of mathematics. A core issue that arises in methods courses, especially online mathematics methods courses, is how to assess PTs' understanding. Assessing the development of PTs' pedagogical understanding is difficult because methods courses usually do not include PT-student interactions. These interactions typically occur later in a practicum setting. For this reason, PTs are assessed on their knowledge of research literature and their analyses of episodes (readings or videos) of others' teaching. These episodes serve as proxies to help PTs think about their future teaching and might differ from how they envision interacting in their own classrooms. Additionally, since the practicum is often supervised by someone other than the instructor of the methods course, it is difficult to pinpoint which activities completed in the methods course had their intended effects. Thus, it is challenging to adjust the activities within the methods course using an informed approach. In other words, methods courses aim to improve both theoretical knowledge of pedagogy and practical knowledge of how and when to enact that pedagogy; methods courses tend to focus only on the latter.

Purpose

The primary tool utilized in this study, called a *lesson play* (Zazkis, Sinclair, & Liljedahl, 2013), involves PTs writing scripts of imagined teacher-student interactions, envisioning themselves as the teacher-character in these scripts. The novel variation of this approach is to assign two lesson plays around the same mathematical scenario. One lesson play is assigned at the beginning of the online methods course, before relevant course activities [e.g., reading literature on discourse patterns, questioning strategies, or cognitively guided instruction (e.g., Carpenter et al., 2015, Smith, & Stein, 2011)]. The second lesson play is assigned at the end of the course, after these activities. The comparison of the two scripts allows both researcher

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

instructors and PTs to assess how PTs think about approaching teacher-student interactions differently in response to the methods course activities. This approach to assessment might facilitate the researcher-instructor with making modifications to future methods course activities to maximize the positive impact on practice. Our central research questions are:

1. What can be learned about how PTs envision teaching using pre-post lesson plays?
2. What can be learned about using pre-post lesson plays as a means of methods course improvement?

The purpose of this project is acquiring new insights about a relatively novel tool for examining PTs' pedagogical understandings in a mathematics methods course. We aim to refine the pre-post lesson play method so that other researchers and instructors of PTs can more effectively implement it in their online and face-to-face methods courses.

Theoretical Framework Lesson Play in Teacher Education

This study builds on Zazkis et al. (2013) notion of lesson play, an imagined teaching interaction in which a script-writer, typically a PT, creates an imagined idealized dialog of an interaction between a teacher and students, imagining herself as the teacher-character. Lesson play can thus be thought of as what Grossman, Hammerness, and McDonald (2009) called an *approximation of practice* as it allows PTs to approximate components of teaching in a setting with reduced complexity. Past studies that utilize lesson plays provide novel insights into PTs' understanding of mathematics (e.g., Zazkis, 2014, Zazkis & Zazkis, 2016), triangulation of some known results (Cook & Zazkis, 2017) and a lens into PTs' conception of pedagogy (e.g., Zazkis & Koichu, 2015; Zazkis, et al., 2013). We are proposing to expand the use of lesson play to be a pre-post lens into pedagogical understanding, which we expect will make it a valuable tool in the assessment of PTs' knowledge of pedagogy, PTs' knowledge of how and where to enact that pedagogy, instructors' development of activities in methods courses for PTs, and as a research tool for those interested in PT education.

Conceptual Framework

Our conceptual framework draws on four iterative stages of designing good mathematical tasks identified by Liljedahl, Chernoff, and Zazkis (2007). Using these four stages, we will investigate lesson play as a tool for improving methods courses and as a lens into how PTs envision their teaching.

1. PREDICTIVE ANALYSIS occurs before using a new task in a teacher education context. In this phase, predictions are made in regard to pedagogical affordances of a task.
2. TRIAL occurs by implementing the task in a teacher education classroom context and "liberating" the affordances.
3. REFLECTIVE ANALYSIS on the task occurs after the trial to highlight new affordances or constraints of the task.
4. ADJUSTMENT of the task, based on the reflective analysis, occurs to improve the task to meet pedagogical goals.

Methods Participants and Context

We began with a pilot of eight PTs enrolled in an in-person methods course to test pre-post lesson plays. The positive results from this pilot catalyzed expanding data collection to an online, asynchronous, mathematics methods course for elementary school teachers (n = 80). This methods course is delivered 100% online for 15 weeks, the first in a series of two required elementary mathematics methods courses offered through the College of Education, and required for students enrolled in the elementary education program. Prior to taking this course, students take two content courses in the mathematics department designed for pre-service elementary education teachers. In the online methods course, students are required to complete readings, watch lectures and supplemental videos, participate in a group discussion, and take a quiz each week. The course is designed to enable PTs to gain deep content and pedagogical knowledge for teaching rational numbers and proportional reasoning.

Data collection took place within an online methods course for PTs at a land-grant university in the Western United States. The data consists of the pre lesson play assignment from Week 2 and the post lesson play assignment from Week 13 of the online methods course.

The larger research project is in process and will proceed in five phases over two years (Figure 1).

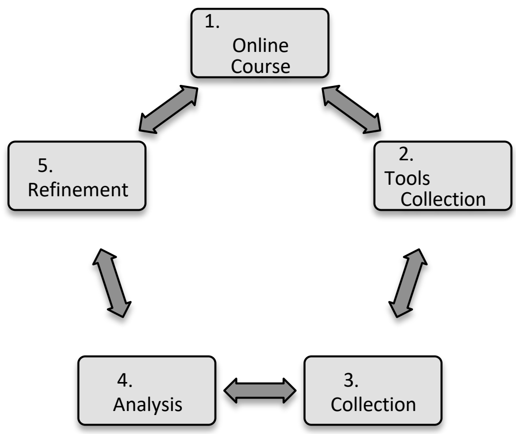

Figure 1: Phases of Data Collection and Analysis

Each phase is described in detail and aligns with the conceptual framework. For the purpose of this brief research report, we share preliminary data from phases 1-4.

Data Collection and Analysis

Phase 1: Analysis of online course (predictive analysis). We analyzed the sequence and content in the modules of the online course and identified places where we can introduce students to the lesson play assignment, the Five Practices for Orchestrating Productive Mathematical Discussions (Smith & Stein, 2011) and the Standards for Mathematical Practice (SMP; CCSSO, 2010).

Phase 2: Building tools for data collection (predictive analysis). We created a pair of matched lesson play assignments that fit within the mathematical backdrop of the methods course and developed questions to guide PTs' commentaries on the lesson play assignments. The purpose of the questions is to determine how the methods course has impacted PTs' thinking about how students learn and how to teach mathematics. For example, a major component of the course is learning the "five practices for orchestrating productive mathematics discussions" (Smith & Stein, 2011) and the SMP (CCSSO, 2010).

Phase 3: Data collection (trial). Using tools developed in Phase 2, the pre-post lesson plays were administered to about 80 pre-service elementary teachers during the researcher-instructor's online methods course. After the PTs completed the post lesson play assignment, they were asked to complete a written assignment to answer reflection questions on similarities and differences that they see between their pre and post lesson plays. These questions included:

- What teaching strategies did you include in your post lesson play that were not present in your pre lesson play?
- How did engaging in the pre and post lesson plays impact how you think about teaching proportional reasoning and ratios?

Phase 4: Data analysis (reflective analysis). We are in the process of identifying repeating themes in participants' scripts, commentaries, and reflections, while acknowledging unique instances. Themes will be organized according to (1) the five practices for orchestrating productive mathematics discussions: anticipating, monitoring, selecting, sequencing, connecting (Smith & Stein, 2011) and (2) the SMP (CCSSO, 2010). We expect additional themes will emerge.

Phase 5. Course refinement (adjustment). We will use what we learned from Phase 4, to refine both the pedagogy related content and the pre-post lesson play assignment with the dual goals of course improvement and more refined data collection. We then repeat Phases 3 and 4 in the next year with the refined methods course activities, lesson play pre-post assignment, and reflection questions to assess the viability of pre-post lesson plays as a course improvement tool.

Results from Pilot

The pre-post lesson plays allowed us to chronicle the influence of the activities in the methods course on how these PTs conceptualized idealized teacher-student interactions. For example, the course involved reading and discussing the five practices for orchestrating productive mathematics discussions (Smith & Stein, 2011), which are actions a teacher can take to manage the direction and progress of an in-class discussion. The interactions between the PTs and methods course instructor revealed that PTs grasped the definitions of pedagogical concepts but not how to apply these concepts meaningfully in a classroom setting. In particular, there were multiple instances where PTs missed opportunities to incorporate particular teacher moves into their scripts, in spite of setting up scenarios where those moves were warranted. This critical information, regarding which discussion practices PTs envision using and in which situation, were gleaned through the lesson play assignment. As such, the pre-post lesson plays provided a new lens for research on PTs' pedagogical understandings. Using lesson plays to assess gaps in PTs' enactment of pedagogical concepts will allow for targeted improvement of the course activities. Thus, pre-post lesson plays might function as a tool for methods course improvement.

Discussion

We expect similar results from the full study of 80 PTs. As this study continues to unfold, we wonder what differences we might see between the pre-post lesson plays in the face-to-face course as opposed to the online course. We expect that our findings will lead to better understanding of developing PTs' knowledge of pedagogy as it relates to teaching mathematics. By studying lesson play as a pre-post lens, we anticipate making significant contributions to mathematics teacher education by developing a tool that instructors can use for refining their online and face-to-face methods courses.

PRESERVICE TEACHERS' NOTICING IN THE CONTEXT OF 360 VIDEO

Karl W. Kosko

Videos of mathematics instruction are commonplace in mathematics teacher education. However, videos' effectiveness in facilitating mathematics preservice teachers' attention is often contingent upon their decomposition and/or approximation of practice. This pilot study examined whether 360 video technology affected the specificity of mathematics attended by PSTs viewing mathematics instruction. Results suggest that viewing 360 videos with a virtual reality headset associates with more explicitly noticed mathematics, while viewing 360 videos without a headset was observed to have similar effectiveness as standard video.

Keywords: Instructional activities and practices; Technology.

Video is commonplace in preservice teacher (PST) education, and has been for the past several decades (Grossman et al., 2009; Sherin & Star, 2011). Use of video in PST education has demonstrated positive effects on PSTs' professional noticing (Jacobs et al., 2010; van Es & Sherin, 2002), and their pedagogical content knowledge (Ball et al., 2008; Brunvard & Fishman, 2007). Video's usefulness in professional training stems from its capacity to present a viable representation of teaching and learning, as well as through application of accompanying approaches to decompose and/or approximate practice (Grossman et al., 2009; Herbst et al., 2016). However, a perennial issue with the use of video, and other similar representations of practice (animations, comics, etc.), is that PSTs often do not attend to key aspects in a teaching scenario with the level of precision that teacher educators desire (Estapa et al., 2018; Gaudin & Chaliès, 2015; Seidel et al., 2010; Sherin & Star, 2011; Stockero et al., 2017; van Es & Sherin, 2002). Stated differently, PSTs are often inconsistent in the quality of their professional noticing because they do not attend to the actions, events, or content that more experienced teachers do.

A recent innovation in video technology has emerged that holds promise for improving aspects of video use in teacher education. The *360 video* format distinguishes itself from traditional video in that it records a spherical view of a scenario, allowing the viewer, rather than the videographer, to select what is viewed in a scenario. In considering the use of this technology in teacher education, we pondered whether a higher sense of immersion translated into improved situational awareness, and thus, improved precision in PSTs' professional noticing. Therefore, the purpose of the present study is to examine whether and how the use of 360 video affects PSTs' professional noticing in the context of elementary mathematics.

Theoretical Framework

Teachers' professional noticing involves identifying aspects in a classroom scenario, relating those aspects to one's professional knowledge and norms, and applying this to reasoning about the scenario at-hand (van Es & Sherin, 2002). Jacobs et al. (2010) defines professional noticing similarly for the context of noticing children's mathematical thinking: attend to children's strategies, interpret children's understandings, and decide how to respond. Much of what is described in the literature on mathematics teachers' professional noticing focuses on *what* PSTs attend to (Schack et al., 2013; Stocker et al., 2017; Teuscher et al., 2017). Since PSTs tend to

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* St Louis, MO: University of Missouri.

notice different things in a teaching scenario than more experienced teachers (Huang & Li, 2012; Jacobs et al., 2010), and more specific noticings often correspond with improved interpretations and decision making (Jacobs et al., 2010; Teuscher et al., 2017), such a focus in professional noticing research is understandable. This relationship has led to various efforts in improving the specificity of what teachers attend to by examining variations in representations of practice. For example, scholars have compared the specificity of what is visually conveyed in representations by using animations, comic-based representations, video, and written records (Herbst et al., 2013; Friesen & Kuntz, 2018). Although differences in how participants interact with these representations have emerged, such differences do not include the specificity of attending to the content in such scenarios.

To date, the majority of research on representations of practice focuses on variations in how the representation conveys practice. By contrast, we focus on what of practice is conveyable by a representation. We use the constructs of perceptual capacity and embodied interaction to account for this focus. *Perceptual capacity* refers to a medium's ability to allow aspects of the scenario to be perceivable, including but not limited to what is potentially viewable (Ferdig & Kosko, in review). One aspect of perceptual capacity is the idea that a representation can convey a sense of the space in which a scenario occurs (Endsley, 2000; Herbst et al., 2011). Much of the literature on use of 360 videos for professional training focuses on participants' perceived immersion in the context recorded, and has generally found that viewers of 360 videos report statistically significant higher degrees of presence and immersion (Ferdig & Kosko, in review; Harrington et al., 2017; Roche et al., 2017). While perceptual capacity describes a medium's allowance for what is perceivable in a scenario, it does not describe all aspects of interaction with the spatial aspects of a scenario. Scholars studying virtual environments use the term *embodied interaction* to describe approaches that cue the body "to enact certain actions and create physical representations that facilitate conceptual understanding" (Lindgren et al., 2016, p. 174). Cuing the body may be purposeful, or may simply be part of using a specific technological tool (Riva, 2008). In the context of the present study, we consider the use of 360 videos from this latter perspective. Specifically, 360 videos are viewable in two primary ways. Most common is for viewers to watch a 360 video on a screen device (laptop, tablet, phone) and to adjust the perspective either by using a mouse or using their finger, via touchscreen, to adjust left, right, up, or down. Another means of viewing 360 videos is through some form of VR headset (OculusGo, Google Cardboard, HTC Vive, etc.). To adjust the perspective on these videos, viewers move their head left, right, up, or down. Thus, use of the headset better approximates how an individual may move their body if observing a classroom in the field.

To date, we have been unable to locate literature examining the use of 360 videos in the context of teacher noticing. The only studies with empirical data come from Roche et al. (2017) and Ferdig and Kosko (in review). Because 360 video appears to have a higher degree of perceptual capacity, and viewing such videos with headsets may also better support PSTs' embodied interaction, we sought to examine these facets. Thus, the purpose of this pilot study is to examine the specificity of mathematics noticed by PSTs in the context of perceptual capacity and embodied interaction. To fulfill this purpose, the study seeks to answer the following research questions: *Is there a difference in the specificity of mathematics noticed by PSTs when viewing a standard video, 360 video on a laptop, or 360 video with a virtual reality headset?*

Methods

Sample

Participants included 34 PSTs (one male & 33 females) enrolled in an early childhood education program at a Midwestern U.S. institution. Participants were enrolled in their first semester of their senior year; the semester preceding full-time student teaching. Following recruitment, PSTs were randomly assigned to one of three sessions occurring outside of class/program requirements. In each session, PSTs watched a video of a third grade lesson informally introducing the Commutative Property of Multiplication. Participants engaged in the same tasks surrounding the video, with the only difference between conditions being the format of video (standard or 360) and the technological hardware used to view it (laptop or VR headset). In the *standard view laptop* condition, participants viewed a standard version of the video (1280 × 720) on a laptop screen. In the *360 view laptop* and *360 view headset* conditions, participants viewed a 360 video that allowed them to adjust the position of what was viewable in a 1280 × 720 frame. The 360 view laptop and 360 view headset conditions differed in the hardware used to view the 360 video. Those using a laptop were able to adjust the perspective on the 360 video by using a connected mouse to point, click, and move the video view. In the 360 view headset condition, participants each wore an Oculus Go headset and were able to adjust the perspective on the 360 video by moving their head in the direction they wished to look.

Participants in each session completed a 30 minute teacher noticing activity involving three parts. In Part One, PSTs were provided with a synopsis of the task in the video, along with accompanying materials to examine it. The task included a 7 by 8 array (7cm × 8cm) with accompanying Cuisenaire rods, a color-coded length based manipulative (black rods = 7cm, brown rods = 8 cm, etc.). In the video, students were tasked with using only one color of rod to cover the array exactly. After becoming familiar with the task, PSTs wrote predictions of what pivotal moments (moments of interest for the teaching or learning of mathematics) they expected to see in the video. In Part Two, participants viewed the video for the first time and were then asked to type all pivotal moments they had noticed in their initial viewing. In Part Three, participants were asked to view the video a second time and to revise and/or add to their previous list in a new prompt. PSTs were then instructed to select two pivotal moments they believed were ‘most informative for (them) as a future elementary math teacher,’ to describe the most salient part of each pivotal moment, and to share why they selected that pivotal moment. Participants concluded by completing a brief follow-up survey that assessed their perceived immersion and presence. The current paper focuses on initial analysis of written response from Part Three of the noticing activity.

Analysis and Results

PSTs’ written responses, following the second viewing, were analyzed for the specificity participants attended to the mathematics in the scenario. Data included PSTs’ modified list of pivotal moments, as well as their described pivotal moments of focus. This allowed for an initial analysis of attended moments signified by PSTs as significant in some manner. Given that the recorded lesson focused on an informal introduction to the Commutative Property (the property was not formally identified in the video), analysis of PSTs’ mathematical specificity focused on the Commutative Property of Multiplication. The first and third authors analyzed PSTs’ responses developed an ordinal coding scheme (0 = not conveyed; 1 = tacitly conveyed; 2 = implicitly conveyed; 3 = explicitly conveyed). Responses were independently coded before both authors met to reconcile. Prior to reconciling the codes, a Kappa statistic of .651 was calculated, suggesting substantial reliability in the coding process (Landis & Koch, 1977). Descriptive statistics suggest that 24.2% of participants did not describe any aspects related to the Commutative Property. PSTs who *tacitly conveyed* commutativity (39.4%) often described students attempting to fit one set of rods on top of another (i.e., identifying seven rods of 8cm overlapping eight rods of 7cm). PSTs who *implicitly conveyed* commutativity (21.2%) elaborated further by specifying such student actions signaled identifying that 8×7 is the same as 7×8. By contrast, *explicitly conveyed* noticing of commutativity (15.2% of participants) specifically named the property in their written descriptions.

Table 1: PSTs' Level of Noticing the Commutative Property of Multiplication

	None	Tacit	Implicit	Explicit	Total
Standard View Laptop	2 *1.9*	2 *3.2*	4 *1.7*	0 *1.2*	8
360 View Laptop	5 *2.7*	3 *4.3*	3 *2.3*	0 *1.7*	11
360 View Headset	1 *3.4*	8 *5.5*	0 *3.0*	5 *2.1*	14
Total	8	13	7	5	33

Note: Observed values are in regular text and expected values are in italicized text.

We calculated a chi-square statistic to examine differences in participants' specificity of noticing the Commutative Property across viewing conditions (see Table 1). Results suggest that the observed frequencies are statistically significant (χ^2 (df=6) = 18.754, p = .005). This indicates that the relationship between PSTs' mathematical specificity was not independent from the viewing condition. One apparent trend across the three viewing conditions is that in both the standard and 360 view conditions, no participants were observed to explicitly identify the Commutative Property. While all explicit noticing was observed in the 360 view headset condition, none of these participants were observed to convey the Commutative Property implicitly in their noticing. Additionally, participants in the headset condition were observed to have higher than expected tacit noticings than expected by chance, while those in the other two conditions were observed to have lower such frequencies than expected by chance.

Discussion

This study provides a comparison between standard and 360 videos in regards to the specificity of mathematics PSTs attend when viewing representations of practice. Results suggest that PSTs who viewed 360 videos using the Oculus Go headset were more explicit in their noticing of the Commutative Property than participants viewing the same scenario with a standard video, or with a 360 video on a laptop. Thus, this study provides preliminary empirical evidence supporting the use of 360 videos in facilitating teacher noticing of mathematics.

Prior research on teacher noticing has observed improved specificity in professional noticing when engaging PSTs in decomposing or approximating practice (Schack et al., 2013; Stockero et al., 2017; Teuscher et al., 2017), but not when simply responding to a representation of practice (Friesen & Kuntz, 2018; Herbst et al., 2013). As 360 video and VR headset technology evolve and become more commercially available, both the perceptual capacity of such videos and the ability for facilitating PSTs' embodied interaction will also evolve. Future study on the effect of 360 videos should, therefore, consider not only the perceptual capacity of the representation, but the associated embodied interaction that the hardware device may facilitate or limit.

NEW TEACHERS' UNDERSTANDINGS OF GROUP WORK TASKS VERSUS GROUPWORTHY TASKS IN THE ELEMENTARY MATHEMATICS CLASSROOM

Kathleen Jablon Stoehr
Santa Clara University
kstoehr@scu.edu

Amy M. Olson
Duquesne University
olsona@duq.edu

Recent scholarship in mathematics education has increasingly supported the benefit of providing elementary students with opportunities to engage in groupworthy mathematics tasks in the elementary classroom. This study explores new elementary teachers' understandings of group work tasks versus groupworthy tasks and how they believe the two types of tasks may influence student learning. We highlight how new teachers define group work tasks versus groupworthy tasks, their experiences with groupworthy tasks as students and as preservice teachers, their commitment to offer groupworthy mathematics tasks to their future students, and how they envision supporting students' learning of mathematics through groupworthy tasks.

Keywords: Teacher Education-Inservice/Professional Development, Elementary School Education, Equity and Diversity, Instructional Activities and Practices

Purpose of the Study

All students need "access to high quality mathematics curriculum, effective teaching and learning, high expectations, and the support and resources needed to maximize their learning potential" (NCTM, 2014, p.59). Yet many students are denied equal access to the curriculum as well as have minimal participation in the classroom based on teacher perceptions of their perceived ability. This often results in some students continuously experiencing success while others meet with a series of failures (Cohen & Lotan, 2014; Lotan, 2003). One way to address this critical issue is to create a learning environment that embraces "students' different kinds of problem-solving strategies and intellectual competence" (Lotan, 2003, p.75.) Called "groupworthy" tasks, these activities have the potential to positively impact learning by creating opportunities for all students to experience success (Featherstone et al., 2011; Lotan, 2003). But if teachers are unable to distinguish between traditional group work and groupworthy tasks, the means to provide equitable mathematics learning opportunities for all students is not realized.

Perspective

Many elementary teachers utilize group work as a means to support student learning. Lotan (2003) defines group work as tasks where students "follow clear and detailed procedures to arrive at a correct answer or a predictable solution" (p.72). Often times, students are assigned tasks that can be done individually and do not support group learning. As a result, some students in the group take over and complete the task while other students are denied access to the task.

Featherstone et al. (2011) examined specific ways to offer access to all elementary mathematics students by creating student learning through "*groupworthy tasks.*" Groupworthy tasks are tasks that are complex in nature and offer multiple ways of thinking in order to be solved. Groupworthy mathematical tasks leverage the *mathematics smartness* of all students in mixed-ability groups, thereby providing opportunities for all students to gain deeper mathematical understandings. Groupworthy tasks are designed to mimic real world problems and issues and to be open-ended and challenging. They allow for multiple strategies to be considered when solving them and showcase students' knowledgeable abilities. They require students to work together by assigning different roles or jobs to be completed by the different group members (Featherstone, 2011; Lotan, 2003).

Previous research has not examined new teachers' understandings of group work versus groupworthy work, but such understandings may improve how mathematics methods teachers approach teaching groupworthy tasks. In this study, we explore how new teachers think about these two terms, their experiences with groupworthy tasks, and how they envision implementing groupworthy mathematics experiences for students.

Methodology

The participants in this study were sixteen newly credentialed elementary teachers who had completed a Master of Arts in Teaching degree. The teachers were primarily in their mid-twenties. They had all completed two quarters of elementary mathematics methods as part of their teacher preparation program and had spent an academic year in an elementary classroom. Having been introduced to groupworthy tasks during their mathematics methods courses, the teachers were interested in learning more about how to facilitate this type of teaching in their own classrooms. To meet this goal, they chose to attend a weeklong professional development workshop focused on utilizing equitable mathematics teaching through groupworthy tasks.

Data collected for this study included mathematics tasks, mathematics lesson plans, and individual reflections that centered on creating groupworthy tasks for students. The data was collected over all five days of the workshop. The different types of data were collected to gain an understanding of how the teachers perceived group work tasks versus groupworthy tasks.

We began our analysis with multiple subsequent readings of the data. We then conducted an iterative analysis (Bogdan & Biklen, 2006) to demarcate the phrases that pertained specifically to group work tasks and groupworthy tasks. For each teacher, we identified narratives within their text passages that included key phrases specific to group work tasks and groupworthy tasks. We created tables to illustrate the teachers' understanding of each of the terms. We then looked across the data sources to examine the teachers' experiences as mathematics learners and as prospective teachers with group work tasks and groupworthy tasks. We end our analysis with the teachers describing their rationale for incorporating groupworthy mathematics tasks into their future teaching and the qualities they possessed to support their students' groupworthy learning experiences.

Findings

Table 1 outlines the sixteen teachers' descriptions of group work tasks whereas Table 2 highlights key elements of groupworthy tasks that the teachers identified.

Table 1: Key Phrases Teachers Used to Describe Group Work

Any task where students work or discuss with multiple people	Working with a group on an assignment/task	Working on individual work as a group	Students deciding what they want to do to complete a task	Requires students to complete a certain portion of the work
Students working together as a	Work is usually not evenly split	Some students do the majority of the work &	No shared responsibility	Free for all

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

team to complete a task	nor organized effectively	others do a limited amount	for each other's learning	

Table 2: Key Phrases of Groupworthy Tasks as Identified by the Teachers

Tasks where everyone is learning and increasing the learning for their peers	Tasks where group members are responsible for each other's learning and support each other through the task	Tasks that create learning opportunities for all students	Tasks that involves and engages group members to work collaboratively to achieve a goal	Tasks where everyone gets a specific job, which ensures everyone's participation
Tasks where each member of the group contributes to the solution	Tasks that require collaboration and communication amongst the entire group	Tasks that allow students to help each other to solve a particular task.	Tasks that focus not on simply completing the task but on helping each other understand	Tasks that bring multiple strengths and allow multiple math talents to shine

Experiences with Groupworthy Work as K-12 Students

All sixteen of the teachers reported that prior to entering their teacher preparation program, they had no previous experience or knowledge of groupworthy tasks. However, the teachers all stated that as K-12 students, they had as one teacher described, "done plenty of group work as a student." Another teacher shared that when she engaged in group work as a student "very rarely did my peers try to make sure I understood the task. The focus was always on just completing the task." Upon reflecting on her experiences of group work learning one teacher recalled, "I think I did do tasks in school that could have been groupworthy but they weren't structured and managed in a way that made them so."

Experiences with Groupworthy Tasks During Student Teaching

Six of the teachers reported observing some evidence of groupworthy tasks being utilized in their student teaching placement classrooms. All six shared that the examples of groupworthy tasks they saw tended to be limited to a one-time only experience for students. In addition, they reported of the groupworthy tasks they saw their mentor teachers utilizing in the classroom, the tasks tended to be missing at least one key attribute associated with a groupworthy task. For example, many of the groupworthy tasks did not incorporate roles to ensure that all students in the group had a contribution to make to the final project. All of the teachers stated that they did not see any examples of groupworthy tasks being used during mathematics lessons. The groupworthy tasks they did see were incorporated into social studies lessons.

Characteristics of Groupworthy Tasks

After completing the workshop, the teachers reflected on the features they believed groupworthy tasks should possess. Table 3 outlines their responses.

Table 3: Characteristics Needed to Create Groupworthy Tasks

Tasks that students are excited to solve	Tasks that link to real world connections	Tasks where all students' voices are heard and incorporate different types of students thinking	Tasks that build positive relationships among students	Tasks that require students to persevere and not give up
Tasks that afford the opportunity for students to solve in multiple ways	Tasks that allow students to see that math is everywhere	Tasks that provide ample time for students to learn the concept(s)	Tasks that are engaging and hands-on	Tasks that incorporate all students' ideas

Choosing to Commit to Groupworthy Tasks in Their Future Classroom

All sixteen of the teachers expressed a commitment to provide their students with groupworthy mathematics experiences in their future classroom. They spoke of how groupworthy tasks have the potential to shift the focus from valuing individual learning to focusing and valuing the learning that occurs across group members. By engaging in the different mathematical tasks throughout the week, the teachers also reported how each other's diverse thinking of how to solve the tasks deepened their own mathematics understanding. They also shared that they believed that groupworthy tasks might help to alleviate students experiencing mathematics anxiety, as group members share their mathematical strengths with each other.

Supporting Students' Learning of Mathematics Through Groupworthy Tasks

The teachers shared their teaching strengths that they believed would support the use of of groupworthy tasks in their future mathematics classrooms. Some of these strengths included using groupworthy tasks to listen to all students' mathematical thinking, construct a learning environment where all ideas matter, have the opportunity to facilitate deeper student content knowledge, and thinking "on the spot" if the task needed to be modified. In addition, the teachers believed that they would be able to show students the relevancy of mathematics in everyday life, create hands-on activities to engage their students, build respectful relationships among students, and generate excitement for mathematics learning. The teachers also spoke about modeling the importance of determination and perseverance when learning mathematics.

Conclusion

This study suggests that newly credentialed elementary mathematics teachers have an understanding for how groupworthy tasks have the potential to support student learning and that they envision providing groupworthy mathematics tasks for their students. What remains to be seen however, is to what extent new teachers will embrace groupworthy mathematics tasks with fidelity as they assume the multiple responsibilities of teaching. Data reported in this paper indicate that teacher education programs may want to consider offering more opportunities for preservice teachers to practice groupworthy mathematics tasks. Additionally, it is important that mathematics teacher educators ensure that preservice teachers develop the critical skills to know when they are enacting group work versus groupworthy tasks. An important consideration that this paper highlights is the disconnect between elementary preservice teachers learning about mathematics groupworthy tasks in their mathematics methods course with little evidence of this type of learning occurring in their elementary placement classrooms. This reveals the importance of providing in-service professional development opportunities that teach groupworthy tasks and the necessary critical reflection to enact them well.

BE BEAUTIFULLY UNCOMFORTABLE: INSPIRING LINGUISTICALLY RESPONSIVE TEACHING OF MATHEMATICS

Mary P. Truxaw
University of Connecticut
mary.truxaw@uconn.edu

Eliana D. Rojas
University of Connecticut
edelasr@gmail.com

This research investigates elementary preservice teacher (PST) education experiences designed to inspire linguistically responsive teaching (LRT) of mathematics. A math methods course involved various opportunities for PSTs to engage in readings, discussion, reflection, and activities related to supporting emerging bilinguals with mathematics. This paper focuses on a lesson designed to promote "beautiful uncomfortableness" by having PSTs experience instruction in Spanish (not the primary language for most of the PSTs) using Mayan numbers (not familiar to PSTs). Data were analyzed qualitatively. A teacher learning cycle to promote LRT of mathematics is proposed and examined.

Keywords: Equity and Diversity; Instructional Activities and Practices; Affect, Emotion, Beliefs, and Attitudes

Objectives/Purposes

Linguistic diversity of students in U.S. schools continues to increase (National Clearinghouse for English Language Acquisition, 2011). Although some might consider mathematics to have limited language demands, research suggests that language is vitally important to teaching and learning mathematics (Moschkovich, 2002, 2013). Further, there is evidence that, overall, U.S. schools are not adequately supporting English learners (ELs) with mathematics (National Center for Educational Statistics, 2015). Clearly, there is an urgent need to prepare mathematics teachers who have beliefs, knowledge, and practices to teach ELs effectively (Lucas & Villegas, 2013). However, because teacher preparation programs have many demands, preparing preservice teachers (PSTs) for linguistically responsive teaching (LRT) may require strategic infusion of experiences (Ewing, 2017; Lucas & Villegas, 2013).

This research investigates experiences infused within an elementary math methods course that were designed to inspire LRT. Throughout the methods course, PSTs engaged in readings and activities related to supporting ELs. This paper focuses on a Mayan numbers lesson designed to promote "beautiful uncomfortableness" by having PSTs experience instruction in Spanish (not the primary language for most of the PSTs) and use of Mayan numbers (not familiar to the PSTs). The lesson was based on an experience that author 1 (A1) had in a Guatemalan school and that was unpacked via cogenerative dialogue with author 2 (A2) (Tobin & Roth, 2005). A teacher learning cycle (TLC) to promote LRT is proposed and examined.

Perspectives

This research is informed by Feiman-Nemser's (2001) professional learning continuum and its application by Lucas & Villegas (2013) to tasks for learning to teach ELs. It is beyond the scope of this paper to explain or apply all components of their work; however, we identify aspects that support our data analysis and a proposed teacher learning cycle (TLC). From among Feiman-Nemser's central tasks of PST preparation, we acknowledge the importance of "analyzing beliefs and forming new visions" (p. 1016). Lucas and Villegas mapped this central task onto "reflecting on and interrogating one's preconceptions about ELL students, language diversity, and the role of other languages in school" (p. 103). We focused on these central tasks because of their potential to help PSTs to shift from deficit thinking about linguistic diversity toward more affirmative, proactive beliefs and LRT practices (Feiman-Nemser, 2018).

Along with drawing from the literature, we build ideas from our own research and experience as mathematics teacher educators, particularly, as we worked to better understand affordances and challenges when the primary language of instruction is not that of some or all of the learners. Our self-study (Truxaw & Rojas, 2013, 2014) helped us to identify a possible ***teacher learning cycle*** (TLC) to enhance LRT (see Figure 1). In the cycle, ***awareness*** (of affordances and challenges) is enhanced through attention to both *academic* components (e.g., literature, research, etc.) and also *experiential* components (e.g., immersion, simulations, etc.). ***Reflection*** on enhanced ***awareness*** can motivate new ***teaching practices*** (that also benefit from *academic* and *experiential* components). Double arrows indicate that movement could *and should* go in more than one direction – ***reflection*** enhances both ***awareness*** and ***teaching practice***. To investigate the TLC in the context of the math methods course, we set up experiences that built from our own and that aligned with ones documented by others (e.g., Ewing, 2017; Gort, Glenn, & Settlage, 2011).

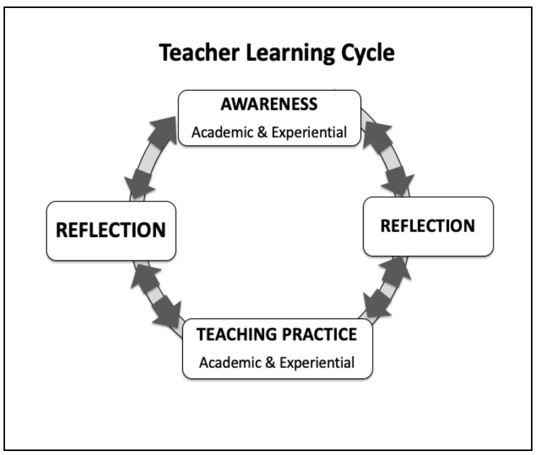

Figure 1: Teacher Learning Cycle

We ask the following research question:
How can LRT be infused within an elementary mathematics methods course?

Modes of Inquiry

Participants were elementary education PSTs (n=122) from three different years (2015, 2016, and 2018) of a math methods course taught by A1 in the semester prior to student teaching. Although the course varied somewhat from year to year, all included readings, videos, reflections, and activities related to linguistic diversity. The focus of this paper is analysis of a Mayan numbers lesson.

Data sources include: selected audio and video recordings of in-class experiences; documentation of readings, activities, and course materials; PSTs' written reflections and work samples; and instructor journals. Qualitative data analysis involved constant comparative methods and thematic coding (Strauss & Corbin, 1990). Selective codes were drawn from our earlier research and from the literature (e.g., Truxaw & Rojas, 2013, 2014; Lucas & Villegas, 2013; Moschkovich, 2013). Open coding allowed additional themes to emerge. Comparisons were made between our self-study learning trajectories and those of the PSTs.

Results and Discussion

We briefly document the focus lesson within the math methods course, noting connections to the TLC. Within the course, the PSTs had experienced readings, activities, and reflection to enhance their *academic* ***awareness*** related to teaching ELs. We recognized that awareness and reflection that were predominantly academic could go only so far in "analyzing beliefs and forming new visions" (Feiman-Nemser, 2001, p. 1016). Infusing powerful experiences, accompanied by reflection, had potential to further enhance ***awareness.*** Therefore, the Mayan numbers lesson was designed to encourage *experiential* ***awareness***. To introduce the lesson, A1 told PSTs that she had had a powerful experience in a second-grade Guatemalan classroom. "I'm going to give you some of the experience I had … If this feels uncomfortable, then I'm doing what I intend to do." (A1, October, 2018). Instruction, slides, and handout were in Spanish. A handout labeled "Numeración Maya," asked students to "Forma el número …" followed by numbers written in Spanish. Many of the PSTs spoke some Spanish (i.e., they were emerging Spanish learners). When the handout, slide, and verbal instructions asked PSTs to "Forma el número trienta y nueve" (form the number thirty-nine), many PSTs wrote "39" on their handouts. A1 then "clarified" that they should "forma el número 39 *usando los numerales Mayas*" (form the numeral 39 using Mayan numbers). After showing the "repuesta" (the answer) using Mayan representations (see Figure 2), A1 provided verbal feedback in Spanish. Next, A1 provided an explanation in Spanish, accompanied by visual representations and Spanish text on a slide (see Figure 3). PSTs were given opportunities to practice with other numbers. A1 circulated throughout the classroom, observing, providing feedback (in Spanish) and asking students to speak only in Spanish. Very few PSTs were able to successfully complete the requested tasks. After the initial lesson, A1 asked students to ***reflect*** about how they felt during the lesson. PSTs shared strong feelings of frustration, feeling unintelligent, and tendencies to shut down and give up. One PST said, "I felt frustrated when you came over and tapped on my paper because I hadn't written anything down. I was like, what do you expect me to do? I don't know how to do it." (See Table 1 for additional PST quotes.) A1 commented, "This is a room of educated, intelligent people … and you felt like shutting down."

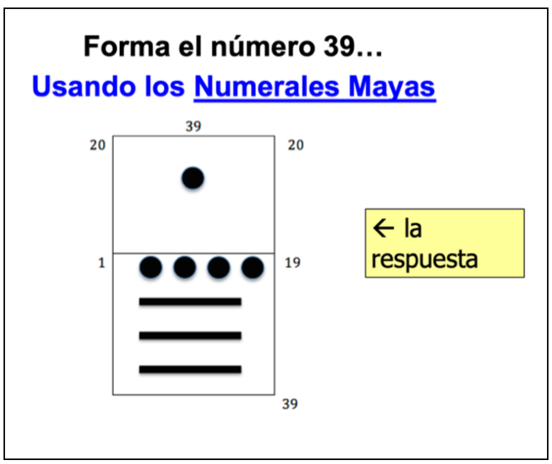

Figure 2: Example "Answer" Slide

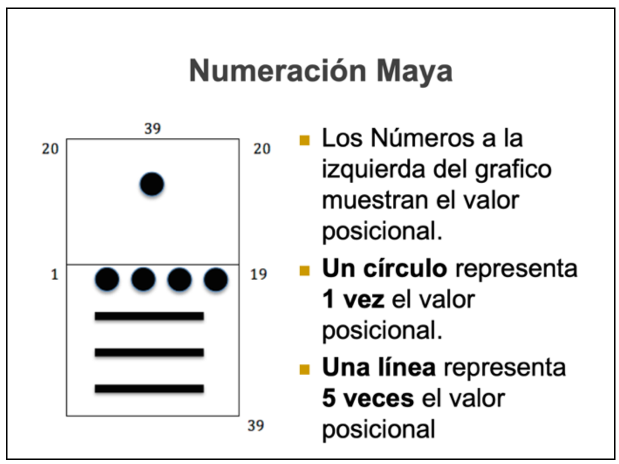

Figure 3: Explanation Slide

Following the group ***reflection*** discussion, A1 provided a worksheet and slides that included Spanish, along with English translations. Additionally, A1 provided more "think time" and encouraged PSTs to speak *in any language* with peers to try to make sense of the ideas. Many more of the PSTs were able to generate Mayan representations. The class then ***reflected*** again about their experience as learners and also about **teaching practice** that might support emerging bilingual students. Further discussion, along with recognizing challenges, acknowledged that students may be held back from learning important concepts and skills because of language. Discussion included focus on keeping cognitive demands high while providing linguistic supports (e.g., Cummins, 2000). Then, small groups worked together to generate and share posters of ideas to support linguistically and culturally relevant ***teaching practice***. One poster included a phrase that inspired the title for this paper, "Be beautifully uncomfortable." Table 1 shows examples of themes and quotes from PSTs that are aligned with our earlier work and the literature. Additional findings will be shared during the presentation.

Table 1: Themes and Evidence from Mayan Numbers Lesson

Challenges	Example PST quotes
Lack of opportunity to reason in one's primary language can hinder sense making.	"I was thinking, 'if she would just put the instructions in English, I'd be able to do this…' A lightbulb went off – okay, if teachers were doing this with ELL learners, it would be so much easier if they could put it in Spanish."
One is likely to appear (and feel) less intelligent than one really is.	"I was disengaged because I was frustrated and confused." "It just makes me want to hug my ELL students."
Academic language is more challenging than conversational language	"Being someone who spoke Spanish, … I was fine. But then … everyone was like, what is it if *yours* is wrong? … I don't know Mayan numbers."
Working to understand even basic instructions can be challenging.	"I thought it was really powerful because it's what a lot of English language learners experience. … it's hard to put into words how someone feels ... I was really confused."
Asking meaningful questions in a second language can be difficult	"I didn't understand how to ask you in Spanish, 'Can you teach me how to do Mayan numbers?'"

Note: PST quotes are from 2015, 2016, and 2018.

Conclusions

This research demonstrates potential for informing teacher preparation programs about strategic infusion of experiences to promote LRT. The TLC provides a scaffold for considering the importance of interactions of ***awareness***, ***reflection***, and ***teaching practice*** – including both academic and experiential opportunities. Indeed, experiences such as the Mayan numbers lesson, scaffolded with the TLC, show potential to promote "analyzing beliefs and forming new visions"(Feiman-Nemser, 2001, p. 1016) and "reflecting on and interrogating one's preconceptions about ELL students, language diversity, and the role of other languages in school" (Lucas & Villegas, 2013p. 103). These are small, but important steps in preparing linguistically responsive teachers of mathematics. Long journeys begin with small steps.

A CHANGING TIDE? EXPLORING MATH IDENTITY IN PRESERVICE ELMENTARY TEACHERS

Stephanie B. Purington
University of Massachusetts Amherst
spurington@educ.umass.edu

*The math identity that teachers hold can influence how they teach and the math identities that their students develop. This study on preservice elementary teachers (*N *= 13) describes the feelings the participants have toward teaching math, how they developed those feelings, and how they view the identity of "not a math person." Unlike previous studies, the participants in this study expressed very positive feelings about math and about teaching math. Feeling competent in math, having a strong "math for teaching" course, and seeing math as relevant to daily life were the key components to their positive feelings. Although they know that people identify as "not a math person," they believe that no one is born unable to learn math.*

Keywords: Affect, Emotion, Beliefs, and Attitudes; Teacher Education-Preservice

In our culture, it seems that it is perfectly acceptable to claim that one is "not a math person." While the definition of "not a math person" likely varies from person to person, it seems to involve feeling anxious about math, that math is something that one is not destined to master, and not performing well in math. There appears to be a societal acceptance, and even expectation, that some people are born to be math people and others are not. What happens, then, when someone who has self-identified as "not a math person" becomes an elementary school teacher who must teach math?

The purpose of this pilot study was to explore how preservice elementary teachers identify as math doers and teachers through the following research questions.1) How do preservice teachers describe their feelings about and their readiness for teaching mathematics? 2) What experiences do preservice teachers report as instrumental to their feelings about math and readiness for teaching math? 3) How do preservice teachers describe what it means to have an extreme math identity – to be a "math person" or "not a math person?"

Conceptual Perspective and Related Research

This study uses the frame of mathematical identity in looking at how preservice teachers (PSTs) see themselves as learners, doers, and teachers of math. Gee (2000) proposes using identity as an analytic lens for educational research, and he looks at identity as "being recognized as a certain 'kind of person'." How preservice teachers develop their math identity might depend on how quickly math comes to them, how their schools have defined their capacity or abilities, how they have engaged with others about math, or how they see the community of elementary school teachers interact around math. They might have been expected to be passive receivers of mathematical knowledge and so disengaged from mathematics (Boaler & Greeno, 2000). Their identity might also be influenced by the math-related narratives told about them by their teachers, parents, or peers (Sfard & Prusak, 2004).

Gender has been indicated as one factor in the development of a negative math identity, and college students may select majors that reinforce this identity. Most elementary school teachers are female, and elementary education majors have been found to have the highest rate of math anxiety of any college major (Betz, 1978; Baloglu & Kocak, 2006). Palmer (2009) found that only 5% of her female preservice participants came into her math course with a positive math identity. Preservice teachers (PSTs) who have math anxiety often cite their own elementary and secondary teachers as the source of their discomfort with math (Bekdemir, 2010; Jackson & Leffingwell, 1999). Research has also indicated that girls with strong gender role affinity can "catch" math anxiety, which can be part of the "not a math person" identity, from their female teachers (Beilock, Gunderson, Ramirez, & Levine. 2010).

Mathematics anxiety, a fear of all that is related to mathematics (Hembree, 1990),has been shown to reduce a PST's expectations for student mathematics achievement (Mizala, Martínez, & Martínez, 2015), and studies have shown that teachers tend to underestimate girls' math abilities starting in the first grade, and often grade those girls more harshly than the boys in the class (Cimpian, Lubienski, Timmer, Makowski, & Miller, 2016; Lavy & Sand, 2015). These authors further state that this sort of underestimation and poor feedback can lead to waning confidence and engagement, which leads to reduced learning and performance. That in turn leads to forgoing higher level math classes and whole areas of professional exploration.

Those who do not attempt or succeed at higher level math courses are left out of many professions and career paths. The U.S. Department of Labor estimates that in 2018, nine out of the ten fastest growing occupations requiring a bachelor's degree will require the employee to have had significant science or mathematics training (Hill, Corbett & St. Rose, 2010). It is crucial, then, that we better understand the development of math identity in preservice teachers in order to provide a path for them to construct a positive "math person" identity.

Methods

This study was intended to describe the responses of preservice elementary teachers about their readiness and feelings about teaching math. The participants were students (N=13) enrolled in a one-year, dual master's degree and elementary education certification program.

All participants took part in one-on-one, semi-structured interviews prior to starting their student teaching or taking a mathematics methods course. Interview questions were intended to determine how each participant felt about teaching mathematics and how well prepared they felt to teach that subject.

In the interviews, participants were also asked about their level of math anxiety, using the Single-Item Math Anxiety Scale (Núñez-Peña, Guilera, & Suárez-Pellicioni, 2014). Each participant also shared with me a math autobiography, describing their K-16 experiences with math and the areas in which they were most and least confident, written at the beginning of September for their course in Elementary Math Methods.

I analyzed the autobiographies and interviews using thematic analysis (Braun & Clark, 2006), first reading all of the responses to familiarize myself with the data, then creating some initial codes based on my research questions and the topics I was noticing in the responses, and noting where those ideas were mentioned or highlighted. After grouping the similar comments, I looked for patterns within the grouped responses, and coded for themes.

Findings

Analysis of both the interviews and math autobiographies showed that most of the participants had quite positive math identities, contrary to what was found in the previously cited study by Palmer (2009), though many still expressed struggles with higher-level mathematics. In this section, I address their attitudes toward being teachers of math, then focus on the experiences that they report as affecting those attitudes, based on the themes that emerged through analysis across participants.

Teaching Math

It was not surprising that Molly, who majored in math, said that she "felt great about being a math teacher." More surprising was that all but one of the participants gave an answer similar to Molly's. The only participant who did not express excitement about teaching math was Marie, who felt that she did not have the background experiences with children that most of her peers did. Compared to the other subjects, she noted that she felt "a little better" about math.

All of the participants also reported feeling well prepared to teach math, even before taking additional coursework on methods for teaching mathematics or starting their student teaching experiences. Claire, who was homeschooled for most of her early education, noted that "Taking [specific undergraduate math courses for education majors and minors] was a great course in understanding that material and not just teaching kids how to get the answer, but how to understand the math." Molly mentioned that those same courses had led to her feeling very prepared to teach.

Based on the autobiographies and the interview responses, all 13 participants' identities toward teaching math indicated a positive disposition. In order to gain more understanding of their feelings of readiness, I next explored the factors that they said contributed to their feelings about doing and teaching math.

Instrumental Experiences: Competence and Relevance

Competence and relevance were the two ideas mentioned most often when I asked the participants about what led them to feeling so positively about math and teaching mathematics.

Many of the participants mentioned feelings of competence with math, especially at the elementary level, in explaining their positive inclination toward teaching math.

In contrast, several mentioned feeling competent with math up to a point, either high school or college, and then losing that confident identity.

When participants talked about interest in mathematics, it was generally in the context of the math being relevant or having a utilitarian function Ten out of the thirteen participants noted that relevance was an important component in understanding or feeling competent in mathematics. The participants also talked about how keeping math relevant affects elementary school students, and how they want to teach those students.

What it Means to Be, or Not Be, "A Math Person"

Since none of the preservice teachers identified as "not a math person" or even "a math person," I asked them what they thought a student might have experienced or be thinking if they told the teacher "I'm just not a math person." I also asked if they thought that some people were born to be better at math than other people, a common refrain when discussing "math people."

Eight out of the thirteen participants thought that poor teaching quality was a component leading to "not a math person" beliefs or to strong negative math identity. Seven participants mentioned lack of effort on the part of students as contributing to the claim of "not a math person." Most participants felt that people might have some innate quality that makes math learning easier, but that everyone can learn math if they are willing to put in the effort.

I asked the participants what they would say to the student who claimed to be "not a math person," and many of them replied, as Zoe did, that "there is no such thing as a 'math person'." She went on to add that she would tell them "there's lots of different ways to learn math and some people learn it quickly and some people don't, and that's okay."

Because math anxiety has been linked to identifying as “not a math person” (Nosek & Smyth, 2011), I asked participants to rate their math anxiety on a scale of one (none at all) to ten (extremely high). Responses indicated that the PSTs in this study do not suffer from math anxiety.

Discussion

Prior studies (e.g. Cribbs, et al., 2015; Alghazo, McIntyre, & Alghazo, 2013; Chen,McCray, Adams, & Leow, 2014; Uusimaki & Nason, 2004; Bekdemir, 2010) and personal experiences had suggested that many or most of the preservice teachers would claim to be not “math people,” with the related negative feelings and lack of readiness to teach math. Their responses were largely in opposition to that notion. Not one of them expressed hating math or having a lot of math anxiety, and they were almost unanimous in their positive responses about teaching math. The responses given by the participants in the interviews were confirmed in their math autobiographies, which they could not have anticipated I would see. Whether this cohort is an anomaly or a new normal remains to be seen.

As they talked about their readiness to teach math, many of the participants commented that they felt very competent with elementary-level math content, and so felt comfortable with teaching that content. Even those who did not have positive experiences in their own K-12 schooling felt that they possessed the necessary concepts and skills to teach elementary mathematics. The idea that knowing content means readiness for and competence in teaching is common in preservice teachers (Chen et al., 2014), but there is a significant difference between content knowledge and pedagogical skills for teaching content (Ball, Thames, & Phelps, 2008; Shulman, 1986). While the PSTs were excited for their practicum experiences so they could learn about classroom management and teaching techniques, they would likely also find that their pedagogical skills are still developing, and would find that they needed more skills to be the excellent teachers they hoped to be.

Many of the participants identified specific math content courses designed specifically for those planning to teach elementary school as having a strong impact on their readiness to teach math. Several mentioned that they wish they had learned math in this conceptual way in their primary schooling, and that they planned and hoped to teach that way in their own classrooms. The shift away from procedural teaching and learning may have allowed the participants to develop a new sense of agency around mathematics and a more robust math identity (Boaler & Greeno, 2000)

Contrary to my expectations, none of the participants claimed an extreme math identity as “not a math person” or even “a math person.” They were unified in their response that there is no such thing as “a math person,” in the sense that they do not believe that some people are born to be mathematically capable and others are not.

Conclusion

So, is the tide turning for math identity in prospective teachers? While it is exciting to have this cohort of prospective teachers feeling so positively about math, many questions remain about the causes of their feelings and the impact of their positivity. Has the K-12 math education community changed instruction and expectations in a way that encourages a more positive math identity, or is this an anomalous cohort of preservice teachers? A larger study of preservice teachers that included more regions and institutions would be needed to begin to answer that question. Does the positive math identity, positive feeling, and sense of readiness to teach math that these preservice teachers claim to hold mean that they will be stronger math teachers and less likely to trigger math anxiety or negative math identities in their students? How much will the realities of teaching affect the confidence of the novice teacher, and what might it take to repair any losses in their positive math identity? A longitudinal study of their classroom practices and the effects on their students would be necessary to address those questions.

"YOU CAN'T TEACH AN OLD DOG NEW TRICKS": INVESTIGATING A NEW PRESERVICE TEACHER LEARNING MODEL

Jamie S. Pyper
Queen's University
pyperj@queensu.ca

John Bosica
Queen's University
j.bosica@queensu.ca

Stephen MacGregor
Queen's University
stephen.macgregor@queensu.ca

Many issues co-exist for preservice teachers' learning, such as the incredible amount of mathematics in the curriculum, the challenges of acquiring and teaching 21st century skills and managing inclusive education issues, the diversity of students' abilities, and the increasing knowledge of 'best-practice' pedagogical strategies. A Problem-based Learning (PBL) model for preservice teachers models and aligns with classroom practice and begins with an identified 'problem of practice'. This mixed methods study captures significant changes in secondary school mathematics preservice teacher experiences and explores task implementation over four consecutive PBL cycles by examining preservice teacher beliefs, teacher efficacy, journals from tutors, recordings of PBL task meetings, and preservice teacher thoughts.

Keywords: Teacher Education-Preservice, Teacher Knowledge, Teacher Beliefs

Introduction

Consider three influences on the efforts to improve the teaching and learning of secondary school mathematics: the diversity of preservice teacher backgrounds, student diversity and needs, and the socio-global expectations and experience of being a 21st century learner. These influences often cause tensions within the preservice teacher's own learning. First, there is the intellectual (mathematical) and social diversity of secondary school mathematics preservice teachers that affects their understanding of mathematics and teaching. Second, managing inclusive education issues and the diversity of secondary school students' abilities, personal life histories, and motivation is more than just teaching mathematics, while grappling with the increasing knowledge of 'best-practice' pedagogical strategies. And third, preservice teachers have the challenge of acquiring 21st century skills for themselves while learning how to promote these skills for their students.

Mathematics educators may implement a constructivist learning environment, but often feel they are dragging preservice teachers into some kind of thinking rather than helping them engage in thinking. As one preservice teacher previously stated upon leaving on the last day of class, "I think I learned some things from your course, but you know what they say about teaching an old dog new tricks…", implying she was going to teach in the same transmission manner she experienced as a learner. A Problem-based Learning (PBL) model for preservice teacher learning models and aligns with classroom practice and an inquiry model of inservice professional learning in collaborative learning communities. Beginning with an identified 'problem of practice', PBL inherently answers the questions 'why are we learning this?' 'how is this relevant to my teaching in a classroom?' The research questions for this study are,

1. What is the effect of a PBL professional learning model on secondary mathematics
preservice teacher attitudes and beliefs towards their teaching and students' learning?

2. What is the nature of their teacher efficacy before, during, and after learning in a PBL professional learning model?
3. What is the nature of their mathematics beliefs and problem-solving beliefs before, during, and after learning in a PBL professional learning model?

Literature

This study of PBL as a mathematics teacher education pedagogy draws on literature that examines problem-based learning, problems and problem solving in the context of mathematics and secondary school mathematics teaching and learning, and teacher efficacy and its sources that influence teacher practice.

Problem-based Learning

PBL is a way of learning that incorporates small groups of learners working together, and experts (called tutors) working with the small groups, on relevant and realistic problems the learners might encounter in their professional practice. PBL is not about creating a realistic environment that replicates the learners' professional practice environment, but creating an authentic environment in which learners can develop the necessary knowledge and skills to be successful in their professional practice. The curricula for PBL is designed to "provide students with guided experience in learning through solving complex, real-world problems" (Hmelo-Silver, 2004, p. 239). Five goals underlie PBL's design to help the learner: "Construct an extensive and flexible knowledge base; Develop effective problem-solving skills; Develop self-directed, life-long learning skills; Become effective collaborators; and Become intrinsically motivated to learn" (Hmelo-Silver, 2004, p. 240).

Research on PBL has shown a number of positive and valuable outcomes from this style of learning (Strobel & Van Barneveld, 2009). For example, in comparison with control groups of students not in PBL, learners in PBL can show greater self-regulation and problem-solving skills (Seyan, 2016), as well as improved perceptions of problem-solving ability (Temel, 2014); increased creative thinking ability, self-regulation learning skills, and proficiency in self-regulation (Yoon, Woo, Treagust, & Chandrasegaran, 2014); and an increase in academic achievement (Gunter & Alpat, 2017).

PBL exists in undergraduate and graduate learning. McMaster University in Hamilton, Ontario is widely accepted as the first formal use of PBL in a university setting, starting PBL in its school of medicine in 1965. PBL exists in other notable universities, such as Maastricht University in Maastricht, the Netherlands in undergraduate learning since 1976. PBL has been employed as a learning strategy for graduate or professional school learning, for example, with prospective chemistry teachers, secondary school science teachers, preservice physics teachers, law students, and with a cohort of elementary school preservice teachers in a mathematics methods course at the University of British Columbia. At this point, there does not appear to be a PBL program running for secondary school mathematics preservice teachers.

Problems and Problem Solving

Problem solving is a cognitive process employed when an answer or solution is desired for a problem that does not have an apparent, obvious, or immediate strategy or method. This cognitive process is expressed as goal-directed behaviour as the problem solver selects and applies strategies to achieve the goal of solving a problem (Mayer & Wittrock, 2006). With mathematics, problem solving is valued as a way to increase students' understanding of mathematics (Hiebert & Wearne, 2003), where understanding mathematics means to know about facts and procedures, to know why they exist, and to know when to use them (see ‘knowing-to’ in Mason & Spence, 1999).

There are two key characteristics of problems—routines and structure (Mayer & Wittrock, 2006; Hollingworth and McLoughlin, 2005). Creative thought and critical thinking are required to figure out what can be done to solve non-routine problems, and with ill-defined problems the data is not complete or readily available. Any procedures or steps could be taken and the decisions one makes while problem-solving may not appear to converge towards a solution. Problem design must be completed carefully to consider the many aspects of the intent of the course, the problem, and the capabilities of the students.

Teacher Efficacy

Teacher efficacy, in the context of the professional practice of teaching, emerges from social cognitive theory (Bandura, 1997) and one’s self-efficacy beliefs. Teacher efficacy is a belief a teacher possesses concerning his/her/their capabilities to perform in a way to affect student learning outcomes. Teacher efficacy as used by Tschannen-Moran and Woolfolk Hoy (2001) illustrates the classroom contextual nature of teacher efficacy; their teacher efficacy scale has three subscales: instructional strategies, student engagement, and classroom management.

Teacher efficacy is relatively static, although it can be malleable and change given a gestalt shift or important experience that causes a conscious moment of critical thinking and reflection. Teacher efficacy has been shown to be a powerful construct. In conjunction with social learning theory (Rotter, 1982) and internal and external locus of control (the influence one attributes to achieving a particular outcome), teacher efficacy has been shown to improve student achievement, student motivation, and teacher enthusiasm, commitment, and classroom practice.

Given an appreciation for the impact teacher efficacy has on teacher practice, and on student learning, research is recently focusing on the activities and experiences that might impact teacher efficacy. Exploring these activities and experiences that become the sources to teacher efficacy becomes the foundation to understanding what might be done to improve professional learning.

Theoretical Framework

Teacher cognition (Borg, 2015) is a key pillar to the theoretical framework for unpacking and understanding teacher learning in relation to the mathematics teaching and learning context. Teacher cognition consists of teacher knowledge and beliefs. Teacher knowledge is the present and available knowledge a teacher has at a given time, and Shulman’s (1986) description of teacher knowledge as the body of content knowledge, pedagogical knowledge, and pedagogical-content knowledge, is the seminal articulation of teacher knowledge. Teacher beliefs is being more narrowly defined as teacher efficacy and its sources. Teacher beliefs consist of the evaluation and judgement individuals make that affects the way they interact with the world around them.

Methodology and Methods

A sequential four-phase mixed methods study is used to capture insight into preservice teacher learning relevant to a PBL experience as well as insight into the programmatic implementation of PBL as a learning model within a non-PBL teacher education program. The primary participant group comprises 45 preservice teachers, two-thirds female and one-third male or other gender expressions, in a post-undergraduate secondary mathematics education methods course, at one mid-sized Canadian university. The secondary participant group comprises five PBL tutors (school-board teachers, graduate students, and the course instructor).

Data was captured four times: pre- and post-learning in an introductory learning block consisting of instructor-led workshops, seminars, and collaborative classroom activities (data collection times 1 and 2); and pre- and post-PBL learning block (data collection times 3 and 4). For the preservice teachers, quantitative data came from the 12-item short form of the Teachers' Sense of Efficacy Scale (TSES) (Tschannen-Moran & Woolfolk Hoy, 2001); 18 items from the Beliefs About Mathematics Problem Solving (BMPS) questionnaire (Kloosterman & Stage, 1992) from the Effort, Understanding, and Usefulness subscales; and two ranking questions pertaining to teacher concerns and teacher orientation to teaching. The qualitative data came from short answer questions about (a) concerns preservice teachers expressed at each time, and (b) preservice teachers' perceived program contributions to their learning. Qualitative data collection is ongoing for focus group meetings of PBL tutors.

Data analysis for this study is ongoing. Quantitative analysis will include descriptive statistics, reliability tests, confirmatory factor analysis of both the BMPS and the TSES, and a two-way mixed ANOVA of time in the course versus teaching subject to explore change over time of the average scale and subscale scores from the TSES and the total scores from the three scales in the BMPS. Qualitative analysis will follow a general three-step constant comparison analysis. All data will be examined for relationships across data types that provide details to confirm quantitative results and explain qualitative themes using a convergent parallel design (Li, Marquart, & Zercher, 2000).

Conclusions and Educational Significance

At the time of writing this proposal, data is being collected, and analysis will be complete by the end of summer of 2019. Full results and conclusions will be complete by October 2019 in time for the conference. Preliminary analyses have shown all scales to exhibit an acceptable level of internal consistency (i.e., Cronbach's alpha of .7 or greater). Several statistically significant findings suggest changes in preservice teachers' problem solving beliefs and their teacher efficacy: (a) an increase in the Understanding subscale of the BMPS, $F(3, 129) = 3.866$, $p = .01$, partial $\eta^2 = 0.08$, between times 2 and 4 (which includes practicum and curriculum course work) and between times 3 and 4 (which is over the PBL section of the course); (b) an increase in the Usefulness subscale of the BMPS, $F(3, 129) = 4.664$, $p = .01$, partial $\eta^2 = 0.10$; and (c) an increase in teacher efficacy between times 3 and 4, $F(3, 129) = 3.350$, $p = .02$, partial $\eta^2 = 0.07$. There is clearly something happening with preservice teachers' thinking about problem solving and their teacher efficacy between time points 3 and 4 (i.e., before and after the PBL learning block), as we see positive growth in both teacher efficacy and problem-solving beliefs. While we are not forwarding claims of causality, anecdotal insight from preservice teachers is very positive. Comments made to the PBL tutors and those recorded during the concluding meetings of each PBL task indicate preservice teachers gained valuable learning about mathematics teaching and learning, and comments from the PBL tutors indicate they are observing noticeable professional discourse and learning gains from the preservice teachers.

The 2005 OECD report, "Teachers Matter," states teachers' roles are changing and that teacher learning needs to (a) be evidence based, (b) connect preservice with inservice learning, and (c) align with school needs. Recent research on preservice teacher learning echoes this call for inquiry-based education models and alignment with the professional learning community models of inservice teacher professional development that is classroom practice-based and that begins with an identified 'problem of practice'. PBL offers a different learning model, one authentically articulated by teacher cognition and connected to mathematics problem solving and the problem solving of teachers' daily professional practice. PBL also meets more, if not most, of preservice teachers' learning needs, is authentically inclusive for all students' learning, and promotes the principles of quality learning and teaching of mathematics.

AN UNDERGRADUATE PRESERVICE TEACHER'S MATHEMATICAL AND PEDAGOGICAL CONTENT KNOWLEDGE OF CONDITIONAL PROBABILITY

Kaitlyn Stephens Serbin
Virginia Tech
ksserbin@vt.edu

Jesse L. M. Wilkins
Virginia Tech
wilkins@vt.edu

It is essential for preservice teachers (PSTs) to develop mathematical knowledge for teaching to prepare for their careers. This study investigated an undergraduate mathematics PST's mathematical and pedagogical content knowledge of probability. We specifically focused on a PST's common content knowledge, knowledge of content and students, and knowledge of content and teaching in the context of probability (Ball, Thames, & Phelps, 2008). We explored how a PST understood concepts related to probability, anticipated and interpreted student reasoning, and used evidence of student thinking to inform her pedagogical response to the student.

Keywords: Teacher Knowledge, Probability

Several tasks performed by mathematics teachers, such as anticipating and responding to students' thinking, designing tasks, and fostering discussion in the classroom, require them to use their mathematical knowledge. It is essential for teachers to hold both mathematical knowledge and pedagogical knowledge and intertwine them in their teaching (Ball, 2000). In this study, we explored an undergraduate mathematics PST's mathematical and pedagogical content knowledge of probability. We investigated this PST's Common Content Knowledge, Knowledge of Content and Students, and Knowledge of Content and Teaching (Ball, Thames, & Phelps, 2008).

PSTs commonly hold the same incorrect conceptions of conditional probability that secondary students commonly hold, including the representativeness heuristic and the Falk phenomenon (Kahneman & Tversky, 1972; Nabbout-Cheiban, 2017). We explored the conceptions that an undergraduate PST held regarding conditional probability, and investigated her occasional use of these incorrect conceptions. We also explored how this PST anticipated students' use of these conceptions and developed pedagogical approaches for helping students better understand conditional probability. These research questions were addressed: How does a PST reason as she performs conditional probability tasks? How does a PST anticipate and interpret students' reasoning on probability tasks? How does a PST respond to student thinking?

Theoretical Framework and Literature Review

We focused on exploring three of Ball et al.'s (2008) Mathematical Knowledge for Teaching constructs: Common Content Knowledge (CCK), Knowledge of Content and Students (KCS), and Knowledge of Content and Teaching (KCT) regarding probability. Several other studies have examined PSTs' understanding of probability (e.g., Nabbout-Cheiban, 2017; Koirala, 2003; Carter & Capraro, 2005; Maher & Muir, 2014). Some PSTs struggle to reconcile their intuitive informal probabilistic reasoning with their formal mathematical knowledge learned in undergraduate courses (Koirala, 2003). Some PSTs exhibit incorrect probabilistic conceptions commonly held by secondary school students. In particular, PSTs often exhibit incorrect probabilistic conceptions regarding the use of the representativeness heuristic (e.g., Nabbout-Cheiban, 2017; Carter & Capraro, 2005; Maher & Muir, 2014). One who uses the *representativeness heuristic* "evaluates the probability of an uncertain event, or a sample, by the degree to which it is: (i) similar in essential properties to its parent population; and (ii) reflects the salient features of the process by which it is generated" (Kahneman & Tversky, 1972). Furthermore, some PSTs exhibit incorrect probabilistic conceptions regarding conditional probability, such as the Falk phenomenon (e.g., Nabbout-Cheiban, 2017). The Falk phenomenon occurs in the context of finding probabilities of a conditioned event that occurs before its conditioning event (Shaughnessy, 1992). Students and PSTs often struggle with the somewhat counterintuitive idea that the probability of the first outcome can depend on the second outcome.

PSTs should be aware of conceptions and intuitions potential students may hold regarding probability. These skills are a part of KCS, which is knowledge of mathematics combined with knowledge of students' conceptions of mathematics (Ball et al., 2008). Maher and Muir (2014) investigated PSTs' ability to identify errors in students' responses to probability tasks and explain what those students could be thinking in the task. PSTs in their study could identify students' errors, but they struggled to appropriately explain why students made those errors.

PSTs should learn how to address students' conceptions (whether correct or incorrect) in the classroom. This skill is an aspect of KCT, which combines knowledge of mathematics content and teaching practices. Watson, Callingham, and Donne (2008) found that some teachers exhibited ease in predicting hypothetical students' ideas on probability tasks, yet the teachers had difficulty in describing suggestions for responding to students' ideas and designing instructional interventions. Chernoff and Zazkis (2011) also found that PSTs struggled with suggesting appropriate pedagogical responses to hypothetical students' answers to probability tasks.

Methods and Procedures

The PST, Lauren, participating in this study was a senior undergraduate majoring in mathematics on the math education track. The participant self-identified as a White female. She was enrolled in a course on mathematics for teachers, in which she learned probability concepts. This course, however, did not address the representativeness heuristic or the Falk phenomenon.

A deck of playing cards has 52 cards and four suits: Spades, Clubs, Diamonds, and Hearts. Spades and Clubs are black cards, and Diamonds and Hearts are red cards. Each suit has 13 cards: Ace, 2, 3,4, 5, 6, 7, 8, 9, 10, Jack, Queen, and King.

1. What is the probability that you will draw a red card, then a black card, then a red card?
2. What is the probability that you will draw a 4, given that the card has an even number on it?

If a fair coin is tossed, the probability that it will land heads up is ½. Let H represent the result of a coin landing heads up and T represent the result of a coin landing tails up.

3. If the coin is tossed 6 times, which of the following ordered sequences of coin toss results is more likely to occur? Choose one.
   a. HTTHTH b. THTHHH c. HTTTTT d. TTTHHH e. These all have an equal chance of occurring.
4. Suppose a fair coin is tossed 6 times, and each toss lands heads up. What would you expect the result of the next toss to be?
5. Suppose a fair coin is tossed 4 times, and each toss lands heads up. Suppose the coin is tossed 6 more times. How many heads would you expect to get in all 10 tosses?
6. Suppose a fair coin is tossed 20 times, and each toss lands heads up. Suppose the coin is tossed 80 more times. How many times do you expect the coin to land heads up out of the 100 total tosses?

A bag has 7 white marbles and 5 red marbles in it.

7. Suppose you drew three marbles (one at a time) from the bag without replacing them. The first marble you drew was red, and the second marble you drew was white. What is the probability that the third ball you drew was red?
8. Suppose you drew one marble and hid it without looking at it. The second ball you drew was white. What is the probability that the first marble you drew was white?

Figure 1: Interview Tasks

A 45-minute semi-structured clinical interview (Clement, 2000) was conducted, in which Lauren performed probability tasks (see Figure 1). We used Ball et al.'s (2008) categories of CCK, KCS, and KCT to design the interview protocol. We designed the tasks in a way that could potentially trigger her to use the representativeness heuristic or bias in conditional thinking (the Falk phenomenon). After completing each task, Lauren was asked how she thought a student might approach the given task. She then read a task solution written by a hypothetical student. Lauren was asked how the student was reasoning about the task, how she would respond to that student, and what influenced her to use that pedagogical approach. Lauren's written work was collected, and the interview was video-recorded and transcribed for retrospective analysis.

We coded Lauren's responses according to whether they demonstrated CCK, KCS, or KCT. The transcript portions that were relevant to CCK were categorized into sections corresponding to her understanding of sample space, her responses related to the representativeness heuristic, and her responses related to the chronology of conditioning and conditioned events. The transcript portions related to her KCS were classified into categories of anticipating student thinking and interpreting student thinking. We categorized the transcript sections relevant to her KCT by the nature of the suggested teaching approach.

Results

Common Content Knowledge

Lauren did not use the representativeness heuristic when predicting future outcomes, yet she did use it when considering the likelihood of the sequences of coin tosses on Task 3 (see Figure 1). She used the representativeness heuristic by claiming that sequences of coin tosses that had a majority of heads or a majority of tails were less likely to occur. She narrowed down her options to the sequences HTTHTH and TTTHHH, since they both have a 50:50 ratio of heads and tails. She decided on HTTHTH as the most likely sequence because having three tails in a row, as in the sequence TTTHHH, is less likely to occur. This incorrect conception could be due to her not recognizing the sequences as comprising a sample space. She did not use the representativeness heuristic on Tasks 5 and 6. Lauren acknowledged that coin-toss results are independent events, so the result of prior tosses does not influence the probability of the result of future tosses.

Lauren did not seem to experience any difficulty on the conditional probability tasks that involved conditioning events occurring before or during the occurrence of the conditioned events. On Task 2, Lauren was not perturbed by the conditioned event and conditioning event occurring simultaneously. Lauren recognized the need to restrict the sample space when working on the probability tasks in which the conditioning event occurred before or during the conditioned event. However, her reasoning in response to Task 8, which involved a conditioning event occurring *after* the conditioned event, was indicative of the Falk phenomenon. She responded to Task 8 with the probability of drawing a white marble on the first draw as $\frac{7}{12}$, without using the information about the color of the second drawn marble. She claimed that the second event does not affect the probability of the first event occurring. She did not use the given information about the conditioning event to reduce the sample size for computing the probability of the conditioned event. The reversed chronology of the conditioning event and conditioned event seemed counterintuitive for her, which led to her bias in conditional thinking.

Knowledge of Content and Students

Lauren anticipated conceptions that students might hold as they approached each probability task. She pointed out a potential source of confusion for students regarding the conditioning event's effect on the sample space in Task 2 (see Figure 1). Lauren thought students might also struggle with forgetting to restrict the sample space after taking out marbles from the bag in Task 7. She acknowledged that students might struggle with knowing when it is appropriate to multiply probabilities of events occurring and when they should use the presence of conditioning events to restrict the sample space. Lauren also anticipated that students could use ideas related to the representativeness heuristic. She described how a student might use the gambler's fallacy on Task 4. She anticipated that students would think "I'm due for a tails up because it's been heads for so long, and I've had a 50-50 shot." Also, for Tasks 5 and 6, Lauren claimed a student might think that the coin would land tails up more often in the remaining coin flips, since they've already had several tosses land heads up. She described that some of these ideas are natural to assume, which indicates her awareness of students' intuitions that could potentially be employed.

After reading a hypothetical student's response to each task, Lauren gave her interpretations of the student's response and provided a potential explanation for the student's reasoning. For example, the hypothetical student's response to Task 2 (see Figure 1) was: *There are four cards with a 4 on them, and 4 is an even number, so the probability is* $4/52$. Lauren recognized that the student did not restrict the sample space when given information regarding the conditioning event. Lauren appropriately described the logic that the student employed in the given response. Lauren demonstrated strong KCS in her ability to anticipate and interpret students' reasoning.

Knowledge of Content and Teaching

In response to the hypothetical student's reasoning, Lauren suggested appropriate teaching approaches for helping the student better understand the concepts in the tasks. One of her suggested teaching approaches involved asking questions to the student about their thought process and using the evidence of student thinking to build on what they already know. Lauren also suggested using the teaching approach of asking questions to lead the student to see their own error. For example, on Task 4 (see Figure 1), the hypothetical student's response was: *The next toss should land tails up because all of the previous tosses have landed heads up. It's time for the coin to land tails up.* In response to this, she claimed, "I'd say okay so you have five tosses landing heads up out of ten tosses total, so that means well we've already had four heads up. So, you're thinking one of the six is gonna be heads up?" Lauren suggested asking questions about the student's response would help the student look for another way to solve the task.

Lauren also described another teaching approach of using simulations and models to illustrate the situations in the tasks. For Task 4 (see Figure 1), she suggested having the students imagine a simulation of flipping a coin six times, putting the coin away, and flipping a new coin, which had an equal chance of landing heads up or tails up. Her purpose in using this was to illustrate that the "coin's last toss doesn't have any influence on the current toss." She claimed that this would help students intuitively understand how the coin tosses are independent events. Lauren also suggested using a model on Task 7 (see Figure 1). She suggested using a drawing of the marbles in the bag and crossing out the drawn marbles to illustrate the changed sample space.

Discussion

Lauren's aspects of Mathematical Knowledge for Teaching (Ball et al., 2008) seemed to be well-connected. Her conceptions of probability seemed to influence her anticipation of students' conceptions and her interpretations of what the student did. She had to draw on her CCK to think of possible ways students might reason about the mathematics tasks. Lauren also used her interpretations of what the student was thinking to design a pedagogical approach in response to the student's reasoning. She seemed to connect her KCS with her KCT. Future research can explore connections between aspects of PSTs' Mathematical Knowledge for Teaching.

We document secondary mathematics teacher candidates' (TCs') development of skill responding to errors in whole-class discussions through a scripting task—a constructed transcript of classroom dialogue that follows a provided scenario. We discuss how TCs' responses changed over a methods course and what those changes suggest about TC learning. This work offers implications for research both characterizing and supporting TC learning.

Keywords: Teacher Education-Preservice; Instructional Activities and Practices

A focus on core teaching practices (Ball & Forzani, 2009) has resulted in the growing use of teacher education pedagogies such as "approximations of practice" (Grossman et al., 2009) that have teacher candidates (TCs) enacting teaching in situations of reduced complexity. This raises the need to document TCs' learning through approximations of practice (Shaughnessy, Boerst, & Farmer, 2019). We investigate TCs' development before and after a secondary mathematics methods course through the use of scripting tasks, in which TCs produce dialogues and rationales in response to a written classroom scenario. We describe shifts in how TCs respond to errors in whole-class mathematics discussions. Specifically, we address the following research questions: How do TCs' responses to a scripting task change over a secondary mathematics methods course? What do the changes in TCs' responses to a scripting task suggest about their learning around the practice of responding to errors in whole-class discussion?

Background and Theoretical Framework

In scripting tasks (Crespo, Oslund, & Parks, 2011; Zazkis, 2017), TCs are presented with a scenario and asked to write a dialogue, showing how they might continue the discussion. The scripts then serve as representations of practice that carry meanings beyond themselves (Herbst, 2018). Some scholars have used such dialogues to make claims about skill with practices (e.g., Crespo, 2018; Lim, Roberts-Harris, & Kim, 2018; Rougée & Herbst, 2018). This existing research includes a range of teaching practices and theoretical perspectives.

We have used scripting tasks to document aspects of TCs' skill with the practice of responding to errors in whole-class discussion (Baldinger, Campbell, & Graif, 2018a). Responding to errors—contributions that are incomplete, imprecise, or not yet correct—requires a balance of keeping student reasoning central, making progress toward identified goals, and not conveying problematic ideas. While errors are key to students' learning process (Brodie, 2014), they are often positioned negatively by teachers' responses, such as correcting them or avoiding them entirely (Bray, 2011; Santagata, 2005; Tulis, 2013). The context of whole-class discussion presents additional demands, as teachers must balance the needs of the student who contributed the error with the needs of the rest of the class, who may or may not share that student's conception. This presents different considerations for responding to errors as compared to interview settings (Hallman-Thrasher, 2017) or through written work (Son, 2016).

Teachers must be supported in learning communities to develop vision, understandings, dispositions, practices, and tools (Hammerness et al., 2005). We draw on this framework to attend to and make claims about aspects of TC learning. In the context of responding to errors in whole-class mathematics discussion, tools and practices include awareness and skilled use of moves such as orienting (Chapin, O'Connor, & Anderson, 2013) and tabling (Milewski & Strickland, 2016). Dialogues provide a window into the moves TCs think to use, and the way they use them, in a particular situation. For vision and dispositions, a teacher must consider the nature and role of errors in a way that positions them as formative and sensible and that positions students as sense-makers. Dialogues illustrate TCs' sense of how a classroom situation might play out, either practically or ideally. Finally, the dimension of understandings includes a teacher's sense of how students learn and develop mathematically. A teacher must know that a mathematical idea is incorrect or incomplete, how a student may have come to a particular conception, and how the classroom activity could productively take up that conception without ignoring or quickly correcting it. Dialogues provide access to TCs' understandings based on the way they attend to the mathematics of the scenario and how they represent student voice.

Methods

Our work is the product of an ongoing, multi-year collaboration situated in secondary mathematics methods courses at two large public research institutions focused on how purposeful opportunities to approximate and reflect on practice provide opportunities for TCs to develop skill with responding to errors. This serves as a foundation for our use of pedagogies of teacher education such as coached rehearsals (Lampert et al., 2013) and scripting tasks.

We focus on one scripting task centered on the use of a sorting activity (Baldinger, Campbell, & Graif, in press) intended to refine the definition of a polygon. In the scenario, the teacher asked students for cards they easily knew were polygons. Rosalia says Shape Q (see Figure 1) is a polygon because "it is a square" and that "all the sides are straight lines." Next, Jessie offers Shape J (see Figure 1), comparing it to Shape Q. TCs were asked to construct dialogues (representing the next five to eight turns of talk), starting from Jessie's contribution.

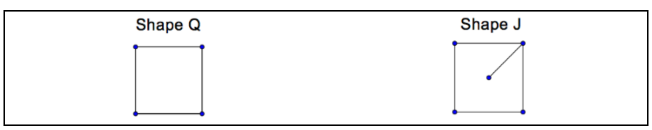

Figure 1: Two Cards Presented in the Scenario as Examples of Polygons

TCs' responses to the polygon scripting task across both institutions were collected twice during the 2017-2018 academic year—once early in Fall 2017 and once at the end of or after the methods course. We analyzed 19 pairs of responses ("Initial" and "Follow-up") from TCs.

Data analysis began with two authors individually coding each dialogue (38 total) using an established coding scheme (Baldinger et al., 2018a). Coding included a set of analytic questions focused on features of the dialogues such as the teacher moves used, the mathematical focus, the introduction of new "students," and whether or not the error gets "resolved" in the short dialogue. Disagreements among the coders were resolved through discussion. We then engaged in a process of analytic memo writing and theme building (Miles, Huberman, & Saldaña, 2013) to identify the most salient features in the dialogues. Next, we reviewed pairs of responses from each TC and constructed analytic memos describing the similarities and differences across the two responses. These individual memos informed a collective memo interpreting how the responses demonstrate TC skill and development over time.

Initial Findings

The Use of Teacher Moves: Developing Tools and Practices

We found TCs used teaching moves differently over time—either using different moves or using moves in different ways—which corresponds to the dimensions of tools and practices.

Teacher revoicing. Instances of using a revoicing move—when a teacher restates the substance of a student's contribution—increased over time. Revoicing moves appeared to have one of two purposes: to reiterate an idea for clarification or to pose more specific prompts that incorporate and connect to student contributions. This latter purpose was more prominent in the Follow-up dialogues. For example, part of a dialogue included the following:

Teacher: Alright, does anyone agree or disagree that Shapes Q and J are polygons because they are squares?

Student: I don't think Shape J is a square. A square only has 4 sides that are straight lines. That shape has 5 straight lines.

Teacher: What do you think about what Student said about this shape not being a polygon because it isn't a square?

In this excerpt, the TC constructs teacher moves that incorporate elements of students' contributions, rather than using a more general revoicing move. This use and refinement of moves is evidence of how TCs are developing tools and practices related to responding to errors.

Tabling ideas. Another move used more often in the Follow-up dialogues was a teacher's decision to table an idea or explicitly move on temporarily from a topic of conversation. TCs can be reluctant to table ideas, particularly errors, so as to not give the appearance of affirming a contribution (Baldinger, Campbell, & Graif, 2018b). Accordingly, most Initial dialogues continually focused on Jessie's contribution, which in some cases led to resolving the error.

Examples from the Follow-up data demonstrated how a tabling move could provide an alternative way to facilitate a whole-class discussion when an error is presented. For instance, one response used a tabling move after some discussion between Rosalia and Jessie, with the teacher suggesting that the card could go in the "maybe pile" and that they could "come back to it." In another response, the TC made the decision to record Jessie's reasoning and elicit other cards as "examples," so as to not "immediately signal that there's something 'wrong' with Jessie's sorting of Shape J." While tabling moves were still only used in some dialogues, the increased use offers insight into how the scripting task can capture such tools and practices.

Orienting student to one another. Instances of TCs using orienting moves—through which a teacher invites other students to reason about, engage with, and/or contribute to a student contribution—were common across both the Initial and Follow-up data. However, the nature of the use of those moves appeared more deliberate and productive in the Follow-up data, serving as evidence of how TCs developed. While orienting moves such as asking students to add on to another student's idea or eliciting agreement or disagreement were common, a notable change in the Follow-up data was the use of "turn-and-talk" moves, particularly in moments of student disagreement. In one dialogue, where students raise the question of whether the "extra segment" in Shape J affects its classification, the teacher responds, “I'd like everyone to discuss in their groups whether the line segment matters in deciding whether Shape J is a square.”

The evolving use of orienting also seemed to correspond with an increase in the average number of students included in each dialogue, and with more dialogues including two or more students, including the introduction of students other than Jessie or Rosalia. This shows that TCs were increasingly aware of the context of the scenario—a whole-class discussion—and were able to use teaching moves that allowed additional students to engage with Jessie’s contribution.

Authenticity of the Representation: Developing Vision, Disposition, and Understandings

We also noted the way in which responses in the Follow-up data were more authentic, either in terms of the situation (e.g., how the error was discussed) or the representation of student voice. We posit this provides insight into the development of vision and dispositions—as TCs come to new ideas of how a discussion can transpire—and understandings—as they represent student voice in ways that are more reflective of what one might hear in the classroom. In an example of this shift, a TC concluded the Initial dialogue (eight total talk turns) with the following:

Teacher: Could anybody give me a reason that Shape J would not be classified as a polygon?
Rosalia: Well if the line from the middle to the corner is a side, wouldn't there be an intersection of more than two sides at a point?
Teacher: That is correct. So what can we conclude about Shape J, and why, Jessie?
Jessie: Shape J is not a polygon, since sides of a polygon intersect at exactly one other side at each endpoint.

This excerpt is reflective of a feature of some dialogues, where a conclusion is reached that Shape J should be sorted as a non-polygon, in part through clearly articulated ideas from Jessie. We see responses like this as representing a vision and disposition that errors can and should be corrected relatively quickly. We also see evidence of an understanding of students that is not authentic—that students who contribute errors can quickly be convinced of alternative ideas.

The dialogue provided by the same TC for the Follow-up highlights the ways in which one can develop their vision, dispositions, and understandings that contribute to more authentic representations of practice. In the dialogue, after Jessie acknowledges the line segment in the middle of the shape, the conversation continues in the following way:

Teacher: Good observation (records reasoning on the board), it appears that there is a line segment from the middle into a corner of Shape J. Does anybody sort this card differently?
Rosalia: We didn't know how to sort it because of the line segment, so we kind of just left it in the middle.
Teacher: That's okay, we can come back to this card a little later.

In addition to the use of revoicing, orienting, and tabling moves, this excerpt illustrates important shifts in other aspects of the TCs’ skill. Notably, the TC presents a student—Rosalia—who is not sure and also imagines a situation where errors and uncertainties can go unresolved. Such shifts in TCs’ vision, dispositions, and understandings are important for their development of skill in responding to errors in whole-class discussions.

Discussion and Conclusion

We highlight the ways TCs' development of skill can be documented through their responses to a scripting task. Importantly, we found that changes in TCs' dialogues provided evidence of learning not just practices and tools, but also vision, dispositions, and understandings. Future analyses will incorporate the corresponding rationales, which will inform inferences made from analysis of the dialogues. Future work will include connecting the analyses from these scripting tasks to other aspects of our broader design, such as rehearsal cycles, to consider threads of ideas to better understand what might be attributed to parts of TCs' development. Future work will also follow up with TCs—through the continued collection of scripting responses, as well as data from student teaching or early career teaching—to understand continued development over time.

SUPPORTING THE DEVELOPMENT OF FUTURE MATHEMATICS TEACHERS: MATHEMATICS AS HEALING

Jennifer Holm
Wilfrid Laurier University
jholm@wlu.ca

This research examines the preconceived notions that pre-service teachers bring into a mathematics methods course about both how mathematics should be taught as well as their own capabilities in mathematics. Initial responses of pre-service teachers support a procedure-oriented view of mathematics and a range of their own feelings from feeling extremely confident to feeling extremely incompetent. This research examines the initial categories of the pre-service teachers and then the shifts in their beliefs and personal feelings toward the subject through changing their understandings of and about mathematics. Finally, the research looks at the components within the methods course that supported those changing beliefs and feelings. This research starts the conversation about changing the mathematics stories of future teachers through positive mathematics experiences.

Keywords: Affect, emotions, beliefs and attitudes; Teacher education-preservice; Instructional activities and practices

Allen (2016) defines math trauma as something that "stems from an event, a series of events, or a set of circumstances experienced by an individual as harmful or threatening such that there are lasting adverse effects on the individual's functioning and well-being in the perceived presence of mathematics" (PowerPoint slide). This concept of math trauma is very real for many pre-service teachers (PSTs) who are entering a teacher education program. Before they begin teaching others, PSTs need to confront these feelings to avoid perpetuating their negative feelings when interacting with students. To some of the PSTs, these feelings about mathematics serve as a roadblock to prevent their learning mathematics and ultimately causes difficulties in teaching the subject. This research discusses activities that were carried out in the classroom community during the methods courses to help remove the feelings of trauma related to mathematics and support PSTs in changing their feelings about themselves and mathematics while developing their own knowledge of mathematics.

Literature

Philipp (2007) notes that "beliefs might be thought of as lenses that affect one's view of some aspect of the world or as dispositions toward action" (p. 259). As such, beliefs are "situated" and specific to the teacher and student interactions (p. 274). Researchers suggest that past efforts to change teacher practices have failed partially because of not accounting for the beliefs of the teachers being impacted (Grant et al., 1994; Handal & Herrington, 2003). Previous research with PSTs has also shown how the beliefs about mathematics are tied with their own learning about mathematics (Holm & Kajander, 2012). This focus on beliefs is critical in this research as Holm and Kajander (2012) has shown how the beliefs one holds about mathematics does impact how the PSTs interact with the course and learning mathematics.

As mentioned previously, math trauma is the result of past experiences with mathematics that negatively impact the way a person feels about mathematics. There are many different causes and traditions that increase the likelihood of math trauma in learners including the use of labels related to ability and a focus on speed and accuracy (Allen, 2016). Another example is that those who struggle with memorization become anxious even though mathematics is not all about memorization (Willis, 2010). Allen (2016) also cites the long tradition of mathematics being viewed negatively in today's culture adding to the setting for trauma. Boaler (e.g., 2013, 2015) has extensively written about changing the idea that there is a fixed ability in mathematics and works on developing growth mindsets in mathematics classrooms worldwide. The detrimental dichotomy of those who can and those who cannot do mathematics has shown that many PSTs develop this idea that there are people who just cannot do mathematics. Through her research with PSTs, Allen (2016) has created a list of themes related to the causes of math trauma stemming from actual events or people in the past to actual points in the mathematics curriculum that were defined as traumatic. Experiences with math trauma have helped to colour the view of future teachers on the subject of mathematics, so this research looks at this important area to focus on how to support the mental well-being of future teachers and change their beliefs about not only what mathematics is but how to teach it. This research project is grounded in the experiences of PSTs and acknowledges that first dealing with the math trauma became essential before any new learning could effectively take place.

This research project uses a phenomenographical approach to the research by focusing on the stories of the participants. Phenomenography was used because of the attention paid to the individual stories in order to examine themes within the data (Ashworth & Lucas, 2000; Yates, Partridge, & Bruce, 2012). In order to examine the experiences of mathematics within the methods course, as well as the past experiences of the pre-service teachers, general themes were created from the research data, but individual stories of individual participants within the categories are also explored further. This research program was developed based in experiences with PSTs who were so frightened and disengaged with mathematics that they could not absorb the new content and often avoided it completely.

Methods

This research report looks at a subset of data in a larger study focused on the beliefs, values, and opinions of pre-service teachers around mathematics and how to support changing opinions and possibly healing some of the past trauma through a methods course. For the purposes of this research report, two different cohorts (one lower elementary and one upper elementary) in their first mathematics methods course at the beginning of their two-year teacher education program were examined. Early in the course, PSTs set an initial goal for the course and voiced their concerns that they had about completing the methods course in mathematics. Only the 34 PSTs who expressed initial concerns were considered in this data set in order to keep the focus on this more vulnerable population within the total population of 75 PSTs. At the beginning of the semester, PSTs were asked to reflect on their own experiences in mathematics and what they believed mathematics is. Throughout the course, they were asked to revisit what they initially thought about mathematics and their own experiences and how this would impact their futures as teachers. Interviews were then conducted with a subset of the participants who volunteered for a total of 12 interviews. Interviews were used to gain more information about the reflected changes and what participants noted caused them. In order to construct this report, the reflections were analyzed and the rest of the data was coded to add to the initial observations. Tenets of thematic analysis (Braun & Clarke, 2006) were used in order to create codes within the data set that would describe the reasons for some of the changes within the participants, which were later collapsed into overarching themes. In this report, the subset of the 34 PSTs in the two cohorts of a single academic year were examined to provide some initial understandings about pre-service elementary teachers.

Findings

Preliminary findings showed a dramatic shift in most of the PSTs in their feelings about teaching mathematics as well as their perceptions about themselves as mathematics students. In reflecting on the past, all PSTs included in this data set noted some variation that mathematics was about memorizing formulas and being able to find a correct answer. Many participants added that speed was a factor in mathematics, and there was an embarrassment in being slower or wrong that made it intimidating. Many of the participants made a note that they just were not "mathematics people" and would not be able to do it. All PSTs initially commented on how their feelings of success or failure in elementary and high school related to how well they were able to memorize the formulas and perform the operations with accuracy and speed.

Throughout the course, a community of learning was set up to support PSTs who were by and large terrified of mathematics, and a byproduct of this feeling was they hated the idea of coming to a mathematics course or having to teach it in the future. I used the metaphor of "mathematics as healing" throughout the first-year courses and focused on changing the perspectives of the PSTs through increasing their own understandings of mathematics, while broadening the definition of what mathematics is. I also endeavored to avoid the traumatic traditions of the past by allowing flexible due dates, resubmission of assignments, no reliance on speed, and allowing discussion and collaboration in solving problems and engaging with inquiry-based mathematics.

In looking at the participants as a whole, there was a major theme of those who wished they had been taught in this manner throughout school because they finally understood it. They also vowed to teach mathematics in a way that would avoid their future students from feeling like there were mathematics people and those who are not. All of the PSTs cited places in the methods course or their placement experiences as reasons for their changes in opinions, and these experiences related to either gaining understandings of mathematics for themselves or seeing the students gain an understanding of mathematics in a way that was not formula driven. All of the changes were rooted in their newfound confidence in their own understandings of mathematics and, as a result, a greater confidence in being able to teach it.

When speaking with the participants in the interviews and analyzing their responses about reflecting on the course, several themes came up about what impacted their own development: the use of models and manipulatives, seeing that not all of the adults could actually use or remember the formulas, and seeing that mathematics could be fun and enjoyable. In using models and manipulatives, the one activity that came up in most of the stories was exploring the operations with base 10 blocks. The second most common model mentioned was exploring fractions using fraction kits and games. In both of these experiences, participants noted how they never understood the purpose of the steps in the procedures until they saw how it worked with the models. On the first day of the course, an anonymous activity was used to bring out the fact that there was a general dislike or distrust for mathematics (Holm, 2018), and this was mentioned by several participants that it allowed them to see they were not alone. Working with other PSTs who also struggled throughout school became a strong turning point as well in realizing they were not the only ones who were afraid of mathematics. By seeing how the approach of memorizing formulas did not work for others and how there may not be a "math gene" as they were able to gain understandings, PSTs began to consider alternatives for teaching mathematics. Through their experiences, many also mentioned realizing how much they really did not know about mathematics beyond the memorized formulas (if they even remembered them), and they did not even question there may be more to mathematics. The final way the course started making changes was through engaging in games and activities to learn mathematics content. To most of the PSTs, seeing that they were learning so much through the games and activities, they saw the power for their own classrooms and saw firsthand that math can be more than just memorized formulas and drill activities.

Discussion

Initial views of experiences pointed to areas of trauma identified by Allen (2016) in their past that had led to a negative view of mathematics and their own abilities. It should be noted that even in this subset of participants, not all of the PSTs did identify these experiences as traumatic and had a more positive view of mathematics, although there was a fear in their own abilities to teach or learn it. Mainly it was those who were deemed “unsuccessful” in mathematics (either from their own perspectives or someone else’s) who held a negative viewpoint of the subject, although there was a much smaller group who were deemed “unsuccessful” and still held a positive viewpoint of mathematics.

Many of the activities and experiences within the methods course started to change the PSTs’ perspectives about mathematics and themselves as mathematics learners. “Once you reopen doors that were previously closed by negative feelings, math is revealed to students as an accessible, valuable tool to help them understand, describe, and have more control over the world in which they live” (Willis, 2010, p. 15). It was this progress of starting to see mathematics as something useful and that there was another way to teach it that would not perpetuate the traumatic experiences of their past. Many of these PSTs expressed multiple times how they wished they had learned mathematics in this way in their own experiences because it changed the way they felt. As well, many of the PSTs whose initial reflections mentioned terror about the idea of being in a mathematics course admitted in the end that the methods course became their favourite class and that they looked forward to attending every week. In the end, the majority were very excited about getting to teach mathematics and showed a willingness to continue growing and learning in order to support their future students in mathematics experiences that would not be traumatic for them. It was through experiences that changed their views of what it means to be mathematical and increase their own understandings that they felt a shift in perceptions and confidence. Although a few PSTs still expressed concerns over their own understandings, there was a definite positive shift in their feelings that they could teach and learn mathematics with more work and effort.

In considering future directions for methods courses, the observations shared by the PSTs indicated that experiencing mathematics in a way that was fun and honoured their knowledge, while they learned the content deeply, was important for changing their perspectives about mathematics and their willingness to teach mathematics in a different way in the future. As Boaler (2013) notes, “The awareness that ability is malleable and that students need to develop productive growth mindsets has profound implications for teaching” (p. 145) and certainly had profound implications for the PSTs in this study by acknowledging that they too could learn mathematics. Having PSTs acknowledge their traumatic experiences and negative beliefs, while changing their feelings about mathematics in parallel with their understandings, became essential for supporting stronger and more positive future elementary mathematics teachers.

INTERSECTIONALITY AND MATHEMATICS TEACHER TRAINING: DISTINCT DISTRICT TRAJECTORIES OF DIFFERENT TEACHER SUBGROUPS

Andrew Brantlinger
University of Maryland
amb@umd.edu

Laurel Cooley
Brooklyn College
lcooley@brooklyn.cuny.edu

Matt Griffin
University of Maryland
griff23@umd.edu

This paper reports on the results of a quantitative analysis of retention trends of alternatively certified mathematics teacher subgroups working in low-income urban schools over the course of a decade. We draw on theories of intersectionality and longitudinal data on 620 secondary mathematics teachers from one large certification program to examine the district retention trajectories of different teacher subgroups after three, five, and eight years. We show that, not only do different subgroups have markedly different trajectories, but also that their retention appears to be highly malleable, shaped significantly by both the content of training and the context of school assignments.
Keywords: Policy, Equity and diversity, Mathematics teacher retention

Systems of social stratification based on race, class, and other characteristics are intersectional and enmeshed (Collins & Bilge, 2016). White women are positioned differently by societal institutions than either Black women or White men and, although not determinative, this influences how they understand and act in the world. While qualitative research has taken intersectionality seriously (Frank, 2018), quantitative research in education has not. This study illustrates the promise of intersectionality theory for quantitative research by addressing the following question: *How is the retention of different mathematics teacher subgroups shaped interactively by different approaches to teacher training and initial school assignments?*

Perspective

Consistent with theories of intersectionality and mixed methods research on teacher preparation (Humphrey, Wechsler, & Hough, 2008; Johnson, Berg, & Donaldson, 2005), we view the outcomes of teacher preparation as being the product of interactions between subgroups of new teachers (e.g., young Black females who live in the community they teach in, White mathematics majors from very selective colleges), the schools they work in, and the preparation and support they receive in those schools (see Humphrey et al., 2008; Johnson et al., 2005). Teacher candidates enter educator preparation programs with diverse experiences, strengths, needs, and goals, and, as such, do not uniformly take up and act on the messages they receive during preparation (Humphrey et al., 2008; Johnson & Birkeland, 2008). At the same time, members of particular subgroups tend to react similarly to these messages and differently than members of other subgroups. Finally, we also posit that teacher preparation outcomes depend on how different subgroups, trained in particular programs, integrate with the people and culture in the schools they work in (Meagher & Brantlinger, 2011; Humphrey et al., 2008).

Methods

In this paper, we are concerned with fast-track training of mathematics teachers in a large alternative route program and the programmatic outcome of retention. To model the retention for different mathematics teacher subgroups from a fast-track alternative route program, we drew from data on 620 secondary mathematics Teaching Fellows (SMTFs) who entered the New York

City Teaching Fellows (NYCTF) program in either 2006 or 2007.[1] At that time, NYCTF had four universities and colleges collaborating in secondary mathematics teacher training. As Table 1 indicates, training for secondary mathematics differed across the universities (Author, 2013). UnivB and UnivD emphasized mathematics content and methods whereas UnivA and UnivC emphasized subject-general themes. Of the latter two, UnivA emphasized technical aspects of teaching (e.g., classroom management) whereas UnivC placed a comparative emphasis on theories of adolescent development.

Table 1: Curricular Emphasis of NYCTF's University Partners

NYCTF Partner	Comparative Emphasis of Training	Percentage of Coursework	
		Math Content	Math Methods
UnivA	Practical, Subject-General	23	18
UnivB	Theoretical, Mathematics-Specific	28	37
UnivC	Theoretical, Subject-General	18	19
UnivD	Theoretical, Mathematics-Specific	35	45

We drew on three data sources: (1) *service history data* on SMTFs' school assignments, roles and years of paid service from the New York City Department of Education (NYCDOE), (2) *demographic, academic and professional background information* on SMTFs collected on surveys, and (3) *school demographic and climate (survey) data* collected by the NYCDOE and the New York State Department of Education on the 1600-plus public schools in New York City. We used the service history data to create dummy variables for district retention after three, five, and eight years. We created the teacher background variables using NYCDOE-provided and survey information about SMTFs' age, gender, ethnicity, high school (location), college, and post-secondary degrees. We created the training variables using NYCTF-provided information on initial certification, university assignment information and survey data on the quality of NYCTF's contribution to pre-service training, namely, Clinical Advisory.

We used logistic regression to model SMTFs' district retention at three and eight years (Table 2). We included variables for the characteristics of SMTFs, training, and their first schools. Consistent with our theoretical framework, we included bivariate interactions between independent variables but only kept those that were significant (see Author, under review). To help interpret the interaction terms in the models, we created a taxonomy of SMTF subgroups (i.e., ideal types) (Bailey, 1994). In this paper we focus on two subgroups, namely, on *Young Elite White Outsiders*[2] and *Mature Black Insiders*[3,4].

Results

The regression models indicate that the content of fast-track training is predictive of mathematics teacher retention in urban schools at three and eight years (Table 2). (While we discuss it, we do not present the eight-year model here due to space limitations.) Specifically, these models show that, in shaping retention, fast-track training for secondary mathematics: (1) operates differentially on different teacher subgroups working in particular school contexts, (2) depends on the substance – and not just the fast-track structure – of this training; and (3) has both long- and short-term effects on teachers' district and school retention. When viewed in light of Table 1, fast-track training that emphasizes 'practical' concerns (i.e., their expressed concerns on pre-service surveys) like classroom management is linked to improved SMTF retention generally, although this differs by teacher subgroup.

At the broadest level, the models show that mathematics teacher selection shapes programmatic outcomes like retention. In particular, we find that: (1) Black SMTFs are much more likely than non-Black SMTFs to remain in the district at 8 years; (2) SMTFs from very selective colleges are less likely than others to remain in the district at 3 and 8 years; and (3) SMTFs who started as NYC outsiders[1] have significantly lower estimated rates of three- and eight-year district than the NYC insiders. However, consistent with intersectionality, there also were significant interactions between these and other variables in the final models.

Table 2: Logistic Regression Model of SMTF District Retention at Three Years

	Constant	3.770**
Teacher	From NYC Suburbs[1] (vs. NYC Insider)	0.193**
	NYC Outsider[1] (vs. NYC Insider)	0.215**
	Selective College (vs. Very Selective)	2.035**
	Less Selective College (vs. Very Selective)	1.513
Training	Grades 5-9 Certification (vs. Grades 7-12 Cert)	0.288**
	Top Clinical Advisory (vs. Other Clinical Advisory)	1.758*
Teacher * Training	Grades 5-9 Certification * From NYC Suburbs	5.427**
	Grades 5-9 Certification * NYC Outsider	3.833**
Teacher * School	Asian * Black-Latinx Students Below 61%	0.672
	Asian * Black-Latinx Students Above 98%	0.541
	Black * Black-Latinx Students Below 61%	1.220
	Black * Black-Latinx Students Above 98%	6.927*
	Latinx * Black-Latinx Students Below 61%	0.690
	Latinx * Black-Latinx Students Above 98%	0.716

Figures 1 and 2 illustrate this intersectionality, presenting the "district trajectories" (i.e., estimated district retention over time) of the *Mature Black Insider (MBI)* and *Young Elite White Outsiders (YEWO)* subgroups (see end notes). A comparison of Figures 1 and 2 illustrates the distinctive district trajectories of different subgroups. Examining each figure separately illustrates the malleability of SMTF retention depending on members of particular subgroups interact with the content of training and contexts of their assigned schools.

MBIs have the best estimated retention outcomes in comparison with all other SMTF subgroups. None of their individual characteristics alone account for this. Although Blackness is associated with superior SMTF retention, MBIs have better retention estimates than all other Black subgroups. Compared to MBIs, YEWOs have much lower odds of remaining in the district in the long run (i.e., eight years). Their status as NYC outsiders and as elite college graduates seem to drive YEWO turnover as all of the elite outsider subgroups have high turnover estimates.

There are implications for training above and beyond those for teacher selection. In particular, the regression models point to ways that fast-track training might be modified to improve the retention of particular teacher subgroups. Specifically, *practical training* seems particularly important for retaining elite outsider subgroups. Relative to *theoretical training, practical training* doubles the estimated odds that *YEWOs,* and other elite outsider subgroups (e.g., *Mature Elite Latinx Outsiders*) will remain in the district beyond eight years. While *practical training* is associated with superior outcomes for most SMTFs, including both MBIs and YEWOs, when it comes to shaping retention outcomes, *mathematics-specific training* seems to have worked just as well for a few subgroups (e.g., *Maturing Latinx Insiders*[2]).

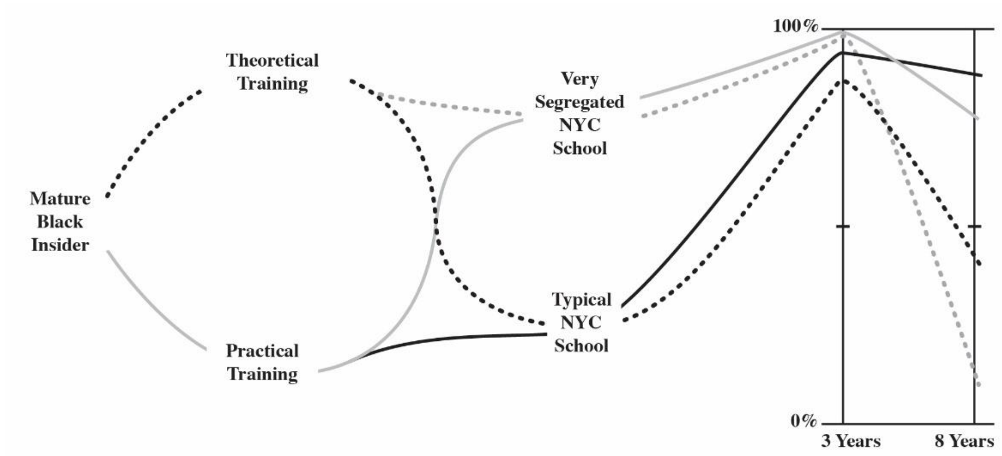

Figure 1: Mature Black Insiders' District Trajectories

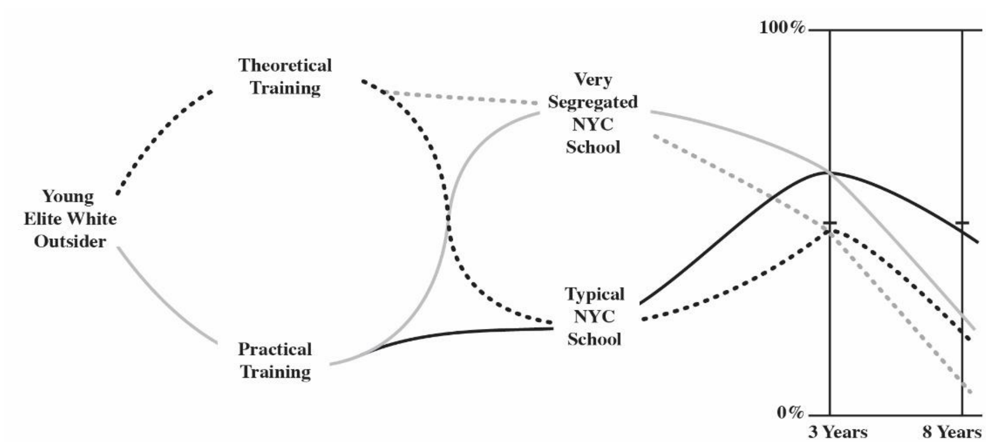

Figure 2: Young Elite White Outsiders' District Trajectories

Significance

Although specific to NYCTF, we believe these results generalize to other secondary teachers selected and trained in fast-track alternative route programs. Some of the results, for example those about practical training, seem particularly relevant to teacher preparation programs that prepare teachers to work in low-income schools serving mostly students of color. That said, the candidate-dependency (i.e., interactivity, intersectional-nature) of the retention results serve to challenge the policy assumption that individual preparation programs can be validated as being either effective or ineffective. Ostensibly proven approaches to teacher training (see TNTP, 2005), mathematics or otherwise, might simply be what works best for middle class, White outsiders, over-represented in teacher preparation programs nationally (Ladson-Billings, 1995).

Endnotes

1. NYCTF's partner universities and colleges are referred to as UnivA, UnivB, UnivC, and UnivD.
2. *Elite* SMTF subgroups include the graduates of very selective colleges (Barrons, 2009).
3. The *NYC Insider* subgroups include those SMTFs who graduated from an NYC high school, the *NYC Outsider* subgroups include those SMTFs who graduated from a high school located 150 miles from the NYC border, and the *Suburban* subgroups include SMTFs who attended high school outside of NYC but located less than 150 miles from the city limits.
4. The *Young* subgroups include those SMTFs aged 21-23 years when they entered NYCTF, the *Maturing* subgroups include those aged 24-27 years old, and the *Mature* subgroups include those who entered when they were 28 years older.

Prior work has shown that teaching simulations are valid and fair ways to assess novices' skills with eliciting student thinking. In this study, we sought to explore a fundamental question about the use of live, interactive simulations, that is, whether it is possible to design a student profile that sufficiently covers the breadth of questions that preservice teachers might ask during an interaction. Our results reveal that it is possible. Implications are discussed.

Keywords: Assessment and Evaluation; Instructional activities and practices

Successful teacher preparation requires innovations in assessment that can inform preservice teachers (PSTs) and those who prepare them. Of particular importance are assessments that provide information about PSTs' abilities to actually <u>do</u> the core tasks of teaching. This requires combining instructional techniques together with specialized knowledge of the content and insights into students' thinking and development. Although many current assessments of teaching, including observation tools (e.g., Danielson, 2013) and portfolios (e.g., Teacher Performance Assessment developed by Darling-Hammond and Pecheone, 2010), do offer useful information, additional tools are needed to supplement what can be learned through these types of assessments. Further, we must move beyond traditional forms of assessment to create sustainable and fair ways to assess such capability throughout initial teacher preparation.

In recent years, the use of simulations in teacher education has expanded and there is growing interest in the use of simulations for learning and assessment. By *simulation*, we mean a live instance in which a preservice teacher (PST) interacts with an adult whose actions are guided by a profile of a K-12 student's reasoning about content and responding to questions. In such a simulation, PSTs are engaged in the interactive work of teaching and there are opportunities for teacher educators to see and appraise PSTs' developing capabilities and skills (Shaughnessy & Boerst, 2018). This work builds on the use of live, interactive simulations in medicine, dentistry and other professional fields. Doctors and dentists in training engage in simulations of physical examinations, patient counseling, and medical/dental history taking by interacting with "standardized patients." Evaluation of medical students' interactions with standardized patients makes possible common and sustainable appraisal of candidates' knowledge and skills (Boulet, Smee, Dillon, & Gimpel, 2009).

The use of simulations in teacher education has been growing (e.g., Dieker et al., 2014, Dotger, 2015; Dotger & Sapon-Shevin 2009; Mikeska & Howell, 2018; Self, 2018), but there has been limited research on the design of simulations that would be needed for wider-scale use. In this paper, we build on our past efforts to design and study the use of simulations to assess PSTs' skill with eliciting and interpreting student thinking. Specifically, we investigate the robustness of the design of the simulation. In the particular version of simulations that we develop, we design a “student role protocol” which captures the student’s process and understanding and the ways in which they respond to questions about their mathematical work. The “student” uses information from the protocol to guide the ways in which they respond to questions posed by the PSTs. In this study, we examined a student role protocol that we developed for one such simulation and video records of PSTs’ performances. We investigated how and to what extent the student role protocol provided guidance in responding to questions posed by PSTs.

Design Considerations for Simulation Assessments

Since 2011, we have been developing and studying simulations as a means to assess PSTs’ capabilities with eliciting and interpreting student thinking. We have used simulations to learn about the eliciting and interpreting skills that novices bring to teacher education as well as to assess their progress as they move through their professional training. In our simulations, PSTs engage in three stages of work. First, they are provided with student work on a mathematics problem and given 10 minutes to prepare for an interaction. The task for the PST during the interaction is to determine the process the student is using to solve the problem and the student’s understanding of the core mathematical ideas involved in the process. Second, PSTs interact with a “student.” The role of the “student” is carried out by a teacher educator whose words and actions are guided by a student role protocol. As described above, the protocol is a detailed profile of a particular student’s thinking and rules that govern this student’s interactional norms. PSTs have five minutes to interact with the “student,” eliciting and probing the “student’s” thinking to understand the steps she took, why she performed particular steps, and her understanding of the key mathematical ideas involved. In the third stage, PSTs respond verbally to a set of questions that are designed to probe their interpretations of the “student’s” process and understanding and their prediction about the “student’s” performance on a similar problem.

Our assessment development process considers teaching practice itself and how it can be decomposed for the purposes of assessment. We also consider the assessment situation and the opportunities it creates for PSTs to demonstrate their skills in light of a practice-focused developmental frame (see Shaughnessy & Boerst, 2018 for more details). In our simulation assessments, the student role protocol (see Figure 1 for an excerpt) is crucial both for enacting the assessment and for providing consistent opportunities for PSTs to demonstrate their capabilities with eliciting student thinking. We have three main design considerations (Shaughnessy & Boerst, 2018). The first is the *mathematics content* itself that is embedded in the student work sample. The second is the *characterization of the student’s process and understanding*, including the student’s process for solving the problem, the student’s understanding of the process and related mathematical ideas, and the accuracy of the student’s answer. The third is the *student’s way of being,* which refers to the student’s dispositions, interactional style, and use of mathematical language. A student role protocol articulates each of these considerations and this constitutes general guidance for responding to PSTs’ questions. We also script responses to likely questions that are aligned with the three design considerations.

Methods

Thirty-six PSTs enrolled in an undergraduate university-based elementary teacher education program in the United States participated. The assessment was administered at the mid-point of the teacher education program as a regular part of the program. The performances on assessments were video recorded and written artifacts were collected. We used the software package Studiocode© to code the assessment video. We began by parsing the video into talk turns. Then we identified what we refer to as "cases" which contain a question posed by a PST. For each case, we characterized the question posed by the PST using one of three codes:

- *Scripted response available*: A scripted response exists in the student role protocol that could be used to respond to the question posed by the PST
- *No scripted response, but there is general guidance*: No scripted response exists in the student role protocol that could be directly used to respond to the question posed by the PST; however, the general guidance provides information that might be used in response
- *Guidance not available:* There is no scripted response in the student profile that can be used to respond to the PST's question and no guidance for responding to the student is available in the general guidance section

Two coders independently coded each video. Discrepancies in scoring were examined by the full team, referencing the codebook as needed to reach consensus.

$\frac{3}{7} = \frac{6}{14}$ $\qquad$ $\frac{2}{5} = \frac{6}{15}$

$\frac{6}{14} > \frac{6}{15}$

So: $\frac{3}{7} > \frac{2}{5}$

Mathematics topic: Comparison of fractions

Characterization of the student's process and understanding:

The student's process: The student is using the common numerator method to compare fractions. To determine which numerator to use, the student finds the least common multiple of the numerators of the original fractions. The student generates equivalent fractions by multiplying the numerator and denominator of each fraction by the same number. Then the student compares the denominators to determine which fraction is larger.

The student's understanding of the ideas involved in the problem/process: The student knows you have to multiply (or divide) the numerator and denominator by the same number to generate an equivalent fraction but does not understand why that process works. Once the student has common numerators, the student understands that when you have the same number of pieces, you can use the denominator to determine which fraction has larger pieces and therefore which fraction is larger.

Other information about the student's thinking, language, and orientation in this scenario: The student knows of other strategies for comparing fractions, but the student thinks that the common numerator methods works best with the given example.

The student's way of being: The standardized student gives the least amount of information that is still responsive to the PST's question.

Specific responses based on the identified mathematics topic, characterization of the student's process and understanding, and the student's way of being (*a subset of them*):

PST prompt	Response
What did you do first?"	"I wanted to change the fractions so that there would be something in common."
Asks about how 6 was identified as the common numerator	"I wanted the numerator to be 6 because it was the least common multiple."
"Why can you compare fractions by comparing the denominators when the numerators are the same?"	"When you make the numerators the same it means you have the same number of

	parts so all you need to think about is how big the parts are."
"Why is 6/14 greater than 6/15?"	"Fourteenths are larger than fifteenths."

Figure 1: An Excerpt from the Student Role Protocol

Results

Our analysis focused on the extent to which the student role protocol provided guidance in responding to questions posed by PSTs. Across the 36 performances, there were 457 cases in which PSTs posed a question to the "student." In 70% of the cases (319 of the 457), a scripted response was available in the student role protocol. For example, one PST asked, "how did you pick 6 as the common numerator?" There is a scripted response for "asks about how 6 was identified as the common numerator." In another 25% of the cases (112 of the 457), there was no scripted response available, but the "student" could respond by drawing on other guidance provided in the student role protocol, such as information provided about the student's understanding of relevant mathematical concepts and general demeanor. For example, one PST posed an additional problem for the student to solve in which the student generated equivalent fractions which had a common numerator of 12. The PST then asked the student, "How did you use 12 as the numerator?" The response for this exact question was not scripted but the PST could reasonably use the general information available in the profile and the scripted response for a common numerator of 6 to generate a response to the question. Another way of interpreting these findings is that for 95% of the questions posed, there was some guidance available in the student profile for responding. These results suggest that the student profile is sufficient for providing guidance to the "student" for responding in standardized ways.

In the remaining 5% of the cases (26 of the 457), there was no guidance available in the profile for responding to the question. This means that in these cases, the "student" had to improvise to construct a response to the question. We examined how these 26 cases of "no guidance in the profile" were distributed across PSTs. Because the PSTs asked varying numbers of questions, we calculated the percentage of "no guidance" cases for each PST. We found the percentage of instances in which no guidance was available ranged from 0% to 29% with mean of 5% and a standard deviation of 10%. There were 5 PSTs for whom the percentage of cases with no guidance available was higher than 15%. This suggests that cases of "no guidance" were somewhat idiosyncratic and clustered around a small subset of PSTs .

Discussion

Our study establishes that it is possible to design a "student role protocol" with scripted responses that address the vast majority of questions posed by PSTs in a simulation. Further, in the case of this simulation, it was crucial to provide a general frame for how the student was thinking in addition to scripting responses to specific questions. The general guidance was needed to respond to 25% of the questions posed in the study. Further, because interpreting an unscripted question and determining an appropriate response based on guidelines are complex activities, these findings suggest that it is necessary to have a live "student" ready to take up unique lines of questioning. As part of a broader study, we are investigating the fidelity of the implementation (i.e., the degree to which "students'" responses adhere to the profile). Results from our analyses are promising. Individually any of these questions is important, but as a set they constitute what Cohen and Ball (2007) characterize as "scaling in" to establish internal components of the initial intervention that is a crucial precursor to scaling up.

CONVEYING RESPECT FOR STUDENTS THROUGH THE PRACTICES OF ELICITING AND INTERPRETING STUDENT THINKING

Meghan Shaughnessy
University of Michigan
mshaugh@umich.edu

Timothy Boerst
University of Michigan
tboerst@umich.edu

We examine what it might mean for preservice teachers to convey respect for students through their eliciting and interpreting of students' thinking. We report on a conceptualization of what it means to convey such respect and challenges at the beginning of teacher preparation.

Keywords: Instructional activities and practices; Equity and diversity

All students have the right to work with a teacher who is interested in their mathematical thinking and has the requisite mathematical knowledge, pedagogical skills, and commitment to support their day-to-day, lesson-to-lesson, task-to-task learning. Tragically for subsets of the student population – sentences like this have driven national standards (NCTM, 2000), legislation (No Child Left Behind [NCLB], 2002), and research for nearly half a century without redressing disparities in mathematics achievement. Recently scholars have argued that this "achievement gap" reflects serious "opportunity gaps" that must be rectified (Milner, 2010; Horn, 2012; Flores, 2007). Opportunity gaps are created and replicated through mathematics instruction, with instruction defined as the interaction among teachers, students, and mathematics content (Cohen, Radenbush, & Ball, 2003). Studies demonstrate that "no in-school intervention has a greater impact on student learning than an effective teacher" (p.1, NCATE, 2010). Thus, the opportunity gap is a problem of teaching and likely to be, at least in part a function of the preparation of mathematics teachers.

The professional learning of teachers often includes opportunities for preservice teachers (PSTs) to interact with students around mathematics content. Teachers need opportunities to hone their use of mathematical knowledge and practical skills to redress the bias and inequity that produce opportunity gaps. However, because opportunities to interact with children commonly occur in the context of teaching in K-12 school contexts, it is often not possible to predict, let alone ensure, that opportunities to redress the bias and inequity will manifest themselves. In a very real sense there are gaps in PSTs' opportunities to learn to teach in ways that could redress gaps for students in opportunities. Given the challenging nature of reliably providing these experiences, it is particularly important to develop options that can.

Our project focuses on the development of PSTs' capabilities with eliciting and interpreting students' mathematical thinking. The goals of this collective work include enhancing awareness of teaching that could produce opportunity gaps and developing mathematical knowledge, pedagogical practices, and dispositions that enhance equity, access, and inclusion. In particular we focus on attending to and taking up student ideas as such moves are the hallmark of responsive teaching. This is a place where it might be possible to see biased or gap-producing teaching moves. In our past work, we noticed PSTs' attending to and taking up student thinking in ways that appeared to be counter to goals of enhancing equity, access, and inclusion. For example, after learning that a student has used a non-standard (but valid) process to solving a problem, we commonly notice patterns of asking questions focused on why the student has "not done" another process, often a "standard" process with which the teacher either was more familiar or preferred for solving a problem. In some cases, such approaches went further with teachers telling a student that they could not use their valid process, but instead needed to use the "standard" algorithm. When interpreting student thinking, we observed that while PSTs noticed attributes of a student's process or their understanding, they characterized the student's thinking in deficit-focused ways when the student used a non-standard process. Another kind of problematic characterization, of a more general nature, entailed derogatory statements about the student's general mathematical aptitude or skill (e.g., this student is really confused and must have problems in math). We began to wonder about how we could capture the ways in which teachers were respecting students and their thinking as they engaged in the work of eliciting and interpreting student thinking. The choice of these teaching practices is strategic as they undergird much of the work that happens in classrooms. Specifically, our study examined the respect (or disrespect) for students and their mathematical knowledge that was evident when eliciting and interpreting student thinking at the beginning of teacher preparation. We next turn to our conceptualization of the teaching practices of eliciting and interpreting student thinking.

Eliciting and Interpreting Student Thinking

In teaching, "teachers pose questions or tasks that provoke or allow students to share their thinking about specific academic content in order to evaluate student understanding, guide instructional decisions, and surface ideas that will benefit other students" (TeachingWorks, 2016). We conceive of the work of eliciting student thinking as involving: (a) eliciting and probing the student's process and understanding; (b) taking up the student's ideas in questions, including respecting the student and their thinking; and (c) using mathematical language and representations. This work involves teachers listening to and interpreting what students are saying, generating and posing questions to learn more about the student thinking, listening to and interpreting what students are saying. Teachers make sense of what students know and can do based on evidence from interactions and other artifacts of student work. This practice entails: (a) making qualified claims about valued outcomes that can be used as the basis for future action, (b) using evidence to generate and test claims, (c) matching the scope and nature of the claim to the amount and type of information available (d) actively working to prevent bias or distortion, and (e) developing and/or using appropriate criteria to focus or inform judgments.

Using a Teaching Simulation to Formatively Assess Skills with Respecting the Student When Eliciting and Interpreting Student Thinking

Many practice-based professions (e.g. dentistry, law, pharmacy) use simulations to assess novices' knowledge and skill with core elements of interactive work. Simulations are "approximations of practice" that place authentic, practice-based demands on a participant while purposefully suspending or standardizing some elements of the situation. Simulations provide a predictability that cannot be replicated through live work in classrooms, interactivity that cannot replicated through video study, and access to feedback and collective work on practice not replicable through written reflection.

Since 2011, we have been using teaching simulations to study PSTs' skill with eliciting student thinking (Shaughnessy & Boerst, 2018a; Shaughnessy & Boerst, 2018b). In these simulations, a PST interacts with a "standardized student" (a teacher educator taking on the role of a student using a well-defined set of rules for responding) around a specific piece of written work. We design teaching simulations to have a consistent three-part format. First, PSTs are provided with student work on a problem and given 10 minutes to prepare for an interaction. The task for the PST during the interaction is to determine the process the student is using to solve the problem and the student's understanding of the core mathematical ideas involved. Second, PSTs have five minutes to interact with the standardized student, eliciting and probing the "student's" thinking to understand the steps they took, why they performed particular steps, and their understanding of the key mathematical ideas involved. The role of the "student" is carried out by a teacher educator whose words and actions are guided by a detailed profile of a particular student's thinking and rules that govern this student's interactional norms. To ensure standardization of the role, the "student" is trained to follow the highly specified rules for reasoning and responding, including responses to questions that are commonly asked by PSTs. Third, PSTs respond verbally to a set of questions that are designed to probe their interpretations of the "student's" process and understanding and their prediction about the "student's" performance on a similar problem.

We designed this simulation to be one in which a student uses an alternative algorithm for solving subtraction problems (see Figure 1). The process involves writing the value of the minuend and subtrahend in expanded form and then making any necessary trades. When trading, the student works from right to left. The student then subtracts the numbers place-by-place in expanded form, starting with the hundreds place. This student has conceptual understanding of expanded form, the meanings of addition and subtraction, and when, how, and why to make trades. We selected this algorithm because it is one that we anticipated would be unfamiliar to our PSTs. This enabled us to learn about the ways in which they respected the student and their thinking in a context in which the student work was unfamiliar.

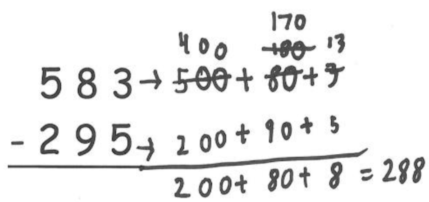

Figure 1: Student Work

Methods

Thirty-two PSTs enrolled in a university-based teacher education program in the United States participated at the beginning of their teacher education program. The simulations were video-recorded. Our analysis focused on respecting students and their thinking. For eliciting student thinking, we used the literature and our research on the work of teaching to identify two characteristics that show respect for students and their thinking: (1) establishing and maintaining a focus on the student's approach while refraining from directing the student to a different process in a way that competes with the student's process; and (2) establishing and maintaining a non-evaluative space in which students can openly share their thinking. For interpreting student thinking, we focused on PSTs' use of a non-deficit focused language to describe the student and their thinking. We focused on three characteristics: (1) characterizing the student's process in asset-focused terms (or ways that are not in deficit terms); (2) talking about the student's process itself without repeated reference to a different process; and (3) characterizing the student's mathematical knowledge and skills in asset-based terms or ways that are not deficit-focused. Two independent coders applied all of the relevant codes to each performance. Disagreements were resolved through discussion and by referencing a code book.

Results

Eliciting Student Thinking

We examined the eliciting of the PSTs to see whether it had characteristics that show respect for students and their thinking. We found that 78% of the PSTs (25 of 32) established and maintained a focus on the student's process. This means that 22% of the PSTs directed the student to a different process in a way that competed with the student's initial reasoning. For example, one PST quickly launched into a series of questions focused on getting the student to solve the subtraction problem without expanding the numbers. Another PST asked a series of questions about the student's process and then told the student that a way to do the problem differently (that would make it easier) would be trade from right to left (rather than left to right). The student indicated that she had seen people do it that way but preferred to trade from left to right. Seventy-five percent of the PSTs (24 of the 32) established and maintained a non-evaluative space in which students could openly share their thinking while 25% of the PSTs employed moves that showed repeated evaluation of the student's thinking such as characterizing as "correct" or "incorrect" each step shared by the student.

Interpreting Student Thinking

We examined the PSTs' interpretations of the student's thinking. In other words, the ways in which they characterized the student and their thinking when we asked them to talk about the student's process, including the student's understanding of the process and the generalizability of the process from a mathematical perspective. We found that 69% of the PSTs (22 of the 32) characterized the student's process in asset-focused ways or ways that were not deficit-focused. In contrast, 31% of the PSTs characterized the student's process using deficit terms. Ninety-one percent of the PSTs (29 of the 32) talked about the student's process itself without repeated reference to a different process meaning that the remaining 9% repeatedly talked about the student's process in terms of a different process. Eighty-four percent of the PSTs (27 of the 32) characterized the student's mathematical knowledge and skills in asset-based terms or ways that were not deficit-focused while 16% characterized the student's mathematical knowledge and skills in deficit terms. When we looked across the characteristics of respecting the student when characterizing their thinking, we found that 38% of the PSTs used one or more moves that we considered to be problematic related respecting the student's thinking.

Discussion

Our study examines an approach for noticing and naming the ways in which PSTs convey respect for students and their thinking when eliciting and interpreting student thinking. As shown in this study, simulations can be designed to raise teaching dilemmas that will surface PSTs' teaching practices, mathematical knowledge, and potential biases, thereby making them available for noticing and addressing. In addition to naming ways to notice the respect of students that can unfold in the work of eliciting and interpreting student thinking, the findings suggest that PSTs at the beginning of teacher preparation are in need of interventions focused on respecting students and their thinking in order to teach in ways that promote access, equity, and inclusion. Further, even those PSTs who did not characterize the student and their thinking in deficit-focused ways were not always carrying out an asset-based approach to characterizing student thinking. In future work, we seek to leverage the simulation to support professional learning at the interactive intersection of teachers, students, and content.

NOTICING STATUS IN SMALL GROUPS: ATTENDING VERSUS INTERPRETING

Brent Jackson
Michigan State University
bjackson@msu.edu

Byungeun Pak
Michigan State University
pakbyun1@msu.edu

This study explores how eleven prospective secondary mathematics teachers noticed status issues occurring small group while watching a video of mathematics instruction. Analysis of written noticings indicate that teachers' noticings concentrate in attention with teacher, quantity of talk, access to space/tools, and displays of authority. Status deriving from larger social hierarchies (i.e. race and gender) was not included in participants written noticings to reason about the noticed interactions. Moreover, the characteristics of noticings varied whether a student positioned as lower status or higher status was more salient in the video. Implications for teacher educators are discussed.

Keywords: Teacher Education, Equity and Diversity; Teacher Noticing, Group Work

Introduction

Group work has the academic and social benefits on the part of students (Cohen & Lotan, 2014; Davidson, 1990). The careful use of group work in mathematics classrooms has been suggested as one approach to making mathematics instruction equitable across diverse learners (Boaler, 2006; Gresalfi, 2009). Yet, inequitable group work arising from status issues has been documented to limit marginalized students' opportunities for learning (Bishop 2012; Langer-Osuna, 2011). We pay attention to status, "an agreed upon social ranking where everyone feels better to have a high rank within the status order than a low rank" (Cohen & Lotan, 2014, p. 28), because it influences students' expectations about who can participate, and in what ways, which results in inequitable opportunities for learning in small groups.

Successful teachers working with diverse learners notice students' forms of participation and positionings among each other (Hand, 2012; van Es, Hand & Mercado 2017). Given that these teachers attend to status in small groups, teacher preparation ought to develop prospective teachers' (PTs) noticing of status in small groups. To better support PTs, it is necessary to understand what PTs notice in relation to how they focus on details of interactions (e.g., Langer-Osuna, 2011; Wells, 2017) and/or socially constructed categories, such as race or gender (Esmonde, Brodie, Dookie and Takeuchi, 2009). This line of inquiry is not well developed. As such, we argue that PTs are sensitive to noticing status in small groups in various ways; however, additional scaffolding is necessary so that status is interpreted in connection with socially constructed categories that carry influence (Cohen & Lotan, 2014). This understanding may allow teacher educators to promote PTs' noticing abilities.

Theoretical Framework

Previously, we argued that noticing status in small groups can help PTs to reason about how to facilitate equitable learning in small groups (Pak & Jackson, 2018). For example, noticing status, such as a dominant group member that ignores questions from peers, can suggest PTs to intervene in the small group by modeling questioning and extending ideas as a way to respect each other's ideas. Alternatively, a PT might respond by assigning competence to the student's question and highlighting why the particular question is important to consider (Cohen & Lotan, 2014). For PTs, dealing with status in small groups is unlikely to be an easy endeavor (Featherstone, et al., 2011). To help scaffold PTs' noticing in this regard, teacher educators need to offer representations of practices that respond to status as a means to create equitable opportunities for learning.

Following van Es and Sherin (2008), we view teacher noticing as involving two processes: *attending* and *interpreting*. Attending to status means noticing the details in students' interactions. These details include body language (gaze, gestures and body position), authority (decision-maker, task assigner), quantity of talk (how much a student have an opportunity to talk), and access to space/tools (who occupies more space or who has more chance to use tools). Wells (2017) argued gesture and body positioning as "indicators that a teacher should try to notice in a classroom setting which related to the understanding of a group of students" (p. 184). In other research, PTs' noticing via video analysis (McDuffie et al., 2014), one of the foci was how PTs noticed the authority students held working on mathematics as an indicator of status. Cohen and Lotan (2014) and Featherstone and colleagues (2011) suggested quantity of talk, access to space/tools, and authority as details teachers need to attend to.

Interpreting status in small groups extends beyond the details of the interactions to consider how hierarchies developed from socially constructed categories, such as race, gender, and socio-economic status (SES) operate in students' small groups interactions. The social hierarchies in wider society are often reflected in small groups as status (Featherstone et al., 2011; Cohen & Lotan, 2014), which gives rise to the different interactions described in the previous paragraph. Although there is a lack of research on PTs' interpretation of status, Esmonde and colleagues (2009) offer insight as to the importance of students' social identities in small groups. Their analysis showed that "students experience mathematics classrooms as sites for power struggles that are often related to their social identities" (p. 39). As such, marginalized students shared preferences to work with students of the same race, gender, and/or working style because they felt they could learn more in these groups than others. Moreover, teacher noticing is shaped by dominant ideas "that position students from non-dominant communities as mathematically deficient rather than as sense-makers whose ideas should form the basis for further learning" (Louie, 2018, p. 55). Taken together, this research leads us to think of social identities as crucial aspects of what PTs need to notice in order to treat status issues in small groups.

Methodology

Eleven PTs, enrolled in their fourth and final semester in a mathematics methods course, at a large midwestern university participated in this study. In their first methods course they were introduced to the ideas of complex instruction (CI; Cohen & Lotan, 2014) and continually engaged with the ideas from CI by designing group worthy tasks, debriefing videos of group work and identifying aspects of status, among other activities. The data for this study comes from PTs' responses from a class activity after watching the Staircase Problem (Roche, 1996). In this video, high school students work in small groups to determine a closed formula for a growing geometric pattern. First, the PTs engaged in the pattern task. Second, they watched the whole video without stopping (15 minutes). Third, PTs watched the video a second time but in an order so that footage from each of three groups shown in the video was continuous. After watching the video segment of each group, the video was paused and the PTs were asked to draw a status hierarchy in a simple diagram and write a statement answering three questions. These questions were: (1) What evidence of status did you see in the video? (2) Explain why you drew the status hierarchy the way you did, and (3) In what ways did you see status hierarchies reinforced or disrupted?

To analyze the written statements, we drew on the framework of attending and interpreting described above with provisional codes (Miles & Huberman, 1994) of body language, authority, quantity of talk, access to space/tools, race, gender, and SES. After our initial read of the data we added *attention with teacher* as a code because of the frequent references PTs made in their statements. We read each written statement (n=33) and independently assigned the provisional codes to each statement; at times, a single statement referred to the same code multiple times (i.e. mentioned the quantity of talk more than once) and in these instances the code was assigned only once to that statement. Some statements had more than one code, thus, we ended up with 89 noticings, which are phrases that PTs used to describe status from the video.

Next, we analyzed the status hierarchy diagrams in which PTs ranked the students in small groups from the video in terms of status. We noted that in the diagrams to the first video group, one student was unanimously positioned as having lowest status. In the diagrams that correspond to the second and third video groups, two students were each unanimously positioned as having highest status within their respective group. We named these focus students of their respective groups. We then analyzed the written statements and coded only noticings within the statements that directly related to the focus student.

Findings

We present two preliminary findings. First, the PTs' noticings were concentrated in four characteristics related to attending: quantity of talk, attention with teacher, access to space/tools, and authority. Second, the characteristics of noticings varied by whether a focal student was positioned as low or high status. We expand on each of these finding below.

In relation to the first finding, as shown in Table 1, the frequency of the codes used across the 33 noticing statements, the most frequently used codes were attention with teacher (29%), quantity of talk (28%), access to space/tools (18%), and authority (17%). The codes we applied to the teachers' noticings came solely from the codes we characterized as attending in our methodology. It is notable that no noticings could be coded from the interpreting category (i.e. race, gender, SES). Although the PTs specifically used race and gender as markers to identify students in their statements, race and gender were not used to interpret and reason about why the students were positioned in the ways represented in the videos.

Table 1: Frequency of Codes

	Total noticings (n=89)	Focal student 1 (n=16)	Focal student 2 and 3 (n=38)
Attention with teacher	29%	0	39%
Quantity of talk	28%	38%	26%
Access to space/tools	18%	50%	5%
Authority	17%	0	26%
Gaze, Posture, and Gender	8%	12%	4%

For the second finding, the status hierarchy diagrams revealed that in the first video group, focal student 1 was consistently positioned as having low status. As shown in Table 1, the 16 noticings attributed directly to focal student 1 were concentrated in the categories access to space/tools (50%) and quantity of talk (38%). In the second and third video groups, focal students 2 and 3 were each positioned as having high status within their respective group. The 38 aggregated noticings directly attributed to focal students 2 and 3 were concentrated in attention to teacher (39%), quantity of talk (26%), and authority (26%). The noticings attributed directly to the low status student were different from the noticings of the high status students. For instance, when interpreting the interactions of a student positioned as low status, half of the noticings made reference to the ways in which a student was physically denied access to the space in which other group members were working. In contrast, the higher status students were *not* noted as *having* access to space/tool, taking up space, or holding onto tools. The PTs more frequently attended to the students as having higher status by noticing attention with the teacher, often in the form of explaining the current understanding of the group and asking questions. Similarly, attending to the high status students was through disciplinary and directive authority, which allowed the student to decide what the understanding of the group was at a time, ask questions, decide whose ideas to pursue, and direct other students what to work on at a given moment.

Implications and Conclusion

The preliminary findings from this study indicate that, similar to McDuffie and colleagues (2014), PTs are able to see status in small group interactions. What PTs noticed was the ways in which status hierarchies become visible in the small group interactions. The statements that teachers wrote as a part of this study did not reveal the ways in which the PTs interpreted and reasoned about why the status hierarchies exist within the small groups themselves. For example, focal student 1, was a Black male and we found no evidence of PTs hypothesizing race as a possibility of why the student was physically blocked from the ability to more centrally participate. CI is a pedagogical approach that suggests teachers be aware of the ways in which broader phenomena influence classroom interactions and students' opportunities for learning. In terms of noticing, PTs must connect what they see in videos or their own classrooms as instances of broader phenomena (van Es & Sherin, 2008). We wonder how PTs might draw on socially constructed categories to make sense of and reason about students' interactions when considering their own students they are familiar with, versus students they have limited knowledge about via video tape. This suggests that teacher educators should further consider the affordances and constraints of using video from different sources. Moreover, videos that represent students from different backgrounds and identities, do not necessarily ensure that PTs will bring larger ideological structures to hypothesize and reason about the students' interactions. As such, teacher educators need to be prepared to prompt discussion to bring issues of race, gender, SES, and class to hypothesize how these socially constructed categories privilege or constrain access to students' opportunities for learning.

ONE UNIVERSITY'S STORY ON TEACHER PREPARATION IN ELEMENTARY MATHEMATICS: EXAMINING OPPORTUNITIES TO LEARN

Casedy A. Thomas
University of Virginia
cat6hu@virginia.edu

This multi-case study examines how three elementary mathematics methods instructors in the same teacher education program (TEP) provide their teacher candidates (TCs) with learning opportunities. The findings suggest that the instructors' beliefs and teaching philosophies influence the content that TCs have the opportunity to learn and the nature of the TCs' opportunities to learn (OTL). Through analytic induction, three assertions were developed to understand and explicate: similarities in OTL, differences in OTL, and perceptions about the purpose of the methods courses across the three cases.

Keywords: Instructional Activities and Practices, Teacher Beliefs, Teacher Knowledge

This multi-case study is part of a longitudinal study that focuses on pre-service teacher preparation in elementary mathematics and English Language Arts in a large-scale study involving six preparation programs across three states; a primary focus is on novice teacher perceptions about their experiences and learning opportunities in their TEPs. This study specifically examines how elementary mathematics methods instructors provide TCs with learning opportunities within their courses. Recent literature (e.g., Lampert et al., 2013) unpacks ambitious pedagogies in mathematics teacher education; yet, as documented by Clift and Brady (2005), there still much to learn about the various instructional strategies employed by mathematics methods instructors as well as the learning opportunities afforded to TCs (Cavanna, Drake, & Pak, 2017). Therefore, the study reported here is significant because it helps us to gain a deeper understanding about TCs' OTL in one of the TEPs, and therefore, may point toward what can be done in the future to better prepare teachers in elementary mathematics education.

Conceptual Frameworks

This study operates under Schmidt and colleagues' framework for OTL, defining it as, "the content to which future teachers are exposed as a part of their teacher preparation programs" (Schmidt, Cogan, et al., 2011, p. 140). This framework differentiates the content that TCs have the OTL within their mathematics teacher preparation coursework based upon four categories: mathematics, mathematics pedagogy, general pedagogy, and practical experience (Schmidt, Blömeke, et al., 2011; Youngs & Qian, 2013). In particular, the study is interested in TCs' OTL *high-quality* mathematics instruction as indicated by the National Council of Teachers of Mathematics (NCTM, 2000) process standards and the dimensions of the observation measure, Mathematics-Scan (M-Scan; Berry et al., 2017). Further, I take the position that "Teachers' beliefs influence the decisions that they make about the manner in which they teach mathematics" (NCTM, 2014, p. 10).

Content that Teacher Candidates Have the Opportunity to Learn

In addition to being knowledgeable about indicators of high-quality instruction, TCs need opportunities to acquire mathematics content knowledge (MCK) and pedagogical content knowledge (PCK). MCK has been defined as, "a comprehensive understanding of breadth, depth, connectedness and thoroughness" of mathematics (Ma, 1999; Hine, 2015b, p. 2). PCK is defined as "knowing a variety of ways to present content and assisting students in deepening their [mathematical] understanding" (Hine, 2015a, p. 483). There is also increasing support for mathematics knowledge for teaching (MKT) in teacher preparation, especially in elementary education (Delaney, Ball, Hill, Schilling, & Zopf, 2008). Thus, when instructors in this study are referencing to OTL "methods," they are generally talking about what is widely accepted as PCK or MKT, and when they mention content knowledge, they are talking about MCK. Having OTL MCK, PCK, and MKT helps novices teach for conceptual understanding and tackle students' mathematical misconceptions (e.g., Karp, Bush, & Dougherty, 2014; Cardone & MTBoS, 2015). The National Research Council (NRC, 2001) defines conceptual understandings as "an integrated and functional grasp of mathematical ideas" (p.18).

The Nature of the Teacher Candidates' Opportunities to Learn

TCs' OTL include their exposure to *representations* and *approximations* of practice. *Representations* in the context of teacher education have been defined as teachers having the opportunity to watch and/or read about others engaging in teaching practices (Cavanna, Drake, & Pak, 2017). *Approximations* emerged from the work of Grossman, Hammerness, and McDonald (2009); they essentially entail having safe places to practice what TCs will actually be expected to do as full-time teachers. Approximations can come in various forms such as practicing classroom management, engaging in teaching episodes, creating and/or grading assessments, and making lesson plans.

Research Questions

- How do three elementary mathematics methods instructors implement instructional strategies (teaching practices) in their courses and why?
- How do these elementary mathematics methods instructors provide opportunities to learn for teacher candidates?
- How do these elementary mathematics method instructors perceive the purpose of elementary mathematics method courses?

Methods

Participants and Procedures

The sample for this work includes the three elementary mathematics methods instructors at Robins University (pseudonyms are used for the university and the participants). The names of these instructors are William, Brittany, and Megan. In regard to the participants' level of education, William has completed his M.Ed. and was nationally recognized as an exemplar elementary teacher; Brittany is an associate professor with a Ph.D.; and, Megan is an assistant professor with a Ph.D. All of the instructors are White and have taught at the elementary level. Their ages range from late-30s to late-50s. The instructors taught two different, consecutive courses taken during TCs' fourth and fifth years within a five-year TEP.

Throughout the 2017 Fall semester, I gathered observational data both through classroom observations and "other reportable events." "Other reportable events" in this study includes informal conversations with the participants, e-mail correspondences, and/or brief scheduled meetings. I also collected additional forms of documentation while in the field performing these observations such as classroom artifacts and TC work samples. I conducted eight classroom observations for the three instructors accounting for 20 cumulative hours. The courses were at various times, on different days of the week, yet all classes were two and a half hours long.

Furthermore, I conducted two rounds of interviews with all three instructors. Prior to conducting classroom observations, I individually interviewed the instructors. The interviews were all recorded and transcribed allowing for member checking, and they ranged from 60 to 90 minutes. Following classroom observations, additional interviews were arranged to have the instructors further unpack some of the instructional strategies and learning opportunities that were noted within the observations. These interviews were all approximately 45 minutes.

Data Sources and Analysis

This study drew upon Erickson's (1986) model of analytic induction. As indicated in my methodological log, following each observation, fieldnotes were transferred into write-ups, and all of the audio from the interviews in the first round were transcribed. From write-ups, transcripts, and other reportable data and documentation, analytic memos were written intermittently to document emerging themes and inferences. The audio from the second round of interviews was listened to repetitively to document inferences and supporting evidence which appeared in my final analytic memo. Data sources were triangulated and re-read and re-coded to document emerging patterns and assertions. I compared confirming evidence and disconfirming evidence for each emerging assertion and continued to adjust the assertion until all evidence was accounted for, inclusive of connections between the assertions. Throughout this inductive process, data were reduced to three assertions for the focus of this paper.

Findings

Assertion 1: Similarities in Beliefs. Similarities identified in instructor beliefs associated with teaching philosophies led to parallels in the content that teacher candidates had the opportunity to learn as well as the nature of teacher candidates' opportunities to learn.

***What* TCs have the OTL.** All three of the mathematics elementary instructors engaged in instructional strategies that called for "non-traditional" forms of teaching, believing that mathematics instruction should be student-centered, open-ended, inquiry-based, and highly interactive. Although there were evident differences in instruction based on instructor beliefs (which will be unpacked in Assertions 2 and 3), all three instructors focused on teaching students for conceptual understanding, such that the instructors were pushing back against teaching procedures and rules for the sake of efficiency. All of the instructors discussed how these "rules" or memory tools have to be accompanied with activities that build conceptual understanding; otherwise, they will lead to mathematical misconceptions, especially if the rules expire as the students advance through mathematics (e.g., Karp, Bush, & Dougherty, 2014).

***How* TCs have the OTL.** The two most prevalent types of instructional strategies utilized were *representations* and *approximations* of practice (both have been defined within the theoretical framework). Though representations took various forms across the three classrooms, approximations most often appeared in the form of mini-lessons which the TCs had to plan and present as if they were in the classroom with elementary students.

Assertion 2: Differences in Beliefs. Differences identified in instructor beliefs associated with teaching philosophies led to differences in the content that teacher candidates had the opportunity to learn as well as the nature of teacher candidates' opportunities to learn.

When the methods instructors were asked about their teaching philosophies, they each placed emphasis on different instructional strategies. The observations revealed that even though the instructors collaborate extensively, they each have their own approach and beliefs which impact *what* and *how* TCs have OTL. In Case 1, William focused more (than the other instructors) on OTL that addressed the NCTM process standards (*what*) through reflection and feedback (*how*).

In Case 2, Brittany created OTL that placed more emphasis (than the other instructors) on MCK (*what*) through hands-on activities, technological applications, and interdisciplinary instructional strategies (*how*). In Case 3, Megan created OTL around research in the field (*what*), often having TCs engage in group work linking research and practice while focusing on the presence of multiple mathematical representations (*how*). Mathematical representations (different than those in Assertion 1) include symbols, graphs, pictures, words, charts, diagrams, and physical manipulatives used to demonstrate mathematics concepts (Berry et al., 2017).

Assertion 3: The three methods instructors expressed a common purpose of seeking to influence their teacher candidates' mathematical mindsets. However, the methods instructors each emphasized different (from one another) dimensions of high-quality mathematics instruction in terms of M-Scan when interviewed about the purpose of the elementary mathematics methods courses.

Though there are certainly similarities across the three cases, as witnessed in their desire to influence TCs' mathematical mindsets (e.g., Boaler, 2016), there were noted differences in how the methods instructors talked about and acted upon the purpose of the methods courses. These differences have been unpacked by looking at each case or instructor separately in this assertion. However, it is important to note that even though the instructors emphasized certain dimensions of high-quality instruction more than others when discussing their purpose, that does not mean that they did not address all dimensions of high-quality instruction at various points throughout the semester. William placed the most emphasis on cognitive demand, problem solving, discourse, and explanation and justification; Brittany on structure and accuracy; and Megan on cognitive demand, mathematical representations, mathematical tools, discourse, and explanation and justification. Even though this assertion focuses heavily on interview data, it also compares how participant interview data about course purposes compares to what was observed in the classrooms which was unpacked in Assertions 1 and 2.

Discussion and Educational Importance

In summary, the first two research questions align directly with Assertions 1 and 2. Assertion 1 focuses on teaching for conceptual understanding and combatting mathematical misconceptions (*what* they have the OTL) as TCs most often experience OTL through representations and approximations (*how* they have the OTL). Assertion 2 unpacks the differences identified in instructional strategies and OTL for TCs across the different methods instructors. Assertion 3 helps answer the third research question, addressing how the different methods instructors perceived the purpose of the elementary mathematics methods courses. Within this assertion, I have demonstrated how each method instructor's perception of the purpose of the methods courses aligned with dimensions of high-quality mathematics instruction as indicated by M-Scan, and in doing so, I have indicated differences across the three cases.

This multi-case study may prove influential as we continue to reflect upon the larger, longitudinal study and the development of ambitious instruction with TCs. However, as it directly relates to the purpose of this study, the findings expand upon literature (e.g., Clift & Brady, 2005; Cavanna et al., 2017) on the range of teaching practices in elementary mathematics methods courses and OTL for TCs. Further, this study, like others (e.g., Koedel et al., 2015), continues a larger conversation about an overarching critique in our field regarding how OTL may vary across methods courses, and so, TCs who attend the same TEP may have different experiences and OTL. This is pivotal as we reflect upon the development of high-quality or ambitious instruction and deserves further attention in mathematics education research especially when we contemplate the ways in which generalizations are sometimes made at the program level when unpacking teacher preparation. More qualitative work is needed in the field to examine similarities and differences in OTL across methods instructors for TCs in the same TEPs. Also, more work is needed to examine how these observed OTL correlate with beginning teachers' mathematics teaching practices across various dimensions of high-quality instruction.

In this study, we investigated the types of knowledge secondary preservice teachers (PSTs) gained from their field experiences and then integrated into methods course discussions. In particular, we analyzed the level of detail, stance, and nature of what they noticed in their field experiences and explored the influence this knowledge had on the PSTs opportunity to integrate their knowledge. Our analysis informed us that PSTs typically provide a wide range of general statements about pedagogy and learners when sharing observations from their clinicals, and this sharing resulted in a greater opportunity to integrate their knowledge. Directions for future research will also be discussed.

Keywords: Teacher Knowledge, Teacher Education-Preservice

Background

Secondary mathematics teachers must develop a thorough and connected understanding of mathematics (M), pedagogy (P), and learners (L) in order to plan effective lessons, implement mathematical tasks, and interpret student thinking. Unfortunately, many pre-service mathematics teachers (PSTs) do not have ample opportunities to connect their knowledge during their undergraduate programs. They often see their methods and mathematics courses as discrete, unrelated topics (Ball, 2000). In this paper, we investigate the role that field experiences may play in the important process of knowledge integration.

Field experiences provide PSTs an opportunity to notice student mathematical thinking, which NCTM (2014) has identified as an essential skill for teaching. Van Es, Cashen, Barnhart, and Auger (2017) reported PSTs attending to learning goals, student thinking, teaching strategies, classroom discourse norms, and connections. In addition, the knowledge gained from practice is more naturally integrated. Hiebert, Gallimore, and Stigler (2002) stated that a, "characteristic of knowledge that is linked to practice is that it is integrated and organized around problems of practice" (p. 6). The variety of knowledge that PSTs use in their field experiences provide teacher educators an opportunity to draw upon these field experiences as a means to promote knowledge integration. In this paper, we provide preliminary findings for the following research questions: 1) What knowledge did PSTs gain from field experiences that was shared in their methods courses? and 2) To what extent does the knowledge acquired from field experiences influence PSTs opportunities to integrate knowledge in their methods course?

Theoretical Foundation

For this study, we define *knowledge integration* as the coordinated use of multiple knowledge types in order to reflect on, or make, instructional decisions. Bishop and Whitefield

(1972) proposed that teacher decisions are made using a framework or schema. The main operation of a schema is to store knowledge through a network of connected pieces of knowledge called "elements" (Marshall, 1995, p. 43). The more connections that exist within a schema, the more useful the schema will be. Hence, the process of knowledge integration leads to the development of a more robust schema, resulting in the potential for more informed instructional decisions. The knowledge types used in this study are defined as follows:

> *Knowledge of Mathematics (M)*: knowledge regarding the mathematical content under investigation. Includes the connections and relationships among ideas, the ways and means of justifying and proving these ideas, and conversations focused on mathematics and reasoning about the mathematical topic.
> *Knowledge of Pedagogy (P)*: knowledge regarding the tasks, curriculum, instructional goals, or questions used to further the lesson. Includes comments centered on the lesson implementation or decision-making regarding the flow of the lesson.
> *Knowledge of Learners (L)*: knowledge regarding student thinking. Includes observed as well as anticipated student thinking, conversations about student characteristics, habits, or misunderstandings.

Our definitions of knowledge of mathematics, learners, and pedagogy are related to other models of teacher knowledge, such as mathematical knowledge for teaching (MKT) (Hill, Ball, & Shilling, 2008) or pedagogical content knowledge (Shulman, 1987). However, the definitions in this study are broader in scope, as we are focused more on the *interactions* among these knowledge sets (i.e. knowledge integration).

Methods

Field notes were collected for every session of a senior-level secondary methods course at a teacher preparation program in the Midwest. In conjunction with the methods course, PSTs participated in a ten-week field experience where they attended the same secondary classroom each day. Field notes were initially read to identify individual episodes—sections of the transcript centered on a single idea. Following the identification of episodes, the above definitions (i.e., M, L, P) were applied to code all episodes. If multiple forms of knowledge were used during a single episode, we defined this to be an example of potential knowledge integration. We note that evidence of multiple knowledge types does not ensure knowledge integration, only that the potential of knowledge integration was present.

Our next step in analysis was to further analyze the episodes where the PSTs shared what they noticed during their field experience. Each field-experience-related episode was coded to identify attending statements--statements made by a PST indicating she had focused her attention (Sherin et al., 2011) on something from her field experience. These attending statements were further analyzed and coded based on three aspects: level of detail (general to specific), stance (descriptive, evaluative, and interpretive), and category (objectives, pedagogy, timing/pacing, classroom structure, assessment, student behavior, student thinking, and student participation). The operational definitions for level of detail and stance were adapted from van Es (2011), and the operational definitions for the categories were developed through an open coding process (Miles et al., 2014).

Findings

From the field notes, we identified 57 (out of a total of 268) episodes that contained references to field experiences. During these 57 episodes a total of 146 attending statements were identified. In other words, there were 146 instances where a PST drew upon what they had noticed at their field experience to make a contribution to the methods class conversation. The following episode is an example.

> Matthew then moves to the problem $3(x+2) = 5x - 2$. Meredith says that this problem is troublesome because what if the students are missing appropriate prior knowledge such as the distributive property. Meredith also comments that the symbolism can be confusing to algebra students. Phyllis then shares that at her clinical placement her CT has been working with similar problems. The CT covered simplifying and solving equations in a single day because she assumed that the students already knew the material and it would just be review. Phyllis then shares that the students were confused the next day because they really did not understand.

This episode contains a conversation about the importance of addressing appropriate prerequisite knowledge, and the impact it may have on student understanding. In the middle of the conversation, Phyllis shares an observation she made from her field experience. She describes a situation in which the teacher assumed her students had the relevant prerequisite knowledge, covered the material quickly, and this unfortunately led to student confusion. Although this observation from her field experience did not add any new ideas, it reinforced a connection between the PSTs knowledge of pedagogy and learners.

The above example provides a single episode of a PST bringing an observation from their field experience to their methods class conversation. Table 1 and 2 display a summary of the 146 attending statements that the PSTs brought to their methods course conversations. Table 1 displays the number of attending statements at each level of detail and stance, Table 2 displays the number of attending statement for each category.

Table 1: Number of Attending Statements for Each Level of Detail and Stance

Level of Detail			**Stance**		
L1 - General	L2	L3 - Specific	Descriptive	Evaluative	Interpretive
16	48	9	44	6	23

Table 2: Number of Attending Statements for Each Category

Objectives	**Pedagogy**	**Pacing**	**Structure**	**Assessment**	**Student Behavior**	**Student Thinking**	**Student Participation**
6	25	3	3	7	7	18	3

From the data, we see that the PSTs brought a variety of attending statements to their methods course. As it pertains to knowledge integration, it appears that the field experiences were a significant source of statements regarding pedagogy and learners. However, this data alone does not imply knowledge integration and raises a few questions. The PSTs level of detail was not very specific; does this limit the potential for knowledge integration? Does the stance of the attending statement influence the potential for knowledge integration? Research has shown that when teachers make and justify their decisions they often use their knowledge in an integrated fashion (Barker et al., 2019). Does the act of interpreting lead more naturally to integration than describing? Although we cannot answer these questions with our current analysis, we can share some additional data on the influence these field experiences had on the potential to integrate knowledge.

Table 3 displays the number of episodes that contained the different knowledge combinations (M, P, L, MP, LP, ML MLP) for the episodes that included a field experience connection and those that did not. For instance, the 44 in the next to last column indicates that 44 of the 57 episodes that included a clinical connection resulted in statements that included the knowledge of learners and pedagogy.

Table 3: Knowledge Types Used in Episodes with and without Clinical Connections

	M	L	P	ML	MP	LP	MLP
Episodes with Clinical Connection	0	3	7	0	1	44	2
Episodes without Clinical Connection	4	7	85	2	16	86	11

82.5% of the episodes that included a clinical connection resulted in statements with more than one form of knowledge; 54.5% of the episodes that did not have a clinical connection contained more than one form of knowledge. The data appears to support the idea that including field experiences into methods course discussions can promote knowledge integration. However, for this particular class, the data also reveal that this integration is primarily between the knowledge of learners and pedagogy.

Having looked at the PSTs' integration of their knowledge of mathematics, learners, and pedagogy, we turned our attention to how PSTs might integrate the practical knowledge obtained at a clinical site with the theoretical knowledge gained in a methods course. We observed two distinct processes that appear to support PSTs' integration of theoretical and practical knowledge. The first we have termed *confirmation.* In this process, the PSTs are asked to look for and reflect on a particular aspect of teaching that they had read about in the methods course. Later, as PSTs debrief during their methods class, they are asked to describe events that they observed in their clinical experience that illustrate the particular idea from their readings. This process of "observe and report" allows PSTs to confirm the practical applications of the theoretical idea being examined in class. We view this as an initial step for integrating theoretical and practical knowledge.

The second process that appears to support PSTs' integration of practical and theoretical knowledge we have termed *responding to a dilemma*. In this situation, a PST presents a situation/question/dilemma from their clinical site, the class discusses the dilemma, and then proposes potential solutions. This process often requires the use of theoretical knowledge gained in class to address the challenge found in the practical setting of the clinical experience. It is our current belief that the process of confirmation is most beneficial to PSTs in their initial clinical experiences as they are acquiring the necessary knowledge for teaching. However, we would encourage the addition of the process of responding to a dilemma as they begin using knowledge for the purpose of instruction.

Discussion & Implications

Focused field experiences have the potential to be an important source and mechanism for knowledge integration. Based upon our preliminary analysis, PSTs bring a variety of knowledge from their clinical placements to their methods courses. In addition, episodes that contained references to field experiences were more likely to involve multiple types of knowledge. This coincides with the idea that knowledge that is linked to practice is "integrated and organized around problems of practice" (Hiebert et al., 2002).

HOW DOES CONTENT KNOWLEDGE AFFECT SECONDARY PRESERVICE TEACHER LESSON PLANNING?

Matthew S Winsor
Illinois State University
mwinsor@ilstu.edu

National organizations such as the Association of Mathematics Teacher Educators recommend that secondary preservice teachers (PSTs) have a strong understanding the content they will teach. Other studies (e.g. Monk, 1994) suggest that the more mathematics courses preservice teachers take after a certain point do not affect their pupils' learning. This study aims to find evidence that participating in mathematics courses tailored for secondary PSTs as recommended by the Conference Board of Mathematical Sciences have the potential to help PSTs gain knowledge that promotes student-centered learning. This paper will share preliminary evidence from a case study that seems to provide evidence of a mathematics experience that promoted a change towards more student-centered teaching.

Keywords: Teacher knowledge, Instructional activities and practices, Teacher education-Preservice

National organizations such as the Association of Mathematics Teacher Educators (AMTE) and the Conference Board of Mathematical Sciences (CBMS) recommend that secondary preservice teachers have a strong understanding of the mathematics they will be teaching (e.g. AMTE, 2017, CBMS, 2001, 2012). Shulman (1986, 1987) as well as Fennema and Franke (1992) proposed that content knowledge, coupled with knowledge of pedagogy and knowledge of learners forms the foundation of teacher knowledge. In what seems contradictory to the claim that content knowledge is essential for teaching, Monk (1994) found that taking more mathematics courses in an undergraduate course of study provided diminishing returns with respect to pupil learning. Understanding how content knowledge affects teaching may facilitate planned experiences for preservice teachers that might help develop their teacher knowledge more effectively.

The objective of this study was to examine how a secondary preservice teachers' content knowledge directly affected their teaching. The literature on the negative effects of inservice teachers' limited content knowledge on teaching is established (e.g. Brown and Borko, (1992); Carlsen, (1993); Mosenthal and Ball, (1992); Stein, Baxter, and Leinhardt, (1990); Van Dooren, Verschaffel, and Onghena, (2002)). Given that preservice teachers are novice teachers, which could obscure how their content knowledge affected their teaching, I decided that lesson planning was a context in which preservice teachers could represent their content knowledge in a lesson without the pressures of actual teaching.

Theoretical Foundations of the Study

Foundational pieces of research on teacher knowledge (e.g. Shulman, 1986, 987) and mathematical knowledge for teaching (e.g. Ball, Thames, & Phlelps, 2008) have moved the field of mathematics education forward by showing that mathematics teaching is more than just being a successful mathematics student in college. Teaching mathematics requires teachers to use their knowledge of mathematics, learners, and pedagogy in tandem (Barker, Lannin, Winsor, and

Kirwan, 2018) to promote mathematics learning. The challenge for researchers is demonstrating how secondary preservice teachers employ their different types of knowledge while teaching.

One potential avenue for uncovering how preservice teachers' content knowledge affects how they teach can be found in Swafford, Jones, and Thorton, (1997). The authors wanted to discover what affect an intervention program designed to increase teachers' knowledge of geometry and student cognition had on teachers' instruction. The intervention consisted of a four-week summer seminar focused on geometry and the van Hiele levels (van Hiele, 1985) as well as six half-day seminars held during the academic year. Participants were asked to plan a geometry lesson before and after participation in the study. Participants were also assessed on their geometry knowledge and their own van Hiele levels before and after participation in the study.

Swafford, Jones, and Thorton (1997) found that teachers' content knowledge grew significantly. Participants' conceptual knowledge of geometry, as measured by the van Hiele levels also increased. Researchers measured the percentage of lesson goals that fell into the four van Hiele levels, level one being the lowest and level four being the highest. For the first set of lesson plans, it was found that 39% of the lesson goals were rated a van Hiele level one and 58% were rated a van Hiele level two. For the second set of lessons there was a change of 73% of lessons goals being rated at a van Hiele level two, which was significant with $p < .001$.

Given the findings from Swafford, Jones, and Thorton (1997), it seems that a lesson plan, connected with a content assessment, is a potential instrument to detect the connections between a preservice teachers' content knowledge and their knowledge of pedagogy. Shulman (1987) suggests that a preservice teacher would connect their knowledge of mathematics to their knowledge of pedagogy during the planning process. Shulman notes that the ideas that teachers understand must be transformed if they are to be taught to students. The transformation of ideas requires a combination of the following steps: 1) preparation of the material in the textbook including the process of critical interpretation, 2) representation of the new ideas in the forms of new examples, analogies, and so forth, 3) instructional selections from a set of teaching methods and models, 4) adaptation of the representations to fit the general characteristics of the students to be taught, and 5) tailoring the adaptations to the specific students in the class.

In each step described by Shulman (1987), there is a connection of different types of knowledge. For example, the representation stage requires teachers to connect their knowledge of mathematics to their knowledge of pedagogical artifacts, such as examples or analogies used in the lesson. Adaptation of representations to fit the general characteristics of the students being taught requires the teacher to employ knowledge of content, pedagogy, and of their students (learners) in tandem. Therefore, a lesson plan seems to be fertile ground for uncovering how the preservice teachers' knowledge of mathematics is connected to and affects their use of other types of teacher knowledge.

Methods of Inquiry

This study took place at a large university in the Midwest. I conducted a case study (Merriam, 1998) of six secondary preservice teachers, three females and three males. Participants were asked to plan an introductory lesson on the topic of functions for a class of high school freshmen before and after participation in my study. I chose the topic of functions because of the substantial work that has been done on preservice teacher understanding of the topic (Cooney, 1999; Even, 1990, 1993; Hitt, 1994; Lacampagne, Blair, and Kaput, 1995; Vinner and Dreyfus, 1989; Wilson, 1994). I also administered a pre and post content assessment focused on the concept of functions.

The main intervention of this study was a series of five study sessions where participants would be able to examine the concept of functions from an advanced standpoint, as recommended by CBMS, (2001, 2012). I used material from Usiskin, Peressini, Marchisotto, & Stanley, (2003) to help participants examine the concept of functions. Each study session was structured to start with a problem to solve. The problem was designed to lead into the topic of the day as well as to generate discussion. The lesson would then proceed into a variety of planned activities. The end of the study session consisted of completing several problems out of the text as a group. Participant solutions were offered and discussed. Finally, the journal prompt was put on the board for participant response and a small amount of homework would be assigned. All study sessions were recorded for later analysis.

Data Analysis

For the purpose of this paper, I will share the data from one participant, Craig. Craig believed that his college mathematics courses were not necessary to help him become a mathematics teacher because they did not have connections to the mathematics that he would teach in high school. Furthermore, he shared that he had learned all the mathematics he knew in high school. I chose to share Craig's data because there seems to be a clear connection between his content knowledge and what he planned in the lessons.

The first type of analysis I completed was examining the participant's definition of functions. I used Vinner and Dreyfus' (1989) categorization of teachers' definitions of functions to categorize Craig's definition of function both in the pre and the posttest. Then, I examined Craig's pre and post lesson plans looking for evidence that Craig's definition of function affected the content of the lessons. In the remainder of the paper I will provide detailed descriptions of shifts in content knowledge as well as how Craig's definition of functions seems to affect his pre and post lesson.

Findings

Pretest and Pre Lesson Plan

Craig's definition of function on the pretest was, "An equation in which each value of an independent variable results in one and only value of a dependent variable." Craig's definition corresponds to Vinner and Dreyfus' (1989) category 5, which says that a function is an algebraic expression, equation or formula. Moreover, in an additional question, Craig noted that, "a function is a specific type of equation." There is no direct mention of univalence (Even, 1993) where each element in the domain is assigned to a single element in the codomain. Craig's definition seemed to narrowly focus on the mechanics of functions whose domain and range are subsets of the real numbers.

Craig's pre-lesson plan seems to be motivated by his definition of functions. Craig's lesson starts by showing students a table of x and y values and then asking students to identify the pattern in the table. He continues with two more tables asking students to supply a y-value for certain given x-values based on the pattern students observe. The next segment of Craig's lesson focuses on examining the graph of $y = 2x$. He asks students to identify the y-values for given x-values from the graph. He then asks students to generate a formula that relates x and y. Craig then notes if a student identified that the graph identified was $y = 2x$ he would tell students that this is a function. The definition that he would give students of function is, "a function shows a relationship between two variables". Craig emphasized in his lesson that he would want to give a definition that was easy for students to remember and conceptualize.

Posttest and Post Lesson Plan

Craig's definition of function on the posttest was, "An operation that maps elements from a set A to at most one element each in set B." He also noted "equations are one way to represent mathematical functions." Craig's definition of functions shifted to what Vinner and Dreyfus (1989) call a correspondence, which notes that there is a relationship between two sets such that every element in the first set gets assigned to only one element in the second set. The concept of univalence (Even, 1993) is much more evident in Craig's definition.

Craig's post lesson plan started with representing sets with two ovals containing elements inside each oval. Arrows connected elements of the first set to elements in the second set in a way that was consistent with Craig's enhanced definition of function. Craig then stated he would give more examples and non-examples of functions (e.g. pets assigned to their owner), asking students to identify the main characteristics of a function. Craig notes that once he was satisfied with students' responses, he would change the elements of the two sets to be numbers and ask if they could identify the rule that assigned elements from the first set to elements of the second set. It seems that Craig connected his old definition of functions with his new definition of functions.

Discussion

Prior to participating with in the study, Craig was fluent with the procedural aspects of functions. He could find patterns, identify graphs that represented functions using the vertical line test, as well as identify 1-1 functions using the horizontal line test. Craig's pre-lesson plan seemed to mirror his definition of functions as well as his procedural fluency with functions. Craig's procedural view of functions was not altered by the required mathematics courses in his degree. Monk's (1994) finding that PSTs taking more math classes do not affect pupils' learning seem to coincide with Craig's beliefs that college math courses were useless and that he had learned all he needed to know in high school.

After participating in five learning sessions modeled after a capstone course (CBMS, 2001, 2012) and taught in a student-centered manner ((NCTM, 1989, 1991, 2000), Craig's definition of functions and the way functions were manifest in his lesson changed. Craig's definition focused more on the idea that a function is a relationship between two sets and less on equations and tables, which was mirrored in his post lesson plan. Perhaps because the study sessions focused on the more conceptual aspects of functions and that they were taught in a manner that was more conceptually focused promoted change in Craig's definition of and lesson on functions. From the evidence, it seems that mathematics courses can be meaningful to future teachers and can affect their teaching if they focus on the conceptual underpinnings of high school mathematics in a student-centered manner.

Moving forward, I plan to expand my analysis to focus on data collected from 45 secondary preservice teachers who participated in the same intervention at two other universities. I will examine questions such as: What evidence does a preservice teachers' lesson plan provide of their use of integrated knowledge? How does participating in a student-centered mathematics course focused on examining secondary school mathematics affect preservice teachers' ability to plan a conceptual, student-centered lesson on functions? How does a preservice teachers' understanding of function develop while participating in a capstone course as recommended by CBMS (CBMS, 2001, 2012)?

NEGOTIATING DISCIPLINARY IDENTITIES DURING AN INTERDISCIPLINARY COLLABORATION MEETING

Hanan Alyami
Purdue University
alyamih@purdue.edu

Integrated science, technology, engineering, and mathematics (ISTEM) education provides opportunities for interdisciplinary groups to form. To explore the nature of interdisciplinary collaborations, I investigated the disciplinary identity of 11 preservice teachers (PSTs) enrolled in an ISTEM methods course. Each PST joined one of three interdisciplinary groups to collaborate on designing and implementing an ISTEM curricula. For this report, I analyzed the initial collaboration meeting of each group. Through positioning theory, findings indicate that PSTs take a strong disciplinary identity position in their discipline. Their identification in other disciplines varied. These identification levels were negotiated throughout the meeting by shifting either positively or negatively. Future research should investigate potential ways to disrupt negative disciplinary identity shifts, while encouraging positive ones.

Keywords: Disciplinary Identity, Positioning Theory, Preservice Teacher Education

The increased adoption of ISTEM curricula has increased the need to prepare teachers to design and implement ISTEM instruction (National Research Council, 2013). Preparing PSTs for such tasks could be achieved through providing opportunities to experience ISTEM with an emphasis on integration in methods courses (Stohlmann, Moore, & Roehrig, 2012). However, ISTEM methods courses would immerse PSTs who come from an established disciplinary way of knowing in an interdisciplinary community that is not as well-defined as their own disciplinary community (Bybee, 2013). Therefore, methods courses that emphasize ISTEM promote PSTs to collaboratively negotiate the boundaries of their disciplinary ways of knowing (Friman, 2010). To gain insight into the nature of interdisciplinary collaborations, I investigate PSTs' negotiation of their disciplinary identities during an interdisciplinary collaboration meeting. I specifically explore, through positioning theory, the following question: How do PSTs negotiate disciplinary identities as they engage in a collaborative interdisciplinary meeting?

Theoretical Framework

To answer the research question, I take a sociocultural perspective into identity formation. I specifically adopt positioning theory (Davies & Harré, 1990), which describes identity formation through an active process of interactive positioning (of others) and reflexive positioning (of self). Negotiating local expectations, practices, and roles in social activities leads to identity development (Nasir, 2002). Disciplinary identity then is a socially constructed identity that relates to a discipline-specific context. Such an identity can be negotiated through taking up, compromising, or withdrawing discipline-related positions. Harré and van Lagenhove (1999) represent the constant acts of positioning and repositioning with an equilateral triad: position, storyline, and social force. They clarify that social forces are any type of institution (as big as an organization or as small as a classroom group). This framework is adopted because if PSTs use storylines to make sense of their position relative to the surrounding interdisciplinary group context, then such social surrounding could impact their positioning and repositioning acts.

Methods

Context and Participants

Participants in this study comprise 6 undergraduate and 5 graduate students from a variety of STEM disciplines. Participants were enrolled in a 3-credit semester-long ISTEM methods course, designed for PSTs seeking a teaching certificate in one of the STEM disciplines, and for graduate students seeking a graduate certification in STEM education. While the students in the course were pursuing different degree areas at different levels, they are all identified in this study as PSTs because they were all enrolled in a methods course. I was the graduate teaching assistant for the course, which had two more co-instructors from different disciplines (i.e., technology and engineering education and agricultural education). Participants formed three interdisciplinary groups of their choosing (Table 1). Each group collaborated to design an ISTEM unit, which they eventually implemented in a middle-school classroom.

Table 1: Participants Groups, Degree Programs, and Unit Focus

Group Unit Focus	Participants (pseudonyms)	Degree programs
G1 Science	Jenna	Technology and Engineering Education
	Pamela	Science Education
	Faith	Science Education
	Laila	Mathematics Education
G2 Technology	Jesse	Technology and Engineering Education
	Mary	Technology and Engineering Education
	Audrey	Science Education
	Diana	Education Psychology
G3 Technology	Karl	Technology and Engineering Education
	Rosie	Technology and Engineering Education
	Leona	Technology and Engineering Education

Note: G3 was considered interdisciplinary since Leona has an MS in biomedical engineering.

Data and Analysis Process

During the semester, the groups collaborated at least 5 times. An audio recorder was placed on the table in front of each group during their collaboration. The data sources for this report are the three, 30-minute audio recordings of the initial collaboration meetings of each group. The initial meeting prompted PSTs to brainstorm at least three ideas in their ISTEM unit.

Because identity is constructed through the social practice of positioning a person in relation to their self and others (Davies & Harré, 1990), I analyzed PSTs' identity construction through their interactions with each other during collaboration meetings. The analysis explored PSTs' disciplinary identification with their own discipline and in relation to other disciplines. I used a whole-to-part inductive approach for coding (Erickson, 2006), beginning with playing and listening to the entire recording without coding, stopping, or pausing. In this phase, I took preliminary field-notes. I then played the video and used NVivo software as described by Wainwright & Russell (2010) to code the media files. At this stage, the unit of analysis was one or more sentences that formed coherent statements. Using magnitude coding (Saldaña, 2013), I conceptualized disciplinary identity as positions on a continuum of disciplinary-knowledge perceptions expressed by PSTs. The continuum ranged from very weak, on one end, to very strong on the other end. Coding involved how PSTs positioned themselves within the continuum and then the shifts in these positions as the collaboration evolved. I then identified and categorized the storyline and social context of the positioning shifts (Harré & Lagenhove, 1999). Negotiating disciplinary identity involved identifying shifts that occurred in the PSTs self-positioning along the continuum. Positive shifts were associated with changing one's position positively (e.g., starting at a moderate positioning then identifying more strongly as the collaboration evolved). Conversely, negative shifts were associated with changing one's position negatively (e.g., starting at a moderate positioning, then identifying weakly with the discipline).

Findings and Discussion

For their own disciplines, most PSTs had a very strong disciplinary identity. However, relative to other disciplines, there were varying degrees of disciplinary identification positions that were initially taken up. Negotiations of these positions were associated with PSTs shifting these positions (repositioning) during the collaboration, by identifying either more or less with the discipline. I present below the three themes that represent repositioning of disciplinary identification. While these themes were recognized in all three groups, I present them with examples in the form of focused episodes from each group. All three episodes also include evidence of PSTs' very strong disciplinary identity relative to their own disciplines.

Positive Shift: Relating to a Previous Experience of Other Disciplines and/or Finding Interest in Learning Other Disciplinary Perspectives

While many PSTs positioned themselves with a very strong disciplinary identity in their own discipline, some PSTs' initial disciplinary identification positions were moderate to weak in other disciplines. In many cases, negotiating such position involved shifting positively to a moderate or strong position. These shifts occurred by relating to the other discipline through familiarity with a concept or personal experience. For example, Jenna in G1 had a very strong technology education identity, but a weak science education identity. The following excerpt shows the positive shift from her initially weak science disciplinary identification:

> Jenna: I know squat diddly about like earth and space science, especially from the global warming standpoint, I know a lot about space! Because that was the environment I grew up in, I don't have any grand ideas besides just *space is awesome*, but it also depends…
> Pamela: … so I looked at the standards for like earth space and science for eighth-grade, and there's four, there's literally four, there's water cycle greenhouse gases and, maybe how we use the environment?
> Jenna: Okay that makes me sad, earth space and science…
> Pamela: … a lot of them in sixth-grade, then seventh-grade is bio, and eighth-grade is chemistry and physics, um sorry a little bit of bio then chemistry, so she (the cooperating teacher) also says animal classification, I don't know if you are more familiar with that?
> Jenna: Nope! [laughing] So one of the reasons I'm doing this is I want to learn like outside of my field

By relating to her knowledge and love of space, Jenna shifted her science identification positively to moderate. Prior experiences are recognized as a strong influence on the identities of new teachers (Flores & Day, 2006). Another form of negotiating disciplinary identity involves being eager to learn about other disciplines (Shen, Sung, & Zhang, 2015), which Jenna indicated: that she joined the ISTEM methods course because she wanted to learn outside her discipline.

Neutral: No Change in Disciplinary Identification Position

There were some moments where PSTs did not negotiate the disciplinary identification of other disciplines. For example, G2's ISTEM unit was technology based with an integration of science. All the members in G2 had very strong disciplinary identities relative to their own discipline. The following excerpt occurred towards the end of brainstorming some ISTEM unit ideas that were focused on technology and science education, and relates to Diana's identification with those disciplines:

> Diana: Whatever you guys decide, I'm gonna probably go with the person who's doing the introductory lesson, because I really don't know anything about this stuff
> Jesse: That's fine, you'll do great
> Diana: I hate to ask for a special offer, but after you figure out the lesson, I can incorporate maybe a motivational aspect to it, and then I'm gonna do the introductory

Diana had a very strong education psychology identity. She even advocated for that identity through potentially implementing a motivational aspect to her lesson. However, knowing "nothing" about either science or technology disciplines constrained her flexibility. If identity development is viewed as an increased involvement in the social context (Lerman, 2001), Diana's limited willingness to learn about other discipline implies a minute shift in her position.

Negative Shift: Compromising One's Disciplinary Identification Position

To have an interdisciplinary group, everyone could interactively have a very strong identity relative to their own discipline. Yet the following excerpt indicates the varying levels of disciplinary identification during the initial discussion to decide between focusing the ISTEM unit on electricity or manufacturing:

> Rosie: Electricity is not my strong suit, that's for sure, I'm willing to *learn it*, just a fair warning on that
> Karl: I like circuits, circuit chips are fun…
> Rosie: … I'm saying as long as someone is willing to help me with it I'm willing to pick it up
> Leona: Yeah, so, I mean I was an electrical engineering major for my undergrad, and that's ultimately what I would like to go back and teach at the college level, so, I would obviously love to do electricity, but my current research is on perceptions of manufacturing at this grade level so really either way
> Rosie: I am fine with either one, just a fair warning on the electricity stuff, that someone's gotta help me with that
> Karl: I know more about electricity than I do manufacturing, but compared to you, I know nothing, if you majored in it [talking to Leona]

When Leona positioned herself with very strong electrical and manufacturing education identities, she interactively positioned Rosie and Karl with weaker identities. In this case, they can either take up this positioning, or attempt to negotiate it (Harré & Lagenhove, 1999). The excerpt shows how Karl started with a moderate electrical education identity. However, he took up the interactive position that Leona presented by compromising his position, and negatively shifting his electrical education identity from moderate to weak.

Conclusion

In their own disciplines, PSTs in this study had strong or very strong disciplinary identities. However, identification in other disciplines was initially weak to moderate. Positive shifts in PSTs' identification in other disciplines occurred by relating to previous knowledge or personal experiences of the discipline. Positive shifts were also associated with willingness to learn about other disciplines. Negative shifts occurred when a PST compromised their position if another PST expressed a very strong disciplinary identity. The varying degrees of disciplinary identities must be acknowledged when an interdisciplinary group comes together. Further research should look at minute disciplinary identity negotiation and potential ways to disrupt negative shifts in identification while encouraging positive ones.

TEACHING ACROSS DISCIPLINARY BOUNDARIES: A CASE STUDY OF A PRESERVICE TEACHER TEACHING OUTSIDE HER DISCIPLINE

Hanan Alyami
Purdue University
alyamih@purdue.edu

Teachers of integrated science, technology, engineering and mathematics (ISTEM) curriculum find themselves responsible for teaching disciplines outside their areas of certification. To gain insight into the experience of teaching a different discipline, I explore how a preservice teacher (PST) in an ISTEM methods course facilitated discussion when she micro-taught a lesson from a different discipline. Through a commognitive lens, I examined how Pamela, the PST, facilitated the discussion to elicit learning. Preliminary findings show that when disciplinary boundaries were crossed, discipline-specific words were not recognized or addressed. Teachers implementing ISTEM curriculum could benefit from negotiating authority and participating as learners, through embracing uncertainty in unfamiliar disciplinary discourses.

Keywords: Commognition, Instructional Activities and Practices

Research on ISTEM education is providing evidence of its positive impact on learning (Honey, Pearson, & Schweingruber, 2014). However, teachers implementing ISTEM curricula supplement the teaching of content outside their area of academic certification. In such cases, teachers' disciplinary ways of knowing are challenged (Friman, 2010). In education, integration aims to engage disciplinary communities and merge disciplinary perspectives (Wang, Moore, Roehrig, & Park, 2011). However, while implementing an ISTEM curriculum, some teachers have expressed their preference for teaching their own discipline (Stohlmann, Moore, & Roehrig, 2012). Teachers also expressed seeing themselves as experts in their own discipline but novices in others (Venville, Wallace, Rennie, & Malone, 2002), indicating a sense of competence in teaching their own discipline. Yet policy documents (e.g., National Research Council, 2013) continue to ask teachers to teach content outside their disciplines as part of ISTEM curricula. To gain insight into the development of learning to teach ISTEM curricula, I address the following question through a sociocultural perspective: How does a PST in an ISTEM methods course elicit learning when teaching outside of their discipline?

Theoretical Framework

To explore teaching curricula outside one's discipline, I focus on classroom discourse as viewed by Sfard (2000) as "the totality of communicative activities, as practiced by a given community" (p. 160). Learning in a classroom is conceptualized as a change in discourse (Sfard, 2008). Discourse is described through four characteristics: word use, visual mediators, routines, and narratives. I specifically focus on word use because discipline-specific words have explicit definitions and are used in unique ways in that discipline (Morgan & Sfard, 2016) despite use and overlap of such words in other disciplines and/or colloquial discourses. A teacher crossing disciplinary boundaries might be familiar with discipline-specific words, but not in the specific way the words are used in that discipline. For example, the word *scale* means something different in a mathematics discussion than it does in colloquial speech. Teaching through the commognitive lens involves creating opportunities to elicit and encourage changes in discourse.

Eliciting learning through changing word use involves providing opportunities for learners to expand their discipline-specific words and properly use these words (Tabach & Nachlieli, 2016).

Methods

Context and Participant

A 3-credit ISTEM methods course was the site of this study. The course was designed for PSTs seeking a teaching certificate in a STEM major and for graduate students seeking a graduate certificate in STEM education. There were 6 undergraduate students and 5 graduate students from various disciplines that formed three groups. Only one group included a mathematics education student. The course was taught by two co-instructors from disciplines outside mathematics education (technology and engineering education and agricultural education). I was the graduate teaching assistant for the course and provided resources for mathematics education as required. Students in the course engaged in three micro-teaching sessions, where they taught curriculum for 25 minutes to peers and course instructors. Students in the first micro-teaching session presented a lesson from their own discipline. During the second and third micro-teaching sessions, students presented lessons from an ISTEM unit designed by the groups throughout the semester.

In this case study, I focus on how Pamela elicited learning during her micro-teaching sessions. Pamela is a science PST who focused her first micro-teaching on an introduction to (tectonic) plate boundaries, a topic from the science curriculum. Her third micro-teaching session was focused on scale and scaling, a topic from the mathematics curriculum. Prior to micro-teaching the scale lesson, Pamela asked to meet with me to inquire about her approach to the lesson. During the 30-minute meeting, I encouraged her to consider scale as a proportional relationship between two quantities.

Data and Analysis Process

All micro-teaching sessions were videotaped. Videos of Pamela's first and third micro-teaching sessions are the data source. The analysis in this report explores how Pamela utilized words to create opportunities for learning. I used a whole-to-part inductive approach (Erickson, 2006), beginning with watching the entire video without coding, stopping, or pausing. In this phase, I took preliminary field-notes focused on the teacher's facilitation of the discussion. I then played the video and used NVivo software to code the media files (Wainwright & Russell, 2010). To ensure that the video coding of words was appropriate for the disciplines of mathematics and science, I partnered with a science-teacher educator. Together we identified video excerpts in which Pamela used words to elicit learning.

Findings

In this section, I present some episodes from the micro-lessons. These episodes are representative of Pamela's facilitation of the micro-teaching sessions and her use of discipline-specific terms to elicit learning in her own discipline and in a different discipline. When micro-teaching her own discipline, Pamela elicited information and then provided the discipline-specific terms. Conversely, when micro-teaching a different discipline, Pamela's approach involved attempting to elicit information through discussion, then providing the discipline-specific term; however, that approach evolved to the point that she began to participate in the discussion as a learner.

Learning Science through Word Use
