Land Acknowledgment

The Local Organizing Committee acknowledges the Osage, Sioux, and Miami Tribes, among others, on whose ancient and sacred land we held this conference. We note that the state colonially known as “Missouri” has no federally-recognized Native American reservations, underscoring the profound extent of the genocide, forced displacement, and cultural erasure of indigenous peoples. As a PME-NA community we recognize the ever-present systemic inequities that stem directly from past wrongdoings and we commit ourselves indefinitely to respecting and reconciling this long history of injustice.

PME-NA History and Goals

PME came into existence at the Third International Congress on Mathematical Education (ICME-3) in Karlsrühe, Germany, in 1976. It is affiliated with the International Commission for Mathematical Instruction. PME-NA is the North American Chapter of PME. The first PME-NA conference was held in Evanston, Illinois in 1979. Since their origins, PME and PME-NA have expanded and continue to expand beyond their psychologically-oriented foundations.

The major goals of the International Group and the North American Chapter are:

1. To promote international contacts and the exchange of scientific information in the psychology of mathematics education;
2. To promote and stimulate interdisciplinary research in the aforesaid area, with the cooperation of psychologists, mathematicians, and mathematics teachers; and
3. To further a deeper and better understanding of the psychological aspects of teaching and learning mathematics and the implications thereof.

PME-NA Membership

Membership is open to people who are involved in active research consistent with PME-NA's aims or who are professionally interested in the results of such research. Membership is open on an annual basis and depends on payment of dues for the current year. Membership fees for PME-NA (but not PME International) are included in the conference fee each year. If you are unable to attend the conference but want to join or renew your membership, go to the PME-NA website at http://pmena.org. For information about membership in PME, go to http://www.igpme.org and visit the "Membership" page.

PME-NA Steering Committee

Elected Members

Cindy Jong (chair), *University of Kentucky*, cindy.jong@uky.edu
Eva Thanheiser, *Portland State University*
Shari Stockero, *Michigan Technological University*
Crystal Kalinec-Craig, *University of Texas at San Antonio*
Jennifer Holm, *Wilfrid Laurier University*
Theodore Chao, *The Ohio State University*
Chandra Orrill, *University of Massachusetts - Dartmouth*
Jessica Hunt, *North Carolina State University*
Ana Isabel Sacristán, *Center for Research and Advanced Studies (Cinvestav)*
David M. Bowers, *Michigan State University*
Osnat Fellus, *University of Ottawa*

Appointed Members

Aaron Brakoniecki (webmaster), *Boston University*, brak@bu.edu
Ji-Yeong I (treasurer), *Iowa State University*, jiyeongi@iastate.edu

Conference Chairs

Past Conference Co-Chairs (2016–2019)

Andy Tyminski
Clemson University
amt23@clemson.edu

George Roy
University of South Carolina
roygj@mailbox.sc.edu

Tommy Hodges
University of South Carolina
hodgeste@mailbox.sc.edu

Current Conference Co-Chairs (2017–2020)

Samuel Otten
University of Missouri at Columbia
ottensa@missouri.edu

Amber G. Candela
University of Missouri at St Louis
candelaa@umsl.edu

Zandra de Araujo
University of Missouri at Columbia
dearaujoz@missouri.edu

Cara Haines
University of Missouri at Columbia
carahaines@mail.missouri.edu

Chuck Munter
University of Missouri at Columbia
munterc@missouri.edu

Future Conference Co-Chairs (2018–2021)

Ana Isabel Sacristán
Center for Research and Advanced Studies (Cinvestav), Mexico
asacrist@cinvestav.mx

José Carlos Cortés-Zavala
AMIUTEM / Universidad Michoacana de San Nicolaìs de Hidalgo, Mexico
jcortes@umich.mx

Strand Leaders

The Local Organizing Committee is extremely appreciative of the following people for serving as Strand Leaders. They managed the reviewing process for their strand and made recommendations to the Local Organizing Committee. The conference would not have been possible without their efforts.

Preface

Dear Colleagues,

On behalf of the 2019 PME-NA Steering Committee, the 2019 PME-NA Local Organizing Committee, and the University of Missouri (Columbia and St. Louis), we welcome you to Saint Louis, Missouri, USA, for the Forty-First Annual Meeting of the International Group for the Psychology of Mathematics Education – North American Chapter, held at the Hyatt Regency St. Louis at the Arch.

This year's conference theme is **"...against a new horizon."** We decided on an intentionally intriguing and possibly provocative motto, taken from Vice President Hubert Humphrey's 1968 dedication of the St. Louis Arch. Originally, the phrase was intended to invoke the backdrop of "westward expansion" behind the newly constructed and picturesque arch. But for the Indigenous people of the continent, that development meant displacement and death. And the very erecting of a monument on the banks of the Mississippi River also displaced many African American residents and businesses in St. Louis. From perspectives within these nations and communities, the expansion was likely something to be "against."

These differing views on "expansion" mirror the differing views in relation to many issues our country generally, and our field of mathematics education in particular, face today. Events that some view as a positive new horizon may actually constitute a form of oppression for others... something to be against. We acknowledge our work is not done in isolation but rather in spaces with others. We acknowledge the complexity of the space this conference occupies and encourage attendees to learn more about St. Louis's past and present as we connect those events to our respective contexts. (For further information on Missouri's history in relation to Civil Rights, visit http://mohistory.org/exhibits/1civilrights/.)

We hope this conference serves to provoke open and critical dialogue from which we all will learn. To this end, we have reconceptualized the plenary sessions. Rather than using the plenary sessions and communal meals to share and discuss empirical research, we are inviting a variety of unique voices to help spur innovation and reflection on what contested ideas such as "expansion" and "growth" might mean in mathematics education from different perspectives.

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

This year's conference will be attended by more than 500 researchers, faculty members, and graduate students from around the world including Canada, Mexico, Turkey, Korea, and nearly every state in the USA. Each paper was reviewed by multiple referees in a double-blind process. The result was an overall acceptance rate of 68%, with 32% of research report submissions accepted as research reports, 53% of brief research report submissions accepted as brief research reports, 65% of poster submission accepted as posters, and 81% of working group submissions accepted. The papers eventually accepted comprised 67 research reports, 184 brief research reports, 126 Posters, and 13 Working Groups.

For this conference we created new strands and reframed others. We reintroduced equity and justice as a strand (in addition to its presence in the submissions as keywords) and precalculus, calculus, and higher mathematics as well as newly adding instructional leadership, policy, and institutions/systems. We merged technology with curriculum and statistics & probability with geometry. We also added miscellaneous topics to the theory and research strand. The most popular strand continues to be preservice teacher education.

We thank the many people who generously volunteered their time over the past year in preparation for this conference. We thank Helen Novielli for her assistance with formatting the conference proceedings and we have extreme gratitude for the work of Kate Stottle in helping us secure the conference venue, lead the registration process, create the conference app, and generally making everything run smoothly.

We hope this conference will establish a space to look forward in our field, perhaps toward a new horizon that we can all be *for*, clear-eyed and in solidarity. :-P

Cheers,
Sam Otten, Amber Candela, Zandra de Araujo, Cara Haines, & Chuck Munter

Chapter 1:
Plenaries

BUILDING REGIONAL BRAIN REGIMES TO SUPPORT MATHEMATICS ATTAINMENT

William F. Tate IV
Washington University – St. Louis
wtate@wustl.edu

Author's note: This paper is based in part on "Beyond Education Triage: Building Brain Regimes in Metropolitan America," in *Facing Segregation: Housing Policy Solutions for a Stronger Society*. This paper was adapted from an address given during Facing Segregation: Building Strategies in Every Neighborhood, the 2019 annual conference of the Metropolitan St. Louis Equal Housing and Opportunity Council, on April 12, 2019, at Central Baptist Church, St. Louis, Missouri. The paper was presented through a partnership between the Center for Social Development at Washington University in St. Louis and the council. An earlier version of this paper appeared in Tate (2019a). A version of this paper served as the foundational remarks for the opening plenary session of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.

Thank you for the opportunity to speak with you briefly. I begin my remarks by defining a term. Usually we hear the term *regime* and we think of something negative. But regimes vary. Positive and negative regimes exist. Here in St. Louis, we experience an example of a negative regime. We call it a segregation regime. A regime equates with a public–private arrangement organized to make and execute governing decisions (Stone, 1989). In my opinion, this city and many other urban cities put together public–private partnerships arranged and orchestrated in such a way that they are elite and effective. They influenced the community in a negative fashion, but in light of their goals proved effective. It's possible to harm, yet produce the desired result. That's extremely important to understand.

We also have here a great sports regime; in fact, we have public–private partnerships that support the advancement of our teams. Recognized across the United States and the globe, the Cardinals offer an example of an exemplary sports franchise. It's an amazing sports regime. We even had a football team here called the Rams. And if you recall, we organized a public–private partnership to generate close to $500 million to keep a losing football team in St. Louis. They were losing then, and it amazed me how quickly that financial package was done—how well it was done. To create what? A giant house. We organized a public–private partnership, a sports regime, to create a giant house to keep a sport associated with brain injury (Mez et al., 2017). Brain injuries result from more than physical contact. Our environment harms and protects the brain. Ultimately, I raise this question for every city across this country: Why can't we organize public–private partnerships to protect and to nurture the brains of our children? It should be easy. We do it for sports. We are elite at segregation regime building. Why can't we do it to protect the babies and children?

Theoretical frames guide. I'm going to illustrate my guiding theory in quick fashion: communities matter. Communities interact with schools, and there's a symbiotic relationship between schools and communities. On average, high performing and functional schools exist in "good" communities and low performing schools operate in less desirable communities.

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

Everybody knows it; the real estate agents preach it; and that's the way it goes, right? And if students reside in a community associated with fewer protective factors, there's a residual product. They experience increased risk of school dropout, unemployment, poor health, and other less-positive developmental outcomes. These factors increase the likelihood of ending up subsidized by the government's social welfare or criminal justice programs. This pathway operates in circular fashion feeding back into the community. That's the negative pattern of Figure 1.

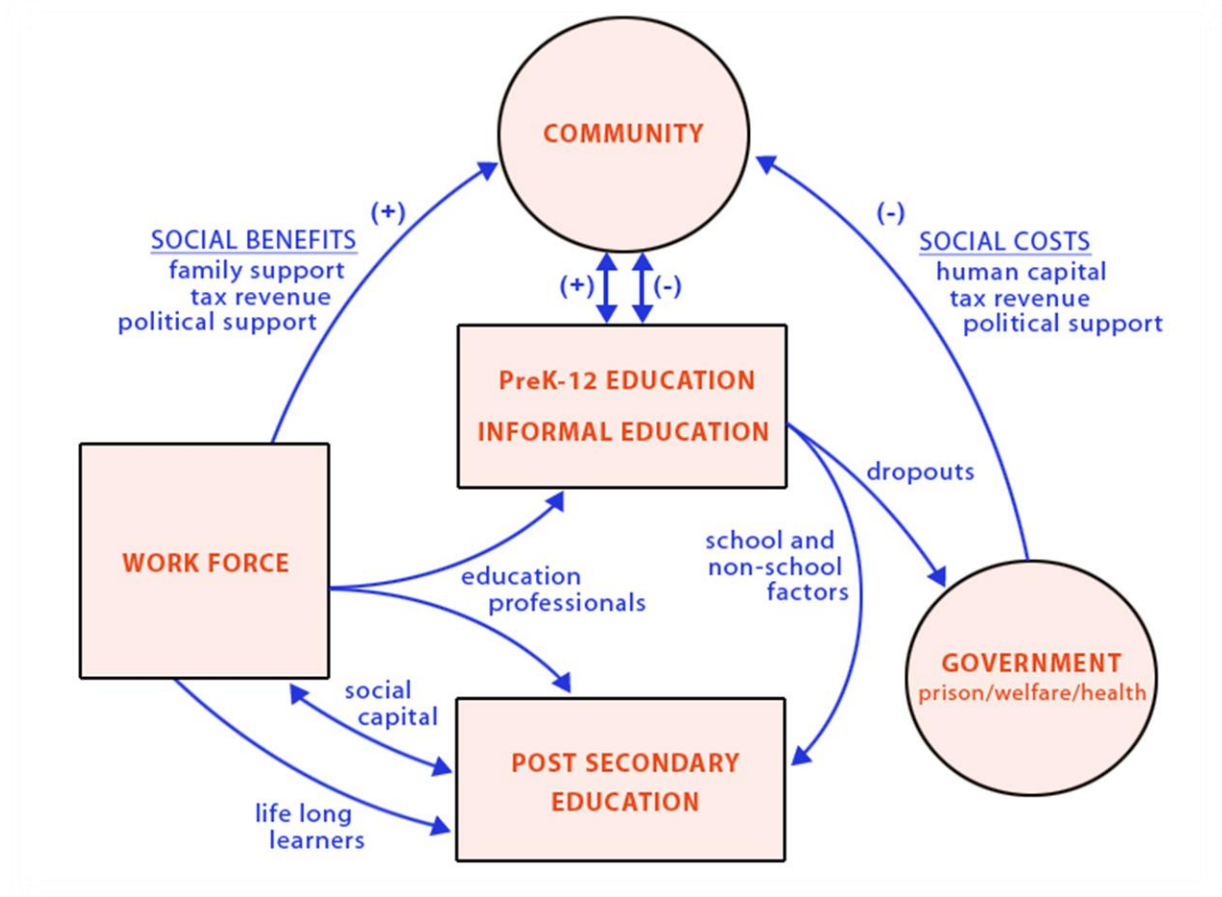

Figure 1. Conceptual model of community, education, and life course outcomes

In contrast, the other pathway generates a net positive result. And these communities stay intact over time. In the communities where the institutions work well, the schools work well; the young persons end up in postsecondary education or network into jobs; they become politically active; they generate positive tax revenue; and the residents with this experience return to live and to maintain the same kind of communities. This pattern replicates itself over and over. These two—communities and schools—are married. Rarely does the pattern change without massive intervention (Johnson, 2012).

From my perspective, this matter involves geography. I'm interested in how geography works and whether or not the first law of geography captures how opportunity organizes in our lives. Some of you might say, What is the first law of geography? It's straightforward. The first

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

law of geography is that near things are more similar than distant things (Tobler, 1970). Things that are close together are very much alike. It's a very, very clean conceptual idea. What does that mean for residents in Missouri and St. Louis?

Figure 2 is a map with an equation at the top:

$$y_1 = B_o(u_1, v_1) + B_1(u_1, v_1)x_{i1} + B_k(u_1, v_1)x_{ik} + \varepsilon_i$$

To understand the idea behind the equation, we need Siri. Has anyone here asked Siri what the weather is in Missouri? You can do it right now.

What did she say? Did she tell you the weather in Jefferson City, in Kansas City, or in another metro region? I have never heard Siri give a weather report for the state of Missouri. You know why? State weather reports are less useful for most decisions. And Siri operates just like my equation; it gives you a local report on conditions.

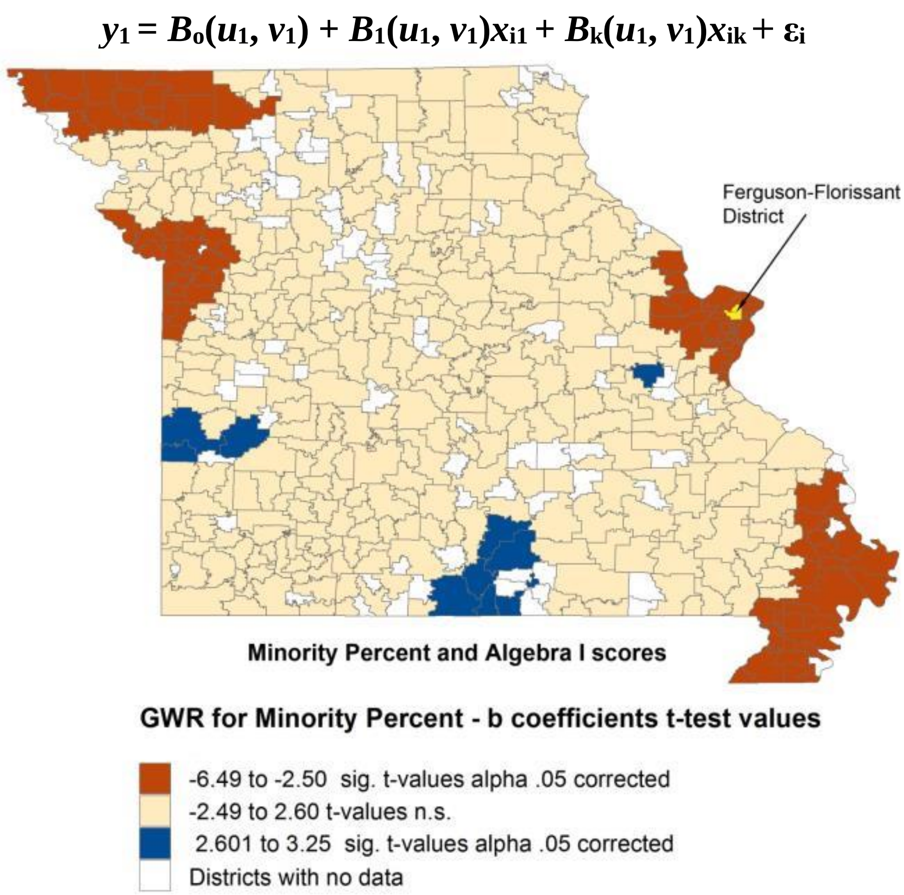

Figure 2. Minority percentages and Algebra 1 scores. GWR = geographically weighted regression. Adapted from "Place, Poverty, and Algebra: A Statewide Comparative Spatial Analysis of Variable Relationships," by M. C. Hogrebe and W. F. Tate IV, 2012, Journal of Mathematics Education at Teachers College, 3, p. 18. Copyright 2012 by the Program in Mathematics and Education, Teachers College, Columbia University in the City of New York. Adapted under Creative Commons Attribution 4.0 International Public License.

I want to know how my neighbor is doing. My equation tells us how we're doing in our neighborhood. Initially, I examined two variables. My interests include mathematics attainment. I investigated the relationship between the percentage of minority students in schools and algebra scores, and I modeled the relationship using my equation to get the local report in the context of the state of Missouri. And I discovered that the first law of geography captures the relationship—similar relationships cluster. The map illustrates that in the St. Louis metro region. There is a negative relationship between the percentages of minority students in schools and algebra performance: the more minorities, the lower the score.

And notice that, across the state, Kansas City looks the same way. And strikingly, so does our rural neighbor, the Bootheel. I don't have time to talk about the Bootheel, but I want to point out that the Bootheel and many of our urban communities have many similarities. We just haven't figured out politically how to operate together. The urban and rural divide represents a political shortcoming in light of the empirical evidence.

I'm very interested also in how students experience school discipline. Research demonstrates a relationship between school discipline and mathematics achievement (Lacoe & Steinberg, 2019). I sought to determine the relationship between school discipline and mathematics attainment in Missouri. Does clustering exist? Do these things happen in tandem? We have to think about youth in terms of layers: They're in our schools; they're in residential housing; they're in communities; and so on. And here in the state of Missouri, we have one of the largest gaps between Blacks and Whites in suspensions. In fact, as Figure 3 shows, our region experiences many of the largest racial disparities in the country.

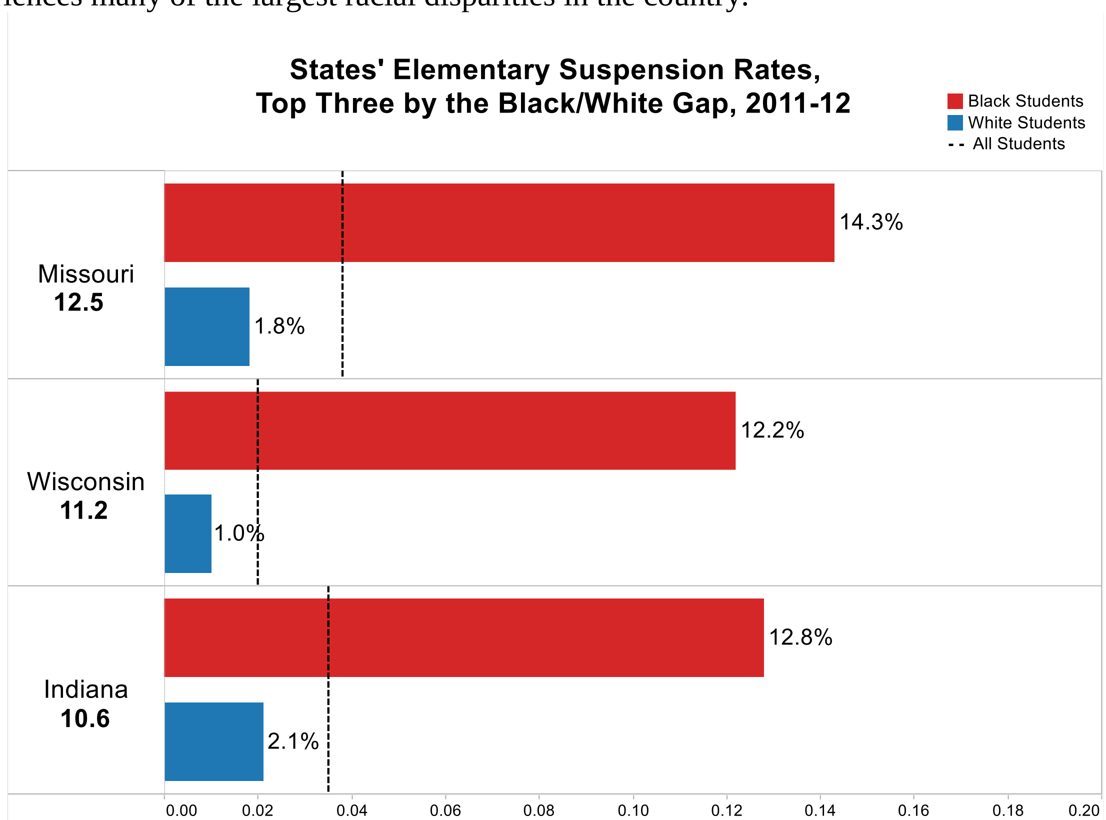

Figure 3. Adapted from "Ferguson and Beyond: A Descriptive Epidemiological Study Using Geospatial Analysis," by B. D. Jones, K. M. Harris, and W. F. Tate IV, 2015, *Journal of Negro Education*, 84, no. 3, p. 235. Copyright 2015 by the *Journal of Negro Education*.

Of the six highest suspending districts in the United States of America, three are in metropolitan St. Louis. That's important because it's geographically aligned. It's clustered. Are you following the pattern? The first law of geography applies. Near things appear more similar.

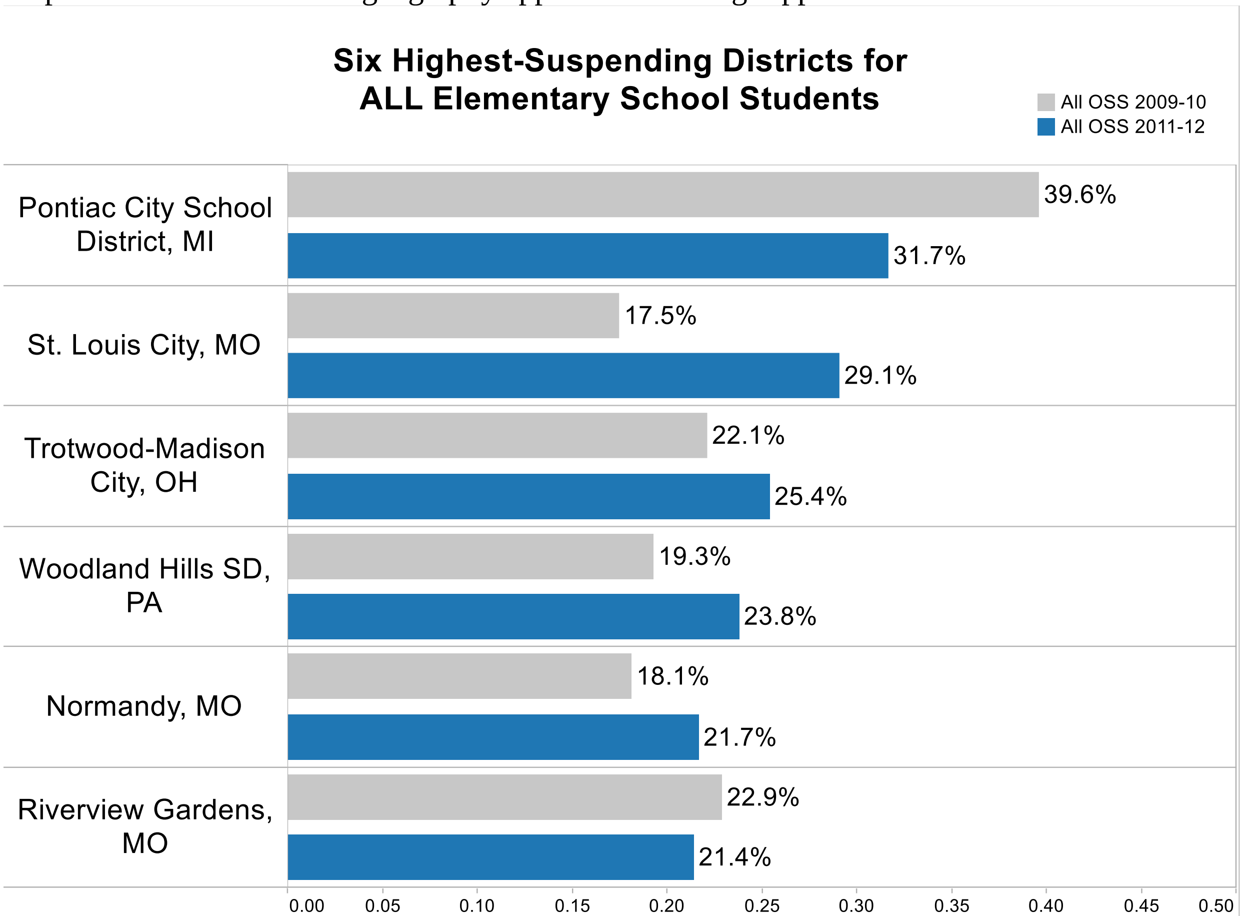

Figure 4. OSS = out of school suspensions. Adapted from "Ferguson and Beyond: A Descriptive Epidemiological Study Using Geospatial Analysis," by B. D. Jones, K. M. Harris, and W. F. Tate IV, 2015, *Journal of Negro Education*, 84, no. 3, p. 235. Copyright 2015 by the *Journal of Negro Education*.

Now remember my question of interest focuses on mathematics attainment, so I want to know whether a relationship between learning algebra and discipline exists. Figure 5 illustrates the relationship between discipline in schools and algebra performance in Missouri. A negative relationship exists with clustering in metropolitan St. Louis-the higher the discipline rates, the lower the algebra scores in the school.

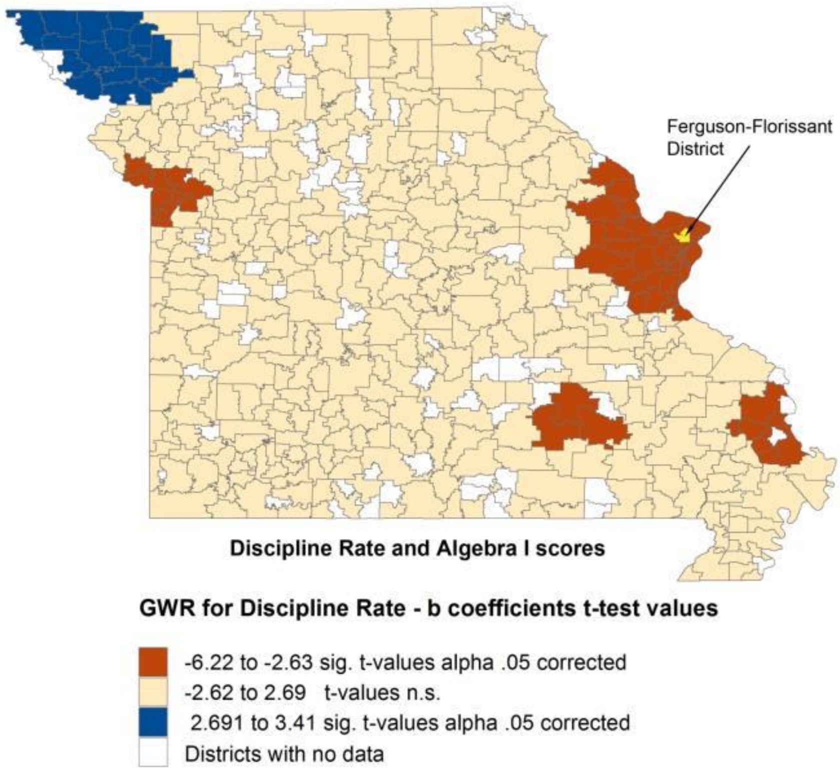

Figure 5. Adapted from "Place, Poverty, and Algebra: A Statewide Comparative Spatial Analysis of Variable Relationships," by M. C. Hogrebe and W. F. Tate IV, 2012, *Journal of Mathematics Education at Teachers College*, 3, p. 19. Copyright 2012 by the Program in Mathematics and Education, Teachers College, Columbia University in the City of New York. Adapted under Creative Commons Attribution 4.0 International Public License.

This relationship requires intervention. The *For the Sake of All* project described solutions consistent with sound developmental science (Purnell, Camberos, & Fields, 2015). Space does not permit a review of the recommendations here. My point is that we have a challenge. Housing is related to our challenge. Geography captures our challenge. And based on my initial model, if this continues, those young people won't learn algebra; the region's workforce and their academic opportunity pathways require an understanding of fundamental algebraic concepts. Our research indicates that algebraic understanding clustered geographically and without intervention will cause these young people and their communities to continue to experience economic stress. So let's think about it further. What happens when we think about the share of students receiving free- and reduced-price lunches—whether receipt is related to graduation rates? The relationship clusters. The higher the share of students that receive free and reduced lunch, in terms of distribution within the school, the lower the graduation rate. Metropolitan St. Louis and metropolitan Kansas City are the only places in the state of Missouri where that relationship is statistically significant (Tate & Hogrebe, 2015). Be clear, we should attend to all students throughout the state. However, the two metro regions offer an opportunity for targeted policy.

My colleagues and I sought to understand better the relationship between socioeconomic status and dropout rates. We examined the association between free and reduced lunch and dropout rates. Again we found that similar pattern in metropolitan St. Louis, Kansas City, and the Bootheel: a positive relationship between free and reduced lunch and the dropout rate. The higher the share of students with free and reduced lunch, the higher the dropout rate—those three areas represent the only places where that relationship is statistically significant in the state (Tate & Hogrebe, 2015).

I offer my recommendations in succinct fashion. First, we need prenatal care at scale in St. Louis. We know differentiation by race exists. It's extremely important to intervene. Second, we need a consumer report on preschool quality. Financial resources and tax incentives support; yet tax credits don't help consumers distinguish good preschools from less robust learning environments. Finding a good preschool proves especially difficult if the child's caregiver lacks the benefit of the right social networks. Third, we need to expand health insurance to families. Health insurance for children supports the care that fosters brain development and positive cognitive outcomes (Cohodes et al., 2016). I don't understand why the economic calculus is so misunderstood. The cost–benefit on this investment offers clarity. We know that if we give insurance to children only, it falls short of the robust effect associated with family coverage. These recommendations offer evidence-based practices to guide a positive regime change. We don't have to speculate.

Fourth, we need to build our teacher workforce. I work in education, and the shameful state of education saddens me. In some places, permanent substitute teachers teach students. And the students are being assessed with high stakes accountability. We know that teacher disparities abound and teacher effects are greater than school effects. If I showed you the distribution of teacher quality across the region, you would see that the disparities are stark and geographically cluster in a fashion consistent with the first law of geography (Schultz, 2014). We need to intervene.

Fifth, we need to attend to the role of artificial intelligence and the distribution of health and human services. I wrote about this topic for the *St. Louis American* (Tate, 2019b), and I expanded on it in *Diverse Issues in Higher Education* (Tate, 2019c), noting that the emerging area of algorithmic justice represents the new frontier of civil rights. Housing and residential patterns loom large in computational models informing the distribution and access to social benefits and economic opportunity. We need robust K–12 science and math education to develop stronger citizen scholars. People need to be prepared to understand how algorithms guide policy and to be taught to engage in thoughtful debate. Bob Moses called math and science the new civil rights (Moses & Cobb, 2001). He was correct. The massive funding disparities in education must be dealt with, and it's not just what the government distributes. We know that affluent families invest more money into their children than less wealthy families; and that their resource hoarding represents a foundational challenge to the democratic project (Reeves, 2017).

Sixth, we need to reclaim all the people who have been pushed out of school. We have pushed millions of people out of school in the United States, and we just ignore them.
And finally, the food deserts. My colleagues at *For the Sake of All* made some extremely important contributions (see, e.g., Cambria, Fehler, Purnell, & Schmidt, 2018; Purnell, Camberos, & Fields, 2015). I was happy to be on that team. They recognized the importance of food and nutrition as foundational to cognition, development, and human health. So if we don't deal with food deserts, the cycle of negative social outcomes articulated in my theory continues.

All of this leads me back to the point that we need a brain regime. And it's fitting that we're meeting in the backdrop of the arch landing and the Mississippi riverfront. We're going to need an effort akin to the engineering of the arch and the power of the great river-i.e., a great design and a strong will respectively.

Fannie Lou Hamer is my hero. In *Beyond the Big House,* my colleague Gloria Ladson-Billings characterized various people, including Hamer, and how they challenged the segregation regime of our society (Ladson-Billings, 2005). I will end by saying all of us need to get a little bit of the Fannie Lou. Thank you.

CHALLENGING IDEOLOGIES, CULTIVATING COGNITION, AND REKINDLING COMMUNAL-BONDEDNESS: ADDENDUM TO "BUILDING REGIONAL BRAIN REGIMES AND SUPPORTING MATHEMATICS ATTAINMENT"

Jerome E. Morris
University of Missouri - St. Louis
morrisjer@umsl.edu

Author's note: This paper is part of an opening keynote address at the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education. This paper represents the second part of a scholarly conversation with Dr. William F. Tate IV, who authored the first paper, "Building Regional Brain Regimes to Support Mathematics Attainment." Participants convened in St. Louis, Missouri, from November 14–17, 2019.

I want to thank the organizers for the opportunity to engage in this intellectual and scholarly exchange about enhancing education and specifically supporting mathematics attainment with Dr. William F. Tate--someone that I admire for his intellectual insights and ongoing contributions to the academy, the public, and the development of future scholars. As an interdisciplinary researcher whose own research examines the nexus of race, social class, and the geography of educational opportunity with a focus on the U.S. South, the examples and focus that Dr. Tate presented resonated with aspects of my research. Also, I would like to note that students from a course that I teach at the University of Missouri - St. Louis (UMSL) are in attendance. I want to acknowledge them.

A conversation about building regional brain regimes and mathematics attainment must first offer a critical understanding of rigid notions of perceived intellectual ability and the brain. Although not specifically stated in Dr. Tate's paper, enduring ideological beliefs about Black and Brown people's intellectual abilities--whether locally or globally--serve as a major impediment to building racially and gender inclusive regional brain regimes. These beliefs must be challenged. If one examines the historical literature concerning intelligence, an inference may be drawn that the fields of psychology and mathematics have maintained an allegiance to racist and sexist themes that have perpetuated the perception that Black people, Native Americans or First Nations People, women, and other groups are innately intellectually inferior to White men. In many instances, psychological research legitimated (however subjectively) overt racist themes concerning the presumed intellectual inferiority of non-European groups.

As Dr. Tate described, regimes that are effective, but not necessarily good, do in fact exist. He illustrated how sports serves as one example. Dr. Tate made the point that if political, business, and civic stakeholders can garner resources and muster the will to support sports regimes such as what was done in St. Louis in order to keep the St. Louis Rams football team in the city, then building regional brain regimes that empower people should be pursued, especially in regions such as Saint Louis. In terms of the sports example that he used, however, I would like to add that an important variable that must not be overlooked is that sports regimes are tied to economics. This kind of regime building, especially as it relates to major revenue generating spectator sports such as basketball and football, is predicated on the accrual of wealth via the disproportionate reliance on Black people's bodies (Hawkins, 2010).

Sports regimes are pervasive in the U.S. and play a critical role in creating economic prosperity for some and illusions of opportunities for others. For example, although schools, colleges, and universities are supposed to support students' brain development, administrators and systems eagerly support collision sports such as football that contribute to brain injury. Why? Because high schools and universities use the publicity from major revenue generating spectator sports such as football and basketball to heighten institutions' branding, and thereby, increase student enrollment and alumni donations (Adeyemo & Morris, in press; Donnor, 2005). On the other hand, Black males who disproportionately play revenue generating spectator sports at many of these top academic and athletic institutions graduate at lower rates than their athletic and non-athletic peers (Harper, 2016). An article by philosophy and education professor Randall Curren and law professor J.C. Blokhuis note how:

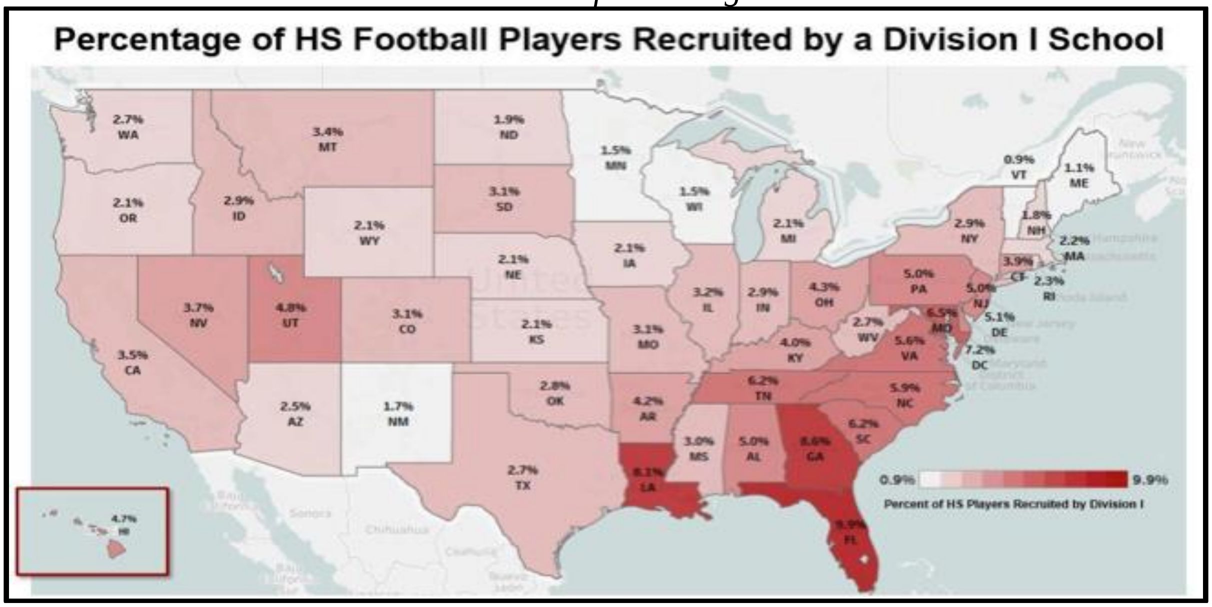
> U.S. public schools' sponsorship of tackle football is ethically indefensible and inconsistent with their educational aims. Their [Randall & Blojuis'] argument relies on three ethical principles and a growing body of evidence that many students who play football suffer traumatic brain injury and cognitive impairment that undermine their academic success and life prospects, whether or not they suffer concussions (p. 141, Curren & Blokhuis, 2018).

Despite such ethical dilemmas, these sports regimes experience astronomical economic growth. While racial achievement gaps often fall along gender lines and Black males find themselves struggling academically, sports regimes have found ways to ensure that significant numbers of Black males go through an educational and social system to ensure that a so called product--in the form of an athlete--becomes displayed on the field or the basketball court. This is not unlike that which occurred during enslavement. As a former college quarterback who grew up in Birmingham, Alabama, I know first hand, as well as scholarly, about the sports regime.

A former graduate student of mine who worked with me when I was on the faculty at the University of Georgia, Dr. Adeoye Adeyemo who is now a visiting assistant professor at the University of Illinois-Chicago, and I have researched how geography and race are shaping the experiences and beliefs of Black male high school students who play sports in the South and Midwest. In our forthcoming *Teachers College Record* article, we note the imperativeness of developing young Black male students who become valuable members of society as a result of their academic promise and achievements, and not solely because of their potential and ability to play sports. Too often, these students end up participating in an industry that generates billions of dollars for others, while leaving them feeling exploited once their playing days are over. I would like to further note that Dr. Adeyemo is doing some wonderful research around the beliefs and aspirations of Black male high school students who play sports.

The following map illustrates how geography and history are implicated in high school and college football sports regimes today. As Map 1 reveals, in states such as Georgia, Florida, and Louisiana, almost 10 percent of male high school students who play football become recruited by a Division I football program. What do we know about these states as they relate to geography, history, and race? First, we see the point that Dr. Tate made about the first law of geography and how nearer things are more similar than distant things (Tate, 2019; Tobler, 1970). We see that the southern states are disproportionately darker red in comparison to the other regions of the United States. A general understanding of history and geography informs us that these represent former slave states in the South and once served as vital cash crop states in order to build the economic base of the United States. It is not coincidental then that universities in these same former slave states now rely on Black male students who play football to increase universities' student enrollment and further grow the wealth of these sports programs. College sports represent a new form of a plantation system as Hawkins (2010) asserts.

Map 1: High School Football Players, Division I Recruits, 2015-2016
Source: National Federation of State High School Associations



Notes: Percent derived from the number of DI football recruits from 2013-2016 divided by the number of boys football participants per state in 2015-2016 as reported by the National Federation of State High School Associations. Alaska (1.2%) not pictured.

On the other hand, poverty is disproportionately along racial lines in the South, as well as throughout the United States. As I have written elsewhere, the U.S. South continues to play a unique role in understanding the intersection of race, place, poverty, and the experiences for Black people in a range of areas (Morris & Monroe, 200). It is the region where most Black people historically have lived and continue to live. It is the poorest region of the country and the majority of its public school children are minority and low-income (Southern Education Foundation, 2007, 2013). Whereas White children living in the South are also more likely to be poor in comparison to other regions, as Figure 1 illustrates, we see that Black children living in Deep South states are much more likely to live in poverty than White Children (see Fass &

Cauthen, 2005; Morris, 2008). Black children attending public schools in the South are four times more likely to live in poverty in comparison to White children. Black children also are more likely to experience extreme forms of segregation (known as hypersegregation) along multiple dimensions such as where they live, the extent of their interactions with other racial groups, and their concentration in neighborhoods (Massey & Tannen, 2015). The South, as a region, has the most hypersegregated metropolitan areas.

The South, as a region, is not alone in terms of understanding how place adversely shapes social and educational opportunities and outcomes for Black people. Although the South has the majority of hypersegregated metropolitan areas for Black people, many of the metropolitan areas with the *most extreme* black hypersegregation are located in the Midwest. These metropolitan areas include Chicago, Cleveland, Detroit, Milwaukee, and St. Louis. St. Louis remains one of the most hyper-segregated cities in the United States (Gordon, 2009; Massey & Tannen, 2015).

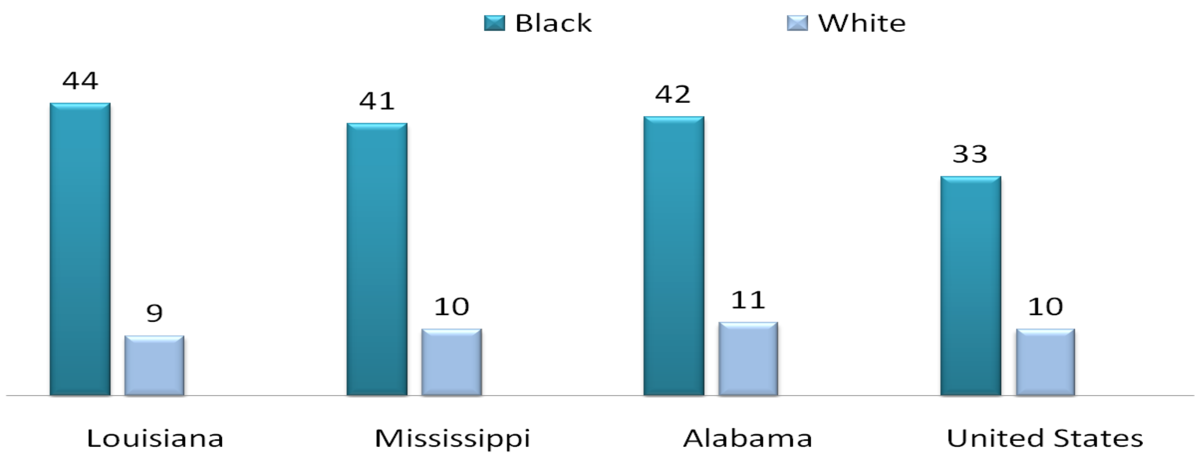


Figure 1: Poverty percentage for Black and White children in selected southern states and in the United States as a whole, 2004. Data are from the National Center for Children in Poverty (www.nccp.org). Copyright 2005 by National Center for Children in Poverty. Adapted with permission.

Shifting Ideology

The above highlighted how race, place, and poverty buttress sports regimes, and how such regimes rely on Black bodies as a source of revenue. Building regional brain regimes within a world view that relegates Black people to a subordinate status, and that views Black people as primarily physical, but not necessarily intellectual, will require the disruption of such ways of thinking. How can one disrupt these rigid notions of race and intellectual ability, along with entrenched racial patterns of schools and communities? On a micro-level, an example from my Black achievement research study in the U.S. South captures how one Black family challenged such rigid ideas (Morris, 2006-2011).

Jahmel, a third-grade student from a working class family in Metropolitan Atlanta, Georgia, took an entrance exam to attend the public school district's high achievers elementary school--which was a racially diverse magnet school. Jahmel's exam score did not meet the cutoff score set by the school. Committed to ensuring that Jahmel benefited from the excellent teaching that is available to high achieving students in such schools, Jahmel's mother and his uncle demanded a meeting with school administrators in order to discuss his overall academic record, beyond the entrance exam. Jahmel was later allowed to enroll into the high achievers' school and earned mostly A's throughout elementary and middle school. Six years later, Jahmel, a 9th grader, enrolled in the district's high-achievers' high school. Jahmel eventually graduated from high school with a 3.8 unweighted GPA, scored in the 92nd percentile on the SAT, and received the most distinguished scholarship given to an incoming freshman at a major state university. In my ethnographic interview with Jahmel and his mother, Jahmel believed that a third grade admission test could not adequately measure his academic potential or aptitude. He went on to describe how the intense preparation he received in school, as well as his determination and persistence, were instrumental in his academic achievement in school and performance on the SAT.

Another example, this one from my college classroom teaching experience, further highlights the importance of challenging ideological beliefs. In one particular course, a White male teacher, who was a student in my university-level course, described how his misperceptions of students' academic abilities shaped the way he responded to various students by race:

> In one of my classes, an Asian-American student did not perform well on most of his math homework. When he would turn it in, I allowed him to re-work the questions and would often say to him, "I know you can do this!" So, I was lenient on him because I had high expectations, honestly, because he was Asian. However, when I think about it and my view of Asian-Americans in this way, I do not know if I would have allowed a Black student to have had so many opportunities to prove that he was smart.

Although Asian-American students are often perceived as high-achievers and model minorities, many face academic and social challenges within schools and classrooms (Lee, 2009, 1994). This particular Asian-American student's academic gaps were not attributed to his intellectual abilities, but to an inability to grasp certain mathematical concepts at that time. Unfortunately, too many educators simply give up on Black students and assume that they are incapable of doing high-level academic work, particularly in mathematics. This example further demonstrates how the assumptions and mindset that some educators bring to their interactions with Black students can limit academic options, and ultimately, opportunities to fully develop academic talent. An ideological shift about the nature of race and intellectual ability is a first step in envisioning the building of a regional brain regime that reflects inclusivity and equity.

While I presented how one Black mother and an uncle pushed back against ideological views of one students' academic abilities, the reality is that a myriad of structural factors constrain the opportunities for poor Black children in U.S. public schools. Too often, where students live and go to school, as well as their race and economic status, limit their academic opportunities. Quite often, children of color are disproportionately represented among those living in poverty (Aud, Fox, & KewalRamani, 2010) and attending high-poverty schools. For example, forty-six percent of Hispanic students and 44 percent of Black students attend high-poverty schools--schools in which more than 75 percent of the students are eligible for free or reduced-priced lunch. Moreover, Black children are significantly more likely than any other group of students to experience extreme segregation by neighborhood and school (Massey & Tannen, 2015). Given the intransigence of racial isolation and poverty within schools and communities, what must be done? One may call for the continued pursuit of integration in U.S. schools, but will that be the case in a racially-stratified society where fears within the real-estate market and about school quality have become culpable in the maintenance of rigid boundaries between Black and White people? (Fox, Cybelle & Guglielmo, 2012). I'll return to these questions in the latter part of this paper.

A second aspect around brain development and mathematics attainment that Dr. Tate described, but often is ignored, is the role of early childhood nutrition in brain development. Dr. Tate mentioned the *For the Sake of All* research project, led by Dr. Jason Purnell and colleagues (2015), which included Dr. Tate. They focused on the imperativeness for healthy children, families and communities. I would like to expand on their thinking by asserting the importance of thinking about children's health and nutrition in utero and at birth--optimally with human mother's milk. I am co-leading a research team that is researching why some African-American mothers are successful at breastfeeding, contrary to the research that focuses heavily on disparities. Mary Muse, a public health researcher, is the lead researcher and director of the research project based in St. Louis (Muse, Morris & Dodgson, 2019). Building a brain regime will require encouraging, supporting, and sustaining optimal nutrition for infants within the region. For example, the scholarly literature has noted how human breast milk is best in a child's overall development. In fact, the benefits are there for the babies and mothers. Research has shown a positive link between breastfeeding and children's overall health and intelligence, even years after breastfeeding has concluded (Angelsen, Vik, Jacobsen & Bakketeig, 2001; Mortensen, Michaelsen, Sanders & Reinisch, 2002; Isaacs et. al, 2010). The above illustrates the importance of considering the ecological and sociohistorical context of nutrition and how structural, cultural, and historical forces contribute to the disproportionately low rates of breastfeeding among African-Americans, which then adversely affect mother infant bonding and children's early cognitive development.

A third point I will expound on is this notion of "community" in the building of a regional brain regime. Dr. Tate mentioned the importance of communities and how they are symbiotic in their relationships with schools. While that may be the case for many schools that are considered "good" schools today, we have seen how numerous educational reforms and policies--over decades--such as desegregation, charter schools, district restructuring, and state takeovers have undermined the symbiotic relationships that historically Black schools once had with Black students, families, and communities. I agree that supporting communities and schools is essential. But how do you support schools and communities that have been undermined through ongoing social and political forces? How do you support and sustain schools that continue to serve overwhelmingly low-income and Black students, families, and communities? I would like to suggest that in order to move forwards, we must look backwards. There is a West African concept called Sankofa, which captures this sense of going backwards first (The Spiritual Project, 2011). I know it probably sounds counterintuitive. Please follow me in my thinking.

Schools are part of a larger ecological structure (Bronfenbrenner, 1979) and serve as important places in communities and the lives of families and students (Driscoll, 2001; Morris, 2004; Payne & Ortiz, 2017; Warren, 2005). Schools play an important role in students' connectedness and in their overall educational experiences, outcomes, and well-being (Furrer & Skinner, 2003; Nasir, Jones & McLaughlin, 2011). Students who feel connected to schools demonstrate greater motivation than those who are not (Furrer & Skinner, 2003), and this sense of connectedness and belonging may be associated with students' improved academic achievement (Hawkins, Guo, Hill, Battin-Pearson & Abbott, 2001; Mendoza-Denton et al., 2002; Walton & Cohen, 2007, 2011; Walton & Brady, 2017). Thus, schools, as places, have also had meaning in Black people's lives. Unfortunately, there has been a deep sense of loss between Black people and their schools (Ewing, 2018; Morris, 2019b; Siddle Walker, 2000). Part of the reason is that policymakers and reformers who express interest in strengthening the relationships between schools that serve predominantly Black students, families, and communities tend to dismiss historical models that were built on trust, a sense of caring, and that reflected strong bonding in the relationships among schools, students, families and communities.

As a scholarly community, we now have a robust body of *historical research* about the "good" that existed within Black school-communities during the pre-*Brown* era (e.g., Anderson, 1988; Foster, 1997; Jones, 1981; Morris & Morris, 2002; Morris, 2008; Savage, 1998; Siddle Walker, 1996, 2000). A key focus of my scholarship has been developing theoretical understandings and conceptual frameworks that support *contemporary* education through sociological and ethnographic studies of exemplary Black schools during the post-*Brown* era — an era characterized by White resistance to *Brown v. Board* vis-a-vis White flight, and serious fiscal and social crises within urban communities. From a synthesis of my scholarship and the body of historical studies that captured the ways in which schools once solidified Black communities, and educators demonstrated care and concern for students, I have distilled the tenets of a theoretical model known as *communally-bonded* schooling: (1) intergenerational trust and cultural-bonding between educators and students; (2) critical presence of Black educators; (3) educators who reach out to families; (4) principals as academic leaders who bridge schools and communities; and (5) schools serving as pillars in communities (Morris, 1999, 2002; 2004; 2009; 2019a). Given the intransigence of racism in U.S. schools and society (Bell, 1992; Ladson-Billings & Tate, 1995), and the important roles that schools can play in communities, I put forth *communally-bonded schools* as a conceptual—but pragmatic—framework for supporting schools' relationships with Black students, families, and communities (See Figure 2).

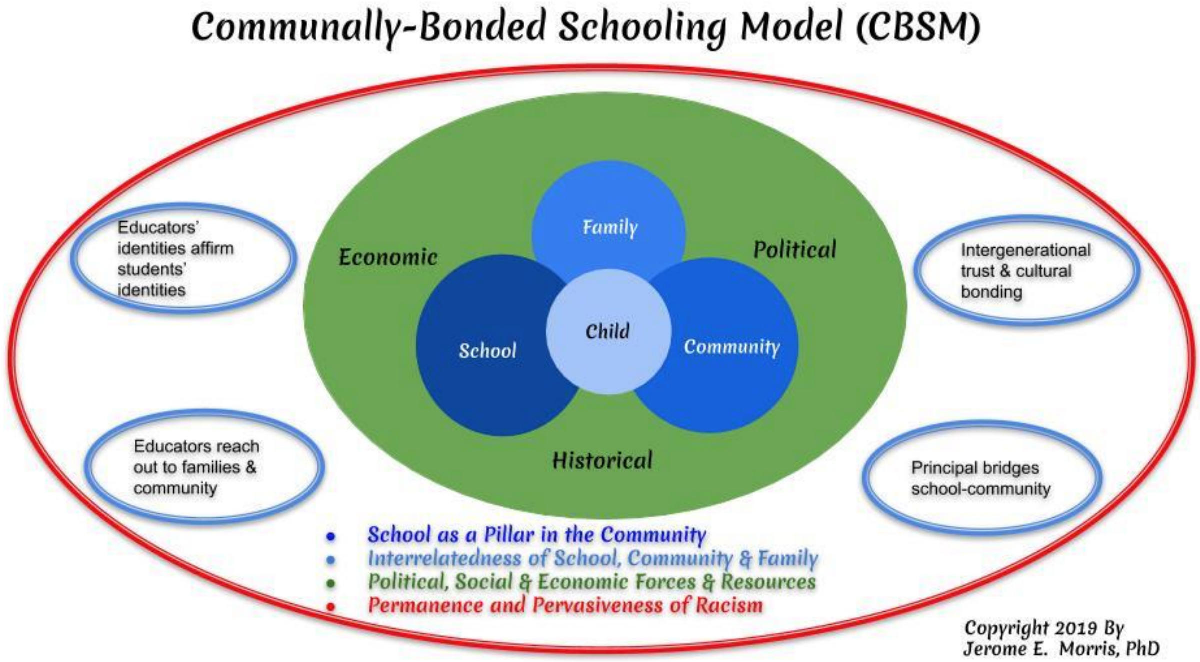

Figure 2: Communally-Bonded Model

Why St. Louis Matters: Building Brain Regimes and Rekindling Communally-Bonded Schooling

Generating the political will necessary for the building of regional brain regimes is another point to address. St. Louis is in a unique position given the international attention brought to the region as a result of the 2014 *Ferguson Unrest*, which was spurred by the killing of an unarmed Black male, Michael Brown, by Darren Wilson, a White police officer. This protest heightened the awareness of the inequalities facing Black communities, families, schools, and youth in the region. The *Ferguson Unrest* also spurred the creation of the Ferguson Commission, which developed the *Forward Through Ferguson: A Path Toward Racial Equity Report* to address the St. Louis region's deep-seated racial and economic inequity (Ferguson Commission Report, 2015). These events have generated some interest by well intentioned people in the region who desire to do something about the persistence of inequalities in education, health, employment, policing, etc. Expanding on and in concert with the numerous recommendations offered by the *Forward Through Ferguson* report, I see the building of regional brain regimes among historically marginalized communities as part and parcel of one way to structurally address lingering racial and class inequalities. Moreover, as I noted earlier, such a regime must not be viewed as an approach that targets individuals. Instead, the focus, I assert, must center families, schools, and communities. Thus, I am encouraged about the potential of building regional brain regimes within the context of also rekindling communally-bonded schooling for youth, families, schools, and communities.

WRESTLING THE THEORY/PRACTICE GAP

David Kirshner
Louisiana State University
dkirsh@lsu.edu

From a Kuhnian perspective, multi-paradigmatic sciences like psychology attain scientific maturity if and only if a shared perspective is achieved on the foundations of the science. This underlying imperative toward unification mitigates against our accommodating education to the present reality that learning is diversely theorized in the various branches of psychology.

Keywords: Learning Theory; Teacher Knowledge

I begin this provocative plenary presentation by asking: What is good teaching?

Undoubtedly, some participants at the meeting accommodate by relating practices of teaching they find to be useful and effective, and these are duly recorded. Then someone offers a definition of good teaching with which no one disagrees: Good teaching is teaching that supports learning.

This leads, inexorably, to a next question, What is learning? Since this is a Psychology of Mathematics Education meeting, we rephrase the question: What is learning as theorized in psychology?

The conversation becomes more fragmented. Some reference one school of psychology, some another. Just the major branches—behavioral, cognitive, developmental, sociocultural—provide a dizzying variety of fundamentally different conceptions of learning. Alexander (2007) points out that some are "hard perspective" theories that brook no compromise on their unique prescription for learning, while "soft perspective" theories like social constructivism or situated cognition theory stake out a more integrative vision. But the inescapable circumstance of our time is that learning theory is fragmented across multiple branches of psychology. None of these theories, be they hard or soft, have won general acceptance; psychologists remain cloistered in their independent theoretical communities. Learning theory is fragmented.

This little exchange, brief though it is, points to an uncomfortable truth: The discourse of teaching is disjointed from the discourse of learning. For if pedagogy were truly aligned with theory, we would have to respond for each recommended practice of teaching that it is indexed to one or another of these diverse theorizations of teaching.

That we don't qualify our characterizations of good teaching in relation to a particular theorization of learning does not mean we don't care about theory, or that our pedagogical recommendations are not steeped in theoretical perspective. We do, and they are! But our discourse does not demand of us that we qualify our prescriptions for teaching as specific to a particular theorization of learning, and this means that our perspectives on teaching enter together into a theoretically undifferentiated discursive space.

Outside of design research enclaves in which a teacher works with a team of researchers who actively apply a particular theoretical perspective to inform pedagogy, it is this theoretically undifferentiated discursive space that constitutes the interface between the world of theory and world of practice. It has been pointed out that even for reform teachers committed to restructuring education "activities, as opposed to ideas, are the starting points and basic units of planning" (Windschitl, 2002, p. 138). But is there any realistic alternative in a discursive environment in which recommended practices float free of specific theoretical grounding?

Sociology of Science Context to our Discursive Construction of Pedagogy

I would like to be able to report that our discursive practice of talking about teaching practices outside of specific learning theories is the result of a deliberative process. After all, in applying psychology to education we are dealing with challenges of fragmented science that few other professions face. Medical practice is informed by many different basic sciences—anatomy, genetics, biochemistry, physiology, etc.—but these sciences share in common a basic point of view about the nature of physical reality (Weinberg, 1993), so they support and enhance each other. In contrast, we in education have been grappling with irreconcilable theorizations of learning for 130 years, since the advent of scientific psychology in the late 1800s (Lagemann, 1989). Surely, we must have sat down together as a community to deliberate about how to meet this challenges!

The historical record does not show this to be the case. In the early/middle decades of the 20th century, psychologists in various schools sought to capture the mantle of psychology for themselves, so educators flocked to the banner of behaviorism, or Gestaltism, or Functional Psychology (Dewey), declaring the others invalid—notwithstanding the resulting impoverishing and factionalizing of education. Mid-century, when cognitivism knocked behaviorism from its leading position (Gardner, 1987), some became cognitivists, and some shifted allegiances to constructivism (Piaget) or to sociocultural theory (Vygotsky) continuing the winner-take-all antagonisms of the earlier era (Cobb, 1994). In the mid-1980s, the limited ability of Information Processing theory to account for context (Lave, 1988) led to the establishment of hybrid theories like situated cognition theory (e.g., Brown, Collins, & Duguid, 1989) and social constructivism (e.g., Ernest, 1998), notwithstanding the fact that these unions of incommensurable perspectives are irreconcilable in principle (Sfard, 1998). So in the current fashion, we offer pedagogical guidance reflecting our grossly or subtly differing theoretical perspectives—no, not individually in our own teacher education courses, but in our collective contribution to the world of practice.

Psychology as a Preparadigmatic Science

Why should it matter that we have allowed psychologists to guide us through the dilemma of multiple theories of learning? The answer is that psychology is not only a multi-paradigmatic science; it is preparadigmatic in the sense of Kuhn (1970).

In Kuhn's (1970) famous theory, all sciences begin in a state of fragmentation. Science during this preparadigm period progresses in separate schools. For instance, the science of optics was pursued in "a number of competing schools and sub-schools, most of them espousing one variant or another of Epicurean, Aristotelian, or Platonic theory" (p. 12).

During this adolescent phase, progress is hampered by the absence of a shared perspective. Scientists constantly are in a position of having articulate and defend fundamental assumptions. What's more, theorists operating under different paradigms "see different things, and they see them in different relations to one another" (Kuhn, 1970, p. 150). So, paradigmatic divisions can never be resolved through rational argument, because rational argument requires shared starting assumptions.

Despite the incommensurability of its theories, it is possible for a preparadigmatic science to achieve unity of perspective and thereby break through to mature scientific status. This happens when a particular school offers such a compelling vision that members of the competing schools abandon their agendas and join with the ascendant school. In the case of optics, it was Newton's (1730) *Opticks* that led to theoretical consensus and the achievement of scientific maturity. But unlike physical sciences, social sciences like psychology remain in the preparadigmatic, fragmented, stage (Flyvbjerg, 2001; Geertz, 2000).

This Kuhnian analysis alerts us to the downside of relegating to the community of psychologists the responsibility that we have as educators to negotiate the multiplicity of learning theories. For across the broad spectrum of psychology, the common goal that underlies all efforts is the eventual unification of perspective that marks transition to scientific maturity. This doesn't mean that psychologists, intent on making their own paradigm ascendant, actively subvert education. But it does mean that psychologists will not spontaneously offer to educators a strategy that reifies separate and independent notions of learning. Thus, we have missed what is the most direct and obvious way to accommodate the fragmented state of learning theory.

Genres of Teaching

If learning is independently theorized in separate branches of psychology, and if our goal is to articulate theory-based guidance for pedagogical practice, our most direct and obvious strategy is:

- Identify the basic notions of learning pursued in psychology that together span the broad interests of educational practice;
- Construct a separate theorization for each based in the relevant learning theories; and
- Articulate a separate genre of teaching (teaching methodology) for each informed by this theorization.

Note *constructing a theorization* is not a matter of simply selecting an intact theory from psychology. In some cases, multiple theories may address the same basic notion of learning and insights from all of these should be drawn upon to inform the associated pedagogical practice. In others, the competitive imperative in psychology may induce psychologists to assert as solid accomplishments what are really only research programs (e.g., Skinner's, 1958, attempt to extend operant theory from unmediated response conditioning to verbal behavior, beaten back by Chomsky's, 1959, withering critique). So theorizations have to be assembled to ensure that boundaries between the basic notions of learning are cleanly drawn.

As articulated by NCATE (2002) and its successor CAEP (2016), education is motivated by a trio of learning goals: *skills*, *knowledge* (concepts), and *dispositions* (cultural practices). Skills are theorized in behavioral psychology, implicit learning theory of cognitive psychology, and connectionist theory. Concepts are theorized in developmental psychology (Piaget). Dispositions (understood as modes of cultural participation) are theorized in sociocultural psychology and cultural psychology. These provide a basis for articulating independent genres of teaching for skills, concepts, and dispositions, respectively (Kirshner, 2016).

Summary / Conclusions

Educators have deferred to psychology in developing strategies for dealing with the independent theorizations of learning that psychologists have generated in the various branches of their science. But psychology is driven by an underlying motive of eventual unification as needed to move from the preparadigmatic phase to full scientific maturity (Kuhn, 1970). This deference has kept us from considering a full range of strategies including what is arguably the simplest and most direct way to ground pedagogy in diverse learning theory: the genres strategy, as outlined above.

Looking at the historical record, the strategies we've adopted have been wanting. In the first half of the last century, we opted for a favored psychological school, discrediting the rest. This led to overly narrow conceptions of educational practice (e.g., behaviorism's eschewal of such basic constructs as *mind*), as well as to divisiveness when educators have opted for different psychological theories (e.g., the Reading Wars and the Math Wars). Next, we gravitated to integrative theories like social constructivism and situated cognition, heedless of the fact that these theories are incommensurable (Sfard, 1998). This produced grand visions of learning and teaching, but no real theoretical principles for realizing these grand plans. More recently, under the rubric of *design science* we assemble theories specific to a particular educational context or problem (Cobb, 2007; Lesh & Sriraman, 2005), thereby guaranteeing the impossibility of scaling up theory based pedagogical perspectives to serve the needs of mass education.

The genres approach (Kirshner, 2016) avoids all of these pitfalls. Diverse theorizations of learning give education the scope it needs, without the conflict that comes from antagonistic claims. Because each theorization is focused on a particular learning goal, we get the specificity of direction we need for strong theoretical support of practice. Agreement on a stable set of theorizations enables broad scale-up for the needs of mass education. But to finally accept and deal with the reality of fragmented learning theory would break with a century-long junior partnership (Lagemann, 2000) in which we unwittingly have joined with psychology in its ultimate quest for unification. Demonstrably, this partnership has not served us well. Do we have to courage to critically analyze the holistic and integrative visions of learning that psychology now purveys as a harbinger of the grand unification it so dearly seeks?

CREATING A HEALTHY AND RIGOROUS CULTURE OF RESEARCH BY REVEALING OUR WORK

Eric Siy
University of Wisconsin-Madison
epsiy@wisc.edu

Graduate students experience high levels of mental health issues such as anxiety and depression. In this provocation, I focus on the imposter syndrome as one of the sources of these issues. I urge our community to chip away at imposter syndrome by revealing the messiness of research through three practices. As we face a new horizon, my hope is these practices shift the culture at conferences (and academia) so we can all be a little kinder to ourselves.

In 2019, graduate students can create online collaborative meeting spaces, access books and journals from their pockets, and use software that make typing out a reference list seem archaic. All of these resources should make the life of a graduate student in 2019 easier. There is, however, a darker trend—the growing awareness of graduate student mental health. There is no systematic, large-scale investigation of graduate student mental health (Flaherty, 2018). Most research is isolated by institution, field, and region, but there are notable similarities across these studies. Graduate students experience mental health issues at alarming rates such as high levels of anxiety, depression, and suicidal thoughts (Barreira, Basilico, & Bolotnyy, 2018; Garcia-Williams, Moffitt, & Kaslow, 2014; Levecque, Anseel, De Beuckelaer, Van der Heyden, & Gisle, 2017; Lipson, Zhou, Wagner, Beck, & Eisenberg, 2016) with women and trans individuals experiencing higher levels (Evans, Bira, Gastelum, Weiss, & Vanderford, 2018). It would be naïve of the mathematics education community to presume immunity from this trend.

An unfortunate given in academia is the normalization of imposter syndrome (IS), the feeling of getting away with fooling experts of one's own success. Clance and Imes (1978) first documented this phenomenon as a psychotherapy issue with highly successful women. They indicated the "clinical symptoms most frequently reported are generalized anxiety, lack of self-confidence, depression, and frustration related to inability to meet self-imposed standards of achievement" (p. 242). Graduate students *just have* IS as part of becoming an academic. Ergo, graduate students *just have* the mental health issues linked with IS. In this paper, I focus on how we can minimize IS in order to work towards a healthier academia.

IS can be exacerbated by academia's focus on product over process. A large part of graduate students' apprenticeship into research is reading journal articles and watching research talks. In these mediums, the researcher presents a finished product, the end of their labor (apart from writing). The journey to achieve these products, however, are concealed by terse statements and magical phrases such as "multiple rounds of coding" or "until the researchers came to a consensus." The absence of a focus on explicit methods is not only a feature of conferences but also written reports. Bikner-Ahsbahs, Knipping, and Presmeg (2015) noticed "detailed descriptions on how methodologies are substantiated in a specific project, how they are implemented to investigate a research question, and how they are used to capture the research objects are normally missing" (p. v). The self-imposed standards of achievement indicative of IS are set because of the overexposure to clean, finished products. Thus, when things go wrong, take too long, or halt, the imposter bubbles up because "I don't know what I'm doing. They'll find out." How can graduate students begin to know if they are "doing it right" if they do not even know how senior scholars worked through the murkiness of research? My multiple attempts and misfires while analyzing my dissertation data began to take a toll on me. I became withdrawn and my anxiety ran amuck. Why could I not do research? Why can't I produce?

As a mathematics education community, we can begin to change our academic culture by focusing and exposing *both* the products and process of research. As we look towards a new horizon with graduate students' mental health issues in mind, I issue the provocation:

Reveal our work.

We can begin by shifting the conversations and culture at conferences. If graduate students are expected to "have knowledge of multiple research methodologies and statistical measures" (Reys, 2017, p. 938), researchers must expose the messiness of research. This knowledge includes making pivotal research decisions ranging from recontextualizing methods from other research projects to dismantling and rebuilding entire analytical frameworks. By exposing our stumbles, we can inject misfires as part of our culture and hopefully, slowly replace the impossible standards we set for more realistic ones reflective of the research process. To begin the shift, I propose three practices we can enact during conferences and other academic spaces.

Disclose our misfires. I frequently hear the statement, "You can read more about it in the proceedings" at PME-NA and similar conferences. Our presentations mirror our written work, but this time we show videos and extended transcripts. In 2017, I was in a session where the presenter began by saying, "We would like to focus our attention today on results we have concluded since we submitted our edited proceedings." I felt I was privy to new information. It made sense. Why would we spend hundreds of dollars to watch a presentation when we can read about the results for free? We can use conference presentations to supplement our written reports and present the details behind the reports by:

- *Showing initial research questions*. When I took a literature review course in my doctoral program, the instructor always asked a set of questions. Of the set, he asked two questions that anchored our conversations: (1) What was the research question? (2) Did the researchers answer the question? As a new doctoral student, I was under the impression that a research question was pivotal and ironclad. As I worked with more researchers, however, I understood that changing the research question of a project or publication is normal. One of my mentors urged me to keep my research question at arm's length by concentrating on the affordances of my data and change the question if needed. I changed my research question four times. We can use presentations to show the evolution of research questions, especially changes after data collection.
- *Showing initial rounds of analysis.* Initial passes at analyses are meant to be refined. We make decisions to drop, refine, and add analysis. These decisions are not necessarily reported in publications and presentations. We can use presentations to show analysis before the final iteration and why the changes were made. This could provide some researchers with ideas for initial passes at analysis for similar data sets.
- *Acknowledging limitations when collecting data*. It is normal to report limitations to our projects. I have used the same limitations since writing research papers in high school such as "need more data" or "conduct the study with a different population." I continue to read similar limitations in research journals today. We can identify new ones by

> acknowledging our limitations as researchers, particularly how our identities play a role. Researchers bring their visible and enacted identities to research which influences the way participants and researchers engage with each other (Yoon, 2019). We usually address this with a researcher positionality statement, a standard practice of researchers who research equity issues. I urge *all* researchers to acknowledge their positionality and how it potentially limited their data collection. For instance, a White student participating in an interview about fractions may work differently with an Asian-American female researcher than a Black male researcher.

I want to be clear that I am not advocating for researchers to make presentations laying out every granular decision. I am aware of the limited real estate for presentations. I am suggesting specific parts of our work that are normally hidden. For instance, I attended a colloquium by a researcher who examined students' reasoning. She spoke about her position as a White researcher in a mainly non-White school, which I do not usually see in presentations from her research area. She used two minutes of her presentation to reveal the work she and her research team did to build rapport with the school and the students because of her positionality.

Make processes products. By the time my parents were my age, they owned a house and had two children—a different life than mine. I found conversations where I talk to them about why they made certain life decisions as important and, sometimes, more fruitful as the decisions themselves. I urge researchers to start similar conversations in public. In conversations with a good friend, they recounted how they outsourced their mentorship to another institution because their institution did not have faculty with similar research interests. In the same way I honor conversations with my parents about their thinking, they found conversations with their outsourced mentor about the research process as fruitful as conversations about results. They were only able to begin such conversations by going to conferences and networking. There are more graduate students who do not or cannot attend conferences but are in need of mentorship. We need to find new avenues to document and publicize our research processes.

We can begin by increasing publications and presentations about methods. I have read work or heard researchers claim there is no consensus on how to analyze the phenomenon; yet, when I find accounts of methods are limited possibly to accommodate word counts. Thus, the limited ways a particular phenomenon is studied remains in the dark. In past years, presentations in the "Theory and Methods" strand have consistently been below 10% of all reports published at PME-NA (see Table 1) and I assume reports exclusively about methods is lower. In most of our presentations, we allot one slide describing the work we did. We can expand these slides into tangible products researchers can use to understand processes. If graduate students are required to wrestle between two different theoretical approaches to intersubjectivity, there should be opportunities to wrestle with different analyses of the same concept such as pieces found in the special issues on affect in Educational Studies in Mathematics (Zan, Brown, Evans, & Hannula, 2006) and symbolic tools in the Journal of the Learning Sciences (Sfard & McClain, 2002).

Table 1: Percentage of Reports in the "Theory and Methods" Strand at PME-NA

Year	Research Reports	Brief Research Reports	Poster Presentations
2015	7.61% (7/92)	2.08% (2/96)	1.47% (2/136)
2016	4.81% (5/104)	4.9% (5/102)	3.15% (7/222)

2017	4% (3/75)	4.93% (7/142)	1.8% (3/167)
2018	7.25% (5/69)	5.84% (8/137)	3% (4/133)

Creating robust research methods and constantly changing them are not less than 10% of our work. We can create products revealing this work. I want to be clear, I am not advocating for the field to downplay results. I am advocating for a focus on creating accessible publications and presentations about the work done in conference rooms. My mentor advised me to use my research memos as data to write a rich methods chapter for my dissertation. In the end, the chapter was longer than others, but it provided a more accurate account of my work.

Practice academic humility. My dad once told me that academics are just people who are paid to say why other people are wrong. To this day, this resonates with me. At my first PME-NA, I watched a senior scholar press a graduate student to justify their use of the word *x*. The senior scholar resisted the graduate student's answer. They explained *x* means *y*. I read the scholars' work on *x* and the graduate student could not save face unless they said "*x* meant *y*."

Academic arrogance creates a hostile environment where one feels debunking is the rational response to a disagreement. Thus, diminishing participation of those who hold different views (Lynch, 2018, n.d.). Academic humility involves "owning of one's limitations, a healthy recognition of one's intellectual debts to others, a willingness to improve one's knowledge of the world, and low concern for intellectual domination and certain kinds of social status" (Lynch, n.d., p. 4). We can practice this humility by setting up spaces for scholars to see how other interpretations may enhance our explanation of teaching and learning. I suggest researchers not only be upfront and publicly acknowledge their limitations and own their biases but also acknowledge when other research areas can help explain data. There have been countless times in the past few years where I have heard researchers complain about the questions "Where's the math?" and "How does your research address equity?" We need to build epistemic trust (Lynch, 2018) by creating an environment where we can rely on others for knowledge. With technology, we can collaborate and create dialogue across research agendas to form diverse groups of researchers and support one another's work. We can create a culture where "I don't know, but I think another research area, *x*, can explain it" is as powerful statements as "Our research shows."

I hope my provocation begins a shift from normalizing imposter syndrome to normalizing the publication of the messiness of research so we can be a little kinder to ourselves. As a millennial, I may have (as a New York Times columnist described) a coddled mind with an inability to understand the way the world (of academia) works; however, many graduate student stories reveal academia as a space where the bottom-line matters. This is ironic for a field that privileges thinking, not the answer. We can either be complicit with the status quo of feeding graduate students' inner imposters or change our culture of apprenticeship. By revealing our work, we do not diminish our results. We expose the rigor of research. These accounts can support graduate students to engage in the work of research while keeping the inner imposter at bay.

Epilogue: To Those in Power

There are more factors outside of my provocation contributing to graduate students' declining mental health. Stipends hover between $15,000 and $20,000 a year (the 2019 federal poverty level for a household of one is $12,490). Most doctoral programs offer health insurance that fails to offer many necessary services (Crow, 2019). More than 12 percent of doctoral students who completed their programs will have a combined undergraduate/graduate student-loan debt around $70,000 with rates higher in the social sciences and education (Patel, 2015).

Even with the promise of a burgeoning career after graduation, 30% of graduates with a PhD in the field of education have “no definite commitment for employment or postdoctoral studies” (National Science Foundation & National Center for Science and Engineering Statistics, 2018). Moreover, one in ten female graduatestudents experience harassment and majority of the cases involve unwelcome physical contact (Cantalupo & Kidder, 2018). Graduate school should be challenging, not traumatic (Wedemeyer-Strombel, 2018). Graduate students should not have to defer medical treatment, go hungry, or put their life on hold because they simply cannot afford it.

This is an extended call to academics who have access to spaces where there are no graduate student bodies, yet policies are made and cultural norms of academia are set. Graduate students need faculty-allies in those spaces. Staunch, unrelenting allies advocate for graduate students by listening to them and acting on their behalf. It can begin with the New York subway rule: When you see something, say something. There will be times where allies are confronted with the difficult decision: Be silent and support a system launching generations of new scholars into poverty, poor mental health, and a toxic academic environment or speak truth to power and advocate for those not in the room. I urge everyone to act so we can make academia a thriving, fulfilling, and healthy space for all scholars, especially graduate students.

TWO PATHS: TENSIONS OF AN EMERGING SCHOLAR[1]

Lauren Baucom
University of North Carolina - Greensboro

In 2018, I attended the 40th annual PME-NA conference in Greenville, SC. One of the plenary messages was jointly given by Drs. Marta Civil and Laurie Rubel. At the end of their talk, an emerging scholar of color asked for their opinions about entering the field being known as a mathematics education researcher who focuses on equity work. The two scholars on stage varied in their advice: Dr. Civil advised emerging scholars to wait to begin pursuing equity-oriented research until after they had been granted tenure to assure successful promotion. Dr. Rubel suggested that all scholars should be allowed to be wholly themselves in this field and in their work, using their identities and passions as impetus in the pursuit of their research. I was struck by the stark difference in their responses, and since then have heard similarly contrasting advice on several occasions. As a newcomer in this community and as an emerging scholar of color, the conflicting messages affected me in particular ways and made me wonder, "Can I be whole and find success as a mathematics education researcher?"

As a junior scholar, my emerging understandings about wholeness and identity situate my thinking about my own wholeness as a mathematics education researcher and member of this community, while knowing that my learning of these concepts in their complexity has just begun. Our identity-in-practice is in constant negotiation between a narrated identity-in-practice (or who I say I am) and an embodied identity-in-practice (who I bodily perform to be), authored in-the-moment, but is also set against an historical backdrop of both institutional and personal struggles (Lave & Wenger, 1991; Lave, 1996; Tan, Calabrese Barton, Kang & O'Neill 2013). This collision of historical-institutional struggles with historical-personal struggles, or one's "history-in-person", is carried across spaces and time (Holland & Lave, 2001). Our identities-in-practice are in constant negotiation due to the constraints of the communities in which we operate, and can only be fully legitimized when the more powered others in our community recognize the identities-in-practice that we are authoring.

In 2009, Gutiérrez outlined a working definition of equity and proposed that it is not enough to help students achieve in mathematics, nor is it enough for students to use the mathematics they learn to question their society. Rather, students must be able to "play the game to change the game," to find success in the K-12 educational system as it currently is while simultaneously pressing on the oppressive structures of that system to transform their world into a more just society. This framework of "playing the game to change the game" is helpful in describing each of the different responses I heard at PME-NA. Both Drs. Civil and Rubel were suggesting that educational researchers should "play the game to change the game," yet they differ in when to begin. Dr. Rubel's advice of *begin as you mean to go* echoes the "play the game to change the game" model right at the onset of the doctoral journey, where emerging scholars squarely center their work on equity to produce scholarship that pushes against systemic injustices in the field of math education within which they reside. Dr. Civil's advice of *waiting to begin* implies a "play the game to change the game" approach in which scholars who wish to focus their research on critical dimensions should first find success in academia by securing promotion and tenure with

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

work that might not be as centered on equity, in hopes of then being able to return to push against these structures after successfully securing tenure.

I am a Black, biracial, cisgender woman of color. I am a mother, raising a young daughter of color in the South. I am a mathematics educator, currently pursuing a doctoral degree in mathematics education research. I view mathematics through each of these core identities, and each core identity comes with lived experiences that are laminating my identity-in-practice into the mathematics education researcher I am becoming. As a student, I was told that I did math “really well for a black girl.” As a biracial educator, I was told that I was “not black enough” to celebrate my history for Black History Month. As a critical mathematics teacher, I was told to “stay in my lane” and quit teaching lessons that ask students to analyze issues of social justice in the mathematics classroom. As a mother, I feel a sense of urgency to address issues of systemic change as my daughter will soon enter a public school system that too often refuses to acknowledge and value her identity as a student of color. I author this statement of positionality to contextualize how I received the messages regarding these two pathways and the reflective process by which I made meaning of each.

These different messages seem to chart two distinct paths of entry into the field of mathematics education research in this area of focus. Although they converge on the idea that scholars should do work centered on justice and equity, they diverge with respect to when to begin. As an emerging scholar of color standing at that point of divergence, I see each pathway as a combination of both risk and reward, and I wonder: what will be the cost of taking either one?

Path 1: Waiting to begin

The path in which I delay centering my scholarship on equity-oriented research brings with it the reward of an increased likelihood of a “successful” navigation through the promotion and tenure process, which typically requires sufficient numbers of published articles in premier journals and an untarnished teaching record, along with adequate service contributions to the community. Although these criteria are not judged equally (Park, 1996), finding success in research, teaching, and service may be easier if one does not have a critical orientation in one’s scholarship. The chase of promotion and tenure has been documented to be more difficult for scholars of color (e.g. Martin, 2009; Stanley, 2007; Turner 1998; Turner, 2002), as they work to develop an academic identity against a historical backdrop that is traditionally resistant to change (Diggs, Garrison, Estrada & Galindo, 2009). With the knowledge that faculty of color experience additional barriers in seeking tenure and promotion than their white colleagues, choosing to begin one’s scholarship without a critical orientation promises the reward of a position that provides safe haven from termination, so that one can complete their life’s work of equity-oriented research without fear of professional retribution.

However, there are several risks that accompany this “successful” storyline. As Lave and Wenger (1991) suggest, “Who you are becoming shapes crucially and fundamentally what you ‘know.’ ‘What you know’ may be better thought of as doing rather than having something” (p. 157). Therefore, becoming a scholar is mediated by the kinds of research tools that one uses to “do” scholarly work, which authors the kind of scholar that one will become. In the process of using tools that help to define particular fields of scholarship, researchers are authoring their identities-in-practice as scholars in the field, and our identities, through recognition by others, stabilize into the researchers we will become. In essence, the identity that we embodied before the doctoral journey is no longer the same identity that we embody at the end of the doctoral journey. And if that roughly four-year pursuit of a doctoral degree is followed by a six-year chase of promotion and tenure, we might consider the scholar's "maturation" as being at least a decade-long process.

The research tools, methodologies, and theories that equity-oriented scholars use are specific and complex, and require care to assure one is not reproducing inequities in communities that have historically been marginalized. Learning to use the tools, methodologies, and theories of equity-oriented research in mathematics education requires a significant investment of time. If the first ten years of a researcher's journey are defined by using "apolitical" or "benign" research tools, methodologies, and theories that are not critically focused on equity and justice, how reasonable is it to expect that scholar to change her repertoire of tools to be able to emerge as a robustly grounded, critical scholar, when she has had little experience with critical theories and methodologies most suited to pursuing equity work?

Equity-oriented scholars who choose the post-facto "play the game to change the game" pathway must choose to mute some core identities and amplify others, with the assumption that at the end of the promotion and tenure process we will be able to "change the game", despite the fact that we would have laminated a different mathematics education researcher identity. The concomitant identity work that takes place while we engage in playing the game may inadvertently blunt our critical edge, even as we achieve "success" in this system. This system serves those in positions of power and privilege by normalizing the *waiting to begin* doctoral pathway as the journey with the most "reward" by promising safety, while inadvertently silencing would-be equity-oriented scholars for at least a decade. Further, while these junior scholars play the game, another generation of K-12 students pass through the largely unchanged US school system—a generation that will soon include my own daughter. What is the cost of my decade of "playing the game" if the scholar I become in that time does not have the skills to then effectively "change the game"?

In this pathway, a collision occurs between my narrated, embodied, and history-in-person identities-in-practice, as I will enter into negotiation with my sense of self against the backdrop of the institutional and historical narratives that constrain the work of equity-oriented scholars. The person I would be authoring myself to become would not be aligned with the person I am narrating myself to be, and I would sit in an incongruous state as what I am "doing" (Lave & Wenger, 1991) does not lead me to who I want to become.

Path 2: Begin as you mean to go

The second pathway suggests that scholars should *begin as they mean to go,* and embark on the journey of producing equity-oriented scholarship aimed at "changing the game", if this aligns with the identity-in-practice they author themselves to be, while simultaneously "playing the game" of navigating promotion and tenure. Here, "success" is twofold. First, it is defined from a source of identity, that one is first true to oneself, and that the reward is fully embodying one's lived experiences and identity-in-practice in one's scholarship and in the community, despite the known collision with one's history-in person. (Holland & Love, 2001; Tan et al., 2013). Second, success means that one is welcomed as an emerging scholar into the community by the more powered others that acknowledge the type of game that one is playing.

For me, embarking on a journey of equity-oriented work would mean focusing my scholarship on the disruption of normed messages of privilege and power structures in mathematics that are similar to the ones I have experienced in my past. As a critical scholar, this would imply that my research would foreground what Gutiérrez (2013) characterized as dimensions of a *critical* axis of equity (identity and power) as they relate to dimensions of a *dominant* axis (access and achievement). In working within the elements of identity and power, the purpose of my research would be to understand how students' and teachers' identities are narrated, performed, or backgrounded by institutional systems, while looking for opportunities to "desettle" (Bang, Warren, Rosebery, & Medin, 2012) the systems of privilege that often surround unjust social structures like education.

I would choose this pathway of becoming a critical scholar in mathematics education research because, like many, I draw from the well of my historical identities both as a mathematics learner and as a mathematics educator—salient identities that play crucial roles in shaping my emerging perspective as a woman mathematics education researcher of color. There are examples of critical scholars of color similarly responding to and drawing on their lived experiences (e.g. Fasheh, 1991; Ladson Billings, 1995; González, Andrade, Civil, & Moll, 2001, Delpit & Dowdy, 2008; Delpit, 2012; Frank, 2018), forging a possible pathway for newcomers to follow as they wrestle with the related tensions in the education field between mathematics and equity, as well as tensions between theory and practice, and the urgency to attend to systemic change (Foote & Bartell, 2011; Squire & McCann, 2018). In this way, many mathematics education researchers of color have come to do equity-oriented work out of a sense of wholeness as they balance the historicity of their core identities of being a mathematics learner and educator with being a person from an historically marginalized community.

While there are examples of those who have seemingly found success in being whole in the pursuit of equity-oriented scholarship, the risks of this pathway are grave. Dunn (2016) speaks to the real "danger" that comes with pursuing any line of research that is equity-oriented, as junior scholars navigate the complexity of departments whose mission statements may promote equity and equality, but whose actions prove equity-oriented work is supported and touted insofar as it is profitable, rather than to create a just world that humanizes people from marginalized groups. For Black emerging scholars in particular, McGee and Martin (2011) discussed the stereotypes of inferiority that high-achieving Black undergraduate and graduate students in mathematics and engineering frequently must manage and relations between that emotional work and their racial and mathematics identities. Such examples point to the risk of having to negotiate one's identity-in-practice as it is set against the backdrop of the historical narratives that certain subgroups may experience more difficulty because of the skin they are in and/or the line of work they choose to pursue. The risk of being yourself in your work is the lack of welcoming from the community at large.

Authored into the identities of many people of color is the idea that we must work twice as hard in order to gain half of the reward (DeSante, 2013). Even without a specific lens towards equity-oriented work, it has been documented that faculty of color devote more hours to both community service and mentoring, as they are producing a comparable quantity of scholarship as others (Turner, Myers, & Creswell, 1999; Villalpando & Delgado Bernal, 2002; Antonio, 2002; Turner, González, & Wood, 2008). Similarly, scholars of color teach a disproportionate number of classes centered on equity in teaching and practice—courses that are required for many teacher preparation programs, yet receive consistently low evaluations at predominantly white institutions as many students experience existential crises due to conflicting dispositions and beliefs (Turner, González, & Wood, 2008). Thus, the feat of achieving promotion and tenure is made more difficult simply by being a scholar of color, and that risk is intensified when one chooses to pursue equity-oriented work from the beginning.

An additional risk comes when the community's powerful choose not to welcome emerging scholars who choose to pursue critically-oriented research. Critics might frame such scholarship as dilution or disruption rather than a source of innovation, creativity, and expansion of the field, asking, for example, "Where's the math in this?" (Martin, Gholson, & Leonard, 2010). Such resistance works to limit the space for new ideas to be taken up in our community, and repeatedly demands that critical scholars defend the legitimacy of their scholarship on ontological rather than mere methodological grounds (Hand & Goffney, 2013). In response, alternative spaces have emerged, such as journals like the *Journal of Urban Mathematics Education,* or conferences such as Mathematics Education and Society. But even these are "risky endeavor(s)" (Matthews, 2008, p. 1), as such outlets may not rise to sufficiently "top tier" status for tenure reviews in some institutions. On top of this, the expansion for which critical scholars have pushed is not just under question inside the field; it is challenged by external sources as well, as attacks on scholars in our community (PME-NA, 2018a; 2018b) reveal the risks to one's livelihood that can unfortunately follow from engaging in equity-oriented scholarship. If those in this area of mathematics education research are having to defend their line of work rather than focus on their scholarship, what message does this send to others who would consider its pursuit?

The obvious risk to those who choose to *begin as they mean to go* is namely what the *waiting to begin* pathway is trying to assure: that scholars who wish to "change the game" are actually able to do so after the tenure chase. In 2019, the annual status report published by the American Council of Education (Espinosa, Turk, Taylor, & Chessman, 2019) reported an increase in scholars of color completing doctoral degrees between 1996 and 2016, with a larger proportion of Black and Native Hawaiian or other Pacific Islander doctoral students completing their doctoral degree in the field of education than any other group. Despite an increase in the diversity of the student body, the faculty body remained largely white. According to the Council, of all full-time faculty positions, American Indians held 0.4%, Hispanics[2] held 4.7%, Black faculty held 5.7%, and Asians held 9.3%, while white faculty held 73.2% of all full-time faculty positions (Espinosa et al., 2019). The disproportionate number of white faculty increased when delineated by the hierarchical structure of promotion. Thus, despite seeing an increase in successful graduation of doctoral candidates of color, the field is not seeing the same increase in diversity across full-time faculty ranks. These statistics paint a grave picture for an emerging scholar of color, without even considering the additional barriers of taking a critical orientation with one's scholarship. If those scholars who pursue equity-oriented research—and thus a more difficult and riskier path toward tenure—are largely scholars of color, in what ways is this community complicit in the oppression of marginalized groups?

As an emerging scholar of color in this community, I take note of the collision that occurs in this pathway between my narrated, embodied, and history-in-person identities-in-practice, and the choices I must weigh between risk and reward. While this pathway allows for me to pursue work from a legitimized sense of self from a narrated perspective, the institution writ-large, as currently configured, will likely continue to delegitimize not only my scholarship, but my core identities as a Black, biracial, woman of color, raising a daughter of color in the South. This delegitimization is no different than the messages of oppression I received as a learner, teacher, or parent of a learner of mathematics.

The Right to Wholeness in becoming a Mathematics Education Researcher

Neither of the paths described above is ideal. Each one promises rewards, but also presents risks for an emerging scholar attempting to find "successful" entry into this community of mathematics education. I have weighed these messages as I continue to author who I am becoming in this field. Others' core identities privilege them in ways that protect them from having to experience the severity of the tension between these paths, while for many the collision is nearly constant. As evidenced above, for scholars who choose to pursue equity-oriented research, there is no path that comes with taking zero risks. These risks are not the same as those inherent to the enterprise of intellectual risk-taking. Instead, these risks are rooted in the institutional and historical structures that refuse to value the core identities of those who do not align with the mainstream, dominant culture. So, what might be a research path that promotes wholeness for emerging scholars of color?

Wholeness would mean that I could engage in scholarship with my self in my work, bringing my collective experiences to bear on what I study. Wholeness would also include a sense of being welcomed into the community—welcoming not only me, but also my innovation and desire to expand the field in my scholarship. This imagined path of wholeness would require merging the definitions of success, to allow for both achievement and identity through the legitimization of our work from the community's more powerful members. Actively supporting the research pathways of emerging scholars requires this community to not only accept, but also embrace new ways of doing research.

I recognize the "risk" that I take in writing this from the position I am in within the system, as a third-year doctoral student seeking entry into and support from this community. It is often difficult to critique the very system in which we try to find individual and professional liberation. Yet, if we refuse to critique the institutional structures that continue to mirror the norms and values of the dominant culture, then we ignore the historical-personal and historical-institutional collisions occurring for emerging scholars and erase the work done by those who have come before us. How can we carve a new path – one of wholeness – for all scholars in our community of mathematics education research?

Endnotes

[1] I am grateful to my advisor, P. Holt Wilson at the University of North Carolina at Greensboro for his continued support and advice throughout this process. I would like to thank Naomi Jessup at Georgia State University, Edna Tan at the University of North Carolina at Greensboro, Allison McCulloch at the University of North Carolina at Charlotte, and Charles Munter at the University of Missouri for their careful reading and thoughtful critique on earlier versions of this article.

[2] I use the term "Hispanics" here, as was used in the status report, despite its erasure of those who identify as Latinx, and/or those who do not share the common language of Spanish.

SHOULD THERE BE LESS MATHEMATICS EDUCATION?

Niral Shah
University of Washington, College of Education
niral@uw.edu

Mathematics education is typically seen as intrinsically beneficial to individuals and to society. More broadly, access to STEM education is considered essential in a technology-driven modern economy, particularly for people from racially minoritized groups. In this article, I interrogate the underlying logic of these dominant narratives by asking: Should there be less mathematics education? *I argue that although mathematics and STEM education do have value, they come with significant current and future costs to society. Further, I question the net benefits they promise for people from racially minoritized groups. I conclude by provoking the field to consider what might be* gained *from having less mathematics education, and how that might better serve a vision of racial justice.*

Keywords: Equity and justice, STEM education, curriculum, policy matters

Should there be *less* mathematics education? That's not a question our field asks very often. We talk about quality (*how* we do mathematics education), but rarely about quantity (how *much* mathematics education there should be). Perhaps we don't because we assume the fundamental value of mathematics, both on its own and as a cornerstone of STEM. We see the joy that doing mathematics can bring people. We know that mathematics is required for college access and high-paying STEM jobs. We're grateful for the medicines and technologies that save the lives of our families and friends. And we acknowledge the role mathematics plays in the economy—often through STEM—as fuel for international competitiveness. To be clear, I believe we do need mathematics education. But to answer the quantity question, we must interrogate the visions we hold for society—who they center and who they exclude—and whether mathematics education can help us fully realize them.

To date, I have done mathematics education because I thought it would contribute to a vision of the world with justice for minoritized groups. Living in the United States, this means repairing the ongoing effects of the genocide and plunder wreaked by slavery and settler-colonialism. But I have become impatient, and I am skeptical of mathematics education as a viable pathway. I also now see ways that mathematics education can actually work against this vision. Everything has costs, including mathematics education.

The Costs of Mathematics Education

The costs of mathematics education vary between what happens *during* K-16 and what happens *after* K-16. For decades mathematics has played a starring role in U.S. schools. Its role expanded after the *No Child Left Behind* law in 2001, as accountability-era reforms further elevated mathematics—specifically, the arithmetic-to-algebra-to-calculus sequence that dominates U.S. education. But the curriculum is zero-sum: more time for one subject means less time for another. During this same period, we've seen cuts to science, art, and physical education in U.S. schools. Mathematics education is not solely to blame for this, but its ascendancy has imposed an opportunity cost on the rest of the curriculum.

After K-16 schooling there are other kinds of costs. Focusing for a moment on the types of jobs that come out of the STEM "pipeline," it is true that mathematics education has helped produce climate scientists and cancer researchers. But under capitalism, that's not all that comes out of the pipeline. We know that some STEM graduates end up on Wall Street as "quants"—building the mathematical models and trading algorithms that fuel predatory capitalism and that enabled the mortgage crisis and Great Recession of 2008 (O'Neil, 2017). We also know that STEM graduates gravitate toward Silicon Valley, where they might develop technologies that lead to massive job loss, or work for social media companies with the potential to destabilize democracies. As someone who worked in both the business world and tech world prior to becoming an educator, I have a unique perspective on these scenarios. One might argue that the majority of STEM graduates don't pursue such pathways, but the problem is that modern technologies wreak harm that is easily scalable. It just doesn't take that many STEM professionals to cause system-wide damage.

As a final point about costs, I believe we must also gaze far into the future and anticipate where mathematics education is taking us as a species. From the first time I saw *Star Trek* as a boy, I fell in love with space and the idea of living on other planets. One day mathematics and STEM education will take us beyond the moon to the outer reaches of the galaxy, but I worry about what we will bring with us. Could we end up with a McDonald's on Mars and racism on Jupiter? Mathematics educators may not want this future, but capitalism does not care what we want. Social studies or music education will not take us to other planets; this will be an ethical quagmire created by mathematics and STEM education.

But Can't More Mathematics Education Lead to Equity and Justice?

For decades mathematics educators have argued that access to mathematics is a matter of equity for minoritized groups (Moses & Cobb, 2001; Schoenfeld, 2002). This argument has moral elements, but it is also grounded in basic economics. If STEM jobs are among the most lucrative, then pursuing STEM is a logical response to wage stagnation and rampant income inequality: at the end of the day, people must be able to provide for themselves and their families. With respect to race, then, more racial equity in mathematics classrooms has been conceptualized as a pathway to more racial justice in society writ large. Indeed, for nearly twenty years, this view has driven my own work against racism in mathematics classrooms. But now I see certain problems with this logic.

One problem is that regardless of the amount of mathematics we make available to racially minoritized students, White-dominant systems have a way of reconfiguring themselves to re-secure advantage (Bullock, 2017; Martin, 2019). "Algebra for All" has been a decades-long equity struggle, but where does it all end when parents are lobbying for eighth graders to take calculus (Mathews, 2019)? From that perspective, the quantity of mathematics education makes little difference for racially minoritized people.

Another problem is that while greater Black and Brown participation in the STEM workforce may attenuate racial wealth gaps, it does not account for how STEM has been deployed to dehumanize people of color. We know that STEM classrooms are places where racist narratives undermine the intellectual capacity of Black and Brown students (McGee & Martin, 2011; Shah, 2017). Even Asian students—typically (and falsely) deemed "good at math"—become dehumanized as the presumption of their mathematical prowess positions them as "human calculators" (Shah, in press). A more racially just world can't only be about economics; it must also be one where people of color are recognized as full human beings.

Finally, there is the matter of representation. Perhaps we believe that more mathematics education for minoritized people will lead to greater representation in the elite sectors of society. But is our goal simply more women engineers at Facebook and a Native person running Goldman Sachs? Wouldn't it be a better world if these institutions simply didn't exist?

My point is that we should be humble about the prospects of mathematics education to effect justice at the societal level. School-level equity work in mathematics education is needed, but I now see it is an incremental project of harm reduction, not radical transformation. For example, I co-developed a tool to help teachers address implicit bias (Reinholz & Shah, 2018). This may lead to more girls of color and more emergent multilingual students participating in mathematics classrooms, but it still ends up giving these students access to mathematics and the world *as they are*. The endpoints of their educational journeys have not fundamentally changed.

What is Gained from Less Mathematics Education?

We hold deep ideological and material investments in mathematics education, which is why it's easier to focus on everything we would *lose* by having less of it. But I believe we have much to *gain* from less mathematics education. A simple but provocative question for us to ask ourselves is: If we had less mathematics education, what could we do with that newly opened space in the curriculum?

Imagine if we required every student to learn about voter suppression tactics or take a course on the politics of Indigenous sovereignty. What if every student had a chance to grapple with the details of climate policy or health care reform? What would it look like to implement a robust ethics curriculum interwoven throughout K-16 STEM education? Critical mathematics education has engaged these kinds of topics (Gutstein, 2006), albeit by making inevitable compromises within the constraints of the dominant curriculum. Ceding curricular space for more lessons and entire courses squarely focused on these issues would be a more direct route to justice through education. Lobbying for such curricula would be politically difficult, but a first step would be to open room for them.

My goal in this brief article is not to propose and debate "solutions." Engaging the question of quantity opens a gamut of new pathways for thinking about the structure of K-16 education, of which the few possibilities posed here are just a small sample. Instead, my hope is that we begin to seriously consider strategic divestments of mathematics education and their value to society. It's simply not enough for each of us to focus on our individual silos of research or practice and be content with incremental change. I argue that the field of mathematics education should prioritize a goal of justice for minoritized groups and do so with urgency, even if it means there should be less mathematics education.

Acknowledgments

Several friends and colleagues, including Danny Martin, Maisie Gholson, Daniel Reinholz, Elham Kazemi, Nirav Shah, and Anjali Shah, listened to nascent versions of these ideas and gave feedback on versions of my attempt to articulate them in writing. I am also grateful to the Local Organizing Committee of the 41st Annual Conference of the North American Chapter of the International Group for the Psychology of Mathematics Education (PME-NA) for the opportunity to present them during a plenary session.

This paper reports on a design-based implementation study of the use of a diagnostic classroom assessment tool framed on learning trajectories (LTs) for middle grades mathematics, where teachers and students are provided immediate data on students' progress along LTs. *The study answers the question: "How can one characterize the challenges encountered when a school implements a diagnostic assessment system around learning trajectories at scale?" by identifying three explanatory themes: shifting to classroom assessment, understanding the concept and content of the LT, and seeing the results as a call to action. Each theme is discussed with references to observed activities and discussions with participants and related to the challenges connected with taking the concept of LTs to scale.*

Keywords: Learning Trajectories, Assessment and Evaluation, Teacher Knowledge

Introduction

Many believe that LTs hold great promise for widely strengthening mathematics instruction by informing teachers about the knowledge of the empirical patterns on how students learn (Daro, Mosher, & Corcoran, 2011). However, locating the disparate research contributions poses a significant risk to influencing practice at scale. Confrey and colleagues have sought to address this need by creating a software tool, Math Mapper 6-8 (MM)(sudds.co), organized around a learning map of nine big ideas, 25 relational learning clusters (RLCs) and 62 constructs. Each construct delineates a LT based on a synthesis of the related research (Confrey, 2015) that draws from the same research base as turnonccmath.net (Confrey & Maloney, 2012). MM is based on the idea of a LT as a research-based model of how students' thinking increases in sophistication relative to a domain-specific concept, in the context of instruction that is operationalized through the use of digitally-administered and scored diagnostic assessments, which return data to students and teachers immediately. These 30-minute assessments consist of items that are aligned with the levels of the LTs and to avoid excessive testing, include the content covered in an RLC. Because LTs can span multiple grades, teachers can select relevant grade-level tests (6, 6-7, 7, 7-8, 8, 6-8). Multiple equivalent forms of a test are administered in a classroom to ensure all LT-levels are assessed across students[1]. Assessment items are written by the team in consultation with inservice teachers and designed to elicit student thinking and raise issues worthy of classroom discussion. We have reported elsewhere on the validation (using item response theory (IRT)) of the trajectories based on data from students with varied demographics from our six partner middle schools (Confrey & Toutkoushian, 2018; Confrey, Toutkoushian, Shah, 2019). Our goal is to use the tool at scale across all teachers and all topics (except Algebra 1) in middle school(s) to strengthen instruction based on empirical results from our assessments.

We would argue that mathematics education needs to tackle more issues at scale and specifically how to improve learning for all students as evidenced on valid, reliable, and equitable measures.

Study after study has demonstrated the naivety of assuming that data from assessments alone sufficiently informs instruction that leads to more learning (Nelson, Slavit, & Deuel, 2012). Likewise, our studies of the use of MM reinforce the view that implementation of multifaceted learning systems is a complex activity requiring significant professional support and attention to organizational factors (Mandinach, Gummer, Muller, 2011; Tyack and Cuban, 1995). Recognizing this complexity, we asked the research question: “How can one characterize the challenges encountered when a school implements a diagnostic assessment system around learning trajectories at scale?” We recognized that the answer to this question would have conceptual and practical components.

Introducing new forms of classroom assessment in schools frequently has to overcome the barriers formed by negative reactions to the high-stakes testing required by *No Child Left Behind*. However, there remains an appetite for formative assessment practices (Black & Wiliam, 1998; Brookhart, 2015; Heritage, 2008). Classroom assessment is designed to focus on student learning and growth, rather than to view assessment as a means to measure summative accomplishment (Heritage, 2008; Wilson, 2018). Heritage describes these as including a clear statement of the learning goal, an emphasis on self-regulated learning, and focus on movement along a learning progression. She, and others, emphasize the use of assessment *for* learning (Black, Harrison, Lee, Marshall, & Wiliam, 2004) and stress that using an assessment formatively depends not on the instrument, but *how* it is used practically. It requires the focus to be on what the data show about the state of one’s understanding and how to move forward. Such assessment requires students and teachers to shift to a growth mindset (Dweck, 2006).

Math Mapper 6 - 8: A Diagnostic Classroom Assessment Tool

MM is designed to be compatible with varied curricula and scope and sequence documents. Prior to implementation of MM at a site, a few lead teachers align the assessments to relevant timepoints in the school’s scope and sequence. Any teacher can administer any assessment at any time, but a coordinated schedule of assessment supports teacher discussion, analysis, and planning at grade level. Our assessment approach involves having teachers conduct initial instruction (with or without pretesting), and about ⅔ of the way through the allotted instructional time, to give a diagnostic assessment on the relevant material using MM. After testing, teachers initiate data reviews and address topics needing further development as shown in Figure 1.

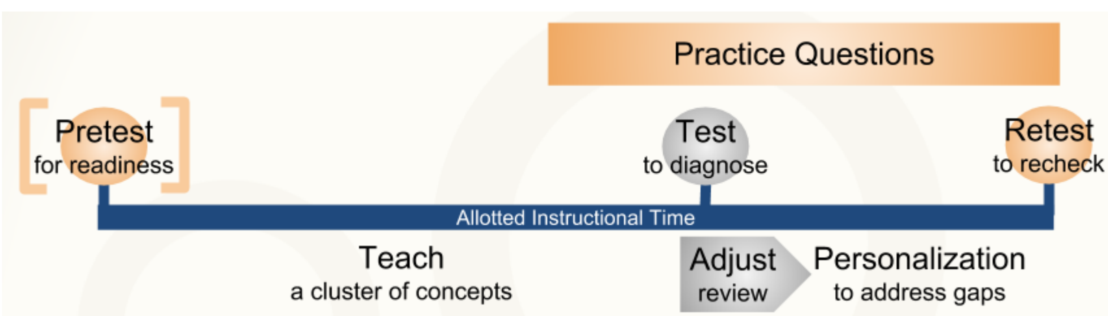

Figure 1: A Model for Implementing Classroom Assessment and Data Review

The student data are returned using a visualization of the cluster from the map with dials reporting the percent correct for each construct. Students can access a LT ladder showing the levels tested and their score by level. Students can also scroll to an item matrix showing items by level where they can review their responses and revise and resubmit answers. The teacher's display is called a heat map (Figure 2) where she sees the student performances ordered in columns from weakest to strongest[2] by construct and the levels ordered from lowest to highest in rows. The white boxes indicate untested levels for the student whose data are in that column. The other boxes are colored coded from orange (incorrect) through shades of blue to darker blue (correct). Teachers are taught to approximate Guttman[3] curves in order to identify which levels need re-teaching and which students need additional help.

The teachers have routinized two approaches to data return. In the first, using whole class instruction, they decide which levels to review based on the heat map. They tend to look for a level that is predominantly orange. Then they open it to view the item. The item can be viewed with or without the correct answer, an item analysis of student responses, and/or a report on the frequency of common misconceptions. Teachers vary substantially in the degree of student involvement in the review process, despite the research team's efforts to promote learner-centered reviews. The second approach developed by teachers is to use the data to form student groups (usually homogeneously exhibiting similar error patterns) to discuss the problems, revise, and resubmit. There is a practice feature in MM at the construct level, where individuals or groups of students can access additional items at levels of their choice and receive immediate feedback on the correctness of their responses.

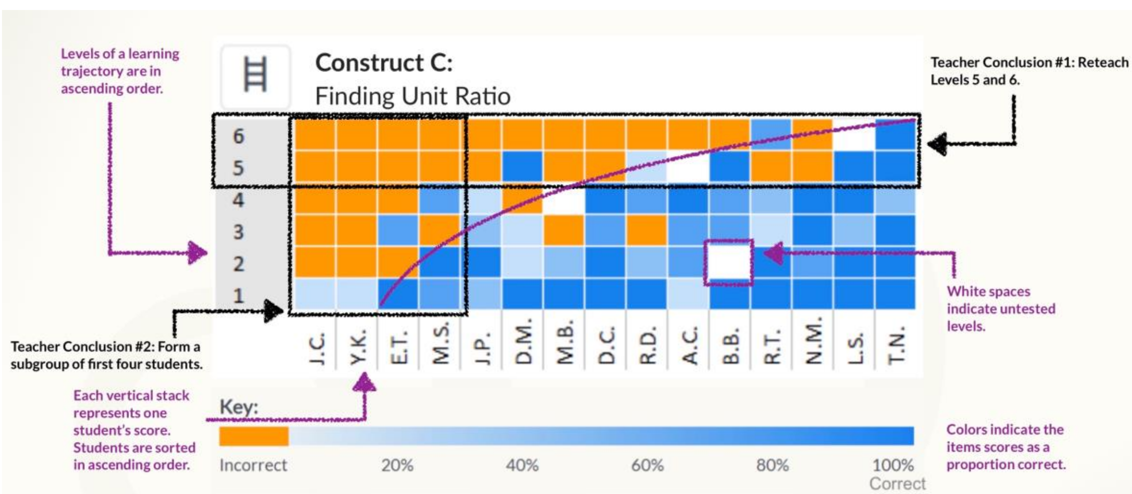

Figure 2: Sample Heat Map on "Defining and Measuring Center" With Labeled Components

Theory

The theoretical approach to the study is grounded in constructivism (Confrey and Kazak, 2006; Steffe & Gale, 1995; von Glasersfeld, 1982), with its focus on understanding how students build their knowledge gradually, working through carefully sequenced tasks in the company of peers, building gradual understanding. The process exemplifies what Piaget called "genetic epistemology" (Piaget, 1970) and Freudenthal and colleagues called "guided reinvention"

(Freudental, 1991; Gravemeijer & Doorman, 1999). It rests on the central construct of a learning trajectory (Clements and Sarama, 2004; Confrey, 2019; Simon, 1995) as a

> researcher-conjectured, empirically supported description of the ordered network of constructs a student encounters through instruction (i.e., activities, tasks, tools, forms of interaction and methods of evaluation), in order to move from informal ideas, through successive refinements of representation, articulation, and reflection, towards increasingly complex concepts over time. (Confrey et al, 2009, p. 347)

Secondarily, the research draws on a socio-cultural perspective on how students in classrooms engage in mathematical practice, share their approaches, cultural experiences, resources and insights, and gradually internalize the mathematical norms and expectations of a field in classroom practices (Lehrer and Schauble, 2000; Vygotsky, 1978; Yackel & Cobb, 1996). The project also draws extensively from the research on teachers' professional knowledge of content, pedagogical content knowledge (Shulman, 1986) and mathematical knowledge for teaching (Ball, Thames, Phelps, 2008), including LT-based instruction (LTBI)(Sztajn, Confrey, Wilson, & Edgington, 2012). For teachers to successfully achieve a learner-centered classroom (Confrey et al., 2017) engaging students in highly productive tasks (Stein, Engle, Smith & Hughes, 2008), they must seek to draw out student ideas and know how to orchestrate successful discussions from emergent models (Gravemeijer, 1999). Finally, our approach draws on the literature on professional growth by teachers sharing and discussing data in professional learning communities (PLCs) (Grossman, Wineburg, & Woolworth, 2001; Mandinach et al., 2011).

Methodology and Data Sources

This methodological work is situated as "design-based implementation research" (DBIR) carried out with our six demographically diverse research partner schools in 3 districts (Fishman, Penuel, Allen, Cheng, Sabelli, 2013). The schools approached the research team, wanting either to implement forms of "classroom assessment" (Pellegrino, Chudowsky, & Glaser, 2001) in which their teachers could receive data in a timely way during instructional units to revise and improve instruction and/or wanting more information about LTs. The collaboration among teachers, learning scientists, psychometricians, and software engineers involved conversations with school leadership and curriculum supervisors, from 2-4 days of summer professional development (PD) on the tool and underlying approach to learning trajectories, and then implementation of the assessments periodically during the year customized to the school's curriculum. Feedback to the research team occurs during regular grade-level PLC meetings where teachers reviewed data, discussed challenges, requested additional features and learned from peers. Data for this study were collected digitally through the use of the assessment system (n = 62000 tests), through observations and video records of classroom data returns, PLC meetings, and PD meetings meeting notes with school leadership, and monitoring ongoing participation in communication networks among teachers and researchers. Analysis of data for this paper was undertaken by the research team reviewing the video and artifacts to understand how teachers implemented the software and interpreted and acted on the data. From the classroom observations, the data review and discussions with district leaders, a set of three themes emerged to describe and explain the challenges inherent in using the software as intended to strengthen learner-centered practices and increase learning. They are summarized and discussed in terms of their conceptual and practical implications. Further, they are offered as hypotheses for future research.

Results

Theme 1: Shifting to Classroom Assessment

The observations of data returns by teachers suggest that in order to change typical views of testing by teachers and students, a shift to classroom assessment requires intentionality, explicit actions, and discussion with students. According to teachers, most students view tests as indicators of how knowledgeable, smart, and hard-working they are, and anticipate the results with trepidation and anxiety. However, classroom assessments, used formatively, are intended for feedback rather than personal evaluation and judgment. The diagnostic feedback should support informed decision-making and actions, the involvement of the students as partners, and the use of student thinking to inform next steps.

Based on our observations and teacher reports, many teachers quickly draw students' attention to their opportunity to revise and resubmit with MM. Students appreciated the opportunity to rework problems and they frequently expressed surprise that simply by rereading the problems and trying harder, they could get correct answers and experience the reward of seeing the dials immediately show their improvement. This is perhaps the most evident, simple, and direct example of the tool being used for classroom assessment.

Teachers who chose to group students together based on the heat maps seemed to be most successful in using the tool to strengthen attention to students' self-regulation, a key element of classroom assessment. One teacher, after organizing his students into groups, requested that they practice in constructs on the levels needing improvement based on their results and then return to revise and resubmit incorrect answers. His goal was to encourage them to learn the level and not just the item. Observations of his groups showed students explaining the ideas about the measurement of circles successfully to each other, calling over the teacher when more help was needed. These examples represent successful transitions to classroom assessment.

Observations also tended to reveal many teachers using the heat maps for data review by pulling up items from predominantly orange levels and simply again telling students how to solve the problems. They included admonitions to students to recall prior advice such as "I have told you to begin by drawing a T chart and building a table". These teachers seemed to view students' weak performance as needing quick and direct remediation rather than as opportunities to examine student thinking. Over time and with encouragement, teachers began to recognize that the students, having worked the problems, could provide valuable insights in their thinking. For instance, one teacher, on review of the data, recognized that she had neglected to teach percents greater than 100. She used an item at this earlier level, where the percent was 200, to reteach the concept and then relied extensively on student contributions to solve an item at a higher level involving 245% (Confrey, Maloney, Belcher, McGowan, Hennessey, & Shah, 2019). She referred to the MM items as "stretch items" and helped her students recognize their own potential to solve them. These observations have led us to recognize that even though the data provide direct evidence of students' learning needs, many teachers, especially in our lower performing schools, need additional support to learn how to orient their instruction to actively draw on students' thinking and utilize tenets of productive discourse (Stein et al., 2008).

A major challenge in shifting the orientation to a growth mindset occurred due to the weakness in overall performance by students, which may be due to the assessment's focus on conceptual understanding and reasoning. The score averages by cluster typically range from 40-60% correct, and are thus approximately 20-30% lower than on typical unit tests and quizzes. For students to understand these lower scores, teachers need to help students understand that these assessments are diagnostic and that in order to provide valuable information for all students, are designed to result in lower scores. This lower range is essential to allow for space in which to measure growth. Even so, the research team has also been concerned with the extent of the weakness in student performance, and has checked the alignment with grade level standards and asked students to judge if the material has been taught; they confirm it has. It is possible that the weak performance is an indicator of excessive procedural instruction. This would be consistent with other research which reports that middle grades students are being given excessive amounts of procedure-based materials (Dysarz, 2018) and that many teachers struggle to distinguish procedural understanding from higher conceptual levels, much less, LT-based levels (Supovitz, Ebby, and Sirinides, 2013). Further evidence for this emerged from some schools within the other themes where we discuss its implications for our future work.

How teachers responded and handled the challenge of shifting to classroom assessment and focusing on learning varied significantly by school. Schools with strong internal professional community supervisors, coaching, and district leadership transitioned more easily. In those settings, the teachers mediated the student responses, helping students to see low percentages simply meant "there was more work to do." She encouraged students to persevere by saying "our average was at 70% but this was just the first time… you'll have a chance to revise", and later, after students had revised much of their work, saying "If you're a risk-taker you can try a higher level." The strongest teachers focused on the content of the items, drawing connections to similar or related problems they had done, how to work through their reasoning, and how to coordinate the use of a variety of representations. Others focused on improvement, reporting back that "we have doubled our average score" and on refreshing the heat map to show all the students who had revised and resubmitted correct responses. In settings in which competing initiatives, especially around assessments, provided different data and direction, or mentoring and supervision were absent or weak, the initiatives encountered more problems.

These observations illustrate the complications of moving towards measurement-oriented classroom assessment. It appears that prior expectations influence the interpretation of the scale and that only if teachers explain reasons for the differences, focus on growth and the content itself, do they successfully shift the class's orientation towards using assessment for learning.

Theme 2: Understanding the Concept and Content of the LT

A second challenge of working at scale with MM comes from the need to assist teachers in understanding the conceptual foundations of the LTs in the map. The learning map in MM provides teachers access to all 62 LTs and the related misconceptions. Common Core State Standards are identified and aligned to each construct, and each level is mapped to its projected grade level. During a 2-day PD workshop, teachers are introduced to the conceptualization and research underpinning two clusters on ratio within the big idea of "compare quantities as ratio, rate or percent and operate with them". This consists of discussions of the relationship among the three constructs of ratio equivalence, base ratio, and unit ratio; and of how these form the foundation for building up, comparing ratios, and finding missing values, as well as the sequencing of the levels within each construct.

In going to scale with LTs, we have found that not reviewing all the LTs at the same level of detail and simply providing access to the LTs is insufficient for affecting practice. Observations at PLC meetings indicate that teachers seldom review LTs in planning instruction. The distinctions between levels and sequencing of levels are often overlooked by teachers. We anticipated that this would be the case, but we had hoped that providing the teachers data on students' performance would result in teachers recognizing the LT's value and relevance.

LT-based assessments differ from typical assessments that comprise of items that sample the various topics in a content domain, often referred to as "domain sampled" assessments. When teachers give domain-sampled tests, they often review only the difficult items, sometimes followed with extra explanations or practice. The item is viewed as a case of that portion of the domain. In an LT-based assessment, the item is also a case, but it is a case of likely student reasoning for that level of the construct. The meaning of an item therefore is situated in a construct for that level, and moreover, the level is situated in a sequence which delineates prior and subsequent ideas. When we observe most teachers reviewing data, the item is simply treated as an item to solve. This lack of recognition of the role and value of the trajectory became evident at one of the PLC meetings when a teacher said, the "levels [on the heat map] were random". If teachers do not recognize the significance of the LT, then much of the potential efficiency of the approach is lost.

Some teachers showed difficulty in understanding the structure of the LTs. During one of the PD sessions, the teachers complained that the ratio problems included internal multiplicative relationships that were too difficult, saying "[MM] gets too decimal-y [sic] and into fractions too quickly. We need to stick with 'numbers'." These comments showed a lack of familiarity with the Finding Missing Values in Proportions LT and strategies to find missing values in a 2 by 2 ratio box. Level 1 begins with whole number multipliers within and across the proportions, level 2 moves to combinations of multiplication and division (e.g. multiplication by 3 and division by 20, referred to as daisy chains (Confrey et al., 2014)), and level 3 tests for the resultant rational number operation (e.g. $4 \times \frac{3}{20}$). After reviewing this approach, teachers' positive reactions suggest a lack of familiarity with pedagogical approaches like daisy chains which make multiplication by a rational number more accessible to students.

Some teachers indicated that they expected the assessments items to "mirror" the items that they had taught in class. When reviewing the data, they advised students to solve the item procedurally rather than urge students to explain their thinking or engender discourse around the item. For instance, one teacher stated that, "Any time you are given three values and one unknown, that's kind of a hint that this is proportions". Such an approach is unlikely to support students in recognizing the fundamental multiplicative relations inherent in proportions (levels 1-3) and, subsequently, in distinguishing proportional from non-proportional relations (level 6).

It is becoming increasingly clear that to effectively use the tool, districts and schools will have to invest significantly in PD around the meaning of the LTs. Our experience has convinced us to begin to provide further information about the LTs and how they are situated in clusters. We see significant professional opportunities in also working with others who use other forms of evidence of student progress on LTs such as work samples (Petit, 2011; Suh & Seshaiyer, 2015).

Theme 3: Seeing the Results of LT Assessments as a Call to Action

As a diagnostic assessment tool, MM highlights issues of student understanding, and while the LTs can point out directions for movement, the effectiveness of the tool depends on the actions taken by its users (students and teachers). Responding to MM's results can be particularly challenging because classroom assessments from a robust LT-based diagnostic assessment can initially result in substantially lower student scores than other more traditional or teacher-created tests, especially if these common assessments focus primarily on procedures. We observed contrasting teachers' responses to their students' weaker performance data on these diagnostic assessments. Some teachers approached these results as a challenge, or as a call to action, encouraging their students to revise their work while simultaneously displaying the class's immediately increasing scores in real-time on a screen at the front of the classrooms, as students continued to work on these revisions. Other teachers exhibited resistance to the data.

One type of resistance that emerged was by questioning the test itself: one teacher felt that he should be able to anticipate his students' scores before they take any test, and if the scores are not what he expected, then clearly something was wrong with the test's ability to accurately assess his students' abilities. Secondly, teachers expressed beliefs that this LT-based assessment is not aligned to their curriculum, or is not aligned to "how I taught it". It is important to note that the LTs within MM and these teachers' curriculums are both aligned with Common Core State Standards, which means that these two systems are not misaligned, as some teachers claimed. A third concern of teachers is viewing the data as a form of exposure for them personally, as the results vary considerably from teacher to teacher, even within the same school. There is clear apprehension that the results will be used to evaluate them. Administrators played a key role in how this concern played out. In our highest performing school, an able mathematics supervisor kept discussions focused on the students and how to use the data to meet their needs. In a lower performing district, the administrator emphasized that low scores should not be the focus, but demonstrations of improvement should. In a third setting, with more site-based orientation, the degree of accountability ranged from strong to weak based on the instructional leadership provided by principals and other administrators.

When teachers encountered results that were lower than they expected and responded by only or excessively expressing concerns with the measure itself or of curricular/instructional misalignment, the research team noted that the response allowed them to avoid any sense of accountability for their students' LT-based data. Most often such responses to MM and the data occurred among the same teachers who expressed a preference for the use of highly procedural practices. For instance, in one school, teachers expressed a preference for using a computer system that focuses primarily on procedures. In another, teachers avoid more complex or conceptual orientations by developing their own simplified curricular materials. Thus, these observations suggest that if districts and schools want their teachers to view the results of an LT assessment as a call to action, rather than resist and reject the information, then additional supports need to be put in place to ensure their teachers understand and value an LT-based approach to learning, over a procedural approach.

Conclusions

In this paper we describe a disruptive innovation, MM, (Christensen, Raynor, & McDonald, 2015) that sits at the intersection of classroom formative assessment theory and LTs. We propose a critical goal of taking such an innovation to scale is to strengthen instruction through a model of personalization that is driven by data from valid, reliable, and equitable measures of student learning. However, taking any innovation to scale requires iterative cycles of "ramping up" toward full and successful implementation, informed by insights from classroom practice. Our DBIR study exposed important insights into the fit between MM's design and typical classroom practice. We characterized insights from our classroom observations into three preliminary themes as a means to describe the necessary shifts in practice, the need for teacher supports around LTs, and required collaborations among administrators at schools/districts. We see these descriptions as informing the development of "guardrails" to increase the likelihood of successful implementation at scale of MM. Our study also demonstrates that in order to realize the promise of LTs at scale, more resources must be devoted to helping teachers understand the foundation of each LT and cluster.

Endnotes

1 Most RLCs have 3 constructs averaging 6 levels, resulting in 18 possible levels to be tested in an assessment. With shorter tests averaging 8-10 items, not all levels are tested.

2 Teachers can display student initials to aid their own interpretation which is supported by a student matrix below or hide them for anonymity during classroom projection.

3 The display of Guttman curves and related advice on which levels to re-teach and which groups to form are currently planned for automation.

Mathematics teachers are vital components in determining what mathematics students have the opportunity to learn. There are a vast number of factors and reasons that influence a teacher's instructional decisions. As such, teachers rely heavily on their curricular reasoning (CR) to make decisions about what content to teach, how that content is taught, and the tasks to use to facilitate student learning. In this paper, we outline five strands of CR gleaned from research with middle grades mathematics teachers as they plan and implement instruction with unfamiliar curricular resources. These strands lay the foundation for our Instructional Pyramid model of CR and provide a lens through which teacher decision-making can be further understood and enhanced.

Keywords: Instructional Activities and Practices; Curriculum Enactment; Instructional Vision

Mathematics teachers are critical constituents in creating learning environments that provide students with the opportunity to learn important mathematics and that assist in developing student mathematical knowledge. One of the most important tasks required of mathematics teachers is the planning and enactment of instruction—the "what" and "how" of mathematics teaching. Figure 1 (Mathis, 2019 adapted from Stein, Smith, & Remillard, 2007) highlights the many instructional decisions during the teaching process that shape the overall mathematics lesson. While there are many decisions teachers make during the teaching process, we focus on *mathematical decisions*, defined as those decisions that influence students' opportunity to learn mathematics, and teachers' reasoning for those decisions.

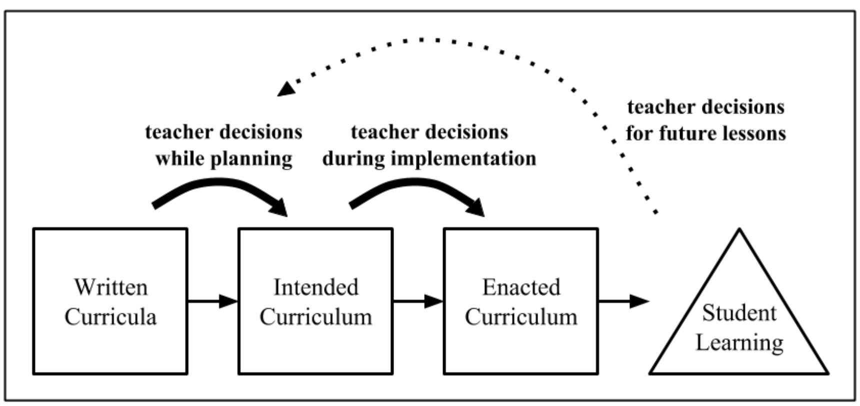

Figure 1: The Teaching Process and Teachers' Decisions That Affects Students' Opportunity to Learn (Mathis, 2019 adapted from Stein et al., 2007)

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* St Louis, MO: University of Missouri.

Researchers have sought to identify connections between teachers' implied decisions and possible factors influencing the teaching process (Bush, 1986; Graybeal, 2010; Nicol & Crespo, 2006; Remillard, 2000; Stein & Kaufman, 2010), but have rarely studied teachers' reasons for their decisions. These *factors* are not teachers' reasons for their decisions, but rather internal (e.g., mathematical knowledge, prior experiences) or external (e.g., professional development, textbooks) entities that influence or correlate with teachers' implied decisions. In contrast, *teacher reasons* are their own justifications for their decisions. Stein and Kaufman (2010) identified teachers' implied decisions during the teaching process based on learning opportunities afforded students. The authors investigated whether teachers' capacity (e.g., teacher experience, teacher education, professional development) or teachers' use of the curriculum correlated with the learning opportunities afforded students. Stein and Kaufman (2010) found that teachers' attention to the big mathematical ideas (i.e., implicit decision), which was related to the different curricula teachers used (i.e., factors), was highly correlated with students' learning opportunities. These data imply that the teachers' decisions about the big mathematical ideas within a lesson affected students' opportunity to learn mathematics. However, we do not know *why* some teachers choose to focus on the big mathematical ideas within a lesson and others did not, namely the teachers' reasons for their decisions that led to the differing student learning opportunities.

Other researchers have explicitly researched teachers' decisions and their reasoning during the teaching process; however, they hypothesized about specific factors or teacher reasons they think affect the teaching process rather than considering all potential factors or teacher reasons to give insight into teachers' decisions. Choppin (2011) hypothesized that teachers' *understanding of resources* and *attention to student thinking* would impact teachers' decisions about how they used curriculum materials; however, it may be the case that there were other factors or teacher reasons that were more prominent for why teachers used the curriculum materials in the way they did. Researchers have identified many different factors or teacher reasons that suggests we may not have a full understanding of teachers' mathematical decisions made during the teaching process if we do not consider all factors or teacher reasons.

With such a wide array of factors and teacher reasons identified that influence teachers' decisions throughout the teaching process, we suggest that teacher reasons are connected to their curricular reasoning (CR) – defined as *the thinking processes that teachers engage in and employ as they plan and enact the mathematics curriculum*. The purpose of this paper is to present a framework to characterize mathematics teachers' CR. We do this by defining and presenting five teacher-thinking processes that we refer to as CR strands. We then argue for the need to modify the Instructional Triangle (Cohen, Raudenbush & Ball, 2003) by adding a fourth dimension resulting in the Instructional Pyramid. Finally, we present the relationship of the five CR strands to the Instructional Pyramid and the interrelatedness of the CR strands in regards to teachers' mathematical decisions.

Context

As part of our NSF-funded project (#1561542, 1561554, 1561569, 1561617) that examines teachers' mathematical decisions and their reasoning as they navigate the teaching process, we developed our framework based on a sample of grade 8 mathematics teachers who taught a unit on geometric transformations (reflections, translations, rotations, and sequence of transformations). The topic of geometric transformations has historically been included in high school geometry courses; however, with the widespread adoption of the Common Core State Standards for Mathematics (CCSSM) this content was moved to grade 8 (Tran, Reys, Teuscher, Dingman & Kasmer, 2016). In addition, the authors of CCSSM use geometric transformations to build the definition of congruence, an approach rarely used in past standards nor in middle grades textbooks.

Teachers in our project were given the *University of Chicago School Mathematics Project (UCSMP)* geometry curriculum (Benson et al., 2009) to serve as the foundation for their instructional decision-making. This curriculum was chosen for two reasons: (1) its alignment with the approach to geometric transformations as found in Grade 8 CCSSM; and (2) its unfamiliarity to teachers in our study. Therefore, we aimed to identify teachers' mathematical decisions during the teaching process and their reasoning when planning with these unfamiliar curricular materials (*UCSMP*) and enacting this geometric transformation unit that was new to their grade level.

CR Strands

The teacher reasons for their decisions and reflections fell into five CR strands. In other words, we identified five key *thinking processes* that teachers used when making mathematical decisions during the teaching process. These strands are *Viewing Mathematics from the Learner's Perspective, Mapping Learning Trajectories, Considering Mathematical Meanings, Analyzing Curriculum Materials*, and *Revising Curriculum Materials.* Three of these strands—*Viewing Mathematics from the Learner's Perspective*, *Mapping Learning Trajectories*, and *Revising Curriculum Materials*—build from previous research on CR (Roth McDuffie & Mather, 2009; Breyfogle, Roth McDuffie & Wohlhuter, 2010), while the remaining two strands were identified through the open coding of our data. Below we define each CR strand and provide an example to demonstrate teachers' decisions and their reasoning for the particular CR strands. The interview excerpts below use pseudonyms for the participating teachers in the study.

Viewing Mathematics from the Learner's Perspective

As teachers make decisions or reflections, teachers reason about how their students will perceive and view the mathematics of the lesson. This thinking process is *Viewing Mathematics from the Learner's Perspective*, and defined as the teacher discussing the mathematics content of the lesson through the lens of student interpretations. Specific indicators of this CR strand are when teachers reasoned with specific details of the mathematics within the lesson and one of the following: (a) predicted (actual) student interpretations of the mathematics; (b) predicted (actual) areas of what students will do (did) with the mathematics or assessed student understanding; or (c) predicted (actual) student misconceptions. This reasoning allowed the teacher to articulate the perceived mathematical needs or mathematical knowledge held by the students. From a practical standpoint, this CR strand was typically utilized by the teacher when considering the students' prior knowledge, the students' responses to other students' thinking, the students' needs or struggles, the students' access points to the mathematics in the lesson, or students' anticipated thinking about the mathematics in the lesson.

To illustrate this CR strand, we use the following excerpt where Helen provides her reasoning for how the definition of reflection assisted her students:

> Helen: I think it helped them to recognize the pattern and recognize why those patterns were there. It also helped them, going back to that word "orientation" … and how that effects the ordered pair.

In this reflection of her lesson, Helen reasons about how the mathematics of the lesson, namely the definition of a reflection and the concept of orientation, helped her students to recognize and generalize patterns when reflecting across the different axes on the coordinate plane. To this point, she is reasoning about the lesson from the students' perspective regarding what helped them to be successful in the lesson.

Mapping Learning Trajectories

Another CR strand is related to teachers' reasoning about how a teacher maps out a lesson, either within the immediate lesson, or across units within a school year or across courses. We termed this thinking process as *Mapping Learning Trajectories*, and defined it as a teacher considering either how the mathematical concepts will unfold within a lesson, or discussing how the mathematics topics of a current lesson connect to either past or future mathematics topics students learn. Specific indicators for this CR strand are teachers' reasoning about: (1) how the mathematical concepts or skills in a lesson connected (did not connect) to past or future mathematics content; or (2) how the concepts or skills unfolded within a lesson or a unit. Therefore, the idea of a learning trajectory can take on either a short-term nature, where the teacher reasons about how the day's lesson will progress or how the given unit of lessons for geometric transformations are sequenced, or a longer-term outlook, where the teacher envisions how the lessons will connect with the mathematics content taught either in a given grade-level or across multiple grade-levels.

To illustrate this CR strand, in the following excerpt, Jill shares her reasoning for the success of her translation lesson.

> Interviewer: Do you feel like your task overall promoted student learning in the way you had hoped? How so?
> Jill: Yes, I feel that it did. It allowed the kids to explore the composition [of] reflections to determine what a translation is, and then we talked about the translation properties and which ones are preserved, and then they actually practiced. So, I feel like it did go, do what I was hoping it would do.

In her response, Jill reasons with the short-term nature of mapping learning trajectories, examining how the sequence of the lesson helped to support student learning by focusing on translations and their properties first before the students attempted to translate figures.

Considering Mathematical Meanings

The role of mathematical knowledge in the art of teaching is fundamental, and that knowledge plays a critical role of planning and enacting instruction (Ball, Thames, & Phelps, 2008). The CR strand *Considering Mathematical Meanings* is defined as the teacher's mathematical meanings of the mathematics within the lesson, or articulation of the anticipated student mathematical meanings that will be developed as a result of the lesson. Specific indicators for this CR strand are: (1) the teacher expresses his/her own mathematical meaning, which could be correct or incorrect, of the mathematics related to the lesson; or (2) the teacher expresses the mathematics students should learn during the lesson. This CR strand differs from the *Viewing Mathematics from the Learner's Perspective* in that the *Considering Mathematical Meaning* strand is from the viewpoint of the teacher and focuses on what the teacher thinks students should know, while the *Viewing Mathematics from the Learner's Perspective* strand stems from the viewpoint of the students—their misconceptions, their interpretations of the task, and their potential ways of thinking.

In the following excerpt, Judy reasons with her mathematical meaning about the relationship between reflections and rotations:

> Interviewer: Do you see a connection between reflections and rotations, besides the equal distance idea?
> Judy: …So it's really just that equal distance, but the congruent shapes are still there. And I mean, as I was talking in 2nd period, that's things they still said. But I don't know—besides that, besides them being equal and have that equal distance, I'm not sure that there's anything else I would compare those.

In this response, Judy reasons with her meaning of the properties that connect reflections and rotations. In the *UCSMP* textbook, rotations are seen as a composite of two reflections across intersecting lines (e.g., a pre-image in the first quadrant of the Cartesian coordinate system that is reflected over the *x*-axis and then over the *y*-axis results in the same image that is rotated 180° around the origin). In addition, the connection between reflections and rotations serves to highlight the properties shared by these two transformations. As this is not an approach traditionally taken in many textbooks, Judy shares her mathematical meaning of the distance preservation property, but does not discuss other properties shared by these two transformations (e.g., preservation of angle measures, collinearity of points).

Analyzing Curriculum Materials

As teachers make decisions regarding the mathematics lesson, they often use textbooks, online resources, and/or other supplementary materials at their disposal. These curriculum materials, defined as the "printed or electronic, often published, materials designed for use by teachers and students before, during, or after mathematics instruction" (Stein, Remillard, & Smith, 2007, p. 232), help to organize and structure the learning opportunities created for students. *Analyzing Curriculum Materials* is defined as when the teacher reasons about the curriculum materials by comparing the curriculum materials to other materials, providing analyses of potential strengths and weaknesses and detailing differing approaches. Specific indicators of teachers reasoning with this CR strand are (1) an analysis of a curriculum, pointing out appealing features or components that were unfavorable or that would be changed; or (2) a comparison of two or more curricula with respect to how these materials provide coverage of topics, how topics are sequenced, or for activities the teacher favored when enacting the lesson. In our analysis, we included standards documents, namely CCSSM, and state assessments in our definition of curriculum materials. Given CCSSM's important role in determining what is taught at given grade-levels as well as the prominence given to state-mandated assessments, these forms of curricula influence the decisions teachers make and play a critical role in a teacher's CR.

To illustrate this CR strand, we share a response from Ava who used the *Connected Mathematics Project* (*CMP3*) (Lappan, Phillips, Fey, & Friel, 2014) as the district adopted textbook. Given her preference for the *CMP3* curriculum, Ava was asked to compare *CMP3* to the *UCSMP* materials she was given to plan the unit on geometric transformations.

> Ava: I like the launch of them [*UCSMP*] creating their own [figure]; *CMP* just gives them a flag and tells them to reflect it. So I like that idea of starting with a white piece of paper and doing their own thing.

Ava reasons with the *Analyzing Curriculum Materials* strand as she compares the two curriculum materials, discussing features of both curriculum she liked. In subsequent data collections, Ava continued to contrast the *UCSMP* materials with what she normally taught in *CMP*, making it apparent she held a favorable disposition towards the curriculum in which she was more familiar.

Revising Curriculum Materials

The final CR strand concerns the iterative process of reflecting upon one's practice and changing parts of the lesson in order to improve the implementation or modify parts of the lesson that did not go according to plan. The *Revising Curriculum Materials* CR strand is defined as a teacher considering modifications and changes to a lesson based upon past teaching experiences. This reasoning, however, suggests a dynamic relationship between the teacher and the curriculum materials, one in which teachers reason with their CR to alter the curriculum based on experience.

In the following excerpt, Tracy is asked about her upcoming lesson that she planned, but based upon how the same lesson went in a prior class period, she is second-guessing her approach.

> Interviewer: Do you expect to get through all of the questions?
> Tracy: [Laughs] Sure, but now I'm like, NO! I mean I…no. So now I have to decide...
> Interviewer: So if you had to decide which ones you would skip or leave out, what would you decide?
> Tracy: I would probably skip the overlapping one. I did a grid one in their video of overlapping, and so I probably would skip the overlapping one. The other thing I might do is, say out of these three [questions], do two with a MIRA and do one with a protractor. So that they [students] get through the three things, but they're picking... they don't have to do it each twice. Because the protractor is going to take a little more time than the MIRA is, so if they just do one with the protractor. I mean, because I'm going to have to walk them through one, I'm going to have to go through one. I guess I need to decide which one I'm going to go through with them, because they don't know how to use that stuff. And then whichever two, they have to do one with a MIRA and one with a protractor. That probably, honestly, would be time management-wise, OK.

Based upon Tracy's reflection of the previous class period's lesson, she decided to skip some of the problems she had developed for her students. This revision of her lesson stems from student confusion during the previous class period's lesson as well as the fact that some of the problems in the planned lesson were repetitive from problems Tracy had already worked with her students.

Interplay of CR Strands

One of the predominant models regarding mathematics instruction is the Instructional Triangle (Cohen, Raudenbush, & Ball, 2003), which connects teachers, mathematics, and the students as vertices of the triangular model and where the edges of the triangle signify the interactions among these three critical components in the classroom environment (Nipper & Sztajn, 2008). This model highlights how various factors and resources influence teachers' instruction and subsequently student achievement. However, given our lens in focusing on teacher's CR and the role curriculum materials play in teachers' mathematical decisions during planning and enactment of lessons, we argue that a fourth component—the curriculum—should be added to include the various interactions that occur as teachers engage in the teaching process. Figure 2 illustrates our model that reflects the four main components of the Instructional Pyramid that influence teacher decisions during the teaching process.

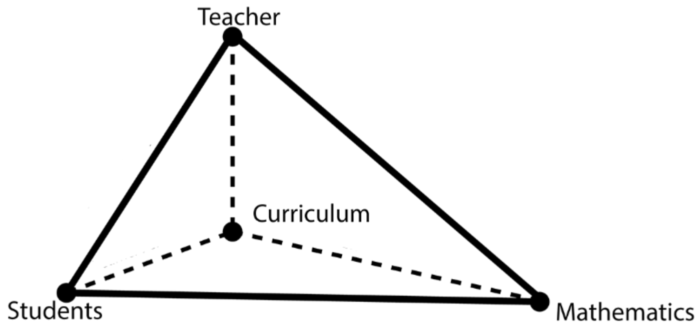

Figure 2: Instructional Pyramid for Curricular Reasoning

In the Instructional Pyramid, the edges represent CR strands, teachers' reasoning behind their mathematical decisions during the teaching process. The faces of the pyramid illustrate the use of multiple strands that interplay with one another as teachers plan and enact instruction. Figure 3 depicts the edges of the pyramid correlated to the CR strands used by teachers.

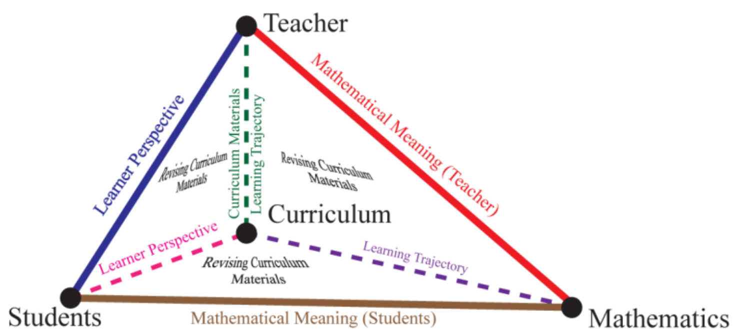

Figure 3: Model of CR Interplay

Our data set illustrates instances where teachers reason with one CR strand when making a decision, therefore existing along an edge of the pyramid. In other instances, teachers may coordinate multiple CR strands, thereby existing on multiple edges or faces of the pyramid. To highlight the interplay of these CR strands as teachers make and enact mathematical decisions, we use an interview excerpt from Judy, who planned to teach an overview lesson that would introduce her students to the language and vocabulary used with rigid transformations. Students were given a stack of geometric shapes that were translated, reflected, and rotated, and students were asked to describe what had happened to each figure.

> Interviewer: Are you planning to define any of the transformations, or are you just going to leave them in the vague terms?
> Judy: I might stay more vague today. My guess is that the words will come up, because they've heard them before. So I'm sure they'll come up. But I'm hoping that, so after this,

> I'm hoping that we'll get into days of, OK, here's a reflection. Tell me what it is. And that's when we're going to define it more. But today I think I'm going to stay a little more vague on it, and then later we'll get into more details.

In this exchange, Judy reasons with two CR strands: *Mapping Learning Trajectories* and *Considering Mathematical Meanings*. As Judy decides to "stay more vague with the definitions of each transformation" she employs the *Mapping Learning Trajectories* strand as she reasons about how the language of transformations can be more formalized over the coming days and weeks of the unit. With this reasoning, she is focusing on the Curriculum-Mathematics edge of the Instructional Pyramid. Building from this reasoning, Judy reasons with the *Considering Mathematical Meanings* strand as she delves into her thinking about staying more imprecise in this lesson. She sees this approach as fine for an introductory lesson, as she knows there will be time later in the unit to solidify the definitions of reflections, translations, and rotations. In this excerpt, Judy is imparting what she wants students to understand and gain from the day's lesson. With this reasoning, Judy is focusing on the Students-Mathematics edge of the pyramid. Taken together, the interplay of the *Mapping Learning Trajectories* and the *Considering Mathematical Meanings* strands suggests Judy's reasoning lies on the Students-Mathematics-Curriculum face of the Instructional Pyramid, as she reasons about the mathematical content of the lesson, what her students should know and understand about that content, and how that content will develop and grow throughout the unit.

Our data analysis is ongoing, but our hypothesis contends that teachers who reason with multiple CR strands when making mathematical decisions, and thus whose reasoning exists on multiple faces of the Instructional Pyramid, can provide different opportunities for students to learn mathematics. While teachers who reason with single CR strands may miss important support features in the teaching process that can improve their ability to assist student learning. The goal of the Instructional Pyramid is to provide a framework by which we can examine how teachers reason with the CR strands outlined above. This will allow researchers to examine the factors and reasons that drive teachers' decisions as they plan and enact mathematics lessons. By focusing on the CR strands teachers reason with when making mathematical decisions, teacher educators can work to support teachers' ongoing development of their use of these CR strands, thereby allowing teachers to flexibly move from the edges to the faces of the Instructional Pyramid. This will allow teachers to put into practice multidimensional CR and thus better support their abilities to make mathematical decisions that assist in promoting student learning.

EXAMINIING MATHEATICAL MODELNG OF FIFTH GRADERS: USE OF INTERACTIVE COMPUTER SIMULATIONS

Azita Manouchehri
The Ohio State University
Manouchehri.1@osu.edu

Azin Sanjari
The Ohio State University
sanjaripirmahaleh.1@osu.edu

We analyzed 5th grade students' interactions with one computer-based modeling simulation to examine how they defined and prioritized variables in a dynamically simulated environment. Results revealed that exposure to the simulation environment helped students visualize continuous motions, interpret the different quantities present in the model, and connect how variables related to each other. Additionally, students became more precise and systematic in adjusting the variables to explore the problem, test hypotheses, and achieve desired outcomes.

Keywords: Modeling, Technology, Elementary School Education

Due to the need to establish connections between mathematics and real-world problems, studies in mathematics education have focused on mathematical modeling in recent years (Lesh et al., 2007). Calls for inclusion of modeling experiences in K-12 curriculum have been reflected in various Standards documents (CCSAM, NCTM). Despite this there is evidence that students are typically not provided with enough modelling opportunities in elementary and middle schools (Suh et al., 2016; Stohlmann & Albarracin, 2016). There has also been strong scholarly support for inclusion of technology as a "tool" for introducing learners to modeling activities Greefrath (2011), assisting them in visualizing real-world problems, and exploring their properties (e.g., Ferri, 2007). While the use of digital tools in modeling problems is studied in more detail among high school and undergraduate students, there has been limited research on their impact and the support they provide in encouraging mathematical modeling skills among elementary school learners (Greefrath et al., 2018; Geiger, 2011). In this work we aimed to address this gap by examining how interactions with one computer-based simulation influenced 5th graders' mathematical modeling process. In particular, we investigated: (1) the learners' perceptions and interpretations of a situation model concerning the impact of rate of change on distance travelled in time (2) ways that these interpretations and perceptions changed as the result of exposure to an interactive simulation depicting the same scenario.

Background Literature

Blum and Ferri (2009) define mathematical modeling as "the process of translating between the real world and mathematics in both directions" (p. 45), where real-world encompasses situations that lie outside the world of mathematics. The modeling process involves observing a real-world situation, conjecturing about it, conducting mathematical analysis, obtaining results, and evaluating the model by comparing its result with the real-world situation (Lingefjärd, 2004).

Mathematical modeling cycle describe the modeling process (Blum & Leiß, 2007; Borromeo Ferri, 2007), allow a focus on cognition, and provide a means for understanding how to trace individual thinking (Borromeo Ferri, 2007; Czocher, 2017). Blum's modeling cycle encompasses aspects of the modeling process described by Lingefjärd (2004) and serves as our theoretical framework for studying student's thought process. When encountering a real-world problem, the

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

modeler initially produces a situation model. The situation model is then simplified to a mathematical model by adding structure and considering conditions and variables and restricted parameters. This formal mathematical model is analyzed, outputting mathematical results, which are interpreted in terms of the real model. The results are validated as they are checked against the real-world conditions and constraints. This process iterates until a satisfactory model is obtained (Figure 1).

Greefrath (2011) proposed an extension to Blum's modeling cycle (Figure 1) by adding technology as a bridge between the mathematical model and mathematical results. Greefrath proposes that in addition to being able to directly solve a mathematical model to arrive at mathematical results, the modeler can also build a computer model based on their mathematical model. Running a simulation is the process of executing the computer program developed to implement the mathematical model, and the outputs are denoted as computer results. The computer results are then translated back to mathematical results. The next steps are again similar to the original model, being the mathematical results and real results.

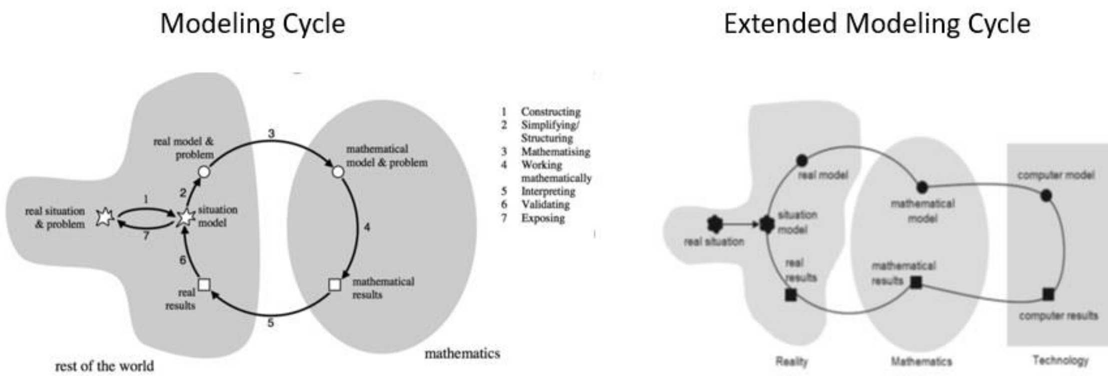

Figure 1: Modelling Cycle (Blum and Leiß 2006) and Modeling Cycle with Added Computer Model (adapted from Greefrah, 2011)

The extended cycle is advantageous as its steps do not need to be followed in order, allowing transitions between any of its stages. We used Greefrah's (2011) extended modeling cycle to track the modeling path of the students as they worked on a simulation.

Methodology

Participants

A semi-structured task-based interview (Maher and Sigley, 2014; Goldin, 2000) was used to study how 3 students examined and defined relationship among different variables as they attempted to predict specific outcomes associated with modeling a problem involving rate of change. The participants were fifth-grade students enrolled in an elementary school in the Midwest. All three were female and representing different levels of mathematical knowledge.

Procedure

Each participant (Marry, Nikki, and Tina) was interviewed three times. Each interview lasted approximately 50 minutes. During the first interview students were asked to solve The Three Runners problem (Table 1), requiring them to compare the distance between two runners, each runner's distance to the finish line, and given their speed determining which one would reach the

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

finish line first. Participants' responses to this question provided baseline data on their interpretations of the task, procedures they used and factors they considered when doing so.

During the second interview participants were introduced to a computer simulation environment depicting a running scenario which paralleled the task used in the first interview. Following a free play time, they were asked to solve the same problem using the interactive simulation. During the last interview session they were asked to solve the task they had considered during the first interview without using the interactive simulation. The purpose of the last interview was to trace any shifts in their thinking as the result of exposure to the simulation.

Table 1: Interview Questions (Three Runners Problem)

	Three Runners Problem
Step 1	Three runners are racing: a. Runner 1 is 18 meters away from the finish line, and is running towards it with the speed of 6 meters per second. How long does it take the runner to reach the finish line? b. Runner 2 is 14 meters away from the finish line, and is running towards it with the speed of 2 meters per second. How long does it take the runner to reach the finish line? c. Which runner reaches the finish line sooner? Why? d. Now suppose Runner 3 is 15 meters away from the finish line, and is running towards it with the speed of 3 meters per second. How long does it take the runner to reach the finish line? e. This time which runner reaches the finish line first? Runner 1 or runner 3? Why?
Step 2	If students' answer to part (c) or part (e) is runner 1, it means runner 1 passes runner 2 or runner 3 at some point. Following questions are: f. Can you tell when this happens? g. Can you determine where this happens?
Step 3	Irrespective of their answers to parts (c) and (e) students were asked to: h. Draw a graph of the motions of runners 1,2, and 3.

Simulation

We used the "cat and mouse" simulation during the second interview. This simulation is a part of Gizmos platform, including different interactive math and science simulations, which are designed for students in grades 3–12 aligning with the National Science Educational standards (Cholmsky, 2003). Gizmos mimics the real-world phenomena and allows the users to control several important factors while presenting information in a way that is easy to manage.

In this simulation (Table 2), students are able observe the evolution of a system over time. They explore how different objects move through time and if they satisfy a certain condition at a certain time. They also learn about acceptable parameter regions and how they should use constraints to solve the problem. Additionally, the distance between the cat and mouse, the speed of the cat, and the speed of the mouse are the parameters that students can tune. The simulation provides a continuous graph of the movement of cat and mouse running, as well as their location on the x-t plane. Table 2 summarizes the objectives and the content areas addressed in the environment.

Table 2: Modeling Simulation

Simulation	Cat and Mouse (https://www.explorelearning.com/index.cfm?method=cResource.dspDetail&ResourceID=108) Associated Task (Modeling Problem)	A small mouse plays on the floor, unaware of the cat creeping up on it from behind. The cat springs and the mouse desperately runs away. Will the mouse reach its hole in time to escape the cat?
Variables	Distance between cat and mouse, cat speed, mouse speed
Objectives	Inferring the effect of variables on two objectives: - The indicator of cat catching the mouse - The time it takes for the cat to catch the mouse
Content Area	Algebra-linear system

Data Analysis

Data analysis followed a two stage process. First, videos of each of the interview sessions were transcribed and reviewed to distinguish the different types of comments students made and actions they took as they worked on tasks. These comments and approaches were mapped against the phases of extended modelling cycle (Greefrath, 2011). The participants' interactions with the environment were examined to capture how exposure to the simulation shaped their modeling behaviors. Transitions between the mathematical model to the computer model, the simulation settings, and interpreting of the simulation results were of particular interest to the researchers, which were sought out amongst the data. The frequency of occurrence of each event was tallied to characterize each transition. The transitions were then analyzed in more detail, were used to study how students analyze and interpret the computer results, and were used to assess how the subsequent analyses of students regarding the problem is affected after being exposed to the simulation environment.

Findings

Table 3 offers an overview of the three participants' performance during each of the three interviews according to the answers they provided to the questions asked and their explanation of their thinking. It also describes how each student used the simulation environment and what they seemingly gained from the experience of working on the simulation to respond to a compatible context. In the following each interview session is discussed in more detail.

Interview Session 1

In the first session students answered questions (see Table 1) without using the simulation environment. The goal was to study their understanding of a problem that concerns distance/time travel in presence of rate of change, and what mathematical concepts they referenced or used. This interview served as a baseline for tracing ways that the use of simulation environment may impact their understanding of the problem or their solutions to it.

In the first session Marry showed difficulty representing the physical quantities mathematically even though she was capable of using algebraic tools (i.e., could easily carry out operations). While she correctly completed the questions in step 1, she could not justify her the algorithm she had used for computing answers for instance why she should divide distance by speed to calculate the time. She explained that she did so because she thought it is an “easy” thing to do. In an attempt to responds to questions in step 2, she drew a line to denote the location of each runner on a line, but did not correctly place the runners’ locations. Given that runner 1 is 20 minutes away from the finish line and runner 2 is 14 meters away, she put runner 1 at unit distance of the finish line, and struggled to find a way to show that runner 2 has a head start.

Figure 2: Marry's Representation of Runners’ Locations on a Number Line

Nikki seemed more comfortable with step 1 questions though part (e) seemed challenging to her. She could justify how her mathematical manipulations helped her compute physical quantities however, in response to part (e) she needed to compute the net effect of speed and distance but instead she only focused on speed and ignored distance. In step 2 she used geometric representations of physical quantities by drawing a line, and analyzed the running process in 1 second intervals to answer the question. Although she could explain how a solution to step 2 questions meant in physical quantities (for instance a runner passing another means at some time the runner is behind and in the next second is ahead), she did not know how to express this event mathematically.

Tina seemed more comfortable with algebraic operations. She completed step 1 questions easily. She correctly answered part (e) and justified her answer. She also correctly explained that in answering step 2 question she needed to check if there existed a time for which both runners were at the same distance from the finish line. She correctly used her understanding to compute the location of each runner at each time, moving in increments of 1 second, and successfully answered where and when the two runners would meet, or never meet at all. Interestingly, she did not use geometric representations, such as drawing a line, to answer these questions. She was the only students who moved to step 3 in session 1. She successfully identified the axes of the graph, correctly denoted runners’ initial location, and identified the point denoting the location of each runner after one second of movement. Although she computed the location of each runner at each given time, she did not realize that the location versus time graph is a line, and did not complete the task. Finally, she seemed more comfortable using algebra to solve the problems rather than drawing figures or graphs to explain her answers.

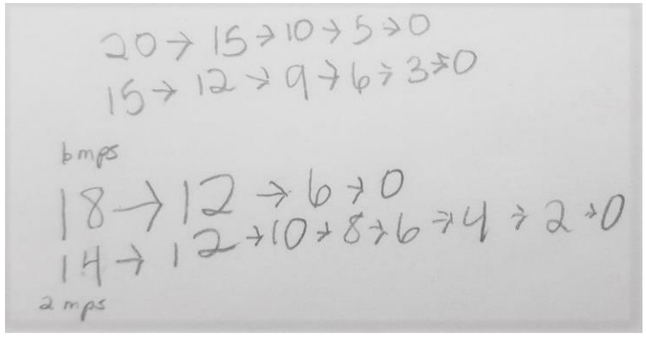

Figure 3: Tina's Computation on Runners' Locations in Time to Determine When and Where They Meet in Interview Session 1

Interview Session 2

In session 2 students were introduced to the simulation. They were given some time to explore the environment prior to the interview questions, initially all students seemed to “play” with the simulation settings. However, gradually they became more purposeful with their setting selection. In the course of the participants’ interactions with the simulation they showed a tendency to test extreme values (i.e., largest and smallest values of each variable, and moderate values) to discover the possible behaviors of the simulation with the least number of simulation trials.

Marry initially focused on the animation generated by the simulation environment, of the cat chasing the mouse, and how the location versus time graph represented this process. She spent a big chunk of her time on these outputs and used them to explain how she could represent locations, such as the head start of the mouse, on a line denoting the location to the finish line.

Nikki focused mostly on the graphical representation provided by the media and following several trials concluded that the cat catching the mouse meant that they were both at the same location at the same time. She further explained that by scaling all variables by the same value, say doubling them, the output, (i.e., if the cat catches the mouse and the time it happens) remains unaffected.

Tina seemed to follow a different approach to the use of the simulation. She immediately started with putting variables at extreme values and gradually changing them to learn about the environment. Instead of focusing on the animation or the graph, she generated ta able in the next tab explaining how this table would inform her about where the cat and mouse were at each given time point. She elaborated on how she could use this information to deduce answers. She then went back to the graph and explored how different settings affected it. She noticed the linear structure of the graph, and she extracted information from it so answer questions.

Interview Session 3

In this session students answered the same question they had encountered in session 1. After working with the simulation environment Marry correctly represented the locations on a line, distinguished the scaling of the problem, and accurately interpreted units of distance and time.

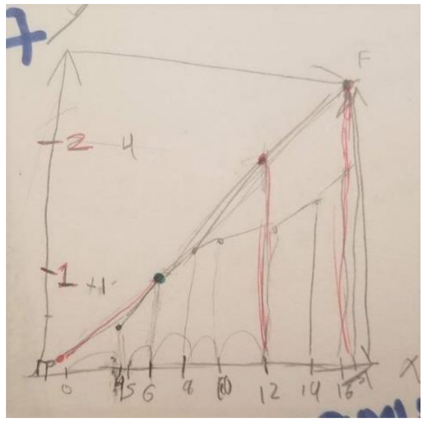

Figure 4: Marry's Representation of the Time Versus Location Graph

She successfully answered step 2 questions, and used a number line to determine if and where the runners met, similar to Tina's solution in session 1. She also completed step 3 and could explain her thinking; however, she was not as comfortable working with a graph. During the first session Nikki could only determine if the wo runners met and approximated the location where this meeting occurred. During the third interview she computed the exact values for time and location of the runners' intersecting. She also drew the location versus time graphs and explained her answers. Tina completed the graph which she could not produce in session 1, and explained how it would be affected by changing the variable values.

Table 3: Summary of Students' Performance and Use of the Simulation

	Marry	Nikki	Tina
Interview 1	-Completed step 1 but not did not correctly answered steps 2 and 3 - Mathematically representing/comparing the physical quantities	-Completed step 1 but partially answered step 2 and did not answered step 3 -Geometric representation, good understanding of the physical concepts -Taking advantage of algebraic tools to simplify and speed up the calculations	-Completed steps 1 and 2 but partially answered step 3 -Good grasp of physical quantities and mathematically expressing the relations. Using algebra to solve the problem -Geometrically and physically interpreting the results
Interview 2	-Completed steps 1, 2, and 3. In particular, successfully drew the location versus time graph.	-Completed all steps successfully. In particular, took advantage of algebraic methods as well as geometric methods.	- Successfully completed all tasks.

Interview 3	-Visualize physical quantities and study their evolution in time. Afterwards, we could mathematically describe and manipulate them	-Learn how to mathematically manipulate quantities, in particular, algebraically describe the problem and solve it using mathematical operations rather than geometric representations	-How to connect mathematical relations to physical quantities and learn about their connections.
Shifts	-Learns how to compare different distance values	-Used to draw figures and compute locations in steps of one second to arrive at a solution. Afterwards, she used mathematical manipulations without drawings to solve.	-Could not describe the graph initially, with the help of simulation gained a better understanding of the problem as a process

Discussion

At the initial stage of exposure to the simulation students shifted between the computer model and computer results for an extended period of time as a means to discover the impact of change in various variable values on the outcomes depicted on the screen. They tended to design a simulation setting, run it, and compare the computer results with what they had computed mathematically, confirming their initial ideas. By repeating this procedure, they seemed to form a more refined understanding of the problem leading to development of more precise descriptions. For instance, Nikki was comfortable using abstract algebraic methods to solve a problem in fewer steps, rather than relying on her visualization skills. On the other hand, Tina seemed to have made a connection between her abstract formulations of key physical patterns, and how they corresponded to a representation or a graph. All three participants, irrespective of their background knowledge, benefited from interacting with the simulation environment as evident in how they solved the task during the third interview. Each student used the simulation environment differently, and tested settings that helped them learn about specific aspects of the problem with which they had struggled the most. In particular, they used the simulation environment to visualize the dynamical system and its evolution, how different quantities relate to each other, how they can be represented mathematically, and if their solution is correct.

harringtonr@wou.edu

Our consortium of four universities conducted case studies with five teachers in Grades 1 through 4 to explore how elementary teachers are implementing digital curricula, particularly whether they are developing the Mathematical Practices with digital curricula. Through observations with the Mathematics Classroom Observation Protocol for Practices (MCOP^2), a survey, and interviews, we found evidence that there is a broad range of implementation strategies for digital curricula—from occasional use to daily use and from supplemental curricula to full curricula. This study indicates that best practices can be identified and developed for implementing digital curricula effectively in elementary mathematics classrooms. The research has implications for teacher educators and for professional development of inservice teachers teaching with digital curricula.

Keywords: Technology, Elementary School Education, Digital Curricula, Curricula Analysis

With the transformation to digital learning, many school districts are shifting toward one-to-one technology for all students. Due to such initiatives, school budgets for digital curricula are quickly rising: from $1.8 billion in 2013 to $4.8 billion in 2014 (Cauthen, 2017). From 2015 to 2016, digital curricula expenditures increased by 25% so that digital curricula cost "now exceeds all K12 spending by $3.5 Billion" (Kafitz, 2017, n.p). The promise is that "digital devices, software, and learning platforms offer a once-unimaginable array of options for tailoring education to each individual student's academic strengths and weaknesses, interests and motivations, personal preferences, and optimal pace of learning" (Herold, 2016, n.p.). Companies are "rolling out programs in America's public schools with relatively few checks and balances" (Singer, 2017, n.p.). EdSurge (www.edsurge.com) currently lists 175 digital core curricula for elementary mathematics. These curricula are rapidly spreading into elementary classrooms. For instance, Dreambox claims that over two million students are currently using their K–8 program in the United States (Singer, 2017). With pressure on schools to improve test scores and rise to expectations of the Common Core State Standards (CCSS; National Governors Association Center for Best Practices, Council of Chief State School Officers, 2010) or individual state standards, districts are seeking solutions for differentiated learning and data-driven instructional decision making. The shift to digital curricula to personal math instruction leads to questions about its support of student learning.

For our study, we examined how teachers implement digital curricula, particularly in regard to Mathematical Practices. We adopted the definition proposed by Pepin, Choppin, Ruthven, and Sinclair (2017) for "digital curriculum materials/resources/programmes" (DCR):

> It is the attention to sequencing—of grade- or age-level learning topics, or of content associated with a particular course of study (e.g., algebra)—so as to cover (all or part of) a curriculum specification, which differentiates DCR from other types of digital instructional tools or educational software programmes (p. 657).

Further, Choppin & Borys (2017) note that "digital materials have potentially transformative features, such as enhanced interactivity, customization, and adaptive assessment" (p. 663). Accordingly, we adopted Pepin et al.'s definition and further clarify it to include only digital curricula that collect and save student data for teachers' use, as assessment is a powerful aspect of digital curricula that can impact teachers' instruction.

Related Literature

Researchers are just beginning to study the effectiveness of digital curricula and the results vary. The self-funded study conducted by the digital curriculum iXL in California found a strong positive correlation between iXL usage and state test scores (Empirical Education, 2013). A randomized control study with 4th-grade students and the Odyssey program found no significant increase in students' achievement when students used the program for one hour per week (Wijekumar, Hitchcock, Turner, Lei, & Peck, 2009). SRI International is studying learning behaviors in digital learning environments as well as the efficacy of the Reasoning Mind mathematics curriculum (SRI Education, 2018). These studies generally focus on the students' experience rather than what teachers do in the classroom.

In another study, Taylor (2013) reported that more than 29,000 classrooms in 216 countries were using Khan Academy (KA). Salman Khan, founder and executive director of KA, recommends using KA to personalize instruction, freeing up class time for engaging, high-yield activities like student discourse and meaningful collaborative projects (Khan, 2012). Khan added that, "ironically, the technology makes the classrooms more human for the teachers and students. It has also made the teachers that much more valuable" (Weltner, 2012). Contrary to Khan's recommendation, however, in a small study, Cargile and Harkness (2015) found that KA was not used to foster more active learning in the classroom; nor was instruction customized to students' progress and achievement levels. Based on the limited and conflicting research on how these programs are being implemented in schools, we have much to learn about choices teachers are making and the mathematics students are learning with digital curricula.

Theoretical Framework

Our theoretical framework consists of four factors that influence teachers' decision making with digital curricula. The first factor is teachers' self-efficacy about their mathematics and technology knowledge. "Academic self-efficacy, teacher self-efficacy, and computer self-efficacy are important predictors of the attitude toward computer-assisted learning" (Yeşilyurt, Ulaş, & Akan, 2016, p. 592). Many elementary teachers bring their own mathematics anxiety with them into the classroom (Bursal & Paznokas, 2006; Haciomeroglu, 2014; McAnallen, 2010; Swars, Daane, & Giesen, 2006). Teachers with confidence in their mathematics tend to better transform lower-cognitive-demand problems into higher-demand problems (Son & Kim, 2016). The teacher's attitude toward using technologies in the classroom is a major factor in how successful technology integration will be (Tabata & Johnsrud, 2008).

A second factor is teachers' perceptions of the balance between procedural fluency and conceptual understanding. "Procedural fluency is the ability to apply processes, techniques, and strategies accurately, efficiently, and flexibly; to transfer these methods to different problems and contexts; to build or modify procedures from other procedures; and to recognize when one strategy or approach is more appropriate to apply than another. . . Procedural fluency builds on a foundation of conceptual understanding" (NCTM, 2014).

Teachers' perceptions of the Mathematical Practices' role in learning is a third factor. Confrey and Krupa (2010) contend, "For students to become proficient in mathematics, they must internalize the eight Mathematical Practices (MP) as the means to learn and understand the content standards. The practices sustain mathematics as the content evolves" (p. 10).

Teachers' perceptions of the affordances and constraints of digital curricula that lead them to enactment patterns is the fourth factor. Studies on the teacher's role in the implementation of new curriculum have examined teachers' curriculum strategy frameworks (Remillard, 1999; Sherin & Drake, 2009), their curriculum enactment patterns (Son & Kim, 2016), and aspects of factors related to teachers' decisions on tasks or problems that they enact during class (Son & Kim, 2015). The decisions teachers make about curriculum can potentially enhance or hinder students' understanding of mathematics (Nguyen & Kulm, 2005).

Methods

Participants and Setting

Participants included five elementary classroom teachers in mostly Title I schools located in three different states that are located in three different regions of the United States: midwest, south, and west. All five teachers were using digital curricula to support student learning of mathematics. This was a purposeful sample (Patton, 2002) since we wanted to analyze the enactment of digital curricula in elementary classrooms and its impact on teaching and learning.

Data Collection

We chose to conduct case studies of five teachers in order to get a deeper understanding of how they approach the use of digital curricula in their classrooms. For our case studies, we used a survey, observations, and interviews to triangulate the data (Patton, 1999), which allowed us to develop a comprehensive understanding of these teachers' enactments of digital curricula. We developed a teacher survey to gather data about teachers' demographics; beliefs about teaching mathematics, teaching with technology, and teaching mathematics with digital curricula; use of digital curricula assessment data; beliefs about how the MPs are supported with digital curricula; and developing students' MPs. To follow up on their responses to the survey, we observed teachers' instruction that included digital curricula. We used the validated Mathematics Classroom Observation Protocol for Practices (MCOP^2) (Gleason, Livers, & Zelkowski, 2015) and field notes during classroom observations. The MCOP^2 is designed to measure the degree to which a K–16 mathematics classroom is aligned with the various practice standards set out by the Council of Chief State School Officers, NCTM, and MAA. While there are different state standards, there is a commonality across states regarding MPs, which is captured by the MCOP^2. Following classroom observations, we used a semi-structured interview (Hitchock & Hughes, 1989) to learn more about teachers' beliefs about teaching and learning with digital curricula.

Results

On the teacher survey, all five teachers strongly agreed that: a) All students need to have a range of strategies and approaches from which to choose in solving problems; b) Mathematics learning should focus on developing understanding of concepts and procedures through problem solving, reasoning, and discourse; and c) The student's role is to actively make sense of mathematics tasks by using varied strategies and representations, justifying solutions, making connections to prior knowledge or familiar contexts and experiences, and considering the reasoning of others. All five teachers disagreed that: a) Students need only to learn and use standard computational algorithms; and b) The role of the student is to memorize information that is presented and then use it to solve routine problems on homework, quizzes, and tests. For the other two questions: a) two somewhat agreed and three disagreed that mathematics learning should focus on practicing procedures and memorizing basic number combinations, and one somewhat agreed and four disagreed that students can learn to apply mathematics only after they have mastered the basic skills.

All five teachers reported that they were confident in their use of technology in the classroom. However, their confidence differed in using digital curricula to teach mathematics: one was very confident, one confident, two somewhat confident, and one not confident. These teachers also varied in their responses to the effectiveness of digital curricula to learn mathematics and to develop factual recall, procedural fluency, conceptual understanding, and mathematical reasoning/problem solving (see Table 1)(no teachers disagreed).

Table 1: Teachers' Responses to the Effectiveness of Digital Curriculum

	Mathematics Learning	Factual Recall	Procedural Fluency	Conceptual Understanding	Reasoning/ Problem Solving
Strongly Agree	1	2	1		
Agree	2	2	3	4	2
Somewhat Agree	2	1	1	1	3

Further survey results indicate that all five teachers use digital curricula for skill and practice, four use it to differentiate instruction, and four use it for acceleration of content; only one teacher uses it to support critical thinking. During their planning and instruction, four teachers often and one teacher sometimes intentionally spends time developing either the MPs or their state's own process/practice standards. See Table 2 for a summary of the varied ways the teachers report using digital curricula to assist students in developing the MPs.

Table 2: Teachers' Reported Use of Digital Curricula to Develop the MPs

	MP1	MP2	MP3	MP4	MP5	MP6	MP7	MP8
Extremely Well						1	1	1
Well	3	3	2	4	4	4	3	4
Not So Well	2	2	2	1	1		1	
Not At All			1					

To capture further evidence of teachers' enactment of digital curricula and its impact on MPs, we share case studies of each teacher.

Case Study of Allison

Allison is a 3rd-grade teacher with an emergency credential in her second year of teaching. She is a confident early-career teacher who loves teaching mathematics and is passionate about her students understanding concepts and developing procedural fluency. She has never taught any other way than with digital curricula. Her district requires her to use Go Math! daily for primary instruction and Reflex Math for practicing procedural skills. Each Go Math! lesson begins with whole-group video instruction on a particular math concept.

Allison is keenly aware of the importance of developing the MPs with her students. She is not satisfied with simply pressing "play" for the Go Math! videos and having the computer "teach" her students. Instead, she designs preliminary activities to get her students thinking about the concepts prior to watching the video. When students watch the video, Allison stops it at key moments and poses questions to her students. She finishes the lesson with an additional activity designed to enhance students' conceptual understanding. For example, when teaching a lesson on fractions, Allison had the students first think about a "fair share." While analyzing squares divided into fourths two different ways, Allison asked the students to think about whether all the pieces in the squares were fourths and to be prepared to justify their reasoning. After individual time, pairs met to discuss their thinking. She then chose certain students to explain their partner's thinking and how it was the same or different from than their own (example of MP2). She purposely chose those students to provide a range of perspectives.

After this class discussion, Allison started the Go Math! video lesson. She frequently—about every 30 seconds—stopped the video to pose purposeful questions: What do you think he will do next? (MP1). What do you think of the strategy he uses? Is there another strategy? (MP2). Can you draw a picture of what he is talking about? What would be a word problem for this number sentence? (MP4). Can you write that number sentence a different way and get the same answer? (MP4). After the Go Math! lesson, she gave each student a square from a chocolate candy bar, asked them to break the square into two or more pieces to form a new shape, and then asked, "Do you still have a fair share even though it is a different shape?" (MP4).

As Allison considered how to make teaching with digital curricula more effective for her students, she wondered: What things can I do before that will enhance the digital curricula? Where should I stop the video and discuss/predict? How can I make it more meaningful for them? She was enthusiastic about the data available on individuals' progress and eager to make use of that data to inform her teaching choices and differentiate instruction. Allison resisted when administrators insisted on fidelity of the program's implementation, arguing that she was acting in the best interest of her students' understanding. She was very concerned about other teachers in her building who were not as confident in teaching elementary mathematics and would simply press play and let the program "teach" their students. Even as an early-career teacher, she was considering ways to help enhance other teachers' work with digital curricula.

Case Study of Elise

Elise is a 4^{th}-grade teacher who has been teaching for 14 years. She is certified for Grades 4 through 9. She truly enjoys teaching mathematics, and teaches it for about 75 minutes each day. The school district adopted Eureka Math as the paper curriculum and Zearn as the digital curriculum. Although it's not required, the administration strongly encourages her to use Zearn. Each week, Elise's students use it for about 45 minutes during math class, an additional 20 minutes outside of math class, and about 45 minutes at home. The content the students explore in

Zearn typically aligns with the daily objectives. She chooses to use Zearn for acceleration, differentiation of instruction, remediation, and skill and practice.

Students typically used Zearn for 20 minutes when Elise organized different stations. All Zearn lessons began with *Number Gym* or an individually adaptive fluency experience for math skill practice. Next, students completed a fluency *Blast* that was aligned with the lesson and was the same for all students. Students then completed a guided practice and solved real-world problems that used the concrete, to pictorial, to abstract approach (MP1). Afterward, students transferred their digital learning to pencil and paper to draw representations of their thinking process (MP4). Finally, students began independent practice in the *Tower of Power*. Elise did not interact with the students while they worked on Zearn. Therefore, Elise did not personally engage the students working on Zearn in developing MPs.

During the interview, Elise expressed, "I would rather me doing instruction with them, and me working with them than having a computer program work with them." She did not feel that using digital curriculum changed her instruction: "I am still very much concrete, pictorial, abstract." She believed that it was "hard to monitor when they are on a computer because you don't even know if they are on the program half the time." As for teaching the MPs, she felt, "it is hard with Zearn. I see it like a remediation of what we have done in class." She wanted "to see their work" so that she could ask the students to analyze their work and "learn from their mistakes and have a discussion about it." She informed me that she knew students need to do math on the computer because they take the state test on the computer. She believed that there is a time and place for digital curriculum, but she did not want to be required to use it because it limits her teaching. "It's almost like you're micromanaging instead of trusting the individual teachers to make best choice for best practice for the students in their classroom." Elise did clarify that her confidence in teaching mathematics allowed her to see herself as a math teacher, but most elementary teachers "don't see themselves as a math teacher . . . they don't know the why behind the how." Those teachers, Elise felt, may rely on digital curricula more than she would, because she won't let the computer take over her teaching.

Case Study of Lindsay

Lindsay is a 1st-grade teacher who is in her third year of teaching. Her school district adopted Pearson's enVisionmath2.0(C) as the paper curriculum and Istation as the computer adaptive web-based platform, utilized for about 60 minutes during Specials time in a computer lab once a week. Istation is used during regular class time for an additional 20 minutes per week. Even though Istation covers 1st-grade content, it is not meant to align with the daily mathematics objectives. Lindsay utilizes its content for acceleration, skill practice, and Specials time.

Lindsay's two observations during class and during Specials time were noticeably different. Lindsay's typical 45 minutes of instruction began with a brief introduction to balancing equations. The class then proceeded to work in groups of 2–4 students with various mathematics manipulatives, such as Unifix cubes, two-color counters, dice, blocks, and balances, as well as dry-erase markers and whiteboards (MP4). Students were tasked with writing multiple equations that would balance (e.g., $4 + 1 = 5 + 0$) and explaining their logic to their group (MP1, MP3, and MP7). Lindsay constantly walked around to help struggling students and to encourage students to do their best. At the end of the lesson, the students came back together on the carpet to review what they had learned, with some students sharing their equations with the whole class (MP6).

As opposed to this interactive whole-class discussion and activity lesson, the Istation lesson involved students individually working on their mathematics problems. Students wore headphones and were encouraged to be quiet and work hard by themselves. If students struggled with the content, Lindsay answered their questions. Individual Istation problems varied, based on student ability. Many of the problems included interactive components, with students often singing or dragging virtual manipulatives around the screen. If students had difficulty with a concept, they were given multiple problems to help them. If they passed, they would move on in the content; if they struggled, the program would not move on to new content. Throughout this lesson, Lindsay did not engage students personally in developing MPs.

During her interview, Lindsay expressed her love for teaching mathematics face-to-face and the importance of student interactions. Lindsay felt that digital curricula were helpful as practice for procedural and conceptual fluency. She also felt that the more advanced students and those who struggled preferred digital curricula. The advanced students like to work at their own pace, and those who struggle felt the computer was sort of a safe space for them because they could make mistakes and no one would see them struggle.

Case Study of Sarah

Sarah is a 5th-grade teacher with nine years of teaching experience. She is certified for kindergarten through 5th grade and recently earned the Elementary Mathematics Instructional Leader Specialization. She truly enjoys teaching mathematics and is considered a leader in her district and school. The school district uses Eureka in 3rd-5th. The teachers also have access to IXL, which was chosen by district administration. Teachers were not given specific professional development on how to use it, and it is their discretion on how to implement it. Sarah's students typically spend one day a week on IXL, and she chooses a standard from that week's instruction for them to explore. In the interview, she shared that she sees IXL as a time for students to practice at their own pace. She also sees it as a time for students to have a "break" from Eureka and for her to have a "break" from planning. She does not use the data generated by IXL for instructional purposes, and she does not share results of student work with parents or guardians.

Sarah was observed twice: once while teaching a typical lesson and once on an IXL day. In the typical lesson, she introduced the concept of division. She had students out of their seats, grouping themselves into different animal herds. She asked the students to make observations about group size, number of groups, and remainder size (MP1, MP2, and MP4). On the IXL day, students worked quietly on tablets as she moved around the room answering individual questions. Sarah focused most of her time on a few students who needed extra support. In contrast to the first observation, Sarah was developing only MP1 with her students.

Case Study of Shelby

Shelby is a 3rd-grade teacher who is in her sixth year of teaching. She taught 8th grade for one year at a different school; since then, she's taught 3rd grade at her current school. Shelby's school district adopted Pearson's enVisionmath2.0(C) as the paper curriculum and Istation as the digital curriculum, which the students utilize for about 40 minutes during Specials time in a computer lab once a week and 1.5 hours per week during class time. The main digital curriculum for 3rd grade is Istation, but the computer lab teacher is also piloting Prodigy for potential future use instead of Istation. Students may access Istation at home, but are not required to do so. The Istation lessons are not meant to align with the daily mathematics objectives but do cover grade-level content. Shelby utilizes its content for acceleration, homework, differentiation, remediation, skill practice, and Specials time. Students independently work at their own pace with the content.

Shelby's two observations were clearly different. Shelby's 60-minute in-class observation involved students working on a warm-up as a review of previously learned mathematics concepts. Students then went to the carpet. Shelby gave certain students construction paper and students worked through scenarios as a class involving fractional relationships, such as $\frac{1}{4}$ and $\frac{3}{5}$

(MP3 and MP4). Students then went back to their seats and listened to the ebook *Give Me Half* by Stuart Murphy. Shelby asked students to write certain answers to fraction questions, and also reinforced their learning with playdough-based fraction work (MP1 and MP4). Lastly, Shelby had her class complete a fraction pizza worksheet (MP7). Shelby actively walked around the class, asking engaging mathematics questions and helping struggling students (MP6).

During the Istation lesson, students were quietly working through problems on their own. If stuck, some students used whiteboards or paper and pencil to figure out problems. Some students had difficulty with the vocabulary, in which case Shelby reassured them to try their best. Like Lindsay's students, Shelby's students often had interactive mathematics manipulatives on their screens that they could drag and drop to figure out such concepts as multiplication and rounding. Throughout this lesson, Shelby did not engage students personally in developing MPs.

During her interview, Shelby expressed her desire for more control over the content students were learning in the digital curricula, and she wanted the ability to choose the weekly math standards. Although there were downsides to Istation, Shelby felt the engagement aspect of digital curricula was good for students. She also liked that the program identified students' strengths and weaknesses, and that it provided practice. In addition, Shelby felt that unmotivated students or students who have "tuned out" the teacher learn best from digital curricula.

Discussion and Conclusion

Although there was some consistency in teachers' beliefs about teaching mathematics and in their confidence in using technology, there were some inconsistencies among their confidence in teaching mathematics with digital curricula, their beliefs about the effectiveness of digital curricula, and their use of digital curricula to assist students in developing the MPs. Several other differences were evident in how teachers enacted the digital curricula—independent work, large-group instruction, and stations. Two teachers enacted digital curricula during Specials, while three teachers enacted it during math class.

The perceived benefits of digital curricula also varied. One teacher noted the personalized instruction aspect and thought that the advanced students enjoyed being able to work ahead, while the struggling students felt safe making mistakes without being noticed. Identifying students' strengths and weaknesses, instant feedback, practice time, and students' increased success on standardized assessments were also perceived benefits. The change from interacting with peers to interacting with the computer was a concern of one teacher. Not being able to see students' work so that she could analyze their mistakes with them was a reason one teacher would rather use paper and pencil versus a computer for instruction. Several teachers expressed concern that they lacked control over what content students learned or what websites they explored, or even felt a loss of their own teaching identity.

Navigating the shift to digital learning presents several obstacles for teachers, and teachers need ways to deal with such obstacles. There is a separate knowledge base for teaching with paper and pencil than for teaching with digital curricula, and addressing this knowledge base needs to be one focus of preservice teachers' education programs and inservice teachers' professional development programs. With the advancements of innovative technologies in this digital age, digital curriculum is here to stay—at least for the near future. Teacher education and professional development programs must support teachers through the shift to digital learning. The State Educational Technology Directors Association, in *Navigating the Digital Shift 2018: Broadening Student Learning Opportunities*, recommends that "States must provide leadership as educational opportunities switch to the use of digital instructional materials to support student learning and successes" (p. 2). We echo this call and further recommend that teacher education programs address preparing preservice teachers to navigate this shift.

INFRASTRUCTURE TO SUPPORT STUDENTS EXERCISING CONCEPTUAL AGENCY

Isaac Nichols-Paez
Vanderbilt University

Corey Brady
Vanderbilt University
corey.brady@vanderbilt.edu

Generative activities have been shown to support students to engage in space-creating play and exercise their conceptual agency to generate a mathematical space (e.g. Stroup et al. 2004), yet these studies implement generative activities only with their resonating counterpart, classroom networks, technological infrastructures that connect multiple, co-present students into a shared, digital representation. Because these technologies are in continuous redesign and still inaccessible to many classrooms, we need to understand the crucial features their infrastructure provides to the classroom system. By analyzing the strains on the classroom without classroom networks and how they relieved that pressure and revive the system, we found that the collective public displays provided students with a collective orientation and a sense of connection and individualism.

Keywords: Design Experiments, Technology, Rational Numbers

Introduction

Generative activities are activities operating at the individual, small group, and whole class within which students are actively constructing connections and relations of mathematical ideas in both prepared and emergent participation structures that reflect and build on the mathematical ideas that the group creates (Stroup, Kaput, and Ares 2002; Stroup et al. 2004; Stroup, Ares, and Hurford 2005; Ares, Stroup, and Schademan 2009). In these types of activities, the class's social group functions to explore mathematical structures together and uses their social dynamics as a purposeful resource to support their exploration. A common means for designing and developing such activities take a standard, closed-form question as a starting point, and "inverts" it, making the *answer* of the standard question into the prompt for the generative activity. For example, instead of asking students to "simplify 4(x-3)+12" (a closed-form question, with correct answer "4x"), one might ask them each to create several expressions that are "the same as 4x" (Stroup, Kaput, and Ares 2002). By inverting the traditional one-correct-answer task, generative activities provide ways for students to construct or apply mathematical principles (e.g., exploring additive inverses by repeatedly adding "+x-x" to an expression known to be equivalent to 4x. When this kind of construction is occurring in parallel across the classroom, students are able to use the diversity of their group and their ideas for experimentation to generate a mathematical *space*.

Stroup et al. (2002; Stroup, Ares, and Hurford 2005) describe the resonance of generative activities with classroom network technologies to provoke new theoretical, methodological, and design frameworks. They articulate two main principles in the flow of a generative activity: (a) space-creating play and (b) dynamic structure. Space-creating play is the idea of students generating a mathematical space via experimentation, exploration, and playfulness. Dynamic structure refers to the emergent set of connections and meanings that appear as the students produce mathematical creations and respond to each other's work, both by commenting and by imitating, expanding on, or combining work to make new creations. Dynamic structure makes use of a functional sense of activity structure that is brought into being through students' playful actions and characterizes the unfolding space students are generating. Stroup et al. use these two ideas to argue that the relationship between mathematical/scientific structures and social structures is dialectical, with each mutually building off of the other. Essential to this process is the collective, public display of students' mathematical space, either in some physical/digital inscription or through social display.

As a complementary perspective of these public displays, we can consider them a space for *conocimiento* (Anzaldúa 1987 cited by Gutiérrez 2012), or sense of becoming familiar, connecting, and receptive of others. Through students' shared solidarity in generating the mathematical space, they develop their conocimiento of both the unfolding mathematical structures and the persons engaged in the display. Additionally, public displays of their work at the whole-class level may support students' sense of *nos/otras* (Anzaldúa 1987 cited by Gutiérrez 2012), or the juxtaposition of the collective and the individual. Further connections of this perspective with generative activities and classroom networks is unexplored and possibly very fruitful because of their differences in framing knowledge but similarities in positioning participants as generators of that knowledge.

Though Stroup et al. further describe the *resonance* between generative activities and classroom networks, arguing that the networked classroom is particularly suited to support a dialectic relationship between space-creating play and dynamic structure, few studies have explored these constructs in mathematics classrooms without the technology[1]. Substantial research has shown the impact of these new networking technologies and their resonance with generative activities (e.g. Ares, Stroup, and Schademan 2009; Ares 2013; Stroup, Carmona, & Davis, 2011), but these technologies are both largely unattainable for most classrooms and still going through continuous redesign. Thus, we need to understand the specific features of the classroom network critical to fostering collective mathematics inquiry through space-creating play and dynamic structure and which are optative. Furthermore, understanding which of the features should be customizable and which are fairly generic to collaboration will both support continued technology design and strengthen the underlying theory of collective mathematics. To investigate these features of classroom networks, we investigate 1) Do generative activities and collective mathematical exploration put strain on normal classroom infrastructure? (and, how?) and 2) Which aspects of classroom networks alleviate that pressure? (and, how?).

Classroom Networks and the Group-based Cloud Computing System (GbCC).

Classroom networks have been an area active, but uneven, research and development for over 20 years (or much longer, depending on one's definition (see Abrahamson 2006; Abrahamson and Brady 2014; Roschelle, Penuel, and Abrahamson 2004)), with a varied history of research and commercialization efforts. For the purposes of this paper, a classroom network (c.f. Brady et al. 2013) is a representation and communications infrastructure (Hegedus and Moreno-Armella 2009) consisting of hardware, software, and curricular/activity components. The hardware includes a set of devices (laptops, smartphones, or other custom communications-enabled "computers"), with each student (or, less commonly, each small group), having a device. These devices are networked to communicate directly or indirectly with each other and with a teacher computer, which is connected to a public display (usually a digital projector). Software, running on the classroom computers and/or on a networked server, provides aspects of communications infrastructure by routing messages among the participating devices in configurable, activity-specific ways. Software also provides a representation infrastructure, offering students and teachers views of the activity and tools to contribute that are appropriate for the discipline, the activity, and the participants' roles. Finally, at the curricular/activity level, "documents" or other specifications of roles or goals can be sent to participants to configure their devices and displays, and to facilitate the activity in real time.

GbCC (Brady et al. 2018) is a system of this kind, emphasizing flexible programmability and rich discipline-specific representations for mathematics, science, and the social sciences. It leverages browser-based open-source tools, building upon the NetLogo Web agent-based modeling environment (Wilensky 2015), married with GeoGebra Web (https://www.geogebra.org/) as a dynamic mathematics platform for geometry and algebra in Euclidean and Cartesian representations; and several other extensions to support mapping (Leaflet, https://leafletjs.com/) and 2d physics (Box2d, https://box2d.org/). As a platform for design-based research environment, its programmability supports an open-ended array of activity structures, and it can be run on any browser-enabled device (phones, tablets, or laptops). Its flexibility, configurability, and programmability make it ideally suited to exploring our research questions.

Data and Methods

The current study was a single four-week cycle from a larger design-based research (DBR) project. The 20 participants came from a 5th grade classroom at a public middle school serving a racially (39% Black, 6% Hispanic, 4% Asian) and economically (41% free or reduced lunch) diverse population within a large metropolitan district in a midsize southern city in the USA. The class period of the DBR study was not students' normal mathematics class but a time when students were tracked based on standardized tests in order to provide individualized attention (called Personal Learning Time, PLT, in the school). The participants from the current study were considered math tier 2 students (i.e., on target but needing some extra time for mathematics). Because of the nature of standardized testing and the flexibility of this class period, students moved from tier to tier or subject to subject depending on the most current testing. Thus about half of the students in the current study had participated in a prior implementation of a design cycle with generative activities without technology[i]. The first author facilitated about 2 class sessions each week over a four week period totaling of 8 sessions, each 30-45 minutes in length, and the classroom teacher either co-facilitated or pulled specific students for individual work.

The primary data source for the current study was design and field notes taken by the first author. Audio and video recordings of each lesson were also collected and used to triangulate findings. Analysis was ongoing and continuous throughout the design where the humble theories of the class's mathematical thinking and engagement were revised after each lesson (Cobb et al. 2003), in conversations among the researchers and with the teacher. Posterior analysis took the form of reviewing the progression of the lessons contrasted with the predicted learning trajectory. We paid special attention to anticipated and unanticipated challenges and strains on the classroom system prior to introducing network technology and the nature of how those challenges and strains changed when using it.

Mathematical Context and Predicted Learning Trajectory

We chose to target 5th grade fractions standards involving equivalence, operations, and comparison for this study. Fractions have been found to be a particularly difficult concept for students, yet they can be readily used as the basis for generative activities because the mathematical space of equivalent fractions is both core to the standards and very rich. We created a sequence of generative activities, to explore equivalence for the first two weeks and then operations on fractions for the second two weeks. The activity for both topics followed a similar rough structure. The first day of each of the two weeks focused on "space-creating play" to generate the space of ways to make ½, either with equivalent fractions or with fraction operations, depending on the topic. Students worked in small groups during these times, to foster connections in their space-creating play and reflection on the dynamic structure they were creating. Following this small group work to make ½, a whole-class discussion explored the different kinds of objects in the space (to make ½) and the mathematical principles students used to generate the space. Building off this the following class session (a week later), students returned to small groups to generate ways to make a fraction of their group's choice followed by another whole-class discussion of the mathematical principles. This trajectory was supported by research both on fractions (Lamon 2012) and generative activities (Stroup, Kaput, and Ares 2002; Stroup, Ares, and Hurford 2005), the key difference from the latter was the lack of networking technology. Beyond the curricular goals, we predicted the generative activities would support students to take conceptual agency (Boaler and Greeno 2000) in the classroom to create mathematical principles of equivalence and operation and to voice their conceptual perceptions even without technology. We remained open to the question of whether these technologies would be needed, by observing the classroom system, students' engagement in the tasks, and the degree to which they exercised conceptual agency.

Results

Through our design and analysis of generative activities to support students' conceptual agency in exploring fractions *without* technology, we found that these activities put multiple strains on the classroom system for students to engage and participate. Without the technological infrastructure and additional ways to participate in the activity, the whole-class discussions led by the first author were not able to support students to have a platform to show the work they did in small groups, or to have much of a "voice" at the whole-class level. This central strain reduced students' engagement over time, and following the second whole-class discussion (week 2), the necessity of additional infrastructural support was apparent, both to the authors and to the classroom teacher. Upon the introduction of technology, students' re-engagement in the generative-activity process was visible, as usual with the introduction of any new technology. Yet more meaningfully, students' engagement was sustained through the last two weeks, and their conceptual agency increased in that time. This process contrasted significantly with the time without technology when their engagement and utilization of conceptual agency decreased over the course of the same time period. By comparing the strains on the classroom system during generative activities without technology and how the infrastructure provided by the technology relieved those strains, we can begin to identify some of the crucial features of classroom networks.

Generative Activities' Strains on the Classroom System

Progressively throughout the first two weeks of equivalent-fraction generative activities, we documented how students became less and less engaged and utilized their conceptual agency less and less. This process came to a climax when the classroom teacher requested a change in the activity in order to re-engage students at the end of week two. Upon analysis of the design, students' disengagement was progressive. Students engaged readily in the initial generative activity convening the space-creating play in almost all the small groups. Some groups even utilized their conceptual agency to recognize patterns and methods in their generation of equivalent fractions. Yet, during the whole-class discussion, students struggled to know how to participate in productive ways and see their hard work validated. Multiple students made various bids to read aloud their list of fractions in its entirety, but with upwards of over 30 fractions, this was not logistically possible. Moreover, without a means to organize or represent these contributions visibly, a reading would not have contributed to the dynamic structure. Instead, the first author focused on having students share out their methods of generating fractions and patterns they observed in their set of equivalences. While students did engage in the discussion and built multiplicative conceptual resources for fractions, field notes capture a number of students' feelings of discontent.

The following week, the first author launched another generative activity to build on students' work with ½ by generating fractions the same as a fraction of their choice. Unlike the start of the previous activity, the teacher and the first author struggled to support students to begin the activity (even to choose a fraction), and to convene space-creating play in their small groups. In the students' eyes, the small group work had lost its importance and meaning after the previous week's whole-class discussion when they perceived their work was left unchecked, ungraded, and unshared with the class. While either adult was present, students would work together to generate equivalent fractions, but their motivation reflected a perceived lack of importance of their work at the whole-class level. Thus, students' patterns and methods were much less robust during the whole-class discussion the following day, and fewer students participated. Additionally, one of the students from the previous week made another bid to read all of her fractions aloud, demonstrating a continued desire to showcase her work at the whole class level, to hear her voice as part of the group, and receive validation for the effort she had put in. Because of students' steeply declining engagement, we decided to introduce technology to re-engage students and support their sustained participation in generative activities. Our prediction was that the introduction of technology would quickly re-engage students with the task of generative activities, and that comparison in students' sustained engagement would reveal the some of the crucial features of classroom networks to support students' collective mathematics in generative activities.

Adjusted Learning Trajectory and Use of Classroom Networks

Because of the strains of the classroom system for students to see their work as meaningful at the whole-class level, we adjusted the research plan to incorporate GbCC support for the activities in the final two weeks. Since the activities designed with the technology did not strictly align with the original learning plans, we adjusted the curricular goals to target fraction comparison instead of fraction operations. We planned to use GbCC's public display to create a joint representation for students to see a reflection of themselves and their classmates as they engage with mathematics. The classroom network assembled students' fraction input as a character moving on a vertical line between a teacher-defined maximum and minimum value, with its y-coordinate corresponding to the fraction value. The class appeared as a collection of these characters moving between the max and min values. If a student's fraction input was outside of this range, their character was shown into a gray area above or below. The goal of the first week was for students to make connections from their work with equivalence within the technology as a way to begin to understand the representational forms it used and then for the class to quickly transition into comparing 'easy' fractions. We wanted students to have the chance to explore within a technologically enhanced representational world and for the class to see each other's explorations to discuss our methods and strategies. In this way, the classroom network would provide additional communicative pathways for students to feel their work and their classmates' work were meaningful at the whole-class level. We planned to end the activity sequence with supporting students to see the *density* of fractions (i.e. that between any two fractions there is another fraction). We conceptualized this as a 'zooming in' effect with the technology where the teacher could make the range a subset of the previous defined range and fractions could still be found.

The first two days of implementing GbCC went as predicted. The technology served to revive students' engagement and enthusiasm while also providing additional tools and representations to the work they were doing as a whole class. The public, anonymous display provoked a collective responsibility to fill it, positioning students to hold each other accountable during the activity, and during whole-class discussions, this public representation was a collective object for us to reference. During this space-creating play, students exercised their conceptual agency by choosing personally relevant numbers (not something seen the previous week). For example, one student found the fraction equivalent to 1/7th where the numerator was her birthday (mmddyy). Students patterns and methods extended the ideas from previous weeks using multiplicative relationships to generate equivalent fractions.

The final week of the study focused on comparing fractions, with the goal of students' having insight into the density of fractions. We started with a whole-class discussion of the previous weeks' work and asking if students had ways to know if one fraction is bigger than another (no technology). Even without technology, the class sustained a meaningful discussion, leveraging the collective perspective provided by the classroom network activities the previous week. In the following two days of activities, students sustained engagement and motivation, unlike the second week without classroom networks. Furthermore, students' utilization of conceptual agency grew as their fluency with the technology grew, compared to declining as their engagement declined, in the first two weeks. As students interacted with and in the mathematical space, a few began to use the public display as a dynamic representation - moving their characters across the screen by manipulating their fraction input successively. This type of play showcased how the classroom network became an embedded infrastructure for students to represent movement and communicate their actions to me and to others. Additionally, while these playful actions were unexpected and in fact went against the underlying goal of the activity for students to develop insight into the density of fractions, students were developing individual and share-able fluency with manipulating and comparing fractions in service of the personally-meaningful goal to predict the movement of their character up, down, and into the middle. Such spontaneous, and unpredicted, utilization of conceptual agency was not present without the classroom network's representational and communication infrastructure.

Crucial Features of the Classroom Network

The above analysis explored how generative activities strained a classroom system without adequate representational and communicational infrastructure and identified features of classroom networks that were crucial to relieving those strains and supporting students in utilizing their conceptual agency. The collective, public representation of students' work with fractions was the focal point of two such crucial features that supported collective mathematics and that were very difficult to provide without technological support. First, as demonstrated in the first week and the follow-up discussion without technology, the *public display of an aggregate representation of students' contributions* provided an essential means of discussing the activity, referring to students' work in context, facilitating activity flow, and sustaining students' attention. Leveraging this feature, we were able to facilitate whole-class discussions where students engaged in illuminating the underlying multiplicative structure of equivalent fractions and continue the conversation even when the technology was temporarily removed. These types of whole-class discussions were very different prior to implementing the technology when students did not have such a collective orientation, and they made multiple bids to reorient the discussion towards what they felt was important (e.g., their personal lists of equivalent fractions).

The second crucial feature relating to the public display was *the communal, real-time dynamic nature of the public representation*. Students displayed a sense of both collective effort and individual publicity, or *nos/otras* (Gutiérrez 2012). Simultaneously feeling both connected to the community and represented as an individual was essential for collective mathematics. The importance of this feature was demonstrated first when the classroom network was first introduced as students began to hold each other accountable to participate in the activity, and it grew further when students began utilizing their conceptual agency and publicizing their new skill of predicting the movement of their character, showing their abilities to others and sharing how they did it.

Discussion: Students Utilizing Conceptual Agency with the Technology

Understanding how the representational and communicational infrastructure of classroom networks support students' space-creating play and utilization of their conceptual agency can provide insight into these technologies' functionality and support their ongoing design. At the same time, it also can inform efforts to enact generative activities without classroom networks, identifying needs and resources for alternative supports in such classrooms. Based on our comparison here of a classroom with and without technology, two crucial features of the dynamic infrastructure emerged, in the collective orientation provided by the public representation and the simultaneous communicative avenues of collective and individual voice developing a sense of nos/otras. These aspects are vital to keep in mind as we continue to design classroom networks, infrastructure, and activities to further support students exercising their conceptual agency.

Additionally, generative activities need to be flexible enough to support students' adaptation of the task as they exercise their conceptual agency. Similar to work in microworlds (Edwards 1998), generative activities supported by classroom networks are not capsules of disciplinary learning and conceptual agency. Rather, we need to design for and encourage students to make expressive and unpredicted conceptual moves as they interact with the representations and concepts of the activities. On the other hand when the classroom system does not have the infrastructure of classroom networks, traditional infrastructures must be adjusted to foster collective orientation and nos/otras. Specifically, students need some form of collective representation of the concept to orient their individual or small-group work towards each other. Furthermore, social infrastructure must support students as they make their work public to both hear their own voice and, metaphorically, hear the voice of the choir. Over time, classroom systems can develop these types of social infrastructures through socio-mathematical norms, but classroom networks may foster more rapid development of them or a lower threshold of effort for sustaining them over time.

Implications for Further Research

Classroom networks provide a flexible space for students to interact, both with mathematical ideas and with each other, and a dynamic, public display of their work as it unfolds. This space quickly creates infrastructure in the class to foster students' prolonged engagement and utilization of their conceptual agency. Yet pragmatically, teachers, administrators, and researchers may question the necessity of this technology when compared to its cost and disruption. By observing and documenting first how a classroom group experienced strain without the technology and then was supported by it, we understand better the value of the technology, what types of additional activities may supplement it, and ideas on how we might support the classrooms without it. Additional work should compare other types of representational and communication infrastructures (Hegedus and Moreno-Armella 2009) and curriculum activity systems (Roschelle, Knudsen, & Hegedus, 2010) to better understand how students participate in collective inquiry and the necessary of these infrastructures to support students in exercising their conceptual agency. Specifically, previous studies have shown collective inquiry is possible without technology (e.g. Ball 1993; Lehrer, Kobiela, and Weinberg 2013; Fiori and Selling 2016), and exploring the infrastructure imbedded in these types of classrooms will provide insight into both the dynamics of group mathematics learning and into the design of networking technology.

Endnotes

Stroup's introduction of the construct of generative activities clarifies that their roots lie outside of mathematics, connecting to work in reading comprehension by Wittrock and in shared identity building by Freire (the identification of a community's "generative words").

[2] A disruption of losing half the participants and gaining the same number of new students caused analysis of the two design cycles to lose much of its meaning, but the class during the analyzed cycle remained intact.

A COMPARISON OF U.S. AND CHINESE GEOMETRY STANDARDS THROUGH THE LENS OF VAN HIELE

Lili Zhou
Purdue University
Zhou756@purdue.edu

The aim of the present study is to investigate through a van Hiele theory lens the difference between Common Core State Standards of Mathematics (CCSSM, 2010) and Chinese mathematics standards—Compulsory Education Mathematics Curriculum Standards (CMCS, 2011) in descriptive geometry. A descriptive learning expectation (DLE) is defined as a standard which focuses on properties of figures and relationships between figures without considering the exact quantity. Based on the DLEs in CCSSM and CMCS, Different types for each van Hiele levels were developed and each DLE was identified into a van Hiele level and a particular type. Through examining DLEs distributions of van Hiele types, this study investigated how CCSSM and CMCS portray the development of students' geometric thinking. The findings suggest that CCSSM and CMCS emphasize different approaches in geometry teaching and learning.

Keywords: Standards, van Hiele theory, Descriptive geometry

Purpose of the Study

Through cross-national comparative studies, researchers identify differences between nations which enables them to suggest ways to improve teaching, learning and curriculum development from a unique perspective. The purpose of comparisons is to identify factors that can support student success in mathematics learning and performance. One factor influencing student learning is the curriculum. Teachers and students determine what should be taught and learned based on the previously-developed curriculums. What is taught and learned is informed by standards (Schmidt et al., 2001) in addition to other factors including teachers' beliefs and districts' or schools' policy.

This study considers standards as curriculum learning goals and focuses on a subset of geometry standards for CCSSM and CMCS. These two documents were published at roughly the same time and have been shown to have great influence on teaching and learning practices in their respective countries (Reys, 2014). Through investigating the differences and similarities of CCSSM and CMCS, this study intended to reveal how the two documents delineate the learning expectations and how standards influence other curricula. In addition, this study investigated how CCSSM and CMCS depict the development of students' geometric thinking.

Theoretical Framework

Van Hiele theory (Van Hiele, 1984) identifies five levels of students' geometric thinking and provides a framework for curriculum development, teaching and learning (Clements, 2003). Van Hiele theory have been used by many researchers in different ways. Some researchers used it to describe students' geometric thinking levels (e.g., Fuys, Gerddes & Tischler, 1988; Mayberry, 1983; Senk, 1989; Usiskin, 1982), whereas other researchers used van Hiele theory as a framework to inform curriculum development (e.g., Dingmen, Teuscher, Newton & Kasmer, 2013; Newton, 2011). In this study, I examined the expectations of geometric thinking in CCSSM and CMCS through a van Hiele theory lens. This framework makes explicit how standards portray the development of students' geometric thinking, specifically, what approaches address students' geometry levels and lead them to formal deduction. However, in terms of individual students, they have different ways to learn and think. Even though two students are in a same van Hiele level, they may not have the same geometric thinking characteristics (Wang & Kinzel, 2014). Therefore, categorizing students' geometric thinking into general levels is not convincing. In order to remedy this limitation, based on Fuys et al' s (1988) van Hiele level descriptors, I developed different types for each van Hiele level, which explicitly describe characteristics for each van Hiele level in terms of descriptive geometry standards (See Table1).

Table 1: Van Hiele Types

Van Hiele Levels	Van Hiele Types
Level 1	Recognizing figures (RF) Composing and decomposing figures (CD)
Level 2	Recognizing figures by their specified attributes (RFA) Understanding relationships between 3D and 2D figures empirically (UF) Recognizing transformation empirically (RT)
Level 3	Describing hierarchical nature of classes of figures (DH) Understanding definitions (UD) Understanding postulates (UP) Developing informal proofs (DIP) Constructing figures (CF)
Level 4	Writing formal proofs (WFP) Understanding the axiomatic system (UA)

Methods

In this study, a descriptive learning expectation (DLE) is defined as a descriptive geometry standard, while the learning expectations related to quantities and coordinates are not considered. The following Example 1 is a DLE which is included in the study, and Example 2 is a Non-DLE which is excluded in the study.

> Example 1. Distinguish between defining attributes (e.g., triangles are closed and three-sided) versus non-defining attributes (e.g., color, orientation, overall size); build and draw shapes to possess defining attributes. (CCSSM, p. 16)
> Example 2. Recognize area as an attribute of plane figures and understand concepts of area measurement. (CCSSM, p. 25)

Each DLE was coded into a van Hiele level and a particular type. There are two stages for coding. In the first stage, two researchers who are literate in both English and Chinese languages work together to identify the DLEs from all geometry learning expectations in CCSSM and CMCS. In this stage, the two researchers had fewer divergences. In the second stage, the two researchers coded DLEs in CCSSM and CMCS in terms of van Hiele levels and types independently. After all DLEs in CCSSM and CMCS were examined, the results were compared, and the researchers reached a more than 50% consensus. Then, discrepancies were discussed until consensus was reached.

The study performed the analysis by looking at the percentages and frequencies of DLEs in van Hiele levels and types. The distributions of van Hiele levels reflect the spirit of van Hiele theory (Newton, 2011) and the distributions of van Hiele types allowed the researcher(s) to see the respective emphases of CCSSM and CMCS.

Results

As shown in Table 2, the total number of DLEs in CCSSM and CMCS are quite different since CMCS describes DLEs in more detail, while CCSSM describes them more generally. The percentages of level 1 and level 2 DLEs in these two documents are similar with only slight differences. The numbers and the percentages in level 3 and level 4 are quite different.

Table 2: Frequencies and Percentages of DLEs of Each Level

	Level 1		Level 2		Level 3		Level 4		Total
CCSSM	5	6%	10	12%	48	59%	18	22%	81
CMCS	7	5%	23	16%	62	43%	51	36%	143

When digging into types in each level, the differences become discernable. As appearing in Table 3, CMCS contains more formal definitions and postulates than CCSSM. CMCS has 19 formal definitions and 10 postulates, whereas CCSSM has 10 formal definitions and no postulates. The two documents share five common definitions: *congruence*, *angle*, *circle*, *perpendicular line*, and *parallel line*. Both documents define the common definitions in the same way except for *congruence*. CCSSM gives the precise definition in high school level "Understand that a two-dimensional figure is congruent to another if the second can be obtained from the first by a sequence of rotations, reflections, and translations*"* (CCSSM, 2010, p. 55).

In the CMCS, *congruence* specifically refers to triangle congruence; the definition is given in middle school level as the equality of all corresponding pairs of sides and all corresponding pairs of angles.

Table 3: Percentages and Frequencies of Types in Level 3

Level 3	CCSSM		CMCS	
Describing hierarchical nature of classes of figures (DH)	4	8%	2	3%
Understanding definitions (UD)	10	21%	19	31%
Understanding postulates (UP)	0	0	10	16%
Developing informal proofs (DIP)	20	42%	13	21%
Constructing figures (CF)	14	29%	18	29%
Total	48		62	

In terms of developing informal proofs (DIP), CCSSM provides a 42% proportion of DLEs as DIP, compared to CMCS which only provides 21% DLEs as DIP. The results show that CCSSM and CMCS have significant differences, supporting van Hiele theory in their own ways. CCSSM emphasizes intuitive thinking and an inductive approach, hence CCSSM expects students to make adequate preparation in informal proofs to reach formal deduction. On the other hand, CMCS emphasizes logical thinking and a deductive approach, expecting students to develop theoretical reasoning through constructing definitions, postulates, and theorems systems.

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

Discussion and Conclusion

The analyses of the data collected from distribution of DLEs consistently showed that CCSSM and CMCS have significantly different learning goals in geometry. Both CCSSM and CMCS emphasize the construction of figures, but they expect this to be accomplished using different approaches. CCSSM holds open attitudes towards tools and suggests a variety of approaches such as: freehand drawing, technology, compass and straightedge, reflective devices, paper folding, and dynamic geometric software. In contrast, CMCS only expects using a compass and a straightedge or a ruler to construct figures. In addition to the different approaches, DLEs in these two documents also have different aims. In CCSSM, some DLEs for constructing figures make preparation for further learning. For example, CCSSM addresses expectations of constructing triangles by three measures of angles or sides to prepare the criteria of triangle congruence. In CMCS, each DLE for constructing figures is corresponding to a definition, a postulate or a theorem. Instead of preparing for further learning, the aim of construction is to enhance comprehension of definitions, postulates and theorems. These results are consistent with the difference in U.S and Chinese textbooks' emphases which are already identified by the existing research.

Additionally, the results of this study resonate some differences in mathematics education in the U.S and China. For instance, the tendency for Chinese teachers is to expect students to choose generalized and abstract strategies, and for U.S teachers to encourage students to use particular and concrete strategies to solve problems (Cai, 2004; Cai & Hwang, 2002). Moreover, the DLEs in CMCS emphasize formal definitions and formal proofs which indicates that CMCS expects the theoretical achievement more than practical achievement. This finding is in line with the previous studies which found that Chinese students performed better in procedure tasks than U.S. students, but underperformed than U.S. students in creative tasks (Cai, 2000). Understanding the differences in teaching and learning in mathematics in the U.S and China can shed light on understanding the differences in standards which are set for different teaching and learning goals in the two nations.

Compared to CMCS which is concerned with the abstract and logic, the DLEs in U.S geometry curriculum focus on visual and manipulation geometry. As van Hiele-Geldof (1957) in her dissertation pointed out, for visual and manipulation geometry, cutting and pasting can help students acquire better insight into the basic concepts of geometry. Students need to have sufficiently mastered manipulations, because they can accomplish conscious perception in a geometric sense. However, to achieve a higher logical level, students should not rest on understanding the relations through concrete example visual and manipulation geometry as well as logic geometry are indispensable aspects of geometry. On the one side, visual and manipulation cannot ensure logical thinking and deduction. On the other side, only emphasizing logical thinking may fall into depending on memories instead of developing deductive ability. In order to success in geometry, students need to develop both of them. Standards should address and balance learning expectations for these two aspects of geometry. Therefore, for the further revision of CCSSM and CMCS, I suggest adding appropriate DLEs on logic geometry for CCSSM while addressing more DLEs on manipulation, especially on using dynamic geometry software for CMCS.

ANALYZING THE TRANSITION AWAY FROM MONTESSORI WITH A MATHEMATICS POINT OF VIEW: THREE PARTICULAR FACTORS

Zachariah Benton Hurdle
Southern Arkansas University
ZBHurdle@saumag.edu

Angela Stanford
Southern Arkansas University
AGStanford@saumag.edu

Our study investigates three specific factors hypothesized to affect the transition period from third-grade Montessori math to fourth grade non-Montessori math experiences. These aspects are 1) the change in pacing and structure of the classroom, 2) the removal of manipulatives in favor of handwriting methods, and 3) the reversal of roles that teachers and students occupy. The effect of this transition on problem-solving skills of students is analyzed through personalized math metacognitive tools. Overall results show that students identify alternatives strategies when uncertain on unfamiliar problems, often reverting to object-centered methods such as manipulatives, drawings, or finger-counting. The declining use of manipulatives in the classroom is a strong influence in the transition, followed by a clear shift in student and teacher roles. Meanwhile, while pacing and structure of the classroom has minimal effect.

Keywords: Metacognition, Problem solving, Elementary school education

Introduction

Often, Montessori programs focus on “students [who] can be described as self-regulated to the degree that they are metacognitively, motivationally, and behaviorally active participants in their own learning process” (Zimmerman, 1989, p.329). Metacognition, then, is an appropriate framework when approaching self-motivated thinkers as encouraged by how the Montessori system operates because they can describe their thoughts and processes strongly for the study; and while motivation and belief impact performance, persistence, and creativity (Ryan & Deci, 2000), the Montessori program promotes reflection, organization, and planning skills (Bagby & Sula, 2011). A gap in literature regarding Montessori research exists because standardized guidelines and lack of traditional assessment make the comparison with other programs difficult (Mak, 2006; Yen & Ispa, 2000). But while this type of research is indeed rare and inconsistent, particularly involving manipulatives (Laski, Jor’dan, Daoust, & Murray, 2015), the transition from a Montessori system that often serves as early education is vital, and so the transition away from Montessori requires research to improve the knowledge base of educators.

Further, the importance of elementary mathematics education, where this transition often takes place, is considered a vital learning period in student success (Clements & Sarama, 2007). Third-grade is the primary focus of our study and emphasizes independent thinking and confidence development through problem solving (Kamii, 1994). This is vital in mathematics education because students who memorize steps are often setting themselves up for failure in higher mathematics levels (Kloosterman & Stage, 1992). Further, NCTM (2014) stresses that “tasks that encourage students to use procedures, formulas, or algorithms in ways that are not actively linked to meaning, or that consist primarily of memorization or the reproduction of previously memorized facts, are viewed as placing lower-level cognitive demands on students.”

Problem Statement

The purpose of this study was to explore three specific factors related to documentation of difficult student transitions away from a Montessori mathematics program at a particular school. During the prior school year, an issue was identified concerning students exiting the Montessori program after third-grade and entering a more direct-instruction environment in fourth grade, somewhat indicative of the typical transition experience by these types of students. These conclusions can be applied to many students experiencing a similar shift in their own education. Our study followed students in primary grades at a single campus serving PreK-12 (PreK – 3rd is Montessori, and 4th – 12th is traditional), eliminating external variables such as changing settings, peers, and institutions—variables that are commonly referenced in typical post-Montessori studies (Anderman, Maehr, & Midgley, 1999).

Research Questions

The following research questions help evaluate the transition period and how it affects students in mathematics. While metacognition is the framework, problem-solving skills is the context. These questions are elaborated as follows:

1. To what teaching practices and learning opportunities are third- and fourth-grade students exposed, and how are these related to the Montessori approach?
2. How are three specific aspects of the fourth-grade mathematics classroom perceived by students and teachers compared to their previous exposure in the Montessori style?
3. How, and to what extent, does changing the teaching practices and learning opportunities affect the problem-solving strategies of students?

Based on the related research, the three factors referenced in the second research question were: 1) the implemented learning pace and discovery style of the class, 2) the shifting focus away from materials toward handwriting methods, and 3) the difference in the roles students and teachers occupy during the transition. The purpose of the first and third research questions was to determine teaching strategy alignment to theory and provide a measurement to view the effects on student problem solving and mathematical approaches. The conclusion will then appropriately focus on the second research question, supplemented by the information provided through taking the first and third questions into consideration.

Methodology

This study took place in Central America at an International Baccalaureate-certified (IB) school, with a high school English-based math curriculum matching the global, IB curriculum. The lower grades are taught for students to be prepared for this secondary IB curriculum. The school is private, and served approximately 135 students during the time of this study, ranging from pre-kindergarten to 12th grade. Total attendance numbers were approximated because of various relocations of international students mid-year. During this study, more than twenty countries represented the diverse population of the school across the grades, and there were no comparable schools in the surrounding area. This school used a trimester system; the first trimester ran from September 1 to December 14, the second trimester from January 3 to March 31, and the third trimester from April 24 to June 29. This study took place during the first and second trimesters in order to maximize the collection of data during peak student transition.

During the academic year, there were 12 third-grade students and 16 fourth-grade students for our sample, each with a mixed amount of experience in the school's curriculum. Five fourth-grade students were identified from the group of sixteen for further problem-solving analysis.

This analysis was conducted using metacognitive math tools with the goal of targeting the third research question concerning effects on problem solving skills. Participant selection was based on cross-referencing average academic math performance with at least three to four years of experience in the Montessori program, plus teacher recommendations. These parameters lead to our sample of five students, from the population of 16 fourth-grade students.

Analysis Tools

Ten observations were conducted in each of the third- and fourth-grade classrooms, using a modified version of Piburn & Sawada's (2000) Reformed Teaching Observation Protocol (RTOP), adapted to reflect the Montessori and non-Montessori classrooms. These protocols contained 12 statements regarding classroom structures, with a ranking system and qualitative outlet for alignment with classroom theory. All students, both third- and fourth-grade, were interviewed once following a semi-structured interview script regarding learning preferences, classroom perceptions, mathematics favoritism, and role identification (for a total of 28 interviews). Additionally, all four teachers (two teachers co-taught in each grade) were interviewed three times each to discuss similar ideas along with curriculum strengths and weaknesses, classroom experiences, instructional details, and other opinions and observations. The combination of interviews and classroom observations were enough to satisfy the data collection regarding the first two research questions. Coding allowed us to place positive and negative phrases into the appropriate category related to the three factors we analyzed.

The third research question required extra analysis to evaluate what kind of effect this transition was having on students' problem solving skills (thus placing value on the effect that the transition had on mathematical problem solving on a cognitive level). The five selected fourth-grade students were interviewed in two additional settings with metacognitive tool problem sets: one included problems based on addition and subtraction, with some multiplication; the other focused on multiplication, division, and fractional application. These problems were taken from Empson, Junk, & Turner's (2006) "Formative Mathematics Assessments for Use in Grades K-3," closely following some modeling of Cognitively Guided Instruction (CGI) implied through Empson's prior collaboration over such material (Carpenter, Fennema, Franke, Levi, & Empson, 2015; Carpenter, Fennema, & Franke, 1996). Based on student work and dialogue, inferences were made toward their processes based on their progress within the transition and their preconceived notions of mathematics, how to be successful, preferred strategies, and much more.

Findings

The First Aspect: The Changing Pace and Structure

Third-grade students experienced an exploratory curriculum and held some leadership in a mixed classroom of first-, second-, and third-graders. Students approached problems with highly differentiated levels of depth based on ability, not age. One major difference from the Montessori system was the inclusion of a small, weekly group mini-lesson for each subject, and teachers instituted a "follow-up" strategy as a form of assessment. This strategy, combined with weekly homework benchmarks, helped push students forward. While third-graders had learning freedom, fourth-graders were taught as a group through direct instruction. These teachers implemented sequential book lessons to establish routines, where math was designated as first subject of the day. Students then individually performed drill and repeat exercises, and were discouraged from working with others. While third-grade teachers encouraged natural occurrences of collaboration, fourth-grade students were separated. The two fourth-grade teachers each agreed that the lack of differentiation was a problem but that direct instruction was appropriate, yet disagreed on which students were most detrimentally affected—students with high or low achievement performance. Many fourth-grade students appreciated the direct instruction because they perceived they were learning more efficiently than Montessori. They also thought the new structure prepared them more effectively for future grade levels.

The Second Aspect: Removing Montessori Materials

Montessori materials were not the only learning method for third grade. Montessori students used the manipulatives in the classroom as the original source of knowledge, but third-grade students were additionally tasked with transitioning their learning into handwriting with colored markers and, eventually, pencils. While the handwriting goal was to physically represent abstract ideas, many third-graders complained about working through material twice (once with manipulatives, once with handwriting), without connecting these together. They saw older children using handwriting, and believed manipulatives slowed their learning. They valued the new strategies and topics of fourth grade because they were aware of the intention to push themselves as a learner and thinker. To many students, manipulatives were not gradually phased out, but were instead entirely replaced. While third-graders had mixed opinions, many fourth-grade comments were negative toward manipulatives, though a few students appreciated their use. Many fourth-graders also said they were relieved to have moved on from the materials, because they were "boring" and "repetitive," and stopped helping them with math. Teachers agreed that perhaps they had been used for too long in the third-grade stage. Yet when the five selected students were pushed to problem solve, many reverted to them when faced with unfamiliar topics. In fact, the students who found the most success with the metacognitive tool problems were the ones who verbally favored manipulatives and did not denounce them.

The Third Aspect: Reversing the Teacher and Student Roles

In third grade, teachers approached the class mostly as a guide, with brief deviations when taking the responsibility of providing weekly lessons in preparation of lesson structure in fourth grade. By moving confidently in this guide role, the third-grade teachers maintained their capacities in fostering student-led learning, while students actively gained self-motivation and awareness, shown in interviews. These roles were very different in fourth grade. Students were now placed in a system where everyone was taught with the same expectations, with the teacher as the formal source of information. Fourth-graders took the role of passive learner to the teacher's authoritarian role. These observations indicated that the fourth-grade classroom was not only non-Montessori, but also followed a direct-instruction style, particularly for mathematics. Students did not comment negatively toward this new direct-instruction style, but instead embraced the teacher as a source of knowledge for more efficient learning. The teachers actually struggled more than students with identifying their own place in the classroom, especially knowing that their students came from a Montessori learning environment previously.

Conclusions

According to the literature, making the connection from the concrete manipulatives to the abstract symbols is a process that usually involves drawing visual aids as a transitional stage; the use of manipulatives themselves is more for mathematical understanding rather than algorithmic proficiency (Stein & Bovelino, 2001). For the students in this study, this was achieved only as long as meaning and value was apparent. Students generally achieve mathematical understanding if they use the manipulatives as a tool rather than a requirement (Cope, 2015). Therefore, students need to build upon what they learn to grow mathematically (D'Ambrosio, 2003), and the repetitive methods beyond mastery at this school did not reflect such values. This provides insight into correct implementation of Montessori manipulatives in the most effective way possible. Montessori programs may provide students with solid mathematical understanding with physical materials, modeling, and drawing. In fact, this study showed that students tend to revert back to these methods when approached with problems they had less algorithmic built-in strategies to accomplish, as unfamiliar exercises required different processes to be successful. The issues arise when moving into the procedural stages while battling student perceptions, and while our situation was certainly a case study, future studies may explore this stage more fully.

In this research, we explored intergenerational computational thinking in Elementary Schools in a large urban centre. Research has shown that, intergenerational learning between seniors and youth advances the speed at which both parties develop their skills. These studies however analyze learning in environments outside of the classroom, and often emphasize the benefits of the younger cohort learning from the older. This study seeks to analyze intergenerational computational thinking in the context of mathematics learning in a classroom setting. We seek to determine whether the benefits of intergenerational learning still exist between youth of different ages and look at the benefits for both groups of learners in this setting. We seek to demonstrate the impact of this learning on mathematical learning. Directions for further research will be discussed.

Keywords: Technology, Problem Solving, Instructional Activities and Practice

Introduction

Putting learners of different ages together to promote learning in a classroom setting has a long tradition. Specifically, intergenerational learning can be defined as “an interactive process that takes place between different generations resulting in the acquisition of new knowledge, skills and values” (Ropes, 2013). The aim of putting students together who differ in age is about exposing students to different levels of knowledge and experience which allows all those involved to see things from a different perspective. Intergenerational learning is more than people of different ages, its “how differences in their ages can be framed in ways that contribute to content” (Sánchez & Kaplan, 2014). This knowledge transfer offers the potential for a deeper learning than that between peers. However, many studies in this field frame this kind of learning as one group imparting knowledge onto another (Aemmi & Moonaghi, 2017; Findsen & Formosa, 2011). In a classroom setting, this often results in programs such as reading buddies, strong programs as they can be, which make older students help younger students learn how to read. Our study will take a qualitative approach to the learning that was undergone. Implications for curriculum implementation and directions for areas for further research will be discussed. This study is part of a larger research study on computational thinking and spatial learning in middle school students.

Theoretical Perspectives

While a majority of intergenerational studies examine the learning that occurs between seniors and youth, the present study focuses on intergenerational learning with a narrower age range: Grade 3’s and Grade 7’s. We are defining the learning between these groups of students as intergenerational because of the findings by Charles and Runco (2001) that there is a peak of divergent thinking in students around Grade 4. Other research shows there is a drop in creativity from Grade 6 to 7 (Lau & Cheung, 2010). As such, we posit that the groups of learners that we were working with are at essentially different points in their academic careers. This makes our study intergenerational.

Many studies analyzing the transmission of knowledge between generations have shown that intergenerational learning can be bidirectional. However, while some of these studies are set in a classroom, few are set in the context of a computer programming classroom. However, this appears to be the perfect place for such bidirectional learning. For the purpose of our study we define computational thinking as “an approach to solving problems, designing systems and understanding human behaviour that draws on concepts fundamental to computing” (Kotsopoulos et al., 2017). As Resnick et al. (2009) discuss, younger learners are able to benefit from the “low floor” of computational thinking, or the lower bar to entry required for learning while experienced learners benefit from “high ceiling” which allows for learners to continue to find new types of learning. In one study, seniors (aged 60-89) and high school students participating in a high school English class both reported learning from the experience of intergenerational learning (DeMichelis, Ferrari, Rozin, & Stern, 2015). This cooperative learning is a key finding in intergenerational studies. Sánchez and Kaplan (2014) argues that multigenerational classrooms provide opportunity for meaningful learning; participants mutually benefit from exposure to diversity of knowledge and experiences.

Methods

This research was completed in the context of a wider study analyzing the relationship between computational thinking and spatial reasoning. Our specific study examined intergenerational computational thinking between Grade 3 and Grade 7 students at a private elementary school in London Ontario. The study began with the Grade 7 students being taught various forms of coding by the first and second authors from November to March. The classroom teacher was present for each lesson but was not involved in teaching. Initially researchers followed the Pedagogical Framework for Computational Thinking (PFCT), introducing the four pedagogical experiences: unplugged, tinkering, making and remixing (Kotsopoulos et al., 2017) using the online block coding program Scratch. Next the Grade 7 students used Spheros (Figure 1), robotic spheres which are programmable using iPads to roll in any direction.

Figure 1: An Example Scratch Block Programming

Once the Grade 7 students had mastered these activities, they were tasked with teaching the Grade 3 students to code over the course of two, hour-long lessons. Grade 7s were not specifically instructed on how to teach the younger students. For the activities, each Grade 3 learner was randomly paired with a Grade 7 instructor. The first activity was “My Friend Robot” in which one partner would give instructions to direct the other partner, the ‘robot’ though a

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

maze. For the other unplugged activity "Order the Instructions", all students had to number a set of picture instructions which the other partner had to follow to fold a paper airplane. Next, students participated in Sphero activities, including a curling game which allowed students to learn how to estimate distance on Sphero. Students also learned to program Sphero to travel paths of different shapes such as a square. The final activity of each session was programing Sphero to travel through a maze which was created on the floor with a tape outline (Figure 2).

Data collected during these sessions included blog post by Grade 7 students, questionnaire responses by Grade 3 and 7 students, as well as observations recorded by the first author and the classroom teachers to collect data. Students were asked to respond to questions in the form of blogs during class time following both of the coding buddies' lessons. Questions were designed by the first author and asked the Grade 7s such things as, "What was the hardest part of teaching the grade 3's to code?" and "What are the grade 3's better at when it comes to coding?". Grade 3s were asked "What was the hardest part of coding?" and were asked to self identify with such phrases as shy and silly, as well as statements such as, I like school, and I am good at coding.

Results and Discussion

Student responses indicated that coding activities were both engaging and educational for participants. The overall responses to coding were very positive: 95% of the Grade 3 students and 67% of the Grade 7 students responded in surveys that they enjoyed the coding activities. One Grade 3 student wrote "I liked coding because it gave me an understanding of how robots work". A Grade 7 student was also enthusiastic about coding saying, "I find coding fun and really cool". The Grade 7's had to assist the Grade 3's most with left and right as the 'robot' was facing many different directions during the first unplugged activity. Of the Grade 7's, about half believed that the Grade 3's learned coding faster then their class did. One Grade 7 stated "Once you get them down to work they seemed to really enjoy it and know what they were doing."

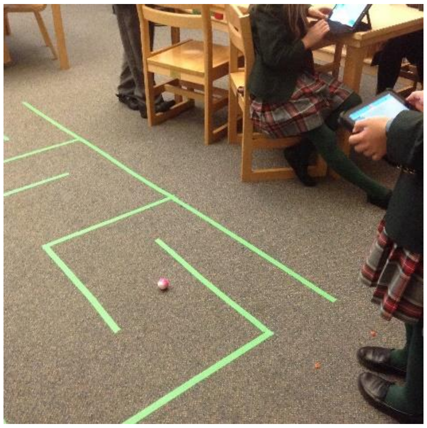

Figure 2: An Example of a Sphero Maze Activity

With the one-on-one instruction, the Grade 3s' were very quick to gain a basic understanding of coding. More interestingly, they were able to demonstrate creative critical thinking that the Grade 7s quite frequently were missing. Once the Grade 7s' taught their Grade 3 buddies the basic controls to operate the Sphero, many Grade 3's inquired about other ways to advance the use of a Sphero. One example of this came when, after being taught by the Grade 7's to make the Sphero to move in a square, one Grade 3 student asked why the loop function wasn't used to simplify the inputs. This innovative thinking was noticed by the grade 7's in a response; "[the

Grade 3's] have a great imagination so they come up with great ideas". Similar sentiments were expressed throughout by the Grade 7 students. Evidently the Grade 7's noticed the creative methods the Grade 3's discovered to program Sphero differently to complete the same task. Here it is important to look at the first time that the Grade 7s were taught coding. Notes made by the first and second author demonstrated that when taught coding by the first and second author, even when Grade 7s were given time to explore and experiment, the vast majority of students simply asked what to do and followed the instructions as they were given. This varies from the inquisitive approach taken by the Grade 3 students, who even during one-on-one instruction wanted to explore alternative approaches. This differences in learning approaches corroborates the difference in divergent thinking typically found in students of these age groups (Charles & Runco, 2001; Lau & Cheung, 2010). This difference in the approaches was noted by Grade 7 students where the claim that their strong imaginations led to more unique ideas than is present for other students.

Conclusion and Implications

These results suggest that intergenerational learning between youth relatively close in age is beneficial for both learners and teachers. The Grade 3's learned important computational thinking skills with one-on-one instructions from students who were better able to understand their learning styles and preferences. The Grade 7's learned from the Grade 3's originality to incorporate creativity into coding as the younger students demonstrated multiple wasys of reaching the same goal. A Grade 7 student said "I think my problem-solving skill is improved because when I have problems or question about coding games I would have more choices than just asking teachers or [the first author]. Instead I would use other parts of the code and work towards that to solve my questions". In the present study, intergenerational learning proved to be very useful and an effective way to promote fluid learning, rather than simply instruction, which translates into a variety of applications in a school setting as there is always multiple ages of students who could benefit from learning together. Intergenerational learning should be leveraged for a variety of academic subjects to enrich the learning of the students involved. Moreover, the fact that the students were teaching each other promoted interest which teachers may not have been able to trigger.

THE IMPACT OF MATHEMATICALLY CAPTIVATING LEARNING EXPERIENCES

Secondary students do not often have positive experiences with mathematics. To address this challenge, this paper shares findings of a design-based research project in which a mathematical story framework was used to design mathematically captivating lesson experiences ("MCLEs"). We provide evidence that designing lessons as mathematical stories shows promise. That is, students reported improved experiences in MCLEs when compared to randomly-selected lessons. The MCLEs also impacted the students' descriptions of their experience.

Keywords: Curriculum; Curriculum enactment; Affect, emotion, beliefs, and attitudes

How can mathematics be taught so that students describe the subject as amazing, surprising, and full of wonder? Unfortunately, most evidence to date suggests that these descriptors do not describe the typical student experience in mathematics in the United States; students have increasingly poor attitudes in mathematics as they advance into higher grades (Mullis, Martin, Foy, & Hooper, 2016). One way to respond to these poor mathematical experiences has been to explore how lessons can be aesthetically enhanced to increase student engagement and interest by drawing on the affordances of what makes literary stories compelling and pleasurable. Analyses of high school mathematics lessons with heightened positive aesthetic responses (e.g., student exclamations of "Wow!) have linked narrative moves (e.g., misdirection) with positive student aesthetic reactions, such as anticipation, curiosity, and surprise (e.g., Dietiker, Richman, Brakoniecki, & Miller, 2016).

Building on this work, this present study is focused on learning whether lessons that are intentionally designed as mathematical stories improve student experiences. Working with six high school teachers, 18 *mathematically captivating learning experiences* ("MCLEs") have been designed and tested using the mathematical story framework. This paper reports on the results of the first design-and-test cycle of a three-year project of design-based research (Edelson, 2002), addressing the question *What impact, if any, do lessons designed as mathematical stories have on student aesthetic experiences?* Our results suggest that even in their first iteration, the design and enactment of mathematical stories shows promise.

Theoretical Framework

For this study, *aesthetic experiences* describe the way in which experiences move or compel an individual to act, such as by asking a question, persevering through difficulty, or even laughing or gasping. Therefore, the study of aesthetic dimensions of an experience examines how a particular experience enabled the compelling effects (or lack thereof) to occur. Since the audience of an enacted mathematical story is arguably the students, the students' evaluation and description of the experience is an appropriate measure of its aesthetic value.

Here we take the perspective that mathematical sequences can be interpreted as a form of *mathematical story*—a designed sequence of mathematical events (such as tasks or discussions) experienced by students connecting a beginning with its end (Dietiker, 2015). Mathematical stories have a plot, which enables the description of how a sequence can generate suspense (by setting up anticipation for a result) and surprise (by revealing a different result than the one anticipated). In this study, we use the math story framework as a conceptual resource for design.

Methods

Three pairs of experienced teachers were recruited from three high schools in the Northeast of the United States to design and test MCLEs. Each high school was selected to offer contrasts: (1) a small independent charter school with mostly Latinx students and a subject-specific curriculum, (2) a large public school with a very diverse student body (representing multiple ethnic groups) and an integrated curriculum, and (3) a large public school with a majority white student body and a subject-specific curriculum.

To prepare teachers to design MCLEs, the six teachers attended a two-week professional development in Summer 2018 at which lesson design was studied along three dimensions: captivation, coherence, and cognitive demand. The captivation and coherence dimensions were directly addressed through the mathematical story framework. A focus on the cognitive demand framework (Stein, Smith, Henningsen, & Silver, 2000) was also included to encourage to incorporate mathematical complexity as they designed MCLEs for curiosity and/or suspense.

Following the professional development, the teachers met weekly in pairs with researchers to design three MCLEs per teacher. Courses of focus were chosen to provide a wide array of topics, grade levels, and tracked levels (i.e., honors or non-honors). Teachers selected content based on topics that they had difficulty motivating in the past. Non-mathematical aspects (e.g., real-world contexts, games) that would likely influence student interest were avoided. In addition, the entire group of teachers and researchers met three times throughout the school year to share the emerging MCLE designs and get feedback from teachers from different schools.

At the start of each school year, all students were given a disposition survey using Likert items from TIMSS (2016) and the TRIPOD (Ferguson & Danielson, 2015) to measure captivation (e.g., do you like math?) and student perceptions (e.g., does the teacher care?) on a scale of 1 to 4 (see Riling, Dietiker, Gibson, Tukhtakhunov, & Ren, 2018 for more information). An aggregate "captivation" measure was then generated for each student using this instrument.

To learn if lessons designed as mathematical stories can improve the experiences of high school students, we compared the reported student experiences for MCLEs with randomly selected lessons taught in the same classrooms. In addition to 3 MCLEs per teacher, between 2 and 4 non-MCLEs per teacher were also observed. A single protocol was used to collect data for all enactments so that students would not know which lessons had a special design. After each lesson, we collected Lesson Experience Surveys (LES) for each participating student. The LES asks students to select three descriptors (e.g., intriguing, dull), displayed in a random order, and asks them to rate how they felt during the lesson from very bored (1) to very interested (4) (see Riling, Dietiker, & Gates, 2019 for more information). It also asks students to rate whether they found the content of the lesson challenging or not and to indicate to what level they agreed with statements such as "time flew by" and "the content of this lesson was relevant to my life."

Through prior work, we found that the more a student reports liking mathematics overall, independent of any particular lesson, the more they are likely to report positive experiences with a mathematics lesson ($R = 0.423$). Because of this relationship, we factored in students' mathematical captivation level when comparing MCLE and non-MCLEs. We also controlled for the teacher in order to acknowledge that students who learn from the same teacher and learn in the same classroom have related mathematical learning experiences.

Findings

Overall, the emerging results suggest that MCLEs improve the lesson experience of students and can alter the types of experiences students report.

The Impact of MCLEs on Student-Reported Lesson-Specific Interest Measures

Of the 8 classes in this study, 7 showed an increase in average student interest (on a scale of 1 to 4) with MCLEs. Table 1 displays the distribution of classes, along with the course and grade level and the average number of students surveyed across the observed lessons.

Table 1: Distribution of Classes (where "124" = school "1," teacher "2," and period "4") with Subject, Grade Level, and Interest Measures for MCLEs and Non-MCLEs

Class	Subject	Grades	Non-MCLE Avg. Rating (n)	Avg. MCLE Avg. Rating (n)	Difference
113	Algebra 2	10	2.71 (n=17)	2.89 (n=17.5)	+0.18
116	Algebra 2	10	2.81 (n=16)	2.94 (n=18)	+0.13
124	AP Calculus	12	2.60 (n=15)	2.92 (n=13)	+0.32
215	Integrated Math 3 H	10, 11	2.85 (n=24)	3.06 (n=21)	+0.21
224	Integrated Math 1	9	3.04 (n=15.5)	3.56 (n=13.5)	+0.52
311	Algebra 2	11, 12	2.76 (n=12.3)	2.77(n=15)	+0.01
322	Geometry	10	2.67 (n=12)	2.80 (n=10)	+0.13
327	Algebra 2	10	2.33 (n=10.5)	2.62 (n=9)	+0.29

At the student level, this improvement can be modeled. The graph in Figure 1 shows the linear regressions for the student interest measure by captivation for non-MCLEs and MCLEs. The influence of an MCLE on student interest in a lesson is statistically significant when taking into account student captivation and teacher, improving student experience by 0.21 ($p<0.001$). However, we did not find a statically significant difference between non-MCLEs and MCLEs on other measures, including student perception of challenge or whether time flew by.

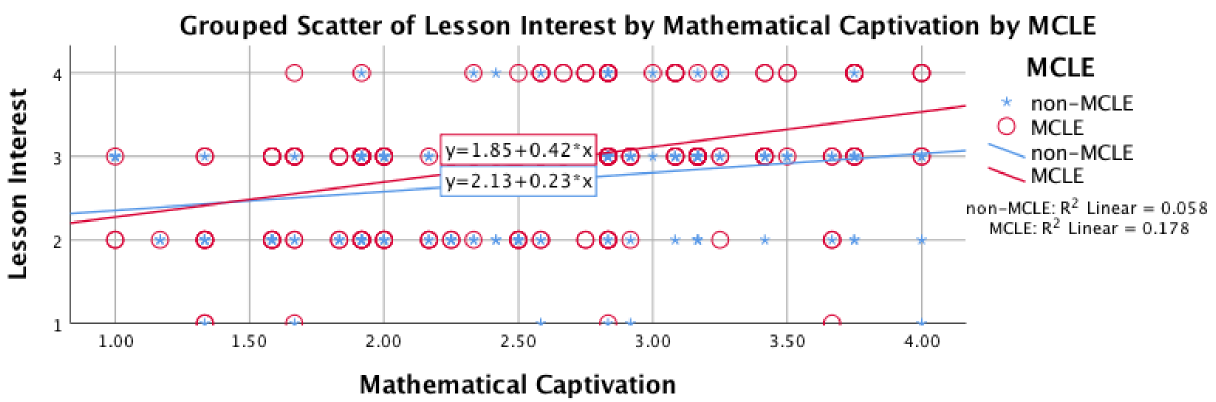

Figure 1: Scatterplot of Student Measures: Lesson Interest, from the Lesson Experience Survey, by Mathematical Captivation, from a Survey of Mathematical Disposition

Overall, MCLEs appear to differentially influence the experiences of students with different mathematical dispositions. On average, MCLEs did not change the general experience of students with the lowest lesson experience, while students with very positive views of mathematics saw the most benefit. For example, the models predict that a student with low captivation (1) will report similar interest in MCLE and non-MCLEs (non-MCLE: 2.36, MCLE: 2.27). Yet students with high captivation (4) benefit by a factor of 1.16 (non-MCLE: 3.05, MCLE: 3.53).

MCLEs were not experienced differently by students based on their gender (p=0.089). It is difficult to assess any impact of student racial identification on aesthetic reports, because the racial breakdown of each school in the study is so different that it is difficult to distinguish between the effects of a student's school and their racial identification.

The Impact of MCLEs on Student-Reported Lesson-Specific Aesthetic Descriptors

MCLEs appear to have also been successful in changing the type of aesthetic experience of the students. For example, the descriptor "intriguing" was selected on 28.0% of surveys after MCLEs, but by only 18.8% of students surveyed about non-MCLEs. On the other end of the spectrum, 6.6% of students selected "dull" to describe MCLEs, compared with 15.4% of students selecting this descriptor for non-MCLEs. In addition, when analyzing whether MCLEs received more positive, neutral, or negative aesthetic descriptors, we found that students who experienced both types of lessons used more positive descriptors when describing their experience with MCLEs and that this difference was statistically significant (p=0.001). Overall, students used positive descriptors 58.1% of the time when describing MCLEs (compared to 47.1% for non-MCLEs), while using negative descriptors 11.1% of the time for MCLEs (compared to 17.3% of the time for non-MCLEs).

Even among MCLEs, the descriptors selected by students varied. For example, students were less likely to select descriptors that have extremely positive connotations, such as "amazing" or "fascinating" than other positive descriptors, such as "thought-provoking." The students who selected these extremely positive descriptors reported higher interest levels, on average, compared to students who selected all other descriptors with the exception of "suspenseful." An example of how different MCLEs are from each other is that 23% of students surveyed about an MCLE in class 224 about geometric transformations selected "amazing," while 24% of students surveyed about an MCLE in class 215 about finding the roots of a polynomial function selected "fascinating." These classes both had high levels of student interest among both students who selected these descriptors and those who did not. For these MCLEs, the students in class 224 reported an average interest level of 3.46 and the students in class 215 reported an average interest level of 3.20; these MCLEs had a high positive impact given that the average interest level reported across all student surveys is 2.84.

Discussion

With persistent negative views of mathematics by students, particularly at the secondary level, there is a pressing need to identify ways to improve the experiences students have with mathematics. Already from our early results, we are encouraged by evidence that designing for a more positive experience is possible, and are hopeful that providing students with more captivating lesson experiences such as these can impact their views of mathematics as a whole.

In addition to designing for improved reactions overall, our work thus far suggests that it is possible to design for specific aesthetic opportunities, such as suspense and surprise. We are also heartened that students find MCLEs to be more "intriguing." As the MCLEs go through more design cycles, we are interested in learning if more students will continue to report these aesthetic responses along with others.

LEARNING FROM NOVICES: CURRICULUM CAPACITY IN A CHANGING CURRICULUM LANDSCAPE

Corey Drake
Michigan State University
cdrake@msu.edu

How and whether to teach prospective elementary teachers about mathematics curriculum materials has been a persistent tension in mathematics teacher education. This tension has been exacerbated in recent years by the rapid development of an even wider range of instructional materials, including new curriculum series purporting to be aligned with the Common Core, open resource materials, and materials available on websites including Teachers Pay Teachers and Pinterest. In this paper, I present novice elementary teachers' perspectives on the range of curriculum contexts in which they work, as well as novices' responses to these contexts. I conclude with implications for teacher educators, curriculum developers, and school and district leaders.

Keywords: Curriculum, Teacher Education-Preservice

Purpose

How and whether to teach prospective elementary teachers about mathematics curriculum materials has been a persistent tension in mathematics teacher education. Two common reasons for this ongoing tension have been 1) the wide range of available curricula in terms of quality, content, and design and questions about whether there exist "curriculum-proof" (Taylor, 2016) strategies that would be useful for novice teachers across the range of curriculum contexts and 2) the persistent perception that well-prepared teachers create their own lessons instead of using curriculum materials (e.g., Ball & Feiman-Nemser, 1988). This tension has been exacerbated in recent years by the rapid development of an even wider range of instructional materials, including new curriculum series purporting to be aligned with the Common Core, open resource materials, and materials available on websites including Teachers Pay Teachers and Pinterest. In this paper, I explore the perspectives of novice teachers on their curriculum contexts and the implications of these contexts for understanding the curriculum capacity of preK-12 school systems and for the preparation of elementary teachers.

Theoretical Perspectives

Curriculum capacity refers to the ability of an educational system to accomplish instructional goals and provide high-quality, responsive instruction to students through the interactions of teachers, curriculum materials, and contextual supports (Drake, Land, & Gichobi, 2009). Elements of curriculum capacity include teachers' knowledge, beliefs, and practices; the quality and features of the curriculum materials; and the availability of professional development and material and social resources to support curriculum use. An important aspect of curriculum capacity for the current study is the finding that different districts make different choices about where in the system to invest to develop curriculum capacity. For example, while some districts choose to invest in high-cost comprehensive curriculum materials that provide multiple supports for teachers within the materials, other districts choose to adopt free on-line curriculum resources and spend their available funding on professional development for teachers in using the materials

(Drake, Land, & Gichobi, 2009). As a consequence, the types of knowledge and skills needed for teachers to be productive and responsive curriculum users in the first context differ significantly from those needed to be successful in the second district. Given the recent changes and expansions in the curricular landscape, as described above, the range of knowledge, skills, and curriculum use strategies with which teachers need to be prepared to fit with the range of curriculum contexts in which they might work as novice teachers seems to be expanding and requires further study.

The construct of curriculum capacity builds on two lines of teacher-curriculum research. First, Remillard (2005) describes the participatory relationship between teachers and curriculum materials, in which both the characteristics of teachers and the features of materials contribute to this relationship. Remillard (2005), as well as Remillard and Heck (2014), situate these participatory interactions between teachers and curriculum materials within specific school and district contexts that also present both supports for and constraints on the interactions between teachers and curriculum materials. Here, I am drawing on these accounts to explore the ways in which individual teacher characteristics, features of curriculum materials, and aspects of school and district context interact to produce to different types and levels of curriculum capacity. Second, Brown (2009) introduces the construct of pedagogical design capacity, or teachers' capacity to use curriculum materials to accomplish instructional goals. In this study, I build on Brown's conceptualization of capacity, but expand the construct to be a function of the interactions across individual teachers, curriculum materials, and contexts. Students are also a key element of these interactions; in this paper, they are considered as aspects of the context contributing to curriculum capacity.

Methods

The findings reported here are part of a larger study of novices' enactment of ambitious instructional practices in elementary mathematics and language arts. The larger study investigates the interactions among individual characteristics, opportunities to learn in teacher preparation programs, and the contexts of novice teaching in supporting or constraining the enactment of ambitious instruction among graduates from five different teacher preparation programs. In other words, the study investigates what works, for whom, and under what conditions in terms of novices' ambitious instruction. Data sources include surveys, interviews, and classroom observations with novice teachers in their first three years of teaching, as well as interviews with teacher preparation program personnel and surveys of cooperating teachers, student teaching supervisors, mentor teachers (during novice teaching), and principals.

For this paper, I analyzed interviews from 61 participants during their first year of teaching to understand the range of elementary mathematics curricular contexts in which novice teachers are working and the ways they are responding to those contexts. These interviews were transcribed and analyzed using a series of "big bin" codes, including ambitious instruction, opportunity to learn, challenges, resources, and context. I then conducted secondary analysis of the excerpts within the "challenges" code that related to the use of curriculum materials and used this secondary analysis to characterize the range of curriculum contexts identified by first-year teachers (FYTs). This secondary analysis included both further detailing of the nature of the challenge, as well as coding for the type of response FYTs enacted to address the challenge, including seeking additional resources and information, adapting their practices, and exiting the context.

Findings

Curriculum Contexts

Across the 61 FYTs participating in our study, the curriculum contexts ranged from no prescribed curriculum at all, requiring teachers to locate and construct their own curricula, to highly prescribed use of a single textbook or set of materials. In between these two extremes, participants reported curriculum contexts that involved combining multiple sets of materials, either with or without guidance, or using a primary set of curriculum materials and then supplementing those materials to meet specific student needs and/or contextual needs (e.g., preparation for high-stakes tests). Across these curriculum contexts, FYTs also perceived a range of contextual supports for and constraints on curriculum capacity, as illustrated below. Three quotations illustrating this range of curriculum contexts and curriculum capacity are provided below:

> I like coming up with my own curriculum and I like doing what I want but I also need a balance of 'this is what you should be doing'… I have no curriculum… so it's frustrating to be like, alright, make every activity, every worksheet and task…

> So, we do use *Envision* and that's pretty much what we stick to. It's our first year – or the district's first year – using it, so they are pretty [much] like, 'This is what you're teaching.' They're not really like, 'Try this and add this and see what you can do here.' I do add a basic – I don't know if it's really a curriculum, but it's called *Thinking with Numbers* and it's basic computation because I found that *Envision* doesn't really teach computation.

> Or in math, we do a lot of like claim-support-question, but that's not in the curriculum. It's just something that I want them to be doing deep thinking. Or like number talks, that's not in the curriculum, but we do them all the time. I kind of just have to prioritize what I want to do and what I think is important.

These quotations illustrate the range of curriculum contexts encountered by FYTs, as well as the elements of curriculum capacity in these contexts that were both supporting and constraining FYTs' use of curriculum materials to support ambitious and responsive instruction. These elements include the FYTs' personal knowledge and skills, ideas and practices learned in teacher preparation, core and supplemental curriculum resources with various strengths and limitations, and school and district expectations for curriculum use.

FYTs' Responses to Curriculum Contexts and Challenges

In addition to describing their curriculum contexts and the challenges they faced in those contexts, FYTs also described the ways in which they responded to these contextual curriculum challenges. In particular, they focused on searching for and finding additional resources and ideas, as well as adapting their use of curriculum materials to be more responsive to students. The first two quotations below represent FYTs seeking out additional resources, while the third quotation represents an example of an adaptive and responsive curriculum use practice.

> I have to teach multiplication and the standards, they have to teach the times table 0-12, but it doesn't really say how you have to teach it and I, I guess I would like more guidance whereas I just have to do a lot of research on my own to figure out how I want to teach it.

> Sometimes these games [from *Envision*] take them like five seconds and then they are bored for the rest of it… so we have a lot of other games we put in too… honestly a lot are from Teachers Pay Teachers."
>
> It's really confusing for some of them. So, I feel like – and I don't know, this is just something I picked up this year and I don't know if it's right – but I try to start with really little numbers even though that's not anywhere in my resources at all…. And then the next day I try… I'll put a wrong problem from the day before that I looked at their worksheet and say, 'What do you notice about this? Let's talk about this.' But with this curriculum and how bulky it is, I feel like I can't do that as much because it's like the next day is a new thing and we've got to keep rolling.

In the presentation that accompanies this paper, I will more comprehensively map the range of contexts – including supports and constraints on capacity – as well as the range of responses described by the FYTs. Taken together, the supports, constraints, challenges, and responses identified by FYTs provide a robust and nuanced understanding of curriculum capacity across contexts and the ways in which novices are and are not prepared to work within these contexts.

Implications

Given the wide range of curriculum contexts in which FYTs might begin teaching, it is important to understand the kinds of knowledge and skills FYTs will need in each context. For example, what kinds of capacity do teachers need to bring to contexts with no curriculum materials as compared to contexts with highly-prescribed curriculum materials? How do teachers learn to pick and choose among available resources and put them together in ways that allow students to experience a coherent curriculum? Thus, this study has implications for teacher educators considering answers to these questions, but also for curriculum developers and school and district leaders. Given that curriculum capacity is realized through interactions across teachers, curriculum materials, and contexts (including students), both curriculum developers and policymakers might consider the ways materials are designed and supports are provided to enhance the likelihood of achieving high levels of capacity.

This research report presents the pilot-year results of a three-year research project on computer science and technology. The Bessie Coleman Project, named for the first African-American and Native woman to receive a pilot's license, provides underrepresented students with opportunities to learn about STEM-related careers by participating in computer modeling and flight simulation. Three-dimensional computer modeling and flight simulation was used as interventions to increase underrepresented students' CT skills, motivation, and persistence. Project staff and facilitators at Boys and Girls Clubs and local schools implemented the project at six sites in Wyoming in 2018. A total of 124 participated in the pilot study: 29 (summer); 95 (fall). Descriptive evidence from survey data suggest that students had sustained interest in technology and qualitative data suggest students had interest in STEM careers.

Keywords: Computer Modeling, Flight Simulation, Computer Science, Technology

The Bessie Coleman Project (BCP) is designed to expand learning opportunities for elementary and middle grade students in the Rocky Mountain (Wyoming and Denver, Colorado) and Mid-Atlantic regions of the U.S. (Philadelphia and Baltimore) by leveraging Universal Design for Learning principles and strategies. It incorporates lessons and activities in 3D modeling, flight simulation, and piloting drones which are designed to bolster students' interest and engagement in mathematics and science learning. Indeed, the overarching purpose of the project is to create new STEM Pathways that provide unique learning opportunities for underrepresented students.

The work of the BCP involves research and development of cutting-edge professional development for teachers that is connected to culturally relevant learning activities for students. This report describes our Year 1 pilot, which allowed the research team to field test the intervention in two different types of informal settings: summer camps and afterschool programs. In this project, we engage students in project-based learning through computer modeling (i.e., upper-elementary students) and flight simulation (i.e., middle-school students) as an entrée to STEM and STEM awareness. Using computer modeling to help children learn to code (grades 4-5) and flight simulation with applications to learn how to use drones for data collection (grades 6-8) builds new knowledge and understandings of complex systems and contributes to the extant literature on STEM education and workforce readiness.

Two of the core research questions that guide the BCP project are:

1. What learning experiences involving emerging technologies (i.e., computer modeling, flight simulations, and drones) effectively enable diverse populations of students to gain familiarity and relevant competencies with these technologies, and what factors influence the outcomes of the learning experiences?

2. What culturally-responsive instructional and curricular practices and models (including place-based education) used by teachers enhance student understanding of and interest in STEM occupations, and what factors influence the outcomes of the practices and models?

Theoretical Framework

The theoretical frameworks that guide **The Bessie Coleman Project** are **Constructionism** (Papert & Harel, 1991) and **Expectancy-Value Theory** (Wigfield, 1994; Wigfield & Eccles, 2000). Constructionism focuses on students' ability to *build knowledge structures* regardless of the learning environment (Papert & Harel, 1991). In this context, the learner has a great deal of autonomy as he/she is guided by the work that proceeds rather than a protocol. The concept allows students to be active learners as they *think* about ideas, investigate that idea, discuss it with peers, and make adaptations within a complex system. The constructionist principle is well suited for teaching computer modeling and flight simulation since students learn to construct various types of models while using a project-based approach. In terms of Expectancy-Value, theorists argue that "individuals' choice, persistence, and performance can be explained by their beliefs about how well they do on [an] activity and the extent to which they value the activity" (Wigfield & Eccles, 2000, p. 68). The expectancy-value framework has been applied to the subject of mathematics and can be adapted to technology. The value a student puts on a subject or task is predictive of future intentions to participate in similar tasks (e.g., enroll in courses, pursue careers, etc.) While self-efficacy measures students' beliefs about success on very specific tasks, expectancy beliefs are measured more broadly with questions such as "How well would you expect to do if you had to learn something new about…" a given topic. Assessing ability-beliefs and values among rural and urban, African-American, Latinx, Native, and female students will add to the literature on broadening participation in STEM.

Methodology

Mixed methods (i.e., field notes, interviews, photographs, and videotapes) were used to collect qualitative data on the nuances of culture and place in after-school clubs and summer camps (Creswell, 1998). One hundred twenty-four students participated in the BCP during summer and fall 2018. The size of the sites varied from seven to 47 students. Recruitment yielded levels of diversity that were somewhat more robust than the general population in Wyoming or the racial composition of school children. About 72% of the study sample were White students and 66% were males. Combined, about 18% of the sample were Black, Latinx, and Native students. More diverse students will participate in Years 2 and 3 in Colorado and Pennsylvania. Finally, most of the participants are elementary students (grades 3, 4, and 5), who were also younger than 11 years old.

Baseline and post-intervention surveys were administered to students, prior to the beginning of the intervention and afterwards. Project staff designed and administered paper surveys for student participants which, in addition to a section on student background characteristics, contained a battery of items in the following three areas: (1) participants' use of technology; (2) participants' feelings about science; and (3) participants' opinions about technology. The various components of the survey were pulled and adapted from instruments in the public domain, including value expectancy (Eccles & Wigfield, 2002), self-efficacy in technology and science (Ketelhut, 2010), and STEM attitudes (Friday Institute, 2012).

Results

Descriptive data from student participants at six intervention sites are presented. This brief report emphasizes the use of technology survey for analysis and discussion.

Students Self-Reports of STEM

Student survey items reflected self-reports of their use of technology. Descriptive statistics are shown for each item. This includes the number of cases, baseline means, and post-intervention means, along with the mean differences between the two. However, in order to more accurately measure gains, the fourth and fifth columns subtracts baseline values from post-intervention values for the same participant. The fourth column shows adjusted gains that have valid data at both time points, while the fifth column depicts the Ns. The purpose of the tables is to examine general patterns across the survey data, rather than to reveal significant differences. There were modest pre- to post-intervention gains on most items (see Table 1).

Qualitative data were also collected during the summer STEM camps on students' perceptions and experiences. To field test the intervention, flight simulation was implemented at a Boys & Girls Club in southeastern Wyoming and computer modeling was implemented at a Boys & Girls Club in western Wyoming. Student comments during a focus group interview included comments such as: "I liked how we could 3D print things and I have never…actually got to do that and do new things on the computer;" "I liked flight simulation;" and "I liked drones." Figure 1 depicts one of the student's designs during the computer modeling camp.

Discussion

Preliminary findings in the Bessie Coleman Project reveal that students gained familiarity and competencies with computer modeling and flight simulation, especially when modeling was tied to 3D printing and flight simulation was tied to flying drones. Students were enthralled as they saw the images they created on the computer come off the print bed. Moreover, they were intrigued with the capabilities of the drones. Mean differences on the use of technology survey items ranged from M= 0.07 to M=0.47. However, students had the lowest gains on how to use data to solve problems, building computer programs, designing computer games, and problem solving in general. Culturally relevant strategies included use of guest speakers and place-based themes (i.e., animal crossovers) to help Wyoming students decide what images to create during computer modeling tasks. Field trips to museums also provided cultural and place-based experiences that students identified during focus group interviews. While this project is ongoing, these preliminary results are promising. In future study years, we will use the drones to collect data to create additional problem-solving opportunities such as geocaching. Cultural relevance will also include the history of Black and female aviators in addition to guest speakers.

Tables and Figures

Table 1: Participants' *Use* of Technology

Variable		Baseline Mean	Post-Interv. Mean	Mean Diff	Adj Gain†	Adj N†
Q1.1	Even if I try very hard, I cannot use the computer as easily as paper and pencil	2.24	1.77	0.47*	*0.53**	*104*
Q1.2	I can use a computer to graph what I found out in my experiment	3.43	3.67	0.25	*0.24*	*103*

Variable		Baseline Mean	Post-Interv. Mean	Mean Diff	Adj Gain†	Adj N†
Q1.3	I can use a computer to help me know what the results of an experiment means	3.73	3.92	0.18	*0.20*	*103*
Q1.4	When I do an experiment, it is hard for me to figure out how the data I collected answers the question	2.43	2.36	0.07*	*0.09**	*102*
Q1.5	I am good at building computer programs	2.97	3.12	0.14	*0.16*	*96*
Q1.6	I am good at fixing computer programs	2.55	2.89	0.34	*0.41*	*102*
Q1.7	No matter how hard I try, I do not do well when playing computer games	1.74	1.47	0.27*	*0.31**	*104*
Q1.8	I am very good at building things in games	3.95	4.23	0.28	*0.31*	*104*
Q1.9	I can use a computer to control toys and tools	3.51	3.85	0.34	*0.39*	*102*
Q1.10	I can learn how to design a computer game if I do not give up	4.11	4.25	0.14	*0.13*	*103*
Q1.11	When solving a problem, I can create a list of steps to solve it	3.66	3.84	0.17	*0.20*	*99*
Q1.12	When solving a problem, I can see patterns in the problem	3.31	3.53	0.22	*0.23*	*102*
Q1.13	When solving a problem, I can break the problem into smaller parts	3.73	4.05	0.32	*0.35*	*102*
Q1.14	When doing an experiment, I can use a computer to help me collect data	3.87	4.14	0.27	*0.25*	*103*
Q1.15	When solving a problem, I can figure out several ways to solve it	3.73	3.88	0.15	*0.21*	*98*
Q1.16	When solving a problem, I can figure out what is the best solution	3.89	4.07	0.18	*0.22*	*104*

Response categories: 1=Strongly Disagree; 2=Disagree; 3=Somewhat; 4=Agree; 5=Strongly Agree
** Gain represents the absolute value since some items are negatively worded.*
†Adjusted values include only participants with valid non-missing data on both baseline and follow-up surveys.

Despite of the significance of visual fraction models for teaching and learning fraction multiplication, how students are supported to learn fraction multiplication through representations remains unknown. By examining the presentation of visual representations in the contexts of word problems and computational processes in representative Korean and U.S mathematics textbook series, this study explores how the Korean and U.S. mathematics textbooks may facilitate student learning of fraction multiplication. Analyses showed that the selected U.S. mathematics textbooks provide more instances of fraction multiplication with various types of word problems and computational procedures in developing fraction multiplication. However, Korean textbooks use representations with different purposes, which in turn leads to students' explicit and meaningful understanding of fraction multiplication concepts and procedures.

Keywords: Fraction multiplication, Textbook analysis, Representations

Introduction

The Common Core State Standards for Mathematics (National Governors Association Center for Best Practices & Council of Chief State School Officers [NGA & CCSSO], 2010) highlight the importance of using "visual fraction models" for teaching and learning fractions to help students explore the underlying ideas of fraction multiplication and deepen their understanding of multiplying fractions. However, it is often reported that students and even teachers have difficulties in using representations for fraction multiplication (Webel, Krupa, & McManus, 2016). For example, although teachers and students may assume the typical area model for the multiplication of fractions is an extension of the area model for whole number multiplication, the area model—prevalently used in current U.S. curricula for fraction multiplication—seems not a direct conceptual extension of the area model for whole number multiplication (Kwon, Son, & I, 2017). It thus requires a careful investigation of the effective use of representations/models to help students deepen their understanding of multiplying fractions.

We noticed two different area models used in various contexts of fraction multiplication: *area-to-area model* and *lengths-to-area model* (Kwon, Son, & I, 2019). However, there is little research on how those models are presented in textbooks and what learning opportunities are provided with the two models to represent the fraction multiplication process. Given the key role of textbooks as the primary resource of learning, this study aims to narrow such research gap by exploring representational transition in textbooks in the contexts of word problems and computation problems through an examination of fraction multiplication in a representative Korean and U.S. textbook series. Since an international textbook analysis examines how curricula in high-achieving countries provide students with opportunities to learn, investigating Korean textbooks compared to a representative U.S. textbook series, Engage NY modules or EUREKA Math (EM) are expected to contribute to the development of students' understanding of multiplying fractions. According to Kaufman, Thompson, and Opfer (2016), more than 60% of US elementary teachers use Engage NY modules or EM in teaching mathematics. The research questions that guide this study are: (1) How is fraction multiplication introduced and developed in Korean textbooks and Engage NY modules? (2) What types of word problems are presented to introduce fraction multiplication? In the contexts of word problems, how and in what ways are representations used? (3) In the contexts of computational tasks, how and in what ways are representations used to introduce fraction multiplication?

Theoretical Perspectives

Table 1 provides four-word problem situations involving multiplication drawn from Carpenter et al. (1999) and the cognitively guided instruction (CGI) framework and three visual models recommended to be used to develop fraction concepts: area models (e.g., rectangular regions), length models (e.g., number lines), and set models (e.g., beans). These word problems and representations can be grouped into two kinds: Action on/Change of Initial Quantity and Operation/Coordination of Two quantities (Kwon et al., 2017, 2019). Action on/Change of Initial Quantity type represents an initial quantity and describe how the initial quantity changes as the operation takes place. Equal group and compare problem situations mostly belong to this type. Operation/Coordination of Two quantities type considers two quantities and illustrate how two quantities have been coordinated simultaneously; there is no distinction between two factors (quantities) because they play the same role. Combination and product of measure problem situations are Operation/Coordination of Two quantities type. Set and linear models can be categorized typically as presenting Action on/Change of Initial Quantity type whereas area models can represent both Action on /Change of Initial Quantity and Operation / Coordination of Two quantities types for fraction multiplication (Kwon et al., 2017, 2019).

Table 1: Two Underlying Problem Structures for Word Problems and Models

	Action on / Change of Initial Quantity		Operation / Coordination of Two quantities	
	Equal Group	Compare	Combination	Product of Measure
Set Model				
Linear Length Model				
Area Model	Area-to-area Model		Lengths-to-area Model	

In analyzing three types of models, we break the area model further by looking at how area models represent the fraction multiplication process: *area-to-area model* and *lengths-to-area model*. Each model reflects different aspects of a fraction and different thinking processes involved with fraction multiplication (Kwon et al., 2019). In the area-to-area model for fraction multiplication, the multiplication is used to figure out a portion of a fraction (of a whole) or a part of a part (of a whole). For example, with the problem of $\frac{1}{2} \times \frac{5}{8}$, the fraction $\frac{5}{8}$ represents the area of a piece of the unit rectangle, where a fraction is regarded as a representation of a part-whole relationship. 1/2 is an operator; thus 5/8 is a number that represents the area of the shaded pieces, and a corresponding action is taking 5 pieces out of 8 pieces equally dividing the unit rectangle. Different from the area-to-area model, with the first fraction as 'operator,' the lengths-to-area model considers both fractions as measures (i.e., 'operand'). In the lengths-to-area model with the above problem, students have a rectangle of two side lengths 5/8 and 1/2. The product of those two lengths represents the area of the shaded rectangle. To figure out the area of that rectangle in the lengths-to-area model, students need to find the unit area and count the number of unit areas inside the rectangle. In this study, we explore how two curriculum resources provide students with opportunities to learn fraction multiplication.

Methods

We chose to examine Korean textbooks (KM) published by the Ministry of Education, Science, and Technology compared to Engage NY modules (EM) due to its popularity. We particularly focused on chapters/lessons on fraction multiplication. In KM fraction multiplication is intensively addressed in Grade 5 whereas EM addresses fraction multiplication from Grade 4 to Grade 5. The data used for this study come from the relevant lessons on fraction multiplication from EM and KM. This study analyzed tasks presented in the lessons and the corresponding pages in the supplementary materials, including the teacher's manuals and student workbooks. During the first reading, coders focused on the first research question, when and how multiplication of fractions were developed. During this process, quantifiable or factual characteristics were identified, including the number of lessons, the recommended time to allocate to each topic, and the stated objectives of each lesson. In the second and subsequent readings, we focused on our second research question: ways in which the lessons support the development of conceptual understanding and procedural fluency. These reading examined qualitative characteristics, including meanings of multiplication of fractions, representations (mathematical models) used, word problem introduced, and ways in which those representations are used. After coding, we first counted the frequency of all the problem/representation types. We conducted the detailed analyses at three tiers: (1) only word problems, (2) word problems with representations, and (3) purely math problems with representation. We repeated this process for computational tasks to answer the third research question.

Selected Findings

How Fraction Multiplication is Introduced and Developed

EM introduces fraction multiplication in grade 4 and continue to develop in Grade 5. Four lessons are devoted to studying fraction multiplication in grade 4, focusing on (a whole number) × (a fraction) and (a whole number) × (a mixed number). The procedure of multiplying a whole number by a proper fraction (*n* times *a/b*) is taught as (n × *a*)/*b* using the associative property and the concept of repeated addition. The multiplication of a whole number by a mixed number is addressed using the distributive property. In grade 5, 13 lessons are devoted to developing different types of fraction multiplication in EM, which include (a fraction) × (a whole number), (a unit fraction) × (a unit fraction), and (a non-unit fraction) × (a non-unit fraction) (see Table 2). Tape diagrams have a central role to help students make sense of each multiplication.

KM introduces fraction multiplication in grade 5, one semester later than EM, and intensively develops fraction multiplication with 12 lessons. Similar to EM, KM introduce (a whole number) × (a fraction) and (a whole number) × (a mixed number) based on repeated addition with an equal group such as interpreting $3 \times \frac{2}{5}$ as 3 groups of $\frac{2}{5}$. Then, (a fraction) × (a whole number) is addressed based on "finding portions of whole units" with an "of" or "out of" idea. For example, $\frac{2}{3} \times 6$ is interpreted as finding $\frac{2}{3}$ of 6 whole units. Using the same underlying idea, KM addresses (a fraction) × (a mix number). Then, "finding portions of portions" are developed using (a unit fraction) × (a unit fraction) and (a non-unit fraction) × (a non-unit fraction) with an area-to-area model in the order. Different from EM, KM introduce (a mixed number) × (a mixed number) using a lengths-to-area model. Furthermore, multiplication of three fractions is introduced by asking students to use representations to find portion of portion of portion. Table 2 shows topic arrangement of EM and KM for fraction multiplication.

Table 2: Structure of Fraction Multiplication between EM and KM

Order	Korean Textbooks	Engage NY	Order
1	Whole number × Proper fraction	Whole number × Proper fraction	1
2	Whole number × Mixed number	Whole number × Mixed number	2
3	Proper fraction × Whole number	Proper fraction × Whole number	3
4	Mixed number × Whole number		
5	Unit fraction × Unit fraction	Unit fraction × Unit fraction	4
		Unit fraction × Non-unit fraction	5
6	Non-unit fraction × Non-unit fraction	Non-unit fraction × Non-unit fraction	6
7	Mixed number × Mixed number		
8	Multiply three fractions		

Word Problems and Types of Models in Word Problems in KM and EM

Table 3 shows word problem types involving fraction multiplication used in this study, emphasizing the role of factors. Prior research classified word problems either based on semantic structures (Smidt & Weiser, 1995), different situations (CGI research studies, CCSSM - Mathematics Glossary Table 2), or learner's mental models (Prediger, 2008). Although such classification helps identify different problem situations involving multiplication and division, roles of two factors that describe multiplication processes is not evident. Drawn from CGI's and CCSSM's whole number multiplication word problem situations that include equal groups, arrays/area, and compare, we provide an exhaustive and a combined list of fraction multiplication word problem situations. In particular, by utilizing qualitative analyses that look at various problem situations included in KM and EM, we extended CGI's and CCSSM's whole number multiplication word problem situations. Eight problem situations were identified as representing fraction multiplication situations, which can be categorized into three types, depending on the roles of two factors in the multiplication: (Operator × Operand), (Operator × Operator), and (Operand × Operand). While (Operator × Operand) and (Operator × Operator) are referred to Action on/Change of Initial Quantity type that describes how the initial quantity changes, (Operand × Operand) represents Operation/Coordination of Two quantities type.

Table 3: Fraction Multiplication Word Problem Situations

Problem Situation	Factor Role	Characteristic	Example
Equal size group	Operator × Operand	Building up the whole using a part by repeating the part.	Windsor the dog ate 2 3/4 snack bones each day for a week. How many bones did Windsor eat that week?
Comparison	Operator × Operand	Multiplicative comparison between a quantity and a referent quantity	A seamstress needs 27 2/3 yards of fabric to make a child's dress. She needs 3 times as much fabric to make a woman's dress. How many yards of fabric does she need for a woman's dress?

Unit Conversion	Operator × Operand	Converting units of measurement using dimensional analysis	Mrs. Lang told her class that class's pet hamster is ¼ ft in length. How long is the hamster in inches?
Finding portion (Partitioning)	Operator × Operand	Finding a portion of the whole	A container holds 2 liters of oil and vinegar. ¾ of the mixture is vinegar. How many liters of vinegar are in the container?
Finding portion of portion	Operator × Operator	Asking a combined operator	½ of the class are girls. ¾ of them are wearing glasses. What fraction of the class are girls wearing glasses?
Scaling (Resizing)	Operator × Operand	Scaling of the magnitude of a quantity with a scale factor, related to length, area, volume.	A company uses a sketch to plan an advertisement. The lettering on the sketch is in tall. In the actual advertisement, the letters must be 34 times as tall. How tall will the letters be on the building?
Combination (Probability)	Operand × Operand	Finding combinations among some objects with a number of possibilities	If two independent events have probabilities ⅔ and ⅘, what is the probability both will occur?
Product of measures	Operand × Operand	Finding the area of a rectangle of given dimensions	A rectangular region on a farm is ⅔ km by ⅘ km. What is its area?

Fraction multiplication word problems are similarly distributed in both curricula in terms of larger categories separated by the roles of two factors (see Table 4). Assuming (Operator × Operator) and (Operator × Operand) type problems are more related to action on or change of the initially given quantity, and (Operand × Operand) type problems are closer to operation or coordination of two given quantities, EM provided 86.6% of fraction multiplication word problems as action on or change of initial quantity type problems and 13.4% as operation or coordination of two quantities type problems, whereas KM provided 85% and 15% of each type. However, taking different problem situations in a consideration, two curricula showed different trends. KM focuses more basic situations of word problems and excluded harder situations, such as comparison, combination, or unit conversion. Emphasizing word problems with product of two measures was also notable. On contrary, EM includes a wide variety of different situations.

Table 4: Frequency Comparison of Fraction Multiplication Word Problem Situations

Factor Role	Word Problem Situations	KM	EM
Operator × Operator	Finding portion of portion	11 (27.5%)	29 (27.9%)
Operator × Operand	Equal size group (Iteration, Rate context also included)	12 (30%)	19 (18.3%)
	Finding portion (Partitioning)	8 (20%)	16 (15.4%)
	Scaling (Resizing)	3 (7.5%)	13 (12.5%)
	Comparison	0 (0%)	13 (12.5%)
	Subtotal	23 (57.5%)	61 (58.7%)
	Combination (Probability)	0 (0%)	4 (3.8%)
	Product of measures	6 (15%)	1 (1%)

Operand × Operand	Unit Conversion	0 (0%)	9 (8.6%)
	Subtotal	6 (15%)	14 (13.4%)
Total		40 (100%)	104 (100%)

Although both area models and tape diagrams are used in EM, a significant amount of tape diagrams are used in representing fraction multiplication (see Table 5). In particular, both area models and tape diagrams focus on one type of multiplying processes: action on/change of initial quantity. Different from EM, KM uses area models intensively but shows both types of multiplying processes with area models: area-to-area model (action on/change of initial quantity) and lengths-to-area model (operation/coordination of two quantities). In addition, KM presents product of two measures type problems as well as (a mixed number) × (a mixed number) type problems by the lengths-to-area model (see Figure 1). In contrast, all area models in EM rely on the area-to-area model (change of initial quantity) (Kwon et al., 2017)

Table 5: Types of Models Used in Word Problems and Computational Tasks

Representation Models	KM	EM
Area Model (Rectangular Array included)	13 (65%)	40 (26%)
Number Line	0 (0%)	1 (0.6%)
Tape Diagram	7 (35%)	113 (73.4%)
Set Model	0 (0%)	0 (0%)
Total	20 (100%)	154 (100%)
Types of Model		
Action on / Change of Initial Quantity	**15 (75%)**	**154 (100%)**
Operation / Coordination of Two quantities	**5 (25%)**	**0 (0%)**

How and in What Ways Models are Used in Computational Tasks

EM contains about 4 times as many tasks of fraction multiplication as those of Korean textbooks in computational tasks (see Table 6). When highlighting the most frequent task types involving calculation, it appears that there was a consistency of frequently used types within each textbook series. In both textbooks, calculation only is most popular, followed by calculation with representation and calculation asking explanation. However, EM additionally includes tasks that ask for both explanation and representation and those asking students to create a word problem related to fraction multiplication.

Table 6: **Problem Type in Purely Numerical Problem Contexts and its Frequency**

	Calculation only	Calculation + explanation	Calculation + representation	Calculation + explanation + representation	Calculation+ word problem	Total
KM	49 (63%)	8 (1%)	21 (27%)	0 (0%)	0 (0%)	78
EM 4 & 5	155 (55%)	20 (7%)	101 (36%)	3 (1%)	2 (1%)	281

27% of computational tasks ask for using representations in KM whereas 37% in EM demand representations. EM presents tape diagrams most frequently in representing (a whole number) × (a fraction) and (a fraction) × (a whole number), whereas KM evenly uses area models and tape

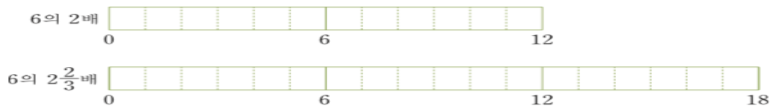
Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

diagrams. For (a fraction) × (a fraction), both EM and KM use area models. Figure 1 shows examples of representation use in two textbook series.

	Representation		Calculation Process	
	EM	KM	EM	KM
W × F	 4 × ⅔ = ⅔+⅔+⅔+⅔=2 2/3	 6 × ½ = 6/2=3	S1: 5 × ¾ = 5 × 3 fourths = 15 fourths S2: 5 × ¾= 5 × 3 × ¼ S3: 5 × ¾ =(5 × 3)/4	S1: 5 × ¾ =¾ + ¾+¾+¾+¾=15/4 S2: 5 × ¾ =(5× 3)/4
W × M	 5 × 3 ½ = (3 × 5)+1+1+1.2=171/2	 3 × 1 ⅕= 3+ ⅗ = 3 3/5	S1: 2 × ⅕ =(2×3)+(2×1/5)=6+⅖ S2: 2 × 31/5=6 + ⅖ =6 ⅖ S3: 2 × 3 ⅕= 2 × 16/5 =6 2/5	S1: 2 × 3 ⅕ = 31/5 + 3 ⅕ =6 ⅖ S2: 2 × 16/5=6 ⅖ S3: 2 × 3 ⅕=(2×3)+(2×1/5)=6+⅖=6 ⅖
F × W	 ⅔ × 6 = 2 × 6/3 =4	 ⅓ × 3 = 1 × 3/3=1	S1: ⅔ × 6 = 2 × 6/3 =4	S1: ⅔ × 6 = (2 × 6)/3=12/3=4
M × W	None	 2 ⅔ × 6 =	None	S1: 2 ⅔ × 6= 8/3 × 6 =48/3=16 S2: (2+⅔) × 6 = (2 × 6)+ (2/3×6)=16 S3: Reduction
UF × UF		⅓ × ¼ 	S1: ⅓ × ¼ = (1×1)/(3×4)= 1/12	S1: ⅓ × ¼ = (1×1)/(3×4)= 1/12
NF × NF UF × NF		¾ × ⅖ 		S1: ¾ × 2/4 = (3 × 2)/(4 × 4) S2: $\frac{3}{8}\times\frac{5}{6}=\frac{1\times5}{8\times2}=\frac{5}{16}$
M × M	None	2 ⅖ × 1 ¾ 	None	S1: 2 ⅖ × 1 ¾= 12/5 × 7/4 S2: $3\frac{3}{5}\times2\frac{1}{4}=\frac{18}{5}\times\frac{9}{4}=\frac{9\times9}{5\times2}=\frac{81}{10}=8\frac{1}{10}$

Figure 1: Representation Use and Calculation Processes in EM and KM

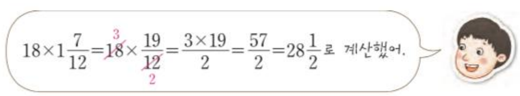
As shown in Figure 1, both KM and EM use representations as an essential means for introducing fraction multiplication and developing students' understanding about fraction multiplication. In each problem type, similar calculation strategies are introduced in KM and EM. Despite the similarity, unique features exist in developing procedures in KM and EM. EM seems to highlight the meaning of a denominator, emphasizing a role of a unit fraction and introduce a denominator as a written word. For example, for a whole number times a fraction such as 5×¾, EM asks students to represent 5×(3 fourths), which leads that (5×3) fourths is 15 fourths, 15/4. EM also asks to break down ¾ as 3×¼ to calculate 5×3×¼, which is 15/4. In contrast, KM relies on repeated addition (i.e., 5×¾ =¾+¾+¾+¾+3/4=15/4) and then address multiplying a whole number times a numerator (e.g., 5×¾). EM's approach may provide pedagogical suggestions to how to additionally address (a whole number)×(a fraction). KM introduces two additional problem types such as (a mixed number)×(a whole number) and (a mixed number)×(a mixed number), which is not addressed in EM. A unique approach in KM is using a comparison method where students are asked to think about relative sizes of two fractions and to generalize a solution method. For example, before addressing computational procedures of (a mixed number)×(a whole number), 2 ⅔×6, KM asks students to represent 2×6 using a tape diagram and then 2 ⅔×6, and compare relative size of each (see figures below).



Afterwards, KM presents two different solution methods shown below and asks students to compare and come up with a solution method for 2 ⅔×6.

$6\times\frac{8}{3}=\boxed{}$ $(6\times 2)+(6\times\frac{2}{3})=\boxed{}$

As students share their solution methods for 2 ⅔×6, KM introduces additional methods shown below with a different problem and asks students to apply the given solution method.



Based on that, KM provides an opportunity to generalize multiplying methods of (a mixed number) × (a whole number). There is a prompt that specifically asks students to explain how to calculate (a mixed number) × (a whole number) in KM at the end of each lesson. KM's guided instruction which starts from representing comparing multiplying fractions using representations, through mathematizing thinking processes using two calculation ways, to generalizing solution methods in each problem type may support students' meaningful and explicit learning of fundamental mathematical ideas embedded in fraction multiplication.

Discussion and Implications

This study contributes to the current literature because it illustrates how formal instructional resources such as textbooks may support students' learning of fraction multiplication. EM provides more instances of fraction multiplication with various situations of word problems in developing fraction multiplication. However, KM seems to provide representations with different purposes to support students' explicit and meaningful understanding of fraction multiplication. While most of tape diagrams and area models used in EM are focused on only one type: action on/change of initial quantity, KM use both types in their area models, including the lengths-to-area model (operation/coordination of two quantities). We also found that EM contains about four times as many problems of fraction multiplication as those of the KM in non-contextual situations. Although there are similarities in the use of representations and calculation strategies in the context of computation, there are unique features in developing procedures in KM and EM. The findings in both textbooks' insights and pedagogical techniques may provide rich information for textbook designers and classroom teachers to refer back to.

This paper reports a study of two high school mathematics teachers' interactions with curriculum materials while planning lessons. Specifically, we address how their attention interacts with their interpretations and responses to the materials, and how the curriculum elements and format of each set of materials influenced these interactions. Further, we report on how teachers' noticing informs student opportunities to learn.

Keywords: Curriculum, Instructional activities and practices, Instructional vision

The concept of noticing is not unique to the study of teaching, nor is it unique in the profession of teaching to interactions that occur solely within the classroom. We expand the construct of the professional noticing of children's mathematical thinking (Jacobs, Lamb, & Philipp, 2010) to describe how high school teachers use curriculum materials during planning. Just as Jacobs, et al. (2010) focus on a "specialized type of noticing" (p. 171), the professional noticing of children's mathematical thinking, we focus on a special type of noticing: the noticing of curriculum materials by teachers for the purposes of using the materials with students in their enacted lessons. Curricular noticing is the set of skills that constitute the curricular work of mathematics teaching, namely: curricular attending, curricular interpreting, and curricular responding. Curricular attending involves "viewing information within curriculum materials to inform the teaching and learning of mathematics" (Dietiker, Males, Amador, & Earnest, 2018, p. 523), curricular interpreting involves making sense of that to which is attended, and curricular responding involves making curricular decisions based on the interpretation of curriculum materials. Figure 1 depicts the Curricular Noticing Framework.

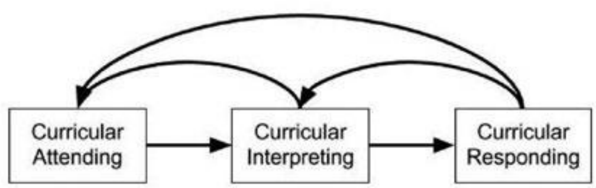

Figure 1: The Curricular Noticing Framework (Dietiker, Males, Amador, & Earnest, 2018, p. 527)

Although these definitions seem to presuppose a sequence, we argue that the process may not unfold in a strictly linear fashion. For example, while a response is dependent on a curricular

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* St Louis, MO: University of Missouri.

interpretation of that to which a teacher attended, an interpretation may trigger a teachers' attention, or a decision to respond may result in the teacher attending to something new.

Purpose and Research Questions

Our purpose is to describe two high school teachers' curricular noticing during planning and the influence of curricular elements and format on this noticing. Specifically, we address:

1. What do teachers attend to in curriculum materials during planning, and what interpretations and responses do they make in relation to this attention?
2. How might curriculum elements and format influence teachers' curricular noticing?

Methods

Participants

This paper focuses on the planning of two teachers who were part of a larger study of teachers' use of curriculum materials. While both taught in the same district, they presented very different contexts for examining curriculum use. First, the two teachers had varying years of teaching experience, Alice having 9 years and Elise being in her first year. Second, Alice was piloting a new set of curriculum materials for the district, and while Elise was using what the district had been using for years, she was also new to using the materials. In this way, we had the chance to observe their curricular noticing as they were reading materials for the first time.

Curriculum Materials

The materials used by the teachers varied on multiple dimensions. For instance, Alice's materials, the CPM Educational Program's *Core Connections Algebra*, classifies as Standards-Based, meaning that it was designed to align with the NCTM (2000) Standards. Elise's materials, Pearson Education, Inc.'s *Geometry,* is classified as Conventional, meaning that it was developed from editions published prior to the release of the NCTM Standards. Comparing the curriculum use with the differing curricula may provide insight into how the curriculum elements and format might influence teachers' curricular interactions.

Data Analysis

We analyzed eye tracking recordings as well as coded each teachers' transcript. We assigned an Attend code when a teacher looked at or read aloud a section of the curriculum materials, with four subtypes: district-adopted materials, materials from previous lessons (produced by the teacher), old materials (e.g. past lesson plans), and online sources. We assigned an Interpret code when a teacher made sense of the curriculum materials, with three subtypes: the curriculum itself, students (e.g. approaches), or mathematics (e.g. working out solutions). We assigned a Respond code when teachers made a decision as to what to include in their plan, with four subtypes: using something from the materials as is, adapt it, not use it at all, or to supplement.

To address the extent to which each teacher's attention interacted with their interpretations and responses, we examined their thought processes via idea sequences. Each time a teacher focused on one big idea in their planning interview, we defined this as an idea sequence. For example, idea sequences included thinking around a particular concept or commentary around the structure of the overall curriculum materials. To explicitly represent an idea sequence, we recorded the sequence of attention and subtypes of interpretations and responses.

Results & Discussion

Idea Sequences

In order to examine teachers' curricular noticing, we identified idea sequences across each planning session. For example, when our two teachers discussed their final thoughts around selecting examples for a warm-up, we generated the idea sequences in Figure 2.

Figure 2a: Idea Sequence Example - Alice

Figure 2b: Idea Sequence Example - Elise

In her idea sequence of one minute, 57 seconds, Alice attended to what she reported as student materials from the previous lesson, discussing her interpretation of the meaning of problems near the end. She continued to attend to the student materials, ending with a discussion of doing a warm-up involving assessment, believing her students needed this opportunity. Elise, in 6 minutes, 22 seconds, attended to curriculum materials from her student teaching, searching through worksheets and interpreting the meaning of problems as she looked for a specific focus. Elise eventually found problems to use, and as she copied them into her class slides, she further interpreted their meaning and how her students would respond. Following these, Alice and Elise moved on to new ideas and thus we defined the next idea sequence of their planning periods.

Despite the different experiences of the two teachers and the different curriculum materials, Alice and Elise had a similar number of idea sequences in their planning. Alice's thought processes are represented by 7 idea sequences, Elise's by 8. This similarity is especially notable when compared to the overall planning times, with Alice spending about 18 minutes and Elise about 57 minutes. We see this more clearly by considering our two teachers' average idea sequence duration - Alice with two minutes, 10 seconds and Elise about 7 minutes. Further, we see a widely varying range of duration when it comes to the idea sequences - a range of about 9 minutes amongst Alice's idea sequences, and a range of about 23 minutes amongst Elise's.

A previous study (Males & Setniker, 2018) indicated that prospective secondary teachers always began to work with new ideas by attending to curricular resources. In this work, Elise, a secondary teacher in her first year, also began each idea sequence with attention to a curricular resource. In comparison, Alice began one of her thought processes by making interpretations about her students from past experiences, which seemed to influence what she was searching for.

Our analysis also indicates that idea sequences are longer in duration across teachers for specific curricular elements. For example, Alice's longest idea sequence is almost 9 minutes, which involved comparing closure problems. Elise's idea sequence around closure is about 6 minutes. In contrast to such similarities amongst Alice's and Elise's idea sequences, those of short duration are not focused on the same thought processes across the teachers. However, we see that while the durations of our two teachers' planning sessions and the duration of the idea sequences within were quite different, they still had similar thought processes defining separate idea sequences, though not necessarily in the same order.

Curricular Elements and Format

Each set of curricular resources used by our two teachers was comprised of numerous individual curriculum elements. In this section, we describe the attention to select elements in order to understand how curricular elements and format influenced teachers' noticing.

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

Alice expressed her general appreciation for the approach of her district-adopted curriculum and furthermore, her familiarity with the format and elements through professional development and some previous collaborative planning. Elise also had a general approach to her curricular resources, in that she did not use her district-adopted curriculum very often. We see that Elise had a skeptical approach to elements in the district-adopted book, through the lens of a short class time, and yet was optimistic about almost any other element she found in other resources.

Further, the degree to which teachers' beliefs are aligned with curricular goals seems to play a large role in approach to curriculum materials and what they notice. For example, Alice had the goal of keeping her students engaged. Throughout planning, this goal was a driving force in analyzing the materials and choosing what to include in her plan.

Conclusion and Implications

Studying the two teachers' interactions while planning with their district-adopted and chosen curriculum materials provided insight into their curricular noticing and how it is influenced by the type of curriculum and also teacher predisposition and beliefs. Before teachers decided what to include in their lesson plans they attended to materials. This was evidenced by an attend code prior to a response code in each of our idea sequences. However, not every idea sequence started with an attend code - specifically, Alice began an idea sequence with an interpretation around students. This was steered by her strong beliefs around student engagement, and with this in mind began a new idea sequence focused on engagement. This was perhaps due to her years of teaching experience and/or her personal views of her students' needs.

While engaging in curricular noticing, teachers were attending simultaneously with interpreting or responding. Our idea sequences indicate that teachers were looking for particular elements that supported their personal beliefs, interpreting the meaning behind various tasks and problems while doing so. For example, Elise, while searching for a problem says "That's a fun problem...it's a converse...see why do they throw area in right there? ...no, alright, that's a good question. They actually need area this time around." Here Elise interprets the point of the question and returns to the objective sheet to confirm that her students have learned area before.

This study contributes to expanding the construct of noticing and understanding how curriculum materials influence teachers' planning and students' opportunities to learn. First, this corroborates the research that indicates that teachers' beliefs and predispositions influence their curriculum use, particularly their attention to certain curricular elements. Further, familiarity with curriculum materials aids teachers in navigating format. However, this may result in important teacher suggestions and opportunities for student learning being missed. Not all elements were attended to in each curricular resource, and even some elements which were attended to were not attended to for more than two seconds. It is likely difficult for teachers to interpret and respond to curriculum materials to plan and enact instruction if they have not attended to the curriculum materials. Therefore, this attention largely influences what students have the opportunity to learn. This underscores the importance of future work describing how curriculum developers and teacher educators may support teachers in optimizing attention to critical curriculum elements.

The goal of the project is to give second grade students an exposure to hands-on engaging ways of coding, thus fostering their reasoning and critical thinking skills. The objective of this study is to examine the impact of exposing second grade students to an early coding scenario and gauge their increase in logical reasoning. The review of literature supports the effects of using play-oriented strategies to improve learning skills of students.

It is well accepted that dramatic and constructive play sequences provide opportunities to use language for questioning, monitoring and guiding the actions of one's self and others, as well as opportunities for decision-making, problem-solving and experimentation with materials and resources (Almon, J, 2003; Bennett, Wood, & Rogers, 1997; Guha, 1987; Smith, 2006; Whitebread & Jameson, 2005). The addition of a play-oriented module in a child's education improves not only their STEM-oriented learning skills, but also their communication and comprehension skills as well. This research is meant to serve to help bridge this gap so that educators can introduce certain aspects of programming in an early age.

Procedures

The participants of this study experienced the following:

1. Every 2nd grade student was given a consent form and pre-test to fill. The pre-test involving logical sequences and a maze was conducted by the classroom teacher during a regular school day as a regular activity. No researcher was present during this time.
2. School officials selected 20 students to participate in the study. The selected students met with the researchers in the school cafeteria. They were read the book “The Very Hungry Caterpillar” and then broken into random groups to play with the Code-a-Pillar®. This was repeated once a month for four months over a semester.
3. Every 2nd grade student was given a post-test, identical to the pre-test. The post-test was conducted by the classroom teacher during a regular school day as a regular activity. No researcher was present during that time.

This poster presentation will explore the results from this test and detail the progress of the participating students at month long intervals over the semester.

This exploratory case study investigates the emerging practices of post-secondary students with mathematics learning disabilities (MLD) (Furlong, McLoughlin, McGilloway, Geary, & Butterworth, 2015; Willcut et al., 2013) in adapting portable electronic technologies to better suit their learning needs, examining: 1) Which technologies do they use fluently and how did they learn to use them? 2) What are the characteristics of their use and adaptations of these technologies? Working from an enactivist perspective that the systems of body, mind and environment are entangled (Merleau-Ponty, 1962), we argue that learning emerges through the interactions between these systems and that there is a potential reciprocal relationship between the use of technology and cognition in the act of learning (Li, Clark, & Winchester, 2010): technology becomes embodied within the learning system in its potential to open up and extend the learner's bodily senses to new experiences and capabilities (Söffner, 2017). Our study is situated within emerging research on the "learner's perspective" on the use of technology (Kukulska-Hulme et al., 2011) in the context of increasing learner autonomy, personal choice of devices and ways to use those devices, and used semi-structured interviews to allow maximum participation and accessibility (Alper & Goggin, 2017). We recruited nine participants with MLD from two post-secondary campuses in Western Canadian cities, enrolled in a variety of programs (e.g sciences, technology, business, social sciences). Each self-identified as being confident and knowledgeable about their use of technology, thus being potentially capable of developing technological adaptations and practices that peers might find beneficial to adopt (Kukulska-Hulme et al, 2011).

Our results reveal that participants used technology as a type of electronic "prosthesis" to effectively support their MLD: using a variety of sources of alternative on-line content to supplement in-class information about mathematic content and possible strategies; accessing aural and textual information (e.g. pausing and repeating audio and video recordings of lectures; supporting reading through electronic readers and software narrators), support for mathematical calculations (calculators to check accuracy of input; spreadsheet software formulae for repetitive calculations); utilizing structural and organizational supports (software that worked across devices; search engines; calendar alerts, etc.) which enabled them to focus their time and energy on their mathematics work. Participants described their method of learning about technology as being "trial-and-error," trying different strategies and keeping what worked. Their resulting "patchwork" practices suggested that the traditional boundaries between traditional assistive and mainstream technologies were becoming increasingly blurred for these participants. Grounded in a "learner's perspective," our work responds to a need for more research to determine how affective new assistive technologies are in supporting academic difficulties (Bryant, Bryant, & Ok, 2014). Evidence-based understandings of students' technological experiences and insights are essential to improve student access and equity, and potentially to inform the design of both assistive and mainstream technologies and their use in classroom and informal learning environments.

UN AMBIENTE DE RESOLUCIÓN DE PROBLEMAS Y TECNOLOGÍAS DIGITALES EN UN CURSO MASIVO EN LÍNEA

William Enrique Poveda Fernández
Universidad de Costa Rica
william.poveda@ucr.ac.cr

Se describe la forma en que una comunidad en línea interactúa con actividades matemáticas y exhibe, proporciona retroalimentación y modifica sus ideas o razonamientos al utilizar diversas tecnologías digitales en un ambiente MOOC (Massive Online Open Course, por sus siglas en inglés). Los resultados muestran que los participantes compartieron y discutieron sus ideas matemáticas, como parte de una comunidad virtual, lo que les permitió formular conjeturas, explorar y buscar propiedades para sustentar relaciones y comunicar resultados. Además, consideraron un problema como punto de partida para involucrarse en la actividad de razonamiento matemático y desarrollar múltiples estrategias para resolver un problema.

Keywords: Resolución de Problemas, Tecnología, MOOC, Diseño de actividades.

Descripción de la investigación

El objetivo de la investigación fue diseñar e implementar un MOOC basado en resolución de problemas matemáticos y el uso coordinado de tecnologías digitales. El curso se estructuró en torno a tres actividades principales (Santos-Trigo 2014) que incluían brindar a todos los participantes la oportunidad de (i) mover objetos dentro de representaciones dinámicas de conceptos y problemas matemáticos; (ii) observar y analizar los atributos de los objetos matemáticos para formular conjeturas; y (iii) buscar argumentos empíricos y, luego, matemáticos para validar esas conjeturas y relaciones. El curso se estructuró de acuerdo con las ideas de Churchill (2016) y Robutti et al. (2016).

El objetivo fue el desarrollo y la práctica de un enfoque inquisitivo, donde los participantes tuvieran que examinar constantemente las propiedades y atributos de los objetos matemáticos formularan conjeturas, compartieran sus ideas, buscaran diferentes formas de justificar las relaciones y comunicaran sus resultados (Poveda, Aguilar-Magallón & Gómez-Arciga, 2018).

En el MOOC se inscribieron 2661 personas con diferentes niveles de estudios, edades, intereses profesionales o personales, ubicación geográfica, etc. Durante el desarrollo de las actividades y a través del foro de discusión, los participantes plantearon preguntas, comentarios y soluciones que fueron organizados por el equipo de diseño del MOOC de tal manera que cada integrante pudiera participar en la discusión de temas que eran importantes y consistentes con los objetivos del curso (Schoenfeld, 1992). La unidad de análisis fueron las conversaciones en los foros (Ernest, 2016).

Los resultados mostraron que los foros de discusión brindaron diversas oportunidades para que los participantes aclararan sus ideas, compartieran sus razonamientos matemáticos y participaran en un enfoque de resolución de problemas en colaboración con otros durante su trabajo en las actividades del curso. Los participantes reconocieron que el aprendizaje de las matemáticas implica enfrentarse a un dilema que necesita resolverse en términos de observar una situación, formular preguntas y buscar diferentes caminos para responderlas.

Agradecimientos

A la Escuela de Matemática de la Universidad de Costa Rica (UCR) por el apoyo brindado para esta investigación.

A PROBLEM-SOLVING AND DIGITAL TECHNOLOGIES ENVIRONMENT IN A MASSIVE AND ONLINE COURSE

This research report analyzes the way in which an online community interacts with mathematical activities and exhibits, provides feedback and modifies their ideas or reasoning mathematical using various digital technologies in a MOOC (Massive Online Open Course). The results show that the participants shared and discussed their mathematical ideas, as part of a virtual learning community, which allowed them to formulate conjectures, explore and search properties to sustain relationships and communicate results. In addition, they considered a problem as a starting point to get involved in the mathematical reasoning activity and develop multiple strategies to solve a problem.

Keywords: Curriculum Analysis, Using Representations, Number Concepts and Operations

Research has shown that elementary school teachers use mathematics textbooks as their principle curriculum guide and source of lessons (Fulkerson, Campbell, & Hudson, 2013). Most mathematics textbooks were similar until the National Science Foundation (NSF) launched a major initiative to create new textbooks based on the vision of teaching espoused by the National Council of Teachers of Mathematics (NCTM) *Standards* documents (Reys, Reys, & Chavez-Lopez, 2004). Research has illustrated that "when students learn to represent, discuss, and make connections among mathematical ideas in multiple forms, they demonstrate deeper mathematical understanding and enhanced problem-solving abilities" (NCTM, 2014, p. 24). A key component of textbooks should be to include multiple representations for students to illustrate their thinking.

Due to the key role of textbooks (Fulkerson, Campbell, & Hudson, 2013) and the bedrock of conventional mathematics being learning how to count (Krasa & Shunkwiler, 2009), this research project compared the representations of counting in two kindergarten textbooks. The objectives of this study are to a) investigate which representations were used in kindergarten lessons for counting in a traditional and *Standards*-based textbook, b) which representations were more prevalent in each book, and c) on average which textbook encouraged more than one representation among its lessons on counting.

Data for this study comes from the textbooks *Everyday Mathematics* published in 2012 and a traditional textbook *Math Connects* published in 2007. They were selected because *Everyday Mathematics* is *Standards*-based and the other is traditional, not aligned with NCTM's vision for teaching. For each book, every lesson was analyzed to determine if counting was included. If counting was in the lesson, then each lesson was coded for the representations that were present: written symbols, oral language, concrete materials, pictures, or real-world context. Descriptive statistics were used to analyze which representations were being used in the texts.

Both books included all five representations. *Everyday Mathematics* had 89 lessons and all of them included counting, while *Math Connects* had 67% include counting. In *Everyday Mathematics*, 100% of all counting lessons included manipulatives, pictures, oral language, written symbols, and real-world connections. In *Math Connects*, 82.9% of all counting lessons contained manipulatives, 90% included pictures, 64.3% included oral language, 70% contained written symbols, and 30% contained real-world representations.

Teachers who use *Everyday Mathematics* as their primary source of lessons will engage their students in using all five representations for counting. When this happens kindergarten students are given the opportunity to gain a deeper understanding of counting, foundational content, through the use and connection of the different representations (NCTM, 2014). Among the representations in the textbook *Math Connects*, pictures and manipulatives were the most prevalent. Additionally, less than one-third of counting lessons in *Math Connects* contained a real-world representation. Hence, the kindergarten textbook *Everyday Mathematics* significantly encouraged more representations for counting than *Math Connects*.

Keywords: Curriculum, Curriculum Analysis, Policy Matters

In this session, we address the theme "Against a New Horizon…" by exploring a topic of importance to state departments of education and school districts that represents a new horizon in education research – the successful and sustainable implementation of high-quality mathematics curricula. Metz, Halle, Bartley, and Blasberg (2013) describe four stages of implementation: exploration, installation, initial, and full. The curriculum-adoption process undertaken by state departments of education and/or school districts corresponds to the exploration stage, during which decision-makers must consider issues such as specific needs, the fit of a curriculum and the feasibility of its implementation, and perspectives of stakeholders (Metz et al., 2013). The National Implementation Research Network created "The Hexagon Tool" (2018) to help individuals and teams address implementation issues related to the adoption of an innovation during the exploration stage. "The Hexagon Tool" includes six implementation-related indicators: Evidence, Usability, Supports, Need, Fit, and Capacity. Despite an overall increase in attention paid to implementation issues across the human services in recent years, relatively little attention has been paid to implementation in the field of education (National Implementation Research Network, 2018). In order to learn more about the support for implementation that states provide to their school districts during the curriculum-adoption process, we asked the following research question: How do state-created curriculum evaluation tools for mathematics intersect with "The Hexagon Tool" created by the National Implementation Research Network?

We conducted a systematic review of every state's department of education website to answer the research question. In phase one, we used Google to search for the following terms: [insert state's name] curriculum evaluation tool. Next, the first author visited each state's department of education website and searched for any curriculum evaluation tools that may have been missed during the first phase. In the third phase, we repeated the Google search using a new set of terms: [insert state's name] instructional materials evaluation tool. State-created tools with an explicitly stated purpose of evaluating curricula and instructional materials related to K-12 mathematics were included for review. The authors independently coded the intersection of the obtained curriculum evaluation tools and "The Hexagon Tool" before comparing results and coming to consensus on any discrepancies.

We compared nine state-created mathematics curriculum evaluation tools produced by seven states with "The Hexagon Tool." All of the mathematics curriculum evaluation tools addressed the Fit indicator from "The Hexagon Tool." Other indicators from "The Hexagon Tool" that were partially addressed by the curriculum evaluation tools include Support, Usability, and Capacity. Evidence and Need were not addressed by any of the reviewed evaluation tools. These findings indicate that few states attend to issues of implementation when supporting school districts to adopt high-quality mathematics curricula. Our hope is that this poster will draw attention to the new horizon of implementation research so that departments of education and school districts are better equipped to implement high-quality mathematics curricula that benefit all students.

Keywords: Number Concepts and Operations, Using representations, Curriculum Analysis

Common Core State Standards (National Governors Association Center for Best Practices, Council of Chief State School Officers, 2010) call attention to two interpretations of division (partitive and measurement) to help students explore the crucial ideas of whole number and fraction division. However, emphasizing the interpretations of division based on a missing factor in semantic structures sometimes hinder students from reflecting other aspects of division that are consistent regardless of number systems, especially when they are asked to explore visual models (Carpenter et al., 1999). These cognitive difficulties require a careful investigation of presentation of models to help developing students' understanding in a systematic way.

Extending previous studies (Kwon et al., 2017, 2019) on multiplication models, this study intended to explore how various models support or hinder students' understanding of whole number division. We particularly looked at whether and how two types of models (action/change-focused and comparison/coordination-focused), were presented in curricula. Two U.S. textbooks, *Engage NY* and *Math in Focus*, and one Korean textbook in Grade 2 and 3 were examined as part of a larger study for how they offer opportunities with arithmetic operation models to foster understanding of arithmetic operation. Tasks and visual models were coded and categorized according to problem situations and model focuses (see Figure 1).

Model Focuses	Problem Structures	Descriptions	Problem Situation - Partitive Division Example	Problem Situation - Measurement Division Example
Action on /Change of Initial Quantity	Operand ÷ Operator	Divide dividend by divisor, Divide/Partition dividend into parts or portions.	 (Engage NY g3m1)	 (Engage NY g3m1)
Comparison /Coordination of Two Quantities	Operand / Operand	Distribute Quantity 1 into Quantity 2, Assign Quantity 1_1 to Quantity 2, Find the ratio/rate between Quantity 1 and Quantity 2.	 (Korean Textbook grade 3)	 (Math in Focus 2A)

Figure 1: Two Types of Division Models

We report that there were two types of division models: the action/change-focused and the comparison/coordination-focused models similar to multiplication models. Each model reflects different aspects of whole number division and different thinking processes involved with the division operation. We found that Korean and *Math in Focus* textbooks used both models frequently, whereas *Engage NY* textbook infrequently introduced the comparison/coordination-focused model for division. This suggests that without a careful conceptualization of the two models in connection with two interpretations of division (partitive and measurement), teachers and students may fail to notice the conceptual ideas of whole number division and connection to the models for whole number division. In this poster we thus will explain the two types of models representing the whole number division processes in detail and discuss how to carefully introduce those models to help students attain a better understanding of division operation.

RELATING DIGITAL RESOURCES TO TEACHER PRACTICE

Zenon Borys
University of Rochester
zenon.borys@warner.rochester.edu

Keywords: Curriculum, Curriculum Enactment, Technology

Teachers increasingly use digital resources. Movements such as curriculum by Pinterest or the open education resources (OER) promoted by the US Department of Education (U.S. Department of Education, 2016) support the trend of teachers sharing instructional resources. While there are benefits to using digital resources in schools, there is also potential to reinforce teaching practices that provide little opportunity for students to engage in meaningful mathematical activity. This study explores teaching practices using digital resources in ways that promote meaningful mathematical activity, informing which practices are worth building on and which are worth standing against.

This study uses a *documentation genesis* framework (Gueudet & Trouche, 2009) to highlight the relationship between teachers' design of lessons and the resources they use, with an explicit focus on digital curricular resources. The documentation genesis framework posits that resources need to be examined in use. By focusing on how features of resources influence use, a process of instrumentation, and how the user influences use, a process of instrumentalization, the framework emphasizes how teachers transform curricular resources for instruction.

This study follows four teachers through the planning and implementation of a curricular unit using the *reflective investigation* methodology (Gueudet & Trouche, 2012). Using interviews and classroom observations, data captures the multiple resources teachers use in designing their unit, the reasoning surrounding didactic design decisions, and how classroom activity is organized around the resources. The focus of analysis is on how teacher uses of curricular resources align to their teaching goals. More specifically, the documentation genesis framework relates the resources, mathematics, and didactics (Trigueros and Lozano, 2012) in teachers' lesson design processes.

Results show that digital curriculum resources did not disrupt teachers' modus operandi. Rather, they supported or amplified teachers' current practices. For example, the use of digital resources did not change the emphasis on modeling and repeated practice as the mechanism of student learning. The use of digital curriculum resources changed when teachers modeled problems in the classroom. Rather than starting instruction with examples of varying difficulty, teachers waited until students were stuck to model specific problem types. The packaging of teaching changed, but the underlying process for student learning was left unchanged.

Additionally, data show teachers privileged digital resources with a capability of exporting and importing data (e.g. problems or results) that directly connected to state exams and standards, making the translation process from one program to another automatic. For instance, websites that post previous state exams in multiple file formats (e.g. .doc, .pdf, .tst) were used because test creation software could directly import .tst files, allowing teachers to randomize questions and create multiple versions of assessments. This focus on ease of translation acted as a filter to limit the resources teachers used.

This poster will present updated results from the study and discuss the merits and limitations of its analytic process.

PROSPECTIVE SECONDARY TEACHERS' WAYS OF ENRICHING CONVENTIONAL WORD PROBLEMS

Wenmin Zhao
University of Missouri
wenminzhao@mail.missouri.edu

Samuel Otten
University of Missouri
ottensa@missouri.edu

Keywords: Word problems, Curriculum, Instructional activities and practices

Word problems are a major component of mathematics curriculum and can serve multiple purposes, such as engaging students in mathematics learning and providing opportunities to develop skills to solve real-world problems (e.g., Masingila, 2002). However, research shows that conventional word problems often fail to meet these goals (e.g., Verschaffel, Greer, & DeCorte, 2000) and are criticized for their inauthentic and oversimplified features (e.g., Niss, Blum, & Galbraith, 2007). As the implementers of curriculum materials, teachers occasionally modify textbook word problems to support students' mathematics learning and develop their problem-solving strategies. To understand the ways in which prospective secondary teachers (PTs) would enrich word problems, this study investigated 20 PTs' ways of modifying conventional word problems to become more authentic and mathematically rich.

The participants in this study were 20 PTs in their third year of a secondary mathematics teacher preparation program at a public university in the Midwestern United States. The PTs had not learned about modifying word problems or other curriculum materials prior to the study. During the study, each PT was asked to modify three word problems selected from secondary mathematics textbooks. One of the problems was: "A population in a small town is 500, and it grows by 2% each year. Determine the population size after 3 years." This problem was chosen for its unrealistic assumption (i.e., constant growth rate) and its non-mathematically-rich nature (i.e., targeting a specific answer and a particular solution strategy). After the PTs revised the three word problems, we open-coded their written responses and categorized the problem characteristics by employing constant comparisons (Glaser & Strauss, 1967).

Our findings reveal four ways in which the PTs enriched word problems: *motivation*, *personalization*, *removal of pre-determined information*, and *removal of mathematical components* (e.g., mathematical operations, representations). For example, one PT in the study modified the word problem to: "You are the mayor of a town. Your town's population is growing exponentially. What will the population be after 3 years?" This revised problem is written with a particular person identified (*personalization*) and does not present students with the initial population size of the town or the growth rate of the population (*removal of pre-determined information*). Another PT adapted the problem to: "The town is worried about when they will run out of space for the amount [*sic*] of people living there. When the town has tripled, there will not be space for any more people. Determine how many years will pass before it is at its capacity." This problem now involves a potentially relatable issue of overcrowding and allows students to consider the town capacity (*motivation*) without providing the embedded mathematical operations (*removal of mathematical components*). More categories will be detailed and exemplified on the poster.

Our study illustrates the ways in which the PTs converted conventional word problems to become more authentic as well as mathematically-richer. Since curriculum materials (or word problems) play a key role in classroom instruction, it is important for mathematics teacher educators to consider how we could support teachers and PTs to adapt word problems in a way that provides more support to students' mathematics learning.

Keywords: Instructional Activities and Practices, Technology, Curriculum Enactment

Flipped instruction is an instructional model in which a teacher assigns videos or other multimedia to be viewed outside of class. Many teachers report adopting this model because they want to have more collaborative time during class (de Araujo, Otten, & Birisci, 2017) and, with content delivery still an important part of their instructional vision, they move the content delivery to the video homework. Because mathematical content is typically delivered via these videos in flipped instruction, it is important that we examine them more carefully to capture how content delivery may differ (or not) between flipped and non-flipped instructional models. Thus, our study examined the following question: what are the features of lecture videos selected/created by Algebra 1 teachers utilizing flipped instruction?

We observed 13 Algebra 1 lessons. Each lesson was taught by a teacher who had adopted a flipped instructional model, however, only 11 of the teachers had assigned videos for the observed lesson. Of the 11 lessons with videos, nine had one assigned video, one had two assigned videos, and one had three assigned videos. We collected digital versions of each of these videos and analyzed them using our Flipped Mathematics Instruction Observation Protocol (Zhao, Han, Kamuru, de Araujo, & Otten, 2018).

In terms of duration, the videos ranged from six minutes and four seconds to 13 minutes and 45 seconds with an average of nine minutes and 44 seconds. All the videos were lecture videos featuring worked examples. All of the videos were created by the teachers, and all but two were created utilizing voice-over recordings of their written work. The other two videos utilized picture-in-picture formats. None involved “lecture capture” (e.g., a person recorded at a whiteboard) which has been found to be most effective in content delivery (Chen & Wu, 2015).

We also examined the instructional quality of the videos (e.g., mathematical development, visual representations, mathematics errors) and the extent to which the teachers adhered to multimedia design principles (e.g., personalization, redundancy between narration and text) (Clark & Mayer, 2008). The instructional quality of the videos varied more than the quality of multimedia design. Our analysis of these lecture videos sheds light on how content delivery may differ between flipped and non-flipped instruction and even among the teachers who have adopted flipped instruction. In addition, it provides a better understanding of current implementation of flipped instruction in Algebra 1, potentially informing supports that we may offer teachers.

In countries throughout Asia the Soroban abacus is used in supplemental math education to increase calculation speed and accuracy (Barner et al., 2016). Students begin abacus training with a physical abacus and progress to an internalization of the technique called "mental abacus" (Cho & So, 2018). This study explores the feasibility of abacus training using a virtual abacus and the efficacy of various types of instructional delivery including action-based practice, observational practice or the absence of practice. Results show learning gains for all students in just 20 minutes of engagement, however, there were no significant differences between instructional delivery type. This work is a first step towards designing effective instructional materials for online abacus learning.

EDUCATIVE FEATURES IN UPPER ELEMENTARY EUREKA MATH CURRICULUM

Amy Dwiggins
University of Missouri
add39c@mail.missouri.edu

Keywords: Curriculum Analysis, Elementary School Education, Teacher Knowledge

Since Ball and Cohen's (1996) call to design curriculum materials that support both teacher and student learning and Davis and Krajcik's (2005) creation of design heuristics for the development of educative curriculum materials nine years later, mathematics curriculum designers have worked to include educative features in written curriculum that support both teacher and student learning. Opportunities for teacher learning may be further enhanced in emerging online curricula such as Eureka Math, which has quickly become the most commonly used published instructional resource for elementary mathematics teachers (Opfer, Kaufman, & Thompson, 2016). The nature of use varied considerably from teacher to teacher with the majority of teachers adapting lessons and tasks due to timing and pacing (Kaufman et al., 2017).

Online curricula have the potential for new educative features relative to traditionally published texts or the same educative features but embedded in the written curriculum in new or different ways. Drawing on Shulman's (1986) categories of content knowledge and two frameworks for analyzing educative features (Males, 2011; Quebec Fuentes & Ma, 2018), two modules of the Eureka Math curriculum were coded. Educative features in the modules, Grade 3 Module 7 *Geometry and Measurement Word Problems* (6 topics, 34 lessons) and Grade 4 Module 6 *Decimal Fractions* (5 topics, 16 lessons), were coded across categories of Subject Matter Content Knowledge, Pedagogical Content Knowledge for Mathematics Topics (Experiences, Differentiation, Activity Sequences, Representations, & Tools), Pedagogical Content Knowledge for Mathematics Practices (Discourse, Proof, Terminology, & Participation Structures), and Curricular Content Knowledge (Curricular Overview, Features, Storyline, & Goals). Each feature was also coded as providing teachers a process to implement (Enactment Guidance) or providing teachers the mathematical or pedagogical reasons for such implementation (Rationale Guidance) (Remillard, 2000).

Initial findings indicate that educative features focused on Pedagogical Content Knowledge both for Mathematics Topics and Mathematics Practices were the most prevalent across the two modules with a strong emphasis on teacher support for enacting the written curriculum at the lesson level. Notably, educative features focusing on Curricular Content Knowledge were found throughout the module in the module overview, in the introduction to each topic, and within most of the lessons rather than concentrated at the beginning of the unit. As a whole, rationale guidance across categories of content knowledge seems less prevalent than enactment guidance, a finding shared with Males (2011). Initial findings point to missed opportunities for teacher learning to be promoted, even in this online curricula where publishing restraints can be minimized. Further research on teacher use of the Eureka Math curriculum as well as comparison with other online curricula is needed.

This research focuses on the retention of students' algebraic understandings one year following a Grades 3–5 early algebra intervention. Participants included 1455 Grade 6 students who had participated in a cluster randomized trial. Approximately half of these students received an early algebra intervention as part of their regular instruction in Grades 3–5, while the other half received only their regular mathematics instruction. Results show that, as was the case at the end of Grades 3, 4 and 5, treatment students outperformed control students at the end of Grade 6 on a measure of algebraic understanding. This was despite the fact that treatment students experienced a significant decline in performance and control students a significant increase in performance after the intervention. An item-by-item analysis performed within condition revealed the areas in which students in the two groups experienced a change in performance.

Keywords: Algebra and Algebraic Thinking

Mathematics education scholars have advocated for some time that students be provided long-term experiences, beginning in the elementary grades, that can support the development of their algebraic thinking. While this view is widely accepted, research is needed to document how the algebraic understandings of students who are provided such long-term, sustained algebra experiences in the elementary grades compare to those of students who have not had these experiences once students are in middle grades. This paper focuses on a retention study in which the algebraic understandings of students who participated in a Grades 3–5 early algebra intervention were assessed at the end of Grade 6, a year after the completion of the intervention.

Theoretical Perspectives

Our work aims to develop and test a model of early algebra instruction in order to produce research-vetted curricular frameworks and instructional materials from which we can better understand early algebra's impact on students' algebraic thinking. This work has involved small scale cross-sectional (Blanton et al., 2015) and longitudinal (Blanton et al., 2019) studies and more recently a large-scale, longitudinal, cluster randomized trial (Blanton et al., in press).

In a process fully described in Blanton et al. (2018), we built a curricular framework, instructional intervention, and associated assessments around the algebraic thinking practices of generalizing, representing generalizations, justifying generalizations, and reasoning with generalizations (see also Blanton, Levi, Crites, & Dougherty, 2011) and the big algebraic ideas in which these practices can occur, namely, generalized arithmetic; equivalence, expressions, equations, and inequalities; and functional thinking.

Previous Research: The Longitudinal Study

In order to provide context, we briefly describe the longitudinal study of the Grades 3–5 intervention that preceded the retention study that is the focus of this paper. The study used a cluster randomized trial design and is fully described in Blanton et al. (in press). Participants included approximately 3000 students and took place in 46 elementary schools across three school districts, with half of the schools randomly assigned to a either a treatment or control condition. Students in treatment schools were taught our early algebra intervention in Grades 3–5, which consisted of 18 lessons per year, as part of their regular mathematics instruction by their classroom teachers. Teachers took part in professional development that addressed the big algebraic ideas and algebraic thinking practices that were the focus of the intervention.

Students completed written assessments prior to the start of the intervention in Grade 3 and at the end of Grades 3, 4 and 5. Assessments consisted of 12-14 items designed to measure understanding of the big algebraic ideas and algebraic thinking practices that formed the basis of the intervention. We found that while there were no differences between groups in performance or structural strategy use (Kieran, 2007, 2018) prior to the intervention, treatment students improved at a significantly faster rate than control students in Grade 3. While students in the two conditions made parallel gains across Grades 4 and 5, the treatment students' initial gains were maintained so that they remained significantly ahead of control students in their understanding of big algebraic ideas and thinking practices as they entered middle school (Blanton et al., in press).

Given the results of our Grades 3–5 study, we were interested in revisiting these same students one year later to assess the intervention's longer-term impact. Our research question was thus the following: *How does the performance of students who took part in a Grades 3–5 early algebra intervention compare to that of students who experienced only their regular Grades 3–5 mathematics curriculum one year after the conclusion of the intervention?*

Method

Participants

Sixth grade retention data was collected from 1455 students across 23 middle schools in the three school districts that took part in the Grades 3–5 longitudinal study. Of these students, 716 were in control schools and received only their regular instruction in Grades 3–5, while 739 were in treatment schools and were taught the intervention as part of their regular instruction.

Context

While participating students were consistently in a control or treatment elementary school throughout Grades 3–5, all students moved to new (middle) schools in Grade 6 and were intermixed. The students who participated in the retention study experienced their schools' regular mathematics curriculum during Grade 6 and no instructional intervention from our project. Grade 6 teachers cited use of a variety of mathematics curricula but in all cases were expected to align their instruction with the *Common Core Standards for School Mathematics* (National Governors Association Center for Best Practices and Council of Chief State School Officers [NGA Center & CCSSO], 2010).

Data Collection

Students completed a written assessment at the end of Grade 6 consisting of 11 open-ended items, most of which contained multiple parts. Nine of these 11 items also appeared on the Grade 5 assessment and will be the focus of the results we share in this paper (see Figure 1).

The graphs below represent the relationship between time spent riding and distance traveled for each rider. a) Who started riding first? How can you tell? b) Who rode faster? How can you tell? c) Is Emma riding the same speed on her whole trip, or is she speeding up or slowing down? How can you tell? 23	Equivalence, expressions, equations	Do the following two equations have the same solution? Explain. $2 \times n + 15 = 31$ $2 \times n + 15 - 9 = 31 - 9$

Figure 1: Items Common to the Grade 5 and Grade 6 Assessments

Data Analysis

Coding schemes developed in previous work (see Blanton et al. [2015] for a full description of this process) were used to categorize student responses to assessment items both in terms of performance and in terms of strategy use. (In the results shared here, we focus only on performance.) Items were coded by trained coders unaware of students' treatment condition.

Changes in overall correctness over time were assessed using a repeated measures ANOVA, with treatment condition as a between-subjects factor. McNemar's test was then used to examine item-by-item changes in performance from Grade 5 to Grade 6 within each condition.

Results

The repeated measures ANOVA showed no significant impact of testing time across all students, but did reveal a significant interaction between testing time and treatment condition, $F(1, 1453) = 160.73$, $p < .001$. Overall, treatment students (M = 47.51% correct, SD = 21.54%) maintained their advantage over control students (M = 37.93% correct, SD = 19.74%) at the end of Grade 6, $F(1,1453) = 78.13$, $p < .001$. However, the gap between the two groups narrowed from Grade 5 to Grade 6, with control students experiencing an overall increase in performance from Grade 5 (M = 33.38%, SD = 19.43%) to Grade 6 (M = 37.93%, SD = 19.74%) and treatment students experiencing an overall decrease in performance from Grade 5 (M = 53.40%, SD = 24.17%) to Grade 6 (M = 47.51%, SD = 21.54%).

McNemar's test was used to compare performance (percent correct) across the two conditions on the nine individual assessment items (with a total of 24 individual item parts) common to Grades 5 and 6. The items are given in Table 1.

Table 1: Percent Correct on Assessment Items Across Conditions and Testing Times

Item	Control	Treatment

* Items on which students showed significant gain from Grade 5 to Grade 6 ($p < .05$)
** Items on which students showed significant decline from Grade 5 to Grade 6 ($p < .05$)

As shown in Table 1, control students made gains in performance on individual assessment items much more so than did experimental students. Specifically, of the 24 individual item parts, control students improved on 15 of those parts and declined on three of those parts from Grade 5 to Grade 6. Treatment students, on the other hand, improved on just one of those parts and declined on 11 of those parts from Grade 5 to Grade 6.

Of particular interest in the control condition is the identification of the areas of algebra in which students made their gains. That is, in which areas did their regular middle school instruction help to close the gap between their performance and that of their treatment counterparts? Of particular interest in the treatment condition is the identification of the areas of algebra in which students a) maintained or gained in their Grade 5 performance levels and b) declined in performance after a year without a focused early algebra education. Answers to these questions will shed light on the algebraic content and thinking practices that “stuck” with students one year after our three-year early algebra intervention—whether because the learning was supported by their “business as usual” middle school instruction or was maintained over the course of the year despite this instruction—and the areas in which this was not the case.

For control students, significant gains occurred across a range of big algebraic ideas and thinking practices. Students showed an increased understanding of equality and equations on some items (Items 1, 10b, 10c). They were increasingly able to identify one-step function rules in words (Items 9c1, 14a1) and in one of these cases make a far prediction (Item 14b). They also made gains identifying an arithmetic property (Items 3a) and representing unknowns along with arithmetic and one-step functional relationships with variables (Items 3b, 5a, 5b, 9c2, 14a2). They did not experience gains on items involving advanced understanding of equality (Item 23), two-part function rules (Items 9e1 and 9e2) or using algebraic expressions of more than one term to represent problem situations (Items 5c1, 5c2).

Treatment students maintained their Grade 5 performance levels on items addressing their understanding of the equal sign (Items 1 and 23) and equations (Items 10a, 10b, 10c). They also maintained their ability to identify an arithmetic property (Item 3a), make far predictions when working with functional relationships (Items 9d, 14b) and represent an unknown with a variable (Item 5a). Treatment students showed a decline in performance from Grade 5 to Grade 6 where they needed to identify one- or two-step functional relationships in words (Items 9c1, 9e1), provide a general argument to justify a statement about the sum of odd numbers (Item 4), and provide a variable representation of more than one term to represent unknown quantities (Items 5b, 5c1, 5c2), an arithmetic property (Item 3b), and functional relationships (Items 9c2, 9e2).

Discussion

Results from our longitudinal Grades 3–5 study (Blanton et al. [in press]) offered evidence that providing students with sustained early algebra experiences across a range of big algebraic ideas and algebraic thinking practices can in fact place them at an advantage in terms of algebraic understanding relative to students who experience a more arithmetic-focused approach to elementary mathematics as they enter the middle grades. The study reported in this paper assessed the algebraic understanding of these students one year after the conclusion of the Grades 3–5 intervention, at the end of Grade 6. The most important result we have to report is that one year post-intervention, treatment students still significantly outperformed control students on an assessment measuring their understanding of big algebraic ideas and thinking practices. That is, early algebra (i.e., the Grades 3–5 intervention) *did* make a difference in terms of helping students be better prepared for algebra in the middle grades.

Digging deeper into the item-by-item results revealed the areas in which treatment students were able to maintain their Grade 5 performance levels and the areas in which their performance dropped. Likewise, we were able to identify areas in which control students made significant gains, likely signaling areas of relative strength in their middle school mathematics instruction.

One important area in which treatment students maintained their performance was the concept of equality and the meaning of the equal sign. This was the core concept with which we started our Grade 3 lessons, and it was consistently revisited throughout the three years of the early algebra intervention. While control students made some gains in this area as well, their gains were not consistent across items and did not include growth on our most advanced item involving the recognition of equivalent equations. While the *Common Core* (NGA Center & CCSSO, 2010) does address students' understandings of the equal sign to some extent, our findings suggest a need to strengthen and maintain this focus over multiple years.

An important Big Idea in our Grades 3–5 intervention in which treatment students' learning was not robustly maintained from Grade 5 to 6 is functional thinking. While treatment students maintained their performance identifying a simple exponential function in words, they experienced a decline on all other items requesting the identification of a functional relationship, whether in words or variable notation. Control students showed some gains on these items, yet they still fell short of the performance of their treatment counterparts. This is perhaps not surprising giving the lack of a deep treatment of functional thinking in the *Common Core* (NGA Center & CCSSO, 2010) prior to Grade 8, calling into question the choice to de-emphasize the role of functional thinking in elementary grades in these standards. Our work with students across Grades 3–5 as well as the work of Blanton and colleagues (Blanton, Brizuela, Gardiner, Sawrey, Newman-Owens, 2015) with much younger students has illustrated that elementary students are capable of engaging in such thinking, beginning with very simple relationships that increase in complexity over time. The decline treatment students demonstrated in performance from Grade 5 to Grade 6 suggests not that they are unable to engage in such thinking, but that opportunities to engage in such thinking need to be sustained over time.

Only one item (Item 4) on our assessment explicitly asked students to build an argument to justify an arithmetic generalization. This was among the most difficult of tasks for Grades 3–5 students in both conditions. By the end of Grade 5, 23.41% of treatment students in the Grades 5-6 retention study were able to produce a general argument to justify that the sum of three odd numbers is an odd number. By the end of Grade 6, only half of these students were able to do so. Control students likewise showed no improvement in their ability to produce such an argument. Like functional thinking, this is an area that does not receive a great deal of attention in elementary curricula. Also, like functional thinking, argumentation is an area in which we know elementary students are capable of engaging. Our previous work (Blanton et al., 2015; Blanton et al., in press), along with the work of others (Carpenter, Franke, & Levi, 2003; Carpenter & Levi, 2000; Russell, Schifter, & Bastable, 2011a, 2011b) illustrates that while building more general arguments is challenging, students are capable of using the context of arithmetic to engage in justifying mathematical claims. In our current work, we are successfully engaging K– Grade 2 students in generalizing and justifying generalizations about even and odd numbers. We thus argue that our findings in this area suggest not a lack of ability on the part of students, but rather a lack of access to important algebraic practices.

Finally, we point to students' performance producing variable representations across a variety of big algebraic ideas to argue that this, too, is an area in need of sustained focus. Treatment students showed a decline from Grade 5 to Grade 6 in their abilities to represent an arithmetic property, functional relationships, and related unknown quantities using variable notation. While control students showed some gains in this area, the performance levels they reached were nowhere near that of their treatment counterparts. We have evidence from our Grades 3–5 work as well as the work of others with much younger students (Brizuela, Blanton, Sawrey, Newman-Owens, & Gardiner, 2015) that students are capable of representing varying quantities with algebraic notation and in fact often prefer such representations over verbal ones. We thus argue again that what is needed is a sustained focus on such experiences over time.

Conclusion

Over twenty years ago, Kaput (1998) called for an end to “the most pernicious curricular element of today's school mathematics—late, abrupt, isolated, and superficial high school algebra courses” (p. 25). He argued that we could do so by viewing algebra as a K–12 experience, integrating algebraic thinking and reasoning throughout the mathematics curriculum. Our work developing and testing a Grades 3-5 early algebra intervention coupled with our Grades 5–6 retention study lends support to Kaput's argument. First, we found that, over time, treatment students retained a significant advantage over their control peers in their understandings of worthwhile big algebraic ideas and thinking practices. Second, we believe our findings lend support to the argument that algebra must be treated as a continuous K–12 strand of thinking, not as a subject that can be infused into students' elementary curricula for a few years only to be cast aside until its more formal treatment.

Systems of equations are an important topic in school mathematics. However, there is limited research examining productive ways of supporting students' understandings of systems of equations. In this paper, we first present a conceptual analysis of potential ways students may leverage their quantitative and covariational reasoning to graph systems of relationships. We then describe results from a design experiment in which we examined the potential of supporting middle-grades students in reasoning in ways compatible with this conceptual analysis. We highlight two different ways of reasoning students engaged in as they compared the relative magnitudes of two quantities with respect to a third quantity and leveraged this reasoning to graphically represent two relationships on the same coordinate system. We draw implications from these results for the teaching and learning of systems of equations.

Keywords: Algebra and Algebraic Reasoning, Cognition, Middle School Education

Systems of equations are an important topic as indicated by its presence in both U.S. and international mathematics curricula (Bergeron, 2015). Despite this, there is a dearth of research examining productive ways of supporting students' meanings for systems of equations (see Häggström, 2008). Several researchers (Olive & Caglayan, 2008; van Reeuwijk, 2001) have noted students can leverage thinking about experientially real contexts to determine solutions for systems of equations involving discrete quantities. For instance, Olive and Caglayan (2008) examined how students solved a system of equations by leveraging their quantitative reasoning (Thompson, 1995) to coordinate several quantitative units to simplify a system of two or three equations into one equation with one variable. In this report, we extend Olive and Caglayan's (2008) work by examining ways to support middle-grades students in reasoning quantitatively and covariationally to construct, graph, and determine solutions to systems of relationships. We first present a conceptual analysis (Thompson, 2008) in which we explain ways of reasoning we conjectured could be productive for students graphing systems of relationships. We then present results from a design experiment in which we highlight students reasoning in ways compatible with this conceptual analysis. Specifically, we highlight that students were able to reason quantitatively and covariationally to construct and reason about two relationships and leverage this reasoning to accurately graph both relationships on the same coordinate system. We discuss implications of these findings for school mathematics teaching and curriculum.

Reasoning Quantitatively and Covariationally to Represent Systems of Relationships

In this report, we adopt Thompson's (1993, 1995, 2008) theory of quantitative reasoning. Specifically, Thompson (1993) noted:

> A quantity is not the same as a number. A person constitutes a quantity by conceiving of a quality of an object in such a way that he or she understands the possibility of measuring it... Quantities, when measured, have numerical value, but we need not measure them or know their measures to reason about them. You can think of your height, another person's height,

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

and the amount by which one of you is taller than the other without having to know the actual values. (p. 165)

We highlight two aspects of quantities as defined by Thompson. First, and consistent with others (Glasersfeld, 1995; Steffe, 1991), Thompson emphasizes that quantities are conceptual entities constructed by an individual in order to make sense of their experiential world. As such, understandings of a quantity can and will differ from individual to individual and it is critical for teachers and researchers to attend to *students'* conceptions of quantities. Second, quantitative reasoning may entail reasoning about numeric values, but such reasoning does not *require* numeric values (Johnson, 2012; Thompson, 2011). Instead a student may reason about the magnitude, or 'amount-ness,' of a quantity without using numeric values.

Leveraging Thompson's characterization of quantitative reasoning, Carlson et al. (2002) defined covariational reasoning as entailing a student coordinating two varying quantities while attending to the ways the quantities change together. They described five mental actions students engage in that allow for fine-grained analysis of students' activity. The mental actions include coordinating *direction of change* (surface area increases as height increases; MA2), *amounts of change* (the *change* in surface area *increases* as height *increases in successive equal amounts*; MA3), and *rates of change* (surface area *increases at an increasing rate* with respect to height; MA4-5). Although researchers (Johnson, 2012; Moore, 2014; Paoletti & Moore, 2017) have described productive ways high school and post-secondary students engage in reasoning compatible with the mental actions, there is a dearth of research examining middle-grades students' reasoning in such ways. In this study, we pay particular attention to MA3 as critical to students representing relationships between covarying quantities.

A Conceptual Analysis with an Example

In this section, we leverage one use of conceptual analysis described by Thompson (2008), namely "describing ways of knowing that might be propitious for students' mathematical learning" (p. 46). We present a conceptual analysis of ways students may leverage their quantitative and covariational reasoning in order to describe and graphically represent a system of relationships. Specifically, we conjectured we might be able to support students in reasoning about and graphically representing a system of relationships by having the students engage in a series of activities. We intended to support students to (a) construct and reason about a relationship between Quantity A and Quantity B, (b) construct and reason about a relationship between Quantity A and Quantity C, (c) compare the relative magnitudes of Quantity B and Quantity C, including when Quantity B is greater than, less than, or equal to Quantity C for all possible values of Quantity A, and (d) leverage the reasoning from (a)-(c) to graph a system of relationships and interpret the resulting graph in terms of the inequalities determined in (c).

We use the Cone/Cylinder Task, which we designed with this conceptual analysis in mind, to describe steps (a)-(d). Prior to the session addressing the Cone/Cylinder task, we spent two to three teaching episodes engaging students with the Cone Task, which entails a dynamic cone with a varying height (the same cone is seen in Figure 1). We ask students to describe quantities they could imagine in the situation to support their reasoning quantitatively. We then task students with describing how either the surface area or volume of the cone varies, without providing numeric values, as the height varies (for more on the evolution of this task see Paoletti, Greenstein, Vishnubhotla, & Mohamed, accepted). We provide students with a sheet of paper showing the cone at five equal changes in height and prompt them to describe how the surface area (or volume) of the cone changes for successive equal changes in height to support their engaging in the mental actions described by Carlson et al. (2002). After coordinating the quantities situationally, each group was able to represent the relationship they conceived between surface area (or volume) and height of the cone in a normatively correct graphical representation.

After addressing the Cone Task, we began the next session with an applet showing the same cone with a growing cylinder next to it (Figure 1). Prior to asking the students to graphically represent the surface area (or volume) of each 3D shape with respect to height, we first asked students to engage in two other activities: (1) we asked students to describe how the surface area (or volume) of the cylinder grows for equal changes in height attempting to promote their reasoning in ways described by Carlson et al. (2002), and (2) we prompted them to describe height values (as defined by the slider, *a*) such that they conceived the surface area (or volume) of the cone is greater than, less than, or equal to the surface area (or volume) of the cylinder. Consistent with quantities being conceptual entities, we were not concerned if the students' approximation for an *a*-value such that the two quantities are equal is accurate. Instead, we intended to explore how the students described the relative magnitudes of the surface areas (or volumes) before and after their determined numeric height value.

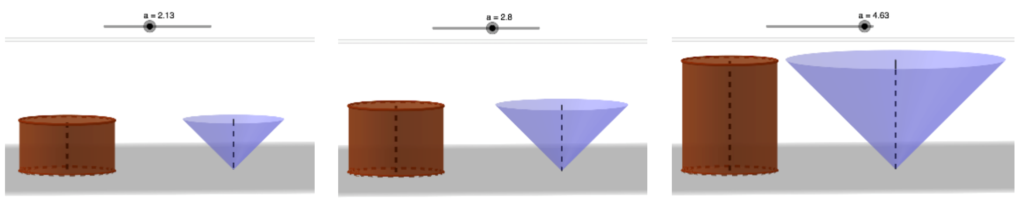

Figure 5: Several Screenshots of Cone/Cylinder Task

After addressing the two aforementioned activities, we asked students to graphically represent the relationships between surface area (or volume) and height of the two shapes on the same coordinate system. We note that since the Cone Task, involving only the cone, required several teaching episodes, each group had already constructed at least one graph representing the relationship between surface area (or volume) and height of the cone but had not yet constructed a graph representing the surface area (or volume) and height of the cylinder.

Methods, Participants, and Analysis

We conducted a design study (Cobb, et al., 2003) consisting of five small-group (one to three students) teaching experiments (Steffe & Thompson, 2000) to examine ways to support middle-grades students' (age 10-13) quantitative and covariational reasoning including the possibility of supporting their leveraging such reasoning to represent systems of relationships. We opted to engage middle-grades students as such students had not yet taken or completed Algebra I and did not have experience graphing systems of equations. The teaching experiments occurred in an underperforming school (as measured by standardized testing), which hosts a diverse student population (over 75% students of color and qualify for free or reduced-price lunch), in the Northeastern U.S. We recruited students through teacher recommendations and we engaged all students who returned consent forms.

To analyze the data, we leveraged a second use of conceptual analysis, "building models of what students actually know at some specific time and what they comprehend in specific situations" (Thompson, 2008, p. 60). Specifically, we generated, tested, and adjusted models of student's mathematics so these models provided viable explanations of each student's activity.

We used open (generative) and axial (convergent) approaches (Strauss & Corbin, 1998) to analyze the data. First, we watched videos identifying instances that provided insights into each student's meanings. We used these instances to generate tentative models of each student's mathematics, which we compared to notes taken during on-going analysis. We tested these models by searching for supporting or contradicting instances in other activities. When evidence contradicted our models, we revised our models and returned to prior data with these new hypotheses in mind to modify previous models. This process resulted in viable models of each student's mathematics. After this, we used cross-case analysis (Yin, 2003) to compare the different students' activity to identify themes in the students' reasoning and meanings.

Results

Across the five groups, we saw two different approaches students used to graphically represent the two relationships on the same coordinate system after comparing the relative magnitudes of the surface area (or volume) of the shapes with respect to height. Four groups initially reasoned covariationally as they accurately represented each relationship on the same coordinate system without attending to the inequalities they determined (e.g., drew a linear graph to represent the relationship for the cylinder and a concave up curve to represent the relationship for cone). Two of these groups later adapted their curves in order to maintain the relationships represented by the inequalities they determined earlier in the session. The third group (a single student) reasoned about two researcher drawn curves on a coordinate system as consistent with her conceived inequalities. Due to time constraints, we were unable to probe the fifth group (a single student) in regards to how she could adjust her curves or interpret curves on a new coordinate system in relation to the inequalities she determined. To exemplify these students' activities, below we present the activities of one pair of students, Zion and Reggie.

In contrast to the other students' activities, one group, Candice and Amber, reasoned about the *difference* between the surface area of the cone and cylinder throughout their activity. By focusing on the difference in the two quantities magnitudes, the pair constructed curves that maintained the relationships they inferred regarding height values such that one surface area was greater than, less than, or equal to the other but did not accurately represent the individual covariational relationships between each shape's surface area and height. The pair adjusted their curves while continuing to reason about the difference between magnitudes to construct normatively accurate graphs.

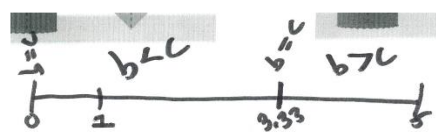
Reasoning Covariationally About Each Relationship then Adjusting: Zion and Reggie

After the sessions in which Zion and Reggie reasoned about the directional and amounts of change of surface area with respect to height of the cone (MA 2-3) and graphically represented this relationship, we presented them with the Cone/Cylinder applet and asked them to determine intervals on which the surface area of the cone (which they defined with the variable b) was greater than, less than, or equal to the surface area of the cylinder (which they defined with c). Moving the slider on the applet, they determined the two surface areas were equal at a height value of 3.33, and that for height values less than 3.33 the surface area of the cone was less than the surface area of the cylinder ($b < c$) and vice versa for values greater than 3.33 (Figure 2*a*).

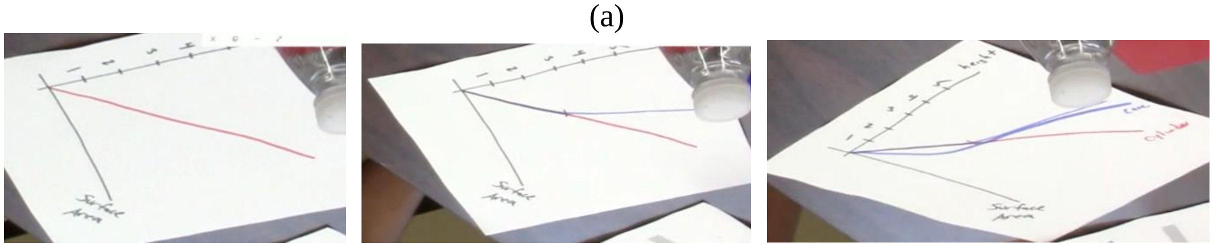
Having compared the two surface areas for all height values, the teacher-researcher (TR) asked the pair to describe how the surface areas of the cone and cylinder were increasing. Based on their activity in the Cone Task, the students spontaneously shaded in areas representing amounts of change of surface area of the cone for successive equal changes in height to argue the surface area of the cone was "growing by more and more each time." Then, the pair worked to represent via color-coordination, amounts of change in surface area of the cylinder for equal changes in height. Specifically, on a paper showing five instantiations of the cylinder and cone, the TR shaded in blue the outer surface area of the cylinder with a height of 1. In the cylinder representing the second change in height (from 1 to 2), Zion shaded in blue the same area shown in the first cylinder (with a height of 1) then shaded in brown area representing the amount the surface area changed by from a height of 1 to 2.

> TR: So that you were trying to make this brown part [*pointing to the cylinder showing the second change in height*] the same as what?
> Reggie: [*Zion and Reggie both point to the surface area representing the cylinder with a height of 1*] Same as this.
> TR: As that one?
> Reggie: 'Cause that's how much it grows every time [*pointing to the surface area of the cylinder with a height of 1*].

Shortly after this, Zion described that the surface area of the cylinder "grows constantly." We infer Reggie and Zion each understood the surface area of the cylinder increased by the same amount for equal changes of height (MA 2-3). Further, Zion sketched a linear graph representing this relationship (Figure 2*b*). We note that although the graph had the horizontal axis labeled "Surface Area," throughout their activity each student made statements that implied surface area and height were represented on the vertical and horizontal axes, respectively, and later in their activity relabeled the horizontal axis "height" when they noticed this label.



(a)



(b) (c) (d)

Figure 2: (a) Zion and Reggie's Segment Representing Height Values and (b)-(d) Several Screenshots of Their Work Graphing Each Relationship on the Same Coordinate System

Immediately after the interaction above, Reggie drew a second curve in blue to represent "the cone" (Figure 2*c*). The TR probed the students to examine if they intended to represent the surface area of the cone and cylinder as being equal for small height values:

> TR: Are they growing from 0, 0 to 3.33 [*marks a point on the curves where the blue and red curve diverge*]… are they the same, are the surface areas the same for that, from 0 to 3.33?
> Reggie: Yeah [*using his fingers to indicate the segment between (0,0) and the point on the*

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

graph where the curves diverge], uh-huh.
TR: Should they be?
Zion: [*crosstalk*] I mean this one would be a little bit lower I guess [*tracing an imaginary concave up curve from (0,0) to where the curves diverge as if drawing a new blue curve*] because it's not…until we said until 3.33 the cylinder is going to be bigger. [*Zion draws a new curve in blue on their coordinate system, Figure 2d, then the TR asks him to explain why he changed the graph.*] What we said is that the, that from this point [*motioning over the interval from 0 to 3.33 on the segment in Figure 2a then pointing to b > c*] that the cu-cylinder is gonna be bigger than the cone and from this point on [*pointing to 3.33 then to 5 on the segment in Figure 2a*] the cone is gonna be bigger than the cylinder [*pointing to b < c*].
TR: How does this graph [*pointing to the graph in Figure 2d*] show you that… the surface area of the cone is less than the surface area of the cylinder?
Reggie: The cone [*tracing over the blue curve from the origin to the point of intersection*] is lower than the cylinder [*tracing over the red curve from the origin to the point of intersection*].

We highlight two aspects of this interaction. First, we infer Reggie argued the two surface areas were equivalent from 0 to 3.33 by interpreting what it would mean for the two curves to overlap on this interval (i.e., using his fingers to indicate the gap between (0, 0) and the point where the curves diverged on the graph), rather than on a conception of the relationship between the quantities' magnitudes. This inference is supported by him quickly assimilating Zion's argument regarding the need to represent the cone's surface area as being below the cylinder's surface area for height values between 0 and 3.33. Second, we highlight how Zion leveraged the inequalities they had determined earlier (i.e. explicitly referencing the inequalities they had determined in Figure 2a) to adjust their curve to create a representation that reflected their stated inequalities; Zion coordinated his activity reasoning about inequalities regarding the two surface areas in relation to height as he constructed two curves representing each surface area-height relationship.

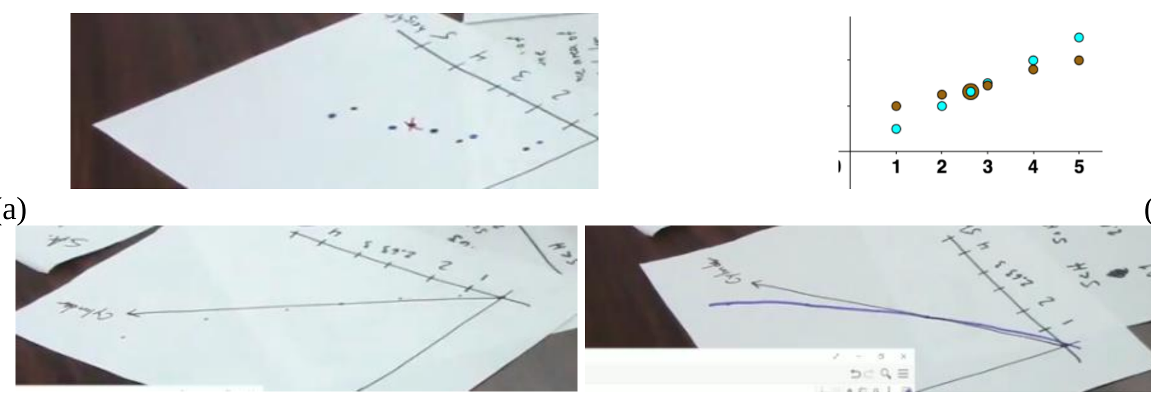
Reasoning About the Difference of Two Quantities to Represent a System of Relationships

Like Zion and Reggie, at the outset of the Cone/Cylinder Task session, Candice and Amber described the surface area of the cone increased by more for equal changes in height (MA 2-3) and the surface area of the cylinder increased by equal amounts for equal changes in height (MA 2-3). When prompted to determine a height value such that the two surface areas were equal, they approximated a height value of 2.63 and indicated for height values between 0 and 2.63 the surface area of the cone was less than that of the cylinder and vice versa for height values between 2.63 until 5. Each student had sketched a linear function to represent the relationship between surface area and height of the cylinder but had labeled their axes differently (Candice labeled the vertical axis "height" and Amber labeled the horizontal axis "height").

Attempting to ensure the students would discuss the same quantities when discussing their graphs representing both relationships, the TR created new axes with height values from 1 to 5 on the horizontal axis and asked the students to color coordinate points (blue for the cone and brown for the cylinder) representing the height and surface areas of the two shapes. Addressing this, each student considered the difference in the two surface areas for corresponding height values as they plotted points. Specifically, after plotting the brown points above the blue points at height values of 1 and 2 (Figure 3*a*/*b*), the TR asked how they had chosen to space the points. Candice maintained the points above the height value of 2 were closer than the points at a height value of 1 and Amber stated the points above the height of 1 should have been spaced farther apart. We infer each student understood that the surface area of the cylinder was bigger than the surface area of the cone and that the difference between surface areas was decreasing until 2.63.

After plotting these points, the TR moved the applet to a height value of 2.63 and each student indicated the surface areas "are going to be the same." Candice then placed a blue point above a height value of 3 and Amber placed a brown point on top of this blue point. Noticing the horizontal placement of the points, the TR motioned to the value on the axis below their points to examine if the students intended to plot points above a height value of 3. Amber quickly indicated their points should be above a point between two and three on the height axis, putting an X on top of their points (Figure 3*a*). Candice then placed a tick on the height axis representing a value of 2.63 and the students plotted overlapping points above this tick. We infer the students understood the two shapes had the same surface area at 2.63, which they understood meant the two curves would overlap at this value.

The students continued plotting points after 2.63 such that the blue point was above the brown point and the distance between points was "getting farther [apart]. Because [the difference between surface areas is] getting bigger." Throughout their activity the students focused on the difference in surface areas as they plotted points. However, they were not explicitly focusing on the locations of the points in relation to an individual shape's surface areas, which the TR conjectured could be problematic. For instance, both he and Amber perceived that the blue points (Figure 3*a*/*b*), representing the surface area and height of the cone, fell in a straight line that did not accurately represent the relationship. Hence, the TR drew new coordinate axes and a linear curve representing the surface area and height of the cylinder, which each student had produced earlier. He then asked the pair to sketch the curve representing the surface area and height of the cone. Consistent with reasoning about the difference between surface areas, Candice plotted points above and below the red line that maintained the difference in surface areas they had described previously. For instance, the spacing between their plotted points and points on the line for height values greater than 2.63 was increasing (Figure 3*c*). Candice then connected these points with a curve (Figure 3*d*). Compatible with attending to difference in surface areas rather than the individual surface areas, when Candice drew the curve, Amber exclaimed "Oh my god! It looks like the other line." Amber then explained the blue curve was similar to the curve they had constructed to represent the surface area and height of the cone in previous sessions.



(a) (b)

(c) (d)

Figure 3: Several Screenshots (and a Recreation) of Candice and Amber's Work

Throughout their activity, we infer Amber and Candice focused on the relationships they inferred creating inequality statements (i.e. a difference) rather than on the covariational relationships they had inferred regarding each individual surface area-height relationship. After plotting points that reflected how the difference between quantities was changing but not the quantities themselves, they were able to use the difference between surface areas to accurately sketch a curve representing the relationship between surface area and height of the cone on the same coordinate system with a line representing the surface area and height of the cylinder.

Discussion

In this paper, we presented a conceptual analysis of four interrelated activities, (see steps (a) – (d) in Conceptual Analysis with an Example), we conjectured could be productive for students graphing systems of relationships. While both pairs of students presented eventually constructed curves representing a system of relationships based on the relationships they inferred in the situation (step (d)), they did so in different ways. Specifically, Amber and Candice's reasoning focused on the *difference* in surface areas' magnitudes which they inferred from comparing the two surface areas (step (c)) as they initially plotted points. They continued to reason about the difference in surface areas to plot points representing the surface area and height of the cone after the TR provided a new coordinate system with a linear graph representing the surface area and height of the cylinder (which they had previously constructed addressing step (b)). This process resulted, to Amber's surprise, in a curve similar to the one they obtained when addressing step (a). In contrast, Zion and Reggie, as well as the three other groups, initially produced a graph of each individual relationship that reflected the covariational relationship they inferred from the situation (e.g. the relationships they inferred in steps (a) and (b)). During this activity, they did not attend to how the two curves may intersect. After considering the inequalities they deduced when comparing the relative magnitudes of the two surface areas (step (c)), two of these groups were able to sketch a graph accurately representing the two relationships they conceived.

The results we presented provide novel insights into students developing understandings of systems of relationships and also add to the literature on students' quantitative and covariational reasoning in two important ways. First, we highlight that the students were never presented with, nor created, values for the surface area of either shape. Rather they reasoned about quantities' magnitudes (Thompson, 1995) when reasoning about the direction and amounts of change of surface area as well as when comparing the relative size of the two shape's surface areas. The students later used height values to describe and graphically represent these varying magnitudes. Hence, the results presented here highlight ways in which middle-grade students can productively reason quantitatively and covariationally about both magnitudes and values to graphically represent relationships.

Second, the results provide empirical examples that, at least some, middle-grades students are capable of leveraging the mental actions describe by Carlson et al. (2002) to reason about and graphically represent relationships between covarying quantities. We conjecture supporting middle-grade students in developing such reasoning as a way of thinking (Thompson, 2016) could serve as the foundation for their developing notions of linear and non-linear relationships as well as rate of change more generally. Future researchers may be interested in examining ways to support middle-grades students engaging in such reasoning to develop such notions as well as to develop other relation classes (e.g., exponential, quadratic relations).

Finally, we note that our focus was broader than determining a solution to a system of equations, which is often a goal of school mathematics (e.g., Häggström, 2008). We were interested in exploring ways students can reason about systems of relationships, including how two quantities are represented when one is greater than, less than, or equal to the other with respect to a third quantity. The students in our study rarely experienced difficulties comparing two quantities magnitudes situationally or graphically. Hence, we encourage future researchers and curriculum designers to examine the possibility of supporting students explicitly comparing two quantities magnitudes or values prior to tasking them with determining unique solutions to systems of equations. That is, we conjecture reasoning about systems of relationships can serve as a foundation for students' developing productive meanings for systems of equations.

FROM COMPUTATIONAL STRATEGIES TO A KIND OF RELATIONAL THINKING BASED ON STRUCTURE SENSE

Cesar Martínez-Hernández

Carolyn Kieran
Université du Québec à Montréal
kieran.carolyn@uqam.ca

This paper provides evidence on how elementary school students from a Mexican public school move from using an operational sense, expressed in computational strategies, to a kind of relational thinking based on structure sense ideas and expressed by number decomposition. Even though the results are somewhat preliminary, they illustrate how students can leave behind their computational strategies and develop a more sophisticated mathematical reasoning regarding equivalence of numerical expressions and equalities; however the strategies they developed tended to be based on "ad hoc decomposition of one side and comparison with the initial form of the other side," rather than on compensation.

Keywords: Algebra and Algebraic Thinking

Background

Among the different approaches to developing algebraic thinking in the early grades, recent studies have begun to distinguish more clearly the notion of structure sense in arithmetic (Kieran, 2018b) and to stress its importance as a key feature of algebraic thinking that should be promoted from an early age onward. Equivalence tasks involving equalities such as $a+b=c+d$ have been shown to be particularly important (Martínez & Kieran, 2018). Among the studies dealing with structure sense, Asghari and Khosroshahi (2016) have described how certain tasks in the elementary grades that use the equal sign can provoke a kind of mathematical thinking involving both operational and structural conceptions.

Pang and Kim (2018), as well as Schifter (2018), in studies on equalities of the form $a+b=c+d$, have emphasized the importance of engaging students in discussions on the structural properties of such equalities. In particular, Schifter states that if students focus on the structure of equalities such as 57+89=56+90 in order to determine their veracity, they are thereby indicating a relational thinking with respect to equivalence tasks, which is considered a fundamental aspect of algebraic thinking (Carpenter, Franke, & Levi, 2003).

Based on Schifter (2018), and the theoretical perspective addressed in Kieran (2018b), Martínez and Kieran (2018) demonstrated that students at early ages accept equalities such as $a+b=c+d$ and are able to rewrite them in various ways when asked to identify the equivalence of both sides of the equality. However, their strategy for rewriting an equality to show equivalence (e.g., 172+18=182+8 as 100+72+10+8=100+82+8) indicates that they have a natural inclination to rewrite the equality in a manner that clearly relates to the total of each side. That is to say that they do not decompose and recompose the numbers with the aim of producing a written form where both sides look alike, for example, rewriting 172+18=182+8 as, among others, 100+72+10+8=100+72+10+8, or as 182+8=182+8. In other words, even when they are able to decompose the numbers, they do not establish a clear relation between both sides of the equality, but rather with respect to the total of each side. Therefore, according to Martínez and Kieran (2018), for students to determine the veracity of an equality (e.g., 172+18=182+8) and its various rewritten forms (e.g., 100+72+10+8=100+82+8), they resort to a computational strategy:

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

calculate the total of each side of the equality. Such a strategy and the form they use to rewrite the equality does not allow them to reason about the expressions of the equality based on structural aspects.

However, the results obtained by Martínez and Kieran (2018), especially the fact that students accept equalities of the form $a+b=c+d$, and that they are able to rewrite them, served as a basis for the current study. This study, which is reported herein, involved designing an equivalence task on numeric equalities where students were to be explicitly instructed not to calculate the total of both sides in order to determine the veracity of the equality. This design was considered to be a pivot for developing in students a sense of structure with respect to equivalence, since accepting numerical sentences as bona fide numerical objects and being able to operate on and with them as objects is viewed as fundamental in looking for and expressing structure in arithmetic (Martínez & Kieran, 2018, p. 169). Hence, the question that guided the research of this study is the following: *What is the nature of the strategies students use to determine the equality of the right and left sides of a numerical equation when they are explicitly asked to not calculate the total of each side?*

Theoretical Framework

Different theoretical viewpoints underpin discussions on the development of algebraic thinking at early ages (see Cai & Knuth, 2011; Kieran, 2018a). One such perspective focuses on seeking, using, and expressing structure in numbers and numerical operations (Kieran, 2018b).

Structure in Numbers and Numerical Operations

The main idea in this perspective lies in the notion of structure sense in arithmetic. As Kieran (2018b) points out, there are several researchers interested in the notion of structure in algebra. Linchevski and Livneh (1999) and Mason, Stephens, and Watson (2009), among others, emphasize structure as a feature of algebraic thinking. On the one hand, Linchevski and Livneh relate the development of structure in arithmetic with the development of structure in algebra. Mason et al., on the other hand, maintain that students need to develop *structural thinking*, that is, a focus on relations rather than on procedures.

According to Kieran (2018b, p. 80), the notion of structure is one of the central ideas in mathematics; however, not only are there different perspectives on it, but also it is often treated as if it were an undefined term. Nevertheless, it is strongly related to generalization in the literature on algebraic thinking. On this base, generalization involves identifying the structural, and vice versa, the structural involves identifying the general.

In contrast, Kieran (2018b) discusses aspects related to structure that might expand this notion and that, at the same time, involve more than just the basic properties of arithmetic. She proposes a focus on the notion of structure in arithmetic that draws on Freudenthal (1983, 1991, quoted in Kieran, 2018b). According to Freudenthal, the whole numbers constitute an order structure. This order structure leads to the addition structure, as well as to the multiplication structure. Following Freudenthal, Kieran points out that structure in numbers and numerical operations involves different *means of structuring*, according to, for example, factors, multiples, powers of 10, evens and odds, decomposition of primes, etc. This perspective is embodied in the idea that developing a sense of structure entails seeing through mathematical objects and drawing out relevant structural decompositions.

Based on Freudenthal´s ideas, and the various perspectives found in the literature regarding the notion of arithmetical structure, Kieran suggests promoting various experiences with equivalence that involve decomposition, recomposition, and substitution. Such experiences would allow students to become aware of different means of structuring numbers and numerical operations. The research literature suggests that students think in a structural way about equivalence when they transfer part of a number to another. For example, Carpenter et al. (2003) have shown how students indicate a relational thinking about equivalence when they implicitly use the associative property to decide about the equality of the two sides. Without writing it as such (e.g., for the numerical equality 56+47=54+49), students express that 56+47=(54+2)+47=54+(2+47)=54+49. Britt and Irwin (2011) have referred to this approach as the compensation strategy, which they express alternatively as follows: 56+47=56–2+2+47=54+49. However, the results from our pilot study (see Martínez & Kieran, 2018) suggested that the compensation strategy is not the one that underpins the approach used by the students when they determined the equivalence of the left and right sides of an equality. Consequently, we had to extend our research.

Method

Participants

For this second stage of the project, three students (S1, S2 and S3) from a Mexican public school participated, ages between 11 and 12 years. When data were collected, the students had just finished elementary school. Those three students were selected because they had taken part in the first stage of the project (see Martínez & Kieran, 2018).

Task Design

The proposed task in this second stage of the project is a redesign of Task 3, reported in Martínez and Kieran (2018). Hence, the task involves the equal sign to show the equivalence of expressions in an equality (e.g., 10+7=5+12). The task has four sections, the first three having the following structure:

- A true equality (numerical equation) is presented.
- Students are asked to show, <u>without calculating the total on both sides</u>, that the equality is true. (The task explicitly asks for them not to calculate the total.)
- They are asked for an explanation of their reasoning.

Section four asks for a generalization of the students' strategy for showing the veracity of the equalities as given in the three previous sections.

Data Collection

Data collection was carried out in one single session, eight months after the initial study (reported in Martínez & Kieran, 2018). The technique used in data collection was that of the group interview, conducted by one of the researchers (subsequently referred to as "I"). The aim of the group interview was to allow students to verbalize their reasoning. During the interview, each participant was given the printed task sheet in order to have a written record of his/her work. The 40-minute session was also video-recorded.

Results and Discussion

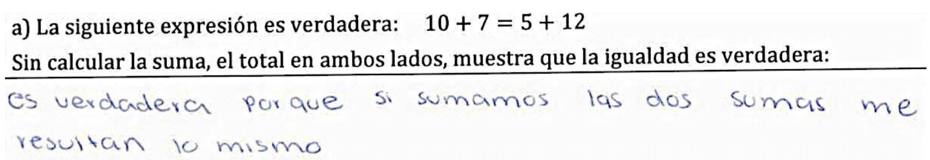
Due to space constraints, this report concerns only the work developed by the three students during the first part of the task, which involved the equality 10+7=5+12, within the setting described in the Task Design section above (where the equality 10+7=5+12 is presented; students are asked to show, <u>without calculating the total on both sides,</u> that the equality is true, along with providing an explanation of their reasoning). Data analysis is based on each student's written work sheets, as well as their verbalizations as evidenced by the video-recordings, and the researcher's field notes.

Spontaneous Exhibition of Operational Sense

The first item in the initial section from the task displays the expression 10+7=5+12 and explicitly asks for showing, <u>without calculating the total on both sides</u>, that this equality is true. Despite the explicit request, students spontaneously referred to the total on both sides of the given equality after individually reading and answering the question. The following verbatim, translated from the original Spanish transcriptions, reflects this moment of the interview:

> I: Would there be a way to show that this equality [is true]? [referring to 10+7=5+12, the interviewer does not complete the question because S3 interrupts]
> S3: By adding [referring to the total; the other students agree]

As can be seen, in spite of the instructions on the work sheet to not calculate the total, S3 answers spontaneously that one needs to add up each of the sides. S1 and S2 explain in a similar manner. Fig. 1 shows S1's work, where her initial written answer is observed ("It is true because if we add the two sides, the sums that are the results are the same.").



a) La siguiente expresión es verdadera: 10 + 7 = 5 + 12
Sin calcular la suma, el total en ambos lados, muestra que la igualdad es verdadera:
es verdadera porque si sumamos las dos sumas me resultan lo mismo

Figure 1: S1's Initial Answer

Based on these answers, the interviewer asks for the possibility of using a particular strategy that the students already know and exhibited in the earlier study (Martínez & Kieran, 2018) – as described in the Background section above, that is, to rewrite the given equality in another equivalent form:

> I: [The researcher writes on the board the equality 10+7=5+12] Is there another way to rewrite this equality?
> S2: As a subtraction.
> S3: As a subtraction [inaudible].
> I: All right, as a subtraction, according to S2 […] For example S2?
> S1: Twenty minus three [note that S1 answers]
> S2: Equals eighteen minus one [S2 completes the equality 20-3=18-1]

As we observe from the verbatim, the strategy followed by S1 and S2 is to search for one or more numbers in such a way as to preserve the total value for each side. These initial results, as reflected in the report of the pilot study, show a strong operational sense in students. They manage each side of the equality in an independent way, guided by the total.

Transition to a Kind of Relational Thinking

From the students' initial responses, the interviewer tries once again to see if the students would apply their earlier strategy for rewriting a given equality (Martínez & Kieran, 2018):

I: Would there be a way to write also [referring to rewriting the given equality] but using, say, these same numbers? [points to the board to the equality 10+7=5+12; see Fig. 2]
S3: Yes.
I: […] For instance, could this [points to the left side, 10+7, but S3 interrupts]?
S3: 5+5+5+2 [verbalizes the expression].
I: Ok, S3 says that this [referring to the left side of the equality 10+7=5+12] could be written as 5+5+5+2 [writes on the blackboard as expressed by S3] Is this OK?
S1 and S2: Yes [both at once].
S3: Is equal to [inaudible].
I: […] This [referring to the right side of 10+7=5+12], in which other way? Look, this [referring to 5+5+5+2] already has a form of, I mean, it [10+7] can be re-expressed in this way [Referring to 5+5+5+2] […]. Ok, Can this [the right side 5+12] be rewritten identically to this? [referring to 5+5+5+2].
S3: Yes.
I: Why?
S2: It gives the same
S1: Because it gives the same.
I: How would you rewrite it?
S3: 5+5+5+2 [verbalizes the expression].
I: Ok, 5+5+5+2 [writes the equality 5+5+5+2=5+5+5+2 as proposed by S3, on the blackboard, see Fig. 2]

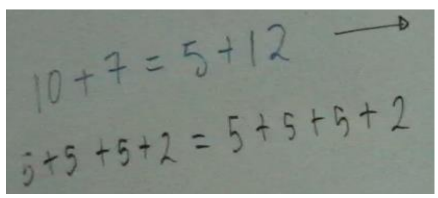


Figure 2: Equality Proposed by S3

As can be observed from the preceding verbatim and from Fig. 2, S3 is able to propose an equivalent form (5+5+5+2=5+5+5+2) of the equality 10+7=5+12, in such a way that both sides of the equality have the same form. This, however, does not necessarily mean that a kind of relational thinking is at play, since the students are working each side separately. Furthermore, S1 and S2 justify based on the preserved total. This is seen when S1 answers: *"Because it gives the same"*.

S2 and S3 are, however, showing that their initial strategies are evolving. The form proposed by S3 is in fact a decomposition of each side of the initial equality. This suggests that S3 is leaving behind the idea of looking for two or more numbers that preserve the total. The evidence for this is derived from the following verbatim:

I: Does this 5 [points to the first number 5 on the left side, 5+5+5+2, of the equality seen in Fig. 2] come from any part here [points to the initial equality 10+7=5+12]? […] Or, are you looking for two or more numbers in order to get 17 [the total]?
S3: Yes, I rewrote the two 5s [the first two numbers of 5+5+5+2] from the 10 [referring to the 10 in the expression 10+7], and from the 12.

S2: From the 7! [S2 interrupts, referring to the 7 in the expression 10+7].
S3: From the 7, we had 2 left, that is why I wrote the plus 2 [S3 explains that the 7 is rewritten as 5+2]
I: And, how would you justify these? [referring to the right side of the equality 5+5+5+2=5+5+5+2, seen in Fig. 2]
S2: The 5 comes from the 5 [of the right side of the initial equality 10+7=5+12], the two 5s and the 2 come from the 12.

As suggested by the verbatim, S2 and S3 are able to decompose each side of the given equality 10+7=5+12 in a common form. They explain, through decomposition, where each number comes from in 5+5+5+2=5+5+5+2. However, the right side in this last equality might be an *ad hoc* writing, in order to coincide with the right side (5+12) of the initial equality – a notion that is synthesized in Fig. 3 and which is discussed more fully in the paragraphs that follow.

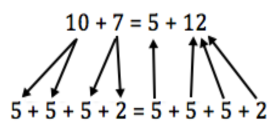

Figure 3: Rewritten Equality Through Decomposition

Based on this new strategy of rewriting each side (or at least one side) through decomposition of numbers and getting both sides of the rewritten equality to have the same form, the interviewer returns to S3's equality to inquire into the need to calculate the total:

I: Seeing it in this way [points to the equality 5+5+5+2=5+5+5+2; see Fig. 2], is it necessary to add up in order to decide if the equality is true? Would you still add [calculate the total] or is the addition no longer necessary?
S3: It is no longer necessary for me.
I: Why not, S3?
S3: Because it is easy to see what will be the result.
I: Ok [….] What is this and this expression like? [pointing to both sides of 5+5+5+2=5+5+5+2]
S2: The same
S3: The same
I: Then, is it necessary to add?
S1: Oh, no!
S2: No, because [inaudible]
S3: But to know the result of each one? [referring to the total of each side]
S2: No, but if it is the same [in the same form], obviously it will give the same [the total will be the same]. If the expression is the same, it will be equal, it will give the same.

As can be seen from the above verbatim extracts, S3 relates the decomposed equality to both sides of the initial equality, but still thinks about the total as a means to validate it. S2 and S1 support the idea that the decomposed equality of S3 is all that is needed for validation, due to the common form in which both sides could be rewritten. It is important to note how S2's speech and thinking have changed. At the beginning of the task, S2 states that the total *"is" the same,* which means that S2 has calculated the total. But now S2 justifies with another tense: *"will be" the same*, which means that S2 is aware that she will get the same total, but that it is not necessary to calculate it. It is enough to observe that both sides of the equality are written in the same form.

As of this moment, the students apply the following strategy to generate an equality equivalent to a given equality and to justify its veracity: rewrite one of the sides of the given equality based on numerical decomposition, and use this to guide the decomposition of the other side; if this decomposition fits the numbers on the other side of the initial equality, then it is not necessary to calculate the total of each side of the newly obtained equality to prove that it is true.

The above described structural approach is clearly observed when the interviewer subsequently asks the students to rewrite in another different form (different from 5+5+5+2=5+5+5+2) the initial equality 10+7=5+12, in such a way that both sides look alike. Fig. 4 shows S1's work during the group interview. However, S1 genuinely decomposes only the left side (10+7) of the initial equality to obtain 2+2+2+2+2+2+2+3, and copies this expression onto the right side. This is made obvious because S1 could not relate the expression 2+2+2+2+2+2+2+3 (i.e., the right side of the equality in Fig. 4) with the right side (5+12) of the initial equality. After a few futile attempts to relate the right side of the equality in Fig. 4, with the right side of the initial equality, S1 starts anew. She proposes a different expression for the right side, 2+2+1+5+5+2, and then guided by this expression rewrites the left side of the initial equality in the same way (see Fig. 5).

Figure 4: Rewritten Equality by S1

Figure 5: Second Rewritten Equality Proposed by S1

Now, the students are able to rewrite an equality by means of a decomposition that clearly shows equivalence; however, the truth of the equality refers to the rewritten form, not necessarily to the initial equality – perhaps because from the beginning they are told that the given equality is true. This is seen, for example, in the explanation offered by S1 (Fig. 6): *"Because if I look and compare each number, they are the same and obviously it is the same"*

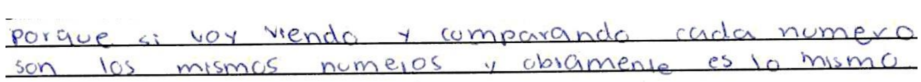

Figure 6: S1's Explanation of the Veracity of the Rewritten Equality

Summarizing, the students' strategy consists of the following: decompose the left (or right) side; copy it to the right (or left side accordingly); compare both sides of the rewritten equality with their corresponding expressions in the initial equality; if they are able to establish the equivalence relation (by pointing to where each number of the rewritten equality comes from with respect to the given equality), then they can conclude that both sides are equal (and that it is not necessary to refer to the total of each side). As previously noted, we refer to this structural approach for generating equivalent numerical equalities as "ad hoc decomposition of one side and comparison with the initial form of the other side".

Interaction Between Participants and Task Design

As could be discerned from the verbatim extracts, the participants' interactions, the task design, and, not least of all, the interviewer's interaction with the students were all crucial for the students to evolve in their mathematical reasoning.

Firstly, it was of the utmost importance to state explicitly to the students that they were not to calculate the total for each side. However, as discussed above, they spontaneously referred to the total as their initial approach for comparing right and left sides of an equality. Thus, the interviewer's role, based on the participants' impulse to calculate, was also crucial in promoting other approaches. For example, a key question that led the students to relate the initial equality with the numerical decomposition they were proposing for their equivalent equality was to have them explain where the numbers came from in their rewritten equality. This helped them focus on the given equality and its rewriting (for at least one side of the equality), based on the involved numbers (see Fig. 3). Lastly, the contribution each student provided in the first part of the task – especially the initial decomposition of the left side proposed by S3 – was crucial for the eventual consolidation of the new strategy that grew out of the students' interactions. The analyzed interview episodes illustrate clearly the significance of a sociocultural environment in the construction of mathematical knowledge.

Conclusions

The first set of results emanating from the designed task of this study support the results and conjectures put forward in Martínez and Kieran (2018). Students show a strong operational sense that leads them to use computational strategies, as a first idea, in equivalence tasks. However, based on their acceptance of equalities such as $a+b=c+d$, students are able to develop a structural sense that is anchored in their arithmetic.

If we compare, on the one hand, the strategy that the students in this study developed with, on the other hand, the compensation strategy reported in the literature, we note several differences. Applying the compensation strategy to the equality 10+7=5+12 involves a simultaneous comparison of the relation between the numbers on the left side (10+7) with those on the right side (5+12), an observation that our participating students never explicitly mentioned. The compensation strategy involves noting that the 10 on the left side is 2 less than the 12 on the right side, and the 7 on the left side is 2 more than the 5 on the right side; so everything is balanced. According to the compensation strategy, this could be expressed as 10+7=10+2-2+7=12+5=5+12. Alternatively, this kind of thinking could be expressed in written form by decomposing the left side into 10+2+5 and the right side into 5+2+10, leading to the equivalent equality, 10+2+5=5+2+10. However, our data did not provide evidence of the use of such strategies. In contrast, the students developed a different structural strategy for generating equivalent equalities – a strategy that has not been reported in the literature up to now.

Such preliminary results lead to further questions regarding whether or not students apply the same strategy for generating equivalent equalities when presented with initial equalities involving much larger numbers where they cannot immediately observe the total for each side or with equalities where they are not told at the outset that the equalities are true. Analyses bearing on such questions are being prepared for follow-up reports.

Finally, even though the students showed a noticeable evolution in the development of their mathematical thinking, we want to emphasize the importance of the role played by the teacher in this development – a role that involved helping the students to move from an operational to a structural kind of thinking in order to determine the equivalence of numerical equalities.

Acknowledgments

We express our appreciation to the Secretaría de Educación Pública (SEP) of Mexico for the financing of the project of the research group "UCOL-CA-102 Educación Matemática" within the program PRODEP 2017. We are also grateful to the authorities, teacher, and students of the participating school for their collaboration.

DE ESTRATEGIAS DE CÓMPUTO HACIA UN PENSAMIENTO DE TIPO RELACIONAL BASADO EN UN SENTIDO DE ESTRUCTURA

Este reporte muestra evidencia de cómo alumnos de primaria, de una escuela pública de México, transitan de un sentido operativo, manifestado en estrategias de cómputo en tareas de equivalencia, hacia un pensamiento de tipo relacional basados en cierto sentido de estructura y manifestado en la descomposición de números. Aunque los resultados son preliminares, estos muestran que los alumnos son capaces de desprenderse de estrategias de cómputo y desarrollar un razonamiento matemático más sofisticado en torno a la equivalencia de expresiones e

igualdades numéricas; sin embargo, la estrategia que desarrollan se sustentan en una "descomposición ad hoc de un lado y comparación con la forma inicial del otro lado de la igualdad", más que en la compensación.

USING NUMBER SEQUENCES TO MODEL MIDDLE-GRADES STUDENTS' ALGEBRIC REPRESENTATIONS OF MULTIPLICATIVE RELATIONSHIPS

Karen Zwanch
Oklahoma State University
karen.zwanch@okstate.edu

The number sequences describe a hierarchy of students' concepts of number. This research uses two defining cognitive structures of the number sequences—units coordination and the splitting operation—to model middle-grades students' abilities to write linear equations representing the multiplicative relationship between two unknowns. Results indicate that students who have constructed a tacitly nested number sequence (TNS), second in the hierarchy, do not represent multiplicative relationships algebraically. Students who have constructed an advanced tacitly nested number sequence (aTNS), third in the hierarchy, do so inconsistently, and students who have constructed an explicitly nested number sequence (ENS), fourth in the hierarchy, do so consistently. Coordinating three levels of units in activity advantages aTNS and ENS students, while splitting further advantages ENS students' algebraic reasoning.

Keywords: Algebra and Algebraic Thinking; Number Concepts and Operations

Literature Review

Algebra is persistently characterized as difficult for students to master (e.g., Kieran, 2007), and is a staple in school mathematics. Preceding a formal algebra course, algebra can be conceptualized as an extension of arithmetic. Russell, Schifter, and Bastable (2011), for example, conclude that arithmetic ideas such as understanding operations, generalizing and justifying, extending the number system, and using symbolic notation contribute to early algebraic reasoning. With these ideas in mind, algebraic reasoning is defined by Hackenberg (2013) as "generalizing and abstracting arithmetical and quantitative relationships, and systematically representing those generalizations in some way… [and] learning to reason with algebraic notation in lieu of quantities" (pp. 541–542).

In addition to defining algebraic reasoning, it is important to consider what concepts support algebraic reasoning. Students' concept of the equal sign is one such concept (Carpenter, Franke, & Levi, 2003; Matthews, Rittle-Johnson, McEldoon, & Taylor, 2012). Students can have two distinct notions of equality (Kieran, 1981): relational and operational. A relational concept indicates an understanding of the equal sign as indicating a balance, or equality of expressions on both sides of the equation. This is the more sophisticated of the two notions, but many children conceive of the equal sign operationally (Baroody & Ginsberg, 1983), indicating a conception of the equal sign as an operator. This is detrimental to students' ability to solve equations (Carpenter et al., 2003), and many mistakes in high school mathematics can be attributed to incorrect uses of the equal sign (Kieran, 1981). Furthermore, a relational concept of the equal sign compliments, rather than replaces, an operational concept (Matthews et al., 2012), implying that students who have constructed a relational concept may also apply an operational concept.

The present research study will examine the ability of middle-grades students to write linear equations representing the multiplicative relationship between two unknowns. Students' concept of the equal sign will be considered as it supports or limits their algebraic reasoning. Finally,

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

cognitive structures that define students' number sequences (Steffe & Cobb, 1988) will be used to model students' algebraic reasoning.

Theoretical Framework

The number sequences (Steffe & Cobb, 1988) were originally developed in research with elementary students, and described a hierarchy of four concepts of number: the initial number sequence (INS), the tacitly nested number sequence (TNS), the explicitly nested number sequence (ENS), and the generalized number sequence (GNS). Ulrich (2016b) subsequently identified a student who had constructed an advanced tacitly nested number sequence (aTNS), and Ulrich and Wilkins (2017) found 36% of sixth-grade students to be operating with only an aTNS. The aTNS falls in the number sequence trajectory between the TNS and the ENS (Ulrich, 2016b), making the trajectory of number sequences for middle-grades students INS, TNS, aTNS, ENS, GNS. The present research will focus on the algebraic reasoning of middle-grades students who have constructed an aTNS, and how their algebraic reasoning compares to that of students who have constructed a TNS and an ENS.

Units Coordination

The number sequences are defined by cognitive structures, such as units coordination and construction (Ulrich, 2015, 2016a). Figure 1 is a visual representation of the levels of units students can coordinate, organized by number sequence. Students with a TNS assimilate tasks with one level of units and can coordinate or construct a second level of units in activity (Figure 1, row 1). Thus, TNS students can immediately conceptualize a number such as seven as seven individual units of one. In mental activity, TNS students can chunk those seven individual units into a single composite unit containing seven individual units (Ulrich, 2015). A composite unit provides economy in reasoning because students must only maintain one unit of seven, rather than seven units of one. However, because the composite unit is constructed in activity, it decays following mental activity (Ulrich, 2015), leaving only seven units of one (i.e., the assimilatory structure) available for reflection.

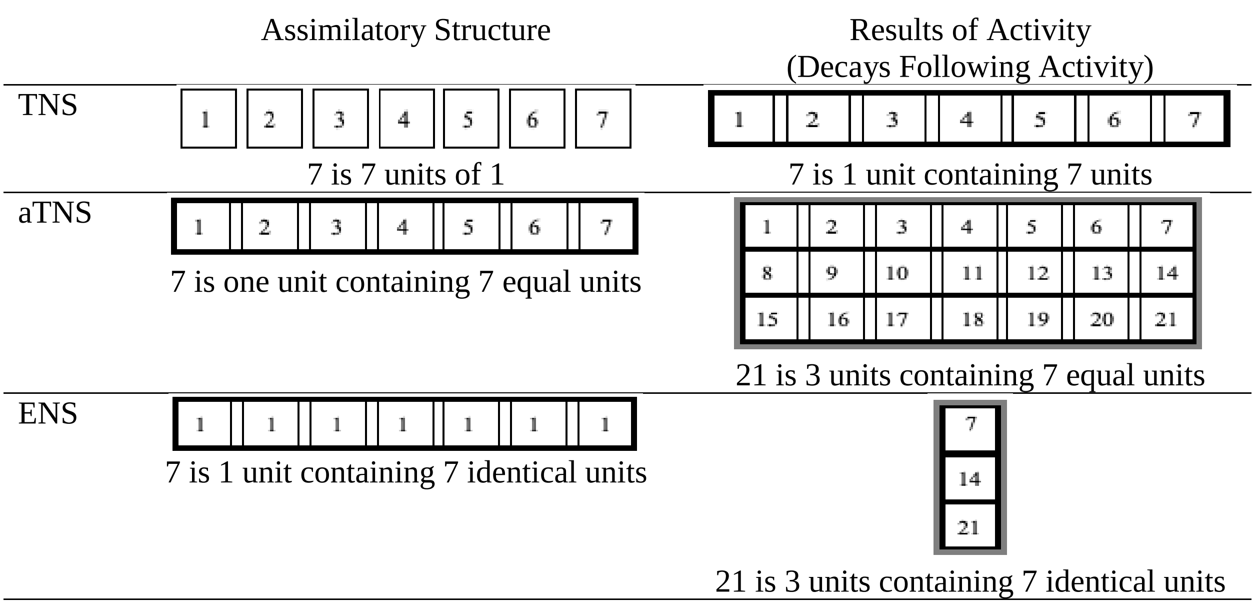

Figure 1: Depictions of 1-, 2-, and 3-levels of Units, Organized by Number Sequence

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

Students who have constructed the next number sequence, an aTNS, assimilate with two levels of units, or a composite unit, and construct a third level of units in activity (Ulrich, 2016b; Figure 1, row 2). aTNS students can conceptualize seven as a single composite unit containing seven units, and can operate on a composite unit to conceptualize a three-level unit structure in activity. This allows aTNS students to conceptualize 21, for instance, as three groups of seven. But, following activity, the third-level of units decays leaving aTNS students to reflect only on a composite unit.

Similar to aTNS students, ENS students assimilate tasks with a composite unit and construct a third-level of units in activity (Ulrich, 2016a; Figure 1, row 3). However, ENS students have also constructed an iterable unit of one and a disembedding operation (Steffe, 2010a; Ulrich, 2016a). These operations advantage their reasoning over aTNS students (Ulrich, 2016b) by supporting a conception of seven individual units of one as identical rather than equal (Steffe, 2010a). ENS students can reflect on the relationships between the units contained within the composite and the composite as a whole, without destroying either quantity (Steffe, 2010a). These operations support multiplicative reasoning because ENS students conceive of the composite unit as seven times the size of each individual unit (Ulrich, 2016a).

Splitting

A splitting operation can also be understood in terms of students' number sequences. The splitting operation, defined as simultaneously partitioning and iterating (Steffe, 2010b), is within the zone of potential construction (Norton & D'Ambrosio, 2008) of students who have constructed an ENS. That is to say, ENS students can learn to split; this is not true for TNS students (Ulrich, 2016b). aTNS students, on the other hand, have been found to *solve* splitting tasks, although Ulrich (2016b) concludes that they do so by *sequentially*, rather than simultaneously, partitioning and iterating. Accordingly, this research will examine how solving splitting tasks by sequentially partitioning and iterating advantages the algebraic reasoning of aTNS students over that of TNS students, and how the simultaneity of splitting advantages the algebraic reasoning of ENS students over aTNS students.

Algebraic Reasoning

Hackenberg et al. (Hackenberg, 2013; Hackenberg, Jones, Eker, & Creager, 2017; Hackenberg & Lee, 2015) use the multiplicative concepts to model students' algebraic reasoning. The multiplicative concepts are based on students' levels of units coordination (Hackenberg & Tillema, 2009). Students who assimilated with three levels of units demonstrated "swift" equation writing when representing the multiplicative relationship between two unknowns (Hackenberg & Lee, 2015, p. 219). On the other hand, students who assimilated with two levels of units demonstrated "effortful" equation writing, and even with considerable effort, only four out of six of these students were able to write a correct algebraic representation of the multiplicative relationship between two unknowns (Hackenberg & Lee, 2015, p. 214). Only two out of six students who assimilated with one level of units represented the relationship between two unknowns algebraically (Hackenberg, 2013). Hackenberg et al. (2017) find that an unknown quantity constitutes a composite unit. This directly ties students' abilities to operate on composite units to their algebraic reasoning, and can be used to explain, at least in part, the difficulty students may have in representing the multiplicative relationship between two unknowns algebraically. The implications of these findings are that students must have constructed an assimilatory composite unit in order to operate on unknown quantities, and that students who assimilate with composite units may or may not represent the multiplicative relationship between two unknowns algebraically.

Existing research uses students' multiplicative concepts to model their algebraic reasoning. The present study expands on existing literature by using the cognitive structures that define students' number sequences to model their algebraic reasoning. The number sequence framework allows this research to distinguish between the algebraic reasoning of two groups of students – aTNS and ENS – both of whom assimilate with composite units, but only one of whom (ENS students) reason multiplicatively and split.

Methods

This report draws from the qualitative results of a larger, mixed methods study. In phase one, 326 students in grades six through nine were given a survey (Ulrich & Wilkins, 2017), the purpose of which was to attribute to each student a number sequence. In phase two, students were selected to participate in qualitative interviews based on the results of the survey. In total, 18 students were interviewed across two days, for approximately 45 minutes each day. Interviews were audio and video recorded for retrospective analysis, and students' written work was collected. The interviews included confirmation of students' number sequence attribution from the survey, characterization of their concept of the equal sign as either operational or relational, and characterization of their algebraic reasoning on 11 tasks.

Results are from the responses of 16 participants who had constructed either a TNS, an aTNS, or an ENS (Table 1). Students were assigned pseudonyms that begin with the same letter as their number sequence attribution (e.g., Ann has constructed an aTNS). The focus of the analysis is on one of the algebra problems, the phone cords problem. Students were told: Steven's cord is five times the length of Rebecca's cord. Draw a picture to represent the two cord lengths, and use algebra to represent the relationship between the two cord lengths (Hackenberg, 2013). The first part of the problem, drawing a picture to represent the cord lengths, will be referred to as the splitting task. The splitting task was considered correct if students drew a picture in which one cord length was about five times the length of the other, and the student explained that Steven's cord was the longer. The algebraic portion of the problem was considered correct if students wrote an equation equivalent to $y = 5x$ and explained that y represented the length of Steven's cord and x represented the length of Rebecca's cord.

Table 1: Participants by Grade and Number Sequence

	6^{th} Grade	7^{th} Grade	8^{th} Grade	9^{th} Grade
TNS	Tabitha	--	--	Travis
aTNS	Ann	Ava	Amanda	Alex
	Aaron	Alyssa		
	Abby	Andy		
ENS	Elle	--	Erin	Elizabeth
	Evan		Emily	Emma

Results

Concept of the Equal Sign

Tabitha and Ann were determined to only reason with a relational concept of the equal sign. On a question that asked if the equation $37 + 29 - 5 = 48 + 14$ was true or false, they both responded false. Although their response was correct, their reasoning indicated that they conceive of the equal sign as an operator rather than a relation. For example, Tabitha said, "I added 37 plus 29 and I got 66. So I subtracted 66 by 5 and I got 61. And on here, it said that 37

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

plus 29 minus 5 equals 48 but actually it equals 61." Ann's response was similar. On the same question, all other students explained that the equation as false by calculating the value of each expression and indicating that they were not equal ($61 \neq 62$). This indicates a relational concept of the equal sign. Therefore, only an operational concept of the equal sign was attributed to Tabitha and Ann. A relational concept was attributed to all other students.

The Splitting Task

Neither TNS student solved the splitting task within the phone cords problem. Tabitha drew a seemingly arbitrary length to represent Steven's cord. She said, "Maybe this long?" but expressed no comprehension of a relationship between the lengths nor did the lengths have a 1:5 relationship. Travis, on the other hand, stated one correct numerical example for Steven's and Rebecca's cords, but did not generate any other correct numerical examples and did not generate a picture of the cords even at the interviewer's request. This is not surprising, given that TNS students have not been shown in previous research to split (Steffe, 2010b). Four aTNS students out of eight solved the splitting task, presumably by sequentially partitioning and iterating (Ulrich, 2016b). All ENS students solved the splitting task, which is again, not surprising, given that splitting is within the ZPC of ENS students (Steffe, 2010b).

The Phone Cords Problem

Neither TNS student solved the splitting task or represented the problem algebraically (Table 2). Both TNS students were prompted to use a numerical example to try to make sense of the relationship. Travis determined that if Rebecca's cord was five feet Steven's would be 25, but that was the extent of his progress on the problem. Tabitha did not generate multiplicatively related cord lengths. She indicated that if Rebecca's cord length was two then Steven's would be seven because, "I went up from two, and then I went up to five, and I counted. Like, 2; 3, 4, 5, 6, 7." When counting from two to seven, Tabitha raised two fingers on her left hand, and then raised one additional finger on her right hand each time that she uttered a number word. On the phone cords problem, Tabitha inappropriately applied additive reasoning to a numerical example of a multiplicative relationship.

Table 2: Number of Students by Number Sequence Who Solved the Splitting Task and Represented the Phone Cords Problem Algebraically

	Solution to the Splitting Task		
Algebraic Representation	Correct	Incorrect	Total
Correct	**7 Total**	**2 Total**	**9 Total**
	0 TNS	0 TNS	0 TNS
	1 aTNS	2 aTNS	3 aTNS
	6 ENS	0 ENS	6 ENS
Incorrect	**3 Total**	**4 Total**	**7 Total**
	0 TNS	2 TNS	2 TNS
	3 aTNS	2 aTNS	5 aTNS
	0 ENS	0 ENS	0 ENS
Total	**10 Total**	**6 Total**	**16**

Results of the ENS students will be presented next so that aTNS students' responses can be situated between those of TNS and ENS students. All six ENS students represented the phone cords problem algebraically by writing an equation equivalent to $y = 5x$, and explained the meaning of each variable (Table 2). Five of the six ENS students first wrote an incorrect equation, but used numerical examples to generate a correct equation. Elizabeth, for instance, first wrote two expressions: $5n$ and $n + 4$. She reasoned that if Rebecca's cord was three feet long then "his [Steven's] consists of, like, five little sections of that, then his would be fifteen feet long. So then five times three does equal 15… yeah, it [$5n$] works." In this excerpt, Elizabeth built on the numerical example $5 \cdot 3 = 15$ to determine the correct expression, and subsequently generated a correct equation $5n = S$.

Erin used a numerical example to decide between an equation ($5R = x$) and an inequality ($x + 5 > R$), despite being specifically asked to write an equation. She explained the inequality saying that "we don't know exactly how long they [the cords] are," so she used an inequality to indicate that Steven's (x) was longer. It was not until Erin worked through a numerical example that she determined the equation $5R = x$ was correct. Comparably, Emily used a numerical example to correct a reversal in her equation, and Evan began with a numerical example and then substituted variables for Steven's and Rebecca's cord lengths into the structure of that example.

aTNS students' solutions to the phone cords problem were inconsistent. Three aTNS students algebraically represented the phone cords problem, and there were two commonalities among these solutions. First, the successful aTNS students all began with numerical examples and substituted variables into the structures of those examples. Second, they all reverted to an operational concept of the equal sign, despite having demonstrated a relational concept earlier in the interview. Both behaviors can be observed in Alyssa's work. Alyssa initially wrote $x5 - y$.

> Alyssa: So Steven's would be *x* and Rebecca's would be *y*. And Steven's is 5 times as long as hers so you do this [multiply *x* by 5] and subtract hers [*y*] and you get the answer, I guess.
> Interviewer: OK. And what would the answer be?
> Alyssa: I don't know because there's no numbers. It just has 5.
> Interviewer: That's OK, but what would it, what would the answer represent? …
> Alyssa: The amount of cord that was timesed onto it. …
> Interviewer: So what if we say, for example, that Rebecca's cord is 3 feet long. …
> Alyssa: His would be 15, cause hers, his is 5 times as long as hers, so 3 times 5 is 15.
> Interviewer: Oh, very good. So if Rebecca's is 3 feet, Steven's is 15 feet. Does that work in our equation? …
> Alyssa: I don't think it would work with that equation [$x5 - y$] because you can't get these two [3 and 5] times each other. So it would probably be *x* equals 5 times 3. And then you would get 15 and that'd be his. … Yeah. *x* equals five times *y*.

It was not until Alyssa considered a numerical example that she rewrote her equation. Prior to that, she tried to multiply five by the length of Steven's cord, which she represented as $x5$ because the problem states that his cord is five times the length of Rebecca's. After determining numerically that Rebecca's cord should be multiplied by five, she was able to generate the equation "*x* equals five times three" and then "*x* equals five times *y*." The use of numerical examples was common among the three successful aTNS students.

The second behavior that can be observed in this excerpt is that Alyssa reasoned with an operational concept of the equal sign when she indicated that the result of $x5 - y$ is "the answer, I guess," and explained that you do not know the answer because *x* and *y* are not assigned numerical values. Alyssa was focused on finding a numerical result, and not on the equality of the expressions. Of the three successful aTNS students, all three reverted to an operational concept of the equal sign, as did Alyssa, at some point in their reasoning.

Interestingly, in Table 2 all TNS and ENS students are represented on the main diagonal—they either solved both portions of the phone cords problem (ENS students) or they did not (TNS students). The reasoning of aTNS students was less consistent. Three aTNS students represented the problem algebraically, and five did not. Of the three who correctly represented the problem algebraically, only one also solved the splitting task. Conversely, of the five aTNS students who did not represent the problem algebraically, three solved the splitting task. The five aTNS students who solved only one portion of the task are on the off-diagonal of Table 2; all students on the off-diagonal are aTNS students. Thus, despite both aTNS and ENS students assimilating with composite units, aTNS students were less successful and the results of the splitting task were disconnected from the algebraic representation.

Discussion

TNS students made very limited progress on the phone cords problem. Tabitha applied additive reasoning, Travis only generated one multiplicative numerical example, and neither student represented the relationship algebraically. All ENS students correctly represented the relationship algebraically. These results are comparable to those of Hackenberg et al., who found that four out of six students who assimilate with composite units (Hackenberg & Lee, 2015) and two out of six students who assimilate with one level of units (Hackenberg, 2013) represented the multiplicative relationship between two unknowns algebraically.

Also, five of the six ENS students interviewed used numerical examples to facilitate their equation writing. This is also consistent with Hackenberg et al.'s (2017) result that students who assimilate with composite units may build this type of equation using numerical examples. Therefore, an unknown quantity is assimilated by ENS students with a composite unit, in which Rebecca's cord length, for example, is a quantity containing an unknown number of units of one. This allows ENS students to operate on the unknown (i.e., the composite unit) in activity to form a three-level unit structure constituting the relationship between Steven's and Rebecca's cords.

Erin was the only ENS student who wrote an inequality to represent the relationship between the cords. This is similar to a student Hackenberg et al. (2017) identified, Tim, who like Erin, could assimilate with composite units. On a problem that is parallel to the phone cords problem, Tim insisted that a five times multiplicative relationship between two unknowns was "approximate" because "we don't know it [the exact lengths]" (Hackenberg et al., 2017, p. 46). Like Tim, Erin expressed a conception that while Steven's cord was longer than Rebecca's, the exact multiplicative relationship was unknown as long as the lengths were unknown. Consistent with Hackenberg et al.'s (2017) analysis, the use of an inequality to represent a multiplicative relationship between two unknowns can be explained as the manifestation of Erin's need to reduce the complexity of the unit structure on which she was operating.

aTNS students did not consistently solve the splitting task or the algebraic portion of the phone cords problem. Three aTNS students represented the problem algebraically, only one of whom solved the splitting task. Three aTNS students solved the splitting task but did not represent the problem algebraically. These results are evidence that although aTNS students may solve splitting tasks by sequentially partitioning and iterating, the sequential nature of that activity is not sufficient to support their algebraic representation of the resulting relationships. The sequential partitioning and iterating behavior of aTNS students is qualitatively distinct from the splitting in which ENS students are likely to engage. This provided ENS students with an advantage in their algebraic reasoning.

Both aTNS and ENS students used numerical examples to build an algebraic equation on the phone cords problem. However, ENS students tended to only work through one numerical example prior to writing a correct equation, while aTNS students tended to work through several. Also, whereas building an equation using numerical examples was a productive behavior for all five of the ENS students who took that approach, it was only productive for three out of eight aTNS students. Furthermore, all three aTNS students who represented the phone cords problem algebraically reverted to an operational concept of the equal sign at some point during their reasoning, despite demonstrating the ability to reason with a relational concept earlier in the interview. In contrast, no ENS students demonstrated reasoning consistent with an operational concept of the equal sign on the phone cords problem. Hackenberg and Lee (2015) conclude that students must assimilate with three levels of units, as would GNS students, before they are likely to represent multiplicative relationships between two unknowns without relying on numerical examples. This explains why all successful aTNS and ENS students, who only assimilate with composite units, relied on numerical examples to some extent. Additionally, this demonstrates a range of ways in which two groups of students who assimilate with composite units may rely on numerical examples to support their algebraic reasoning.

Conclusions

While both aTNS and ENS students assimilate with and operate on composite units, there are qualitative differences in their algebraic representations of multiplicative relationships between two unknowns. Consistent with the analysis of Hackenberg et al. (2017), both aTNS and ENS students are likely to have assimilated the phone cords problem with a composite unit consisting of Rebecca's cord, which contains an unknown number of units of one. Then, in activity, both aTNS and ENS students are assumed to operate on said composite unit to generate the relationship between Rebecca's and Steven's cord lengths; this facilitates their equation writing. Following activity, however, one level of units decays leaving both aTNS and ENS students to reflect only upon Rebecca's cord as a unit containing an unknown number of units of one.

For the three aTNS students who wrote the correct equation, the decay of Steven's cord from the unit structure resulted in their applying an operational concept of the equal sign. In other words, because the relationship between Steven's and Rebecca's cords was lost, the variable that had previously been representative of Steven's cord length was now simply "the answer." ENS students have the same limitation following activity; the third level of units decays and the relationship between the cord lengths is lost. In contrast to aTNS students, however, ENS students did not reason operationally about the equal sign. This is because ENS students are advantaged by the ability to reflect on the results of the splitting operation.

For ENS students, the results of splitting (i.e., Steven's cord being five times the length of Rebecca's) is maintained following activity. Therefore, despite the decay of the third level of units, the splitting operation allowed ENS students to maintain the relationship between Steven's and Rebecca's cords and reason normatively about their equation. In constrast, aTNS students presumably solve splitting tasks by sequentially partitioning and iterating, if they solve them at all, making the results of the splitting task unavailable for reflection following activity. As such, when the third level of units decayed following aTNS students' equation writing, they must recreate the results of the splitting task if they are to interpret the equation normatively.

Reverting to an operational concept of the equal sign has been noted in previous literature (Matthews et al., 2012), and this research provides a theoretical rationale for such a regression in the situation of writing an equation to represent the multiplicative relationship between two unknowns. aTNS students reverted to an operational concept of the equal sign to compensate for the inability to reflect on the results of the splitting task when the third level of units decayed. Therefore, although both aTNS and ENS students assimilate with and operate on composite units, the splitting operation advantaged ENS students' ability to represent the multiplicative relationships between two unknowns algebraically.

In this paper, we draw a distinction between two uses of inequalities, comparative and conditional inequalities, that emerged from our interactions with students. We highlight that despite reasoning quantitatively to make accurate statements with both types of inequalities, conventional notations for conditional inequalities were not sensible from the students' perspective. We describe a third notation we introduced which the students were able to understand and use in later teaching episodes.

Keywords: Using representations, Algebra and Algebraic Thinking

Inequalities are an important topic in both U.S. and international mathematics (Bergeron, 1995). Some researchers (e.g., Blanco & Garrote, 2007; Tsamir & Almog, 2001) have indicated students struggle with aspects of inequalities. Hence, there is a need to better understand ways to support students in developing more productive understandings of inequalities and inequality symbols. In order to examine the potential of supporting students developing understandings of inequalities via their reasoning about varying quantities, we conducted several small-group teaching experiments. The purpose of this paper is to draw a distinction between two distinct uses of inequalities, comparative and conditional inequalities, that emerged from our interactions with middle-grades students.

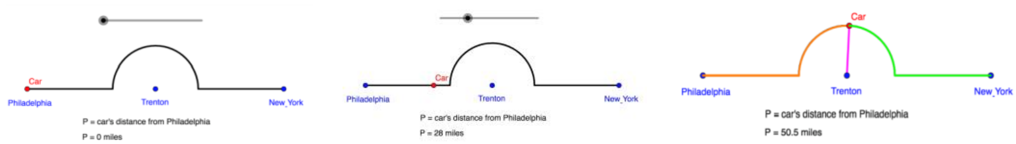
Theoretical Perspective: Mathematics of Students, and Quantitative Reasoning

We contend students' mathematics is fundamentally unknowable to us as teachers and researchers (Glasersfeld, 1995). Hence, when interacting with students, we attempt to build viable models of a *student's mathematics* that explain the student's observable words and actions. Steffe and Thompson (2000) noted, "Our practical stance is that the better we understand [student's mathematics], the better positioned we are to affect students productively…We strive to specify the mathematical concepts and operations of students and to make them the conceptual foundations of school mathematics" (p. 269). We interpret Steffe and Thompson to indicate researchers who build models of students developing productive meanings have the opportunity to support the evolution of school mathematics curricula so as to promote similar meanings for larger populations of students.

Several researchers (see Thompson and Carlson, 2017 for a review of the literature) have begun to explore ways in which students' quantitative reasoning (Thompson, 2011) can support their developing productive meanings for various mathematical ideas. Specifically, and as recommended by other researchers (Castillo, Johnson, & Moore, 2013; Johnson, 2015; Stevens et al., 2017), we asked students to construct and describe quantities changing in dynamic tasks in order to better understand the ways students may compare the relative magnitudes of their constructed quantities.

Two Uses of Inequalities: An Example and a Distinction

Consider a car traveling from Philadelphia to New York on a road that goes around Trenton (Figure 1a-b; this task is an adaptation of Going Around Gainesville as reported by Moore et al., 2018). A student may consider locations where the car's distance from Philadelphia (Figure 1c orange), which they define with the variable P, is greater than, less than, or equal to the car's distance from New York (Figure 1c green), which they define with the variable N (i.e., where $P < N$, $P > N$, and $P = N$). When a student reasons about two quantities' relative magnitudes or values to compare the two quantities, we refer to the student as reasoning about a *comparative inequality*.



(a) (b) (c)

Figure 1: (a-b) Two Instantiations of the Going Around Trenton Problem and (c) One with Distance from Philadelphia (Orange), Distance from Trenton (Pink), and Distance from New York (Green)

To further characterize the comparative inequalities, the student may use the values in the applet (bottom of Figure 1) to determine the car's distance from Philadelphia values such that $P < N$, $P > N$, and $P = N$. For example, the student may determine that for $P = 50.5$ miles, $P = N$; for 0 miles $\leq P < 50.5$ miles, $P < N$; and for 50.5 miles $< P \leq 101$ miles, $P > N$. When the student reasons about range of one quantity's magnitudes or values (e.g. $0 \leq P < 50.5$) such that a certain condition holds (e.g., $P < N$), we refer to the student as reasoning about a *conditional inequality*.

There are several differences between the two uses of inequalities. When reasoning about a comparative inequality, a student is considering a relationship between *two quantities* by comparing their relative magnitudes or values. In contrast, conditional inequalities require students to understand that some particular property is maintained for variations in *one quantity's magnitude or values*, thus necessitating images of variation.

Methods, Participants, and Analysis

To examine ways to support middle-grades students' (age 10-13) developing understandings of inequalities, we conducted a design study (Cobb, et al., 2003) consisting of five small-group (one to three students) teaching experiments (Steffe & Thompson, 2000). We chose to work with middle-grades students because we wanted to work with students who had not completed or yet taken Algebra I, and therefore did not have experience working with algebraic inequalities. To analyze the data, we used both on-going and retrospective analyses consistent with the teaching experiment methodology (Steffe & Thompson, 2000). For brevity's sake, we focus on the first pair of students we engaged in the study, Candice and Amber, as their activity prompted us to consider the two uses of inequalities during on-going analysis.

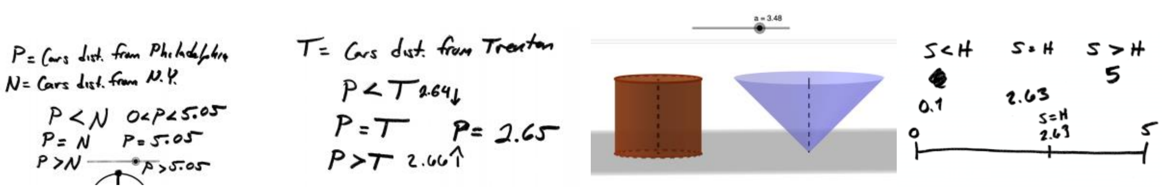
Results

We first describe Candice and Amber's initial activity addressing prompts about inequalities in the Going around Trenton Task (Figure 1). We then briefly present their activity from a later task in which the students were able to use a line segment to viably describe a situation using both comparative and conditional inequalities.

Reasoning about Quantities to Consider Comparative and Conditional Inequalities

Initially, the TR presented a dynamic applet of the Going around Trenton situation without *P*-values visible. When the TR asked the pair where the car's distances from Philadelphia and New York would be the same, Amber pointed to a location on the road directly above Trenton. Amber quickly noted that the car's distance from New York would be longer than its distance from Philadelphia prior to hitting the point directly above Trenton and the car's distance from New York would be shorter after it passed this point. We infer Amber was able to reason about the comparative inequalities involving the car's distances from Philadelphia and New York by comparing their relative magnitudes throughout the car's entire journey.

After the above interaction, the TR presented the applet showing values for the car's distance from Philadelphia (in this first iteration, the values varied from 0 to 10.1 without a specified unit). The TR then defined variables for the car's distance from Philadelphia (P) and the car's distance from New York (N) and wrote $P < N$. After a short interaction, both students understood this notation to represent the distance from Philadelphia was less than the distance from New York and identified this was true from the beginning of the trip until the car reached the point directly above Trenton. The students were then able to interpret the other statements ($P = N$, $P > N$) in terms of quantities' magnitudes (i.e. as comparative inequalities).



(a) (b) (c) (d)

Figure 2: (a) The TR Written Notations Representing Conditional Inequalities, (b) The Students' Invented Notation for Representing the Conditional Inequalities, (c) Screenshot from the Cone-Cylinder Problem, (d) The Students' Written Work for this Problem.

Immediately after this interaction, the TR intended to support the students in understanding a conventional way to represent the interval of values for which each statement was true. He wrote statements next to each of the comparative inequalities to represent the *P*-values such that the comparative inequality was true (seen in Figure 2a) while attempting to convey what he intended this notation to represent. However, both students expressed they did not understand why the TR had written $P > 5.05$ and he spent two minutes attempting to support the students understanding his intended meaning for the notation.

Inventing a Notation for Conditional Inequalities

We infer the students did not understand the conditional inequality statements the TR wrote based on their not leveraging this notation when tasked with a new prompt. When the TR asked them to determine the *P*-values such that the car's distance from Philadelphia (P) was less than, equal to, or greater than the car's distance from Trenton (T), the students first identified a location on the road, with $P = 2.65$, such that car's distances from Philadelphia and Trenton were equal. Then, Candice moved the car to the right, showing a P-value of 2.7, and both students indicated at this value the car's distance from Philadelphia was greater than its distance from Trenton. Indicative of each student understanding using the inequality symbols to compare two quantities magnitudes, the students simultaneously pointed to $P > T$ on the paper (Figure 2b) to represent this comparative inequality. After this Candice indicated this statement was true "for anything past two point six five." However, to represent this, she created a new notation, writing 2.66↑ (see Figure 2b). We infer that the students used their invented notation to represent conditional inequalities. Collectively, we infer the students were reasoning about both comparative and conditional inequalities as they reasoned about and compared different quantities in the situation. Further, the students understood the comparative inequality statements (e.g., $P < T$, $P > T$) in ways consistent with our intentions. However, they invented their own notation to represent conditional inequalities as they did not interpret these statements (e.g., $0 < P < 5.05$) in ways consistent with the TR's intentions.

Negotiating Conventions for a New Notation for Conditional Inequalities

The students' thinking steered us to notice underlying differences between these two types of inequality statements leading us to distinguish between comparative and conditional uses of inequalities. In the next session, we introduced a line segment with endpoints 0 and 101 to represent all possible values of the car's distance from Philadelphia. They were able to use this notation to describe quantities in the Going around Trenton task as well as two months later addressing the Cone/Cylinder Problem (Figure 2c). Specifically, they identified at a height value of 2.63, the two shapes had equal surface areas and, using the line segment notation (Figure 2d), discussed for which height values each shape's surface area was greater than the other.

Discussion

In this paper, we draw a distinction, based on our models of student's mathematics, between comparative and conditional uses of inequalities. Consistent with Steffe and Thompson's (2000) description of specifying "the mathematical concepts and operations of students and to make them the conceptual foundations of school mathematics" (p. 269), we conjecture this distinction has several implications for the teaching and learning of inequalities in school mathematics.

First, the students were able to reason quantitatively (Thompson, 2011) to characterize comparative and conditional inequalities. We conjecture having students engage in dynamic activities, which present changing quantities likely supported such reasoning. Second, we highlight that despite being able to accurately describe each type of inequality via quantitative reasoning, the students did not interpret statements we intended to represent conditional inequalities (e.g., $0 < P < 5.05$) in ways consistent with our intentions. However, when we introduced the line segment notation, similar to the number line notation sometimes used in school mathematics (Tsamir & Almog, 2001; McCabe, Sorto, White, Dover & Andreasen, 2010), the students were able to use this notation to describe intervals on which certain comparative inequalities were valid. This leads us to question introducing notations involving inequality symbols for conditional inequalities early in students' experiences. We concur with Thompson's (1995) recommendation regarding introducing notational conventions, "Separate what is new and conceptual from what is new and conventional, and teach for what is conceptual while postponing new conventions (especially those having to do with conventional notation)" (p. 202). Finally, we conjecture supporting students in becoming explicitly aware of these two uses of inequalities may support them in developing productive understandings of inequalities and call for more research exploring this possibility. For instance, we conjecture using different notations for comparative and conditional inequalities may support students to explicitly differentiate between the two types of inequalities and later more formal notations can be introduced when pedagogically appropriate for students.

CONFIDENT OR FAMILIAR? THE ROLE OF FAMILIARITY AND FRACTION ESTIMATION PRECISION ON METACOGNITION

Understanding fraction magnitudes is especially important for academic achievement, but fraction reasoning is difficult for children and adults. To accurately reason about fraction magnitudes, people may need to monitor what they know and what they do not know. However, little is known about fraction metacognition. In the current study, we examined trial-by-trial fraction estimates, confidence judgements, and ratings of fraction familiarity in adults. Adults' confidence was related to their estimation precision, suggesting accurate monitoring. However, adults judge their confidence in estimating fraction magnitudes, in part, based on their familiarity with each fraction. The role familiarity plays in judgments of confidence with fractions suggests that people may be less likely to check for errors or restudy when reasoning about highly-familiar fractions.

Keywords: Metacognition, Cognition, Rational Numbers, Number Concepts and Operations.

Across multiple countries, children's understanding of fraction magnitudes is predictive of their overall mathematics achievement, even when controlling for SES, working memory, IQ, and fraction arithmetic abilities (Siegler et al., 2012; Torbeyns, Schneider, Xin, & Siegler, 2015). However, compared to whole numbers, children and adults are less precise when estimating the magnitude of fractions (e.g., Siegler & Opfer, 2003; Siegler, Thompson, & Schneider, 2011). One source of difficulty in understanding fraction magnitudes is the *whole number bias*: when knowledge of whole number concepts interferes with fraction reasoning (Ni & Zhou, 2005). For example, children tend to estimate fractions with larger components (e.g., 15/30) as larger than equivalent fractions with smaller components (e.g., 1/2; Braithwaite & Siegler, 2017). The difficulties children face while learning and problem solving with fractions may result, in part, from the limited set of fractions they encounter in textbooks (Braithwaite & Siegler, 2018). For example, computational models make errors similar to those of children when they receive fractions from common textbooks as input (Braithwaite, Pyke, & Siegler, 2017). This limited early environmental input during learning may contribute to the pervasive errors that even adults make on fraction tasks (Opfer & Devries, 2008; Sidney, Thalluri, Buerke, & Thompson, 2018). It remains an open question whether adults are *aware* of whole number bias when reasoning about fraction magnitudes. In other words, are adults able to metacognitively monitor their fraction performance?

Awareness of performance via self-monitoring is important for academic achievement because monitoring influences control of study behaviors (e.g., Dunlosky & Rawson, 2012; Metcalfe, 2009). For example, learners may be more likely to notice and correct errors when reasoning about fraction magnitudes if they can monitor their understanding that fractions with larger components do not always have larger magnitudes than fractions with smaller components (e.g., 15/30 is not > 1/2 even though 15 > 1 and 30 > 2). As this example illustrates, monitoring may be especially important for learning difficult fraction concepts, a domain in which learners often automatically misapply familiar whole number concepts (Siegler et al., 2011), and may need to inhibit this prior knowledge (Siegler & Pyke, 2013).

One way that people can monitor their mathematics performance is through judgments of confidence in their responses (e.g., Bjork, Dunlosky, & Kornell, 2012; Wall et al., 2016). Sometimes people can be *overconfident* (high confidence despite low performance) or *underconfident* (low confidence despite high performance), both of which can undermine achievement (e.g., Dunlosky & Metcalfe, 2008). Thus, assessing students' confidence when reasoning about fractions provides insights into how they monitor their understanding.

Ideally, only a student's ability to generate an accurate answer would affect their confidence, however, familiarity may also influence confidence judgments. For example, in one study of children's whole number magnitude estimation (Wall et al., 2016), most children were more confident and precise in their estimates within smaller, more familiar numerical ranges (e.g., 0 – 100) than larger, unfamiliar numerical ranges (e.g., 0 – 1,000). However, some children's confidence was less well-aligned: they were more confident in their small-range estimates even when they were equally precise in smaller and larger ranges. Others were more confident in the smaller range even when their estimates in this range were *less* precise. Overall, students may feel more confident with smaller numbers due to familiarity with the 0 – 100 range because smaller numbers are encountered more frequently within the environment than larger numbers (Dehaene & Mehler, 1992). Similarly, some fractions may be more frequently encountered in the environment than others (see Braithwaite & Siegler, 2018). Therefore, even adults may be more confident when estimating familiar fractions that occur more frequently in the environment, regardless of their actual ability to precisely estimate.

In the current study, we examined adults' confidence, familiarity, and number line estimation precision for equivalent fractions with smaller (e.g., 1/2) and larger components (e.g., 15/30). We manipulated the size of components because fractions with large components occur less frequently in math textbooks (Braithwaite & Siegler, 2018), components affect how people process fraction magnitudes (i.e., whole number bias; Ni & Zhou, 2005), and little is known about the impact components have on familiarity and confidence. **Thus, we hypothesized that adults would be more precise, confident, and familiar with fractions that have smaller components compared to those with larger components.** We also examined whether confidence during fraction estimation had a stronger relationship to familiarity than to estimation precision. Relying on one's familiarity with fractions might result in real-world educational implications such as mis-allotting study time and failing to detect errors in one's fraction performance.

Method

Participants

A total of 91 community-based adult participants (34 females) met pre-registered inclusion criteria as part of a larger study. Participants (72.5% White) were recruited from Amazon's Mechanical Turk; most had a college degree (45.1%) or completed some college (24.2%). This sample is appropriate for investigating questions about adults' metacognitive awareness in the domain of mathematics because adults use fraction concepts in their daily life at work (Handel, 2016) and when making health decisions (Lipkus & Peters, 2010).

Tasks and Procedure

Participants completed all tasks within an online Qualtrics survey. On each number line estimation trial, participants estimated the location of a fraction and then rated their confidence.

Participants were also randomly assigned to complete number line estimates either under a time constraint or not. We control for time constraint condition in our models, but the effects of condition were not central to the current hypotheses and did not have a meaningful impact on results. After estimating fractions on number lines, participants completed four additional tasks: fraction comparison, fraction equivalence, numerical inhibition, and digit updating span. As with the time constraint manipulation, these tasks were part of a larger data collection on fraction understanding and will not be discussed further. At the end of the experiment, participants rated their familiarity with each of the fractions presented during the estimation task.

Number line estimation. Participants estimated the location of 44 fractions on a 0 to 1 number line, one at a time, by clicking or dragging a slider. The 44 fractions consisted of 11 different magnitudes within the 0-1 numerical range. Each magnitude was represented by four different equivalent fractions that had smaller (e.g., 1/2 or 2/4) or larger (e.g., 12/24 or 15/30) components. We calculated the absolute difference between the provided estimate and actual fraction magnitude and multiplied these values by 100 to transform them into percent absolute error (PAE; see Siegler & Booth, 2004).

Confidence judgments. Immediately after each number line estimation trial, participants rated their confidence on a four-point scale ranging from "not so sure" to "totally sure" (Wall, Thompson, & Morris, 2015).

Familiarity judgments. Participants rated their fraction familiarity on a six-point scale from "not familiar at all" to "very familiar" for each of the 44 fractions that they had previously estimated. Participants made judgments with all fractions presented on the screen at once at the end of the experiment after all other tasks were completed.

Results

Number Line Precision, Confidence, and Familiarity

We evaluated estimation precision by calculating participants' percentage of absolute error (PAE) for each number line estimate, then averaged across all estimates as well as estimates of small component and large component fractions, separately. As can be seen in Table 1, participants were more precise, confident, and familiar with fractions that had smaller components relative to fractions with larger components.

Table 1: Precision, Confidence, and Familiarity for Small and Large Component Fractions

	Small Component (SD)	Large Component (SD)	F-Statistic	η_p^2
Percent Absolute Error	8.15% (8.14%)	9.26% (8.05%)	10.79 **	.108
Confidence Judgments	2.92 (.60)	2.75 (.66)	59.938 **	.402
Familiarity Ratings	4.45 (.90)	3.75 (1.30)	113.32 **	.560

*Note: Percent Absolute Error is inversely related to estimation precision. ** p < .01.*

To further examine adults' ability to monitor their estimation precision, we calculated a gamma correlation for each participant. Gamma is a commonly used measure for assessing trial-to-trial monitoring abilities, and it accounts for the ordinal nature of confidence judgments (Nelson, 1984; Wall et al., 2016). We report inverse values of gamma because lower values of PAE indicate more precise estimates. Participants rated their confidence higher on estimates that were more precise, $M_{\text{gamma}} = .34$, $t(90) = 12.88$, $p < .001$, indicating adults were able to monitor their trial-to-trial estimation performance.

Role of Familiarity in Confidence Judgments

To examine the role of familiarity in confidence judgments, we calculated a gamma correlation between familiarity and confidence judgments for each participant. Participants rated their confidence higher when they were more familiar with the fractions, $M_{gamma} = .51$, $t(88) = 12.64$, $p < .001$.

Of central interest, we compared whether confidence was more strongly related to estimation precision or familiarity by comparing gammas between the confidence-PAE relationship to the confidence-familiarity relationship. Confidence was more strongly related to familiarity ($M_{\text{gamma}} = .51$, $SD = .38$) than to PAE ($M_{\text{gamma}} = .34$, $SD = .24$), $F(1, 87) = 18.07$, $p < .001$, $\eta_p^2 = .17$.

We further examined the role of familiarity in confidence judgments by regressing mean ratings of confidence onto overall PAE and condition. Although PAE (which is inversely related to precision) significantly predicted confidence judgements, $\beta = -0.50$, $t(88) = 5.49$, $p < .001$, adding familiarity in the second block of the model explained an additional 11.4% of the variance in confidence judgments, $F(1, 87) = 16.70$, $p < .001$. Thus, familiarity ratings explained variance in confidence judgements above that explained by adults' estimation precision.

Discussion

We examined adults' ability to monitor their number line estimation performance while estimating equivalent fractions with smaller and larger components. Adults demonstrated whole number bias errors when they were less accurate in their estimates of fractions with larger compared to smaller components. However, they were likely aware of these errors, because their confidence was also lower when estimating large component fractions. Although adults were able to monitor their estimation performance, confidence was more strongly related to familiarity ratings than to PAE, even though adults rated their confidence, but not familiarity, immediately after making each estimate. Fortunately, all three aspects of fraction reasoning--confidence, familiarity, and PAE--were strongly related. One limitation is that participants may have interpreted our measure of familiarity as a broad measure of their confidence. For example, participants might rate how familiar they are with each fraction based on how well they just performed on the estimation task, rather than how often they had encountered the fraction prior to the experiment. Future work should aim to distinguish familiarity and confidence and measure familiarity prior to completing any fraction tasks.

These findings have implications for mathematics education. Adults in our sample tended to be precise when estimating fractions they rated as familiar. The role of familiarity in confidence may be especially pronounced for adults who are less precise when estimating magnitudes, or for children who are just beginning to formally learn about fractions. This presents an opportunity for *growth* in future research on the role of metacognition in mathematics, but it remains to be explored whether familiarity and confidence may work *against* children and adults from lower SES backgrounds who may be less exposed to environmental input about fractions (cf. Siegler & Ramani, 2008 and Ramani & Siegler, 2008 for evidence of variability in environmental input for whole numbers across Head Start and middle income families).

Our results suggest that when adults are presented with highly familiar math content, they will be more confident in their performance. This higher confidence may, in turn, reduce the likelihood that (1) they will allot additional study time to master familiar, yet difficult course content, or (2) they will check for errors when familiar numbers are used in important decision-making scenarios in everyday life (e.g., financial or health decisions). This research is a first step towards a more comprehensive account of how familiarity and confidence with math is related to students' learning and success.

CHILDREN'S ERRORS ON A REPEATING PATTERN TASK AND THEIR ASSOCIATIONS WITH FORMAL NUMERACY KNOWLEDGE

Emily R. Fyfe
Indiana University
efyfe@indiana.edu

Alicia Macchione
Indiana University
almacchi@iu.edu

We sought to provide insight into children's early patterning skills by examining children's errors when creating repeating patterns and how these errors relate to performance on a variety of number tasks. Children (N = 31, ages 4 to 6) completed several pattern abstraction tasks (e.g., recreate this model pattern using different objects) and several early math tasks assessing numeracy knowledge (e.g., count 15 pennies, add 3 candies to 2 candies). Children exhibited moderate performance on the pattern task, and committed six different types of errors. Further, some, but not all, of the errors on the pattern task were related to children's numeracy knowledge, even after controlling for age. Results provide insight into children's knowledge of repeating patterns and how it relates to their performance on critical number tasks.

Keywords: Algebra and Algebraic Thinking; Problem Solving; Number Concepts and Operations

Objectives and Theoretical Framework

Patterning is viewed as a central component of mathematical thinking (e.g., Charles, 2005). The Early Math Trajectories theory includes patterning as a foundational skill in preschool that provides opportunities to deduce rules and structure, which then supports formal numeracy knowledge (Rittle-Johnson, Fyfe, Hofer, & Farran, 2017). Empirical evidence supports this. For example, an intervention that focused on basic repeating patterns for 3- to 5-year-olds led to greater numeracy knowledge a year later relative to typical preschool instruction (Papic, Mulligan, & Mitchelmore, 2011). Also, longitudinal evidence shows that knowledge of patterns at age 5 predicts performance on a standardized math test at age 11 (Rittle-Johnson et al., 2017).

To provide greater insight into this association, we examined children's errors when creating patterns and how these errors related to numeracy knowledge. A previous study documented four-year-olds' errors on several repeating pattern tasks (Rittle-Johnson, Fyfe, McLean, & McEldoon, 2013). In that work, common errors included creating a pattern with a different structure than a model pattern (e.g., seeing an ABB-ABB pattern, but creating an AB-AB-AB pattern), and placing objects in a random order (e.g., seeing an ABB-ABB pattern, but creating an ABBCBACAACC sequence). However, this work was limited to four-year-olds and did not include any measures of numeracy knowledge. Here, we focus on children's patterning skills between the ages of four and six and include three types of numeracy tasks. Based on the Early Math Trajectories theory, which suggests that attention to the rules and structure of the pattern is key, we hypothesized that errors that contained *no* discernible structure (e.g., random order) would negatively relate to children's numeracy knowledge.

Method

Participants

Thirty-one children ranging from 4 to 6 years old (*M* = 5.2 years, *SD* = 0.7) participated in one-on-one sessions in a quiet laboratory space at Indiana University. Children were from the local community and approximately 59% were female and 90% were White.

Measures

During a one-on-one session with a trained tutor, children completed a seven-item measure of patterning skill and a 15-item measure of number knowledge. These are described below.

Pattern Abstraction. Children solved 7 pattern abstraction items by looking at a model pattern and then recreating the same kind of pattern using different materials (see Figure 1).

Figure 1: Example Pattern Task and Materials

The model patterns were repeating patterns made of black circles and squares with two units of repeat (e.g., ABB-ABB, ABC-ABC). Children were given brightly colored shapes to make their pattern. The tutor demonstrated the task on three examples. Further, on each of the 7 target problems, the tutor first explained the model pattern before having the child try to recreate it. Children's patterns were counted as correct if their pattern contained the same structure as the model (e.g., using heart-leaf-heart to represent circle-square-circle). We also coded the errors children made (see Table 1). Interrater agreement on error type was high (kappa = .92).

Table 1: Coding Scheme Used to Identify Children's Errors on the Pattern Task

Error Type	Example Response with an ABB-ABB Model Pattern	Frequency of Use		
		age 4	age 5-6	total
No Error	ABB-ABB recreates structure of model pattern	23%	56%	43%
Partial Correct	ABB-ABC recreates some structure of model pattern, but contains errors	5%	3%	4%
Wrong Pattern AB	AB-AB-AB creates an AB structure	29%	19%	23%
Wrong Pattern Other	ABC-ABC creates a structure that is not the model structure or AB	6%	10%	8%
Duplicating	[places stars in a circle to look like the circle in the model] duplicates the literal shapes in the model pattern	15%	0%	6%
Random Order	ABACBCCCAAAB produces a random sequence of shapes with no structure	15%	12%	13%
Off Task	[places shapes in flower arrangement] uses shapes in a way that is seemingly unrelated to the task	7%	0%	3%

Numeracy Knowledge. Children solved 15 number tasks using items adapted from the Research-Based Early Mathematics Assessment (Clements, Sarama, & Liu, 2008). Three items tapped their counting knowledge (e.g., count 15 pennies), six items tapped their magnitude knowledge (e.g., which is bigger: 3 grapes vs. 4 grapes, which is closer to 6: 9 or 4), and six items tapped their arithmetic knowledge (e.g., 3 candies plus 2 candies, add 10 to 48). Children received a total score out of 15 based on their correct selections and exact numerical responses.

Results

Children did moderately well across the seven pattern items. The average percent correct was 43% (*SD* = 40%, range = 0-100%). When children solved the problems incorrectly, they were making one of six different types of errors, three of which included some structure and three of which did not. The most common error was to produce a pattern with an AB structure rather than the structure of the model pattern. This accounted for 23% of all trials and 40% of all errors. The next most common error was to produce a random sequence of shapes, which accounted for 13% of all trials and 23% of all errors. See Table 1 for a full list of error types. Compared to younger children (age 4), older children (ages 5 to 6) were more likely to make no errors, and less likely to commit the Wrong-Pattern-AB, Duplicating, and Off-Task errors.

Children also did moderately well on the number tasks. Across all 15 problems, the average percent correct was 60% (*SD* = 24%, range = 13-100%). Performance was higher on the items that tapped counting knowledge (*M* = 75%, *SD* = 34%) and magnitude knowledge (*M* = 77%, *SD* =23%) than on items that tapped arithmetic knowledge (*M* = 34%, *SD* = 29%). There were large age differences, with older children (ages 5 to 6) scoring higher across all items (*M* = 71%, *SD* = 19%) than younger children (age 4; *M* = 41%, *SD* = 18%), $t(29) = 4.39$, $p < .001$.

Of interest was the relation between children's pattern skill and their formal number knowledge. First, we ran a linear regression model predicting children's numeracy knowledge from their patterning score and their age. With just these two factors, the model accounted for 58% of the variance in numeracy knowledge. Percent correct on the patterning task significantly predicted percent correct on the number tasks, *ß* = .32, *p* = .03, even after controlling for age. The effect of the patterning task was somewhat stronger for predicting counting knowledge (*ß* = .45) than for magnitude knowledge (*ß* = .18) or arithmetic knowledge (*ß* = .25). Second, we ran a linear regression model predicting children's numeracy knowledge from the frequency of each of the six error types, controlling for age. The model accounted for 70% of the variance in numeracy knowledge, and two error types emerged as significant predictors. The frequency of committing the Duplicate error was negatively related to children's percent correct on the number task, *ß* = –.37, *p* = .01, as was the frequency of committing the Random Order error (*ß* = –.39, *p* = .01). Similar results were found when we compared children who made a specific error at least once to children who never made that error (see Figure 2). Children who committed the Duplicate or Random Order errors had lower numeracy scores than children who never did.

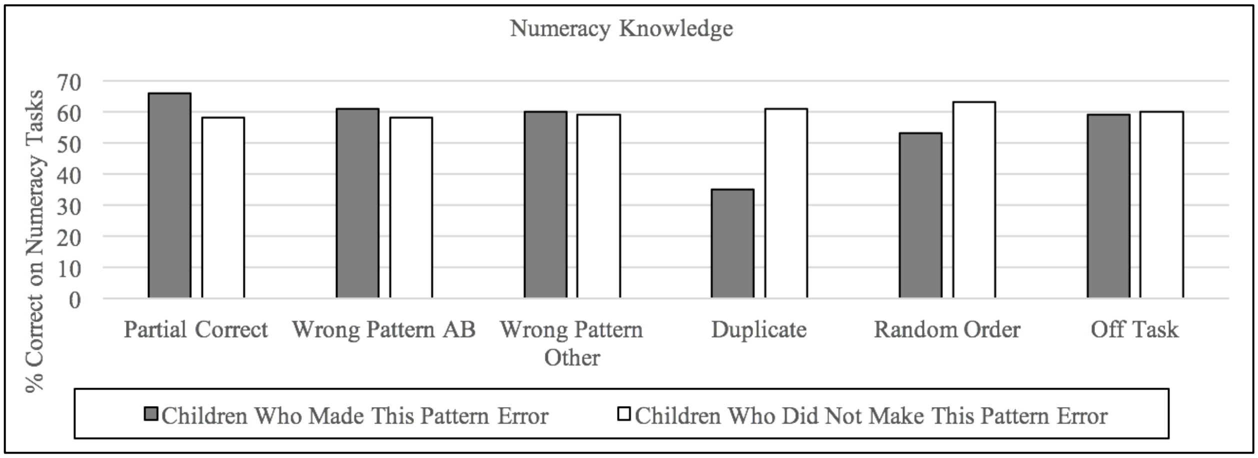

Figure 2: Numeracy Knowledge as a Function of the Pattern Errors Children Commit

Conclusion

We examined children's errors on a repeating pattern task and how these errors related to children's numeracy knowledge. Children made six different errors when trying to recreate a model pattern. Consistent with previous research (Rittle-Johnson et al., 2013), common errors included creating a simpler AB-pattern and creating a random sequence of objects. We also found that the frequency of certain error types decreased with age as patterning skill improved. Importantly, three of the six error types indicated that children's responses contained some rule or structure, and three of them indicated that children's responses did not contain any discernible structure. Consistent with our predictions, two of the three errors with no discernible structure (Duplicate and Random Order) were negatively related to children's numeracy knowledge. The three errors with some structure were not related to children's numeracy knowledge.

These findings contribute to a growing body of research investigating the associations between children's early patterning skills and their formal mathematics knowledge (e.g., Kidd et al., 2013; Kidd et al., 2014; Papic et al., 2011; Rittle-Johnson et al., 2017, see also Burgoyne et al., 2017 for a review). Consistent with this research, we found that higher performance on a pattern abstraction task was associated with higher performance on counting, magnitude, and arithmetic tasks, even after controlling for the effects of age. However, the specific type of errors that children committed also seemed to matter. Attending to the specific structure of the model pattern is important, but just noticing that there is *any* structure may be important as well. This seems consistent with the Early Math Trajectories theory, which suggests that one possible benefit of working with patterns is the opportunity to notice that certain things follow rules and have a certain structure (Rittle-Johnson et al., 2017). Indeed, many numeracy tasks require the ability to detect rules and regularities (e.g., base ten structure, the count sequence, etc.). Our error analysis provides a more fine-tuned measure of children's ability to attend to structure, which may have implications for the development of their foundational numeracy knowledge.

Given that patterning is considered a "Big Idea" in mathematics (Charles, 2005) and that mathematics has been defined as the "science of patterns" (Steen, 1988), this research on early patterning skills and errors may have implications for mathematics education more broadly.

THE RELATIONSHIP BETWEEN ANALOGICAL REASONING AND SECOND-GRADERS' STRUCTURAL KNOWLEDGE OF NUMBER

Helena P. Osana
Concordia University
helena.osana@concordia.ca

Anne Lafay
Concordia University
anne.lafay@concordia.ca

The aim of the present study was to investigate whether analogical reasoning is predictive of children's structural knowledge of number. A group of 94 second-graders were assessed on their conceptual knowledge of place value and tested on their counting skill, arithmetic fluency, and analogical reasoning. Results showed that the most important predictor of place value knowledge was analogical reasoning after accounting for counting skill and arithmetic fluency. Furthermore, children who were classified as Structural-knowers were more proficient in analogical reasoning than children who viewed numbers on their face value. The results suggest that a structural understanding of number is not only dependent on domain-specific skills, but also on domain-general abilities, including analogical reasoning.

Keywords: Analogical reasoning, Structural knowledge of number, Place value

Understanding in mathematics has been conceptualized as facility with the conceptual structure of a domain (Mason et al., 2009; Richland et al., 2012). One goal of mathematics instruction with young children is to help them acquire a conceptual understanding of number (Mulligan & Mitchelmore, 2009). The decimal numeration system is governed by a multiplicative structure where 10 units in one denomination are grouped, or "bundled," into one unit of the next larger denomination (Ellemor-Collins & Wright, 2009). Knowledge of number structure allows children to use place value concepts to invent meaningful algorithms and develop mental computation skills (Carpenter et al., 1998; Kindrat & Osana, 2018).

Our research focuses on the cognitive processes that are predictive of children's structural knowledge of number and the instructional factors that support such knowledge. We adopted analogical reasoning as a theoretical framework for children's acquisition of number knowledge (English, 2004; Richland, 2011). Analogical reasoning is a cognitive process by which conceptual similarities in two contexts are identified and compared through "structure mapping" (Gentner & Colhoun, 2010). Conceptual understanding can be developed through structure mapping because of the attention to the structural relations between two contexts, such as a written numeral and a pictorial representation of its denominations (English, 2004; Vendetti et al., 2015). In fact, interventions based on instructional analogies have been shown to enhance students' understanding in a number of domains, including fraction division (Sidney & Alibali, 2015), proportionality (Richland & McDonough, 2010), and place value (Mix et al., 2017).

Present Study

The objective of the present study was to test the hypothesis that analogical reasoning is predictive of students' structural knowledge of number after controlling for counting skill and arithmetic fluency, two factors that are known to impact mathematics performance (Geary, 2011; Koponen et al., 2016). The data were part of a larger project investigating the physical affordances of concrete manipulatives on second-graders' numeration knowledge. Outcome measures assessed place-value understanding and number decomposition, administered before and after an instructional intervention with manipulatives. Tests of counting skill, arithmetic fluency, and analogical reasoning were administered at pretest. In the present study, we use pretest data on one specific measure of place value, the PicPVT, and examine the extent to which analogical reasoning is predictive of performance on this measure.

Method

Participants

Participants were 94 second-grade children (50 boys; age: M = 92.3 months, SD = 4.8) from 12 schools in a large, urban area in Canada.

Measures

Place value knowledge. The Picture Place Value Task (PicPVT; Kamawar et al., 2010; Osana & Blondin, 2017) was used to assess whether children understand that a digit in a numeral represents a quantity that is determined by its position. Children were presented with a written numeral with one digit underlined (either the units, tens, or hundreds digit) on a screen. A pictorial representation (i.e., sets of dots) was given below the numeral. By responding "yes" or "no," children indicated to the researcher whether the pictorial representation correctly represented the value of the underlined digit. Of the 20 items, 10 "correct display" items required a positive response from the child (Figure 1a) and 10 "incorrect display" items required a negative response (Figure 1b).

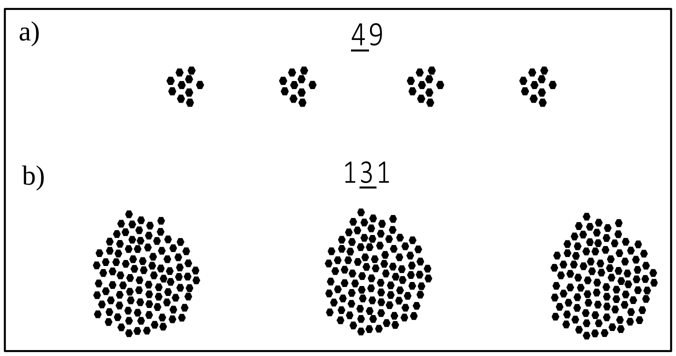

Figure 1: Sample Items on the PicPVT. Panel (a) Shows a Correct Display Item Requiring a Positive Response. Panel (b) Shows an Incorrect Display Item Requiring a Negative Response

Mathematical skills and analogical reasoning. Counting skill was assessed using the Counting and Enumeration task (CE), which required the children to count as high as possible, to skip count by 10 and 100, and to count the number of chips in a collection of 20. Arithmetic fluency was assessed using the Tempo Test Rekenen (TTR, De Vos, 1992), a timed test of mental computation in addition and subtraction. Finally, analogical reasoning was measured using the Raven's Standard Progressive Matrices (Raven et al., 1977). Children chose one picture among four that completed the missing part of a bigger pattern. On all measures, correct responses were assigned 1 point and incorrect responses 0 points.

Results

Descriptive Statistics

The means and standard deviations for all four measures are presented in Table 1 and the zero-order corrections are in Table 2.

Table 1: Means and Standard Deviations for Place Value, Mathematical Skill, and Analogical Reasoning Percent Scores

Measure	*M*	*SD*
PicPVT	.83	.19
Counting and Enumeration (CE)	.75	.19
Arithmetic Fluency (TTR)	.27	.08
Analogical Reasoning (Raven)	.74	.13

Table 2: Zero-order Correlations Between Place Value, Mathematical Skill, and Analogical Reasoning Variables

Measure	1	2	3	4
PicPVT	--	.29**	.25*	.37**
Counting and Enumeration (CE)		--	.33**	.16
Arithmetic Fluency (TTR)			--	.34**
Analogical Reasoning (Raven)				--

*p<.05, **p<.01

Predictors of Place Value Knowledge

We conducted a hierarchical multiple regression to test the relationship between place value knowledge and analogical reasoning. The criterion was PicPVT score. The first two predictors, counting skill and arithmetic fluency, were entered in the first and second steps in the analysis, and were entered together because they were similarly correlated with place value knowledge. In the third step, analogical reasoning was entered separately to allow for an independent assessment of the variance explained by analogical reasoning. The regression statistics are reported in Table 3.

Table 3: Summary of Hierarchical Regression Analysis for Variables Predicting Place Value Knowledge

Variable	R	R^2	R^2 change	Final β	*t*
Step 1	.33	.11	.11		
Counting and Enumeration (CE)				.24	2.24*
Arithmetic Fluency (TTR)				.16	1.52
Step 2	.44	.19	.08		
Counting and Enumeration				.22	2.15*
Arithmetic Fluency (TTR)				.07	0.64
Analogical Reasoning (Raven)				.30	3.01**

*p<.05, **p<.01

At Step 1, the model explained a significant 10.7% of the variance in place value knowledge, $F(2, 90) = 5.37$, $p < .01$. Introducing analogical reasoning in the model at Step 2 explained an additional 8.3% of the variance in place value knowledge, and this change was significant, $F(1, 89) = 9.07$, $p < .01$. Together, the three predictors in the model explained 19% of the variance in place value knowledge. In the final model, arithmetic fluency was not related to place value knowledge. The most important predictor was analogical reasoning, $\boldsymbol{\beta} = .30$, $t(89)=3.01$, $p < .01$.

In a second analysis, we created profiles of place value knowledge by identifying patterns of responses on the correct display and incorrect display items on the PicPVT. Children who correctly answered more than five incorrect display items and more than five correct display items were placed in the Structural Knowledge (SK) profile ($n = 74$). Children in the SK profile understood that a digit represents a quantity depending on its position in a numeral. Children who correctly answered fewer than 4 incorrect display items and more than 5 correct display items likely counted the number of groups, regardless of the number in each group. We argue that these children held a "concatenated digits" view of number (Bergeron & Herscovics, 1990), seeing numerals at their "face value" (Barnett-Clarke et al., 2010). We placed these children in a Face Value (FV) profile ($n = 16$). Finally, four children displayed no discernable patterns of responses and were likely guessing. We removed these four from the analysis.

A one-way ANCOVA was performed with profile as the independent measure (SK, FV) and analogical reasoning as the dependent measure. Counting skill and arithmetic fluency were entered as covariates. A significant effect of profile was found, $F(1, 85) = 198.32$, $p < .001$, partial $\eta^2 = .7$, with higher analogical reasoning scores in the SK profile ($M = .91$, $SD = .10$) than in the FV profile ($M = .53$, $SD = .08$).

Discussion

The findings suggest that analogical reasoning is predictive of children's number knowledge, even when accounting for counting and arithmetic skills. This suggests that a structural understanding of number is not only dependent on domain-specific skills, such counting skill and prior mathematical knowledge (Fyfe et al., 2012; Zhang et al., 2014), but also on domain-general abilities, including analogical reasoning (Geary et al., 2017). Our research thus contributes to the literature on the cognitive predictors of children's structural knowledge of number, a critical element to children's success in mathematics, beginning in the early years (Byrge et al., 2014). In particular, our findings align with those of Collins and Laski (2019), who showed that relational reasoning is predictive of numeral-quantity knowledge and magnitude comparison.

One discernable pedagogical implication that emerges from our research is that educators may wish to focus on developing young children's analogical reasoning skill because of its relationship to structural knowledge of mathematics. Although our research was correlational, the findings allow us to predict that enhancing children's analogical reasoning would increase their conceptual understanding of number and reduce the reliance on superficial aspects of mathematical representations.

INTRODUCING MULTIPLICATION THROUGH *TOUCHTIMES*

In this research report, we work with a novel, multitouch iPad app called TouchTimes, which was designed to develop multiplicative thinking in young learners. In TouchTimes, children express multiplicative relations through two-handed gestures that emphasise the many-to-one abstraction articulated by Davydov and the functional element of Vergnaud. In this study, we analyze a pair of grade-two boys who, without any formal schooling in multiplication, are given an opportunity to experiment with the app. Our analysis suggests that the boys' express multiplication in a simultaneous way that emphasize the coordination of three quantities.

Keywords: Number concepts and operations, Elementary school education, Technology

Introduction

The Common Core characterizes children's first encounters with multiplication in terms of repeated addition. For example, the first reference to multiplication (in grade 3) states: "Interpret products of whole numbers, e.g., interpret 5 × 7 as the total number of objects in 5 groups of 7 objects each" (Standard 1 3.OA). This characterization of multiplication in which the multiplier precedes the multiplicand is sustained through grades 3 and 4. Unfortunately, many students fail to move beyond additive reasoning, which may lead to difficulties in future mathematical learning that include topics such as proportion, ratio, and algebra (Siegler et al., 2012).

Our work is motivated in part by Davydov (1992), who identifies a core element of multiplication as the double many-to-one abstraction. For example, the first many-to-one involves the unitizing of the multiplicand (the group size) in which 3 units become one. The second many-to-one then involves the unitizing of the multiplier in which the 4 units (of 3) become one. We also draw on the work of Vergnaud (1983) on the conceptual field of multiplication, which "explicitly contrasts multiplicative reasoning with additive reasoning and addresses the difference between a scalar interpretation of multiplication and a functional one" (Askew, 2018, p. 407). In Askew's work a double number-line is used to represent doubling (1 → 2; 2 → 4; 3 → 6, etc.), which highlights the way that the multiplicand changes the product.

In this study we work with a novel, multitouch iPad app called *TouchTimes* (from now on referred to as *TT*) (Jackiw & Sinclair, 2019), which was designed to draw on both the functional and unit-based approaches described above. Specifically, in *TT*, children express multiplicative relations through gesture-based actions that promote both the many-to-one abstraction articulated by Davydov (1992) and the functional element of Vergnaud (1983). The overall research objective is to investigate how children's early use of the gesture-based, multitouch *TT* app provides children with richer experiences of multiplication.

Brief Description of TouchTimes

TT is designed with the screen split into two marked by a vertical line down the middle (Figure 1a). When a user touches one side of the screen with a finger or a number of fingers, coloured discs appear under each finger. These different coloured disks are called pips and represent the multiplicand. When the user touches the other side of the screen with a finger or

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

number of fingers bundles of the pips appear under each finger. That is, each pod contains a replica of the configuration, colour and orientation of the pips from the original side; these can be seen as the multiplier. For example, if the user places three fingers on the left side (LS) of the screen, three differently coloured pips appear (Figure 1b). If the user then places four fingers on the right side (RS) while holding the three pips, four 'pods' of three pips appear (Figure 1c). If a finger is lifted from the pips side, all the pods will change accordingly, that is, each pod will have one less pip. Whenever there are pips and pods on the screen, a multiplication statement appears on the top of the screen. For the above situation, the mathematical expression is 3 × 4 = 12 (Figure 1c). When fingers are lifted completely off the screen on the pip side, all disks disappear. When fingers are lifted on the pod side, the pods remain and more can be added, or they can be individually dragged to the trash. In this way, larger numbers can be multiplied rather than being constrained by the number of fingers available. Each hand has a different function, which makes multiplication relational and functional rather than repeated addition.

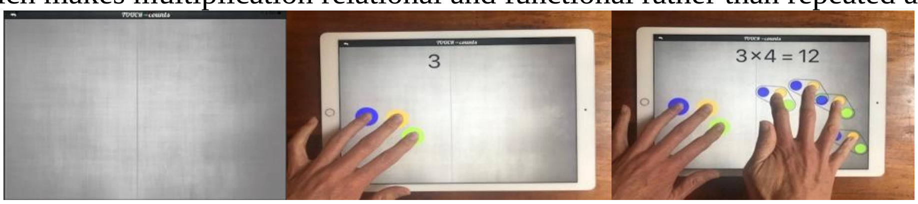

Figure 1: (a) Initial screen of *TT*; (b) Creating 3 Pips; (c) Creating 4 Pods

Theoretical Framing

The theoretical framing of this study is inclusive materialism (de Freitas & Sinclair, 2014). It adopts a monist ontological stance that attends to the learning of mathematics attending to the material context of student bodies and tools. The proposed research therefore draws significantly on theoretically-driven and empirically-tested insights into the significance of embodiment and tool-use in mathematics cognition. There is growing consensus about the significance of embodiment in mathematics education research (Radford, 2013). Existing literature explores embodiment in the context of 1) the positive impact of gesturing on student's mathematical thinking (Alibali & Nathan, 2012), 2) the high correlation of spatial reasoning (including its temporal and tangible aspects) with mathematical achievement (Newcombe & Frick, 2010); and, 3) the temporal, kinetic nature of mathematical thinking (Núñez, 2006). The question we ask in this study is what embodied coordinated gestures including both gestures and verbal expression align with multiplication properties outlined by Davydov and Vergnaud.

Methods

We have pursued a design-based research methodology which involves iterative cycles of design and implementation. We are now in our third cycle of design refinement, following initial experimentation with grade 3 children with limited school-based experiences of multiplication, which has produced some minor changes in functionality as well as specific tasks that, together with TT, enable students to develop the first level of abstraction designed in Vergnaud's theory (Bakos & Sinclair, 2019). In the research reported here, we used this same task with younger children (two grade 2 students; 8 years old) who have not had formal exposure to multiplication.

The two boys, Kevin and Joshua attended an elementary school in a rural part of British Columbia. They were two researchers present. One principally posed questions (first author) while the other video recorded. In analyzing the video data, we identified moments during which either the unit-based or functional character of multiplication emerged. We then transcribed these episodes and conducted a microgenetic learning analysis (MLA) (Parnafes & di Sessa, 2012) in order to study the unique ways in which the boys learn multiplication.

Findings

We present two episodes that highlight the emergence of multiplicative thinking with *TT*.

First Episode: A Rotating Relation

About two minutes into their exploration, both boys touch with single fingers from each hand on their own sides of the screen. The pip-holding boy, Joshua, rotates his two index fingers around, about 180 degrees, as if there was a centre of rotation between his pips. Kevin, who is holding two pods with his two index fingers, sees them also turning, even though he is not moving his fingers. The boys both laugh as Joshua continues to move his fingers. They continue this for 20 seconds; then Joshua says "I'm controlling it". After 20 seconds, Kevin touches his side with his thumb and a new pod appears. The statement 2 x 3 appears on the screen. The boys both continue laughing and then lift their fingers, which makes the pips and the pods disappear. While Joshua is laughing, Kevin's nine fingers are placed on the screen, making 9 pips. He says, "now your turn". One of Joshua's index fingers touches the screen. The statement 9 x 1 appears on the screen. Then another index finger touches the screen, thereby making two pods of 9 pips each. The statement 9 x 2 appears on the screen. Kevin starts moving his 9 fingers in little motions. The boys laugh again. They continue this moving and laughing for almost 60 seconds.

In this episode, we see the emergence of a particular gesture involving both boys and both their hands. The first time the gesture is used, Joshua has his two pip-making index fingers and Kevin has two pod-making index fingers. They maintain this particular four-handed gesture for over 40 seconds as Joshua moves his fingers, which produces changes in the orientation of the pods. Their laughter seems to emerge from their attraction to the movement that is created and perhaps to the fact that one movement is causing another one. Indeed, Joshua's assertion, "I'm controlling it" indicates that he was aware that his movement was causing the pods to change.

The gesture emerges again, but with different quantities and switched roles. This time, Kevin makes the pips and also makes 9 of them. Joshua then makes two pods with his two index fingers. Again, they laugh, perhaps attracted to the effect of the moving pips on the pods, which is slightly different this time since there are 9 pips moving instead of just 2. From this episode, we infer that the movement of the objects on the screen and the cause-effect nature of the moving fingers draws the boys' attention, sustaining their shared gesture for almost a minute. Aside from the statement "I'm controlling it" there were no other verbal exchanges—just negotiated actions. In the next episode, we examine how their emergent sense of how *TT* works is verbalized as a result of the interviewer's intervention.

Second Episode: Attending to the product

Joshua takes the iPad over and make 1 x 7 by holding one pip with his left finger and pressing multiple times on the pip-side of the screen with the other. He then makes 24 = 4 x 6. Kevin asks him to let go of his pod fingers. He does, but also lifts one of his pip fingers, thus making 20 = 4 x 5. Kevin says "oh". Then at 5:22 the interviewer asks the boys what they notice about the numbers. Joshua lets go of his pip-making fingers so they have to start over, this time Joshua makes 35 = 7 x 5. Kevin says at 5:37 "oh I get it so if you have less numbers and you have more numbers over here you get a higher number (pointing to 35) I think". It's difficult to understand his explanation, but he is certainly trying to connect how the number of pips and pods relates to the product. They experiment a little more and then at 5:50 Kevin says "if we have more of these (pointing to the pips) well we can have a higher number". At 5:57, the interviewer says, "I wonder if you can make the number 6". The boys make 9 = 3 x 3 then let go.

Table 1: Attending to the Product

	Voice	Hands	iPad
6:07		J. Places one pip-finger K. Places three pod-fingers simultaneously.	6:08	K. Wait three this is three	K. points to the pip-side	6:09	K. And this is three	K. Points to pod side	
6:10	J. That makes nine	J. Adds two more fingers sequentially to the pip-side K. Still pointing to the pods	
Joshua lifts his fingers, making all disappear. The boys laugh. Joshua then immediately presses three pip-fingers and Kevin says "try two". Joshua presses two pod-fingers, which produces two pods of three and the equations 2 x 3 = 6. Joshua says "yes" in an enthusiastic voice and lifts his fingers. The boys have produced their first multiplicative relation using the two-handed gestures required to make pips and pods and attending to the numerical values in the equation. It is not clear why Kevin suggested that Joshua make two pods, but since he had been conjecturing about the size of the product in relation to the number of pips and pods, it could be that he was aware that there needed to be fewer than 3 pods since 3 pods had previously produced 9.

Discussion and Conclusion

In the first episode, it would seem that the rotating four-handed gestures in which one boy moved the pips, was crucial, both affectively and cognitively, for drawing the boys' attention to the relation between the pips and the pods. The effect of moving the pips on the pods drew the boys' attention to the relation between pips and pods and also encouraged them to repeat and vary a particular kind of gesture that requires the coordination of two sets of hands. In terms of multiplicative thinking, this underlies the functional relation but it may also contribute to the sense of the pods as all being equal units. The boys also become aware that the hand that touches the screen first is the hand that controls the shape of the pods. In terms of multiplication, this relates to a recognition that the multiplicand and the multiplier play different roles and that changing the configuration of the pips changes the configuration of each one of the pods. And in the second episode, they attended also to the product and were able to find a solution to the researcher's invitation to produce 6.

We interpret this short but eventful experience as being very promising both in terms of the boys' attraction to the moving pips and pods, which seemed visually interesting and emotionally engaging, and in terms of the experiments they conducted, sometimes on their own initiative and sometimes in response to questions by the researchers.

In this study we use latent class and distractor analysis, and qualitative analysis of cognitive interviews, to investigate how student responses to conceptual items may reflect different patterns of algebraic conceptual understanding and procedural fluency. Our analysis reveals three groups of students, which we label "mostly random guessing", "some procedural fluency with key misconceptions", and "procedural fluency with emergent conceptual understanding". Student responses revealed high rates of misconceptions that stem from misuse or misunderstanding of procedures, whose prevalence correlates with higher levels of procedural fluency.

Keywords: Algebra, Developmental algebra, Conceptual understanding, Concept inventory

Elementary algebra and other developmental courses have consistently been identified as barriers to college persistence and degree progress (see e.g., Bailey, Jeong, & Cho, 2010). There is evidence that students struggle in these courses because they do not understand fundamental algebraic concepts (see e.g., Givvin, Stigler, & Thompson, 2011; Stigler, Givvin, & Thompson, 2010), and many research studies have documented the negative consequences of learning algebraic procedures without any connection to the underlying concepts (see e.g., Hiebert & Grouws, 2007). However, developmental mathematics classes currently focus heavily on recall and procedural skills without integrating reasoning and sense-making (Goldrick-Rab, 2007; Hammerman & Goldberg, 2003). This focus on procedural skills in isolation may increase the probability that students use procedures inappropriately because they lack understanding of when and why the procedures work (e.g., Givvin et al., 2011; Stigler et al., 2010). In this paper we explore student responses to conceptual questions at the end of an elementary algebra course in college. We combine quantitative analysis of responses (using latent class analysis and distractor analysis) with qualitative analysis of cognitive interviews to better understand different typologies of student reasoning around some basic concepts in algebra, and to better understand how conceptual understanding and procedural fluency may relate to one another in this context.

Theoretical Framework

In this paper we use Fishbein's (1994) typology of mathematics as a human activity as a framework for analyzing student responses. Fishbein outlines three basic components of mathematics as a human activity: 1) *the formal component* (which we call *conceptual understanding*), which consists of axioms, definitions, theorems and proofs, which need to be "invented or learned, organized, checked and used actively" by students; 2) *the algorithmic component* (which we call *procedural fluency*), which consists of skills used to solve mathematical problems in specific contexts and stems from algorithmic practice; and 3) *the intuition component*, which is an "apparently" self-evident mathematical statement that is accepted directly with the feeling that no justification is necessary.

In this study we use the term conceptual understanding to denote both a formal understanding of abstract concepts (e.g. axioms), but also of how, when, and why procedures can be used. This is in contrast to procedural fluency in standard problem contexts, in which a student may be able to quickly solve particular types of standard problems correctly but may not understand of how, why, or when these methods work. Using these definitions, no question is wholly conceptual or procedural, but falls on a spectrum. In this paper we explore how procedural skills and conceptual understanding may relate to one another and how student justifications of answer choices may exhibit intuition components (either correct or incorrect), as well as how these intuitions may relate to both the processes of developing procedural fluency as well as conceptual understanding.

Methods

This study focuses on student responses to the multiple choice questions on the Elementary Algebra Concept Inventory (EACI). For details on the development and validation of the EACI, see (Wladis, Offenholley, Licwinko, Dawes, & Lee, 2018). Here we focus on 698 students who took the inventory at the end of their elementary algebra class in 2016-2017 as well as 10 cognitive interviews that were conducted towards the end of the semester with these students; these were analyzed using grounded theory (Glaser & Strauss, 1967), although a full qualitative analysis is not presented here due to space constraints. The distribution of interviewees among the three classes was not significantly different from the whole quantitative sample. In this paper we used latent class analysis (LCA) of the nine binary scored (right/wrong) multiple-choice items on the inventory (e.g., Collins & Lanza, 2010).

Description of the Classes

LCA revealed three distinct classes of students. Item response patterns, distractor analysis, and qualitative coding of cognitive interviews were then used to interpret the classes, and evidence was found among these different complementary approaches for these characterizations:

- C1 (27%): Answers to most items are indistinguishable from random guessing, likely due to low procedural/conceptual knowledge, low self-efficacy, and/or low motivation.
- C2 (28%): Some well-developed procedural skills but limited conceptual understanding.
- C3 (45%): Some well-developed procedural skills and emergent conceptual understanding.

Firstly, we consider the response patterns of students from each of the three classes. Student responses in C1 do not vary much from what would be expected for random guessing on four-option multiple choice items. C2 answers significantly worse than chance on questions 2 and 6 because of the presence of attractive distractors that likely tap into misconceptions related to the misuse of procedures. C2 and C3 are distinguished by improved performance on the items overall but different proportions of key misconceptions. Students who passed the class were most likely to be in class 3, then class 2, and least likely to be in class 1. An end-of-course standardized procedural test showed a similar outcome. To illustrate how different response patterns distinguish these three classes, we performed a distractor analysis and analyzed cognitive interviews for two exemplars: items 2 and 6, using the Bayes modal assignment to determine class membership.

Two Example Questions: Illustrating Different Class Response Patterns

First we consider item 6, which shows an interesting pattern of responses:

6. A student is trying to simplify two different expressions:

i. $(x^2y^3)^2$

ii. $(x^2 + y^3)^2$

Which one of the following steps could the student perform to correctly simplify each expression?

a. For both expressions, the student can distribute the exponent.
b. The student can distribute the exponent in the first expression, but not in the second.
c. The student can distribute the exponent in the second expression, but not in the first.
d. The student cannot distribute the exponent in either expression.

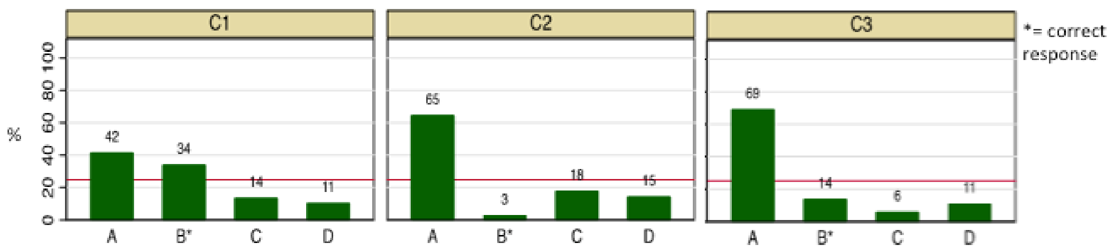

Figure 1: Item 6 Distractor Analysis

The correct answer is b. C2 and C3 were strongly attracted to option a (see Figure 1), likely because they have intuitions stemming from their experiences with procedures that use distributive properties, but they do not recognize the critical differences between distributing multiplication versus exponents—likely because they have no deeper conceptual understanding of how the distributive properties work. Selecting the correct answer is negatively correlated with scores on the procedural exam—students who selected the incorrect option a scored on average 7.1 percentage points higher on the procedural exam ($p < 0.000$) than others. Looking at student interview responses reinforces our interpretation of the three classes, and sheds light on how intuitions developed from procedural practice may impede conceptual understanding.

C1 (chose B): [The difference between the first and second equation] is that there's a plus right there [pointing to the second equation]. I think for this one [pointing to the second equation], you have to add and for this one [pointing to the first equation] you don't….

C3 (chose A): That's how you kind of get rid of the parenthesis and get rid of the outer exponents by distributing it in the inside. Whether it's with another exponent or with a number… You want to add or multiply that exponent [outside the parentheses] to the ones

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* St Louis, MO: University of Missouri.

inside the parentheses but I can't remember whether you add or multiply…

Here the C1 student notices that there is a difference between the two equations and has an intuition that it is important, but doesn't actually know how to perform the distribution correctly. In contrast, none of the C2 or C3 students interviewed was able to describe when or why it is possible to distribute—they all cited different incorrect intuitions related to procedural methods.

Next we consider item 2, which reveals another interesting pattern of responses:

2. Consider the equation $x + y = 10$. Which of the following statements must be true?

a. There is only one possible solution to this equation, a single point on the line $x + y = 10$.
b. There are an infinite number of possible solutions, all points on the line $x + y = 10$
c. This equation has no solution.
d. There are exactly two possible solutions to this equation: one for x and one for y.

For this question, the correct answer is b, (the most popular choice for students in classes 1 and 3) but no examinee in class 2 chose it (see Figure 2). They were strongly attracted to option d, which was also the second most popular choice for students in other classes, although at a much lower rate. Option d is a common response from students asked to solve a system of linear equations for *x* and *y*, which may explain its popularity. Looking at student interview responses reinforces our interpretation of the three classes, and sheds light on students' reasoning.

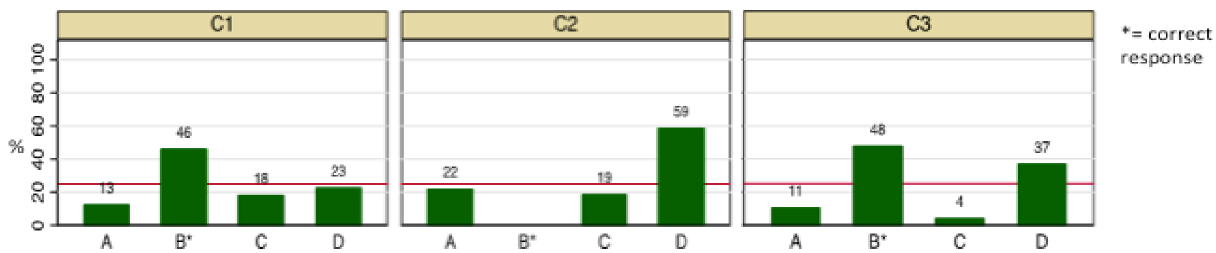

Figure 2: Item 2 Distractor Analysis

C1 (originally chose C, but drifted towards B in the interview): $x + y$ equals nothing so it can't be 10. Right?... It could be possible like it equals 10. [Option D isn't correct] maybe because *x* and *y* could be equal to anything?

C2 (chose D): I know there are certain numbers that will add up to ten, so there could be two solutions, since there's only a *x* term and a *y* term…

C3 (chose B): Ten could equal to many things. Like five plus five could equal ten. Nine plus one could equal ten. Seven plus three…it could be any number that will equal to ten.

The C1 student initially chose "no solution" because they didn't know what *x* and *y* could be, but then they started to relate this to the idea that *x* and *y* could be "anything". While their reasoning is not strictly correct, they are beginning to explore the idea that *x* and *y* may have many possible values, and they show no evidence of faulty intuitions stemming from procedural practice. The C2 student exhibits an intuition about what the equation means to find a single solution, but they do not explore whether there might be others, and they confuse the number of solutions with the number of variables in the solution set, suggesting that their intuitions about the definition of a solution set are incorrect. The student from C3 describes how this equation could have multiple solutions, demonstrating some conceptual understanding of solution sets, including the fact that they describe the relationship between the two variables.

Discussion and Limitations

This study revealed that roughly one quarter of students at the end of the course appeared to guess somewhat randomly on conceptual questions; however, cognitive interviews suggest that these students are able to make some progress towards conceptual understanding by relying initially on more naïve reasoning and that they are not typically hindered by incorrect intuitions stemming from misuse of procedures. About one quarter of students demonstrated some mastery of procedures in standard problem contexts, but demonstrated many misconceptions related to misuse of procedures on conceptual questions. In contrast, roughly half the class showed evidence of emergent conceptual understanding, with lower frequency of misconceptions related to misuse of procedures. For a number conceptual questions, particularly those that were more abstract or non-standard, conceptual understanding and procedural fluency were significantly strongly inversely related. Cognitive interviews revealed that this may happen when students develop incorrect intuitions stemming from the use of procedures.

POST-SECONDARY STUDENTS' MISCONCEPTIONS ABOUT RATIONAL NUMBERS: IMPLICATIONS FOR K-12 INSTRUCTION

Gena Nelson, Ph.D.
Boise State University
genanelson@boisestate.edu

Sarah R. Powell, Ph.D.
The University of Texas at Austin
srpowell@austin.utexas.edu

Keywords: Post-Secondary Education, Rational Numbers, Problem Solving

A strong understanding of rational numbers, specifically fractions, is a mathematics precursor that predicts whether students experience success in algebra (Booth & Newton, 2012), and success in introductory algebra coursework has often been described as the gatekeeper to upper-level mathematics (Eddy et al., 2015). Having skills to access more advanced mathematics coursework may lead to a greater probability of enrolling in college (Byun, Irvin, & Bell, 2015) or an increase in employment earnings in adulthood (Gaertner, Kim, DesJardins, & McClarty, 2014). Given that understanding rational numbers is important for success with algebra, we aimed to investigate the misconceptions of rational numbers that post-secondary students have.

Very few studies have explored students' misconceptions and errors related to rational numbers, and the majority of studies that included college-age students focused on the narrow population of pre-service teachers as well as a focus on mastery of operations with fractions, with few items examining other processes (e.g., identifying the least common denominator) or other forms of rational numbers (e.g., decimals, percentages). To understand the misconceptions that may persist with rational numbers, we administered a 41-item assessment to 331 undergraduate students and we included decimals, percentages, and fractions. We also examined other skills, such as solving rational number word problems, finding the least common denominator, and converting between forms of rational numbers. We coded students' responses and identified error patterns. Students attempted conceptual understanding and calculations problems more often than word problems, and students made fewer errors with conceptual understanding and calculations items. Students demonstrated the most unique errors with calculations and word problems. Given that all items on the assessment required elementary or middle school knowledge of rational numbers, the number and diversity of errors with a sample of post-secondary students illustrates the difficulties that persist with rational numbers.

With this poster, participants will learn about the different types of errors post-secondary students committed with rational number problems. We also share how the types of errors committed by post-secondary students can inform instruction in college-level developmental courses as well as mathematics instruction throughout the elementary and secondary grades.

NUMBER SENSE: THE CASE OF SARA

Valerie N. Long
Indiana University of Pennsylvania
vlong@iup.edu

Yuliya Melnikova
Indiana University of Pennsylvania

Keywords: Number Concepts and Operations, Assessment and Evaluation

The number competencies that children bring to school set the stage for learning complex mathematics (National Mathematics Advisory Panel, 2008). Too many students have entered kindergarten not ready with the math skills necessary to begin formal schooling (Jordan & Levine, 2009). One skill specifically is number sense with a key component being counting. Research has found that students' mathematical difficulties are related to number sense (Geary, Hoard, Byrd-Craven, Nugent, & Numtee, 2007; Gersten, Jordan, & Flojo, 2005) and poorly developed counting procedures (Geary, Hamson, & Hoard, 2000; Jordan, Hanich, & Kaplan, 2003). This poster presentation expands on prior research of students struggling in mathematics due to issues related to counting. The purpose of this exploratory case study was to a) determine the cause of low performance on math achievement tests of a third-grade student and b) monitor the change in performance as she engaged in one-on-one instruction during her fourth-grade year.

Methods

Sara was chosen for this study because her math achievement scores revealed little to no progress during her second-grade year and a drastic drop during the third-grade year. Several interventions during her third-grade year had no effect on improvement of achievement scores. Once the cause was determined, a one-on-one instructional classroom was established at the onset of the fourth-grade with a "highly trained teacher" (Bachelor of Science in mathematics and 80+ hours early childhood methods training), where prekindergarten and kindergartner concepts were initially emphasized. Every nine weeks, Sara's progress was evaluated and revised as needed. Achievement testing, number sense testing, teacher feedback, and classroom observations were the primary means of data collection. Data were triangulated using these multiple sources to analyze the cause of low performance at the end of the third-grade year and to monitor progress during the fourth-grade year.

Results

The cause of Sara's low performance on math achievement tests was due to missing her "first lesson in mathematical language, learning how to count, the bedrock of conventional mathematics" (Krasa & Shunkwiler, 2009, p. 68). Specifically, she had difficulty entering the count sequence and counting forward and backwards for numbers less than 40. Additionally, when given 3 two-digit numbers with one missing (e.g. 35, 36), she was slow in sharing her solution because she needed to count from a familiar number. For Sara, it was as if pre-kindergarten and kindergarten never happened. Sara's change in performance during the fourth-grade showed substantial growth. Her achievement test revealed below average scores (standard score 70) at the end of the third grade and average scores at the end of fourth grade (standard score 92). In conclusion, Sara's case highlights the importance of number sense and counting.

Introduction

Plenty of literature has highlighted elementary students' misinterpretation and difficulty in dealing with an equal sign at different grade levels (e.g., Jones, Inglis, Gilmore & Evans, 2013; Sherman & Bisanz, 2009; Stephens et al., 2013). Studies have suggested various tools to develop a relational understanding of equality (e.g., Ellis & Yeh, 2008; Jones & Pratt, 2006). Leavy, Hourigan, and McMahon (2013) reported evidence of a relational understanding of the equal sign, rather than an operational understanding, in elementary students' work when using a physical balance. In this study, we investigate how often elementary students use their relational understanding of equality using a balance to write a balanced equation of the given situation.

Data, Method, and Results

As part of the broader Measuring Early Mathematics Reasoning Skills (MMaRS) project, we conducted 32 cognitive interviews of elementary students (K-3) to confirm the ordering of skills on a learning progression focused on Properties of Operations. The interview protocol was aligned to the learning progression and included items designed to test students' understanding of various representations of equality. In this study, we focused on students' responses to three questions associated with three different skills on the learning progression. First, a picture of three apples on each side of a balance was displayed, and students were asked to write a number sentence to describe the relationship between the apples on the balance. Second, students were asked to write an equation to describe the balanced scale. Lastly, students were asked to identify if an equation, in the form of a = a, was true or not.

The analysis of 32 interviews revealed that there is a disconnection between students' understanding of equality on a pictorial scale and symbolic representation in the form of a=a. Figure 1 displays the number of students who answered correctly with the associated percentage out of 32 students. In 21 (65%) interviews, the interviewer asked student explicitly if the equation 3=3 described the situation on the balanced scale, and only 5 (24%) students correctly associated the equation with the pictorial representation.

First: Pictorial representation of apples on a balanced Scale	Second: Write an equation (a=a) for the balanced scale	Identify a true equation of form a=a shown on a card.
27 (84%)	0 (0%)	12 (37.5%)

Figure 1: Number of Correct Responses for Three Skills Out of 32

These results show a clear disconnection between pictorial and symbolic representations of equality among these elementary students. Students did not demonstrate a relational understanding of the equal sign. Rather, an operational understanding was evident, as 21 out of

Algebra is a foundation for higher math, yet many students struggle with algebra notation. The abstract and symbolic nature of algebra contributes to the difficulty students encounter during learning (Greenes, 2008). In web-based Graspable Math (GM), students can explore algebraic notation by moving, combining, and substituting symbols in equations and expressions. In the system, GM completes valid transformations (e.g., turning $2x+5x$ into $7x$ when users tap the addition sign) and provides error feedback by shaking (e.g., the expression $5x\div\frac{1}{2}+2x$ shakes back and forth when users attempt to perform addition before division) and by not enacting invalid transformations. Here, we examine the relations between aspects of behavior in GM as recorded in the click-stream data and their associations with algebraic thinking.

We assessed 39 ninth-graders on their algebra knowledge (e.g., solve the equation for x. $3 = (8\text{-}6x)\div 2$; Star et al., 2016), then provided three 20-minute GM sessions on transforming expressions from a starting state to a goal state (e.g., 6+10 => 2×(3+5)). For each GM problem, we measured time spent, proportion of time to first action (i.e., time to first action / total time, an indicator of pause before acting), number of transformations made, and number of errors (i.e., invalid transformation) made in reaching the goal state; and averaged the values across problems within respective measures for individual students. Spearman correlations revealed that students who spent more time to reach the goal state in a GM problem also made more transformations and more errors during problem solving ($.41 < r\text{s} < .51$). Students who spent more time pausing before acting made fewer transformations to reach the problem goal ($r = -.39$). Only the total time spent was correlated with students' knowledge in algebra. Students with higher knowledge in algebra were faster at completing GM problems ($r = -.36$).

The findings have several implications. First, the moderate correlations between GM measures suggest that they may be distinct indicators of students' algebra skills. Second, pauses may reflect thinking and finding efficient strategies to complete GM problems. Last, aspects of students' behavior in GM may be associated with their algebra performance outside the GM environment. Future studies on the relations between GM measures and the potential mechanisms of pausing (e.g., executive functions, algebra knowledge) may provide insights into students' algebra skills.

Research that seeks to identify and detail effective instructional practices is desperately needed in early algebra given the domain's importance to students' future mathematics learning as well as the instructional challenges the domain presents to elementary school teachers (Hohensee, 2015; Katz, 2007; National Mathematics Advisory Panel, 2008). From prior research, we know that activities accompanied with visual representations are often more effective at enhancing students' learning of content knowledge than text-only activities (Kalyuga & Singh, 2015). Elementary teachers who are oriented toward teaching mathematics conceptually are more likely to use visual representations to support students' sense-making as a regular part of their instructional practice (Jansen, Berk, & Meikle, 2017). However, little is known about how teachers use of visualizations might contribute to a more meaningful understanding of early algebraic concepts.

In this poster, we discuss analyses of classroom observations in which Grade 3 teachers taught the same set of early algebra lessons, documenting variations in their use of visual representations. The large-scale nature of this study provides a unique opportunity to identify differences in teachers' use of visual representations and to identify aspects of the practice associated with positive classroom outcomes, as the few studies that have studied instruction are often small-scale or narrowly focused studies (e.g., Jacobs et al., 2007; Webb et al., 2014). The primary questions guiding this study are twofold: *(1) How are teachers' use of visualizations differentiated across the same early algebra lessons? (2) How are the variations of teachers' use of visualizations associated with classroom early algebra learning outcomes?*

To address these questions, we focus on 28 teachers of third grade classrooms in three school districts each within an urban, suburban, and rural area in a southeastern US state. Students were taught the early algebra intervention by their classroom teachers as part of regular mathematics instruction. This study focuses on three separate lessons, each roughly one hour in duration, and that were videotaped. Lesson A addresses generalizations about even and odd numbers and was recorded in 20 classrooms. Lesson B addresses use of variables in algebraic expressions and was also recorded in 20 classrooms. Lesson C addresses identify recursive, covariational, and functional relationships and was recorded in 28 classrooms.

The poster will include several visual representations teachers used and associated classroom outcomes. For example, teachers' use of visual representations that explicitly illustrated uniqueness in a combinatorics problem was associated with a greater likelihood of addressing the conceptual goal of the lesson (e.g., recognizing functional patterns in the data set).

ENCODING NEGATIVE SIGNS AS SUBTRACTION SIGNS: CASES OF SECOND AND FIFTH GRADERS

Theoretical Background and Methods

The perceptual patterns that students encode when they learn whole number addition and subtraction are challenged when they encounter similar problems with negative numbers. Students may not encode negative signs when they first encounter them (e.g., Bishop, Lamb, Philipp, Whitacre, & Schappelle, 2018; Bofferding, 2014). Based on a framework theory for conceptual change (Vosniadou, Vamvakoussi, & Skopeliti, 2008), other students might encode these new perceptual features (i.e., negative signs) but interpret them as familiar symbols, in this case subtraction signs (Bofferding, 2019; Murray, 1985; Vlassis, 2004, 2008). Students may only encode those features they deem necessary for solving a problem (McNeil & Alibali, 2004), but seeing problems and symbols in contrast can also bring new perceptual features to students' attention (Schwartz, Tsang, & Blair, 2016). Therefore, we investigate second and fifth graders' encoding of the negative sign when it appears adjacent to an operational sign, as in adding a negative (+ -) or subtracting a negative (– -), over a series of arithmetic problems. Our research question is when do students treat adjacent signs as two operations (i.e., add then subtract or subtract twice) and how and when does this change over a series of integer arithmetic problems?

We interviewed 102 second graders and 102 fifth graders on a series of 11 integer addition problems (e.g., -9 + 2, 3 + -3, -1 + -7) followed by a series of 16 integer subtraction problems (e.g., 1 – 4, 3 – -1, -7 – 3, -8 – -8) on a pretest and posttest before and after an intervention where students analyzed contrasting cases of integer arithmetic worked examples. We first identified cases where students treated negative signs as subtraction signs when adjacent to addition or subtraction signs. We then analyzed students' strategies on the other problems to identify when and how their use of the signs changed. We highlight these changes through a few cases.

Results and Discussion

In one case, a fifth grader (4.U08) treated negatives as subtraction signs, solving -9 + 2 by subtracting two from nine. The same student solved 3 + -3 by "adding three plus three…and then minus three." However, when the student solved 3 – -1, the fifth grader just subtracted one from three. Perhaps the student needed the adjacent signs to be perceptually different to do both. Another fifth grader (4.Z06) first interpreted an initial negative as nothing for -9 + 2: "Because that [-9] is not a number, like it is, but it's negative, so you just add two more, and that will be 2." For the next problem where the negative was second, 3 + -3, he did three plus three minus three but then later treated all negatives as worth zero. At an extreme, a second grader (4.G04), treated all minus signs as subtraction. If a negative number was first, the student treated it as subtracted from zero; for adjacent signs this student used the first sign with the first number and the second sign with the second number. Therefore, for 4 + -6, the student did 4 + 4 – 6 = 2.

LANGUAGE AND NUMBER: STUDENTS' INTERPRETATION OF "LESS LOW"

Laura Bofferding	Mahtob Aqazade	Maya Cameron
Purdue University	Purdue University	Purdue University
LBofferd@purdue.edu	maqazade@purdue.edu	mcamero@purdue.edu

Keywords: Cognition; Number Concepts and Operations; Elementary School Education

When making comparisons with objects, young children have an easier time interpreting positive terms (e.g., higher, more, or hotter) as opposed to negative terms (e.g., lower, less, or colder) (Smith, Rattermann, & Sera, 1988). However, when asked to compare positive and negative numbers, children will often rely on absolute value (Bofferding, 2014; Bofferding & Farmer, 2019). Yet, when determining which temperature was *least cold*, a compound term made up with of two negative terms, second and fifth graders were better able to respond with all negative number choices (e.g., -8, -9, -1) as opposed to comparing positive temperatures (e.g., 2, 4, 7) (Bofferding & Farmer, 2019). We explored second and fifth graders' interpretations of the comparison language "less low" with and without the support of positive and negative numbers before and after an intervention focused on interpreting language such as "less negative." We examined this research question: when making comparisons about the relative positions of two cats on a staircase, how do second and fifth graders interpret the term "less low," (a) without number labels on the staircase? (b) with number labels on the staircase?

Participants included 102 second and 102 fifth graders from two public elementary schools who took a pretest, engaged in an intervention focused on language and integer operations, and completed a posttest. We focus on problems involving pictures of two cats on a staircase. The cats were placed on different steps in each problem (both low, both high, or split high and low). Students identified which cat was less low in each picture where three pictures had unlabeled stairs and three had positive and negative number labels under the stairs (as in a number line). We analyzed students' correctness, explored their pattern of responses, and identified their most common language when describing their choice and meaning given to "less low."

We found that both second and fifth graders' correct responses increased from pretest to posttest with second graders gaining slightly higher than fifth graders on problems without numbers and fifth graders gaining slightly higher on problems with numbers. Students' typical response patterns included: always choosing the higher cat; always choosing the lower cat (regardless of the cat's location or having numbers on stairs or not); some students chose the higher cat in problems without numbers and chose the lower cat in problems with numbers; and some students always chose the lower cat except for cats positioned at numbers -5 and -2. For instance, a second grader (4.C10) on the pretest problems *without numbers* said, "Because this one [lower] is less." On pretest problems *with numbers* he explained, "Because this one [4] is four and this one [-2] is 2, so this one down here [circles cat at -2]." Choosing the cat located as less low on -2 and -5, he said, "Because this one [-2] is 2 and this one [-5] is more higher than 2 [circles cat at -2]." Students' most common incorrect language explaining what less low means were "really low," "reaches to the bottom," "lowest to the floor farther down," "lower," "under the highest," "less," or "first." Equivalent correct terms for less low involved "from up to down," "would be less down," "high," "a small negative (with two negatives)," or "not low."

TEACHING WITH RACE IN MIND: EXPLORING THE WORK OF ANTIRACISM IN LEADING WHOLE-CLASS MATHEMATICS DISCUSSIONS

Rosalie DeFino
University of Michigan
rdefino@umich.edu

How might teachers of elementary mathematics pursue antiracism through everyday practices such as leading whole-class discussions? This paper reports on an exploratory study of one White woman teacher's efforts to challenge manifestations of structural racism in classroom interactions with students who are predominantly Black. The results include preliminary characterization of three areas of antiracist work: planned and routine practices, in-the-moment responses to student behavior, and ongoing interpretation of classroom events. Implications for research on mathematics teaching and for mathematics teacher education are discussed.

Keywords: Elementary School Education, Social Justice, Instructional Activities and Practices

Recent scholarship on the pursuit of equity in mathematics education has emphasized the importance of teacher and student identity, including racial identity, in supporting the learning of students from historically and currently marginalized groups (Aguirre, Mayfield-Ingram, & Martin, 2013; Bartell et al., 2017; de Freitas, 2008; Varelas, Martin, & Kane, 2012). Additionally, critical scholars emphasize the structural nature of educational inequities and call for broader interrogation of systems of power and social injustices (Gutiérrez, 2013; Gutstein, 2012; Martin, 2015). Mathematics educators often take up questions of identity and power and of race and racism through curricular innovations, developing mathematical investigations of sociopolitical issues like gentrification and housing displacement (Gutstein, 2012). However, there has been less attention paid to how mathematics teachers might teach with race in mind in their everyday practice, especially while working on conventional mathematics topics in elementary classrooms.

In this paper, I report on an exploratory study of one teacher's efforts to work against structural racism in her daily practice of leading whole-class mathematics discussions. I present preliminary findings pertaining to the following research question: *What does the teacher do in the context of day-to-day elementary mathematics teaching that could be considered antiracist work?* The purpose of the study is not to determine the effectiveness of the teacher's antiracist efforts nor to declare universal "best" practices. Instead, the objective is to describe and make sense of this teacher's work as she pursues antiracism in order to raise questions and considerations for the fields of mathematics education and mathematics teacher education.

Theoretical Perspectives

This project draws primarily on three theoretical perspectives: critical race theory, conceptions of teaching as complex and situated interaction, and positioning theory. I draw on critical race theory and particular conceptions of teaching to articulate foundational assumptions that undergird the project as a whole. I apply concepts from positioning theory more directly as tools in my analysis of empirical data.

Premises for Studying Race and Racism from Critical Race Theory

My attention to race and racism is driven and informed by several core concepts in critical race theory (CRT). CRT emerged in the 1970s out of several legal scholars' dissatisfaction with traditional approaches to addressing racial inequality. In the 1990s, Ladson-Billings and Tate introduced CRT to the field of education (Ladson-Billings, 1999; Leonardo, 2013). CRT scholars understand race as a social construct that has real, material consequences (Ladson-Billings, 1999). Moreover, a central idea in CRT is that racism is endemic to U.S. society, so normalized that its presence and effects often go unrecognized, especially by White people (Leonardo, 2013; López, 2003). Given this, CRT helps make visible that racism is at work in familiar contexts and activities, such as a class discussion about a math problem. In addition, CRT scholars understand racism as a system of oppression that creates and maintains a racial structure, *not* just "willful act[s] of aggression against a person based on their skin color" (Parker & Lynn, 2002, p. 9). Thus, from a CRT perspective, being an antiracist teacher must mean more than calling out or avoiding blatant personal discrimination in the classroom; instead, antiracist teaching must strive toward dismantling racist ideas and systems that structure children's lives.

Conceptualizing Teaching: Complex Interaction in Social and Historical Context

A conception of teaching as interactive and situated work is foundational to this study. I adopt Cohen, Raudenbush, and Ball's (2003) instructional triangle, which represents teaching as mutually-influencing interactions among teachers, students, content, and environments. This conception has several important implications for my analysis of antiracist efforts in mathematics teaching. First, it suggests that teaching is not unilaterally determined by any single actor or influence; teachers' intentions depend on students and the environment to be realized. Second, teaching is a complex activity that can have multiple and varied effects upon participants. For instance, there is no guarantee that all students will similarly interpret or experience a teacher's words and actions. Finally, the instructional triangle implies that environments, including endemic racism, enter into teaching and learning in several ways. For one, the institution of schooling brings a long history of social norms and expectations (Tye, 2000). Drawing again on CRT, the social and historical context of schooling includes nominally colorblind policies that disproportionately impact people of color, as well as assumptions of Whiteness as the norm (Bonilla-Silva, 2015; Yoon, 2012). Thus, by highlighting interactions between environments and teachers, students, and content, the instructional triangle model can support serious consideration of social and historical contexts in analyses of teaching and learning.

Positioning: A Conceptual Tool for Bridging the Macro and the Micro

Given CRT's emphasis on the structural nature of racism, applications of CRT in education often focus on school- and district-level issues like tracking, discipline, and funding (e.g., Blaisdell, 2016; Chapman, 2013). To bring consideration of race and racism to the level of classroom interactions, I draw on the concept of *positioning.* As conceived by Davies and Harré (1990), positioning, in part, encompasses the ways that speakers metaphorically locate each other in conversations and jointly construct *storylines*. In a mathematics classroom setting, for example, students may be positioned by themselves and others as more or less mathematically competent. Scholars of mathematics education have used the concept of positioning to examine both micro-level moment-to-moment interactions (e.g., Wood, 2013) and patterns of interaction over time (e.g., Langer-Osuna, 2011). Such studies suggest that teachers' practices have the potential to affirm or challenge storylines of students' mathematical competence. Furthermore, scholars have linked storylines being constructed in classrooms to broader societal discourses and stereotypes. For example, Shah and Leonardo (2016), Nasir et al. (2009), and Martin (2006) demonstrate that students in mathematics classrooms actively navigate racialized discourses and stereotypes about mathematical ability based on race. Such discourses and stereotypes function as possible storylines that teachers and students may contribute to or resist through classroom interaction (cf. Davies & Harré, 1990). In terms of antiracism, I explore the question of whether the storylines the teacher contributes to reflect or challenge broader racist narratives and patterns of mathematics learning experiences. Thus, I use the concepts of storylines and positioning to begin bridging the issues and identities at play in micro-level classroom interactions to macro-level narratives and patterns.

Research Questions

The purpose of this inquiry is to offer a description and exploratory analysis of one teacher's efforts to counter racist narratives and patterns of experience through her teaching of elementary mathematics. In a larger study of a teacher in a two-week summer mathematics class for rising fifth graders, I pursue three research questions:

1. How does the teacher describe her efforts to combat racism?
2. What does the teacher do in the context of day-to-day elementary mathematics teaching that could be considered antiracist work (as defined below)?
3. What tensions and challenges arise in the teacher's efforts to combat racism?

For this paper, I focus on the second research question. I use the following working definition of *antiracist work* in teaching: deliberate efforts to position students in ways that counteract racist ideas (e.g., discourses about the intellectual deficiency of Black children described by Martin, 2009) as well as efforts to disrupt racialized patterns in students' learning experiences, such as having limited access to challenging mathematics instruction (Battey & Leyva, 2018). This is not meant to be an exhaustive or exclusive definition of antiracist work, and I recognize that acting on antiracist intentions in no way guarantees that a teacher's practice is not harmful or problematic. With these limitations in mind, I use this working definition as an entry point for describing and making sense of the focal teacher's practice. In the following section, I describe the research context and methods.

Methods

This project is an interpretive qualitative study. Therefore, the perspectives I bring as a researcher necessarily inform my selection of data, analytical process, and conclusions (Hesse-Biber & Leavy, 2011; Ladson-Billings, 2000). I share my approach and rationale below.

Context and Participants

This study focuses on a two-week summer mathematics class held at a large public university in 2017 for rising fifth grade students. The mathematics class was framed as a laboratory for the study of teaching and included opportunities for adult observers to attend daily pre-brief sessions with the classroom teacher, in-person or remote viewing of the math class, and debrief sessions. All pre-brief, math class, and debrief sessions were video-recorded. Students were recruited by the program director from a neighboring school district. There were 20 students, 10 boys and 10 girls. There were 16 students of color, most of whom were Black, and 4 White students. The math class lasted about 2 hours a day and included a 15-minute break. The teacher of the math class is the focus of this study. The teacher is a White woman with extensive experience teaching elementary mathematics. She is also a prominent scholar of education who has publicly expressed her commitment to challenging racism and other forms of oppression through everyday teaching practices; I chose to study this context because of that commitment.

Data Sources

Data for this analysis were drawn from a larger collection, including video records of the 2017 mathematics class from two cameras capturing different angles of activity, daily lesson plans, and scanned classroom artifacts, such as student notebooks. I attended the 2017 program as a participant observer in a remote viewing room. I took daily field notes including descriptions of events as well as my questions and reactions for the pre-brief, math class, and debrief. I also wrote daily reflective memos. In addition, several months after the summer program, I conducted two 30-minute semi-structured interviews with the teacher about her approach to challenging racism through teaching. Both interviews were audio-recorded and transcribed.

Analytical Approach

Data reduction. I focus my analysis on whole-class discussions because that was the predominant activity structure for Days 1 through 6 of the 2017 class. I was particularly interested in discussions that surfaced tensions and complexities in the teacher's efforts to enact her antiracist commitments. To locate video segments of whole-class discussions and begin identifying particular moments of interest, I watched videos of the class in chronological order and created content logs. I selected one segment of whole-class discussion from each day of instruction, using shifts in classroom activities to bound each episode (Jordan & Henderson, 1995). I transcribed six classroom episodes, parsing discourse into one *message unit* per transcript line (Bloome, Carter, Christian, Otto, & Shuart-Faris, 2010). As defined by Bloome et al. (2010), a message unit is "the smallest unit of conversational meaning" (p. 19). Within a given talk turn, a speaker might impart multiple messages (e.g., thanking a student for contributing and then posing a question to the class). I separated such message units when transcribing to enable more nuanced coding.

Coding. Given that this paper focuses on findings related to my second research question, here I detail my process for coding classroom transcripts. I used *process coding*, or descriptive codes in the form of gerunds (Saldaña, 2016), to characterize the teacher's moves and practices in classroom interactions. I generated one process code for each line of classroom transcript. I also selectively used *versus codes*, such as "addressing distractions vs. maintaining momentum in discussion," to flag tensions and conflicts within the teacher's efforts (Saldaña, 2016). While coding, I iteratively consulted literature on teaching to inform my interpretations (e.g., Ball & Wilson, 1996; Hammerness & Kennedy, 2018; Noblit, 1993), considered insights from interviews with the teacher, and drafted analytic memos (Hesse-Biber & Leavy, 2011; Saldaña, 2016). I sorted all process and versus codes into categories to notice patterns and incongruities (Saldaña, 2016). Finally, I re-watched videos of the six classroom episodes and reread my field notes, reflective memos, and video content logs to recall relevant context, refine analytic claims, and bolster reliability (Cho & Trent, 2006).

Researcher Positionality. Recognizing that my positionality and subjectivity as a researcher inevitably shape the meanings I construct, I aim to transparently name my stances. I am a White woman and former elementary teacher who struggled to conceptualize and enact mathematics teaching that simultaneously supported student learning and challenged racism. Moreover, as a mathematics teacher educator, I am committed to describing and analyzing the complex work of teaching in ways that are pragmatically useful for supporting novice teachers to take on antiracist commitments. I am particularly invested in unpacking the tensions and challenges of antiracist work for White women, as White women make up the overwhelming majority of preservice teachers I work with and over 80% of the U.S. educator workforce is White (U.S. Department of Education, 2016). In addition, I recognize the problematic tropes and histories of well-meaning White women adopting a "savior" mentality (Matias, 2013) as well as liberal, colorblind frames in teaching children of color (Brown & Reed, 2017; Warren & Talley, 2017). To complicate and unsettle my own assumptions and inclinations as a White woman, I deliberately looked to perspectives of scholars of color. I also sought out alternate interpretations of data through discussion with critical colleagues (Jordan & Henderson, 1995).

Summary of Preliminary Results

What did the focal teacher do in the context of leading whole-class mathematics discussions that could be considered antiracist work? Based on my analysis of classroom episodes, I argue that the teacher in question engaged in antiracist work in three domains: (a) planned and routine moves and practices; (b) in-the-moment responses to student behavior; and (c) ongoing interpretation of classroom events. These results are preliminary in that they reflect initial, high-level analytic claims that will be further refined and evidenced when presented with specific classroom episodes. Given the brevity of this report, I summarize categories of the teacher's efforts rather than provide detailed illustrations of particular moves in practice. Brief examples and explanations are included to illustrate the kind of classroom interactions that led to these categorizations. I now turn to describing each domain.

Planned and Routine Work: Broadening Participation and Competence in Mathematics

One area of the teacher's work that challenged racist ideas and structures consisted of the pre-emptive, deliberate moves the teacher made to shape the learning environment and create spaces for students to engage productively with each other and the mathematics. This domain reflects the goals and considerations the teacher put forward in lesson plans, shared with adult observers during pre-brief sessions, and described in interviews. Practices in this domain include efforts to build relationships with students, such as taking care to learn and use students' preferred names, and efforts to depart from seemingly-arbitrary school rules, as with discussions of student and teacher contracts. This domain also includes the teacher's efforts to expand notions of what constitutes mathematics and mathematical smartness and to support broad participation in mathematical discourse. The teacher shared in interviews that she tries to challenge the idea that "Black children don't make mathematics" and to disrupt patterns of "experience[s] that I'm imagining that they may have had with White teachers," including not being seen as smart (Interview 2). Thus, the teacher's proactive practices are premised upon recognizing and deliberately countering racist stereotypes that link children's race with their mathematical ability and perceived smartness.

The teacher engaged in numerous practices that reflect her efforts to broaden the meaning of mathematics and mathematical smartness for her students. For example, the teacher used challenging mathematical tasks with multiple entry points and varying solution spaces, including problems with infinitely many solutions and problems with no solutions. She also emphasized constructing sound mathematical explanations over finding correct answers and invested considerable time in scaffolding and supporting mathematical explanations from students who might have otherwise been positioned by their peers as less mathematically capable. The teacher consistently positioned students of color as making important mathematical contributions, saying things like, "Can you say that again? What you said was really important and I want to make sure everyone hears it." The teacher also highlighted students' agency in deciding what made mathematical sense and how they might participate. She routinely offered multiple ways for students to participate in whole-class discussions, including the options of reading problems, interpreting tasks, posing a new problem, calling on peers, presenting solutions, explaining solutions, and restating ideas. Following my working definition of antiracist work, the teacher's planned and routine practices reflect attempts to counter racist stereotypes and depart from entrenched racial patterns in school mathematics.

Responding to Tensions and Challenges in the Moment

The previous domain consisted of things the teacher could plan for and intentionally construct over time in the classroom space. I now turn to more immediate and unanticipated interactions — how the teacher responded in the moment when student behavior posed challenges and raised tensions. Drawing from my process and versus codes, I separated tensions and challenges into two broad categories: (a) situations involving minor disruptions which the teacher generally handled using commonplace redirection strategies, and (b) situations involving more persistent or egregious disruptions that occasioned novel responses from the teacher. For both categories, I consider the teacher's responses a space for antiracist work because of the well-documented pattern of disproportionate discipline of children of color (Darby & Rury, 2018; Girvan, Gion, McIntosh, & Smolkowski, 2017; Skiba, Michael, Nardo, & Peterson, 2002; Smolkowski, Girvan, McIntosh, Nese, & Horner, 2016). Teacher-student interactions around behavior and discipline carry weighty implications for questions of racial bias and the perpetuation of racial inequalities. Through her momentary responses to challenges, the teacher had the potential to feed into or actively counter negative stereotypes of children of color as being out of control (Milner, Cunningham, Delale-O'Connor, & Kestenberg, 2019) or incapable of discussion-based, challenging mathematical work (Battey & Leyva, 2018).

Routine redirection. When students engaged in commonplace, minorly distracting behaviors like talking with peers, laughing, or commenting out of turn, the teacher responded using strategies suggestive of student-centered and culturally responsive classroom management approaches. For example, the teacher often used physical proximity to students, whole-class reminders to look at the speaker or to listen carefully, and mathematical questions to refocus students on the discussion. These strategies focus on what students should do, operating on the assumption that students want to participate successfully, rather than taking an accusatory or punitive tone. This is consistent with the student-centered *Responsive Classroom* approach to classroom management (e.g., Charney, 2002). Such redirection strategies avoid publicly reprimanding or punishing students for misbehavior, thereby protecting children's dignity (Darby & Rury, 2018). In addition, the teacher's comments in debrief sessions revealed that she consciously chose not to address behaviors if they did not interfere with other students' learning and were solely matters of teacher preference. Choices to ignore certain student behaviors, such as wearing a hood in math class, evoke the culturally responsive classroom management stance that teachers' behavior preferences reflect specific racial and cultural assumptions (Weinstein, Curran, & Tomlinson-Clarke, 2003). Thus, the teacher worked to prevent manifestations of racial bias through her routine responses to minor challenges.

More pressing challenges and complex tensions. Aside from commonplace distractions and minor disruptions, the teacher had to navigate several more complex challenges while orchestrating class discussions. For instance, at times students' side commentary positioned the student who was presenting as lacking mathematical competence, which may have caused emotional harm. Other times, the level of background noise was persistent and distracting enough to make a coherent mathematics discussion untenable. In each of these situations, the teacher's routine redirection strategies were insufficient for returning to or bringing about a productive mathematical discussion. Given that these are the sort of behavior issues that could easily escalate and contribute to racist patterns of disproportionate discipline, I think the teacher's ways of responding constitute a particularly important space for antiracist work.

One of the teacher's responses to these non-routine challenges was giving the class an impromptu task so she could speak privately with an individual student. This approach again protected the dignity of the student being addressed (Darby & Rury, 2018). Another two teacher responses were having students write a "note to self" about goals related to the student contract and making meta-comments about how the class discussion was going. When the teacher responded in these ways, she recognized students' positive contributions, such as doing "amazing thinking," alongside things students needed to work on, such as listening carefully to each other. While the teacher's responses sometimes had the potential to position individual children as troublemakers, the teacher's commentary in debriefs indicated that she was determined not to conflate students' actions in a particular moment with their mathematical abilities, effort, or overall character; she saw each interaction as just one window into students as growing, multidimensional people. This suggests a commitment to countering deficit perspectives about students of color throughout tense, challenging classroom situations.

Ongoing Interpretive Work

A third category of antiracist work was the teacher's ongoing interpretation of classroom events. As scholars of reflective teaching (e.g., Zeichner & Liston, 2014) have documented, teachers often engage in analysis and sensemaking of how lessons and activities unfold, including framing and reframing problems. Given that the focal teacher worked in a context with many adult observers, she routinely made public many of her reflections and analyses. I consider the teacher's ongoing interpretation of classroom events a space for antiracist work because of the potential for deficit framing to bring about damaging patterns in teaching and learning. Teachers' framing of problems such as why students are not volunteering to participate in a discussion, delimits the range of pedagogical solutions they consider and can have profound implications for students' learning opportunities (Horn, 2007). Thus, I argue that framing and explaining classroom events is a space where the teacher engages in antiracist work at an ideological level, but with material implications for student learning and identity development.

The teacher's navigation of racial ideologies in relation to classroom events was particularly evident in her comments during pre-brief and debrief sessions. For instance, when adult observers made suggestions or posed questions that called attention to gaps in students' mathematical understanding or concerns about student behavior, the teacher actively resisted characterizing students in deficit terms. Instead, the teacher regularly pointed to students' mathematical strengths and offered explanations for student behavior that were external to the students themselves. Specifically, the teacher spoke about conflicts between students and disruptions to whole-class discussions as instances where "the social channel" was temporarily louder than the mathematics. The teacher saw students' behavior as understandable given their prior relationships with each other, and she strategized about how to restructure class activities to tap into students' genuine interest and strengths in mathematics. The possibility that the problem was inherent to the students themselves was never entertained. This interpretation of classroom challenges notably departs from deficit ideologies that would frame children of color as lacking in intellectual ability or moral character (Darby & Rury, 2018) and suggests that part of the work of antiracism in mathematics teaching is leveraging an unyielding commitment to seeing and building on the strengths of students of color.

Discussion and Conclusions

This preliminary characterization of one teacher's antiracist efforts while leading whole-class mathematics discussions raises several issues for research on antiracism and mathematics teaching practices. One question is how to think about implications of the teacher's positionality in doing antiracist work. In other words, how does it matter that in this case the teacher is a White woman and that most of the students are Black? This is a question that many texts on equitable mathematics teaching or student-centered classroom management fail to tackle (cf. Boaler, 2016; Charney, 2002; Featherstone et al., 2011; Smith & Stein, 2018). Yet, the identities of the teacher and students invoke particular narratives, stereotypes, and societal injustices that complicate interpretations of classroom interactions, especially with regard to uses of power and authority. For example, there are widely recognized patterns of White women teachers being overly punitive and controlling of Black children's bodies (Battey & Leyva, 2018; Brown & Reed, 2017; Epstein, Blake, & González, 2017; Ferguson, 2001; Smolkowski et al., 2016). If the teacher being studied here were Black rather than White, that particular macro-level pattern would not be invoked in the same way. At the same time, stereotypes that are rooted in narrow, Eurocentric conceptions of mathematics and intelligence (Davis & Martin, 2008) could be reinforced by teachers of any race or gender. In interviews, the focal teacher explicitly described making efforts not to fall into the same patterns that many White women teachers perpetuate. Thus, the teacher's awareness of the relevance of broader patterns of injustice to the identities of herself and her students seemed to inform the particular ways she exercised power and authority in her mathematics teaching. That is, the teacher's identity mattered in her navigation of the line between oppressive and non-oppressive uses of power. Future research could explore how the tensions of antiracist mathematics teaching shift or persist in relation to teachers' identities.

In addition, considering various conceptions of power suggests different ways of navigating tensions stemming from social identities and societal patterns. Bloome et al. (2010) describe three perspectives on power: power as a product, power as a process, and power as caring relations. If exercising power includes centering care for students' well-being, then a teacher might pursue antiracist uses of power through caring. Yet, as Thompson (1998) and Rolón-Dow (2005) demonstrate, notions of care also stem from racialized assumptions and perspectives, namely, White feminist interpretations of care are often colorblind and emphasize niceness, varying significantly from Black feminist interpretations which highlight honesty and authenticity in making sense of racial realities. Thus, there is tension in figuring out how to exercise power and demonstrate care for children of color as a White woman in ways that do not reinforce Whiteness and perpetuate racism. Therefore, teachers' interrogation of their own social identities and assumptions seems central to navigating inherent tensions in pursuit of antiracism.

This exploratory study of one teacher's efforts to pursue antiracism through leading whole-class mathematics discussions suggests that there is great complexity to analyzing race and racism in everyday classroom interactions. Existing literature on mathematics teaching and on antiracism offers little support for teachers in recognizing and navigating these complexities and tensions at the level of day-to-day classroom practice. My findings suggest that additional work is needed to identify and analyze specific mathematics teaching moves and practices in relation to broader antiracist projects. Research that explores challenges that novice elementary teachers face in taking up antiracism, as well as how teaching considerations change in light of different teacher and student identities could inform justice-oriented, race-conscious approaches to mathematics teacher education. To avoid the pitfall of turning studies of teaching practice into superficial prescriptive checklists (Philip et al., 2018), researchers must continually attend to complexity and tensions stemming from identity and power structures. Furthermore, mathematics teacher educators must endeavor to support teachers in the critical analytical and interpretive work of considering how everyday teaching practices relate to macro-level narratives and patterns. The work of antiracism in leading whole-class mathematics discussions and teaching elementary mathematics is not simple; it is ongoing, socially-situated work.

Acknowledgments

I am grateful to Leah Bricker, Maisie Gholson, Nicolas Boileau, Emanuele Bardelli, and Michael Ion for providing critical feedback on earlier versions of this paper. I also want to thank Deborah Ball, Naomi Jessup, and Jacqueline Handley for being supportive thought-partners.

THE MATH AGENCY OF THREE EMERGENT BILINGUALS WITH IDENTIFIED LEARNING DISABILITIES

Juanita Silva
Texas State University
jsilva@txstate.edu

I present study findings that depict three Latinx emergent bilinguals' mathematical agency with identified learning disabilities in 12 discussions centered on the framework of children's mathematical thinking. I utilized qualitative analysis methods to illustrate how they exhibited agency as the power to express their mathematical thinking and make sense of story problems. I argue that when children are given opportunities to voice their thinking in any language and choose how to solve word problems, they are capable of understanding the content and are able to justify their thinking. Implications are offered for the math instruction of emergent bilingual children identified with a learning disability.

Keywords: Emergent Bilinguals, Latinx, Equity

The term "emergent bilingual" (Garcia & Kleifgen, 2010) identifies children as having the potential to become bilingual over time while still utilizing their native language. Unfortunately, the mode of instruction for these children often focuses on memorizing English vocabulary or mathematical procedures (Moschkovich, 2015). Even more problematic is that Latinx emergent bilinguals with identified labels, such as a learning disability (LD) or math difficulties, are often exposed to instruction that focuses on direct explicit instruction (e.g. Brosvic, Dihoff, Epstein, & Cook, 2006). Arguably, these methods of instruction reduce student learning and create barriers that deny them access to mathematical practices (e.g., Carpenter, Ansell, Franke, Fennema, & Weisbeck, 1993) and rich discourse (e.g. Moschkovich, 1999, 2015) that can promote mathematical understandings (e.g. Hunt, Welch-Ptack, & Silva, 2016).

This work is an alternative to reductionist instructional frameworks, positioning instruction as a vehicle to promote access for Latinx emergent bilinguals to mathematical practices utilizing their strengths (e.g. use of prior knowledge and native language) such that they promote mathematical understanding (Quintos, Civil, & Torres, 2011), bolstered achievement (e.g., Webb, Franke, Ing, Wong, Fernandez, Shin, & Turrou, 2014), and increase opportunities to enact mathematical agency (e.g., Turner, Dominguez, Maldonado, & Empson, 2013). I examine the following research question: How do three Latino/a emerging bilingual children labeled with learning disabilities and/or difficulties develop mathematical agency when exposed to mathematical practices?

Conceptual Framework: Promoting Agency for a Marginalized Population

This research is grounded in supporting and extending ways in which children from underrepresented populations can enact agency. I define *agency* as the capacity for children to make their own choices and to enact choices on the world (Holland, Skinner, Lachiotte, & Cain, 1998). Research on agency with Latinx children is of particular interest to many scholars (Gutstein, 2003; Sanchez-Suzuki Colegrove, & Adair, 2014; Turner, 2003). For example, Sanchez-Suzuki Colegrove and Adair (2014) aimed to defy deficit thinking by showing the possibilities of minority Latinx children to do mathematics when given choice. Relatedly, Turner and colleagues (2013) identified positioning moves that allowed these children to build agentic identities through participating in problem solving discussions designed to promote opportunities to share thinking.

In this study, I borrow from Turner's (2003) definition of *critical math agency* which she defines as children's capacity to "(a) understand mathematics, (b) identify themselves as powerful mathematical thinkers, and (c) construct and use mathematics in personally and socially meaningful ways" (Turner, 2003, p. 48). From Turner (2003), I take up children's capacity to "understand" and "see themselves as powerful math thinkers". Thus, I define *mathematical agency* as children's *power* to (a) *make sense* of mathematics and (b) *take ownership* of their mathematical thinking. I define making sense of mathematics as when children are able to understand their solutions and connect those solutions to the word problems they are solving. The term "power to take ownership of mathematical thinking" is defined as children's ability take action on their mathematical thinking.

One way to foster *mathematical agency* is to provide opportunities to participate in mathematical practices that allow choice and the use of prior knowledge (Jacobs & Empson, 2016; Turner et al., 2013). In this study, mathematical practices are defined as those that allow the engagement of children's (a) participation in problem solving situations, (b) invitation to discuss mathematical thinking with others in any language and (c) choice to justify and elaborate on thinking. Over the past several decades, these practices have demonstrated the potential to enhance children's learning and achievement (Webb et al, 2014). Furthermore, in a study conducted by Chval and Pinnow (2018), the teacher's positioning of children's first language as a resource and the sharing of children's thinking allowed students to thrive in building mathematical knowledge. Solving math problems in ways that make sense and discussing mathematical ideas in any language with others were important in developing agency, as are the social learning environments where children can critique the mathematical reasoning of others.

Methods and Data Sources

The case study involved three Latino/a emerging bilingual children, Julia, Martin and Gabriel, in grades three and four from an elementary school located in an urban city in the southern United States. Participants were purposively selected based on the following criteria: (a) Latino/a children who were identified as ELLs, and (b) children who had identified math difficulties (e.g. Tier 3 identification under Response to Intervention model (Fuchs, Fuchs, & Hollenbeck, 2007) or cognitively defined labels of LD. Children who had cognitively defined LD labels were those children who had individualized education goals in math (IEP), sustained, low performance on math standardized exams, and performance measures via the Woodcock Johnson test of achievement and tests of cognitive abilities.

Data collection consisted of 12 instructional sessions that lasted approximately 50 minutes for seven consecutive weeks. Sessions occurred in an after-school setting in a conference room equipped with large tables, manipulatives (i.e. unifix cubes), paper, pencils, and a whiteboard. The instructional sessions were planned by the author and a research assistant using a teaching experiment methodology (Cobb, 2000) to investigate children's enacted agency when engaged in the discussions about each child's mathematical thinking. Base ten and fractional tasks (Carpenter, Fennema, Franke, Levi, & Emspon, 2015) grounded in problem solving were used to support reasoning and sense making.

During the sessions, children were supported to solve problems in whatever ways made sense to them, communicate verbally in any language they were most comfortable, and ask questions

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

about the problems. The teacher-researcher presented children with appropriate story problems, encouraged use of children's prior knowledge, and facilitated discussions and the use of teacher moves to promote agency. Some the teacher moves included were (Jacobs & Empson, 2016) ensuring that children were making sense of the word problems, and assigning competence to children's ideas (Gresalfi, Martin, Hand, & Greeno, 2009; Turner et al., 2013). The data collection process yielded three primary sources of data: video recordings of the sessions, instructor and research assistant field notes, and children's written work.

Data analysis of the sessions was collected as three embedded case studies (Yin, 2009) consistent of ongoing analysis (Powell, Francisco, & Maher, 2003) of the teaching experiment sessions and constant comparison analysis (Glass & Strauss, 1967). I select partial data segments that clearly illustrated changes in one child's agency over time in the findings below.

Findings

The iterative process of coding, comparing and refining yielded three types of mathematical agency: (a) *Limited Math Agency*; (b) *Developing math agency* and (c) *Enacting math agency*. *Limited math agency* refers to a child using procedures without making sense of the mathematical ideas and any actions that might indicate a refusal to participate in sense making. *Developing math agency* refers to a child's capacity to make sense of their mathematical ideas and might begin to share these ideas with peers and the teacher. *Enacting math agency* refers to a child's capacity to make sense and take action on their mathematical ideas. In enacting math agency children will most likely engage in discussions to take up, justify, and argue someone else's ideas.

Below, I illustrate how agency evolved for Gabriel and the teacher moves (e.g., problems written in English and Spanish; read aloud of problems in in both languages) that, in large parts, promoted children's participation in the math practices and, arguably, advanced their agency. All children exhibited limited, developing and enacting agency at one point in the twelve sessions; all had positive shifts in their agency from limited to enacting. Further details of all three children will be presented in session.

Gabriel's Agency

Gabriel began solving word problems by using standard algorithms without connections to the context. In initial sessions, Gabriel explained his final result but refused to share his reasoning behind the final result, thus exhibiting *limited agency*. At first, it was difficult to engage Gabriel in the story problems in an authentic way, but after the third session, I considered that Gabriel was not making a connection to the problem context because he was not interested in the story context that were presented. Thus, in session four, I made a significant change to the story problem where I changed the context from tamales to soccer balls. At first, he didn't seem to understand the context, because when Gabriel explained his answer he exclaimed that it was nine because he had added six and three together. I therefore suggested to Gabriel that he find a second and different strategy. As I turned my back to him, and began to attend to Julia's strategy, I noticed he began to use his fingers. Gabriel began counting six fingers one at a time, then repeated his actions two more times, as if he was counting up to six, then counted up a second set of six and one final set of six. After he counted he immediately shouted "it is 18" so I followed up with some questions.

Teacher: I saw you using your fingers.
Gabriel: No.

Teacher: Its ok to use your fingers, I use my fingers all the time. How did you use your fingers?
Gabriel: [Silent]
Teacher: Did you count 1, 2, 3, 4, 5, 6, [Pauses] 8, 9, 10…or were you doing…
Gabriel: [Shakes his head from side to side indicating a no] I was, I added 6 and 6 that's 12 and added another 6 and it was 18.

Gabriel had begun to make sense of the problem when the context was changed from tamales to soccer balls but failed to completely take ownership of sharing his finger strategy. In this instance Gabriel was exhibiting mathematical agency as *developing*. He was beginning to take ownership of his mathematical ideas, and in seeing them as valid strategies.

Later, Gabriel not only became comfortable sharing his mathematical thinking with others but also began to justify his thinking with others. For example, in session 5, Gabriel began to engage in conversations with Martin about their strategies. In this excerpt, Martin and Gabriel are sitting on the floor. While Martin worked on his strategy Gabriel looked over his shoulder. Martin had solved the problem by making six circles and four dashes in each to represent the soccer balls.

Gabriel: Six? [Gabriel use a questionable tone]
Martin: [Turns and looks at Gabriel] Yeah, he has 6 bags
Gabriel: It is five [Gabriel shows Martin five fingers and references his strategy on his paper]
Martin: Yeah [Martin smiles at Gabriel]
Gabriel: Why did you put six? [Gabriel begins counting to himself the dashes on Martin's paper to verify it is 24] 23?
Martin: No, there is 24 right here [Martin assures Gabriel there are 24 dashes not 23, and smiles at him]
Gabriel: Anyway, you have to put five on each of them [Gabriel points to his circles and dots on his paper] not four.

In this exchange of ideas, Gabriel was trying to convince Martin that his strategy was correct. Gabriel first initiated the conversation by questioning Martin's final answer of six bags. Martin seemed confident about his answer of six bags because he thought the problem said four soccer balls in each bag, instead of five. Gabriel's questioning did not discourage Martin from keeping his answer, so Gabriel took it upon himself to explore the details of Martin's strategy. After noticing the fours inside the circles, Gabriel began to argue with Martin, stating that the problem said five (soccer balls) and not four as Martin had in his strategy. Gabriel realized he had to look at the details of Martin's strategy to find the inconsistencies. Such actions produced Gabriel to take complete ownership of his ideas and succeeded in helping Gabriel make sense of Martin's strategy and locate the source for the mistake in Martin's strategy. Thus, Gabriel exhibited math agency as *enacting.*

Gabriel began to take risks in sharing his ideas about his peers' strategies and in posing mathematical arguments as the sessions progressed. Overall, Gabriel gained a sense of pride in his ideas and his methods for solving problems.

Implications and Discussion

The findings of this study reveal that these children were "able" to make sense of word problems, took ownership, and were empowered to co-construct mathematical thinking with peers. Gabriel shifted from non-explanation for solutions to taking risks in sharing his thinking. Findings point toward an alternative framing of instruction from the majority of research in special education research which supports explicit, directed instructional approaches (Woodward, 2004). If the aim of research and practice is to increase equity for all, then I suggest that special education and mathematics research integrate mathematical practices that promote choices for children to use their native language, work in small groups or individually, and have opportunities to share their thinking with peers into instruction in future studies.

Keywords: Instructional Activities and Practices; Equity and Justice

Introduction

Professional noticing of children's mathematical thinking (PN), as a conceptualization of responsive teaching practice, is the subject of much focus within the mathematics education research community (Sherin, Jacobs, & Philipp, 2011). Our goal was to examine such biases within the component skills of PN and the extent to which they may be influenced by perceptions of ethnicity and gender. The research question was: *How and to what extent does bias emerge within preservice teachers professional noticing of children of differing perceived genders and ethnicities?*

Methodology

An electronic survey was fielded nationwide resulting in a total of 151 completed surveys, with participants being primarily 18-24-year-old white females. PSTs were asked to respond to three prompts (distributed randomly across four cases aimed at eliciting biases related to race/gender)– each aligned with a particular component skill of PN. We examined frequencies per component skill (i.e., attending, interpreting, deciding) rather than by case (i.e., Margaret, Shaquan, William, Miguel) to make some determination regarding the overall presence or absence of bias within participants' enactment of PN.

Findings

Interestingly, participants provided attending and deciding responses that were predominately neutral in nature while participants' interpreting responses were much more varied with respect to biased descriptions of the child's mathematics in a given case. We conducted a chi-square test of the attending ($\chi^2(3)=307.68$, $p<.001$), interpreting ($\chi^2(3)=14.54$, $p=.002$), and deciding ($\chi^2(3)=391.49$, $p<.001$) components and determined that each distribution of rating categories was statistically significant ;however, both the attending and deciding components featured predominately neutral responses while the interpreting component contained mostly non-neutral responses. As such, we disaggregated these responses per case. Examining participants' responses across perceived ethnicity reveals a relatively balanced expression of bias among asset, deficit, and both response types. While participants were slightly more likely to offer an asset-laden response to describe Shaquan's mathematical thinking and a deficit-laden response to describe William's mathematical thinking, we did not detect a disproportionate amount of a particular rating type. We note that, for all four cases, fewer participants offered neutral responses when interpreting the child's mathematical thinking. Much more often, participants interjected some form of bias into their interpretations.

MATHEMATICS AS A CONSCIOUS RAISING EXPERINCE: A BRIDGE TOWARDS SOCIAL TRANSFORMATION

Ricardo Martinez
Iowa State University
ricardom@iastate.edu

Ji Yeong I
Iowa State University
jiyeongi@iastate.edu

This study explores preservice teachers engaging in a ratio activity connecting the wages of men and women to the number of men and women in government positions. Mathematical learning expands the critical literacy framework reading and writing the word situating mathematics as the world itself. Furthermore, the bridging of mathematics, the self and the world, was constructed by incorporating the theory of conocimiento(s) in analyzing how critical consciousness is developed within a mathematics task. This study shows mathematical learning as a conscious raising experience in investigating social injustices towards acts of social justice.

Keywords: Equity and Diversity, Social Justice, Teacher Education-Preservice

Introduction

The purpose of this study is to learn how male pre-service teachers (PSTs) experience a mathematical task that explores wages earned by women and men in various occupations. To compare wages, an activity composed of five tasks using data taken from the 2016 U.S. Bureau of Labor Statistics was used in conjunction with the use of ratios and the creation of mathematical equations. The task was created with the intention of creating a learning space where PSTs would be able to reflect upon the content being learned and were provided with an opportunity to create a figure/diagram to share out any findings. Wherein the activity looked to situate learning in/as a form of revolutionary praxis, the union of action and reflection towards social transformation (Freire, 1976). More so, revolutionary praxis requires a critical consciousness, a socio-cultural-historical-political understanding of the world with the individual acknowledgement of being able to change the world. This study explored how a mathematics activity could transform learning into a conscious raising experience. To understand consciousness development during the learning mathematics, theories of conocimiento(s) (Anzaldua, 2003) were compared with how critical conscious is developed in reading and writing the word (Freire & Macedo, 2005), both described later. Wherein it is impossible to have a critical consciousness without multiple forms of conocimientos.

Without praxis in mathematics, mathematics becomes nothing more than a mechanical process. Any mechanical process can then become a dehumanizing force, shifting the learner from a position of subject to object (Freire, 1970; 2018). Teachers, students and researchers will be unable to address critical issues in mathematics without focusing on the entire experience of learning mathematics. Hence this study focuses on PSTs because "[p]rospective teachers … need to begin to develop the political and ideological clarity that will guide [students] in denouncing discriminatory school and social conditions and practices." (Bartolome, 2004, p.119). The political and ideological clarity Bartolome spoke of is in line with critical consciousness and reflects the political power of teachers controlling learning in the classroom (Giroux, 1988). The activity created for this study uses ratios, algebraic generalization and re-representation of data to make meaning of the real world. The research question driving this study is, "how do pre-service teachers develop critical consciousness through a ratio, algebraic generalization, and representation mathematics activity?"

Literature Review

Critical Consciousness

A critical consciousness is defined as a socio-historical-political-cultural understanding of society with the self-awareness of being able to contribute to change in society (Freire, 1970). Critical consciousness is an elastic concept given society is in constantly flux (Freire, 1970; 2000; 2018). Prior to the development of a critical consciousness, is what Freire (1973) calls a transitional consciousness. Those with a sense of critical consciousness are always in between transitional and critical consciousness. Individuals not seeking critical consciousness are said to have a naïve consciousness (Freire, 1973) where they have been rendered objects due to dehumanization (Freire, 1970). Relative to developing critical consciousness, are ideas of praxis, critical literacy and conocimiento(s). Furthermore, Freire and Macedo (2005) provide a critical literacy approach in reading and writing the word (described later) which inherently allows for a socio-historical-political-cultural understanding of world. The praxis behind reading and writing the world is a revolutionary praxis (Freire, 1970) that requires a critical consciousness. Related to a transitional consciousness, Anzaldua (2004) offers conocimiento, seven stages of how consciousness changes (described later) that provide a more refined way of mapping naïve to transitional to critical consciousness development.

Identity, Mathematics, and Dehumanization in Mathematics Education

Learning how to socialize is inherent in learning mathematics because teaching mathematics is a political act that impacts students understanding of the world (Gutierrez, 2017). Knowing that mathematics is part of the socialization, and identity development of learners helps educators identify factors that contribute to students' futures (Jackson, 2010). Insofar to say the connection between identity and learning is not an unknown relationship (Martin, 2010). Wherein utilizing the identities of students in the learning of mathematics has a growing body of research (Aguirre, 2013; Celedon & Ramirez, 2012; Civil, 1998; 2014; Martin, 2010; Wood, 2013). Specifically, Aguirre, Mayfield-Ingram and Martin (2013) "define a mathematics identity as the dispositions and deeply rooted held beliefs that students develop about their ability to participate and perform effectively in mathematical contexts and to use mathematics in powerful ways across the context of their lives" (p. 14). Although students' identities need our attention, we must also consider the role of the teacher and how their identities impact students (Macedo & Bartolome, 1997). Specifically, if we do not pay attention to students' identities then learning becomes a dehumanizing experience (Gutierrez, 2018) where students are never fully seen or heard and where teachers cannot fully meet the needs of students (Civil, 2014). Teachers (and researchers) need to focus on the development of young learners by paying attention to identity, which should be part of the daily life work of teachers (Aguirre, 2013).

The idea of humanization and dehumanization stems from the work of Paulo Freire regarding dialogue and the learning process known as a problem posing education, a humanizing approach and banking education, a dehumanizing education (Freire, 1970; 2000). A dehumanizing approach to education silences students, ignoring their identities and views students as mere objects. Shifting to mathematics education Gutierrez (2018) offers eight dimensions of humanizing practices for mathematics educators with ideas of participation/positioning, cultures/histories, creation and ownership, all having a direct connection to identity development (Nieto, 2018). Furthermore, a full discovery of identity and humanization allows for individuals to discover or (re)discover their own agency and allows for the development of a critical consciousness (Shor & Freire, 1987). As previously mentioned, viewing the identities and even roles of teachers and students as interchangeable not only negotiates the power of the classroom (Shor, 2014) but also echoes Fasheh (1982) in that, "[t]here is a price for teaching math in a way that relates it to other aspects in society and culture which may result in raising the "critical consciousness" of the learners. (p. 288)."

Critical Literacy, Mathematics, and Critical Consciousness

Mathematics as a form of critical literacy can best be summarized by Gutstein's adaptation of Freire and Macedo's (2005) *Literacy: Reading the word and the world* framework that Gutstein (2006) calls reading and writing the world with mathematics (RWWM). Freire and Macedo's framework is a way to understand the world by understanding the previous world through critical literacy (Freire, 1998). Critical literacy is the ability of communication and reflection inherent in being able to read and write (Freire, 2018). The ability to reflect and communicate is a necessity for revolutionary praxis. Gutstein (2006) developed RWWM and incorporated the role of mathematics to read the current and previous world. A "[c]ritical mathematics literacy enables the oppressed to use mathematics to accomplish their own ends and purpose" (Lenorard, 2010, p. 326). Being able to read and write the world within a critical literacy paradigm leads to empowerment and understanding of one's own agency (Freire, 1970; 2005). Knowing how to read the world and understanding one's agency directly relates to critical consciousness and (re)humanizing mathematics. Where a critical mathematics agency requires individuals to be see themselves as capable and powerful mathematical learners when participating in mathematics in personal and social ways (Aguirre, 2013).

Conceptual Framework

In welcoming the connection between mathematics and the social world, the conceptual framework of reading and writing the word (Freire & Macedo, 2005) was utilized and paired with the theory of conocimiento(s) (Anzaldua, 2003; 2015), which also acted as the analytic framework for this study putting emphasis on mathematics as a way to discover both self and the world. The teaching of mathematics should reflect the social and physical environment when learning, with such an approach augmenting a deeper understanding and imagination (Joseph, 1987). The physical environment is constantly engaged when learning math directly or indirectly, as is the political nature of learning mathematics (Gutierrez, 2018). Furthermore, as Martin states "exposing the links between mathematics and social interests should not be a threat to mathematics" (1997, p.175).

In the understanding of social and structural problems, Freire and Macedo introduced the critical literacy framework, reading and writing the word (2005). Where the reading or understanding of the world requires the reading of the word and in order to read the word one must first read the previous reading of the world (historical awareness). The writing of the world which follows the reading of the world then becomes the new world (Freire, 2005). Where the learning of mathematics is the simultaneous act of learning more about mathematics, the world and self. Insofar to say the world cannot be understood without understanding how the individual fits in said world. The bridge between the conceptual and analytic framework can be seen in the reflection on how consciousness shifts towards the development of a critical consciousness.

Methods

To observe the process of mathematical learning of PSTs while identifying stages of conocimiento(s), a single holistic (Stake, 1995) qualitative case study bounded by the duration of the activity, was conducted. The study focused on understanding how PSTs engage in a contemporary issue that does not require the control of human behavior (Yin, 1998). In this study, the case is bounded by the space time of a classroom in a large Midwest university. The unique feature of this case is the looking at wage disparities between men and women in the U.S. using ratios. The facilitator of the activity was a participant observer and main researcher behind the study. The data includes written reflections from the PSTs after each task and a culminating reflection at the end of the entire activity. Written individual reflections were written prior to group discussions and used to triangulate findings. Group discussions along with whole class discussion were recorded.

Analytic Framework: Conocimientos

Conocimiento(s) consists of seven stages and represents a change in consciousness wherein to say an individual that has experience a conocimiento(s) is no longer the same person (Anzaldua, 2015; Keating 2008). The result of no longer being the same person changes an individual's identity because gaining conocimiento(s) results in action that would be impossible without, the aforementioned, change in consciousness (Anzaldua 1999; Keating, 2016; Lara, 2005). Furthermore, conocimientos is a pivotal theory in the epistemological understanding of the interconnectedness of all people (Keating, 2006) which leads to self-discovery of one's own freewill upon the world (Anzaldua, 2015). This interconnectedness allows for the individual to be interconnected with not only others but with mathematics itself. The seven stages of conocimiento(s)—a non-linear, non-sequential and cyclical (both a cycle and/or repeating) process of consciousness (Anzaldúa, 2003)—described in Table 1, will act as the analytic framework in analyzing the data.

Table 1: Stages of Conocimiento(s) (Anzaldúa's, 2003)

Stage	Description
el arrebato	This is the stage that kicks you out of your comfort zone. This is the stage that pushes you to learn/change. It can be a positive or negative experience.
nepantla	This is the clash of worlds and or ideas both the friction and overlap of two or more thoughts. Since we are always learning we are always in nepantla but necessary not aware of it.
coatlicue	This is the pain of knowing and the realization that you need to change. The coatlicue stage is also known as deconocimientos representing that learning and growing never stops.
compromison	This is the realization that nothing in this world is fixed, which implies change is possible.
putting Coyolxuhqui together	This is where you reinvent yourself as a new person. The transformation that results from fragmentation of self, both positive and negative experiences that you learn from.
the blow up	This is the realization that change has happened and that you are a new person. It is where/when it is first internalized that change has occurred.

shifting realties	This is an internal/external spiritual transformation of being conscious of others, a shift from how this affects the individual to how this affects the world. The act of changing.

Participants

All four of the participants were White male PSTs from Iowa, taking a secondary mathematics methods course in 2017 at a large predominantly White mid-west university. All participants are traditional undergraduate mathematics majors that were one semester away from student teaching. All participants were under the age of 22. The course they were taking did not focus on the development of critical consciousness nor did any other mathematics methods course specifically focus on critical consciousness in the 4-year university-based teacher preparation program. Three of the four PSTs have previously taken one course on multicultural education that is part of the institution’s teacher preparation program. The methods course where data was collected consisted of 12 students, six male and six females.

Task

The task was developed to be part of an algebra methods course with the intent to raise critical consciousness of the learner, where “critical consciousness is brought about not through an intellectual effort alone, but through praxis – through the authentic union of action and reflection” (Freire, 1973). The role of groups was designed to allow students to interact with each other because students need to support each other in meeting their goals (Zacko-Simth, 2013). The understanding of ratios, generalization, and re-representation were the topics covered throughout the algebra methods course. Ratios were selected because the concept is frequently connected to the real world and proportional reasoning is a difficult topic to learn/teach (Lamon, 2007). Generalizations were selected to provide PSTs with the opportunity to make conclusions based on the difference of data over time (Driscoll, 1999). Generalizations allow for the extrapolation of data. Re-representation was incorporated into the activity because of its potential in being the action component of the activity. Re-representation allows learners to reword and reflect on what they have learned using visual representation. The study consisted of an activity created by the researcher comprised of five parts described in Table 2.

Table 2: Task Overview

Part	Student Engagement/Action/Reflection
1	View raw data from 2016 U.S. Bureau of Labor Statistics of weekly median incomes.
2	Construct ratios of weekly women median income to weekly men median income and find the value of ratios. Participants reflected individually then as a group on real-world context of the ratios.
3	The generalization task uses the value of the ratio(s) and creates an equation to predict what happens after a year.
4	Ratios of the numbers of men to the number of women in the US Senate and House of Representatives along with the relationships in state governorships were constructed to the value of each ratio. Participants reflected individually then as a group on real-world context of the ratios.
5	Re-representation of the entire activity.

Analysis

In Vivo coding was conducted (Creswell, 2016) due to its usefulness in thematic analysis (Saldana, 2016), wherein short phases were analyzed. Thematic coding has emerged as a rigorous approach in analyzing themes (Fereday & Muir-Cochrane, 2006) where Braun and Clarke (2006) provided six phases for thematic analysis: (1) *Familiarization with the data*, (2) *Coding*, (3) *Searching for themes*, (4) *Reviewing themes*, (5) *Defining and naming themes* and (6) *Writing up*. After *Coding* was completed in *Reviewing themes* an analytic memo was written for each code. The analytic memos were part of *Searching for themes*, specifically a generative theme emerged from each analytic memo. In Vivo coding was then conducted and accompanied with/by analytic memos for each code. The memos were then coded using the analytic framework. The reflection written on worksheets were used to triangulate and in the reviewing of coding. Next, the codebook was created, see the sample in Table 3.

Table 3: Sample of Codebook

Stage	Code Description	Example invivo codes(s)
C1 – *el arrebato*	Related to discomfort or excitement caused either by the mathematics or by the context or connection to the real world	"a lot of numbers" "You are right holy crap I don't know what to tell her that sucks"
C2 – *nepantla*	Related to the comparisons of mathematics, professions, genders, history and other structures	"so we write ratio as a fraction or what" "because women are dominantly known as teachers, have always been, way back in the day they make less than we do"

Findings

Part 1

The start of the activity provided multiple *el arrebato'*s due to the context of the problem. Mathematical shake ups range from being overwhelmed by the data, "a lot of numbers" to being overwhelmed by the difference in wages (the context) "they should be on the same pay scale" to discovering things by doing mathematics "Men make 700 more dollars … oh wow." This shows that viewing and discussing real world data provides an entry (*el arrebato*) and an environment (*nepantla*) to explore the world. What we found was that the data allowed the PSTs to find contradictions to the view that men always earn more than women by finding cases where women make more. For example, one student said "I got one I got one where women make more" being surprised and excited (*el arrebato*) to find a contradiction (*compromision*) to the fixed idea that men always earn more.

We then began to see a comparison (*nepantla*) not only of wages but of number of employees. The comparison of wages and number of employees can be seen in one PST exploring elementary/middle school teachers where "like 80% women" and another PST asking, "what's the wage" only to hear the wages and say, "wow that is a big jump." The mathematical discrepancy directly relates to the real-world disparity in wages between women and men and to the results in of PSTs trying to justify the differences. At this stage of the activity the mathematics was limited to additive comparisons of not only individual professions but across, as can be seen when one PST said, "weird it is so small when women make more [yet] when men make more it's like a thousand dollars more."

Part 2

In the second part of the activity a shift from direct additive comparisons to the use of ratios, which was expected as a direct result of the task. The shift to using ratios from direct comparisons while exploring different professions among women and men is *nepantla* on multiple levels. On one level when a PST said "so we write ratio as a fraction" ratio and fraction represent the clash of two mathematical sets or worlds. Specifically, the use of ratios was naturally *nepantla* as a ratio represents the relationship between two quantities and even how ratios are represented can be seen as *nepantla* within *nepantla* as one PST said "there are 17 females to 100 males or .17 to every one male." On other levels we see; the comparison of professions in comparing police officers to engineers to teachers; or the comparison of expertise in questions posed by the PSTs like "do you think that has to do with levels of expertise?"; or historical comparisons "because women are dominantly known as teachers, have always been, [since] way back in the day;" or by breaking the border between the mathematical world of the activity and the ones individual world as can be seen in comments like "they make less than we do." Additional *el arrebato's* occurred during task two of the activity. The first was related to limitations of being unable to generalize claims with one PST saying, "from the data we cannot make any conclusions" and another saying, "doesn't matter I am not an expert." The second manifests when unexpected outcomes occur in the real-world data, as one PST said "so why is that not the case for education" in being shocked at male teachers making more even though there are more women in the profession. In this part of the task *el arrebato* and *nepantla* leads to *coatlicue* or the pain of knowing and can be seen when it was said "that the problem [is] you only have four tenths of a teacher." Whereby directly stating a problem hints there needs to be a solution implying the realization of change.

Part 3

Part 3 of the activity began with a shake up as the group selects a profession and one individual saying, "ours is going to be awkward" where a PST's ability of estimation led to *el arrebato*. The group was already aware of the difference in the weekly median income along with the unit rate relationship between men and women but in creating a formula for "*n*" many weeks they discovered "after a year, men have made 10,920, nearly eleven thousand [dollars] more" encountering *el arrebato* once more. Furthermore, in *nepantla*, in the comparison of positive and negative values the group discussed when it would be appropriate to use a positive difference (men – women) versus a negative difference (women – men). One PST said they would always subtract the numerically larger value from the numerically smaller value to ensure a positive number with another replying that means you will always use women subtracted from men only to hear "that was a low blow." Calling it a low blow is a direct result of *coatlicue* and the pain knowing that leads to a *shift in reality* as the conversation connects negative values with disadvantages in saying "it depends on how you want to see the data."

PSTs' reflection on this activity provides an example of a shift moving from *coatlicue* to the *blow up* to the *el arrebato* stages of conocimientos. When asked how the activity makes you feel, one PST instantly said "this makes me feel like shit" this pain shows the realization of change (*the blow up*) because the next statement said "it's like [am] back at my therapist. Here the individual is connecting what was learned in this task to internal transformation. This cause *el arrebato* in others as they default to say, "I don't have feelings" and "men don't have feelings."

Part 4

The beginning of this activity was *el arrebato* as the worksheet for task 4 had 19 women senators and 71 non-women senators which does not equate to 100 senators. Knowing there should be 100 senators shows that the PSTs do have a political understanding of society.

Furthermore, a *shift in realties* can be seen as PSTs look up how many governors are women only to discover "8% of governors are women" as they declare it a "fun fact." One again this reflects the *blow up* of being in *nepantla* in discovering how women are represented in the government because "for every four men there is one woman." As the PSTs travel outside the task in *shifting realties* they discover currently there are "six women governors so the number is going up" a *compomison*, a reminder that the world is not fixed.

At the end of this activity a PST repeated the statement "I can neither deny or confirm this because I am no expert." The first time it was said it represented only *neplantla* because he was in between denial. The PST initially made the claim of not being an expert then became silent. The second time the same PST said "I can neither deny or confirm this because I am no expert" shows a changing by the PST not staying silent and offering his "guesstimation" on how he sees the percentages of women. The act of "guesstimating" represents a *blow up* and *shift in reality*, while the change from silence to speaking reveals a new person, *putting Coyolxauhqui together*.

Final Reflection

When asked how all parts are related, one PST said "it takes money to run for government, right, if all these dudes are out here making more money than there in government more" followed by another PST stating "guys are making more money, so they are donating more and who are they donating to probably guys." This brief exchange shows a *blow up* for both individuals in better understanding why more men may run for office. The following exchange occurred when PSTs were asked "would you use this activity in your future classroom?":

PST A: I would adapt it to talk about what they, the students want to be in the future"
PST D: It would be discouraging if a girl comes up and says I want to be an engineer.
Researcher: what do you tell the girl?
PST D: I say … um … Oh I don't know
PST B: You are right holy crap I don't know what to tell her that sucks
PST C: life is not fair
PST A: She could be the outlier

PST A engages *nepantla* by saying the activity would be useful because of its real-world application then shifts to a *blow up* in wanting to adapt the problem specifically to what learners want to be in the future. PST D then confronts a potential *el arrebato* in the potential pain of knowing (*coatlicue*) for young women engaging in the activity. A further shake up comes when the group was asked what they would say to the young women who discovers she will earn less compared to a man. PST D does not know what to say as he experiences *el arrbato*, while PST B and P PST C are in *coatlicue* a realization that something needs to change. PST A has a shift *in reality* in offering to tell the young women she is not in a fixed world (*compromiosn*) because she can be an outlier.

Discussion

The findings show that stages of conocimientos can be experiences throughout this mathematical activity. The activity provided PSTs with one way to understand the current world by understanding how wages and government forces interact. The tasks within the activity provide a way to read the world as PSTs write the world by engaging in the problems. In going through the task, learners experienced opportunities to gain conocimiento(s) and shifted their consciousness. In bridging ratios of wages and ratios of governmental representatives the PSTs discovered injustices. Discussion on injustices with mathematical discoveries of ratios represents a shift towards developing a critical consciousness. Where "men make more in all my categories" (*nepantla*) is both reading and writing the world in looking at men and women while doing the mathematics to show they are not making equal wages. *Nepantla* alone only represents a naïve consciousness. To say "life is not fair" (*el arrebato*) is one way to read the world, saying "you would adapt it to talk about what is … the future" (*putting Coyolxuhqui together*) enters a transitional consciousness in writing the world. The *coatlicue* and *the blow up* stages of conocimiento(s) are respectively engaged in reading the world where the activity "makes me [PST] feel like shit" while discovering "it is like the rich get richer." Still in transitional consciousness the PSTs wrote the world by saying "it depends on how you use the data" (*shifting realties*) and telling future young women that they "could be an outlier" (*compromison*). Once out of *nepantla* the other six stages only represent a transitional level of consciousness and an imperfect understanding of world. The moment all stages of conocimiento(s) are lived then critical consciousness emerges as a socio-political-historical-cultural understanding in changing reality. Wherein bridging mathematics and conocimientos provides a path to see how mathematics is inherently part of self and world towards the transformion of mathematics itself.

RHETORICOCENTRISM AND METHODOCENTRISM: REFLECTING ON THE MOMENTUM OF VIOLENCE IN (MATHEMATICS EDUCATION) RESEARCH

David M. Bowers
Michigan State University
bowersd2@msu.edu

In this brief research report, I provide a humanist exploration of the constraints of methodocentrism and rhetoricocentrism in our field with particular attention to equity and the propagation of racial (gendered, sexualitied, etc.) violence as reified through the methodological and rhetorical norms of the field of (mathematics education) research. In short, I argue that (1) methodological norms constrain the practice of research in ways that protect White interests, and (2) rhetorical norms further constrain the reporting and dissemination of research in ways that protect White interests. I then conclude that mathematics education research will not be able to adequately address issues of social justice unless these norms are systemically broadened.

Keywords: Doctoral Education; Equity and Justice; Research Methods; Systemic Change

The 41st Annual Meeting of the North American Chapter of Psychology in Mathematics Education invites the mathematics education community to consider the expansion and growth of mathematics education research "...against a new horizon," with particular attention to equity and to the inherent contradiction between normative perceptions of growth/value and the concomitant violence of displacement and marginalization. With that in mind, this proposal seeks to create a space for reflection and conversation around the manifestations of this contradiction in mathematics education research (and research on human beings more broadly), feeding the flames of a larger meta-study of mathematics education research praxis. In particular, this manuscript takes an active stance "against" a looming horizon of uncritical *scientism* that fails to adequately grapple with the unavoidable subjectivities of research performed on human beings by human beings (Howe, 2009; Latour, 2004). Through critical analysis of our (mathematics educations researchers) own subjectivities, perhaps we can better approximate some truth (Kofman, 2018) and more productively stand against the momentum of raced (and gendered, sexualitied, etc.) violence (Kendi, 2016) echoing through the normative practices of our discipline (Bowers, 2019; Coe, 1994; Fendler, 2014; Howe, 2009).

This manuscript will focus on two specific arguments, couched primarily within the tools and paradigms of Critical Race Theory (Delgado & Stefancic, 2001) and Genre Theory (Miller, 1984) - though it is hoped that the conversation thus invited will extend beyond these two arguments and theoretical foundations: (1) Methodocentrism in our field curtails the ways we can make sense of the complexity of humanity in ways that privilege White (cis-male, hetero, etc.) perspectives (Howe, 2009), and (2) rhetoricocentrism further restricts the voices of the marginalized to appease White (cis-male, hetero, etc.) ears (Bowers, 2019; Coe, 1994) through pathosphobic norms. Though these restrictions do not exhaustively cover the sometimes unacknowledged or uninterrogated subjectivities of our practice, they are emblematic of broader norms and trends (Bonilla-Silva, 2015; Leonard, 2009) whereby localized discourses and events act as pieces of larger social narratives which construct and reify White Supremacy within and beyond mathematics education research (Martin, 2009). Following the exploration of these two arguments, I will conclude with implications for future (mathematics education) research practice.

Methodocentrism: Laplacean Dream and Scientific Nightmare

> Since the early nineteenth century, many in the Western world have dreamt of ordering life and reality around the certainty of facts, the predictability of the future, the stability of isolated phenomenon, the universalization of mathematical thinking, the necessity of hypothetical/deductive thinking. This is the Laplacean dream… For this Laplacean science, 'a description is objective to the extent which the observer is excluded and the description itself is made from a point lying de jure outside the world' (Prigogine & Stengers, 1984, p. 52). This view has led to the creation of experimental methods in the sciences which involve a reduction of 'natural' complexity in order to focus attention on measuring specific aspects, or variables, of a phenomenon. As a result, Western science becomes caught up in what we call 'methodocentrism': the belief that particular, pre-formed methods can guarantee the validity of an intellectual investigation into the world by factoring out the vicissitudes of the observer's entanglement with the world (see Said, 1979, pp. 9–10). To use a word that is crucial for Stengers's (1997) conception of science, *methodocentrism* is about trying to minimize the 'risk' of intellectual investigation, an avoidance that *ultimately produces bad science.* (Weaver & Snaza, 2017, pp. 1055-1056; emphasis added)

In the article quoted above, Weaver and Snaza (2017) critique methodocentrism, which they define as the belief that the predetermined method(ology) one chooses to guide research determines its validity, legitimacy, and trustworthiness. Their critique, grounded in science studies and posthumanism, argues that methodocentrism is deeply implicated in anthropocentric and colonialist politics. The argument I put forth here diverges from Weaver and Snaza in two notable ways: (1) I further define methodocentrism to refer to and connote the normalization of quantitative and qualitative methodologies to the exclusion of other research paradigms (Howe, 2009), and (2) I adopt a humanist rather than posthumanist stance in response to concerns that posthumanism can be recolonizing in how it potentially draws attention away from the ongoing humanist projects of social justice and equity (Gholson, 2019).

I will frame this argument using two conceptual tools: (1) the *challenges to color blindness and neutrality* tenet of Critical Race Theory (Delgado & Stefancic, 2001), and (2) application of social process genre theory (Coe, 1994; Miller, 1984) to research methodology. The tenet of color blindness prompts us to interrogate how structures, individuals, objects, or practices that seem neutral actually reinforce Whiteness and White interests; in this case, I ask how normalization of quantitative and qualitative social science methodology to the exclusion of other approaches (e.g. philosophy, history, historiography) reinforces Whiteness. Social process genre theory prompts us to examine, in this case, how the form and function of methodologies interact and interrelate in ways that encourage and/or constrain against particular ways of communicating with and interacting with the world.

As a discursive entrypoint into the broad array of observations that might be made from this theoretical foundation - a jumping-off point for any conversations this manuscript might invite - I begin where all research might be said to begin: with an idea expressed in the form of a research question. In particular, I contend that the interrelationship of form and function shaped by methodocentrism restricts the array of normalized research questions in a way that is not color-blind.

Current methodocentrist norms, which value quantitative and qualitative methodology above others, have been described as the result of attempting to reproduce the practice and perceived success of the natural sciences to the study of human behavior (Gage, 1989). As a byproduct of this history, socially-constructed value has been placed upon social science research questions which can be verified or falsified through relatively straightforward empirical testing (Howe, 2009), and consequently upon questions that do not directly wrestle holistically with the complexity of racism and White supremacy (or any other hegemony); such focus on smaller compartmentalized pieces of racism serves very real and destructive functions in hegemonic discourse, both insofar as "compartmentalizing complex wholes into disparate pieces facilitates the naming and ordering of those pieces and parts in order to have dominion over them," (Patel, 2016, p. 19) and in the sense that focus on individual parts and factors obscures more holistic views and makes it more difficult to challenge overall systems (Patel, 2016). Furthermore, social-value has been placed on research questions which might be described as *objective*, which here might be best translated as "having no visible emotional component and eliciting no conscious emotional reaction." Thus, a question like, "Is there evidence of an achievement gap between White students and students of Color" might be valued above asking "how does racism dynamically and intersectionally manifest and reify itself in the context of high stakes assessment?" even though the former question shields White interests through a failure to name the larger structure of racism as an object of inquiry. Similarly, a question like "how does student racial identity influence mathematics achievement" might be valued above asking "how does White supremacy influence mathematics achievement" due to the strength of the emotional reaction the latter might generate in a reviewer (DiAngelo, 2011), even though the former question tacitly endorses and reifies "postracial" racism through failure to identify and critically wrestle with White supremacy (Bonilla-Silva, 2015).

At this juncture, I wish to highlight that no research question can be truly objective. All research questions are constructed and expressed by people based on their own beliefs, interests, and value systems; no research question has ever been expressed truly absent of emotion, tied up as these questions are in the passions and professional livelihoods of those who ask them. Even the most sterile looking question is guilty of pulling at heartstrings, for within a system of social values that looks favorably on such questions, they will be met with goodwill. Rather than removing pathos from research questions, such articulations merely cloak it, shielding subjectivity from interrogation and critical analysis. Research questions that shield themselves from critical analysis represent *bad science*, and it is time that we as a field made conscious efforts to adopt a more transparent and critical set of methodological norms.

Rhetoricocentrism: The Tyranny of Genre

> What we learn when we learn a genre, such as the genre of academic writing, '…is not just a pattern of forms or even a method of achieving our own ends. We learn, more importantly, what ends we may have…' (Miller, 1984, p. 165). (Bowers, 2019, p. 290)

In the prior section on methodocentrism, part of what I argue is that the fruitless search for "objectivity" has created a system of social values in (mathematics education) research which shields White interests, at the very outset of asking a research question, through the encouraged veiling of researcher subjectivity and pathos. Here, I further contend that this veiling of pathos and emotion continues to constrain researchers and protect White interests at the other end of the research process: the writing up and dissemination of findings.

Consider a researcher, synthesized from the experiences of myself and others, who is conducting research that reflects the complex holism of humanity, such as work at the intersection of race and gender (e.g. Crenshaw, 1991) in the context of mathematics classrooms. This researcher, dedicated to the cause of social justice, is motivated in their work (at least in part) through either personal experience of intersectional marginalization or through empathic connection to those who have experienced such marginalization (Foote & Bartell, 2011). To draw their readers in, frame their argument, and establish an empathic foothold for their readers' shared interest in this work, they begin their manuscript with a quote that evocatively expresses intersectional violence:

> I am very glad to find that in most points I am so fortunate to be of one mind with General Armstrong, who has done more than any one else to help the enfranchised blacks on their way towards a true citizenship. I regret to differ from him in my estimate of the value to the negro of a high purely literary education. The time may come when such a training will bear the same relation to their inheritances that it does to those of the literate class of our own race, but **as a rule the little colored girl was right: 'You can't get clean corners and algebra into the same nigger.' That combination is with difficulty effected in our own blood. The world demands *clean corners*; it is not so particular about the *algebra*** [original emphasis in italics]. (Shaler, 1884, p. 709)

This quote serves several important roles for this researcher's manuscript, but it violates rhetorical norms that demand the veiling of pathos in content and reader reaction; consequently, one or more editors suggest that the quote be removed. In my conversations with researchers whose work acts in opposition to violence and injustice, I find that some version of this story is not at all uncommon. Such researchers are faced with a choice: (1) Remove the evocative quote or language, allowing for publication at the cost of contributing to postracial and other posthegemoic narratives (Bonilla-Silva, 2015), or (2) keep the evocative quote because it serves an important role, risking rejection from publication in so doing.

This particular interrelationship of social value and written form (Miller, 1984) that correlates the socially constructed ideal of objectivity with the veiling of emotion might be reasonably termed *Pathosphobia*. In Aristotelian terms, mathematics education researchers are encouraged to make visible appeals to logos (rational appeal) and ethos (ethical appeal, such as the regular use of citations to convince readers of the author's credibility), but to keep pathos (appeal to emotion) covert for fear of being perceived as biased. Sadly, this veiling of pathos tacitly endorses White supremacy, both through a failure to name it (Bonilla-Silva, 2015) and through weakening the ability of researchers to provide reader's with all-important empathic footholds (Foote & Bartell, 2011) by which to make sense of work that critiques and responds to violence.

Conclusion

To briefly recapitulate, this proposal seeks to create a space for reflection and conversation around the manifestations of conflict between normative perceptions of growth/value and the concomitant violence of silencing and marginalization in mathematics education research (and research on human beings more broadly). In particular, I have argued that methodocentrism and rhetoricentrism constrain researchers in ways that obscure rather than reduce subjectivity, ultimately serving to protect White interests.

I echo the sentiments of Patel (2016): In order to advance (mathematics) educational research, we must begin "with an intentional reckoning with the worldviews used to formulate, conduct, and share research." (p. 20) Though this broad suggestion potentially means many things, and different things for different people in different contexts, one of the things it seems to mean in light of the argument I have forwarded here is that we need to make a conscious effort to identify and reckon with methodological and rhetorical norms that restrict our fields capacity for self-critique and antiracist activism (Kendi, 2016).

KNOW YOUR TERRAIN: A CROSS-CASE STUDY OF TEACHERS' ATTEMPTS TOWARDS EQUITABLE LEARNING

Ruth N. Urbina-Lilback
Naugatuck Valley Community College
rurbina-lilback@nv.edu

Mary P. Truxaw
University of Connecticut
mary.truxaw@uconn.edu

Scholarship on equitable math teaching has demonstrated that knowledge of students is key. But how is the practice field using this knowledge in today's educational context? This paper reports findings from a cross-case analysis on teachers' use of knowledge of their students to advance mathematical learning. Four algebra teachers in grades 9 – 14 joined us on an inquiry process to understand their practice. The teachers worked in institutions with high representation of students from underserved subpopulations and demonstrated a stance on equity. A cross-case model is presented describing the central phenomena in the teachers' use of knowledge of their students. Findings elucidate understanding of situated practice in support of equitable learning.

Keywords: Equity, Instructional activities and practices, Algebra and algebraic thinking, Teacher knowledge

Purpose

The National Council for Teachers of Mathematics (NCTM) has called on teachers to act in support of equitable teaching (NCTM, 2014). Yet, leading scholars have noted that teaching mathematics equitably is challenging (Strutchens, et al. 2012; NCTM Research Committee, 2018). Much of the work on equitable teaching showcases exemplars of frameworks and/or perspectives on equity (e.g., Bonner & Adams, 2012; Gutstein, 2016; Ladson-Billings, 1995a), but does not tell us enough about day-to-day complexities that teachers face as they attempt to support equitable outcomes in their classrooms. This paper reports findings from a cross-case analysis on four teachers' attempts to advance their diverse students' learning in grades 9 – 14 based on what they knew about their students (Urbina-Lilback, 2018). A model describing the central phenomena on teacher's use of knowledge of their students is presented.

Perspectives

Through a critical synthesis of the literature on equitable math teaching, we identified common core characteristics. We found that whether equitable math teachers were reflective and proactive about equity (e.g., Bonner & Adams, 2012; Felton & Koestler, 2015), built on students' lived experiences (e.g., Aguirre & Zavala, 2013; Rubel, 2017), and/or held high expectations for their students (Ladson-Billings, 1995b), they needed to *know their students* (Ladson-Billings, 1997). These core practices required teacher's knowledge and use of students' backgrounds and lived experiences – for example, language use and associated positioning (Civil, 2014; Moschkovich, 2002), relational patterns and interests (Gay, 2000), practices and funds of knowledge (Civil, 2016), etc. Moreover, what teachers knew and used about their students was highly dependent on their teaching context, including the particular student make-up of the classroom. This recognition is not new. Gutiérrez (2002) argued that equity in math education could be advanced by recognizing its situated nature, focusing on "what it takes to enact particular practices, especially ones that relate to certain kinds of students" (p. 171).

Based on the interdependence of the teachers' practice and its context, we employed Lave's

(1991) situated social practice framework to study the teachers' practice. We positioned the teacher, as the implementer of this practice, and studied the teacher in activity, with and arising from the socially and culturally structured world of the teacher. Additionally, we framed what teachers "knew" about their students considering both cognitive and sociocultural perspectives.

Methods

We combined ethnographic (Emerson, Fretz & Shaw, 2011) and case study methods (Yin, 2014) to explore, document, and interpret teachers' situated practice and perceptions (Yin, 2014). We purposefully recruited and selected participants – specifically, math teachers who taught algebra or algebraic applications, and worked in institutions with at least 25% representation of students from underserved populations (e.g., ethnic minorities and/or low SES). From this pool, we obtained recommendations from relevant sources and self-report data from the teachers' related to educational equity issues. Four teachers that met these criteria accepted our invitation and participated in this research. Pseudonyms are used for teachers and schools.

Participants and Context

Beth and Shannon both worked in a high school with at least 79% students of color and 56% students were eligible for free and reduced lunch. Their math program was tracked. We observed Beth in an Algebra 2 course in the lowest track during a unit on rational exponents. Shannon was the only math teacher in a Sheltered Language Instruction program. We observed one of her Algebra 1 classes in a unit on systems of linear equations. Eddy worked in a high school with at least 65% students of color and at least 70% were eligible for free or reduced lunch. The math program was tracked. We observed Eddy in two of his Algebra 1 classes, both in the lowest of placement. Dena worked in a two-year public institution where at least 28% students were of color and about 39% students were of low SES (based on Pell Grant data). We observed Dena in a Quantitative Analysis course during a unit of probability.

Data Sources and Analysis

We observed each participant for the length of a unit of study (approximately a month). Data sources included: teacher interviews and check-ins, ethnographic field notes, audio and video recordings of lessons, samples of student work, and other teacher specific artifacts the teachers used to interpret their students' learning and/or their instruction.

In the first stage of data analysis, we used multiple coding strategies to capture the teachers' use of knowledge of the student—for example: selective coding (Glaser, 1978) beginning with a start list of codes derived from the literature (Miles & Huberman, 1994) and simultaneous coding (Saldaña, 2009). We used constant comparative methods (Strauss & Corbin, 1998) and triangulation of data to uncover patterns related to knowledge of the student, teacher behaviors and learning goals. In the second stage of analysis, we conducted within-case analyses using explanation building methods (Yin, 2014), including pattern codes (Miles & Huberman, 1994).

To uncover deeper structure, we iteratively built analytic models for each case. Through a cross-case analysis, we generated a comparison profile for a cross-case model. All patterns were tested with the individual models and the cross-case model. This paper focuses only on the cross-case model, but it represents the result of the full analytical process.

Results

Analysis uncovered knowledge of students across cases, how teachers used this knowledge, challenges to their use, and the teachers' learning goals. Due to space limitations, we focus on common knowledge of the students used across the four cases and we share the cross-case model that captures the central patterns. Please access the full study for details (Urbina-Lilback, 2018).

Common Knowledge of the Student

Teachers used a wide variety of categories of knowledge of their students, ranging from mathematical aspects (e.g., student thinking) to nonmathematical aspects (e.g., competing priorities outside the classroom and family support). Some of these forms were highly situated, like teachers' understanding of students' mathematical learning development. Of this wide range of knowledge categories, ten knowledge categories were evident in all cases (see Table 1).

Table 1: Knowledge of the Student Used Across All Cases

Mathematical	Mathematical AND Nonmathematical	Nonmathematical
Mathematical Thinking	Learning Attitudes	Cultural Dissonance
Foundational needs	Ownership Over the Learning	Competing Priorities and/or SES Challenges
Language and Structure of Math		Personal Characteristics or Conditions
Mathematical Strengths		

We provide a description here for two categories that are central in the larger phenomenon across cases – mathematical thinking and ownership over their learning.

Mathematical thinking. Teachers highly prized students' mathematical thinking. Most of the classroom activities that teachers facilitated centered on students' exchange of mathematical thinking. Teachers deliberately sought students' partial understanding as opportunities to learn. Mathematical thinking often involved two other categories of knowledge, specifically – foundational needs and mathematical language and structure. Mathematical thinking was found to be both a means and an end and, thus, a central form of knowledge of the students.

Ownership over their learning. Each teacher articulated particular indicators related to students' ownership over their learning. Common indicators included: responsibility in working outside the classroom to do homework and/or study and coming in for help outside the classroom times. In all cases, ownership over the learning process was construed as a form of self-advocacy. Analysis revealed that this was a central form of knowledge of the students.

Cross-Case Model: Your Thinking Can Empower You

The cross-case model (see Figure 1) illustrates the forms of knowledge of the student used across cases, how teachers used that knowledge, the factors that challenged or supported the teachers' knowledge use in practice, and the teachers' learning goals. The model captures the central patterns across all cases. We work from left to right in the model to briefly describe its components and also the larger phenomena that it represents.

Knowledge of the student. There were ten common knowledge categories (see Table 1). In the model, we list only nine to start with. The last one – ownership over their learning – was a characteristic the teachers worked to develop as a long term goal.

Teachers' learning goals. Knowledge about students was filtered through teacher's learning goals – both short term (e.g., how to do a particular problem) and long term (e.g., developing perseverance, self-advocacy skills, organizational skills or problem solving skills).

Teacher's use. This category refers to experiences that teachers created and/or facilitated to support their students' learning. Teacher's use was highly situated and influenced by knowledge of their students and learning goals. Teachers' use of knowledge of their students both mediated and moderated the learning experience. The model depicts the moderating role with two possible outcomes – **engagement** (and/or math thinking) or **low target** (students not engaged in learning).

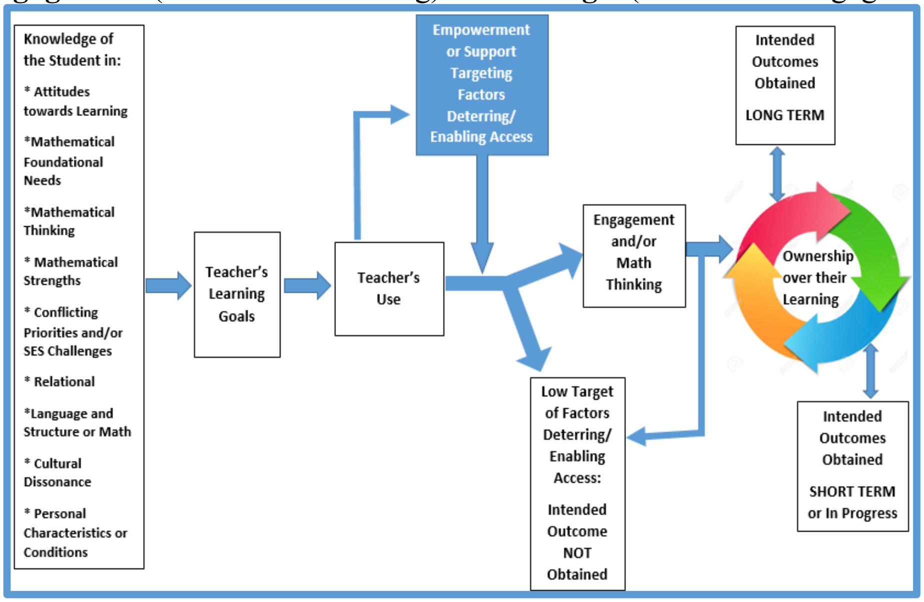

Figure 1: Cross-case Model – Your Thinking Can Empower You

Empowerment or support targeting factors deterring/enabling access. Even when teaching goals aligned with teachers' use, the effort to empower students needed to target particular student needs. Teachers' use depended on how much the teacher knew their students and also on how much the interventions targeted the particular needs. When teachers' empowerment did not target (or the target was very low), the students were less able to engage in learning.

Low target of factors deterring/enabling access. In some cases, teachers ascribed a negative or positive value (or both) to what they knew about their students, depending on whether they saw it as "deterring" or "enabling" learning. If deterring/enabling factors were not targeted (or targeted very low), students' ability to engage in math thinking was affected.

Engagement and/or mathematical thinking. Mathematical thinking was a means and an end in learning. Engagement in this central practice mediated students' development of more long-term outcomes that supported students with their ongoing learning.

Ownership over the learning. Each teacher provided descriptors and indicators of what ownership over learning meant for their students – for example, college and career readiness, mathematical muscle, organizational and self-advocacy skills, and perseverance. In some cases, intended outcomes were in the process of being developed, thus, **in progress** or **short term**. In other cases, intended outcomes were met, empowering students with a set of **long-term**, self-sustaining skills that shifted control over the learning process from the teachers to their students.

Concluding Thoughts

This study demonstrates how equity-oriented math teachers use knowledge of their students within their situated practice furthering both short term and long term learning goals. Mathematical thinking and ownership over learning are central to the cross-case model. Also relevant is that the teachers use many non-mathematical aspects about their students in order to enhance their mathematical learning. Findings are consistent with related research in multiple respects. They provide greater understanding of situated practice in support of equitable teaching and reflect the practice field's tendency towards empowerment through the culture of school.

STRUCTURED PARTICIPATION PROMOTES ACCESS AND ACCOUNTABILITY DURING COOPERATIVE LEARNING IN MATHEMATICS EDUCATION

Nicholas Kim

Frances K. Harper
University of Tennessee - Knoxville
francesharper@utk.edu

This study investigated how the use of structured participation, specifically group presentation roles, supported more equitable participation in doing and learning mathematics. We analyzed videos of two lessons focused on radius, diameter, circumference, and area of circles in which students worked in small groups in a STEM project-based geometry class. Students' mathematics learning was assessed by the teacher through a group presentation where students were assigned individual presentation roles. We identified themes related to access and participation in small group and whole class interactions during this problem-focused lesson and found nuanced differences in both access and participation when compared to students' typical involvement in the more common unit-wide project-based tasks. Findings provide insights into effective uses of structured participation for both group work and whole class interactions to support more equitable doing and learning of mathematics in high school classrooms.

Keywords: Equity and Diversity, Instructional Activities and Practices, High School Education, Geometry and Geometrical and Spatial Thinking

Over the past thirty years, reform efforts in mathematics education have advocated for a greater focus on sense making and explanation and justification (e.g., NCTM, 1989; NCTM, 2000; NCTM, 2014). As reforms have slowly infiltrated more and more mathematics classrooms, the exclusive use of traditional direct instruction strategies has diminished in favor of greater emphasis on peer-to-peer collaboration in small groups (e.g., Boaler, 2008) and whole class discussion (e.g., Smith & Stein, 2018). Cooperative learning strategies found in complex instruction still provide some of the most effective ways of ensuring that peer-to-peer interactions in small groups positively impact student achievement in mathematics for all levels of learners. One of the key principles of complex instruction is the delegation of mathematical authority from the teacher to students, and a common way of ensuring that every student has an opportunity to take on mathematical authority is through the assignment of roles that structure the participation of group members (e.g., facilitator, recorder). The premise of roles is for all students to have important work to contribute in their groups, without which the group cannot function. Cohen and Lotan (1997) found when students take responsibility for each other and encourage everyone to contribute equally to tasks by performing their respective roles, there is an increase in student success in terms of mathematical understanding, and Boaler (2008) found group roles helped promote relational equity within the mathematics classroom. Boaler describes relational equity as "relations that include students treating each other with respect and considering different viewpoints fairly" (p. 168).

Langer-Osuna (2011), as well as Herrenkohl and Guerra (1998), found group roles served as one means of structuring student participation. Structuring participation increases the likelihood that students become positioned as competent, mathematical authorities. Students positioned with authority participate frequently in small groups and are able to gain access to and hold the floor, are able to decide what is correct, are seen as contributing meritorious ideas, and become influential in student-led discussions (Cohen & Lotan, 1995; Engle, Langer-Osuna, & McKinney de Royston, 2008; Inglis & Meja-Ramos, 2009). Erickson and Schultz (1997) defined participation structures as interactionally marked ways of speaking and listening, getting and holding the floor, and leading and following. In complex instruction, roles are typically designed to structure small group interactions, which are not specific to the mathematics work, but instead structure how the group cooperates (i.e., facilitator, not “grapher”) (Cohen, 1994). This study builds on prior investigations of how the assignment of roles for working in small groups can promote access to mathematical understanding typically reserved for higher-achieving students who take over group assignments. We extend this work by exploring a non-traditional approach to role assignment and structure, namely assigning roles that structure how group members will present their mathematics work in a whole class setting. We considered how these presentation roles influenced more equitable access and participation among group members in both the small group and whole class settings. We theorized that, while providing access to mathematics for every learner, presentation roles might also provide teachers more ways to monitor student accountability. Thus, we aimed to investigate whether group presentation roles increased student participation differently than traditional group roles such as leader, time keeper, and materials manager for students who historically let others dominate group work activities.

Theoretical Framework

We draw on *figured worlds* as the theoretical basis for this study. People use figured worlds as a way to interpret particular actor and actions. These “worlds” are socially, culturally, and politically constructed and provide a way to “figure out” the significance of certain acts or the value of particular outcomes (Holland, Lachicotte Jr., Skinner, & Cain, 1998). As various factors (e.g., actors, actions, social/cultural/political forces) come together and relate to each other in different ways, *storylines* emerge that provide a taken-for-granted sequence of events for making meaning of actors, acts, and events (Holland et al., 1998).

For example, a possible storyline for collaborative projects in the mathematics classroom might be: “At the beginning of a project, one student takes the lead.” Students take this action for granted, but depending on who takes the lead, students make sense of that action differently. If a boy takes the lead, he is likely positioned as smart, whereas a girl is likely positioned as bossy for similar actions (Langer-Osuna, 2011). The identities of ‘smart’ and ‘bossy’ are enacted by students and assigned by their peers based on specific classroom expectations for and interpretations of actors and actions, which are in turn are influenced by broader social, cultural, and political interpretations of gender identities.

In this way, the storylines constructed through figured worlds provide the context for what counts as mathematical engagement and for how students make sense of themselves as successful or not in relation to that engagement. In other words, students’ mathematics identities are shaped as they come to see themselves and are seen by others as mathematically capable (or not) in relation to storylines (Horn, 2008). We use storylines to operationalize how students negotiated (i.e., took up, resisted, or shifted) mathematics identities in one cooperative task.

Research Design and Methods

This study was taken from a subset of data from a larger study that reviewed how students took up, negotiated, shifted, or challenged an innovative mathematics teaching approach using STEM project-based learning across an academic year (Harper, 2017). The study took place at a STEM-themed magnet school, in a low-income area of a small Midwestern city, whose mission emphasizes technology-driven project-based learning. The study took place in one ninth grade geometry classroom which consisted of 16 consented research participants. There were six males (4 white, 1 Black, 1 Latino) and ten females (9 Black, 1 Asian American). The teacher participant is a White woman who was in her fourth year of teaching. She and the second author collaborated on various projects focused on equity and social justice in mathematics education for three years, and the teacher frequently attended various professional developments on technology and equitable collaboration. The study will narrow in on one focus group of three females: Rosy, an Asian American student with high status; Carley, a Black student with high status; and Monique, a Black student with low status. We characterize students based on status rather than achievement because the construct of status recognizes that abilities in mathematics are socially constructed rather than cognitively fixed. Status is an idea commonly used in complex instruction to describe the social ordering of individuals based on perceived academic ability and social standing, where everyone agrees it is better to have a higher status (Cohen, 1994). Status can change in moment-to-moment interactions (Wood, 2013), but overarching perceptions of status influence how students describe themselves and others as “good at math” and “not good at math” in more rigid ways.

Focus Lesson Overview

Across two days, students worked in groups of three on radius, diameter, circumference, and area circle problems. The assignment was not part of a larger project, as was typical in this classroom. Instead the lesson involved problem-based learning around seemingly straightforward procedural problems through collaborative group work. The assignment consisted of twelve total circle problems, divided into four groups so that each group was responsible for presenting two or three assigned problems. Instead of the typical group roles used in complex instruction, such as facilitator, materials manager, or time keeper, to maintain accountability, the teacher assigned presentation roles for the whole class presentation to encourage engagement in the activity and accountability for individual learning in small groups. The three presentation roles were: (1) explainer, (2) question answerer, and (3) connector. The explainer was responsible for the initial explanation of the three problems; the question answerer was the only person who could respond to teacher and peer questions after or during the explainer’s presentation; and the connector had to note similarities and differences to other problems presented by other groups to reinforce the big ideas of the assignment (i.e., conceptual connections and relationships across radius, diameter, circumference, and area of circles). During the first day, students worked on agreeing upon solutions to their assigned problems and preparing for their presentation. The students used a large poster board to present their work to the whole class at the end of the first day and into the second day.

Data Analysis

The first author created detailed descriptions of the actions, emotions, and body language in videos alongside a rough transcription of what the teacher and students said across two days in which the mathematics task was enacted. We analyzed this summary of the video in Nvivo (a qualitative analysis tool) by creating codes based on the strong theoretical basis of complex instruction (e.g., status, roles) (Yin, 2009). We identified initial codes independently and then compared preliminary analyses to arrive at final codes, which the first author confirmed by applying to the video and paying attention to exactly what was said along with actions, emotions, and body language. Next, we used the final codes and references to coded instances in the video of classroom observations to continue to refine themes about who and what was granted agency in the doing and learning of mathematics. These themes helped us to identify broader storylines at play during the lesson, based on talk, gestures, actions, etc., that were collectively constructed by and guided interactions among the focus group members, the teacher, and other students in the mathematics classroom figured world. For more information on how figured worlds guided analyses in the larger study, see Harper (2017).

Findings

In this section, we present our findings as the storylines that were collectively constructed by and guided interactions among the focus group members, teacher, and other students in this particular lesson. We provide illustrative evidence of group interactions and talk that show how we came to identify each storyline. These storylines shed light on how access and participation were negotiated among group members and the teacher in both small group and whole class settings by showing who and what was granted agency in the doing and learning of mathematics. More specifically, our findings show a dominant storyline of inequitable participation and access and a momentary, emerging storyline that shows promise for more equitable access and participation following the introduction of presentation roles that influenced who and what was granted agency. The first two storylines were collectively constructed as the group members worked in a small group setting, and the third storyline was collectively constructed during the group's whole class presentation.

Dominant Storyline (Before Teacher assigned presentation roles): Only the "good" Mathematics Students Do the Mathematical Work of the Task

Rosy and Carley, as the students with high status in the group, did the majority of the mathematical work while Monique, as the student with low status in the group, did not engage with the group or the mathematics. Monique's attention was not on any relevant mathematical content, but rather her laptop where she engaged in social media and computer games even after instructed by the teacher to put away all irrelevant technology. Rosy and Carley did not try to engage or encourage Monique to participate as they had become accustomed to Monique's lack of engagement in the class through previous group activities (see Harper, 2017 for evidence of this claim about how Monique was positioned in storylines outside of this specific lesson). After Rosy and Carley discussed how to solve their assigned problems, they shifted their attention to writing on the poster board for the presentation at the end of class. At this time, Monique put her laptop away to make room for the poster board at their tables. Monique began watching Carley telling Rosy what to write on the poster board for each assigned problem, but it was unclear if she was trying to understand the solutions. Rosy and Carley were granted agency for the mathematical work as they were considered high-status students. Being a high-status or "good" mathematics student did not require including other students in the mathematical work of the group.

Emergent Storyline (After Teacher Assigned Presentation Roles): "Good" Mathematics Students Include Other Students in the Mathematical Work

The teacher introduced presentation roles and assigned them to each student after allowing the groups to work for 15 minutes. Rosy and Carley maintained ownership over the mathematical work and direction of the group, based on their status as "good" mathematics students. For example, Rosy expressed how she wanted to do multiple roles because she frequently answered teacher and student questions during individual and whole class interactions:

> Rosy: Shoot, why do we got to all have different jobs, cause like I want to be the explainer and the question answer.

> Teacher: (*After overhearing Rosy's comment*) Well you got to delegate some work out, but you guys only have #9 and #11 when you go up there.

After the teacher's insistence that all group members play a role in the mathematical work of the whole class presentation, Carley and Rosy made a noticeable effort to include Monique and encourage her participation. Carley assigned roles to her group members after this short exchange between Rosy and the teacher (maintaining authority over the group's work). She assigned Rosy to be the explainer, and Rosy agreed. Carley then assigned Monique the position of question answerer. Carley took it upon herself to be the connector even though she was confused about the role and repeatedly questioned the teacher and her group members about the purpose of the role.

After roles were determined, Rosy made the first real effort to engage Monique with the mathematical work she and Carley had completed by asking, "What do you need to be the question answer?" Monique responded so softly that it was inaudible in the video. Rosy began to explain step-by-step how she and Carley solved each assigned problem, and she made additional efforts to ensure that Monique understood the mathematical work. Namely, Rosy provided additional information about circles, such as the relationship between radius and diameter, as she explained the steps:

> Rosy to Monique: (*Carley is looking at her phone but also trying to listen to Rosy)* So, if they ask you a question… so basically, I am going to explain it but like you might have to re-explain it if they ask you a question. If they don't get it, you'll have to explain it again.
>
> So, number 11 says find the radius. So, I said the purple one is radius, right? So that means the radius is half of this line, so the information they gave us is the diameter which is this part right here. We need to figure out radius, so if the radius is 4.8, we have to, we have to split that in half. Because half of the diameter is radius. So, half of 4.8 is 2.4. Okay so it's easy to divide the diameter by 2.
>
> Number 9. So basically, we are finding the circumference of the circle. The circumference is all around the whole circle (*Rosy draws it*). Umm, the given information we have the area. The area is everything inside the whole entire circle. (*Rosy models it on paper again*) You know area right. (*Monique shakes her head yes*) Umm, so basically, we know the formula to find the area is pi times r squared and r stands for the radius. So basically, what we use, we took the area and divided it by pi because that's what we times it by... pi -r squared is the formula to find the area. We divided that by pi to cancel each other out."

Monique rarely spoke and mostly watched and listened to Rosy explaining each part of the problem. Although many might not consider this active engagement on Monique's part, this level of access to and participation in the mathematical work was a notable improvement when compared to her access and participation before the introduction of presentation roles. In both Carley's assignment of a role to each group member and Rosy's "teaching" of the mathematical work to Monique, we see both Carley and Rosy maintaining their status as "good" mathematics students who have authority over the work of the group. However, their actions following the teacher's introduction of presentation roles begin to shift what it means to be "good" mathematics students to include encouraging participation by others in the mathematical work of the group.

Dominant Storyline (During Whole Class Presentation): Only the "Good" Mathematics Students Do the Mathematical Work of the Task

During the whole class presentation, Rosy and Carley enacted their presentation roles as explainer and connector, respectively. Rosy began the presentation with an explanation of problem 9 and then problem 11 when prompted by the teacher:

> Teacher: Okay, what about #11?
> Rosy: We had to find the radius of the circle which is the point in the middle to the side of the circle, but the only information given was the diameter which is one side of the circle to the other. And um so basically, that means the radius is half of the diameter. So, we had to divide the diameter in half. 4.8 divided by 2 is 2.4."

The teacher then asked Carley to make connections to other problems:

> Carley: [Our problem] was similar to all of these problems from 15 to 9.
> Teacher: How is it similar?
> Carley: Because they to do the square and division to get rid of the multiplication (Inaudible)…

These excerpts illustrate how the teacher encouraged both Rosy and Carley to explain further or in greater detail. Thus, both Carley and Rosy, as high-status students, were positioned as student capable of learning and doing mathematics. The teacher's and other classmate's positioning of Monique, however, was noticeably different when Monique enacted her role as question answerer.

> Teacher: Does anyone have any questions for this group?
> Student 1 from another group: Why did you guys use secondary colors [on your poster]?
> Teacher: Monique, do you have an answer for that?
> Monique: Because we just wanted to use them.
> Student 2 from another group: I have a question. Why did you have to find the radius on that problem?
> Rosy: It made it easier for us to calculate 2 pi r when we have r.

In our analyses of other group presentations, the teacher enforced the individual presentation roles for all group members. The above excerpt shows how the teacher's enforcement of the presentation roles changed when Monique engaged with her role. The initial question posed to Monique was a non-academic question in which the teacher required Monique to answer based on her opinion, not on her capability to learn or do mathematics. When another student posed the second question about finding the radius, Rosy immediately answered the question before Monique had a chance to answer. The teacher enforced the roles for all other students but allowed students with high status to take on the role for a student with low status in this instance. This excerpt illustrates the power of the dominant storyline that only "good" mathematics students do the mathematical work of the task and shows how the teacher and other students were complicit in positioning Monique as someone incapable of participating in that mathematical work.

Discussion and Conclusion

Much of the research on complex instruction at the secondary level in mathematics focuses on "master" teachers who are experienced with the pedagogical approach (e.g., Boaler & Staples, 2008) or contexts in which students experience complex instruction across the curriculum (e.g., Horn, 2008). This research extends what is known from previous studies by exploring one aspect of complex instruction within a classroom where the teacher is newer to using complex instruction and where complex instruction strategies are not reinforced across the curriculum by other teachers. Findings from such investigations are important because they can shed light on how the moment-by-moment negotiations that must happen among the teacher and students to shift who and what is given mathematical agency (e.g., Harper, 2019; Wood, 2013). Changes towards more equitable access and participation in mathematics do not happen instantaneously with the introduction of strategies such as structured roles for participation. Instead, these shifts are negotiated, resisted, and (hopefully) taken up over time, and this study contributions to our understanding of how such changes to access and participation may begin. In this final section, we identify and discuss two implications based on the findings presented here.

Pervasiveness of Inequitable Access and Participation

Both the first and third findings above illustrate how powerful and pervasive storylines that encourage inequitable access in and participation in mathematics learning and doing are. In small group work, Rosy and Carley took ownership of the task by discussing and solving their assigned problems, using appropriate terminology and formulas while demanding justification for each process. Unfortunately, Monique had little involvement with the discussion. During the whole group presentations, Monique seemed to encounter yet another missed opportunity for mathematical engagement. Interestingly, the teacher consistently enforced presentation roles for high-status students, and she pushed the high-status students such as Rosy and Carley for justification and more detailed mathematical explanations. She was less consistent with her enforcement of roles for student with low status. The teacher enforced Monique's role as question answerer for a non-academic question posed by her peers but then allowed Rosy to take over Monique's role when a mathematical question was asked. We might speculate as to why the teacher allowed Rosy to take over Monique's role. Perhaps the teacher worried that Monique may not know the answer, and she wanted to avoid calling her out as the question answerer for a mathematical problem. Perhaps the teacher was happy to see Monique participating more than she typically did and wanted to encourage her to feel safe participating in the future. The teacher's knowledge of her students likely played a part in her decision to allow Rosy to take over. Regardless of the teacher's exact rationale, however, one implication to consider is that we, as teacher educators and researchers, may need to better prepare teachers to navigate the gradual and complex shift towards more equitable access and participation. Recognizing how powerfully storylines that encourage inequitable access and participation might resist change may help teachers remain diligent in attempts to incorporate strategies such as structured roles more consistently.

Variety of Roles for Structured Participation

Findings from the emergent storyline show how, after presentation roles were introduced, Monique had the greatest access to and participation in doing and learning mathematics through the whole lesson. Although Carley and Rosy maintained most of the mathematical authority, Rosy used that authority to prepare Monique for her role as the question answerer. Rosy was motivated to engage Monique because she knew that Monique needed to understand the mathematical work in order to answer any questions that arose from the explanation. Monique made an effort to watch and listen to Rosy's explanation and subsequent discussions. Monique did not provide much of her own mathematical thinking, but she made the effort to understand her group's mathematical thinking. Interestingly, a role that was intended to promote more equitable participation in whole class presentations provided greater access and participation in the small group setting instead. This shows that participation structures such as presentation roles, which are not typically associated with complex instruction, might have a larger than intended effect by providing accountability across small group or whole class settings when those roles are enforced.

Although employing various types of structured roles for participation shows promise for increasing engagement, the findings here show that increased participation does not necessarily mean greater active engagement with the mathematics. Students may be motivated to participate more because they are assigned a specific role, but if those roles are not enforced by the teacher with fidelity then students may depend on their peers to do the heavy mathematical work. A combination of the assignment of group presentation roles with teacher enforcement of such might prove an effective way of using this particular structured participation format. If students know they will need to present to the whole class as individuals in a group assignment, they cannot hide completely behind high-status students. They will have to become experts in their problem to be prepared for various question types from peers or teacher. It is the role of the teacher to explain the roles extensively as well as enforcing the roles with the same rigor for every student.

MATHEMATICS TEACHERS' BACKGROUNDS AND THEIR BELIEFS ABOUT TEACHING DIVERSE STUDENTS

Tarik Buli
University of Maryland
tbuli@umd.edu

This study investigates if there is a relationship between mathematics teachers' backgrounds and their beliefs about teaching students of color. To study this relationship, an exploratory factor analysis was conducted on a teacher beliefs survey administered to teachers who entered the New York City Teaching Fellows in the summer of 2006 or 2007. The survey items which were analyzed are rooted in culturally relevant pedagogy. Linear regression models were used to determine if there is a significant relationship between the teacher's background and each belief factor that emerged. Findings indicate that the teachers' race, college selectivity, and age at the start of their teaching career influence their beliefs about teaching students of color who are traditionally underrepresented in mathematics.

Keywords: Equity and justice; Culturally relevant teaching; Affect, emotion, beliefs, and attitudes; Social justice

In recent years there have been repeated calls to increase the talent of the teaching pool while also diversifying it. Selective alternative teacher certification programs (ATCPs) like Teach For America and Teaching Fellows programs are one mechanism for attracting academically elite talent to urban teaching, supplying large numbers of math teachers to high-poverty schools in urban districts nationally. These programs also report admitting increasingly diverse proportions of teachers of color for recent cohorts (TeachForAmerica, 2018).

A question is whether elite, generally White college graduates approach their roles as mathematics teachers differently than Black and Latinx teachers in these programs. Accordingly, what do different kinds of prospective urban mathematics teachers believe about their students of color who are traditionally underrepresented in mathematics, and those students' capacities to learn advanced mathematics? The purpose of this study is to address the research question: is there a relationship between mathematics teachers' backgrounds and their beliefs about teaching students of color in high-poverty schools?

Theoretical Framework

Esmonde (2009) explains that within the mathematics classroom, each interaction amongst members of the community, including individual students, their peers, and their teachers, contributes to constructing, challenging, and reifying their social positions. These social positions are based not only on the internal classroom dynamics, but also on the identities ascribed to individuals as part of their broader community membership. Different community memberships, including racial and cultural backgrounds, are positioned differently within the math classroom. In mathematics education literature, it is well documented that students from marginalized backgrounds, particularly African American, Native American, and Latinx students, are amongst the lowest performers on mathematics achievement tests, especially compared to White and Asian American students (Martin, 2012). Less studied is the relationship between these oft-referenced achievement gaps and the "adverse conditions under which some children are often forced to learn, the privileged conditions afforded to others, and how forces like racism are used to position students in a racial hierarchy" (Martin, 2009, p. 300).

Contrary to perspectives which hold mathematics to be a neutral, logic-based content with no social preferences, in fact mathematics "plays a unique role in producing and maintaining racial inequity in U.S. society" (Martin, 2009, p.308). In mathematics, this may manifest through racial apathy and color blindness as dominant ways to consider problems of racism and race in math environments, rather than recognizing the racialized structure in math classrooms as simply mirror images of race and racism in society at large. Racial apathy refers to the indifference towards racial inequality in society and lack of engagement with social problems related to race (Forman, 2004 [as cited by Martin, 2009]). Color blindness refers to the beliefs that societal institutions function meritocratically, so race is no longer relevant, and any race-based patterns of social inequality are due to individual or group cultural deficiencies. This ideology leads to the resulting belief that no systemic efforts are needed to respond to racialized outcomes.

Furthermore, pressure to recruit teachers who were high achievers has led to the rapid increase of alternative certification programs, which sometimes adopt "missionary-like goals relative to African-American, Latino, and Native American children and position[] White teachers as the savior of these children" (Martin, 2009, p. 305). This focus on high achievers leaves the following questions unanswered: "How do these teachers construct ideas and beliefs about mathematics ability among their students? [and] How are these constructions affected by teachers' beliefs about race?" (Martin, 2009, p. 305). Thus, while these teachers may possess mathematical knowledge, they may lack knowledge related to problems of equity and race.

This work examines how a sample of alternatively certified teachers make sense of mathematics teaching and learning for their students of color at urban NYC public schools. I examine to what degree a sample of NYCTFs agree with widely held social beliefs that may construct students of color from a deficit perspective, which in turn may limit the students' access and opportunities to succeed in mathematics. Additionally, this work considers whether there are group differences among how the sample of teachers surveyed make sense of mathematics teaching and learning for students of color. That is, do teachers' beliefs vary based on the teacher's race, age, where they grew up, and selectivity of the college they attended, with implications for teacher recruitment discussed below.

Methodology

To answer the research question, I analyzed data from a survey that included measures of mathematics teachers' sociocultural beliefs. These teacher participants entered teaching from 2006-2007 through the New York City Teaching Fellows (NYCTF), a selective ATCP that was the largest teacher training program in the United States at that time, training some 300 to 400 secondary mathematics teachers annually. Three hundred and seventy-four of the approximately 620 NYCTF mathematics teachers who entered in 2006 or 2007 took this survey in 2016 and 2017. The racial demographics of the teachers in the analytic survey were 59% White (n=219), 15% Asian (n=55), 19% Black (n=70), and 8% Hispanic (n=30).

Survey Data

A set of 37 survey items were developed to answer the study questions. These questions were rooted principally in Ladson-Billing's (1995) theory of culturally relevant pedagogy (CRP), critical race theory, and Martin's (2007, 2009) research on racialization in mathematics classrooms. They were on a 5-point Likert scale ranging from 1 (Strongly Disagree) to 5 (Strongly Agree). In developing the items, existing measures of teachers' multicultural beliefs, perceived cultural competencies, and racial privilege were referenced. Draft items were reviewed by three mathematics education scholars with relevant expertise. For face validity, the items were vetted with current urban mathematics teachers as part of cognitive interviews.

School Data

These teachers' survey history and school assignment data were reviewed from the NYCDOE. This data was used to link the participants' survey responses to demographic data (race, attendance rates, levels of poverty) on the students in their assigned schools.

Exploratory factor analysis. To study the relationship between the teacher's background and their beliefs, an exploratory factor analysis (EFA) was conducted. The *following* 5 clusters of teacher beliefs emerged from the factor analysis: Culturally Responsive Teaching (CRT), Awareness of Privilege (AP), Teaching Students of Color Rewarding (TSCR), Teaching Multicultural Education in the Math Class (TMEMC), and Teaching for Social Justice (TSJ).

Linear regression. I used five linear regression models to determine if there is a significant relationship between the teacher's background and the five factors identified as part of the EFA. In the linear regression model, the dependent variables are the 5 belief factors that emerged. The independent variables are the aforementioned teachers' background characteristics. This includes the teachers' race (RACE), which is categorized as White, Asian, Black, or Hispanic; the teachers' age (AGE) at the start of their teaching career which is categorized as younger (age 23 or younger), average (ages 24-26), or older (27 or older); where the teacher grew up (LOC), which is categorized as in NYC, NYC Suburb (within 150 miles of NYC) or outside of NYC (greater than 150 miles from NYC); and their college selectivity (SEL), ranging from 1 as very selective to 5 as not selective. Controls were used for the teaching context of teaching fellows' first school where they taught, which included continuous variables measuring the attendance rate of the school (ATT), the percentage of students receiving free and reduced lunch (FRL) and the percentage of students who are Black, Hispanic, or American Indian (BHAI).

Table 1: Regression Results for Five Belief Factors

Measure	CRT	AP	TSCR	TMEMC	TSJ
	Coefficient (SE)	***Coefficient (SE)***	***Coefficient (SE)***	***Coefficient (SE)***	***Coefficient (SE)***

*p<.10; **p < .05; ***p < .01

Note. The referent group is White teachers, age 24 - 26 years at time of entry, who graduated from a NYC high school, and attended a moderately selective college.

Discussion of Results

As shown in Table 1, the teachers' race was significantly associated with two of the five belief factors. In particular, Latinx (β=.552, p=.013) and Black teachers (β=.279, p=.080, significant at .10 level) rated teaching students of color as more rewarding than did White teachers. Additionally, compared to White teachers, Black teachers believed more strongly in teaching for social justice in their mathematics courses (β=.414, p=.011). These findings are consistent with literature that shows that teachers of color, particularly Black and Latinx teachers, who share cultural backgrounds with their students may leverage this connection in their instruction (Kohli, 2018; Lee, 2004).

Attending a highly selective undergraduate institution was a significant predictor of two of the belief factors. Compared to teachers who attended moderately selective colleges, teachers who attended highly selective schools believed more strongly in the importance of incorporating multicultural education into the mathematics classes they taught (β=.309, p=.030) and were most aware of their racial and class privilege (β=.246, p=.089). These teachers may be more privileged themselves, so their heightened awareness may stem from their similarly heightened privilege. Additionally, given their social capital, these teachers may have chosen to become teachers because they believe teaching is a mechanism for social change (Tamir, 2009) and may believe that teaching multicultural education is a means to disrupt the inequities that their students of color may face.

The teachers' age and where the teacher grew up in relation to NYC also significantly predicted their beliefs. The model indicates that teachers who grew up farther away from New York City, or started teaching at younger ages (23 or younger), were more aware of their racial and class privilege than teachers who grew up in New York City or started teaching at ages 24-26. Also, teachers who grew up outside of New York City believed in teaching mathematics for social justice more so than teachers who graduated from New York City high schools. Teachers from outside of NYC may believe in social justice more strongly than those from NYC for similar reasons as to why the elite college graduates more strongly believe in multicultural education. They may choose to come and teach in urban schools for their desire to effect social change.

Of the five belief factors which were analyzed, only the linear regression model for the CRP belief factor had no significant predictors from the teachers' background on their beliefs.

Significance

Because selective ATCPs like NYCTF recruit their teachers from elite colleges which are generally predominately white and tend to severely underrepresent racial minorities, these findings point towards the need to recruit from other networks of potential teachers. This may mean more intentional recruiting from moderately selective colleges which admit and graduate higher rates of students of color, than their elite counterparts. If teachers who are racial minorities themselves have funds of knowledge which enable them to better teach their students of color, and find this process rewarding, then recruitment efforts can be tailored to bring these teachers into the profession. Further study could examine whether similar trends exist among in-service and pre-service teachers trained along traditional routes, and point towards a similar shift toward recruiting more teachers who themselves come from marginalized backgrounds.

STUDENTS' PERCEPTIONS OF OPPORTUNITIES TO LEARN IN TESTING-ORIENTED MATHEMATICS CLASSROOMS: A MIXED METHODS STUDY

Rosa D. Chavez
Stanford University
rdchavez@stanford.edu

This study examined the relationship between testing environment and perceived learning opportunities for students from historically marginalized communities using survey and video data from the Measures of Effective Teaching Longitudinal Database. Student surveys (N=24,208) were analyzed and showed that students perceived their opportunities to learn to increase as testing environment increased. However, representative videos of both high- and low-testing classrooms in which the majority were students of color showed that opportunities to learn decreased as testing environment increased. This indicates a need to shift away from raising test scores towards a focus on how high-stakes testing policies may be influencing perceived learning opportunities.

Keywords: Student Perceptions, Opportunities to Learn, Policy Matters, Classroom Practice

Introduction

Testing practices, now routine and highly consequential, claim to be rooted in equitable practices (Au, 2016; Cross, 2007; Foster, 2016) but do not address the underlying structural issues of inequality that marginalized students face in and outside the classroom (Flores, 2007; Gutierrez, 2008; 2014; Ladson-Billings, 2006). Little work has focused on how high-stakes testing policies enable or constrain opportunities to learn in mathematics classrooms.

Understanding how students perceive their opportunities to learn may offer insights into how students make sense of what they should be learning in U.S schools. Yet, these perceptions may not align with what educators and psychologists believe are robust opportunities. This study examined this tension through the following questions:

1. What is the relationship between federally mandated standardized assessments and students' perceived opportunities to learn within mathematics classrooms?
2. What are the actual learning opportunities in these classrooms as captured through representative videos?

Theoretical Framework

Research has shown that students' mathematical activity is social in nature and developed through participation in communities of practice (Cobb & Yackel, 1996) with particular patterns of interaction, understandings, assumptions, attitudes, and norms (Cobb & Bauersfeld, 1995; Cobb, Gresalfi, & Hodge, 2009; Engestrom, 1999). It is difficult to separate what students are learning from the ways in which they are learning it (Beach 1999; Boaler, 1997; Cobb & Bowers, 1999; Lave, 1988). Thus, this study analyzes students' perceived opportunities to learn in mathematics classrooms using Gresalfi & Cobb's (2006) *Opportunities to Learn* framework, which focuses on learning opportunities that foster the development of positive dispositions towards mathematics.

This paper examines how students perceived the learning opportunities in their classrooms in relation to whether the classrooms were also perceived as highly or minimally oriented towards testing. It then examines whether students' perceived learning opportunities are evidenced by examining classroom interactions across representative videos.

Methods

Data for this study comes from the Measures of Effective Teaching Longitudinal Database (MET-LDB). Through the use of linked survey and classroom video data, this dataset enables connections between the ways students are positioned during classroom interactions and their perceived opportunities to learn. This study analyzed survey responses for 24,208 students and looked at eight classroom videos. The population included 23% White, 31% Black and 35% Latinx students. Roughly 49% were eligible for free or reduced-price lunch and 14% were classified as English Language Learners.

This study looked at the relationship between testing environments and learning opportunities by aligning the student perception survey in MET-LDB to *opportunities to learn* from the literature. Testing-oriented classrooms that focus on state assessments may be leading students to develop particular dispositions towards mathematics. Using results of survey analysis, two classrooms were selected to determine characteristic practices of both high- and low-testing environments. Three additional classrooms in each category were randomly selected to determine if similar patterns exist. Using Nvivo coding software, all eight videos were logged and subsequently coded for student agency, student intellectual authority vs teacher authority, behavioral control, cognitive demand of math being constructed, student participation, teacher content knowledge error, emphasis on answer vs. process, and structure of classroom.

Results

Perceived Opportunities to Learn and Student Achievement Outcomes

Different classrooms provide different opportunities for participation. Overall, students perceived opportunities to learn to increase as their perceived testing environment increased, and the patterns varied across elementary ($\alpha = .88, se = .03, p < .0001$) and secondary ($\alpha = .77, se = .01, p < .0001$) contexts. As students progressed into middle school, the relationship between perceived testing environment and perceived opportunities to learn slightly decreases. (Figure 1).

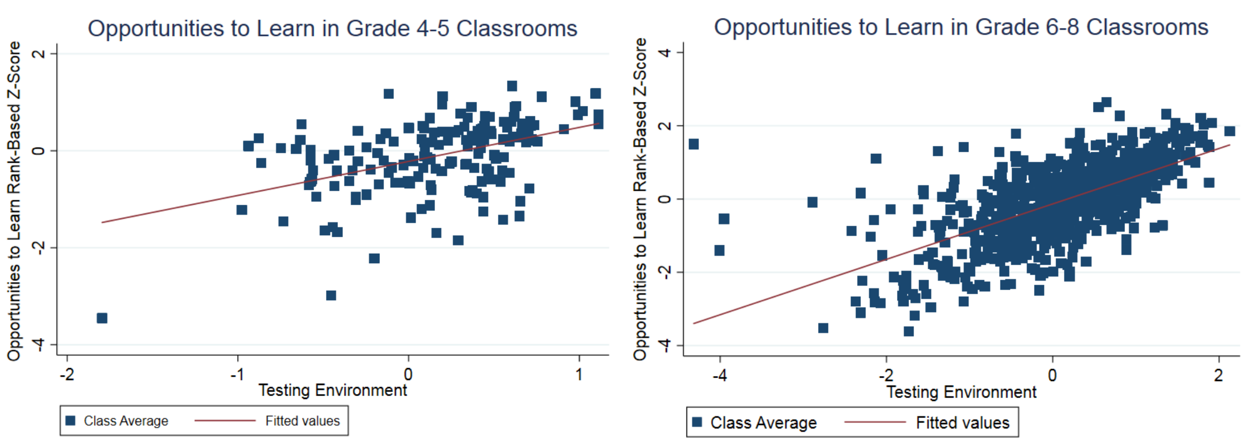

Figure 1: Perceived Opportunities to Learn Across Grades 4-8 Using OLS Regression Models

Instructional Practices in Classrooms

This section reports actual learning opportunities made available through social interactions in representative classrooms with majority students of color, and then compares this analysis to the larger quantitative trends. Four high- and low-testing classrooms were selected.

In low-testing classrooms, teachers provided more opportunities for students to engage in sense-making, procedural fluency, and encouraged students to make real world connections. Across all high-testing classrooms, the cognitive demand of the tasks that students participated in was low, and students were provided less time to meaningfully engage with the task or questions being posed.

Table 1: Code Frequencies for High- and Low-Testing Classrooms.

	Low-Testing Classrooms				High-Testing Classrooms			
Code	A	B	C	D	E	F	G	H

Other	2	0	2	0	2	0	0	0

Low-Testing Classrooms vs. High-Testing Classrooms

In low-testing classrooms teachers encouraged students to make connections and the tasks required students to practice both conceptual understanding and procedural fluency. In high-testing classrooms the math being constructed was more likely to be less cognitively demanding for students, but teachers more often praised them.

Student agency, student intellectual authority, inequitable learning opportunities, control of participation, and asserting teacher authority emerged as characteristic of both high- and low-testing classrooms. However, when classrooms D and H were removed from the sample, student agency and student intellectual authority were no longer characteristic of high- testing classrooms, and inequitable learning opportunities, control of participation, and asserting teacher authority were no longer characteristic of low-testing classrooms.

Discussion

As classroom practices continue to be informed by teachers' interpretations of policy messages (Diamond, 2007), students experience different educational opportunities. Understanding how testing policies influence the opportunities to learn that support the development of positive mathematical dispositions and how these dispositions influence student engagement with mathematics could prove useful in understanding differential achievement across student populations (Gresalfi, 2009). This study showed that different populations did indeed perceive their opportunities to learn differently across testing environments. Furthermore, there was a misalignment between how students perceived their learning opportunities and the actual learning opportunities based on a qualitative analysis of representative classroom videos.

High-testing classroom practices were characterized by teachers emphasizing use of algorithms and procedures, lowering cognitive demand for students. Class time was also dedicated to mostly teacher led instruction or individual student practice (Boaler, 2002; Boaler & Brodie, 2004; Boaler & Staples, 2008), as well as increased control of student behavior and student participation. In contrast, low-testing classroom practices were characterized by teachers encouraging students' sensemaking, agency, and intellectual authority. In these classrooms, teachers engaged students in tasks that allowed them to practice both conceptual understanding and procedural fluency. However, student perceptions of the learning opportunities in some classrooms contradicted what the video analysis showed, raising the question of what narratives students are drawing on to make sense of what counts as opportunities to learn.

While high-stakes testing can be seen as a positive influence on what is taught in contrast to what is taught when tests are not required, it becomes problematic when "*tests drive the curriculum*" (Madaus, Russell, & Higgins, 2009; Shepard, 1990). The learning opportunities that teachers create for students, particularly in mathematics classrooms, can determine whether students are willing to take risks and make mistakes, are able to ask critical questions, and see themselves as capable of learning (Boaler, 2016; Gresalfi & Cobb, 2006; Oakes et al., 1990; Surgenor, 2014).

As shown by this study, students in low-testing classrooms were provided more learning opportunities. These learning opportunities, combined with equitable access to resources, could be a step toward reducing the "opportunity gap" (Flores, 2007), which could eventually reduce the achievement gap for marginalized students.

Conclusion

As testing environment increased students perceived their opportunities to learn to increase, but a deeper analysis showed that low-testing environments in fact afforded more opportunities to learn. However, particular classrooms provided conflicting snapshots.

These findings raise the question of whether additional factors might be influencing students' perceptions of quality teaching and blurring the opportunities to learn in classrooms, convoluting opportunities to learn with increased performance on assessments for students of color. More research is needed that includes analysis of classrooms practices with larger samples in order to push back against accountability narratives that emphasize raising test scores as the solution to close achievement gaps in mathematics for marginalized student populations.

TEACHERS' VISIONS OF (RACIALLY) EQUITABLE MATHEMATICS INSTRUCTION

Cara Haines
University of Missouri
carahaines@mail.missouri.edu

Erica N. Mason
University of Missouri
ericamason@mail.missouri.edu

This paper marks an initial effort to understand the development of mathematics teachers' visions of equitable instruction. The qualitative data on which this study draws includes annual interviews conducted with 51 secondary mathematics teachers over the course of two years. Preliminary analysis revealed that teachers often described equitable mathematics instruction by naming high-quality instructional practices to which they would expect to see students have access. How teachers described those students, however, varied across individuals and aligned with different conceptions of equity within the field of mathematics education. Implications for research and practice are discussed.

Keywords: Equitable instruction, High-quality mathematics instruction, Instructional vision

Over the past few decades, issues of (in)equity have become increasingly central to conversations in the field of mathematics education. "Equity" in mathematics has been consistently described as a matter of students' access to high-quality instruction (National Council of Teachers of Mathematics [NCTM], 1989; 2000; 2014). As a result, mathematics education researchers and professional organizations have made efforts to define practices that constitute high-quality instruction (e.g., Hiebert et al., 1997; NCTM, 2014), and have designated the development of those practices as a primary goal of mathematics teachers' professional learning (Association of Mathematics Teacher Educators [AMTE], 2017). Therefore, how teachers might develop high-quality practices has become a key focus of research.

One way in which researchers have attended to teachers' development of high-quality practices is through the examination of teachers' instructional visions (Munter, 2014). Drawing from Hammerness's (2001) notion of "teachers' vision," Munter and Wilhelm (2019) described instructional vision as "the discourse that teachers or others currently employ to characterize the kind of 'ideal classroom practice' to which they aspire but have not yet necessarily mastered" (p. 2). As a way to assess teachers' instructional visions, Munter (2014) offered a set of interview prompts and rubrics that relate to key dimensions of high-quality mathematics teaching, including the role of the teacher, classroom discourse, and mathematical tasks. Each of the three rubrics (some with subdimensions of practice) delineates a trajectory of teachers' visions along levels of sophistication—with the most sophisticated level aligning with findings from classroom research in mathematics education from the last 30 years.

One limitation of Munter's (2014) visions of high-quality mathematics instruction (VHQMI) assessment tool, as he pointed out, is that it does not account for the development of teachers' conceptions of high-quality instruction that is also *equitable*. While some may consider equitable mathematics instruction as merely access to the high-quality practices like those described in Munter's framework (e.g., NCTM, 2014), others have argued that such conceptualizations of equity (or equitable instruction) are insufficient in that they lack a historical orientation (Martin, 2003; Reinholz & Shah, 2018). Following this argument, we assert that attending to teachers' visions of high-quality instruction is not enough, and argue the need to also investigate teachers' visions of *equitable* mathematics instruction. This study marks initial steps in such an investigation, and was guided by the following questions: Do teachers consider high-quality teaching practices to be equitable in and of themselves, or do they conceptualize equitable instruction in different ways?

Conceptions of Equity in Mathematics Education

Researchers in the field of mathematics education have conceptualized equity in different ways. For example, as noted earlier, for more than 20 years, the NCTM (1989; 2000; 2014) has described equity as a matter of increasing access to high-quality mathematics instruction *for all* students. While increasing access to high-quality instruction for all students may be a necessary waypoint toward equity (Reinholz & Shah, 2018), Martin (2009) has argued that NCTM's (1989) "for all" sentiment is an instantiation of colorblind racism and ignores the systemic oppression of historically marginalized groups of students.

In its later publications, however, NCTM (2000; 2014) moved a step beyond their "for all" rhetoric by expressing concern for particular groups, including students who are "black, Latino/a, [and] American Indian"(NCTM, 2014, p. 60). While the explicit naming of students for whom increased access is required is arguably an improvement from their colorblind "for all" rhetoric, NCTM still did not call for "improving the collective conditions" of students who, historically, have been the least supported in mathematics (Martin, 2015, p. 22). In the analysis we report here, we follow Martin's (2003) argument that definitions of equity in mathematics education must "take into account the collective histories of the groups for whom equity is desired" (p. 13).

Method

The research on which our analysis is based was conducted in the context of a larger research project that took a mathematics-specific approach to decreasing a racial opportunity gap (Flores, 2007) in a Northeastern urban school district. The sample considered in this study includes a total of 51 secondary (Grades 6–12) mathematics teachers (8 of whom were teachers of color, and 43 of whom were white teachers) from two cohorts who were participants in the larger study. Teachers' participation in the project included engagement in consecutive 2-year summer workshops that focused on confronting issues of (racial) inequity in mathematics education. During these workshops, project leaders attempted to support teachers in investigating and addressing inequities in school mathematics by: re-conceiving what it means to know and do mathematics; discussing the historical marginalization of Black students; reflecting on their own (and students') racial and mathematical identities (Nasir, 2011); and developing and enacting ideas for more equitable practice (e.g., culturally relevant pedagogy, Ladson-Billings, 1995).

Data used in this analysis include 84 semi-structured annual interviews that were conducted with the teacher 51 participants over the course of 2 years. All interviews were audio-recorded and transcribed. In these interviews, teachers were asked a series of questions regarding their visions of high-quality and equitable mathematics instruction. Analyses for this study focused on teachers' responses to the following prompt: *If you were asked to observe another teacher's math classroom for one or more lessons, what would you look for to determine whether the mathematics instruction was equitable?* All interview questions pertaining to teachers' visions were structured in this way to allow participants to talk about practices they would expect to see in an ideal, equitable mathematics classroom rather than necessarily describing their own.

Analysis and Findings

For this preliminary phase of analysis, we collected and analyzed 84 responses (from the 51 teachers) to the interview question of interest. Next, for each response, we identified the instructional practices that teachers described as equitable. For some responses, we were able to apply Munter's (2014) VHQMI assessment tool to code the instructional practices teachers named. For others, however, we resorted to an open coding process, as some teachers had described dimensions of instruction that are not captured by the VHQMI (e.g., "culturally-relevant" mathematical tasks and broadening notions of valid participation). While the latter finding provides important insight into teachers' visions of equitable instruction (discussed more in the implications section), for the analysis described here, we focused only on the former cases in which teachers considered equitable and high-quality instructional practices to be synonymous. After identifying those cases, we made note of the practices that teachers named using the VHQMI as a guide. For example, if a teacher said "I would attend to the types of questions the teacher was asking," then we would assign the "teacher question" label from the VHQMI Classroom Discourse rubric. After identifying the practices teachers named, we drew on the different conceptions of equity in mathematics education discussed earlier to characterize how teachers had described students. That is, we paid particular attention *to whom* (which groups of students) the teachers attended in their descriptions and, when applicable, their rationales for naming those students. We found that teachers described students in one of three ways: 1) all students; 2) all students with particular attention to different groups of students; and 3) students with nondominant ways of knowing and doing. These differences, which we interpreted as differences in teachers' conceptions of equity, are discussed in the three subsections that follow.

Colorblind Perspectives

Most teachers described equitable mathematics instruction using "for all" rhetoric (Martin, 2009). In these descriptions, teachers suggested that equitable mathematics instruction would require "everyone" and/or "all students" to have access to particular instructional practices and learning opportunities, but did not provide a rationale for their argument. These descriptions were unique in that they did not distinguish between groups of students in any way but, rather, implied a universal standard "for all" students. As an example, consider the following quote from one participant's interview: "Um, I guess I would look for participation um, you know, from-like if all students were participating." While this participant alluded to an important issue of equity—that all students should have opportunities to participate—their description suggests that equity merely necessitates equal opportunities *for all*, a common colorblind sentiment.

Beyond Colorblind Perspectives

In other cases, teachers still called for equal access to particular instructional practices and learning opportunities, but explicitly named groups of students between which opportunity gaps typically exist (e.g., students of high and low status, girls and boys, students of color and white students). The following quote from one participant is representative of this type of response:

> So I think the key is seeing that all the students are engaged and, um, and being able to, if you feel like "Okay, wait a minute, were the boys called on more than the girls? Or the girls called on more than the boys?" Were, you know, we focused on the white males? Are we focused on the African-American females or- […]

Although this participant still invoked the "for all" narrative, their attention to different groups of students distinguishes this response from the type discussed in the previous subsection. While this type of a response may still indicate a view of equity that is “assimilation-oriented” (Martin, 2009), that participants in this category paid attention to students’ race (and ethnicity, gender, and/or status) suggests an orientation to equity that extends beyond colorblind perspectives.

Perspectives that Acknowledge (Historical) Oppression

Only two teachers conceptualized equitable instruction from a perspective that, beyond calling for equal access or an explicit naming of groups of students, alluded to and offered a response to types of oppression. Another important characteristic of these responses is that in them, teachers alluded to oppressive forces of dominant mathematics (Gutiérrez, 2007), but not to the accumulated historical oppression (i.e., systemic racism) experienced by students of color. As an example, consider the following response from one teacher participant:

> [Teachers should give students] autonomy to be able to decide how they were going to - what direction they were going to take that problem. Maybe they didn't get the right answer, but they were looking at it in a different way, and the teacher showing that- What they did was just was good as what everybody else did…

Although not explicitly, this teacher acknowledged that only particular ways of knowing and doing mathematics are typically privileged in mathematics classrooms and, consequently, other—or nondominant—perspectives are often overlooked and/or marginalized. Given that in these responses, teachers, at least, alluded to the oppressive nature of school mathematics and the students who typically experience that oppression (e.g., students who look at things in a “different way”), we argue that they are both distinct from and more—yet not sufficiently—historically-oriented than the responses that constitute the previous two categories.

Next Steps in Research and Practical Implications

Given that for this analysis we did not assess the sophistication of teachers’ visions of high-quality instruction as we analyzed their visions of equitable instruction, next steps in our research will include using Munter’s (2014) VHQMI tool to assess those visions. That is, in order to determine the degree to which a teacher’s vision of equitable instruction is indeed equitable, one would have to first examine the quality of instruction, broadly, that a teacher articulated in their vision. Such an analysis might contribute to focusing professional support for individuals with unique instructional visions. For example, if a teacher articulated a less-sophisticated vision of high-quality mathematics instruction, then professional learning opportunities aimed at improving teachers’ visions with respect to mathematical tasks, classroom discourse, and/or the role of the teacher would be a necessary step in working towards articulating a more sophisticated vision of equitable mathematics instruction.

Second, as mentioned earlier, some teachers’ visions of equitable instruction extended beyond visions that focused solely on instructional practices that constitute definitions of “high-quality” instruction, such as Munter’s (2014) VHQMI and NCTM’s (2014) Mathematics Teaching Practices. Future research might attempt to define dimensions of equitable mathematics instruction and also consider how teachers’ visions might develop along those dimensions.

Regarding practical implications, the distinctions between teachers’ visions of equitable instruction we have described have important implications for teacher learning and development. For example, if teachers describe equitable instruction by invoking “for all” rhetoric, what types of professional supports might be needed to move teachers’ visions beyond that, and what implications do such visions have for teachers’ instruction and, consequently, student learning?

More importantly, given that none of the teachers in our sample conceived of equitable instruction as a means to account for the accumulated historical oppression of marginalized students, what kinds of professional supports might be needed for teachers to envision and, ultimately, enact mathematics instruction that "improv[es] the collective conditions" (Martin, 2015, p. 22) of students who have, historically, been the least supported in mathematics?

DESIGNING CULTURALLY RELEVANT ENGINEERING CHALLENGES: CONNECTING EQUITABLE MATHEMATICS TEACHING PRACTICE WITH STANDARDS OF MATHEMATICAL PRACTICE

mwkier@wm.edu

To address inequities within mathematics education, many educators have adopted standards-based mathematics to reform disparities in accessing mathematics content and practices. However, such reform efforts do not specify how standards-based mathematics can support the equitable mathematics teaching practices needed to improve minoritized students' learning. Through a researcher-practitioner partnership, we developed professional learning experiences to empower teachers to engage minoritized students in more equitable standards-based mathematics. Such experiences included training teachers to center minoritized communities in mathematics content and practices through engineering design challenges, thus making the teaching practices more equitable and culturally relevant. In this paper, we describe research-based equitable mathematics teaching practices aligning to standards of mathematical practice.

Keywords: Equity and diversity, Social justice, Instructional activities and practices, Culturally relevant pedagogy

Purpose

In the United States, public education systems have received criticism for their failure to teach minoritized students mathematics in equitable ways (Civil, 2007; Dunleavy, 2015; Hodge, 2006). The enactment of state-mandated policies, such as the Common Core State Standards for Mathematics (CCSSM) and Standards for Mathematical Practice (SMP), have further exacerbated the existing inequities experienced by minoritized students rather than lessen them (Bartell et al., 2017; Eppley, 2015). This is because, at least in part, mathematics education remains disconnected from the experiences and realities of minoritized students (Battey, 2013; Civil, 2007; Martin, 2007, 2009). To address such inequities, mathematics educators have sought to resist the inherent whiteness in schooling by centering the lives and experiences of minoritized students and communities into the curriculum and teaching (Skovsmose, 1994; Planas & Civil, 2010). Through such culturally relevant pedagogy, these educators seek to provide educational opportunities that may buffer against the institutional and structural inequities that students are subjected to within classrooms and schools (Ladson-Billings & Tate, 1995; Skovsmose, 1994; Planas & Civil, 2010).

Several scholars suggest problem-solving through design thinking as an approach mathematics teacher may use to model the SMP with their students (Bush et al., 2018). Thus, we created a researcher-practitioner partnership, *E-Communities*, to develop professional learning experiences that empowered teachers to engage minoritized students in designing solutions to real-world problems. Such experiences included training teachers to center minoritized communities in mathematics lessons around engineering design challenges (EDCs), thus developing more equitable and culturally relevant lessons. In this paper, we describe how these research-based equitable mathematics teaching practices link to standards of mathematical practice, thereby engaging students in rehumanizing mathematics (Kier & Khalil, 2018; Gutiérrez, 2018).

Theoretical and Methodological Framework

To centralize the need for more equitable practices, this study describes a design and implementation study that calls on tenets of critical race design (CRD; Khalil & Kier, 2017) to bring together various stakeholders, including minoritized middle school teachers, learners, STEM professionals, and teacher education scholars. Given the researcher-practitioner partnership is in one of the largest Black-majority communities, CRD draws primarily from critical race theory in education (CRT; Ladson-Billings & Tate, 1995; Solórzano & Yosso, 2002) to interrogate inequities in the perspectives, structures, methods, and pedagogies that oppress minoritized learners. Accordingly, CRD uses tenets of design-based implementation research to address inequities through iteratively designed solutions to inequities in mathematics education (DBIR; Penuel, Fishman, Cheng, & Sabelli, 2011).

Through a research-practice partnership, we sought to facilitate professional learning experiences that focus on designing culturally relevant engineering design challenges (EDCs) that connect to real-world problems faced by minoritized communities (Kier & Khalil, 2018). Specifically, we supported mathematics teachers' understanding of the design process by demonstrating its alignment with the SMP. Through this process, we emphasized the need for designers to empathize in order to devise authentically real-world problems, to then foster both the connection between minoritized learners and societal challenges and center their funds of knowledge in learning (Boykin & Noguera, 2011; Coleman, Bruce, White, Boykin, & Tyler, 2016; Moll, Amanti, Neff, & Gonzalez, 2005). Although Bartell et al. (2017) identify several equitable mathematics teaching practices that may engage learners, empirical research has yet to investigate how these practices may actually align with the teaching of the SMP. To bridge the gap, we iteratively utilized a race-conscious lens by connecting education researchers, mathematics teachers, STEM professionals of color, and minoritized students to co-construct culturally-relevant EDCs for middle school mathematics learners.

Data Sources and Analysis

This three year-project engaged 42 mathematics and science teachers in professional learning on teaching through design-based tasks. Professional learning included supporting teachers and STEM professionals to plan lessons that engaged students in culturally relevant EDCs related to social justice challenges broadly, and students' lives specifically. We analyzed 50 recorded virtual professional learning sessions in which researchers, teachers, and STEM professionals, co-planned engineering and social justice lessons, and 14 virtual interactions where students discussed culturally-relevant engineering design challenges with STEM professionals. Additionally, we analyzed six face-to-face focus groups with teachers on community building, racial and social justice, reflections around the implementation of engineering design challenges, and the limits and possibilities of researcher-practitioner partnerships.

We transcribed our data and applied a priori codes to these interactions using Bartell and colleagues' (2017) equitable mathematics teaching practices framework. Next, we searched for the intersections between equitable practices and SMP by using the Dedoose analyze feature to quantify co-occurrences. We then operationalized these frequency codes by how mathematics teachers discussed teaching mathematics through problems and designing solutions that may humanize the curriculum and connect it more closely to students' lives.

Results

Below, we highlight examples of how teachers operationalized the co-occurrence intersections between equitable mathematical teaching practices and the SMPs when instructing their students to complete design challenges.

Using Students' Funds of Knowledge to Encourage Student Voice

Numerous teachers saw the utility in drawing on students' funds of knowledge. Our preliminary analysis demonstrated that students' funds of knowledge supported them to a) make sense of problems and persevere in solving them, b) construct viable arguments and critique the reasoning of others, c) look for and make use of structure, and d) look for and express regularity in repeated reasoning. By validating shared ideas and experiences between her and her students, and connecting instruction to students' experiences and interests, Tiffany came to understand how important students' funds of knowledge is for constructing viable arguments. She recognized that most adults, including herself, are challenged by hearing the way in which students think about real-world problems because they are prioritizing their own hidden assumptions about societal problems and how students may think about them. When taking the time to uncover the ways in which students define real-world problems, she was better able to support a true co-constructed a solution with them, and "make them feel like you're really listening." Here, she elaborated further:

> [The students] give you another point of view, I mean because you're always thinking of things from your adult point of view … I tell them why from my perspective, and then I let them tell me how they think [about problems] from their perspective ... it was less tension, not me just saying do it because I said.

Tiffany surmises that by connecting instruction to students' experiences and interests, she not only validates their ideas and experiences (Aguirre et al., 2013; Bartell, 2011) but also develops a bond where students feel they matter (Dixon & Khalil, 2016). Thus, when standards for mathematical practice are used in concert with drawing on students' funds of knowledge, teachers can teach more equitably as gaining a deeper understanding of their students' backgrounds and experiences.

Recognizing Multiple Forms of Discourse and Language as a Resource

Many stakeholders in the partnership emphasized the importance of code-switching as an essential skill that students need to achieve the life outcomes they expected. Our preliminary analysis demonstrated that recognition of students' multiple modes of discourse supported them to a) construct viable arguments and b) use appropriate tools strategically. Several teachers described how prototyping encouraged students to learn to communicate across their difference of opinions. Leveraging communication styles and instruments promoted students' access to new points and modes to discuss solutions. Caryn described this:

> Prototyping helps develop empathy because learners communicate using their convincing ability in their attempt to build … For instance, a learner may do things a certain way, while another will argue that the process will not work. … As prototyping proceeds, learners realize that the group must work together to reach a common/shared goal.

Caryn describes how the problem-solving process can be frustrating for students but that the physical manifestation, or lack thereof, of what they are imagining forces her students to communicate with one another during their productive struggle. By facilitating an environment that is respectful of differences, teachers can cultivate affirming relationships among students as such endorsing of possible differences in the ways students may communicate with one another demonstrates acceptances of distinct language practices as valid methods of conveying one's mathematical understanding (Civil, 2007; Gay, 2002; Ladson-Billings, 1995; Setati, 2005).

Societal and Cultural Contexts that Connect Students to Math Practices

Our preliminary analysis demonstrated supporting development of a sociopolitical disposition helped students to address the SMP. When teachers provide opportunities for students to explore social justice topics using academic content and engage students in conversations about real-world problems and how mathematics can be used to examine them, they support development of a sociopolitical disposition (Bartell et al., 2017; Frankenstein, 2012; Gates & Jorgensen, 2009; Gutstein, 2006; Skovsmose, 1994; Tate, 1995). Hillary planned to implement a lesson on providing clean, potable water to communities in need as a way to encourage students to use structure in determining how much money they can spend on materials given budget restrictions:

> I think on each of the materials, one of the things we're probably going to do is give them a constraint of, I don't know, $100, and they're going to have to figure out, within that $100, how much you can spend on each material so you can go ahead and make your water filtration system. So, for the social justice [issue] … I think it would be interesting if we gave each of the groups different amounts of money they could spend. That would get them to think about the inequity of different countries and how they don't have the money to spend on clean up, that would be an interesting way to do that.

Following the challenge, Hillary engaged students in the timely social justice topic provided what's happening in many underserved communities across the country, like Flint, Michigan and Newark, New Jersey (i.e., filtering communities' lead-poisoned water supply), into her lesson. This allowed her to take a back seat in her students' learning as she let a relevant social issue drive instruction while students contemplated how they could work within a mathematics structure to solve a real-world problem that plagues many communities in America as well as around the world (Gutstein, 2006; Skovsmose, 1994).

Conclusion

In this paper, we described a partnership between HBCU teacher educators, STEM professionals, and middle school teachers that sought to center equity in standards-based mathematics content and processes. We theorized that teachers' use of culturally relevant and equitable engineering design challenges may empower minoritized students' engagement in the SMP by positioning their daily lived experiences as epistemological resources. By utilizing design and implementation research, within a critical race design framework (Kier & Khalil, 2018), this study facilitated professional learning experiences focused on designing solutions to real-world problems faced by minoritized communities to support teachers in engaging equitable mathematics teaching practices that connected to the SMP.

HOW RELATIONAL CAPITAL EMPHASIZES CRITICAL REFLECTION AND EMPATHY IN DESIGN THINKING TO SOLVE COMMUNITY-BASED PROBLEMS

In the United States, teaching mathematics equitably has been a challenge that continues to diminish minoritized learners' access and opportunities to learn. To address these inequities, researchers have conceptualized various equitable practices that center the community cultural wealth of minoritized learners and teachers. In the present study, we describe how a specific community cultural wealth, the relational capital between minoritized teachers and learners, supported their application of empathy in the design thinking process. Through professional learning experiences, teachers reflected how relational capital elicited the empathic responses needed to solve the culturally relevant engineering design tasks contextualized as community-based problems of practice. Thus, fostering teacher-student relational capital holds promise for promoting equitable teaching and learning in mathematics classrooms.

Keywords: Equity and diversity, Instructional activities and practices, Culturally relevant pedagogy, Affect, Emotions, Beliefs, Attitudes

Purpose

One criticism of standards-based mathematics is that it magnifies the enduring inequities that currently occur in American mathematics education settings (Bartell et al., 2017; Battey, 2013). Further, such reform efforts in mathematics highlight a disconnect between the experiences and realities of minoritized learners and that of their mainstream peers (Brown et al., 2016; Eppley, 2015; Forgasz & Rivera, 2012; Gutstein, 2010), which causes the minoritized students to disengage from mathematics learning (Corso, Bundick, Quaglia, & Haywood, 2013; Crumpton & Gregory, 2011). To address this concern, researchers have called for more equitable mathematics teaching to engage minoritized learners in mathematics problem-solving (Hand, 2012; Luria & Kaufman, 2017; Turner & Celedon-Pattichis, 2011; Turner & Drake, 2016). Bartell and colleagues (2017) argue one way to do this is to focus on infusing equity into standards-based mathematics through the Standards for Mathematical Practice (National Governors Association Center for Best Practices [NGA] & Council of Chief State School Officers [CCSSO], 2010). Scholars argue that because the Standards for Mathematical Practice are intended to motivate learners from *all* backgrounds to participate in mathematical problem solving, they provide more opportunities for all learners to equitably engage in learning (Anhalt, Civil, & Lesser, 2013; Brodie, 2014; Drageset, 2014; Heng & Sudarshan, 2013; Moscardini, 2014).

The design thinking process (a process that includes empathizing, defining problems, ideating, prototyping, and testing solutions to real-world investigations) can support the implementation of the Standards for Mathematical Practice in a manner that encourages empathy with others when applying mathematics to societal challenges and designing solutions (Bush et al., 2018). The literature on how teachers seek to humanize mathematics by attending to minoritized learners affect and experiences when problem-solving is sparse (Goldin, Epstein,

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

Schorr, & Warner, 2011; Frank, Khalil, Scates & Odoms, 2018; Khalil, Lake, & Johnson, 2019). In this paper, we describe how a professional learning experience supported teachers to model empathy when asking students to design solutions to community-based problems in middle school mathematics classes.

Theoretical and Methodological Framework

This study describes *E-Communities,* a research-practice partnership that draws on tenets of critical race design (CRD; Khalil & Kier, 2018) to bring together the professional knowledge and cultural resources of various minoritized stakeholders including teachers, learners, engineers, and teacher education scholars intent on developing more equitable practices. Given the partnership takes place in a predominately Black community, CRD draws from two well-established frameworks, critical race theory in education (CRT; Ladson-Billings & Tate, 1995) and design-based implementation research (DBIR; Penuel, Fishman, Cheng, & Sabelli, 2011). While CRT aids in identifying and interrogating inequities in the perspectives, structures, methods, and pedagogies that oppress minoritized learners, it, along with DBIR, supports iteratively transforming these inequities by design. Thus, CRD epistemologically, methodologically, and pedagogically aims to disrupt inequities through iteratively designing opportunities that support minoritized teachers and learners to use reflective and agential practices.

Seeking transdisciplinary perspectives needed to address the complexity of social inequalities (Solórzano & Yosso, 2002), CRD promotes minoritized learners' innovation, agency, and engagement by designing spaces that center the various assets and capitals stakeholders bring to the classroom (i.e., community cultural wealth, CCW; Yosso, 2005). Based on critical race theory, Yosso (2005) describes six capitals (aspirational, familial, linguistic, social, navigational, and resistant) and explains how these capitals can empower minoritized voices by valuing the capital shared in their stories, thereby and minimizing the power differential that exists between research-practice partners (Guajardo, Guajardo, & Casaperalta, 2008). Several scholars describe these relationships based on trust and respect as relational capital (Warren, 2011, Holme & Rangel, 2012); Gamez (2017) adds that relational capital heavily relies on empathy as a vehicle for compassion and both experiential and generative praxes. Empathy has been promoted as a key application of culturally-relevant teaching as it prepares teachers to facilitate student-teacher relationships, improve communication with parents, and builds trust when empathy is genuine and focuses on interpersonal relationships and the awareness of dominant societal structures that it promotes (Warren, 2015). In this paper we demonstrate how empathy and compassion uses the hope and inspiration inherent in aspirational capital to demonstrate how teachers support students and their academic goals; how experiential praxes in design thinking can connect familial and linguistic capitals to show how the perception of an extended familial or community member may assist teachers in leveraging a positive relationship with students; and how generative praxes links social, navigational, and resistant capitals to allow teachers to negotiate instructional relationships so that students are able to maneuver successfully through educational spaces.

Data Sources and Analysis

For three years, *E-Communities* stakeholders participated in several professional learning experiences aimed at building design thinking practices that can equitably engage learners in culturally relevant engineering design challenges (EDCs; Kier & Khalil, 2017), that were contextualized by community-based problems of practice related to social justice challenges broadly, and students' lives specifically. Professional learning included supporting teachers and

STEM professionals to plan lessons that engaged students in culturally relevant EDCs. Data was collected through recorded observations of collaborative lesson planning during face-to-face (F2F) professional learning sessions, where forty-two middle school mathematics and science teachers and nearly a dozen STEM professionals of color collaborated in interdisciplinary teams to design EDCs in a way that humanized the standards-based mathematics curriculum. Additionally, we conducted six focus groups following F2F co-planning, where teachers reflected on the limits and possibilities of designing and implementing EDCs in formal middle school mathematics and science classes. Finally, we recorded and analyzed 20 virtual professional learning sessions in which researchers, teachers, and STEM professionals, continued to co-design EDCs and 14 virtual interactions where minoritized students discussed their designs with STEM professionals of color. Below we report findings we found by adopting Lichtman's (2010) three C's, which consists of coding, categorizing, and identifying themes that operationalize the relational capital mathematics teachers either demonstrated or reflexively described during either face-to-face or online professional learning sessions.

Results

Below are descriptions of how teachers' relational capital supported their ability to model empathy to students when teaching investigations through design processes. In the following section, we demonstrate how teachers use relational capital to connect to (i) their praxis through critical reflection (Lupinski, Jenkins, Beard, & Jones, 2012), (ii) one another through the shared inquiry of professional learning experiences (Biesta & Stengel, 2016), (iii) their learners through sharing power and situating their narratives as epistemological resources (Kier & Khalil, 2018). For many teachers, incorporating design into their teaching was a way to give students critical agency in addressing societal challenges. By situating design tasks as community-based problems of practice, teachers expanded their learners' agency by helping them view mathematics as a tool that can interrogate inequities and design solutions for problems minoritized communities faced both locally and globally. As sixth-grade mathematics teacher Tasha explained:

> [Design thinking] can help develop empathy in that it forces us to leave our narrow scope of thinking. We include diverse perspectives that may lie outside of our normal world. The idea is exposure. The more you are exposed to, the more aware you are of not only others but also our limited viewpoints. This should create empathy, given a broader knowledge-base and insight from additional sources.

Thus, expanding students' knowledge and awareness of real-world problems shows promise for developing students' agency, as their empathy with the problem helps them create tentative solutions based on applying their application of mathematics knowledge and practices.

Relational capital was demonstrated as a shared inquiry between teachers and with their students. Teachers recognized the importance of empathy during professional learning when they experienced personal frustration during the design process. For example, Hilary, a seventh- grade math teacher, explains how empathy connected her professional education to her learners' experiences:

> Empathy plays a big role in teaching and learning. There should be a connection between the two. That's why, in our training (i.e., professional learning experience), we acted as students so that when we will be in our classrooms and doing the hands-on activities or modeling we

> are ready to answer their questions, we are ready to handle the challenges that our students will meet in a given project.

Hillary's empathy and critical reflection helped her counter the detrimental attributes of negative emotions by empowering changes in her teaching practice, which will lead to meaningful experiences for her students. This sentiment builds upon DeBellis and Goldin's (2006) notion that when teachers are cognizant of their affect and meta-affect, they are more confident in their abilities to support learners academic and emotional needs (Goldin et al., 2011; Khalil, Lake, & Johnson, 2019).

Ned, a seventh-grade math teacher, found that students' relational capital, steeped in empathy, improved their collaborative efforts to address problems and design solutions:

> [Designing in groups] helps build a harmonious relationship among partners/members of a group or team and would lead to improving empathy. Once individuals working as a team understand each other's limitations/weaknesses and strengths, there would be a smooth working relationship. Remarkable things can happen when empathy for others plays a key role in problem-solving. Understanding each other's weaknesses/limitations and strengths would improve any work at hand.

Ned's realization suggests that he has recognized tensions that may cause barriers to learning and is likely to adapt accordingly to meet the needs of his learners, particularly as it relates group dynamics that are based on shared ideas of trust and communalism (Dixon & Khalil, 2016). Horn et al. (2018) discussed how critical this recognition is for teacher development, as it spurs teachers' reflective reasoning, as well as their adaptability in praxis.

Finally, as teachers reflected upon iteratively designing equitable classroom practices for their learners, five teachers shared inquiries on how they might continue to leverage empathy and relational capital in their classrooms. These included:

> How do we get communities and learners to genuinely and continuously commit to a demonstration of empathy? Why are people/communities not readily disposed to meet the demands initiated by empathy? Why is the modern world is not generally endeared toward being empathic? How well can I really show empathy towards my learners? What degree can we expect middle school aged children to be empathetic, and how can we help support this? Does empathy guarantee success in design? Is there another "ingredient" that is needed to ensure success in design challenges? Can we involve the home and community in the process?

Teachers utilized relational capital's empathy to develop their relational teaching and subsequently connect to their praxis through critical reflection (Lupinski, Jenkins, Beard, & Jones, 2012). As the experiences and reflections of teachers indicate, the idea of operationalizing empathy through designing *for others* in mathematics classrooms supported teachers in their professional learning, thereby developing a more equitable environment for their learners.

Conclusion

This study revealed an emerging notion of how teachers' relational capital can be an essential part of enacting equitable mathematics teaching when engaging minoritized learners in design challenges. With empathy being an integral part of design thinking, teachers can readily model ways to humanize mathematics when addressing real-world problems. We propose that drawing on relational capital should be central to teacher-student dynamics in mathematics classrooms, as it connects empathy, both cognitively and affectively, to designing solutions. Re-imagining equitable practices through relational capital promise to inform teachers' ability to serve underrepresented minoritized populations, particularly in design-based mathematics classrooms.

We used a mixed method research design to address the complexity of interrogating issues related to retention of Black mathematics teachers. The research design includes oral history interviews with retired Black mathematics teachers and large-scale survey data collected and analyzed from a Critical Race Quantitative Intersectionality approach. It is our position that the contemporary reality of the dwindling numbers of Black mathematics teachers cannot be fully understood without unpacking the issue with a critical, historical lens. Otherwise, we run the risk of perpetuating the longstanding issue of lack of diversity in the field. Thus, this paper presents preliminary findings of a 3-year research project that advances knowledge of the historical influences, with focused attention to sociopolitical forces, that impede retention of Black mathematics teachers.

Keywords: Equity and Justice, Research Methods

Purpose

Within educational circles and in public discourse regarding teacher retention, stakeholders are having what appear to be two seemingly distinct conversations, at least on the surface. One conversation highlights the need to recruit mathematics teachers to improve American students' achievement outcomes all in the name of increasing global competitiveness and employment in STEM-focused professions (National Math & Science Initiative, 2016). The other conversation calls for the retention of a diverse teaching force for an increasing multi-racial, multi-ethnic and culturally-diverse student population (Casey, DiCarlo, Bond, & Quintero, 2015). These conversations are rarely held simultaneously, meaning few conversations address the need to increase the numbers of teachers of color in mathematics. We contend that these conversations are not mutually exclusive. Further, we argue that these conversations, while well meaning, often commoditize teachers of color. Conversations about "filling pipelines" often treat teachers as data points to meet diversity requirements or to simply achieve demographic matches between students and teachers. Further, the ultimate goal of increasing mathematics teachers and teacher of color tends to always rest on US economic competitiveness rather than goals related to social justice, the public good, and the wellbeing of Black teachers.

Black mathematics teachers are one-third of one percent of all teachers and approximately 6 percent of all secondary mathematics teachers (Neil, 2015). An emergent body of literature highlights the promise of learning with and from Black mathematics teachers based on their unique pedagogical practices that honor Black students' ways of knowing (Birky, Chazan, & Morris, 2013; Clark Badeschter, & Napp, 2013a; Clark, Frank, & Davis, 2013b; Johnson, Nyamekye, Chazan, & Rosenthal, 2013) and also improve achievement for Black students (Dee, 2004; Klopfenstein, 2005). Addressing retention of Black mathematics teachers is key, as Neil found that they have the highest rate of turnover among all mathematics teachers across all racial demographics.

This limited amount of scholarship with respect to Black teachers of mathematics highlights the need to establish a line of research that lies at the nexus of increasing teacher diversity and increasing the numbers of mathematics teachers entering the field. Further, we push back on the notion that recruitment of teachers of color, and specifically Black teachers, is solely a contemporary issue. We posit that the dwindling number of Black teachers noted in the current news cycles and public discourse stems from a long history of systemic marginalization. Historical analyses of Black teachers in mathematics provide a meaningful foundation for understanding the contemporary racialized experiences, perspectives and practices of Black mathematics educators.

We used a mixed method research design to address the complexity of interrogating this broad issue. The research design included oral history interviews with retired Black mathematics teachers. To capture the experiences of current Black secondary mathematics teachers, the research team administered a large-scale survey and will be conducting focus groups. The research questions that guide this work are as follows:

1. What are the mathematical, racialized, and educational experiences of Black mathematics teachers who taught during the periods of *de facto* desegregation in the United States and those who are currently teachers?
2. How do the experiences of former and currently practicing Black mathematics teachers contribute to theorizing about the role of Black mathematics teachers and the content, intellectual, cultural, and social resources they bring to their practice?
3. How do the experiences of former and currently practicing Black teachers inform how schools, policy makers, and teacher preparation programs recruit and retain a diverse mathematics teaching force?

We see this work as an effort to illuminate issues that may not be at the center of either discourse related to retention of Black teachers or retention of mathematics teachers.

This National Science Foundation-funded research project advances knowledge of the historical influences, with focused attention to sociopolitical forces, that impede the retention of Black mathematics teachers. Ultimately, this work informs research methodology in mathematics education by integrating untapped, yet appropriate methodologies suitable for challenging issues of recruitment, retention, and praxis of other underrepresented racial and ethnic groups across time periods and school contexts. The proposed project will also contribute to theories of mathematics teaching, with respect to the role of race and racialized experiences.

Theoretical Perspective

It is important that we acknowledge that race is socially-constructed and historically contingent, not biological, fixed, or causal despite harmful social discourses (Omi & Winant, 1994/2014). As race is socially constructed, humans become part of what Omi and Winant refer to as racial projects, which do the ideological work of shaping and reshaping what race means and how social structures are organized based on that meaning. In the context of mathematics teacher education, this means that Black mathematics teachers’ work is informed by the faulty discourse of Black people as mathematically inferior to their non-Black peers. Racism occurs when society buys into racial projects and reproduces structures of domination based on essentialist categories of race. Within this system, individuals have racialized experiences, i.e., social experiences shaped by racism. We posit that teaching mathematics, in a similar fashion to learning it, is a racialized experience influenced by multi-level external forces (Martin, 2000). Further, due to social, historical, political, and cultural forces, teachers at particular social intersections (e.g., racial, socioeconomic, linguistic) Black teachers may experience teaching mathematics differently than those from dominant communities (Clark, Johnson, & Chazan, 2009).

Research on both recruiting a diverse teaching force and increasing the mathematics teaching force often focus on recruitment issues such as college completion, standardized testing, financial concerns, or the need to create viable pipelines (e.g., Nettles, Scatton, Steinberg, & Tyler, 2011). With respect to retention, researchers cite site workforce conditions like autonomy over curriculum (Ingersoll, 2011; Neil, 2015). While acknowledging the importance of these issues, we assert that much of this work neglects how racism impacts each of these issues. For instance, Achinstein, Sexton, Ogawa, and Freitas (2010) noted that teachers of color highlighted issues such as “low expectations or negative attitudes about students of color, lack of support for culturally relevant or socially just teaching, and limited dialogue about race and equity” (p. 96) as deterrents to retention.

We used critical race theory (CRT) as our guiding theoretical perspective. CRT has its origins in the Derrick Bell’s (1980) legal scholarship. Bell’s work was expanded to the field of education by Drs. Gloria Ladson-Billings and William Tate (1995). CRT rests on the premise that racism is endemic, pervasive, and is normalized through social and institutional structures and practices in public spaces such as schools (DeCuir & Dixson, 2004; Ladson-Billings, 1998, 2013; Ladson-Billings & Tate, 1995; Milner, 2008, 2017). CRT tenets include (but are not limited to): (a) the permanence of racism; (b) whiteness as property (Dixson & Rousseau Anderson, 2018, Harris, 1993); and (c) intersectionality (Crenshaw, 1989; 1993; Ladson-Billings, 2013). Some of these tenets will be addressed in detail in the findings. These tenets hold explanatory power for understanding how race and racism shape mathematics teacher education and impact retention of Black teachers.

Methods

Integrating oral history and critical quantitative analysis via mixed methods research accommodated our interdisciplinary research questions. Specifically, we collected oral history interviews of retired Black mathematics teachers and large-scale survey data of currently practicing Black teachers. Combining what may seem like disparate methodologies, the collected data is helping us identify issues that are intractable across time periods and schooling contexts. We are planning focus groups for summer 2019, which we believe will further corroborate our preliminary findings.

Participants

Survey participants. The results presented in this paper are from two data sets, results from large-scale survey and oral history interviews. We surveyed 555 currently-practicing Black teachers of mathematics nationwide (women, 53%) using a survey we developed, the Black Teachers of Mathematics Perceptions Survey (BTOMPS). We were intentional in aiming to recruit a sample of Black teachers of mathematics that is representative of the Black teaching population in the United States. We also partnered with the Benjamin Banneker Association to garner participation and used social media and teacher social networks to recruit. The participants who participated in the survey ranged between the ages of 21 and 65 years (M =34.9, SD =8.6). A majority of the teachers identified as African American (98.2%). Other teachers specified their ethnicity as Caribbean (1.1%), African, Afro-Latino, and bi-racial/multi-racial (all < 0.5%). Teachers reported a minimum of a Bachelor's degree (50.1%), Master's degree (17.5%), doctoral degree (2.9%), and a specialist degree (2%). The teachers taught mathematics and/or other subjects between 0.5 and 34 years. The teachers taught mathematics and/or other subjects for less than five years (38.7%), between 5 and 10 years (45.6%), and 11 years or more (15.7%). The percentage of years teaching mathematics only are marginally different: less than five years (39.6%), between 5 and 10 years (45.4%), and 11 years or more (15%). They taught regular scheduled classes (at least one class weekly) at elementary (22.2%), middle (45.2%), and high schools (31.9%). The majority of participants (97.6%) taught at public schools, including traditional, public charter, and public magnet schools, and the rest taught at parochial/religious and independent schools (2.4%). The teachers represented more than half of the US states and the District of Columbia, with significantly less representation from the Rocky Mountain states. Most teachers in the sample (64.1%) took a traditional route to licensure for mathematics teacher certification.

Oral history participants. To date, our team has interviewed 13 retired Black female teachers who taught mathematics beginning as early as 1953. With the exception of two participants who came to teaching from other professions, all experienced teaching mathematics in (a) segregated community schools; (b) schools that were undergoing desegregation; and/or (c) schools that had been desegregated within a few years of their arrival. The majority of the participants began their careers in 1960s-1970s, with the exception of the two career changers who began in 1986 and 1991, respectively. We decided to narrow our participation regionally, opting to interview in the Washington, D.C. and Atlanta Metro areas because of the regions' rich histories of Black education due to their booming Black middle classes and thriving Historically Black Colleges and Universities (HBCUs). Snowball sampling procedures (Babbie, 2001) proved to be the most effective means of recruiting participants. We used social media and teacher social networks to recruit senior participants.

Data Collection and Analysis

Survey. All participating teachers completed the BTOMPS, which was designed to align with the literature on Black teachers of mathematics with respect to mathematics teaching and learning, beliefs and awareness, perceptions of race and racism, and working conditions. BTOMPS includes research team-written 4-point likert-style items, with responses ranging from strongly disagree to strongly agree. The research team-written questions were developed from the analysis of about two dozen interviews with Black teachers of mathematics and pre-service teachers (see Frank, Khalil, Scates, & Odoms, 2018 for more on these interviews). We included original and revised questions from the Mathematics Teachers of African American Students Beliefs Instrument ([MT-ASBI], Howse, 2006), designed to capture and measure the beliefs of Black high school mathematics teachers as they relate to teaching. Building on earlier work, the research team also included questions from a mathematical beliefs and awareness survey developed by Campbell et al. (2013). This survey measured teachers' beliefs about mathematics content and pedagogy as well as their beliefs and awareness about students' identities and dispositions toward mathematics. Finally, we amended a microaggressions scale that was initially developed by Harwood, Choi, Browne and Mendenhall (2015). These items were used to assess teachers' perception of race and racism in their school/districts. These items used a six-point Likert-type response scale ranging from '*never*' to '*once a week or more*'. For example, one question is: *People have made me feel intellectually inferior at my school/district because of my race*. To ensure content validity, the research team conducted cognitive interviews with currently practicing Black teachers of mathematics and mathematics teacher leaders. During the first wave of administration, the research team completed psychometric testing to reduce the overall number of items on the survey. Each participant participated in the survey using an online format that was administered via Qualtrics. In this report, we report descriptive statistics in this report and share implications for future quantitative analyses

By foregrounding race, racism, and intersectionality, we chose to frame this issue of attrition of Black mathematics teachers within CRT in order to disrupt how statistical data are interpreted, and to (re)tell, through the lenses of participants, the experiential knowledge and counterstories behind the data (Solórzano and Yosso 2002). Critical Race Quantitative Intersectionality (CRQI), informed by CRT, uses quantitative methodology to frame research, policy, and practice for the purpose of social justice and educational equity in a field dominated by qualitative research methods (Covarrubias & Velez, 2013, Sablan, 2019). Using a CRQI lens, we surveyed the participating teachers about their perspectives on mathematics content and pedagogy, racialized experiences as teachers, and current working conditions.

Oral history interviews. Each participant was interviewed twice, once without formal videography to help them recall their experiences and to familiarize them with the oral history process. The second interviews were recorded using a professional videographer. All interviews, formal and informal, lasted from 1.5 to 3.5 hours. In the tradition of oral history, collected data from primary sources such as newspapers, school board archives, yearbooks, mathematics texts, pictures, and other artifacts pertinent to the participants' lived experiences. Many of our primary sources were shared by the participants.

We used Firouzkouhi and Zargham-Boroujeni's (2015) 4-step analytic process for rigorously analyzing oral history data: (1) data gathering with participants and first-level, inductive coding based on researchers' impressions and memos; (2) second-level coding to determine sub-categories within the first-level codes; (3) third-level coding and determining the main categories; and (4) connecting the main categories to each other to develop a strong narrative. These steps are complementary, connected, and related in a cyclical fashion, such that the final stage connects to the first to form what the authors call an analytic "circuit." Our analysis of this data is also informed by knowledge of the literature about Black teachers from historical and contemporary perspectives. In our analysis of the oral history data, we identified themes that inform connections to, implications for, and divergent experiences from contemporary recruitment and retention issues for Black mathematics teachers.

Post-analysis, we began to identify in the qualitative data set what Sisson called "critical incidents" with respect to race and racism in the mathematics teaching experiences of our teachers, meaning instances are pivotal to the identities and lived experiences of the participants. These critical incidents highlighted the salience of race within the themes generated during the initial oral history coding process. Because we adopted a CRQI quantitative approach (Covarrubias & Valez, 2013; Sablan, 2019), we identified findings in the descriptive data that mirrored the experiences of our oral history participants, and vice versa. Seeking out these reflexive relationships between the qualitative and quantitative data allowed us to begin to put together a narrative about the intractability of racism in the experiences of Black mathematics teachers over time.

Results

Using three tenets of CRT to frame this section, we present preliminary findings and highlight how integrating novel methodologies helps to paint a more complete picture of recruiting and retaining Black mathematics teachers.

The Permanence of Racism

As noted earlier, for critical race theorists, racism is commonplace in the U.S. (DeCuir & Dixson, 2004; Ladson-Billings, 1998, 2013). It follows that it is endemic in education as well (Delgado and Stefancic, 2001). Thus, the one of the goals of critical race theorists in mathematics education is the unmasking of racism when "denotations [of racism] are submerged and hidden in ways that are offensive though without identification" (Ladson-Billings, 1998, p. 9). Our data point to the veiled permanence of racism and the inherent racist structures of district- and school-level practices contribute to the Black mathematics teacher shortage and attrition. We use examples from the qualitative and quantitative data of our study to point out instances of veiled racism. When asked about instances of microaggressive experiences in their schools/districts, the survey participants reported the following: (a) 60.4% responded that people have made them feel intellectually inferior because of their race at least once monthly; (b) 58.2% indicated that at least once per month their contributions were minimized due to their race; and (c) 54% reported having their academic ability or intelligence minimized once monthly or more frequently.

This data was collected in the spring-summer of 2018, yet it mirrors the sentiments of the retired teachers in the study who also shared microaggressive experiences related to having their intelligence questioned. Experiences included those like Mrs. Joyce Lyons, a retired teacher who taught over 40 years in the mid-Atlantic region. She shared an experience from one of her first teaching jobs in the 1960s:

> I just felt like the white teachers thought that we [Black teachers] were not smart as they were. One [fellow teacher] even told me, 'You just don't have the experience to teach math…I don't know what he meant by that, but he kept telling me that.

The qualitative data set is filled with examples such as these that mirror what the quantitative data tells us about microaggression trends related to Black teachers who are currently teaching. Other examples included being doubted and disrespected by administration and parents. These data point to the longstanding, inherent, and overlooked nature of racism that plagues mathematics teaching.

Whiteness as Property

The whiteness as property tenet states that those who are identified as white are guaranteed rights that are equal to, if not more valuable than, material resources that position them in power (Harris, 1993). Often, these rights are so inherently normalized, they are difficult to recognize (Milner, 2017). It is important to note that whiteness is not simply a fixed characteristic of a particular group of people. In the context of mathematics teacher education, teaching advanced mathematics courses is the material property that is withheld from Black teachers. In fact, Neil (2015) found that Black mathematics teachers overwhelmingly teach lower-level mathematics. In her study, she found only 3% and .3% of Black teachers taught calculus and statistics, respectively. Connecting the contemporary to the historical, the teachers in our oral histories consistently recounted being relegated to teaching lower-level mathematics when teaching in more racially-diverse teaching settings. We noted that only when their student populations were

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

predominantly Black were they afforded the opportunities to teach advanced mathematics courses. We see this tenet as interconnected with the previously-discussed tenet of the permanence of racism, as the phenomenon of denied opportunities to "property" like teaching advanced mathematics courses occurs when the racial project of Black inferiority is played out in ways that lead to the minimizing of Black teachers' intelligence and contributions.

Intersectionality

Intersectionality calls for the examination of race in tandem with gender and its performances and expressions, sexuality, social class, nationality, and numerous other systems of oppression or privilege in various settings (Crenshaw, 1989, 1993; Delgado & Stefancic, 2001; Ladson-Billings, 2013). Race structures the lives of Black people in ways that often make it difficult to differentiate how multiple and overlapping systems of oppression impact lived experiences (Crenshaw 1989; 1993). Black people across the diaspora share a collective Black experience, *and*, simultaneously, the Black experience is multifaceted and diverse; i.e., it is intersectional. We knew that the experiences of teachers with respect to gender varied. For instance, Neil (2015) reported that Black female teachers make 32% less that their Asian male mathematics teaching counterparts. She also found that Black female mathematics teachers had the highest rate of turnover in her dataset, across men and women of all demographics.

With respect to the literature, researchers have pointed to how Black male teachers are expected to perform tough love and be disciplinarians, often at the expense of their content and pedagogical expertise (Frank et al., 2018; Bristol & Mentor, 2018; Brockenbrough 2012, 2015). On the other hand, Black female teachers are presented in the literature as caring surrogate mothers, coined othermothers by Dixson (2003) and Dixson and Dingus (2008). Intersectionality, and in particular, the intersection of race and gender are of particular salience to our findings. Our work points to gender differences such as We hypothesized that the BTOMPS microaggression responses would likely vary by gender given what we have learned from the literature about the dominant masculinist perspective of mathematics (Hottinger, 2016) and how it is compounded by race for Black women and girls in STEM (e.g., Joseph, Hailu & Boston, 2017). This research helped us interpret the survey finding wherein half as many Black men (10.3%), compared to Black women (20.4%) believed their intellectual contributions were minimized.

The oral history data point to comparable experiences. Gracie Kenon, retired veteran mathematics teacher of 38 years in Georgia and Washington, D.C. recounted the struggles of majoring in mathematics as a Black woman, even at an HBCU. Inherent in the all of the interviews with our oral history participants, who were all women by coincidence, was the care, both interpersonal and academic, that they poured into their students. Mrs. Gail Radcliffe, former mathematics teacher and administrator, described the othermothering (Dixson, 2003; Dixson & Dingus, 2008) techniques she and the other Black women teachers employed like buying alarm clocks to get their students to school on time and advocating for more rigorous mathematics curriculum for their students. While these women othermothered, many of them also discussed the balancing act of mothering their own children and being present for their students. We anticipate collecting oral history interviews from male teachers in the near future to further analyze how gender intersects with mathematics teaching for Black teachers.

One unanticipated finding with respect to intersectionality was how years of teaching impacted our survey results. The veteran teachers in our sample, i.e., those who taught for more than 10 years experienced significantly less microaggressive behaviors than those who had less experience in the field. For instance, over half of them reported having never felt intellectually inferior due to their race, when compared to over a quarter of teachers with 9 or fewer years reported feeling intellectually inferior by others due to race a few times a month or weekly. We have generated two plausible conjectures for why this pattern may be emerging in the data. First, we wonder if teachers who have taught for an extended number of years are simply more respected for their content and pedagogical knowledge and experience. We draw on our findings from the oral history component of our grant project to arrive at our second conjecture. In our ongoing interviews with retired Black teachers of mathematics we are finding that they do not name racism and oppression in ways that the currently practicing and pre-service teachers do (Frank et al., 2018). For instance, the retired teachers have shared incredible stories of persistence during the desegregation of schools, and yet when asked directly about how race impacted their teaching practice, many said they do not think that it did.

Second, we conjecture that, perhaps, in this current sociopolitical climate in which race is central to national discourse, the teachers in our study who have less teaching experience (and are likely, but not necessarily, younger) are able to name racism and the associated microaggressions in ways that our more senior participants do not, or maybe cannot. In essence, we wonder if generational differences are at play in the data. In all, these results from the microaggression scale highlight the necessity of unpacking quantitative through a CRQI lens to think about mathematics teachers' experiences at the intersections of interlocking systems of oppression and/or privilege. These findings warrant continuing examination of retention factors with respect to how intersecting identities, oppressions, and markers of privilege make mathematics teaching complex for Black teachers.

Conclusion

Clark et al. (2013a, 2013b) proposed that the study of Black mathematics teachers' experience is essential to the field of mathematics education as the field broadens to account for sociocultural (Lerman, 2000) and sociopolitical (Gutierrez, 2013; Nasir & McKinney de Royston, 2013) perspectives on teaching mathematics. They went on to theorize the role of Black mathematics teachers as "boundary spanner[s] with membership in multiple communities, a mathematically proficient and intellectually powerful African American person within a historically disempowered African American community with a history of inaccessibility to and underperformance in mathematics" (p. 1). To better understand the role of Black mathematics teachers as boundary spanners, we propose using mixed methods as described above. In this era of rapid technological advances, with Betsy DeVos at the helm of the U.S. Department of Education, charter schools with "No Excuses" mottos dominating the education of Black children, and a dwindling mathematics teaching force, coupling oral history with other methods of data collection and analysis holds promise for unpacking how critical points in history impact still resonate in the present and hold promise for understanding a pressing issue like retention that the field treats as a contemporary issue despite its longstanding presence in the field.

Our future work will continue to unpack the complexities facing Black mathematics teachers with a nod to intersectionality by considering how race is impacted by gender, region, years teaching etc. We are working on predictive statistical models of Black teacher attrition based on the microaggressions data. Furthermore, the study continues to gather and share the oral histories of retired Black teachers of mathematics who taught Black students in functionally segregated schools pre- and post-*Brown.* We intend to map the intractability of negative racialized experiences over the generations of Black teachers, as well as the persistence of African American Pedagogical Excellence, defined as an ideology, set of beliefs, and instructional practices held by Black teachers that affirm and uplift Black students and their families toward high levels of academic achievement (Acosta, Foster, & Houchen, 2018). Further, we will use the oral history and quantitative data with focus groups of currently-practicing Black mathematics teachers across the country to deepen our understanding of the issue they face and what the field can to address these conditions.

WHAT DOES ATTENDING TO POWER IN TEACHING LOOK LIKE?

Erin Smith
The University of Southern Mississippi
erin.marie.smith@usm.edu

Jonee Wilson
North Carolina State University
jwilson9@ncsu.edu

Keywords: Equity; Social Justice

Although scholars have recognized that *Standards* (National Council of Teachers of Mathematics [NCTM], 2000) based mathematics instruction alone cannot eliminate differential access and opportunity gaps, little movement has been made on a national scale to effectively teach in ways that a.) sustain students' cultural resources and b.) address issues of power–both of which are necessary in order to achieve equity (Gutiérrez, 2012; Gutstein, 2003; Jackson & Cobb, 2010; Leonard, Brooks, Barnes-Johnson, & Berry, 2010). Instead, such teaching is often reserved to isolated social justice or equity-focused lessons. If large scale change is to occur, teachers must be prepared and supported to effectively integrate students' cultural resources and attend to power in their instruction (Gutiérrez, 2002). When teachers attend to power, they consider who gets to speak and whose voice is privileged to ensure equitable participation (Gutiérrez, 2002), provide opportunities to use mathematics to interrogate inequities and increase sociopolitical consciousness (e.g., Gutstein 2003, 2016; Gutiérrez, 2017), value alternative ways of knowing (e.g., non-dominant mathematical practices; Moschkovich, 2002), and understand that mathematics is humanistic (Gutiérrez, 2002). Unfortunately, exemplars of this kind of teaching are limited within the field.

One way to support teachers' refinement and implementation of equitable practices that attend to power is through professional development and resources, such as the videos provided by NCTM. Given NCTM's large membership pool and conferred authority, NCTM has an opportunity to share a vision of mathematics instruction that sustains students' cultures and creates social transformation. To examine how effectively NCTM currently proffers such instructional support to its members, we analyzed the professional videos available to members. To do this, we coded all available videos in the "Principles to Action Toolkit" to identify the ways students' culture and power (as described above) was attended to.

Preliminary findings indicate that while the videos demonstrate examples of "reform-oriented" or "*Standards*-based" instructional practices, they show minimal evidence of instruction that sustains students' cultures and addresses power. More specifically, we found little evidence of instruction that provided opportunities for students to use mathematics to interrogate inequities, valued "alternative ways of knowing," or served to increase students' sociopolitical consciousness. Subsequently, the videos further support Gutiérrez's claim that "reform mathematics alone does not ensure that issues of power in society are addressed" (2002, p. 150). We contend, based on our analysis, that more concrete examples of how to teach mathematics in ways that sustain students' culture and address issues of power are needed if teachers are to implement changes in their practice.

Keywords: anti-racism, equity, professional development

Mathematics education in the United States is a white institutional space that disguises itself as apolitical (e.g., Martin, 2009). In this poster, we share a tool developed to assist mathematics teacher educators to enact an antiracist pedagogy. After two years of doing professional development with a group of teachers working in a small urban district, we realized that we had not developed a collective understanding of what it means to engage in anti-racist mathematics education. Therefore, we sought to learn along-side five teachers through a series of meetings conducted over the 2018-2019 school year. We believe this tool will be useful to mathematics teacher educators as they seek to incorporate and antiracist stance in their professional growth, teaching, and professional development they lead.

We draw on Collins' (2009) four domains of racism: structural, disciplinary, cultural, and interpersonal. The structural domain of power is the ways in which various institutions are networked to uphold the racial hierarchy. The disciplinary domain of power considers the ways in which policies and procedures are carried out or enacted by individuals or organizations. The cultural domain of power maintains a racial hierarchy by perpetuating images and narratives in media, popular culture, and elsewhere. Lastly, at the interpersonal level, racism occurs through prejudices among individuals' interactions that are intended to have a differential and/or harmful effect on members of the non-dominant race. Often the policies and procedures are race-neutral yet have disparate and harmful impact on the non-dominant race because of the ways they are carried out. We define antiracist mathematics pedagogy as actively resisting and countering racism at all four domains within mathematics education.

In our poster, we will share the tool that poses questions to consider and provides examples of resistance in order to enact an antiracist pedagogy within each domain. For example, when considering the disciplinary domain, the tool asks: How does this task reinforce (mis)perceptions about math abilities, who can be good at math, and the ways one demonstrates competence? We hope to generate engaging conversation around this tool to continue a discussion on antiracism within our mathematics education community.

This project is at the intersection of mathematics education, educational history, and Indigenous Studies. We begin by proposing a theoretical argument, followed by a description of an archival research project. We seek to contribute to ongoing historical debates regarding the role of mathematics education in settler colonial curricula in the United States.

Educational scholars have argued that mainstream schooling functions as a *de facto* assimilation force, where the language and practices around academic learning are used to "smuggle" English-only policy, reproduce cultural erasure, and inscribe dominant values and ideology rooted in whiteness (e.g., Benally, 2014; Darder, 1991; Delpit, 2006; Trennert, 1988). The aim of colonial Indian education was to "Kill the Indian but save the man" and to train the Native to subservience (Lomawaima, 1993, 2018). For math education, the argument continues that the contemporary math curriculum acts as an insidious vessel that laces classroom discourse with colonial logics and norms (Gutiérrez & Scott, 2019; Popkewitz, 2004; Warburton, 2015). Without critical pedagogical interventions, these oppressive logics enable "ontological imperialism" (Bamberger & diSessa, 2003) and "cognitive normalization" (J.F. Gutiérrez, 2015) that are constantly at play in the psychology of mathematics teaching and learning. Is the current environment of math education for Native students merely the "de facto" state of affairs, or was it *designed* that way from the start? We hypothesize that oppressive practices in mathematics education are traced to late 19th and early 20th century U.S. assimilation policies, for example, the use of Native American boarding schools to transform not only the appearance and behavior of Native peoples but their *psychology* too—an act of internal colonization (Lomawaima, 1993).

We are launching a collaborative historiographic project in which we will examine our emerging hypothesis. Our research team consists of four scholars from varying fields with methodological expertise, including mathematics education, Indigenous epistemologies, decolonizing methodologies, Indian Education, and Native American history. We will analyze primary and secondary resources such as documents, photographs, and other artifacts, related to math curricula and policies utilized in Native American boarding schools. The main strategy within this archival project is to identify and code connections between historiographical materials and contemporary math education policies, practices, language, and concepts.

Discovering links between settler colonialism, federal assimilation policies, and the psychology of math education is vital for understanding the damaging effects of math schooling. This project can provide additional impetus for stakeholders to re-imagine the purpose of math education and to consider critical pedagogical approaches based on humanizing mathematics, such as represented by *Mathematx* (R. Gutiérrez, 2019), among other decolonizing pedagogies.

Currently in the United States, there are over 179,200 students participating in collegiate athletics at the highest level, Division I. Of these, only 2% will continue on in their collegiate sport professionally (NCAA, 2018). That being said, student-athletes often face discrimination in both the eyes of professors and students, who may view them as being academically inferior and perpetrate the "dumb jock" stereotype (Engstrom & Sedlacek, 1991). Additionally, the students may often find the balance between academics and athletic performance to be a particular challenge (Yukhymenko-Lescroart, 2018). For student-athletes with interests in STEM in general and mathematics in particular, these challenges can be even more pronounced. Student-athletes have reported surprise by their peers and professors alike at their presence in mathematics and STEM courses, even going so far as feeling as though they are "spectacles (Comeaux, Griffin, & Bachman, 2017). This type of "othering" can have severe effects on mathematical performance. In one particular study conducted by Riciputi and Erdal (2017), student-athletes who were primed with questions about demographic identity and their athletic participation before engaging in a mathematics test attempted fewer problems at a statistically significant rate than student-athletes who were primed with questions only about demographic identity.

In this case study, a series of interviews were conducted with a purposively chosen male student-athlete who entered a Division I university in a major athletic conference as a STEM major. The interviews were coded to look for themes of identity and it was found that, as the student's athletic career developed, a shift in dominant identity from STEM student to student-athlete was noticed. Furthermore, due to the demands of Division I athletics, the student ultimately switched career goals out of STEM fields altogether. While this was a case study, further implications regarding analyzing ways to encourage student-athlete persistence in higher level mathematics and STEM coursework through post-secondary education were explored as a result of these interviews.

A FRAMEWORK FOR DEVELOPING CRITICAL STATISTICAL LITERACY

Lauren Baucom
University of North Carolina at Greensboro
lnbaucom@uncg.edu

Keywords: Data Analysis and Statistics, Equity and Justice

In the 2007 *Guideline for Assessment and Instruction for Statistics Education* Report, Franklin and colleagues established that the learning of statistics has equal importance in understanding content knowledge and nurturing the statistical literacy one needs in order to be a productive citizen in today's society. However, it was not until 2012 that many educators were required to teach courses that contained the domain of statistics for the first time due to the adoption of the Common Core State Standards (National Governor's Association Center for Best Practices & Council of Chief State School Officers, 2010) by 47 US states. As a result, data analysis and statistics has gained recent prominence in grades 6 – 12, yet many K-12 mathematics educators are not adequately prepared to teach this new content area because of lack of prior coursework in statistics (Franklin et al., 2015; Shaughnessy, 2007).

Supporting students' skepticism of statistical information is necessary for this current era of data saturation, yet few students have the opportunity to cultivate healthy statistical habits of mind (Lee & Tran, 2015) and instead opt for heavy consumption of data as absolute truth. Literature has shown that students are not learning the statistical thinking and reasoning needed to develop healthy skepticism of statistical information, and that inappropriate reasoning of youth and adults about statistical ideas is pervasive, assiduous, and immutable (Garfield & Ahlgren, 1988). This compounded by teachers' limited experiences with data statistics and analysis which have implications for promoting statistical thinking of students.

Parallel to developing a healthy skepticism in statistics is the need to develop a critical consciousness in students engaging in mathematics learning. Developing students' critical consciousness in statistical thinking requires a sociopolitical turn that empowers students to identify with and transform their world (Gutierrez, 2013). The racial demographics of student populations in the United States schools are currently shifting. Given the large surges of enrollment of students of color and the simultaneous shrinking populations of white students in our public schools (Snyder, De Brey, & Dillow, 2018), it is important that youth of color have a robust, mirroring, statistical experience in K-12 education in order to engage in and critique the arguments around the statistics that classify them. Statistical literacy has been shown to be a fruitful space of radical possibility that could prompt a student to "recognize his or her position in society" and "motivate individuals to action" (Frankenstein, 1989, 1990, 1995, 2009; Gutierrez, 2013).

With a call for statistical reasoning that centers on citizenship of all students (Franklin et al., 2007), there is a need to theorize this work of fostering statistical literacy with a critical lens. As central tenets of the framework, I will use the existing literature around developing healthy skepticism and critical consciousness to highlight progress in this area of research and hypothesize a potential framework.

> How do we develop mutual support systems that can engage us in dealing profoundly and meaningfully with issues that are deeply emotional: how we were treated as learners, how our intelligence was interfered with, how we experienced prejudice and discrimination and saw it affecting others? (Weissglass, 1998, p. 4)

Julian Weissglass' question mirrors the impetus which began our work together as graduate students in mathematics education. As Latinx graduate students entering mathematics education, we are becoming mathematics scholars invested in critical work. Through dialogue, we grapple with questions together: What is a critical mathematics scholar? How do I become one? Our identities as Latinx graduate students provides us with a position to best experience, understand, and speak to the barriers in becoming critical mathematics scholars because we are the ones living the movement (Freire, 2005). We engage in dialogue to reflect deeply on the barriers and to develop our strategies and forms of resistance. We reveal emotion and share stories with each other and the reader. With our vulnerability lies a risk to speak and be heard.

We chose to engage in a living manuscript (Shor & Freire, 1987) in which we are in dialogue after acknowledging the insight our identities provide and our common commitment to action. Dialogues in mathematics education have raised issues about racism and mathematics (Ambrosio, Et al., 2013); we wish to utilize a similar dialectic – centering the voices of graduate students in mathematics education. Each author of this poster is at a different research institution in four different states, each arriving to graduate school from different paths, exemplifying the rich complexity of varied perspectives.

Through engaging in the living manuscript, we found becoming a critical mathematics scholar to be complex. It requires answering the questions, *What is a scholar?* and *What is mathematics?* before asking *What is critical*? More so, the overlapping and layered spaces of our experiences resulted in the opportunity to harness nepantla (Anzaldua, 2013), that space of limitless possibilities, disidentification, and transformation. Nepantla offered us an opportunity to transform and grow as scholars, separated over vast geographical distance. We thus encourage others to engage in dialogue to learn more about self and the world. We end by echoing the words of bell hooks, where "[t]he engaged voice must never be fixed and absolute but always changing, always evolving in dialogue with a world beyond itself" (p. 11, 1994).

TEACHERS' ENGAGEMENT WITH A COMPETING MODELS INFORMAL INFERENCE TASK

Jennifer N. Lovett
Middle Tennessee State University
Jennifer.Lovett@mtsu.edu

Ryan Seth Jones
MTSU
Ryan.Jones@mtsu.edu

Matthew Duncan
MTSU
Matthew.Duncan@mtsu.edu

Informal inference is a critical practice for students to engage in if they are to understand formal statistical methods. However, during informal inference students often utilize complex ideas that many in-service teachers are not prepared for as they have not had the opportunity to think deeply about statistics and develop statistical knowledge for teaching (Groth, 2013). Research shows that engaging teachers in authentic inquiry of content supports the development of that content knowledge, and there is an urgent need to do so through professional developments (PDs). However, there is limited literature concerning PDs in statistics education, and a dearth of research focusing on teachers' engagement with informal inference tasks. This paper describes in detail how two teachers engaged with a seminal informal inference task during a PD, including their reasoning about variability and sample size when making inferences.

Keywords: Data Analysis and Statistics, Teacher Knowledge, Technology

Informal inference is a critically important practice for students to develop in middle and high school if they are to deeply understand more sophisticated inferential methods in later grades (Pfannkuch, 2011). Even if students do not go on to study formal inference this foundation will allow them to question claims presented to them in wider society. However, informal inference makes use of a complicated set of ideas, representations, and practices. What's more, research has shown that most teachers do not have a deep understanding of the foundational concepts related to statistical inference (Lovett & Lee, 2017; Franklin et al., 2015). These findings should not be viewed as shortcomings of teachers, but rather shortcomings of the educational experiences they received in their school mathematics and teacher preparation programs. Even though standards documents such as *Principles and Standards for School Mathematics* (National Council of Teachers of Mathematics, 2000) and *Common Core State Standards* (National Governors Association Center for Best Practice & Council of Chief State School Officers, 2010) have increased the emphasis on statistics, statistics has not been prioritized in K-12 mathematics classrooms and preservice mathematics teacher preparation programs. This has created an environment where teachers, even mathematics teachers, can complete their K-16 schooling without being supported to think deeply about statistics and develop the statistical knowledge for teaching (Groth, 2013) they need to teach the statistical standards in their curriculum. Research has shown that one effective way to increase teachers' content knowledge is to engage them in authentic inquiry that uses the concepts one desires teachers to develop (Borko, 2004). Thus there is an urgent need to support in-service teachers in deepening their statistical knowledge through professional development (PD) to support student learning in this area.

Even with this urgent need there has been a lack of research on PDs in statistics education. There are a few PDs that have researched teachers' statistical knowledge (Bargagliotti et al., 2014; Huey & Weber, 2018; Nieszporek, Biehler, & Griese, 2018; Peters, 2018; Peters, Watkins, & Bennett, 2014; Wassong, 2018) but none that we found report on teachers' approaches, understandings, and misunderstandings of specific informal inference tasks. These studies report pre/post knowledge gains or a retrospective analysis of the impact of the professional development on content (Huey & Weber, 2018; Nieszporek et al., 2018; Wassong, 2018), dilemmas teachers experienced regarding distributions or measures of center (Peters, 2018; Peters et al., 2014), or misunderstandings of sampling variability and regression that emerged as a result of several tasks (Bargagliotti et al., 2014). Thus the purpose of this paper is to share teachers' approaches and understandings on an informal inference task used during a professional development aimed to increase middle school teachers' statistical knowledge for teaching.

Background Literature and Framework

Informal Inference

A number of researchers have defined or described informal inference (e.g., Garfield & Ben-Zvi, 2008; Makar and Rubin, 2009; Rossman, 2008; Zieffler, Garfield, delMas, & Reading, 2008) and the common consensus is there are three key principles of informal inference: 1) claims, generalizations, predictions, parameter estimates, and conclusions, that extend beyond describing the given data; 2) the use of data as evidence for those claims; and 3) acknowledging uncertainty in their claims through the use of probabilistic language. Within informal inference Zieffler et al. (2008) identified three types of inference tasks that allow for the development of these key aspects of inferential reasoning: 1) estimate and draw a graph of a population based on a sample (referred to as *Samples and Populations*); 2) compare two or more samples of data to infer whether there is a real difference between the populations from which they were sampled (referred to as *Comparing Groups*); and 3) judge which of two competing models or statements in more likely to be true (referred to as *Competing Models*). Zieffler et al. (2008) identified three types of *competing models* tasks that have been used sample data to choose between two models or claims. In this paper we focus on one of these, a task used by Lee, Angotti, and Tarr (2010), the Schoolopoly task, which compares data generated by a probability device and the theoretical probability to determine if the probability device was "fair."

Schoolopoly task. The Schoolopoly task is a competing models task that asks students to investigate whether a die is fair or not based on a simulation (https://s3.amazonaws.com/fi-courses/tsdi/unit_3/Schoolopoly%20Task.pdf). There were a total of six dice companies to investigate and each pair of students were assigned one company. The students are asked to "investigate whether the die sent to you by the company is, in fact, fair. That is, are all six outcomes equally likely to occur?"

Variability

Research has shown that grounding statistical inquiry in a deep understanding of variability and supporting students to represent, describe, measure, and model variation in data can support them to understand statistical methods as well as the epistemic role they play in making claims in light of variability (e.g., delMas & Liu, 2005; Peters, 2011; Peters et al., 2014). In spite of the importance of helping students understand variability, research has also shown that variability is a topic that is challenging for people of all ages to grasp and the research on teachers' understanding of variation is sparse (Sánchez, daSilva, & Countinho, 2011). Random variation in everyday life is often perceived as having no structure, mere random differences. Because of this lay understanding of randomness, students and teachers alike often do not conceptualize random variation in ways that are consistent with statistical inquiry. For example, they rarely connect random variation with a mathematical structure that leverages probability to conceive of a distribution of variable outcomes (Lehrer & Kim, 2009; Watson 2006). This challenge extends to the use of variation in order to make predictions of probability situations. Sánchez and Garcia (2008) asked six teachers to predict the number of times each number would occur if a dice was rolled 60 times. Five of the six teachers predicted an equal number of outcomes for each number on the dice; a sequence of 10, 10, 10, 10, 10, 10. These teachers were viewing variability deterministically, looking for a definite answer.

Sampling and Sample Size

When making decisions under uncertainty, most people tend to use judgmental heuristics that can cause errors in reasoning (Harradine, Batanero, & Rossman 2011). One example that applies to competing models tasks is that people tend to believe that even a small sample should reflect all of the characteristics of the population (Kahneman & Tversky, 1972). This misunderstanding can be extended to random samples. Even if a random sample is chosen in an appropriate way and of sufficient size, research has shown that students believe that the random sample is a replica of the population. This way of thinking does not take into consideration the variability across samples (Harradine et al., 2011; Saldanha & Thompson, 2002). Saldanha and Thompson (2002) found when high school students were asked to judge how representative a sample was in relation to a population parameter, students compared their sample to the population parameter and not "on how it might compare to a clustering of statistic's values" (p.265).

Professional Development Context

The task was situated within a year-long professional development program designed to blend online learning resources (*Teaching Statistics Through Data Investigations*, http://go.ncsu.edu/tsdi), an intensive summer workshop, and monthly professional learning community (PLC) meetings. The summer institute was designed to support the development of content knowledge and knowledge of student thinking using resources from a middle grades curriculum called Data Modeling (modelingdata.org). The year-long professional development framed statistical inquiry as the practice of generating knowledge using variable data, engaged teachers with statistical inquiry tasks, and supported them to analyze student artifacts and collectively plan instructional strategies for their classrooms.

The focus task in analysis occurred during day 3 of the five-day summer workshop. We began the first day of the workshop by engaging teachers in making an inference about a randomly drawn reward process to determine if the drawing was fair or biased in order to frame the activity of making model based inferences in the midst of variable systems. With this broad framing, we then engaged teachers with repeated measurements of a common object to engage with variability and distribution, and supported them to make judgements about student thinking using student artifacts from a similar activity. Teachers then explored students' approaches to measuring the center of a distribution, and teachers invented statistics to measure variability. During day 3 the teachers began by creating repeated samples of chance processes to explore sampling variability. The Schoolopoly task occurred after these activities, with the goal for teachers to use ideas about data, distribution, sampling variability, probability, and statistics to make their judgements about the dice companies.

Schoolopoly Task for Teachers

We modified Lee et al.'s (2010) original Schoolopoly task that was designed for middle school students to be used with middle school teachers during our PD (Figure 1). The first modification we made was in the choice of technology. Since Probability Explorer is not readily available to teachers, we used StatCrunch. The same six "companies" that Lee et al. (2010) used are now built into StatCrunch as an app. Secondly, the teachers were asked to investigate all six dice companies instead of just the one company that middle school students were assigned. Finally, teachers were given a limited number of trials that they could assign to the six companies as they wanted to. In Lee et al.'s (2010) study, the middle school students were investigating the role of sample size for the first time and did not have any directions regarding the number of trials. However, since teachers were aware that a larger sample size would produce a more representative sample we chose to limit the number of trials they could run. Two additional parts of the task were added as the teachers were working through the task. They were unaware of these additional parts when they began working. Part B and C of the task allowed teachers additional trials to determine the one fair company. These decisions to modify the task for teachers were made so that teachers would have opportunities to compare empirical data from different populations, and so to provoke a need to make inferences with limited numbers of samples since students in the past often ran large numbers of trials to reduce uncertainty.

Part A: Your school is planning to create a board game modeled on the classic game of MonopolyTM. The game is to be called Schoolopoly and, like MonopolyTM, will be played with dice. Because many copies of the game expect to be sold, companies are competing for the contract to supply dice for Schoolopoly. Some companies have been accused of making poor quality dice and these are to be avoided since players must believe the dice they are using are actually "fair." Each company has provided a sample die for analysis and to investigate:

Luckytown Dice Company	Dice, Dice, Baby!
Dice R' Us	Pips and Dots
High Rollers, Inc.	Slice n' Dice

1. You have 300 trials to divide up between the 6 companies. Test the companies to determine if the company is fair or biased. There is at least one fair company.
2. In a google doc, record your evidence to support your decision if the company is fair or biased and your decision of how to divide up the 300 trials.

Part B: The PD facilitator offers each group 200 additional trials to identify the single unbiased company. Trials can be used to confirm or disconfirm their previous identifications of each company as biased or unbiased.

Part C: The PD facilitator offers each group 50 additional trials if they would like them.

Figure 1: Schoolopoly Task Modified from Lee et al. (2010).

Methodology

Given the importance of developing teachers' statistical knowledge for teaching and the lack of research on teachers' approaches to informal inference tasks, warrants study in the ways that teachers engage in an informal inference task during a PD. In this study we aim to answer the following research questions:

RQ 1 How do teachers engage with the Schoolopoly task?
RQ 2 Within the Schoolopoly task, how do teachers reason about sample size and variability?

To answer our research questions, we utilized a multiple case study design (Yin, 2009) to describe the ways teachers engaged with the Schoolopoly task and the ways they reasoned about sample size and variability. Each case is represented by a pair of teachers working on the Schoolopoly task.

Participants

During the summer of 2017, 20 (2 = males, 18 = Females) middle school mathematics teachers participated in a week-long summer institute housed within year-long professional development project. Teachers were recruited from local Southeastern public schools representing seven different schools across both urban and suburban areas. Seven out of the twenty teachers were African-American and the remainder were White. As a whole, teaching experience ranged from less than one year to twenty plus years.

Data Collection and Analysis

Teachers each had access to a computer but worked in pairs to complete the Schoolopoly task. They collaborated in a google document to organize screenshots of the graphical representations created by StatCrunch as well as their identifications and justifications of each machine being fair or biased. We screen and audio recorded each pair during the task.

After the screen recordings were transcribed, each researcher individually wrote a narrative of the teachers working through the task. The narratives included portions of the transcript, justifications and graphical representations from the google document, and the researchers recording of their actions. Researchers compared their descriptions and collaboratively wrote a single description for each pair of teachers. Then we completed a cross-case comparison (Merriam, 1998) to identify themes in the ways teachers engaged with the task and how the reasoned about sample size and variability. Through this comparison three themes emerged; 1) The ways teachers articulated the two models under competition, 2) the ways teachers described and measured variability, and 3) the ways teachers accounted for sample size.

Results

Due to space limitations, we present one of the three cases of teachers, Myra and Kendall. This case was chosen because in many ways these teachers typified approaches of the other teachers in the PD, but also because of their efforts to formally quantify the variability to inform their decisions, which was less typical.

Kendall and Myra's Work on the Schoolopoly Task

Myra and Kendall began the task by dividing up their 300 roles evenly among the six companies before making any inferences about which companies were fair or biased. Through examination of the graphs Myra and Kendall immediately declared five of the six companies biased without much discussion. They made initial judgements about the status of each company by focusing on how similar the proportions are, explaining "If the dice were unbiased the results would be similar/same for each outcome."

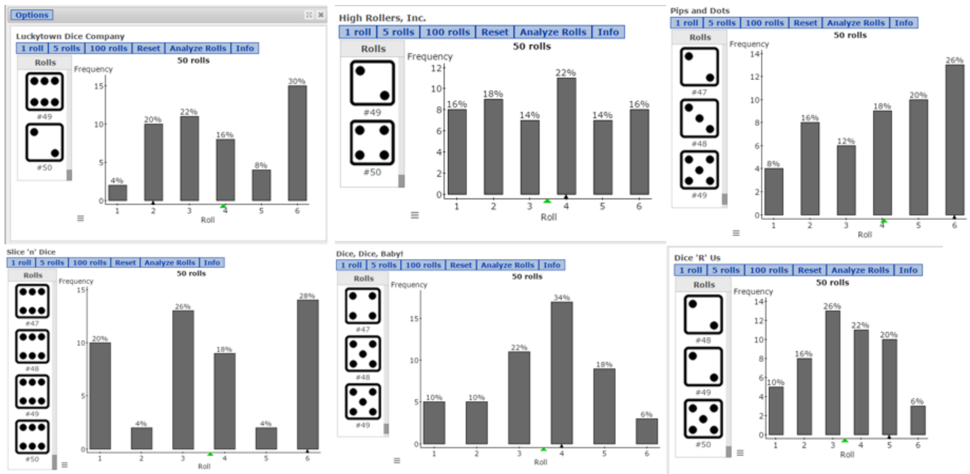

Figure 2: Myra and Kendall's Distributions After 50 Rolls

Myra and Kendall began looking for how similar outcomes were after the initial 50 rolls for each company. They then mathematized the idea of similarity by calculating the difference from the lowest and highest percentages for all six companies. For example, for Luckytown (Figure 2), Kendall and Myra wrote, "Biased. Luckytown has a range of results from 4% to 30%. This tells me that I am very unlikely to roll a 1 as compared to rolling a 6." This was their first method of quantifying the variability in the data. This approach led them to identify all companies but one as biased. The one company they declared unbiased after 50 rolls was High Rollers Inc (Figure 2). Kendall and Myra identified this company as fair since "the range of this data is 6%, making the results similar to each other (within 6% of each other) making this more likely to be the unbiased or fair option. They did not discuss sampling variability or mention what was an expected variation in the occurrences; only that six percent fell into the interval that they felt comfortable calling unbiased.

When Kendall and Myra were offered an additional 200 rolls and they first suggested to use 100 of their additional rolls on High Rollers Inc. to verify their results. Then they decided to consider other companies that may be fair even if they originally judged them as biased. To decide which companies to give additional rolls to they identified companies that had "no way" of being fair based on the first 50 rolls, referring to the difference in the highest and lowest percentages when making this decision. Kendall and Myra decided that a sample size of 50 was sufficient to make this decision as long as the difference was extreme.

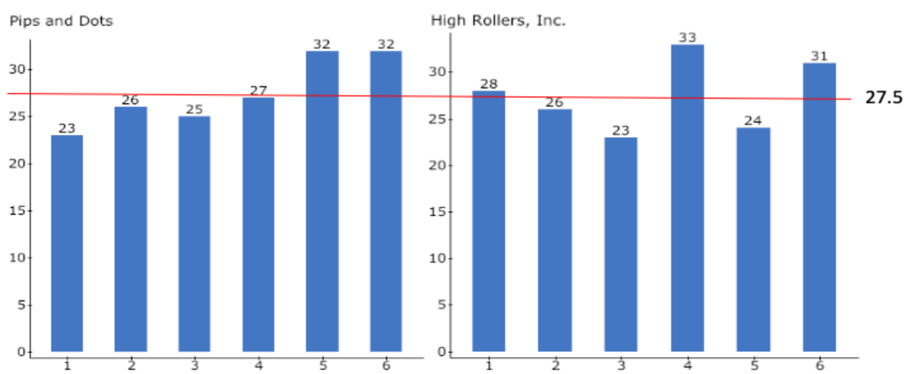
Kendall and Myra decided that the only companies that needed additional trials was Pips and Dots and High Rollers Inc. They give an additional 40 trials to Pips and Dots and High Rollers Inc. and continued with their method of comparing the difference in the percentages of the lowest to the highest occurrence. At this point they again compare all six companies, even though the two companies now have 90 trials and the other four still only have 50 trials. Kendall and Myra did not discuss how the sample size impacted the conclusions they were drawing. Instead continued to focus on companies that they "could for sure say absolutely not" unbiased,

> I feel like these percents are just so far apart like their range is four percent to 28 percent and there's two of them [referring to Slice and Dice and Dice R Us']. And this one we've got six percent to 34 percent [referring to Dice Dice Baby!]. I mean that's almost a 30 percent

difference on these ones. I mean this is 24 difference, this is almost 30. Like 28 and 11 to 22 that's only 11 difference. So are we, do we think Pips N Dots and High Rollers?

Myra and Kendall chose to only focus on High Rollers, Inc. and Pips and Dots. However, at this point in the task examining the differences in the percentages was not providing enough confirming evidence for Kendall and Myra to distinguish which one was fair, so they began looking at the expected values as a possible indication of bias. This was the first mention that the expected value of the dice, “So they should be in the 16 to 17 range so how far are they off from it? Because I feel like half of mine are pretty close to that and half of them are not.” They continued with this line of thinking and continued adding trials to High Rollers Inc. and Pips and Dots until each company had a total of 140 trials. Myra and Kendall decided “to stick with our original company [High Rollers, Inc.] because it seemed fair with Part A and Part B where Pips and dots only seemed the most fair with Part B.” However, they were still not convinced and wanted more trials.

Since Myra and Kendall were still unsure, the PD facilitator offered a final 50 trials. They decided to divide the trials evenly among High Rollers, Inc. and Pips and Dots for a total of 165 trials (Figure 3). Still trying to quantify the variability in the distributions, they determined the expected value for each number on the dice as 165/6 to be 27.5 trials. They then calculated “variability in the data by finding the average distance from 27.5.” They referred to this measure as the M.A.D. For Pips and Dots this was 3 and for High Rollers, Inc. was 3.166. This Myra to comment that Pips & Dots was less variable and Kendall asked if that matters. Mayra said “it showed the outcomes were closer to the expectation if fair”. They then agreed this measure was helpful and declared Pips and Dots a fair company.



Number	1	2	3	4	5	6
Frequency (f)	23	26	25	27	32	32
|f-27.5|	4.5	1.5	2.5	0.5	4.5	4.5
Average Absolute Deviations						3.0

Number	1	2	3	4	5	6
Frequency (f)	28	26	23	33	24	31
|f-27.5|	0.5	1.5	4.5	5.5	3.5	3.5
Average Absolute Deviations						3.17

Figure 3: Myra and Kendall’s Measure of Variability After 165 Rolls

Articulating the competing models. During the task Kendall and Myra never explicitly articulated the two models under competition but as the task progressed there was a shift in their description of their null model. Originally, Kendall and Myra were comparing the distributions their data produced to a uniform probability model. They expected all outcomes for a single company to be “similar/same for each outcome.” However, when using the difference in the highest and lowest outcome was not helping them move forward in identifying a single company, Kendall and Myra shifted their model. For the second half of the task, they described

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

their null model as the expected value either in terms of percentage or number of outcomes. This shift in their null model allowed Kendall and Myra to quantify the variability of each distribution as the dispersion from the expected value.

Describing and measuring variability. In the end, Kendall and Myra tried a total of three ways to describe the variability in the distributions: examining the difference in the highest and lowest percentage, examining the number of outcomes that fell into a middle region around the expected value, and calculated a measure by subtracting each frequency from the expected frequency of 27.5 and taking the average of those distances. These approaches increased in their sophistication when they had to identify a single company as fair. Their first two attempts at quantifying the variability were subjective by comparing the differences in the highest and lowest percentages and the number of outcomes that fell into the middle region. For both of these they subjectively determined an acceptable range in percentages or what constituted the middle region around the expected value. Their final approach, subtracting each frequency from the expected frequency of 27.5 and taking the average of those distances, provide Kendall and Myra a numerical measure to compare the variability in each companies' distributions.

Accounting for sample size. Sample size played a crucial role in the way Kendall and Myra engaged with the task and how they discussed variability. The way in which Kendall and Myra accounted for the sample size at the beginning of the task, evenly distributing the samples, was similar to the way the majority of the teachers engaged with the task. Throughout the task Kendall and Myra appeared to be ok with making a conclusion that a company was biased from a sample of 50 but wanted a larger sample to be able to determine if a company was fair. This was seen when they were comparing Pips and Dots and High Rollers Inc., that each had 90 trials, to the other four companies that only had their original 50 trials. Kendall and Myra continued to classify the other companies as biased with a smaller number of trials. Their struggle with accounting for sample size in their conclusions was also shown when they decided "to stick with our original company [High Rollers, Inc.] because it seemed fair with Part A and Part B where Pips and Dots only seemed the most fair with Part B." Even though Kendall and Myra had an understanding that a larger sample size is better they did not seem to understand that larger samples would produce less sampling variability. Overall, when Kendall and Myra were considering sample size their logic seemed to focus on rolling more trials to find evidence to support the fairness, and not how much variation is expected when a company is fair.

Discussion and Conclusion

Due to the infancy of research in statistics education, many tasks that statistics educators use with teachers in a PD have not been researched with that population. We chose to incorporate the Schoolopoly task into our summer PD to engage teachers in an informal inference task that required them to use ideas about data, distribution, sampling variability, probability, and statistics to make their judgements about the competing models. Thus, we examined the ways in which teachers engaged with the task and reasoned about sample size and variability. In doing so we identified three themes emerged; 1) The ways teachers articulated the two models under competition, 2) the ways teachers described and measured variability, and 3) the ways teachers accounted for sample size.

From our results, there are several changes we would make to our modified version of Schoolopoly task for the future. It is evident that Myra and Kendall expect that a random sample of sufficient size should replicate the population characteristics (Harradine et al., 2011). Therefore, even though teachers know that large samples are more representative of the population they need more opportunities to engage in instructional activities to draw many samples to understand the variability among samples from a population (delMas, Garfield, & Chance, 1999; Saldanha & Thompson, 2002). In the end, we would still limit the number of trials the teachers could use to explore the companies but instead of adding additional trials to their distributions, have teachers generate additional samples of 50 trials and then add to their new samples. This would allow teachers to still examine all of the companies and compare multiple samples of 50 for the same company before determining which companies are fair, providing them the opportunity to estimate the underlying probability distribution of each company, similar to Lee et al.'s (2010) study. Then teachers could continue with the task, examining larger samples and comparing those samples to make a conclusion on which company they believe is fair.

TIME EXPRESSIONS AND ELEMENTARY STUDENTS' REASONING WITH THE ANALOG CLOCK

Darrell Earnest
University of Massachusetts, Amherst

John Chandler
University of Montana
john.chandler@business.umt.edu

*This paper investigates the interplay of words and expressions with students' efforts to indicate times on a clock. We consider how elementary students interpret precise times (e.g., 2:30, 4:30) as compared to relative times (e.g., half past 11) as they describe this intangible quantity using a clock. Interviews with students in grades 2 and 4 (*n*=42) revealed that precise times led to whole number descriptions whereas relative times led to descriptions of part-whole relations consistent with representations of measure. A subsequent analysis of assessment performance of students across elementary grades (*N *= 612) corroborates the differential performance based on expression used in the tasks. Findings suggest that elementary students need further support to treat this invisible quantity according to measurement properties. Implications for theory are discussed.*

Keywords: Time, Clock, Elementary math

Learning mathematics is inextricably linked with the words and expressions used to enact and communicate mathematical ideas. For this reason, theorists have offered sociocultural descriptions of learning that include explicit treatments of word meaning and use (e.g., Halliday, 1993; Sfard, 2008; Vygotsky, 1978, 1986). For the topic of time, modern practices include a variety of expressions both within and across languages around the world that reference time units in substantively different ways. The time 2:15 may be stated as "two fifteen," "fifteen past two," or "quarter past two" depending on the language and community (see Bock, Irwin, Davidson, & Levelt, 2002; Burny, Valcke, DeSoete, & Van Luit, 2013). Even within a language like English, speakers of the same language across countries may draw upon time expressions with different treatments of time unit (e.g., for 11:30, a common phrase in Ireland is "half 11," an expression unfamiliar to many in the United States). Just as a language's counting words are consequential to early understandings of numeracy (Miura, 2001; Ng & Rao, 2010), we investigate if analogous expressions for time with substantively different treatments of time unit lead to differentiated descriptions of time.

Our research from a sociocultural perspective has examined how children draw upon the analog clock as a tool to solve elapsed time problems (Earnest, 2017; Earnest, Gonzales, & Plant, 2018). We share two contentions with current approaches to time instruction. First, time is invisible and untouchable, and for this reason we contend that we must consider the consequential role of words and language as individuals describe time and interpret representations of time (Bock et al., 2002; Tillman, Marghetis, Barnet, & Srinivasan, 2016). Research has established the interplay between words and pathways of mathematical thinking, such as the role of counting words in some East Asian languages that highlight the structure of the base-ten number system (Miura, 2001; Ng & Rao, 2010). Building on Sfard's (2008) treatment of words and narratives (or, the story or description of the "relations between or activities with or by objects," p. 574) in mathematics discourse, we explore such interplay in order to generate a sociocultural description of students' thinking in relation to time words.

Second, as we further consider below in implications, we dispute the current treatment of time in elementary mathematics, which relegates the topic to early elementary grades with a focus on clock-reading procedures. Technology has advanced to the point where reading the analog clock in order to identify the time is no longer an appropriate endgoal—digital clocks easily enable this and are widely available. We do not suggest the analog clock is unimportant; rather, we propose that as a field we ought to re-think the role of time in K-12 education, in particular how representations of time such as the analog clock or the *x*-axis of a graph share structural similarities (Earnest, 2015) together with its relation to other elementary mathematics topics, such as fractions and partitioning (Earnest et al., 2018).

Researchers investigating the learning and teaching of time, including our team, have drawn attention to the minimal research conducted on learning this topic (Burny et al., 2013; Kamii & Russell, 2012). Moreover, even among those studies conducted over recent decades, experimental designs and identified data points suggest different visions for what is critical and necessary in order to investigate children's time-related ideas. Unlike the present analysis, which considers student thinking in tandem with the tool and language, much of the developmental research explored children's emerging intuitions related to duration independent from the standard tools or units we have for time (e.g., Long & Kamii; 2001; Piaget, 1969; Wilkening, Levin, & Druyan, 1987). Also from a constructivist perspective, Kamii and Russell (2012) explored children's elapsed time calculations in standard units, yet independent of an analog clock's spatial representation of time. In one of the few studies that considered how children themselves grappled with time-related ideas together with standard units of and tools for time, Williams (2012) conducted a cognitive ethnography in early elementary classrooms, identifying metaphors upon which children draw as they reason with an invisible and intangible entity (see also, Lakoff & Nuñez, 2000). We therefore see this topic within mathematics education as one in need of more research, in particular because of its underlying role in the mathematics of change that characterizes middle and high school mathematics. Because time is intangible, words and expressions for time take on a prominent role in the construal of meaning, leading us to our research questions focusing on the interplay of words and action.

We address the following research questions: (a) How do students interpret precise and relative times on an analog clock? If students do so differently, (b) is there a difference in performance on such tasks across elementary grades?

Method

Participants for individual paper-and-pencil assessment included students across grades 2-5 (N = 612) from three school districts in urban, suburban, and rural areas in Massachusetts. Students were asked to, for example, "Show 2:30 on the clock" or "Show half past 11 on the clock" (Figure 1), which were two of 35 total items. For the focal tasks, we coded the position of the drawn hands as a point between 0.0 to 11.9, with accuracy coded as $\pm$ 0.2 from the accurate position (for example, an accurate hour hand position for 4:30 pointed between 4.3 and 4.7).

Using scores on the written assessment, a subset of students in grades 2 and 4 (n = 42) participated in interviews in which they solved problems involving an analog clock with independent hour and minute hands. For two focal tasks, the interviewer presented a card that stated the problem (i.e., "Show me 4:30" or "Show me half past 11") and asked the student to describe their solution approach. Our research group coded video data for accuracy of positions for hour and minute hands as described above. Further, we open coded (Corbin & Strauss, 2008) transcripts and video to identify emerging themes drawing upon utterances and activity in problem solving. Narrative categories emerged through multiple passes through the data. We present our findings beginning with interview analysis and, based on those results, turning back to the assessment data as a way to corroborate findings based on interviews. We note two decisions made due to space constraints in the present paper. First, we limit our interview analysis to narratives in data reflecting 10% or more of interviewee responses. Second, we limit our analysis to tasks to the half hour; our presentation will feature additional assessment and interview tasks featuring additional precise and relative times.

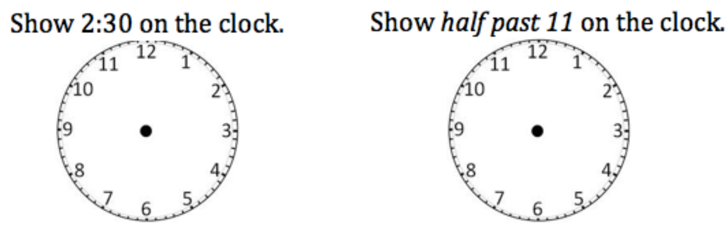

Figure 6: Focal Assessment Tasks

Results

We begin with a description of narratives (Sfard, 2008) that emerged in our open coding analysis of interviews before then detailing how such narratives emerged in students' interpretations of each time expression. Four dominant narratives emerged that reflected 10% or more of responses in interviews: Whole Number, Part-whole Relations, Conversion, and Hand Movement. Table 4 features narratives with frequencies across the 168 possible instances (2 subtasks for 2 problems for each of the 42 students)[1].

Table 1: Identified Narratives

Narrative	Number of Instances	% of total (*N*=168)
Whole Number	93	55.4%
Part-whole Relations	75	44.6%
Conversion	27	16.1%
Hand Movement	20	11.9%

Some solutions reflected ideas related to Whole Number, namely number matching and skip counting. For example, for 4:30, a second grader matched the hour hand directly (and inaccurately) on 4 and the minute hand directly (and accurately) on the 6 and stated: "It was easy, because I already knew *that* [6] was thirty, and I already knew *that* [4] was a four" (Figure 2a). Other students coded as Whole Number drew upon skip counting to count by 5s in order to position the minute hand (Figure 2b)

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* St Louis, MO: University of Missouri.

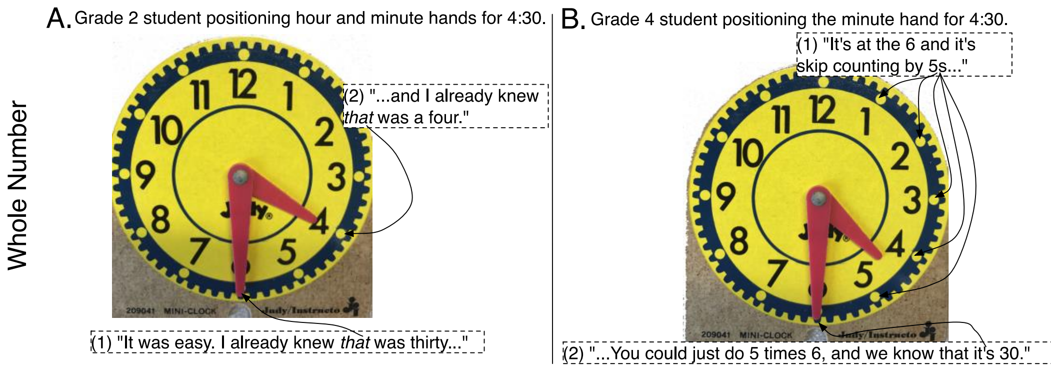

Figure 2: Whole Number Approaches to Hour and Minutes Hands

We coded approaches as Part-whole Relations (Figure 3a-c) when a student identified a unit interval or whole on the clock and described partitioning that unit or whole. For example, a second grader solving 4:30 positioned the hour hand at 4.5, stating, “It’s past the four <*sweeping his finger from the 4 to the 5*> by half, because it was 30 minutes into the hour” (Figure 3a).

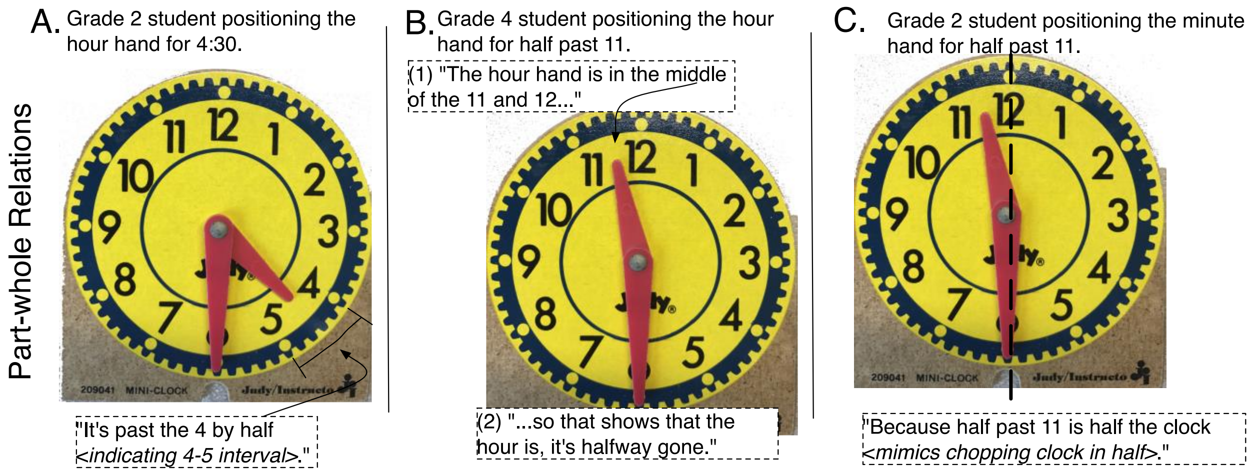

Figure 3: Part-whole Relations Approaches to Hour and Minutes Hands

We assigned the code Conversion when a student described a conversion between hours and minutes, which in our data was either one hour and 60 minutes or half an hour and 30 minutes (Figure 4a). We applied this code only 27 times out of a possible 168 solutions. Hand Movement was applied in only 20 of the 168 possible solutions. This particular code was applied when a student, first, referenced a particular numeral on the clock and, second, positioned the focal hand in tandem with a description of the moving hand; this description, however, did not include reference to a unit or whole (Figure 4b-c).

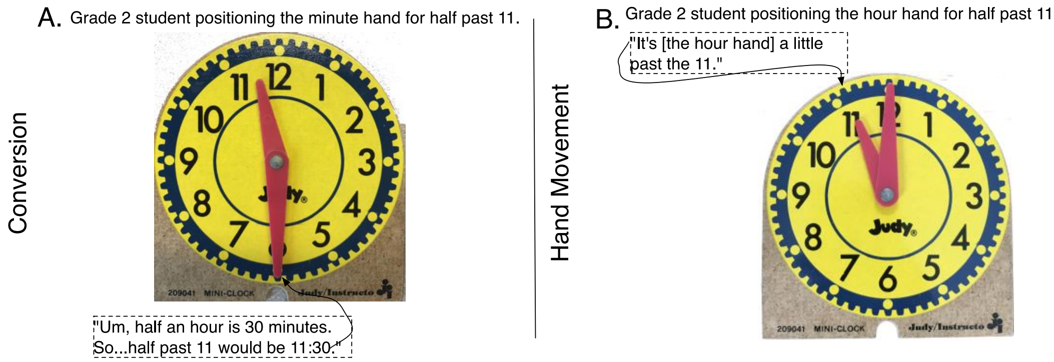

Figure 4: Conversion and Hand Movement Approaches to Hour and Minutes Hands

Expressions of Time and Corresponding Narratives

We now consider how the narratives manifested as a function of the expression in the prompt (4:30 or half past 11) and the hand (hour or minute). When presented as 4:30, students' solution approaches largely reflected ideas related to Whole Number (see left panels of Figure 5). In total, 20 of 42 students drew upon whole number ideas for the 4:30 hour hand and 36 of 42 did so for the 4:30 minute hand. For the hour hand specifically, Whole Number approaches—matching the number in the prompt with a number on the clock—were highly unsuccessful, despite being the most-represented approach for the 4:30 hour hand. Turning to half past 11 (right panels of Figure 5), students' solution approaches for both hour and minute hands largely reflected ideas related to Part-whole Relations, with 24 of 42 students drawing upon this narrative for both of the hands and mostly accurately.

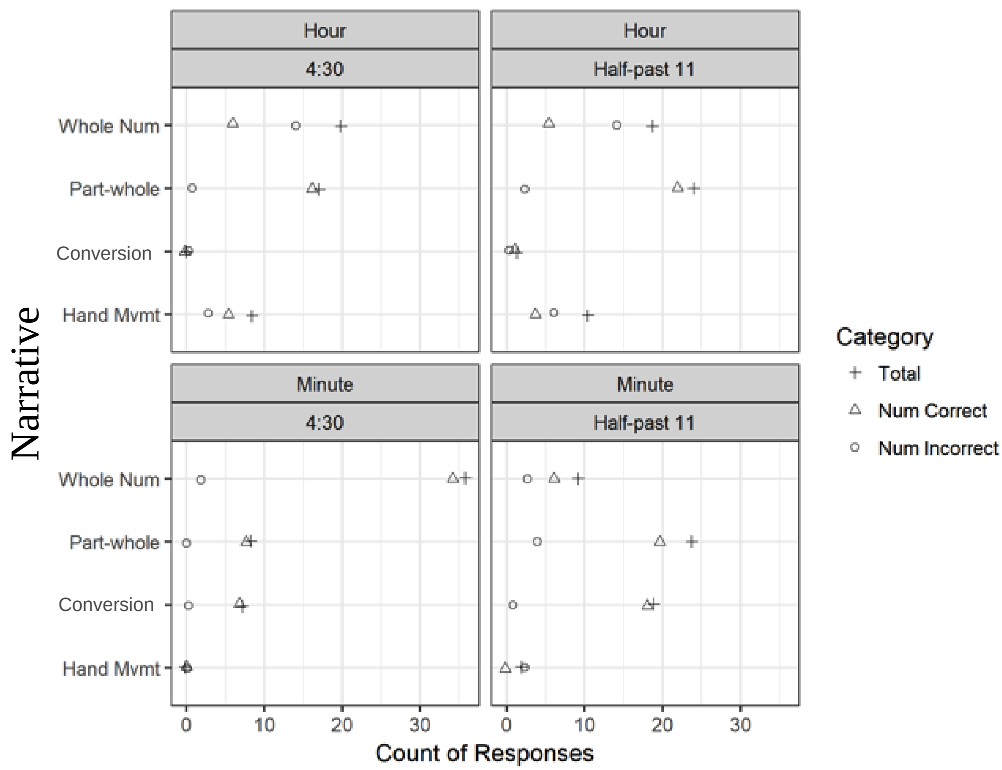

Figure 5: Narratives Emerging in Interviews

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

In sum, the Part-whole Relations narrative was deployed across hands and tasks with general success (73 instances out of 168; 90% accuracy). The Whole Number narrative was more common yet more variable with respect to accuracy (84 instances out of 168, 60% accuracy). Most students with Whole Number descriptions of the hour hand positioned it directly and inaccurately on the hour, whereas those with Whole Number descriptions of the minute hand successfully counted by 5s to position it. The units presented in the prompt were related to the narrative that emerged in children's descriptions, indicating the consequential interplay of time expression and children's descriptions of time, though as can be seen in Figure 6, those students drawing upon Part-whole Relations for the 4:30 hour hand (partitioning the hour interval) were largely successful, unlike those that drew upon Whole Number (matching the numeral 4 in the prompt with the 4 on the clock).

Given these differences in interview performances based on time units in the prompt, we turn back to assessment data for students across elementary grades to either corroborate or refute the trend in interview analysis. On the assessment, we found no statistical difference in performance on the two focal tasks when comparing the overall problems. However, when looking at hour and minute hands separately, a striking pattern emerged: accuracy for the placement of a particular hand in relation to time expression is statistically different. Across all grades, hour hand performance is better for half past 11 (Figure 7, left panel). The reverse is true for placing the minute hand; all grades perform this subtask better for the 2:30 task. Patterns in performance across subtasks are statistically significant. The minute-hand placement had lower accuracy rates relative to the 2:30 minute-hand subtask ($\widehat{\beta_s} = -0.29, \hat{\sigma} = 0.15, p < 0.05$). Hour hand position on the half past 11 subtask was more accurate than that for 2:30 ($\widehat{\beta_t} = -0.87, \hat{\sigma} = 0.12, p < 2 \cdot 10^{-13}$). Despite the fact that the two tasks featured analogous times to the half hour, accuracy in hand positioning appears to depend on which hand and on how time units are referenced in the prompt. Although the analysis involves a comparison of only two tasks and must therefore be interpreted humbly, findings corroborate qualitative trends that emerged in interview data: children are likely to interpret time meaning in relation to the time expression.

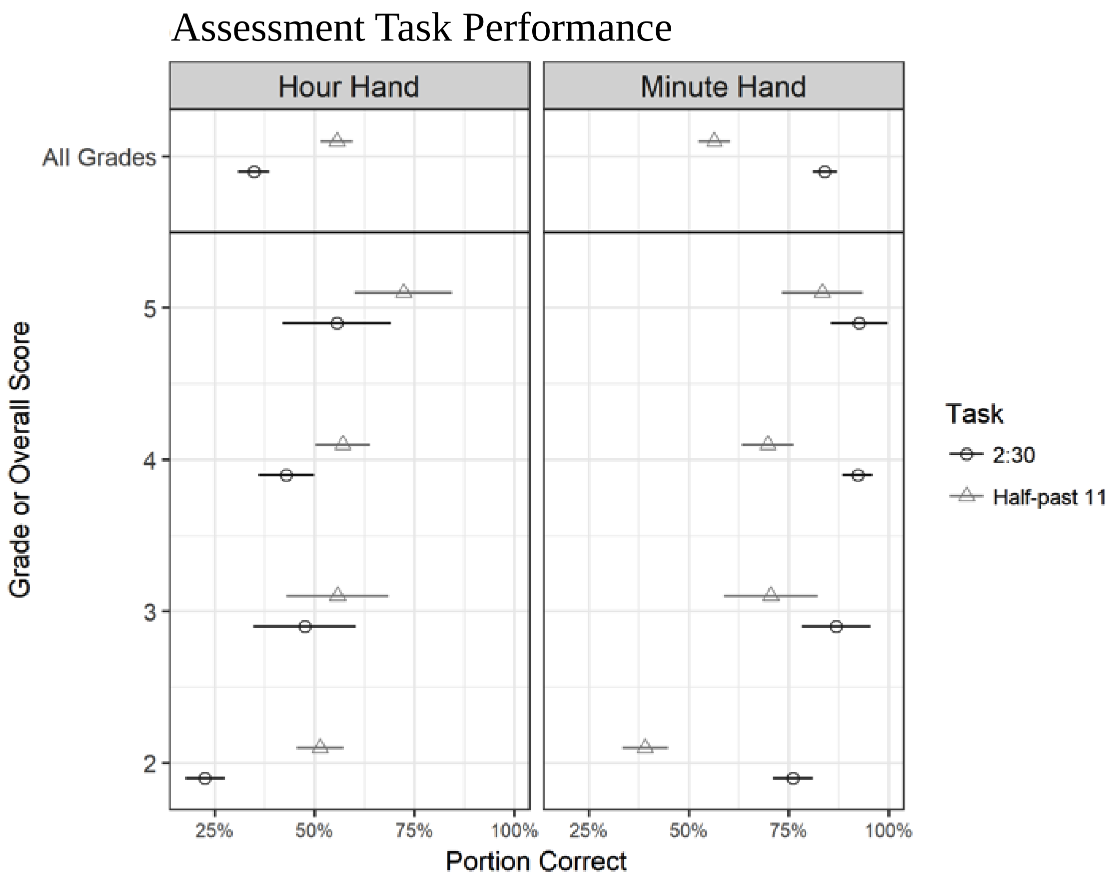

Figure 7: Performance for Hour (left) and Minute Hand (right) Placement for Each Task

Discussion

Time is a challenging topic in mathematics education due in part to its invisible character. Our mixed methods analysis indicates that expressions with substantively different treatments of time units lead to different interpretations of time. Each expression, both of which are appropriate ways to reference the time of day, encodes information about agreed-upon conventions related to unit. The times 4:30 or 2:30 are typically stated with whole number words that highlight whole number features of the clock and, in our data, were less likely to make salient clock features related to fractions and partitioning. Instead, the words are the same as those children have long used to reference whole numbers, a topic that almost assuredly has constituted the bulk of their elementary mathematics experiences thus far. Meanwhile, when presented with the expression half past *h*, many students drew upon part-whole relations, a narrative related to partitioning and measurement. This was evidenced even among the second graders on the assessment, among whom more than 50% positioned the hour hand for half past *h* accurately as compared to less than 25% for *h*:30 (see bottom left of Figure 7); of note is that both tasks are currently identified as grade 1 benchmarks (CCSSO, 2010), even though grade 2 students in our sample clearly struggled with these same ideas.

Why are these results relevant for mathematics education? Time pervades the mathematics of change in later grades as well as basic scientific investigations of the world yet, surprisingly, current time instruction highlights little more than clock-reading procedures in the early elementary grades. We attribute Whole Number narratives above as related to the over-emphasis on clock-reading procedures. Our findings contribute to emerging research with implications more broadly for a need to re-think K-12 instruction related to time. Part-whole Relations narratives—those that typically accompanied the “half past *h*” expression—well reflect measurement principles. Extrapolating these findings to later grades when students encounter other contexts involving representations of time, such as the *x*-axis of a function graph, we conjecture that a Part-whole Relations narrative for working with a clock will be generative and continue to support mathematical insights when working with such representations with structural similarities (see also, Earnest, 2015). Although further research is needed, we are less confident that Whole Number narratives well provide a foundation to support later mathematical ideas involving interval properties of time, potentially leaving students unprepared for complex mathematical ideas involving time.

A narrative is a story of relations or activities among objects (Sfard, 2008). As we found, the words for time expressions are interwoven with particular mathematical narratives that may or may not be consistent with the endorsed ideas about time and time representations. Our current instructional emphasis on clock-reading procedures may emphasize whole number properties of the clock at the expense of interval properties related to fractions and partitioning.

What should children learn about time, and when should they learn it? We do not interpret the findings above to indicate that one phrase ought to be used in curriculum and instruction absent of the other; in fact, such a claim would poorly reflect reality. Rather, our findings highlight the interplay of words and time ideas and underscore some of the complexity we as a field have been overlooking related to emerging conceptions of time. Findings suggest that we ought to be strategic and thoughtful about when and how we draw upon particular expressions and representational systems (i.e., digital and analog clock), how they may support children’s age-appropriate learning of specific time-related ideas, and what the target content goals of doing so are. Further research is necessary to determine how such expressions could be leveraged to support interval interpretations of an analog clock.

Endnotes

Note that occasionally a solution approach was given more than one code, the result of which is that the cumulative percentage in Table 4 is greater than 100%.

This paper reports on an ongoing project aimed at developing an inter-institutional system of professional support for the improvement of the Geometry for Teachers (GeT) courses that mathematics departments teach to preservice secondary teachers. In alignment with the literature on improvement science (see Bryk et al., 2015; Lewis, 2015), it is essential to develop and deploy practical measurement tools to inform improvement. We describe three key forms of measurement our team has been using to drive this work as well as some preliminary findings.

Keywords: Geometry and Geometrical and Spatial Thinking, Post-Secondary Education, Teacher Education-Preservice

Introduction

This paper reports on the development and use of instruments to study instruction at the college level, specifically focused on the undergraduate geometry course offered by many university mathematics departments for pre-service teachers (Geometry for Teachers, or GeT hereafter). The teaching of geometry in schools has been identified as weak and resulting in unacceptable levels of student performance (Clements, 2003; NCES, 2012). High school leaders have often described it as hard to find high school teachers who want to, and can, teach geometry. Thus, we consider increasing instructional capacity for high school geometry a systemic problem. We pose that the university GeT course is a crucial lever in preparing pre-service teachers to teach high school geometry, particularly as one of the few college mathematics courses that directly connects to high school geometry content. Yet, many mathematics education scholars (Zazkis & Leikin, 2010) and mathematicians (Wu, 2011) have questioned whether the content of university courses is sufficiently connected to what secondary teachers need to do their work. This led us to investigate the connection between participation in GeT courses and increased mathematical knowledge for teaching geometry (MKT-G).

We utilize the networked improvement communities approach described by Bryk, Gomez, Grunow, and LeMahieu (2015) to increase the capacity for geometry instruction at the K-12 level. This approach uses an organizational learning perspective in which all stakeholders are involved in the articulation of common problems as well as the design, monitoring, and continuous improvement of strategies to solve those problems. Bryk et al. (2015) indicate that achieving improvement at scale requires that particular attention be paid to variation within the system, and that understanding the sources of that variation is critical to achieving the goal of improvement research projects.

Within the scope of our project, we are currently measuring variation by gathering and analyzing data in the following ways: 1) through an assessment instrument which tests GeT students' mathematical knowledge for teaching geometry (MKT-G); 2) with end-of-term questionnaires used to collect data on course content, student composition, and technology use; and 3) through the use of instructional logs, administered at three points throughout the term, aimed at gathering more nuanced information about instructional practices in GeT courses. In this paper, we describe these measures in more detail, and explore the potential use of the data gathered from these three instruments.

Theoretical Framework

Taking a Networked Improvement Communities Approach

Bryk and colleagues (2015) set out a strategy for educational research and development called networked improvement communities (NICs), meant to harness the creative power of networked communities within an improvement science framework. One of the core principles of this approach is to "see the system that produces the current outcomes" (p. 57). The authors claim that oftentimes the traditional approach to solving complex educational problems is to quickly look for solutions to the problems without fully understanding the complex systems producing such problems. Russell and colleagues' (2017) lay out a framework for the implementation of networked improvement communities and claim that education researchers and practitioners often struggle to find effective solutions as "[the] field is not organized to learn systematically, accumulate, and disseminate the practical knowledge needed for the improvement of teaching and learning" (p. 1). A second core principle of the NIC approach is to "focus on variation in performance" (Bryk et al., 2015, p. 13), with an acknowledgement that complex systems often result in considerable variation. This focus on variation reduces the tendency to oversimplify by looking for universal solutions to the problem, and supports more realistic consideration of which solutions work, for whom, and under what set of conditions.

To study variation in performance, NICs must make use of consistent and practical measurement tools to inform the improvement efforts made by those involved (Morris & Hiebert, 2011). Additionally, a network hub is responsible for aggregating the data from those measures, as well as key insights that emerge, and feeding it back to the network so that innovations can be tested and integrated into new contexts (Bryk et al., 2015). We took on the role of network hub by creating a community of stakeholders and developing measures that would inform the community about progress toward a solution. As part of our work in this role, we facilitate opportunities for the network to engage with each other as well as the data being generated.

Variation in GeT Courses

Grover and Connor (2000) conducted a survey of 108 randomly selected U.S. colleges and universities to study the content and instructional practices of geometry courses through analysis of questionnaire responses and selected syllabi. They found considerable variation in content (e.g., geometries covered and axiomatic approaches employed), pedagogy (e.g., lecture, group work, and alignment with NCTM Professional Teaching Standards), and assessment (e.g., in-class examinations, homework, and forms of alternative assessment).

To see if this variation in GeT courses persists, we conducted an analysis of GeT course artifacts from 17 initial participants in this study (i.e., syllabi supplemented with course catalogs, interviews, and poster sessions). The results of our study of GeT courses were very well aligned with Grover and Connor's (2000) results, indicating that there still exists wide variation in GeT courses.

Methods

As the project is intended to help provide support for the instructors of university GeT courses, it is important to work collaboratively with them in order to help define the problem space. We began by locating institutions with teacher preparation programs—as we are interested in the undergraduate geometry course serving teachers, rather than geometry courses in general. Within those institutions, we looked in mathematics departments for geometry courses serving secondary mathematics pre-service teachers and identified instructors of those courses as the natural members of this community. We conducted a set of 19 initial interviews to gather their professional perspectives as instructors of GeT courses. We organized the interview data according to common challenges that many of the instructors noted as embedded in the work of teaching GeT courses. These common problems, or *tensions*, that many instructors identify in their own work we identify as inherent in the work of teaching college geometry, which are perhaps distinct from the set of problems or defects that an outsider might identify in the work of a GeT instructor (Herbst, Milewski, Ion, & Bleecker, 2018; Milewski et al., 2019).

In June 2018, we held a two-day conference which gathered more than fifty various stakeholders involved in the teaching of the GeT course (GeT instructors, high school district leaders, high school teacher leaders, and education researchers). Using what we had learned from the interviews with GeT instructors about the tensions that come with teaching the GeT course, we worked with conference attendees with a common problem in mind: to improve capacity for teaching K-12 geometry. Two of the tensions most salient in the conversations of the conference working groups were:

- *Knowledge tension:* This tension arises in contexts where GeT instructors need to consider the question “What is the *knowledge* students need to learn in the GeT course?” On one side of the tension, the course exists to provide novice teachers with the knowledge needed to teach the secondary geometry course. This includes knowledge like, “What are the common ways that students think about parallelograms?” or “How does one design good proof problems for high school geometry students?” On the other side, GeT is a university mathematics course that needs to be comparable in terms of rigor with other advanced mathematical coursework that students are expected engage with. Ideally, the course could include both kinds of mathematical knowledge, however, time is a limited resource and GeT instructors need to decide what to prioritize.
- *Experiences tension:* This tension arises in contexts where GeT instructors need to consider the question “What *experiences* can support students’ learning in the GeT course?” On one side of the tension, as GeT is a mathematics course, it would be reasonable to assume that students in the course are learning to think and act like mathematicians. Thus, students should experience opportunities to engage in reasoning, problem-solving, and other mathematical practices, which could serve them as future teachers as it would engage them in work similar to what they would have their eventual students engage. On the other side, the course acts a service course for pre-service teachers who are apprenticing into the work of a teacher, and this would suggest that they should experience opportunities to practice the work of teaching, like explaining a mathematical concept to the whole class or to each other, or interpreting fellow students’ work.

Rallying around these tensions, the conference participants collaborated to establish a set of projects to engage with over the course of the next four years that would address these tensions. Through the use of an online collaboration platform, teams of GeT instructors unite to work on a common project. An example of one of these projects is the *Geometry Knowledge Needed for Teaching* group, where 17 GeT instructors are currently working together to answer the questions: *What is the mathematical content knowledge needed for teaching high school geometry? What do we need to teach our college geometry students so they begin their teaching careers with the appropriate knowledge?* To answer these questions and discuss the tensions that come up in the work of teaching the GeT course as highlighted above, this group meets over video conference once a month, as well as throughout the month asynchronously, on an online forum.

In addition to collaborating on these projects, GeT instructors also volunteer to take and administer various measurement instruments throughout the year. The details of these instruments are outlined in the following section. We understand the potential pitfalls of large variability in those courses at the same time that we honor the academic freedom and professional judgment of instructors. The project forums, like the one described above, are meant to promote improvement by creating community. To inform the improvement efforts made by instructors who participate in the community, we track variation in course offerings and variation in outcomes (in terms of MKT-G), with the hope to ascertain whether changes in the former are related to changes in the latter. If reduction in course variability could be correlated with increases in MKT-G gains, this would lend credibility to the notion that reducing variability in the course offerings would be desirable.

Measures

Mathematical Knowledge for Teaching Geometry (MKT-G)

Herbst and Kosko (2014) have developed and validated an instrument used to measure MKT-G that targets four of the six domains of content knowledge for teaching identified by Ball, Thames, and Phelps (2008). These items are closed-ended and graded as either correct or incorrect. In a prior study, the instrument was administered to 387 inservice teachers from 47 states, as well as 195 preservice teachers from 7 institutions. Results from these tests showed that preservice teachers' scores on the MKT-G after taking a GeT course were .23 standard deviations lower than inservice teachers' MKT-G scores. While this result was unsurprising, it raised the question of whether the test could detect differences in MKT-G gained over the course of a semester of GeT instruction.

Over the course of the project, we will be collecting data from GeT students who will take this instrument at the beginning and end of their GeT course. Progress toward readiness to teach high school geometry will be measured in terms of average change in scores between pre- and post- assessments. Throughout the term, we share three sets of reports with participating GeT instructors: 1) individualized reports showing how their students performed on the pre-test compared to the national sample of practicing teachers; 2) individualized reports showing how their students performed on both the pre- and post- tests, with change in scores over the term reported in relation to the national sample of inservice teachers; and 3) aggregated reports showing each instructor how students from their institution performed on average compared to the overall average scores of all GeT students in this study. Our hope is that the instructors will use the individualized and aggregate results from these reports to reflect on and inform their course design and teaching practices, as well as spark conversations within the network about rationales, costs, and benefits of any potential changes in practice with respect to the knowledge and experiences tensions identified in their work.

Course Questionnaire and Instructional Logs

Inspired by the work of Grover and Connor (2000), we have developed a course questionnaire to be taken by GeT instructors at the end of each term in which the course is offered. In the questionnaire, instructors are asked about the course sequence at their institution, student composition, textbook use, dynamic geometry software use, as well as types of geometry taught in relation to various axiomatic approaches. Some examples of questions include:

- *Approximately what percentage of the students enrolled in the geometry course are prospective high school or middle school teachers?*
- *[What] courses are students required to take before taking this section of geometry?*
- *List the most important Euclidean geometry theorem(s) you cover.*

To better understand the experiences students are having in GeT courses, we have developed a set of instructional logs to be completed by GeT instructors three times throughout the term in which the course is offered. In each of these logs, instructors are asked to report on the planning and implementation of two lessons. As part of each log, instructors are asked to share the set of expectations for the lesson, as well as the amount of class time they devoted to each expectation. Following this, they are asked about the instructional approaches employed throughout the lesson, reporting how much class time was spent on each (e.g., whole class lecture, student presentations). These set of logs serve as one way of describing the experiences students are having in the GeT courses.

We expect these results to be useful in gauging variability across GeT courses, with the hypothesis that variability will be reduced as instructors participate in the networked improvement community. One reason that variability may be reduced over time is that GeT instructors will have access to these aggregated reports, may see evidence of other instructional practices being employed within the community, and will participate in discussions of the data all together.

Preliminary Results and Discussion

Fall 2018 MKT-G Results

In Fall 2018, 94 students from six GeT courses completed the pre- and post- MKT-G assessment. The level of MKT-G possessed by each student was provided as IRT scores derived from the IRT (item-response theory) model which takes account of the difficulty and discrimination of items (how well each item can discriminate participants' ability). In Table 1, we report on the pre- and post-IRT scores of the 94 GeT students, as well as the IRT gains from this sample. An average score of 0 for the sample of GeT students would indicate a level of knowledge equivalent to the average amount of knowledge of a national sample of in-service teachers (N=605) previously collected. The negative IRT scores reported indicate that GeT students' knowledge is below the average amount of MKT-G of the in-service teacher sample (Ayala, 2009; Crocker & Algina, 2006). The positive gain in IRT scores (0.15) between the pre- and post-test indicates that GeT students made progress over the course of the term, on average, with respect to MKT-G, and the gain was significant ($t(93)=-2.85$, $p=0.0027$). The use of the data from practicing teachers allows us to understand the GeT students' relative standing to the practicing teachers.

Table 1: Pre- and Post- test Score Comparison of GeT Students (N=94) and ISTs (N=605)

	IRT θ		
	PRE_IRT	**POST_IRT**	**GAIN_IRT**
GeT students (N=94)	**-1.29**	**-1.13**	**0.15**
ISTs (N=605)	**0.00**	**0.00**	**N/A**

Despite overall positive gains by students on average, only four of the six GeT instructors showed positive gains in their students' IRT scores. The graph below (Figure 1) represents the standing of the GeT students' IRT scores in pre-test and post-test within the distribution of IRT scores from the national sample of in-service teachers. The GeT students' post-test scores are shifted slightly to the right from their pre-test scores, indicating improvement in MKT-G over the semester of GeT instruction. Compared to the ISTs, most of the 94 students have lower than average level of MKT-G in both pre- and post- test scores and this result is consistent with the prior study.

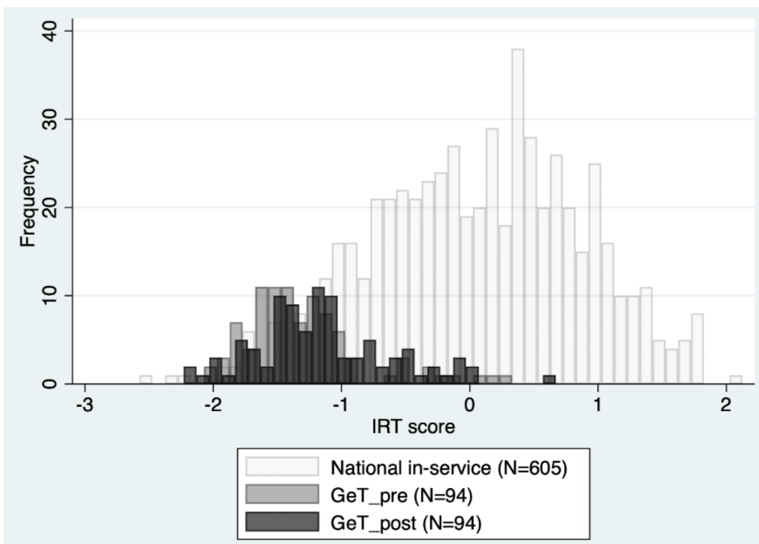

Figure 1: Histogram of the MKT-G Scores of GeT Students (N=94) and ISTs (N=605).

Course Questionnaire and Logs Results

In our first distribution of the course questionnaire, while we have a small sample of instructors (N=7), we are able to make similar observations as Grover and Connor (2000) with respect to large variability in the GeT courses. Some sample responses are shown in Table 2.

Table 2: Descriptive Results from Two Course Questionnaire Prompts (N=7)

	<=50%	51% - 80%	>81%

Q9: *Approximately what percentage of the students enrolled in the geometry course are prospective high school or middle school teachers? (N=7)*	n=2	n=2	n=3
Q31: *Indicate what percentage of the course is devoted to Euclidean geometry. (N=7)*	n=2	n=2	n=3

Also, in the Fall 2018 term, we collected a total of 20 instructional logs from five GeT instructors. An example of results from one such question is shown in Figure 2.

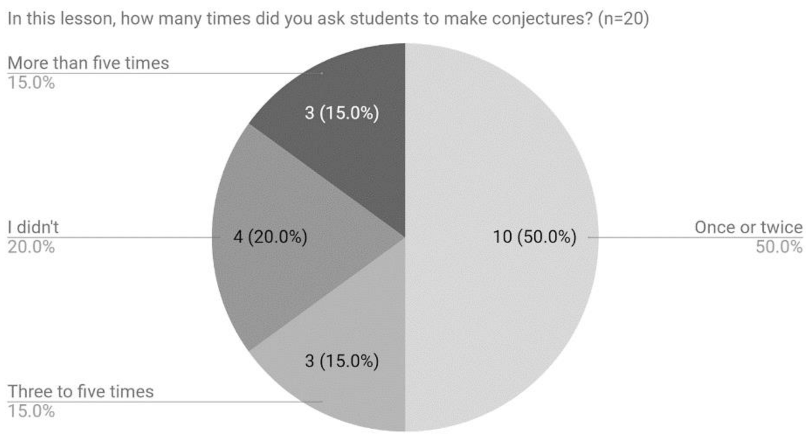

Figure 2: Aggregated Responses (N=20) to One of the Instructional Log Questions

The results from the course questionnaire and instructional logs have the potential to provide evidence of ways in which the knowledge and experiences tensions are present in the work of teaching the GeT course. We may find that GeT instructors with student populations that are less than 50% PSTs are less likely to spend considerable time on Euclidean Geometry, for example. Other uses for the data generated by these instruments is to measure variability across courses over time. The results shared here are from the first instructional term of this study, but we expect to look at how courses change over time when that data becomes available. For the time being, the instruments described here seem promising to allow us to describe the variability present across offerings of the GeT course.

FOUR ATTENTIONAL MOTIONS INVOLVED IN THE CONSTRUCTION OF ANGULARITY

Hamilton L. Hardison
Texas State University
HHardison@txstate.edu

Quantifying angularity is critical for the study of K–12 school mathematics and beyond; yet, quantifying angularity is challenging for individuals across these grade levels. Using data from a yearlong teaching experiment with ninth-grade students, I address the role of attentional motion in quantifying angularity and present four such motions involved in the construction of angularity. Additionally, I consider implications of these motions for teaching and research.

Keywords: Geometry and Geometrical and Spatial Thinking, Quantifying Angularity

Angle measure is a critical topic in K–12 school mathematics and beyond. As a few examples, angle measure is used when characterizing shapes, constructing coordinate systems, and investigating trigonometric relationships. However, individuals' challenges with angle measure have been documented through multiple studies with students and (prospective) teachers across the educational spectrum (Akkoc, 2008; Baya'a, Daher, & Mahagna, 2017; Clements, Battista, Sarama, & Swaminathan, 1996; Crompton, 2017; Devichi & Munier, 2013; ; Fi, 2003; Keiser, 2000; 2004; Lehrer, Jenkins, & Osana, 1998; Matos, 1999; Owens, 1996; Topçu, Kertil, Akkoc, Kamil, & Osman, 2006). Yet, relatively few researchers have elaborated the mental operations necessary for measuring angles, provided empirical support for these hypothesized operations, or documented interventions resulting in productive modifications in students' thinking about angle measure. There have been some notable exceptions, two of which were reports published in roughly the last decade. Thompson (2008) presented a theoretical approach to measuring angles rooted in the principles of quantitative reasoning (Thompson, 1994; 2011) and based on multiplicative comparisons of circular arc lengths. For example, to say that an angle has a measure of *n* degrees in Thompson's view means that an angle cuts off $\frac{n}{360}$ of any circle's circumference, provided that the circle is centered at the vertex of the angle. Following Thompson's (2008) conceptual analysis, Moore (2013) empirically demonstrated the productivity of an arc-length approach to quantifying angularity with precalculus students.

Although this arc-length approach to quantifying angularity is productive, the complexity of this approach renders it an unlikely starting point for early instruction in quantifying angularity. In state and national curricular standards, angle measure is typically introduced in fourth grade (e.g., National Governors Association Center for Best Practices, & Council of Chief State School Officers, 2010); at this grade level, many students are not yet able to instantiate such multiplicative comparisons (Steffe, 2017), much less generalize them as holding invariant across a class of circles. Put simply, more research is needed to understand how individuals begin to quantify angularity (Smith & Barrett, 2017). To this end, I conducted a teaching experiment (Steffe & Thompson, 2000; Steffe & Ulrich, 2013) with ninth-grade students (see Hardison, 2018). In the present report, I elaborate some of the mental operations involved in beginning to quantify angularity with particular attention to the role of motion in the quantification process. Specifically, the primary purposes of this report are (a) to explicate the role of attentional motions in constructing an awareness of angularity, (b) to describe the nature of these motions, and (c) to consider the implications of these motions for teaching and research.

Theoretical Perspectives

The present study was informed by principles of quantitative reasoning (Thompson, 1994; 2011). A quantity is an individual's conception of a measurable attribute of an object or situation; quantities are mental constructions, and examples of quantities that individuals might construct include length, area, time, speed, and angularity. A quantity consists of three interrelated components, which are also mental constructions: (a) an object or situation, (b) an attribute or quality, and (c) a quantification, which is a set of operations an individual can enact on the attribute (e.g., a measurement process). Although all three components are critical, the second component—the attribute or quality—is of primary importance for the present study.

Taking this perspective on quantity, for an individual to construct a geometric quantity (like angularity), she must first construct an awareness of the geometric attribute. Steffe's (2013) analysis of the construction of length provides insight into how such an awareness is constructed:

> The construction of length involves motion of some kind in that it entails an uninterrupted moment of focused attention bounded by unfocused moments. It might be a sweeping of one's hand through space, walking along a path, scratching a path in the frost on a window with a fingernail, or moving ones [sic] eyes over the trunk of a rather tall tree. (p. 29)

According to Steffe (2013), attentional motion is critical in constructing an awareness of length. To be clear, it is the *attention* of the cognizing subject on the motion that is critical and not simply the motion itself. Steffe described three levels of awareness an individual might construct regarding this motion. If an individual is aware of the duration of the motion from beginning to end as well as the visual records of this motion while in the presence of (what an observer would call) a linear object, then an individual has constructed an *awareness of experiential length*. If the individual internalizes the motion—i.e., can re-present the visual records, the bounded motion, and the trace of this motion in the absence of the perceptual linear object—then an individual has constructed an *awareness of figurative length*. Finally, if an individual interiorizes the motion—i.e., can subject the re-presented experience to further mental operations (e.g., imagine the motion backwards, imagine stopping and re-starting the motion, imagine several successive iterations of the motion, etc.)—the individual has constructed an *awareness of operative length*.

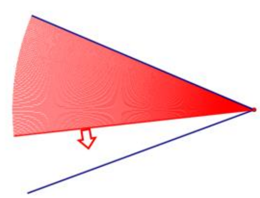

Figure 1: Radial Sweep Through the Interior of an Angle

Generalizing from Steffe's analysis of the construction of length, I consider an awareness of any geometric attribute to involve attentional motion. In particular, the construction of angularity involves attentional motion of some kind through (what an observer would call) the interior of an angular object. Attentional motion through the interior of an angle is critical because, fundamentally, angle measure is a description of the size of the interior of an angle. At the onset of the reported study, I hypothesized an awareness of a radial sweep—the trace of a rotating ray constituting the interior of an angle—would be a critical development in students' construction of angularity (Figure 1). The reason this would be such a critical development in students' quantifications of angularity is because, if the radial sweep were interiorized, then students would be able to subject the interior to further operation and produce, for example, angles three times or three-fourths as open as a given angle. Clements and colleagues (Clements et al., 1996; Clements & Burns, 2000) also argued for the significance of such a motion. However, multiple studies (Clements, et al., 1996; Crompton, 2013; Lehrer, Jenkins, & Osana, 1998; Mitchelmore, 1998; Mitchelmore & White, 1995; 1998; 2000) have shown that students tend *not* to spontaneously insert this rotational motion into non-rotational angle models (e.g., two line segments sharing a common vertex). For this reason, Mitchelmore and White (1998) recommended that angle measure as an amount of turn between two lines be abolished from elementary mathematics curricula. However, failure to insert rotational attentional motion does not imply an individual has not constructed an awareness of angularity. In other words, it is possible that an individual has constructed an awareness of angularity dependent upon some other attentional motion through the interior of an angular object. This issue raises the important questions that will be addressed in this report: what attentional motions might individuals use to constitute the interior of an angular object and what are the implications of these motions?

Methods

The data presented in subsequent sections is drawn from a teaching experiment (Steffe & Thompson, 2000; Steffe & Ulrich, 2013) conducted in the southeastern U.S. with two ninth-grade students, Camille and Kacie, over an academic year. At the time of the study, both students were enrolled in a first-year algebra course, and neither student had taken a dedicated geometry course. The overarching goal of the teaching experiment was to investigate how the students quantified angularity and how these quantifications changed throughout the study (see Hardison, 2018); the author served as teacher-researcher for all teaching sessions. Throughout the study, students engaged in mathematical tasks involving rotational angle models (e.g., rotating laser) and non-rotational angle models (e.g., hinged wooden chopsticks).

Camille and Kacie participated in 14 and 13 video-recorded sessions, respectively, which were conducted approximately once per week outside of their regular classroom instruction; each session was approximately 30 minutes in length. For each student, 2 sessions were initial interview sessions, and 1 session was a final interview session; interview sessions were conducted with each student individually to establish their ways of reasoning at the beginning and end of the teaching experiment. The remaining sessions were teaching sessions wherein the teacher-researcher worked to engender productive changes in students' ways of reasoning in addition to understanding their ways of reasoning; teaching sessions were conducted individually or in pairs. Beyond video-recordings, additional data sources included digitized student work and field notes. The records of students' observable behaviors (e.g., talk, gestures, written responses, etc.) were analyzed in detail during the teaching experiment (on-going analysis) as well as at the conclusion of the teaching experiment (retrospective analysis) via conceptual analysis (Thompson, 2008; von Glasersfeld, 1995). This report focuses on the attentional motions I abstracted from students' observable behaviors at the onset of the teaching experiment, specifically in the initial interview sessions and in the students' first paired teaching session.

Findings

From an analysis of students' activities in the teaching experiment, I abstracted three motions students enacted to account for the interior of angle models. In the subsequent sections, I illustrate each of these motions using data from the teaching experiment.

The First Motion: Radial Sweep

To investigate if students had constructed an awareness of angularity involving a radial sweep (see Figure 1), I posed a rotating laser task to each student during her initial interview. This task was purposefully posed after all other angular tasks in the initial interview to avoid leading students to use a radial sweep on other tasks. The rotating laser task involved a GSP sketch containing the image of a laser pointer. At the click of a button, the laser beam rotated 57° counterclockwise about the endpoint of the ray representing the beam. Initial and terminal positions of the laser pointer are shown in Figure 2. As I introduced the task to each student, I "turned on" the laser by clicking an action button, which showed a red ray emanating from the rightmost end of the laser. I informed the students that I would "turn off" the laser and then click the button to move the laser pointer. I asked the students to keep track of all the places on the screen the beam would have hit if the laser had been "on" as it moved; after the motion stopped, students were asked to shade the portion of the screen the beam would have hit.

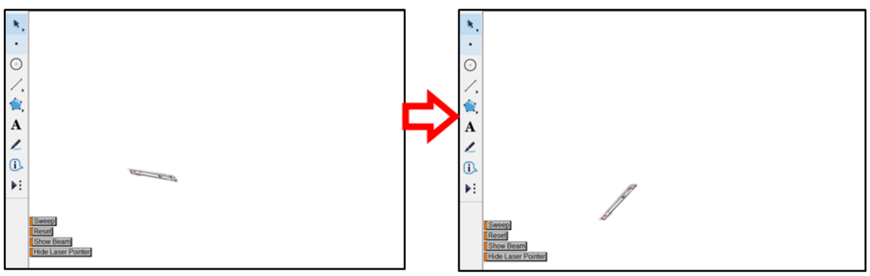

Figure 2: Initial (left) and Terminal (right) Positions of Pointer in the Laser Task

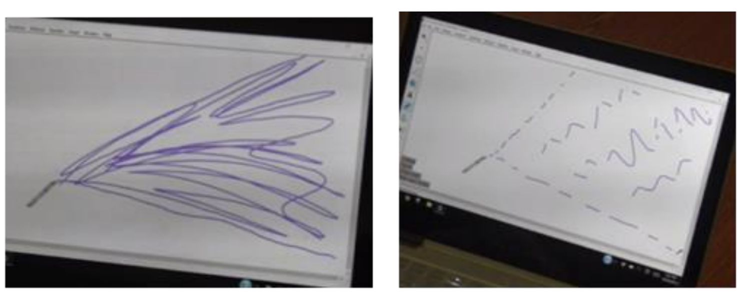

Figure 3: Camille's (left) and Kacie's (right) Shadings on the Rotating Laser Task

Both students shaded the screen accounting for three components: the initial location of the ray, the trace of the ray (i.e., the interior of the angle), and the terminal location of the ray. Camille shaded in the order that the motion occurred—shading the initial ray, then the interior, and finally the terminal ray (Figure 3 left). Kacie shaded in the opposite order (terminal ray, interior, and finally the initial ray), as if re-presenting the experience in reverse (Figure 3 right).

Both students described the boundary of the region as linear and in temporal terms, which indicated the boundedness of the imagined radial sweeping motion. For example, Camille lamented, "I didn't draw it straight but that would be like where it would stop," which indicated

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

her intent to create a linear boundary. Camille's shading of the interior in a counterclockwise motion also indicated that she was reimagining the motion of the radial sweep.

Each student re-presented the uninterrupted motion of the imagined beam, along with its trace, in visualized imagination. Therefore, I consider each student to have demonstrated an awareness of angularity via radial sweep. Camille's activities demonstrated at least an awareness of figurative angularity in that she re-presented the motion of the beam as she had observed it to occur; she had at least internalized the rotational imagery. In contrast, Kacie demonstrated an awareness of operative angularity because she indicated she could imagine reversing the direction of the sweep in re-presentation, which indicated she had interiorized the rotational imagery of the rotating beam.

Considering my hypothesis regarding the importance of a radial sweep, I viewed the students' ability to re-present the rotational motion as a promising base for developing students' angular operations. However, throughout the entirety of the teaching experiment, I saw no evidence that either student ever spontaneously inserted this rotational motion into a non-rotational angle context. In the subsequent sections, I present two other motions, which were not hypothesized, that students inserted into non-rotational angle models on comparison tasks.

The Second Motion: Re-presented Opening

The first angular task posed to each student during the initial interview session was an angular comparison task. In this task, I briefly displayed two pairs of hinged chopsticks (Figure 4) for each student and then covered them with a cloth. I asked each student to draw the chopsticks and describe the similarities or differences they noticed. A portion of Kacie's response is described in the excerpt below where Kacie's actions are described in italicized text.

Figure 4: Obtuse and Acute Chopsticks for the Drawing/Comparison Task

> Kacie: This [obtuse] one is like that [acute] one but it's farther out. [*Holds palms together and fingertips closed (Figure 5 left); then opens fingertips while keeping the bases of her palms pressed together (Figure 5 right)*]. So like they, [*gestures four times as if opening the hinged chopsticks from a closed position in the air*] uh, took it apart, I guess. But, it's still like together. And so, the same with like this [acute] one. It's just like somebody pushed it together [*holds hands open and then closes them some as if closing the obtuse chopsticks to the acute configuration*].

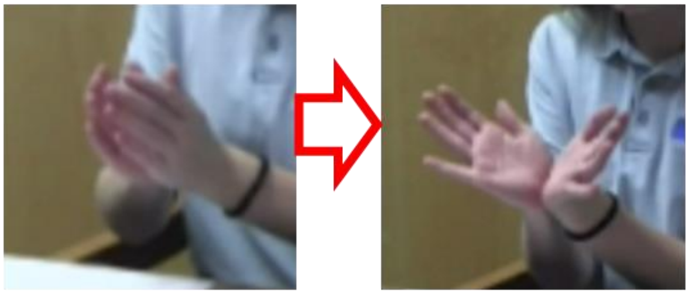

Figure 5: Kacie Imagines Opening Chopsticks from a Closed Position

During the preceding excerpt, Kacie repeatedly opened and closed her hands (Figure 5). From this, I inferred she imagined opening a pair of chopsticks while bounding this motion between two configurations: a closed configuration, which she represented with her hands, and the obtuse configuration she had drawn, which was perceptually available. I use “configurations” rather than “angles” here to emphasize the transformation of a single angle model from one state to another. From her repeated gestures, I infer that Kacie re-instantiated this motion—opening a pair of chopsticks to the obtuse configuration from a closed configuration—in visualized imagination at least four additional times. I interpret Kacie’s verbal description, “so like they, uh, took it apart,” as additional support for this inference. Kacie’s actions indicated she mentally constituted the interior of the obtuse chopsticks by re-presenting the action of opening the chopsticks to the obtuse configuration from a closed configuration. Thus, I consider Kacie to have demonstrated an awareness of angularity via *re-presented opening*.

Some readers may interpret Kacie’s re-presented opening of the chopsticks in terms of rotational motion (i.e., a radial sweep); however, I interpret Kacie’s actions more conservatively. That Kacie re-presented the opening action does not necessitate that she also held in mind a fixed position for the vertex of an angle model. Additionally, I distinguish an awareness of angularity via re-presented opening from radial sweep as the former involves motion on two distinct rays while the latter involves motion of a single ray through the interior of an angle.

The Third Motion: Segment Sweep

To illustrate a third motion used to constitute the interior of an angle, I describe and analyze Camille’s activities on an angular comparison task during the pair’s first teaching session. At this point in the session, Camille was explaining why her long chopsticks, which were set to an acute configuration from my perspective, were less open than Kacie’s short chopsticks, which were set to an obtuse configuration from my perspective.

To compare the two angle models, Camille held her thumb and index finger together over the vertex of the long chopsticks (Figure 6 left) and then dragged her thumb along one side of the chopstick and her index finger along the other (Figure 6 center and right). As she moved her fingers over the sides of the angle model, her thumb and index finger grew further apart. As she moved her hand, Camille explained, “Mine’s starting off really small and getting bigger.” Camille made a similar gesture as she referenced Kacie’s short chopsticks, “and that one’s just like – it’s just open really big,” moving her hands as if tracing out the short pair of chopsticks.

Figure 6: Camille Drags Her Thumb and Index Fingers Across the Angle Model

Camille's gestures over the long chopsticks suggested a new motion through the interior of the angle. She moved as if sweeping a growing segment, whose endpoints were determined by her thumb and index finger, through the interior of the model (Figure 7). Camille's explanation indicated she implicitly considered the experiential rate at which the segment bounded by her thumb and index fingers was lengthening as she moved her hand away from the vertex. I infer Camille compared the openness of the two pairs of chopsticks by considering which chopsticks would cause her fingers to separate more quickly as she moved her hands away from each vertex. In other words, she was not considering the duration of the motion she enacted as she moved her hands over the chopsticks; instead, she was comparing the intensity of this motion.

Because the Camille enacted these motions sequentially (i.e., one after the other) and not simultaneously, I infer she was able to make the comparison by imagining the segment sweep for one angle model while physically enacting the segment sweep for the other. Therefore, Camille demonstrated at least an awareness of figurative angularity via *segment sweep*.

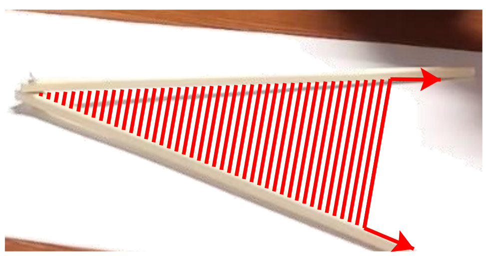

Figure 7: Segment Sweep Through the Interior of an Angle

Discussion

The construction of angularity involves attentional motion of some kind through the interior of (what an observer would call) an angular object. In my analysis of the students' activities, I have presented three such motions: radial sweep, re-presented opening, and segment sweep (Figure 8). A radial sweep involves the rotation a single ray (or segment), whose endpoint is fixed at the vertex of the angle, through an angle's interior. Re-presented opening involves imagining two distinct rays (or segments) opening from a closed position. Radial sweep differs from re-presented opening in that the former motion involves a single rotating ray while the later involves two distinct rays opening from a closed configuration. Segment sweep involves a linear segment, with one endpoint on each side of the angle, moving through the interior of the angle; the length of the segment increases at it is imagined moving away from the vertex. The motions I abstracted from students' activities were likely influenced by the angle models used in my study (i.e., chopsticks and rotating lasers); therefore, future research might investigate whether other contexts lead to other attentional motions.

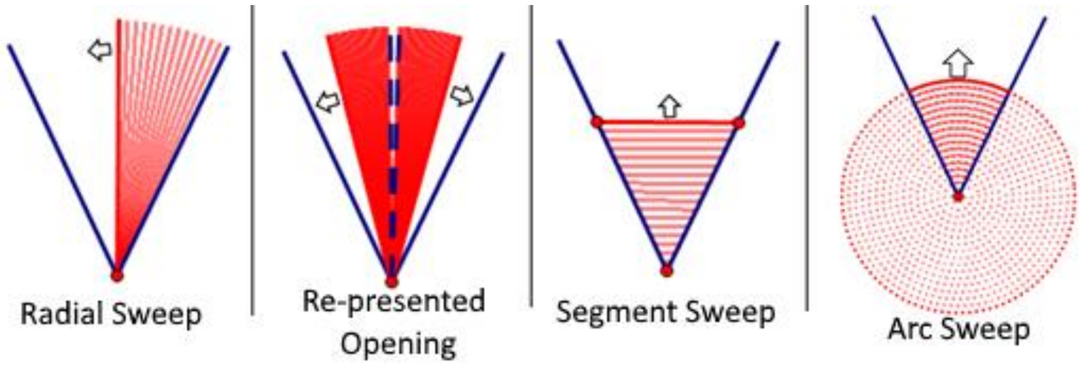

Figure 8: Four Attentional Motions Involved in the Construction of Angularity

In addition to the three motions above, I hypothesize a fourth attentional motion through the interior of an angle—an arc sweep. An arc sweep involves imagining the interior of an angle being swept out by a circular arc bounded by the sides of an angle where the circle containing the arc is centered at the vertex of the angle. Although neither student indicated imagining such an arc sweep, I hypothesize such a motion supports students to develop quantifications of angularity entailing generalized multiplicative comparisons of circular lengths holding across a class of circles (i.e., as advocated by Thompson (2008) and Moore (2013)). Through such a motion, the plane can be conceived as a collection of concentric circles and the angle conceived as a collection of arcs. Future research is needed to investigate this hypothesized attentional motion.

If an individual conceives the interior of an angle model as having an infinite area, all four of these motions can be viewed as being bounded in one sense and unbounded in another. In the case of re-presented opening and radial sweep, the motion is bounded temporally in that the motion has a beginning and an end; the extent of angularity is indicated by the duration of the motion. Re-presented opening and radial sweep are unbounded in a spatial sense, in that the length of the ray(s) moving through the interior of the angle is potentially infinite. In contrast, segment sweep and arc sweep are bounded spatially in that the segment or arc moving through the interior of the angle is always of finite length; however, segment sweep and arc sweep can be thought of as temporally unbounded: the sweeping motion starts at the vertex and continues indefinitely through the interior of the angle. In the case of segment and arc sweep, the extent of angularity is indicated by the rate at which the segment or arc grows as it moves away from the vertex and is, therefore, an intensive quantity (Piaget, 1965) resulting from a coordination of the length of the sweeping entity and this entity's distance from the vertex of the angle. All four of these attentional motions can be productively leveraged to make angular comparisons; yet, I hypothesize radial sweep, re-presented opening, and arc sweep are the most productive motions for developing normative conceptions of angle measure. In contrast, segment sweep may lead to nonnormative conceptions if operations (e.g., iteration) are applied to the sweeping segment.

Further Implications for Teaching and Research

Degrees as a unit of angular measure are often introduced via rotational imagery in terms of a 360-unit angular composite as in the CCSSM. This is a suitable approach for defining degrees if students are considering angles in rotational contexts. However, students' experiences with angles in mathematics classroom often involve non-rotational contexts, such as the interior angles of polygons. Throughout my teaching experiment, students did not spontaneously insert rotational motion into non-rotational angle contexts, which is consistent with the results of previous studies. If students do not spontaneously insert rotational motion into non-rotational angle contexts, introducing units like degrees in non-rotational contexts via rotational imagery is largely inappropriate. However, I do not share the sentiments of Mitchelmore & White (1998), who recommended that angle as turn be removed entirely from the elementary mathematics curriculum. Instead, I suggest that early instruction in angle measure involve both rotational and non-rotational contexts and different approaches for introducing units like degrees are merited depending on the context. Specifically, I hypothesize that emphasizing re-presented opening will be more pedagogically productive in non-rotational angle contexts. After students have interiorized attentional motions and subjected them to further operation (e.g., partitioning and iterating) in different contexts, teachers might work to engender students' recognition of similarities across these two contexts by drawing pictures to represent rotations or inserting rotational imagery into non-rotational angle models, for example.

Future research is needed to determine the prevalence of these attentional motions as students construct an awareness of angularity and the ways in which each motion is related to the other operations constitutive of students' quantifications of angularity. Given that many studies have found students tend to conflate linear attributes (e.g., side length) with angularity, I hypothesize segment sweep may be the most frequently considered motion if students are attending to the interior of non-rotational angle models. In closing, I offer one final hypothesis: generalized quantifications of angularity (i.e., those that are context independent) entail a recognition that different motions through an angle's interior account for the same magnitude of angularity.

INVESTIGATING TEACHERS' PROBABILITY LITERACY

Sara Brooke Mullins
Virginia Tech
sbm3@vt.edu

Jesse L. M. Wilkins
Virginia Tech
wilkins@vt.edu

Probability literacy involves an ability to understand and interpret everyday probability events. It enables teachers to understand different views, approaches, and methods associated with probability, as well as to support students in developing a deeper understanding of probability. However, research has shown that many people do not have a fully developed probability literacy. This study investigates the level of literacy for pre-service and in-service teachers. Results show that, although the teachers in this study demonstrated some aspects of probability literacy, overall they do not have a deep probability literacy and therefore may be limited in promoting students' understanding of probability.

Keywords: Probability, Problem Solving, Teacher Education

The concept of probability has become more prominent in the K-12 curriculum over the past 30 years (e.g., CCSSI, 2010 and NCTM, 2000). Although researchers and educators have recognized probability as an important concept for students to learn, the teaching and learning of probability remains a concern today. In order to be effective citizens, students and adults must be able to read and interpret everyday probability events, thus requiring probability literacy (Gal, 2005). Therefore, it is important for teachers to have a conceptual understanding of probability, so they can support students in developing their own probability literacy. Furthermore, a strong probability literacy will ensure that teachers do not hold common misconceptions as their students, and are able to address student errors (Jones et al., 2007; Langrall et al., 2017; Shaughnessy, 1992). It is then necessary to investigate teachers' probability literacy to determine if they are being supported to develop strong literacy and the steps that may be taken to support this development. The purpose of this study is to examine pre-service and in-service secondary mathematics teachers' probability literacy. Specifically, we ask the following questions: How do teachers think about and solve probability tasks? What heuristics do teachers use to solve probability tasks? How do teachers analyze and respond to student solutions?

Review of Literature

Probability literacy involves the ability to read, interpret, and understand real-world probability events (Gal, 2005; Batanero et al., 2016). Gal (2005) defined probability literacy as "the knowledge and dispositions that students may need to develop to be considered literate regarding real-world probabilistic matters" (p. 40). He also identified five knowledge elements and three dispositional elements that comprise probability literacy. Within this study, we focus mainly on the knowledge elements. The knowledge elements consist of (1) big ideas, (2) figuring probability, (3) language, (4) context, and (5) critical questions. The *big ideas* element relates to foundational concepts such as "variation, randomness, independence, and predictability" (Gal, 2005, p. 46). *Figuring probability* focuses on the heuristics or methods used to solve probability problems. The *language* element is related to how people represent and talk about probability, including terms such as chance, random, likelihood, and certainty. *Context* focuses on probability in the real world, such as different jobs, careers, and fields of studies. *Critical questions* are those questions a person needs to ask of a situation, such as context, source, and interpretation.

Figuring probability involves strategies used to solve probability problems, such as the representativeness, availability, and anchoring and adjustment heuristics (Batanero et al., 2016; Jones & Thornton, 2005; Shaughnessy, 1981, 1992). When using the representativeness heuristic, estimates are based on the similarity between an event and its parent population (e.g., predicting the next flip of a fair coin to be tails, when a sequence of heads just occurred; Jones & Thornton, 2005; Shaughnessy, 1981, 1992). In this case, the distribution of heads is assumed to balance to 50%. For the availability heuristic, estimates are based on memory and recent occurrences (e.g., predict rolling a four on a die because other people previously rolled a four; Shaughnessy, 1981). Adjustment and anchoring are related to making estimates based on initial information given in a problem, commonly known as the conjunction and disjunction fallacies (Jones & Thornton, 2005; Shaughnessy, 1981, 1992).

A more informal method of approaching probability is through the use of intuitions; these are described as a person's beliefs and experiences with probability, either before or after formal instruction (Fischbein, 1975). Primary intuitions are those developed before formal instruction, and come from people's personal preferences or their experiences with past probability events. For example, probability may be estimated based on a person's favorite color or number, without any recognition of theoretical probability formulas (Fischbein, 1975). After formal instruction, secondary intuitions are developed, thus fostering more objective beliefs. It is important to note that secondary intuitions do not replace primary intuitions, but rather build upon primary intuitions (Fischbein, 1975). As a result, primary intuitions may appear in other contexts, and may be overextended, resulting in misconceptions and erroneous approaches.

When considering teacher's understanding of probability, research shows that many teachers do not have appropriate content knowledge for teaching probability (Stohl, 2005). Stohl further highlighted that some teachers hold negative beliefs towards probability, which results in relying on computational and procedural approaches to teaching probability. Stohl also claimed, "without specific training in probability and statistics, preservice and practicing teachers (and perhaps some teacher educators) may rely on their beliefs and intuitions, and have similar misconceptions" (p. 346), thus highlighting the need to develop strong probability literacy.

Methods

This study involved two female pre-service teachers (PSTs; Kim and Pam) and two male in-service teachers (ISTs; John and Allen). Each participant was given a pseudonym. The PSTs were enrolled in a Master's program in education at a large research university in the southeastern United States. In their early-field placements, Kim was teaching Algebra I and Pam was teaching Geometry. The ISTs were faculty at a rural, public school in the southeastern United States and had completed the same Master's program. John had taught for nine years, and was currently teaching Geometry and Algebra II. Allen had taught for four years and was currently teaching Geometry, Algebra Functions and Data Analysis, and Algebra II.

One semi-structured clinical interview, lasting about 70 minutes, was conducted with each participant. During this time, participants completed five probability tasks. After solving the five tasks, participants were asked to examine and respond to hypothetical student solutions for each problem. Then the participants were asked to explain the students' solutions and address students' errors. Interviews were videotaped and transcribed. We first evaluated the correctness of participants' responses to each task. We then determined if they correctly characterized student solutions and examined how they responded to student solutions, making notes of instances where participants appropriately addressed mistakes and how they offered support for students' "incorrect" solutions. From this, we gained insight into the five knowledge elements of probability literacy for each participant, based on how they thought about and solved probability tasks, as well as, interpreted and responded to student solutions.

Results and Discussion

John, Allen, and Kim were able to correctly solve over half the tasks, but Pam was only able to correctly solve two tasks. Table 1 presents participants' correctness of solutions before they examined student work. After examining student work, Allen changed his answer to Task 5 to the correct answer, and Pam changed her answer for Task 4 to another incorrect answer.

Table 1: Task Results

Task and Description	Kim (PST)	Pam (PST)	John (IST)	Allen (IST)	Total
Task 1: If a 6-sided die is rolled, what is the chance that it will land on a 6?	✓	✓	✓	✓	100%
Task 2: If a fair coin is tossed... which of the following is more likely to occur? Choose one. (a) HTTHTH (b) HHHHTH (c) The same chance for each of these sequences	✓		✓	✓	75%
Task 3: Imagine there are two buckets of marbles... a green bucket and a red bucket. Each of the two buckets has 100 black marbles and 100 white marbles in it, all mixed up. You will flip a coin to decide which bucket to draw from. What do you think is more likely to happen? (a) You will pull a white marble (b) You will choose the red bucket, and pull a white marble		✓	✓	✓	75%
Task 4: There are three cards in a bag. One card has both sides green, one card has both sides blue, and the third card has a green side and a blue side. You pull a card out and see that one side is blue. What is the probability that the other side is also blue?					0%
Task 5: A person must select committees from a group of 10 people. (A person may serve on more than one committee.) Would there be: (a) More distinct possible committees of 8 people (b) More distinct possible committees of 2 people (c) About the same number of committees of 8 as committees of 2?	✓		✓		50%
Total for Participant	60%	40%	80%	60%	

Overall, the ISTs demonstrated a more developed probability literacy than the PSTs. The ISTs were able to correctly solve more tasks than the PSTs. Concerning the figuring probability element, the ISTs could identify and compare different approaches and heuristics students used, whereas the PSTs struggled to compare approaches and heuristics, often falling victim to common fallacies. The ISTs also began each task by talking through the problem, discussing their intuitions, and then resorted to using formulas when they needed to. This was different from the PSTs' approaches. Kim relied solely on her formulas, whereas Pam never wrote anything down and relied on her intuitions. Examining the big ideas element, all participants were generally able to discuss some big ideas concerning probability, such as conditional probability and sample space. However, the ISTs were able to talk about these big ideas in more formal and detailed manners, indicating a better understanding of probability language. John and Allen were also more able to engage in deeper conversations about students' use of language, offering alternative ways to ask questions and present the probability tasks, thus helping students to better understand the context of probability. Kim and Pam only engaged in conversations about the meaning of 50-50, equally likely, and same chances when prompted. From this, it was evident that the ISTs had a better understanding of what critical questions to ask of students' solutions. Both John and Allen focused on the why and how questions, whereas Kim and Pam could only ask questions about the meanings of certain words.

Conclusions

Although the ISTs demonstrated a more sophisticated level of probability literacy, we argue that all participants lacked some aspects of a complete probability literacy. Each participant evaluated student responses based on their original response, which is problematic as it caused participants to incorrectly respond to student solutions. Nevertheless, John and Allen possessed some aspects of all five knowledge elements, whereas Kim and Pam possessed limited aspects of only a few elements. Kim and Pam had a limited understanding of figuring probability, big ideas, language, and critical questions, with no attempt to connect the tasks to a larger context. The difference may be due to the ISTs having more teaching experience, knowing what critical questions to ask and how to engage in dialogue with students. However, with only four participants, it is difficult to know. What this study does demonstrate is that even the more sophisticated teachers are not fully literate in their probabilistic thinking and therefore may be limited in supporting students in developing a deep understanding of probability. However, the more experienced teachers did possess a greater ability to ask critical questions, which is an important aspect of literacy to help support their students' learning.

UNDERGRADUATES' EXPRESSION OF CRITICAL STATISTICAL LITERACY

Nina G. Bailey
UNC Charlotte
nbaile15@uncc.edu

Allison W. McCulloch
UNC Charlotte
allison.mcculloch@uncc.edu

Using statistical literacy in a data driven society to critically examine and question is imperative for students to become active and informed citizens. Using a framework adapted from Gal (2002), this study examines the use of critical statistical literacy within online discussion board posts of eight undergraduate students taking introductory statistics. The results indicate that the majority of students (75%) exhibited critical statistical literacy across all discussion prompts. The overwhelming expression of active citizenry demonstrates the potential that discussions boards have to bolster engagement, increase interest, and stimulate reflective thinking within introductory statistics courses.

Keywords: Critical Statistical Literacy, Online Discussion Board

Today's society is data driven and number saturated. Students need to be able to navigate through the abundance of quantitative messages they will undoubtedly encounter in the real world. Perhaps more importantly, those students need to be inspired to weed through such a barrage of data, and to do so requires both statistical literacy skills and taking a critical stance. For the purposes of this paper, I define *critical* statistical literacy (CSL) as the practice of analytically examining and assessing statistical content to inform action or change.

The importance of developing statistical literacy has been noted by many (e.g., Gal 2002; Del Mas 2002; Rumsey 2002). However, what is meant by the phrase *statistical literacy* is not the same for all. While there is no consensus on the elements of statistical literacy, the literature reveals consistent emphasis on understanding the basic terminology and concepts, understanding the need for and generation of data, interpreting different representations and conclusions, and acknowledging the potential for data to generate conflicting interpretations (Del Mas 2002; Gal 2002; Garfield and Ben-Zvi 2007; Rumsey 2002).

Research is rich with work that legitimizes statistical literacy as worthy of study (e.g., Watson, 1997) and describes the components of statistical literacy (e.g., Gal, 2002). Other researchers have detailed how to assess statistical literacy (e.g., Budgett & Pfannkuch, 2010), developed hierarchical frameworks (e.g., Watson & Callingham, 2003), and described curriculum design or reform (e.g., Schield, 2004; Tishkovskaya & Lancaster, 2010). While statistical literacy has gained momentum in the field, there are few examples of research that provides rich examples of how students express *critical* statistical literacy. One exception comes from Watson and Callingham (2004) who surveyed over 600 students across grades 5 through 10 with an aim of fleshing out their hierarchical levels of statistical literacy. Their findings suggest high school students need opportunities "to question critically statistical claims from media sources or other real-world contexts in order to develop the analytical habits of mind that are needed to respond critically to quantitative claims" (p. 133).

Online discussion boards are a potential vehicle for developing students' CSL. Some of the documented advantages of using online discussion boards include increased student motivation and interest when writing, and a stronger desire to produce quality work since both peers and the instructor will read the posts (Zemelman, Daniels, & Hyde, 2005). Furthermore, students have time to think before responding in an online forum unlike classroom discussions (Murphy and Coleman 2004) which nurtures reflective thinking (Hara, Bonk, and Anjeli 2000; Newman et al. 1997) and the co-construction of knowledge by sharing ideas and evaluating classmates' arguments (Gilbert and Dabbagh 2005; Pearson 2010). As a first step toward evaluating whether online discussion boards are an appropriate means to nurture CSL, this study aims to explore how students express CSL skills within online discussion forums used to supplement a face-to-face introductory statistics course at the undergraduate level.

Theoretical Framework

When considering students' development of *critical* statistical literacy, I focused on the critical literacy elements presented within Gal's framework for statistical literacy (2002). Gal's (2002) framework includes five knowledge elements and two dispositional elements. The knowledge elements are the collective set of skills needed to interpret and analyze statistical content in today's world and include literacy skills, statistical knowledge, mathematical knowledge, context knowledge, and critical questions.

What sets Gal's framework apart is the attention to the disposition. Gal describes beliefs, attitudes, and critical stance as playing a vital role in moving from passive interpretation to informed action. Specifically, Gal described critical stance as the questioning nature that is needed to critically assess and examine statistical information which includes a list of "worry questions." Since the purpose of this paper is to examine the expression of CSL, Gal's worry questions were adapted to create a list of five components that students need to be critical thinkers when employing CSL: (1) Ability to notice potential bias (2) Ability to question the sample size, sampling methods, or a lack of information regarding the sample (3) Need for additional information to make inferences (4) Ability to acknowledge conflicting or alternate conclusions (5) Ability to identify if the information uses appropriate descriptive and inferential statistics. Through attending to the ways in which students provide evidence of these components in their work that we can get a sense of their CSL.

Methods

The participants in this study were eight students all of whom took an introductory statistics course with the author at a small private university in the southeast (i.e., the case). This particular course was offered within a learning community on the topic of gender, as such students studied introductory statistics through this lens. The course was a traditional face-to-face class in which students were asked to participate in online discussion boards within the university learning management system to think critically about statistics and connect what they were learning to the other courses within the learning community.

The participants were all between the ages of 19 and 22. Of the eight students, one was male and seven were female. Six of the students are White, one Hispanic, and one Indian. The majority of the participants were majoring in the social sciences; there were a couple students majoring in other fields such as biochemistry and music therapy.

Discussion 5: Does the Wage Gap Exist? DUE 2/13 BEFORE CLASS

Does the wage gap exist? Find some data from credible sources to back up your answer. Based on the data and statistics you find, what is your best estimate of the wage gap if you think it exists.

Figure 1: Example of Discussion Board Prompt

Written responses for five discussion board prompts made up the data for this study. The discussions were structured in an open-ended, asynchronous manner. The prompt topics varied, but many were based on the gender wage gap to align with the learning community theme (e.g., see Figure 1). Students were expected to post and reply to classmates to elicit discussion.

Content analysis (Creswell, 2014) was used to explore how students expressed CSL within online discussion boards. I began by using *directed content analysis* in which I used an initial set of codes based on the aforementioned five CSL components. While coding, one additional theme emerged: (2) increasing social awareness of inequities and motivation for action to improve inequities. Random responses were selected for coding by multiple coders until codes were being applied consistently. After which, all remaining responses were coded by the first author.

Findings

The results indicate that the majority of students (75%) exhibited CSL across all discussion prompts. There was a total of six CSL components included in the codebook. The findings indicate that all of the CSL components adapted from Gal's (2002) worry questions were exhibited (See Table 1). The most frequent components were noticing potential bias and the emergent theme of increasing active citizenry. The ability to notice potential bias appeared across all prompts and all but one student. The theme of active citizenry (i.e., social awareness of inequities and motivation for action to improve inequities) emerged during coding and was exhibited by *all* students in at least 50% of the prompts. Given that active citizenry is a component of CSL that has not been discussed in previous literature, the remainder of this brief report will focus on findings related to this construct.

Table 1: Proportion of Prompts Containing Critical Statistical Literacy by Student

Student	Code					
	Bias	Sample	Additional	Alternate	Appropriate	Active Citizen
Derek	0.3	0.0	0.2	0.2	0.0	0.7
Kylie*	0.6	0.0	0.2	0.2	0.4	0.8
Payton	0.5	0.2	0.2	0.7	0.3	0.8
Naomi	0.7	0.2	0.3	0.0	0.0	1.0
Destiny	0.3	0.0	0.7	0.5	0.0	0.5
Jessica	0.2	0.0	0.0	0.0	0.0	0.5
Charlotte	0.3	0.0	0.3	0.0	0.0	0.8
Hope*	0.0	0.0	0.4	0.6	0.0	0.8

Note: * indicates that the student only completed 5 of the 6 prompts.

Active citizenry was defined in the codebook as the ability to utilize critical statistical literacy to become more socially aware of inequities, fight against inequities, and become an active, informed citizen. While engaging in prompts on the gender wage gap, many students extended the discussion. For example, Payton commented on how race plays a role within the gender wage gap: "First- the wage gap is still ever-present whether we see it in our own lives or not… Second, the wage gap should be analyzed through not just a gendered lens, but a racial lens as well. It would be unfair to fight for ONLY gender equality in pay if there is a racial gap as well." Hope, challenged the audience to consider how to promote equity: "Because different positions require different hours, should aspiring mothers in the business field receive incentives in order to minimize the wage gap?" In her response to Charlotte, she continued to question how society can implement change: "The wage gap is a big problem that needs to be addressed... What do you believe should be done in order for the gap to be fully addressed? Who would address the gap? The government?" Hope continued to demonstrate that she was thinking about potential solutions to a systemic problem in her response to Derek's admittance that he was confused by the lack of support to aspiring mothers:

> As a woman, I do agree with you that the statistics do reveal something that is unacceptable in our current world… Similar to Naomi's thought, where would the money come from for incentives to the aspiring mothers and their desire to work. I agree that business hours are not totally compatible with the average office desk for a mother, but this does not mean that it hasn't been done before… I think it would be crazy debate over a topic that Payton brought up - who has the responsibility? The mother or the employer?

In other instances, students challenged typical gender stereotypes. Naomi stated:

> The author points out that the value of some jobs decrease when women start to work those jobs as well as men. This indicates that employers are biased against women, and that women do not simply "[choose]" lower paying jobs. I think it is interesting that people think women [choose] lower paying jobs.

While some students appear to be moved by emotional reactions, others approached being an active citizen as recognizing the role that our perceptions and personal beliefs play in interpreting quantitative messages. Hope said, "It's interesting to me that even when researchers specifically have data that proves a point about how we live [and] what we do, people will still find a reason to disagree or not try to understand the statistical findings."

Discussion and Conclusion

The students in this study were able to use CSL to increase awareness of inequity, question methodology, acknowledge conflicting conclusions and identify bias, and develop a desire for more information. Watson and Callingham (2004) called for increased opportunity to engage in CSL, and the results of this study suggest that online discussion boards using a variety of open-ended prompts with popular media and articles can provide such opportunities.

The overwhelming abundance of instances where students demonstrated the use of CSL to highlight the need to become a more active citizen points to the potential that discussions boards have to bolster engagement, increase interest, and stimulate reflective thinking which aligns with literature (Hara, Bonk, and Anjeli 2000; Newman et al. 1997; Zemelman et al., 2005). It is recommended that introductory statistics courses provide opportunities to explore data and discuss topics that increase awareness of inequity. Further research is needed to determine if prompts that elicit evidence of active citizenship correlate with increased student engagement.

While the results of this study are promising, there are some limitations. First, it is unclear whether the style of prompt had an impact on the quantity and quality of CSL components. I anticipate that the low frequency of both the sampling and alternate components are connected to the prompt content. A prompt that asks students to evaluate a study might have greater potential for students to exercise CSL. Furthermore, it is unclear if the timing of the prompt played a role.

As the semester progressed, it is possible that students naturally exhibited more evidence of CSL. Future studies should change the order of prompts, to determine if timing plays a role.

It is imperative that we encourage students to develop critical statistical literacy. This study supports the notion that online discussion boards are one such vehicle in the development of CSL. Moving forward, we as a field need to identify other potential vehicles as well as pinpoint the prompt styles that best engage students.

MIDDLE GRADES' STUDENTS' CONCEPTIONS OF AREA AND PERIMETER

Jane-Jane Lo	Hsiu-fei Sophie Lee	Fenqjen Luo
Western Michigan University	National Taitung University	Montana State University
jane-jane.lo@wmich.edu	fei@gm.nttu.edu.tw	fluo@montana.edu

Prior studies have found the relationship between the area and perimeter to be a challenging topic for learners of all ages. Often, students believe that decreasing area for a given shape results in decreasing in perimeter of that shape, or vice versa. Using the theoretical constructs of concept definitions and concept images, this study sought to identify ideas that could be used to design mathematical tasks to develop correct conceptions of this relationship.

Keywords: Measurement, Middle school education

Area and perimeter are important geometrical measurement concepts in school curricula. However, students, including pre-service elementary school teachers, around the world find these topics to be challenging (Battista, 2007; Baturo & Nason, 1996; Livy, Muir, & Maher, 2012; Machaba, 2016; Menon, 1998; Murphy, 2012, Smith & Barrett, 2017). One widely documented misconception about the relationship between area and perimeter is the idea that an increase in area for a given shape results in an increase in perimeter for that shape, or vice versa. Tirosh and Stavy (1999) suggested that this misconception is rooted in intuitive rules (More A-More B, Same A-Same B, Less A-Less B). A common way to counter this misconception is to ask students to explore the relationship between area and perimeter with rectangles. However, working with concrete examples of rectangles of the same area but different perimeters (or vice versa) does not seem to have a long-term effect on this deeply rooted misconception. Smith & Barrett (2017) concluded that "Overall, research has not yet produced a compelling explanation for this challenge or an effective instructional response" (p. 365).

One possible reason for the inadequacy of using rectangles to explore the relationship between area and perimeter, (i.e. this is a common approach to correct the more area-more perimeter misconception for some students) might be due to its heavy reliance on numerical and logical information, while the conceptual understanding of the concepts of area and perimeter and their relationship remains rooted in intuition, spatial reasoning, and everyday experiences.

Theoretical Perspectives

When hearing the words area and perimeter, what pictures come to your mind? How would you explain these ideas to others? These pictures and words are part of your concept definitions and concept images of area and perimeter. Tall and Vinner (1981) described concept image as "the total cognitive structure that is associated with the concept, which includes all the mental pictures and associated properties and processes" (p. 152). These authors defined the words used to describe area as an individual's concept definition, that is, "a form of words used to specify that concept" (p. 152). Both concept image and concept definition take time to develop and may be modified by new experiences. Taking the social-cultural perspective of learning (Cobb, 1994), language, schooling, and everyday experiences are among possible factors that might impact the formations of concept definitions and concept images. The research questions were as follows:

- What were the subjects' concept definitions and concepts images of areas and perimeters?
- What were their understanding of the relationship between area and perimeter? How might those definitions and images affect their understanding of this relationship?
- How might factors such as language, schooling and everyday experiences influence the formations of concept definitions and concept images?

Methodology

This study was conducted in two public schools, one in the US and the other in Taiwan. Participants of the study included 17 seventh-grade students from the US and 12 sixth grade students from Taiwan. Based on the teachers' judgments, both groups were good representations of the various ability levels within the respected student populations. All of them had completed the instruction on area and perimeter of rectangles, triangles, and circles prior to the study. The data for this study were collected through semi-structured interviews. Due to space limitation, this paper focuses on the data gathered from following tasks:

- If I cut a piece off this paper (pointing to a sheet of paper), what would happen to its perimeter? Give me an example of a cut that would result in (a shorter, the same, a longer) perimeter in the resulting shape. Why do you think your example has (a shorter, the same, a longer) perimeter?
- Is it possible to cut a piece off this paper but make the perimeter of the resulting shape different from what you just said? If so, give an example and explain why your example works.

Results

The initial responses for the question "If I cut a piece off this paper (pointing to a sheet of paper), what would happen to its perimeter?" were quite different between the two groups. The results are summarized in Table One

Table 1: Percentage of Different Initial Responses from Both Groups

	US (n=17)	Taiwan (n=12)
Shorter	76.5%	33.3%
No change	5.9%	25.0%
Longer	5.9%	25.0%
Shorter or no change	11.8%	8.3%
Longer or shorter	0.0%	8.3%

While the majority (76.5%) of the US participants seemed to follow the Less A-Less B intuitive rule, relatively fewer (33.3%) Taiwanese participants did the same. About 25% of the Taiwanese participants chose no change and another 25% chose longer. One student commented that the answer could not be shorter because that was too obvious. She further shared her belief that the most obvious answer on mathematics test tended to be the incorrect one.

After the initial responses, all were prompted to consider possible alternative cases and to provide support for each claim. We have grouped all the final responses in three major cases: the perimeter would get shorter, not change or get longer.

The case of a shorter perimeter. All seventeen (100%) US participants and eight (66.7%) of the Taiwanese participants were able to provide a correct example that supported the case of shorter perimeter. Figure 1 shows both the correct and incorrect examples provided by participating students from US and Taiwan.

The justification for why cutting off an entire rectangle along a side were straightforward. Students pointed to the shortened portions of the boundary. Justification for cutting off a triangle at a corner drew from two distinct concept images. The first image was based on the daily experience that the direct route from point A to point B was shorter than going around a corner. The second image was based on the property of triangle inequality. Lastly, one Taiwanese student gave an example of cutting a 1/4 circle at the corner. He explained that the circumference was about 3 times the diameter, therefore, the arc from the ¼ of the circle would be about ¾ of the diameter, which would be shorter than the sum of two radii which was the diameter. Properties of circle is a main topic in the sixth grade Taiwanese curriculum.

Both types of incorrect examples involved cutting off a rectangle or square from the side or at the corner. Note that the former created longer perimeter while the later created equal perimeter. However, when asked for why they knew their examples had shorter perimeters, all these three Taiwan students' explanations indicated that they focused only on the side length that was removed, but not the side length that was created at the same time.

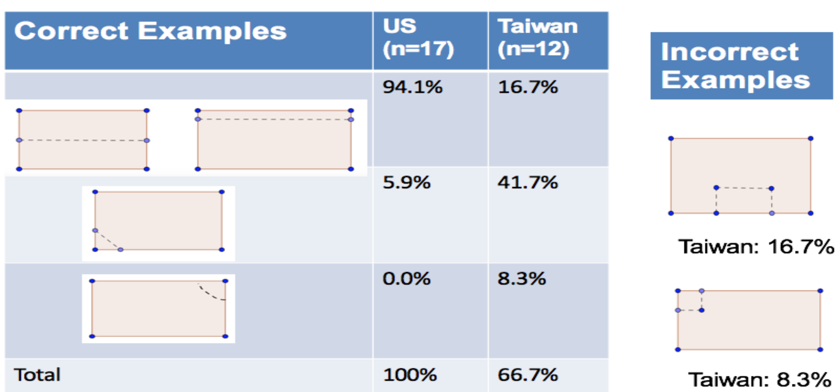

Figure 1: "Cuts" to Create New Shapes That Had Shorter Perimeters

The case of the equal perimeters. Table Two summaries the statistics of participating students' responses to the question of cutting off a piece while maintaining the same. Seven US (41.2%) and three Taiwanese (25%) participants claimed that it was impossible to reduce the area and keep the perimeter constant. While many participants thought it would be possible to do so, only some participants were able to come up with correct examples.

Table 2: Responses for the Same Perimeter Case

	US (n=17)	Taiwan (n=12)
Impossible to make an example	41.2%	25.0%
Incorrect example	17.7%	8.3%

Conceptually possible example	5.9%	0.0%
Correct example	35.3%	66.7%

The most common correct approaches were to cut either a square or a rectangle off the corner These participants were able to explain that since opposite sides of a rectangle (or square) were congruent, the new shape would have a perimeter equal to the original shape. Interestingly, the incorrect examples created by three US students and one Taiwanese all involved cutting a triangle either at the side of corner. They believed that it's possible to have the sum of the two newly created side lengths to be the same as the side length they removed. This is a direct violation of the triangle inequality property.

The case of the longer perimeter. All participants of this study found this to be the hardest case. Table Three below summarize the main results.

Table 3: Responses for Longer Perimeter Case

	US (n=17)	Taiwan (n=12)
Impossible to make an example	58.8%	33.3%
Incorrect example	17.7%	0.0%
Conceptually possible example	5.9%	8.3%
Correct example	17.7%	58.3%

Ten US (58.8%) and four Taiwanese participants (33.3%) claimed that it was impossible to reduce the area while increasing the perimeter. Only three US (17.7%) and seven Taiwanese (58.3%) participants were able to generate correct examples as seen in Figure 2 below.

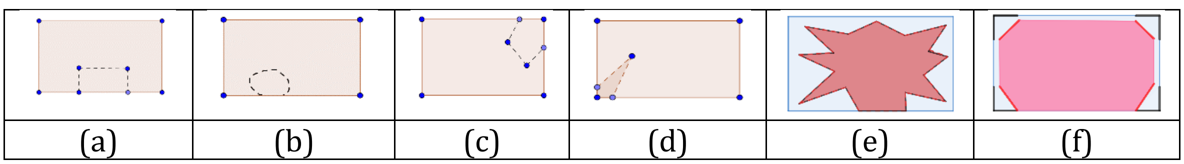

Figure 2: Sample Student Cuts Claimed to Create New Shapes that Have Longer Perimeters

The successful examples generated by students for this particular condition were based on three main concept images: 1) going around is longer than going straight (Figure 2a & 2b), 2) replacing a segment with more or longer segment(s) will result in longer perimeter (Figure 2c & 2d), and 3) shapes with more sides will have longer perimeters (Figure 3a & Figure 3b). While the first and second concept images would lead to correct examples, the third one did not always generate correct examples. Figure 2 also includes examples that were based on the same conception. However, the example seen in 2e did have a perimeter longer than original rectangle, but the example in 2f had a perimeter shorter than the original rectangle. The lengths from one point to another point around the corners (marked in red color) are shorter than the length of the four pairs of corner segments (marked in black).

Discussion and Implications

This study has deepened and expanded our horizon for concept images and definitions in geometry. First, we discovered that some students tried to support their responses with their daily life experiences, such as "direct routes from point A to point B as opposed to going around the

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

corner." Additionally, some students used their mathematical knowledge learned in school, such as triangular inequality, to justify why the sum of the lengths of any two sides must be greater than or equal to the length of the remaining side. Future studies are needed to explore the impact of purposefully-designed activities in these different settings on students' concept definitions and concept images of area and perimeter.

Second, we found that when participating students were asked to justify their initial responses with an example, they started to ponder between generating an applicable and justifiable example and modifying their prior responses. As a result, a lot of insights about middle grade students' concept definitions and concept images of area and perimeters were identified. This went beyond previous findings based on the paper-and-pencil survey only.

Future study is needed to examine the effectiveness of such activities in helping students build a more solid understanding of area, perimeter, and their relationship. It would also be interesting to see if the effect of this sequence of activities can be transferred to the relationship between surface area and volume.

COLLEGE STUDENTS' UNDERSTANING OF CONDITIONAL PROBABILITY

Marcie Tiraphatna
Virginia Tech
marciet@vt.edu

Jesse L. M. Wilkins
Virginia Tech
wilkins@vt.edu

This study investigates one undergraduate student's understanding of conditional probability to explore whether a framework (Tarr & Jones, 1997) originally designed for assessing middle school students' thinking can be successfully used with undergraduate students. A semi-structured clinical interview was conducted with tasks associated with the framework as well as additional tasks more appropriate for an undergraduate student. Findings suggest that the framework can be applied to undergraduate students; however, an additional level may be needed to differentiate more sophisticated understandings of conditional probability.

Keywords: Probability, Undergraduate-Level Mathematics

Conditional probability is the probability of an event (A) given that another event (B) has occurred, P(A|B) = P(A and B)/P(B). When dealing with dependent events or situations in which the relationship between events is not obvious, determining the conditional probability can prove to be difficult for students. Fischbein and Gazit (1984) found that students' performance in determining probabilities differed greatly depending on whether balls chosen from a bucket were replaced or not. Among the reasons that students may have difficulty in without-replacement situations is that the sample space changes or the situation seems counter to their intuition. Students often forget or do not realize a change in the sample space has occurred when the ball is not replaced.

Furthermore, using words such as "after" instead of "given," conditional probability tasks may lead students to believe that conditioning events only precede another event, when, in fact, two events could occur simultaneously or the conditioning event could happen later. An example of this is the Falk Phenomenon (Falk, 1988; Shaughnessy, 1992). When drawing two balls without replacement, (see Q3, Figure 1), finding the probability that the first ball chosen is black (B_1) given that the second ball chosen is black (B_2), $P(B_1|B_2)$, is usually more difficult than finding the probability that the second ball is black given the first one is black, $P(B_2|B_1)$. B_2 naturally seems to depend on B_1 while the converse does not seem possible. This may influence students to believe that $P(B_1)$ is the same regardless of the knowledge of B_2.

Falk (1988) also describes people's struggles with defining the conditioning event and sample space. Consider the three-card problem (see Q6, Figure 1). Most people look at the number of cards possible (two) instead of the number of sides (three). Students may also have issues with the conjunction rule, P(A and B) ≤ P(A). Tversky and Kahneman (1983) found that statistically naïve undergraduate students say the probability of a man having a heart attack was less than the probability of a man having a heart attack and being older than 55. One possible explanation for this is that they are confusing "having a heart attack *and* being older than 55" with "having a heart attack *given that* they are older than 55," P(A and B) versus P(A|B).

Theoretical Framework

Tarr and Jones (1997) created a four-level framework for assessing middle school students thinking related to conditional probability and independence. Students categorized as Level 1

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

tend to use subjective reasoning and usually ignore quantitative or numerical information. Students with Level 2 thinking have a mix of subjective and quantitative thinking. However, their quantitative thinking is limited and not complete; they sometimes revert to subjective thinking if situations do not go as anticipated. Students categorized as Level 3 understand that quantities are relevant, but are not able to assign specific numbers to probabilities. Level 4 students understand how changes in a sample space are related to conditional probability and can give numerical values for probabilities. In any given classroom, students might have different levels of probabilistic thinking.

Q1) Alice, Bob, and Cody are in a class together where students can earn raffle tickets. The teacher draws a raffle ticket from a cup at the end of each day to determine who gets a piece of candy. In the cup, Alice has 4 tickets, Bob has 3 tickets, and Cody has 1 ticket.

a) Who do you think has a better chance of winning?
b) Today the teacher draws one of Alice's tickets, gives her the candy, and then throws the ticket away. Bob says, "That's ok. I have a better chance of getting candy tomorrow since now I have just as many tickets as Alice." Cody says, "I still have 1 ticket so my chance of winning hasn't changed." What are your thoughts with regards to their reasoning?

Q2) The combination for a safe is not 2-8-5, but each digit is one away from 2-8-5.
If I gave you one chance to pick, do you think you could unlock the safe?
Is it more likely that you would unlock the safe, more likely it would stay locked, or is it the same chance?
Go ahead and pick the first digit.
You are correct. Has your chance of unlocking the safe changed? Why or why not?
Pick second digit. You are correct.
Has your chance of unlocking the safe changed? Why or why not?

1	7	4
2	8	5
3	9	6

Q3) A bucket contains 3 black balls and 4 white balls. You pick a ball from the bucket without looking.

a) What is the probability of drawing a black ball?
b) What is the probability of drawing a white ball?
c) Let's say that you draw a white ball. After drawing it, you put it back into the bucket and make a second draw. What is the probability of picking a white ball again on the second draw?
d) Now let's say you draw a black ball. This time you do not return the ball back to the bucket. A second ball is drawn from the bucket. What is the probability that this ball too, will be black? Or white?
e) Draw two balls without replacement. If we know the second ball is white, what is the probability the first ball is black?

Q4) A hospital gathered information from 1000 patients about smoking and lung cancer. The data is presented in the table provided.

a) What is the probability that a person chosen at random from this sample will have lung cancer, if they are a smoker?
b) What is the probability that a person is a smoker if they don't have lung cancer?
c) What is the probability that a person is not a smoker and does not have lung cancer?
d) What is the probability that a person is a smoker and has lung cancer?

		Smoked	
	1000 total	**Yes** (400)	**No** (600)
Lung Cancer	**Yes** (450)	250	200
	No (550)	150	400

Q5) Suppose I shuffle a standard 52 card deck, pick a random card, and without showing you I tell you it is an ace. What is the probability my card is the ace of spades?

Q6) There are three cards in a hat. One card is blue on both sides. One card is red on both sides. One card is blue on one side and red on the other. A single card is dawn and placed on a table. If the visible side of the card is red, what is the chance that the other side is red? What about blue?

Figure 1: Interview Tasks

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

Purpose

The purpose of this study is to investigate one student's understanding of conditional probability and attempt to categorize this student based on the conditional probability portion of the framework (Tarr & Jones, 1997). Although this framework was originally designed for middle school students, we believe it can also be applied to any academic level, specifically undergraduate students. The framework describes different types of thinking and milestones, which are unrelated to age or grade. The framework relies on students' understanding of "with and without replacement" situations which have an explicit change in sample space. The tasks used by Tarr and Jones (1997) did not differentiate temporal ordering or use contingency tables. Studies show that college students still have difficulties with the effect of the time axis and contingency tables (Fishbein & Schnarch, 1997; Watson & Kelly, 2007). Therefore, in this study we will further investigate these issues.

Data and Methods

The study involved one undergraduate student from a large public research university in the southeast United States. The participant, Steve, was a freshman in an applied mathematics major. He had previously taken AP Statistics and a probability and statistics course during his junior and senior year of high school.

We conducted a semi-structured interview involving six conditional probability tasks (see Figure 1). The interview was videotaped and transcribed for further analysis. The tasks were chosen to highlight students' conceptions of conditional probability in a variety of contexts. Q1, Q2, and Q3 minus part e were based on those used by Tarr and Jones (1997) which tested students' understanding of with/without replacement type problems. Q3e and Q5 were included to test the student's ability to work with the time axis. A contingency table, Q4, was used to identify the potential confusion with conditional and conjunctive statements. Q6 is the three-card problem described by Falk. This task was included because of its nuance of defining the conditional statement. Some questions involved little to no calculations, which allowed the student more opportunity to discuss their reasoning. Follow-up questions were asked after the tasks were solved.

Results and Discussion

Identifying the sample space and conditioning event is a crucial part of calculating conditional probabilities. Throughout the interview, Steve demonstrated his awareness and understanding of changes in a sample space, and that given a certain event, the sample space is restricted. When shown a contingency table, Q4, Steve was able to correctly identify the sample space for one event given another. For parts a and b, he pointed to the smoker column and circled the row of people without lung cancer. He even said things like "the precondition is."

Although Fischbein and Gazit (1984) showed and explained students' difficulties regarding with and without-replacement tasks, Steve did not have any issues with such basic tasks. In Q3, he was able to explicitly state the correct probability of drawing a black ball after a black ball was drawn and (not) replaced. With Q1, Steve used part-part reasoning when explaining why Bob is correct, saying, "He (Bob) has the same chance to get candy as Alice." He did not use the same reasoning to explain Cody's logic. Instead, he compared the numerical values, 1/7 and 1/8, to say Cody's chance of winning has increased. This change from part-part to part-whole thinking allowed Steve to recognize that there were fewer tickets, and thus, a better chance of winning for Bob and Cody.

Even if one is able to identify a change in sample space, they still may not be able to identify the conditioning event, as shown with the three-card problem. When given the three-card problem, Steve eliminated the possibility of choosing a blue/blue card, but did not recognize the sample space was the three possible faces of the cards not the two cards. He said, "We pick the red. It could just be that the other side is also red. That would be one possibility. The other possibility is taking the other side is blue. So one half." Here, Steve demonstrated an understanding of a change in some sample space, albeit, not the correct one.

We posed Q4 to test whether Steve confused a conjunctive statement with a conditioning one. When questioned about his reasoning for answering 400/1000 as the probability of a person being a smoker *and* having lung cancer, Steve said, "it's the entire group because it's not just saying 'of this group.' It's the entire group." This suggests conjunctions were not an issue.

Another misconception students often have is the idea that conditioning events need to happen sequentially. To see Steve's understanding of this, we asked Q1 and Q5. When drawing two balls without replacement and knowing the second ball was white, Steve said the following:

> So, if we know that the second ball is white and because we can't put the ball that we took out earlier back…we know that we didn't draw that ball. Because we know we didn't draw that ball, we can eliminate that from the equation if it wasn't in the bag then we have six. So then you have six possibilities minus one white. So then three black balls out of six.

When asked for the probability of a card being the ace of spades given that the card is an ace, Q5, Steve immediately wrote 1/4 down stating "although it says 52 cards, it's ace and there is only four aces." Both of these instances show the participant's ability to solve problems when the conditioning event happened before or during the event being calculated.

Throughout the interview, Steve demonstrated a strong use of numerical reasoning. He was able to assign numeric values to probabilities and explain his reasoning without the use of formulas. When asked to compare the likelihood of two events, Steve would use the numerical value of the probabilities to justify his answer. In all instances, he was able to recognize when and if a sample space had changed and apply it to his responses. He recognized that probabilities do not change in with-replacement situations and they do in without-replacement. Because of this, we would categorize him as someone with Level 4 understanding of conditional probability.

Conclusion and Significance

This study provides one case of an undergraduate student's understanding of conditional probability. We were successively able to categorize him within Tarr and Jones' (1997) framework. However, additional interviews of students with varying experiences, beyond mathematics majors, should be conducted to further validate the use of Tarr and Jones' framework for undergraduate students. More interviews of undergraduate students could also uncover issues with conditional probability similar to those of younger students.

Although we could categorize Steve within the framework due to his use of numeric values and understanding of sample space, he did not have a complete knowledge of conditional probability as he answered Q6 incorrectly. However, Q6 is considered a relatively difficult conditional probability task. This suggests that it may be possible to refine Tarr and Jones framework to include additional conditional probability tasks. The framework discussed in this study could be used by instructors to assess undergraduate students understanding before and during instruction to guide the instruction of conditional probability.

EXAMINING DYNAMIC MEASUREMENT REASONING FOR AREA AND VOLUME

Nicole Panorkou
Montclair State University
panorkoun@montclair.edu

This paper describes the forms of reasoning that students developed as they engaged with tasks presenting area and volume dynamically. The analysis of a series of design experiments with twelve fourth-grade students showed that they reasoned about dynamic measurement in terms of a) the quantities involved in the generation of the space to be measured, b) the dimensional transformation of those quantities, and c) their continuous change.

Keywords: Dynamic Measurement, Technology, Design Experiments

Dynamic Measurement

Dynamic Measurement (DYME) is an approach to geometric measurement that focuses on how space is measured by the lower-dimensional objects that generate it. One way to visualize this approach is by Lehrer, Slovin, and Dougherty's (2014) generation of attributes through motion. For instance, a rectangular area can be thought of as a swipe of a line segment '*a*' for a distance '*b*' to generate an area of '*ab*' (Figure 1a). Similarly, volume can be thought of as an extrusion of a 2-D surface of area '*c*' for a height of '*d*' to generate a 3-D space '*cd*' (Figure 1b).

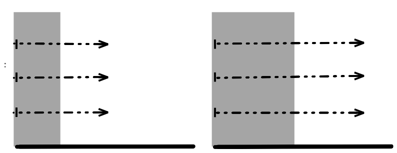

Figure 1a: DYME for Area

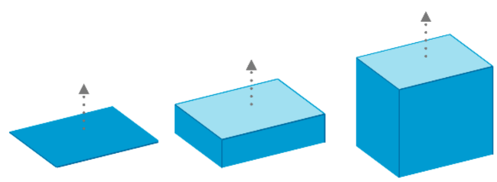

Figure 1b: DYME for Volume

DYME is built on the view that space has a dual nature as both *containment* and *generation* (Panorkou & Pratt, 2016), which is often overlooked by research and practice. As Panorkou and Pratt (2016) argued, "one can see the space as incorporating objects; in this sense, the space contains the objects. At the same time, the space can be thought of as generated by the objects" (p. 213). Typically, measurement is approached using the containment nature of space, for example, counting the number of square units needed to fill a 2-D space, or counting the number of cubic units needed to fill a 3-D object. In such approaches, the measure of area and volume is a multiplicative relationship between the unit of measure (square units, cubic units) and the object that is measured. DYME aims to bridge the two components of space into one construct. In terms of containment, DYME focuses on how the space that is measured by the lower dimensional objects (line segments, surfaces) it contains. In terms of generation, DYME focuses on the role of the lower-dimensional objects that are spanned to create the space that is measured. In this approach, the measure of area and volume is a multiplicative relationship that illustrates a transformation from two lower-dimensional quantities (e.g. *length x width* for area, *area of base x height* for volume.)

This paper reports on the findings of a series of design experiments (DEs) (Cobb et al., 2003) with twelve fourth-grade students working in pairs to describe the qualitatively different ways of

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* St Louis, MO: University of Missouri.

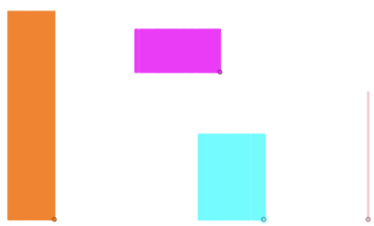
DYME reasoning about area and volume that students exhibited and discuss the means that supported their reasoning. The DE with each pair consisted of 8-10 sessions of 45-50 minutes each and the focus was the area of rectangles and the volume of right prisms and cylinders.

Characterizing Students' Dynamic Measurement Reasoning

The findings of the design experiments identified three qualitatively different but related types of reasoning that I describe in the following paragraphs by giving examples from the DEs.

Reasoning About the Quantities Involved in the Generation of Space

The early tasks in DYME for area involved dragging line segments of various lengths over various distances and reasoning about the size of the rectangle generated (Figure 2a). In terms of volume, the tasks involved dragging surfaces of various shapes and sizes over different distances and reasoning about the size of the 3-D space generated (Figure 2b).



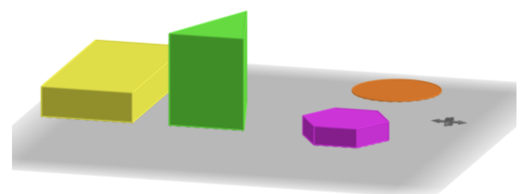


Figure 2a: Dragging Segments Over a Distance
Figure 2b: Dragging Surfaces Over a Height

By dragging the line segments and the surfaces students reasoned about the quantities involved in the measurement process. In terms of area, by dragging a line segment over a distance, students conceived three quantities that are measurable: a line segment (described as a paint roller in our task design), a dragging distance, and a generated area. For example, students argued that the "bigger the roller, the more space you can cover" and that "you can drag it [the roller] more and make a bigger one." In terms of volume, by dragging bases over a height, students conceived three measurable quantities: area of base, dragging height, and 3-D shape created. For instance, students stated that the 3-D shape created "depends on how big the base is, and it also depends on how much you can drag it."

As they dragged the surfaces to generate volume, students perceived the extrusion of 2-D shapes to create 3-D shapes as an action of "expanding," "dragging" "stretching" or "pulling" the base. For instance, Jayden argued that "it starts out as a 2-D base and when you stretch it, it goes into 3D." Students' language of *expanding, pulling, stretching,* and *dragging* shows that they recognized that there is some kind of transformation happening from 2-D to 3-D. While elaborating on their thinking further, some pairs reasoned about the extrusion as an iteration (creating identical copies) of 2-D surfaces. For example, Molly argued "It's like you are taking the base and stacking it over and over again." I noticed that students' reasoning shifted interchangeably from reasoning in terms of a transformation (e.g. stretching, pulling) to reasoning about stacks. This integrated reasoning illustrates that they were able to construct a meaning about the volume of 3-D shapes both as spaces that contain objects (multiple 2-D shapes) and as spaces that are generated by these objects. In other words, they were embracing the dual nature of space as both *containment* and *generation* (Panorkou & Pratt, 2016).

Reasoning About the Dimensional Transformation of the Quantities

The following tasks for area involved asking students to drag a line segment of 5 inches over different distances and reason about the space covered (Figure 3).

Researcher: So how much space does the first [red rectangle in Fig. 3] cover and how much does the second [orange rectangle in Fig. 3] cover?

John: 1 inch and 5 inches, 2 inches and 5 inches.

Figure 3: Dragging a Line Segment of 5 Inches Over Various Distances

Similar to John, students were able to construct a unit for measuring the space of rectangles that was a composite unit made up of the measure of the line segment and the distance of the swipe (e.g. 1 inch and 5 inches). This unit was a result of a dimensional transformation as it included two linear measures for reasoning about an area measure, considering the unit to be a composite of two dimensions. They were also able to construct various units depending on the rectangle they had to measure. The tasks that followed focused on painting rectangles using line segments of varied lengths dragged in different distances. These types of tasks helped students to reason multiplicatively about the length, width, and area. For example, in explaining why the area is 30 inches^2, Sophia argued “Because the width is 10 inches going across and the length is 3 inches. So then 3 times 10 is 30.” Similar to Sophia, for all students, reasoning multiplicatively has shown to be an intuitive way to explain the space covered. In terms of volume, the tasks involved dragging surfaces of various areas over 1-inch and 2-inch heights (Figure 4).

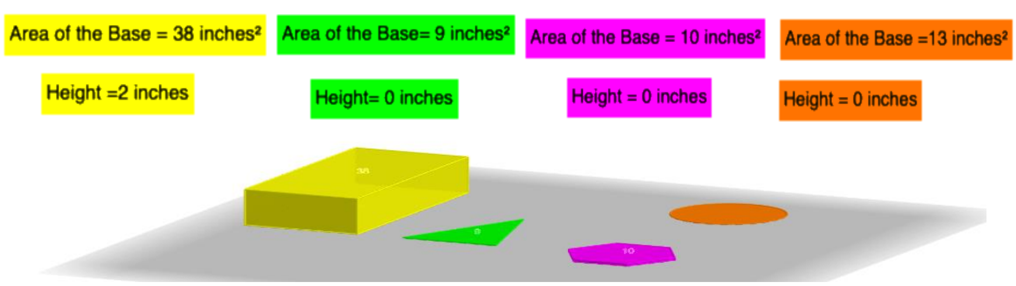

Figure 4: Students Drag Various Surfaces to Different Heights

As students increased the height of the extrusion from 1 inch to 2 inches, they reasoned multiplicatively about the relationship between area of base and height. Students explained their use of multiplication in terms of thinking about the 3-D space as consisting of stacks (copies of 1-inch drags of the specific base). For instance, Jayden argued that the size of the 3-D shape becomes two times bigger if we increase the height to 2 inches, “because it is kind of like stacking this one on top of it because this one says it is 2 inches, so we are going to make this one another inch and it is going to be the same thing.” Jayden’s reasoning shows that he viewed the iteration of 1-inch drags as making copies of one drag, and he multiplied by two to find the volume. In addition, he described this iteration in terms of "make this one another inch and it is going to be the same thing" showing that he coordinated the change in height with the change in volume. As students' thinking progressed, they were able to generalize that volume depends on the size of the base and the number of 1-inch drags of that base. For example, Molly stated, "To find the volume, you have to first find the base, how much is the area of the base and then you multiply by how many drags you have, how many drags you have done." Similar to Molly, students were able to conceptualize *base x height* as a quantitative operation (Smith III & Thompson, 2008) between two quantities (base and height) to produce a new quantity (volume).

Reasoning About the Continuous Change of Quantities

Students were asked to double, triple, and halve lengths and reason about the resulting changes in area. For example, in splitting the width of a rectangle in half a student argued that its area will now be half, stating "Because this is like half of it. And 4 times 6 equals 24, but 2 times 6 equals 12 and it is a half." Similarly, volume tasks focused on changing the linear measures of rectangular prisms of a sculpture and reasoning about the change in volume (Figure 5). Similar to the excerpt below, students were able to recognize that to make the volume *n* times bigger, they need to make the area of the base or the height *n* times bigger. They used covariational reasoning (Confrey & Smith, 1995; Saldanha & Thompson, 1998) to coordinate the two varying quantities and reason about the ways in which they changed in relation to each other.

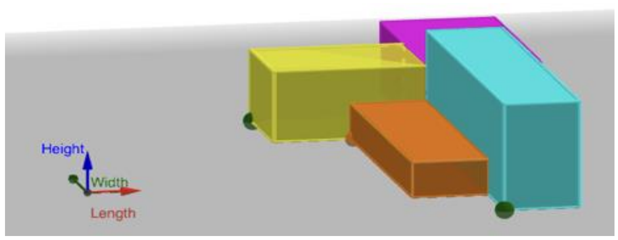

Figure 5: Students Were Asked to Change the Dimensions of the Rectangular Prisms

Researcher: OK, the first one is to double the length of the orange. Before you do it, what do you think will happen to the volume if you double the length?
Ben: It's going to double; it is going to double itself.
Researcher: Why?
Ben: Because we doubled the length. [students double the length]
Researcher: Hmm, let us see. Yes, it doubled.
Ben: Double both the length and the height of the pink one. [states the next task]
Researcher: What do you think will happen?
Ben: It will quadruple.
Researcher: Why?
Ben: Because you doubled two things. […]
Researcher: Double the length and then you half the width. What will happen?
Ben: Nothing.
Researcher: Why?
Ben: Because you halved the width. So, it's just going to go back to its original form because you cut it in half.

In sum, students reasoned about the quantities involved in DYME and how these quantities work together in generating and changing the space created. By exploring what is changing and how it is changing, they were able to conceptualize area and volume as quantities on their own and also as multiplicative relationships between length and width, and base and height, respectively. These findings aim to initiate a discussion about the nature of DYME and how it can be used for developing a conceptual understanding of measurement and other mathematical ideas, such as transformations, multiplication and covariation.

We explored 23 first and third graders' directional language and counting of spaces on a grid when debugging programming code after playing three and six sessions of Coding Awbie™. Students in both grades were more likely to describe a bunny as moving up using specific terms but more likely to describe going right using generic terms. Over half of the students made at least one counting error. Students had fewer counting errors after playing the programming game because many of them more efficiently corrected the programming code.

Keywords: Geometry and Geometrical and Spatial Thinking; Cognition; Elementary School Education

Spatial thinking is crucial for success in not only mathematics but also programming, chemistry, and medicine (Clements, 1999; Jones & Burnet, 2007; Krajewski & Ennemoser, 2009; Kyttälä et al., 2003; Lowrie & Logan, 2016; Sorby et al., 2013). Given the increased focus on students learning programming, mathematics teachers can leverage the finding that programming tasks can promote mathematical practices involving spatial thinking (Heghfield, 2003). For example, one of the Common Core Standards for Mathematical Practice is for students to reason abstractly and quantitatively; this practice involves representing situations symbolically and reasoning about quantities (National Governor's Association Center for Best Practices & Council of Chief State School Officers, 2010). Similar practices are incorporated in programming games for children, which often involve manipulating symbols that tell a character which direction to go in and how far. Therefore, the current study explored spatial thinking through students' explanations as they debugged a symbolic program written to move a bunny to a carrot on a grid.

Spatial Thinking

Spatial thinking involves perceiving and transforming the visual environment (Gardner, 1983), plays a strong role in students' ability to mentally represent and manipulate information or objects (Lowrie & Logan, 2016), and is highly correlated with academic achievement in programming, mathematics, and other fields (Clements, 1999; Jones & Burnet, 2007; Lowrie & Logan, 2016; Sorby et al., 2013). There are two dimensions of spatial thinking; spatial orientation and spatial visualization (Clements & Battista, 1992).

Spatial Orientation and Language

Spatial orientation refers to the ability to understand and interpret the relations among different positions of objects in space (Clements & Battista, 1992; Clements, 1999). Clements (1999) argued that students must have some mathematical ideas for reading and creating mental maps. Students should learn to manage abstraction, generalization, and symbolization in the mapping process. Furthermore, students should develop some ideas such as direction, distance and measurement, and location. Children naturally use vertical terms such as *up* and *down* at an early age, but *left* and *right* require more time (around age 6-8) for students to fully understand (Sarama & Clements, 2009). Teachers should help students move away from generic movement descriptions such as *over* because *over* does not extrapolate well to bidirectional spaces (Sarama & Clements, 2009). Students need to learn to use precise language, and computing programs can provide them with immediate feedback.

Spatial Visualization and Counting

On the other hand, spatial visualization involves imagining and making transformations, such as motions of an object (Sarama & Clements, 2009). Spatial visualization is strong predictor for success of counting achievement in earlier grades. For instance, spatial thinking was positively correlated with kindergarteners' ability to count 16 cubes in four rows and four columns (Kyttälä et al., 2003). Students may miscount (e.g., by double counting) if they do not find structure in the spaces they are counting (e.g., Battista et al., 1998).

Programming, Spatial Thinking, and Mathematics

Programming tasks might leverage spatial thinking because students have the opportunity to learn direction, orientation, measurement, and positional language, as with Logo turtle (e.g. forward 10 steps; Clements, 1999). For example, after using *Turtle Math*, a version of Logo for third to sixth graders, students' computation scores improved (Clements & Sarama, 1996). One current programming game for even younger elementary students (Coding Awbie™) involves tangible programming pieces that allow students to move a character along squares in a grid-like environment. This structured space could potentially support younger students' counting. Further, the programming pieces involve motions, directional arrows, and numbers that might better map to students' ideas about how to move the character. Therefore, we investigated the following research questions: How do first and third graders interpret symbolic location and movement representations and map them onto a 2-dimensional grid? How does this change after practice programming a character to move on a grid (a) in terms of the positional and directional language they use? and (b) in terms of their counting to determine the number of movements?

Method Participants and Setting

The study took place in a Midwestern public elementary school with about 46% students qualifying for free or reduced-price lunch. For this analysis, we focus on data from 23 participants who came from two first- and one third-grade class from our larger study. We selected these particular classes for the analysis in order to have an equal number of participants from each grade; however, we had to exclude one of the 12 first graders because of missing data.

Study Design

The study consisted of a pretest, three sessions playing a programming game, a presentation about programming, a midtest, three more game sessions, and a posttest. During game play, students played Coding Awbie™, a game using the Osmo™ tangible interface. Student pairs were randomly assigned to either engage in free-play for the first three sessions or explainedplay (i.e., students had to tell us their goal for each program and explain how their lines of code would help them meet their goal). During the second set of sessions after the midtest, they switched groups (those who had explained-play had free-play and vice versa).

Pretest, midtest, and posttest. Our analysis focuses on one common item from the three tests, a commenting and debugging problem. For this problem, students had to explain a pair of coding commands meant to move a bunny on a grid to get to a carrot. Students were told that the bunny could not move past or jump over houses, but they could jump over flowers. Students then identified the bug in the code and explained how they would fix the code (see Figure 1).

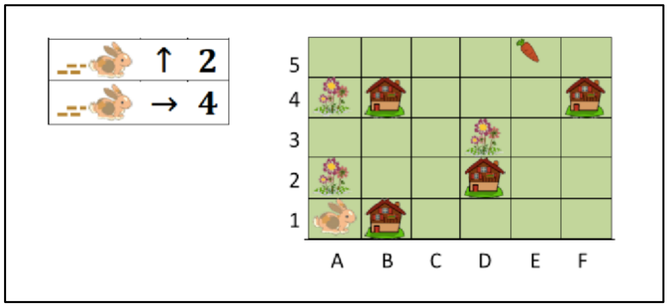

Figure 1: Programming Debugging Problem (Grid Labels Added for Ease of Reference)

Data Analysis

Positional and directional language. We analyzed the data in terms of spatial orientation for the midtest and posttest as we did not ask students to explain the program on the pretest. We expected the students to explain the first line of the program as "walk up two" (as used in the coding game) and the second line of the program as "walk right four." Therefore, we coded students' explanations of each line of code in three categories: movement, direction, and number. We focused on two categories for direction: generic or incorrect language and non-generic language. Non-generic language included the precise terms *up* and *right.* Generic language involved general statements such as *this way*, *that way*, *side*, *over*, and *forward* (incorrect).

Counting. We also analyzed the data in term of spatial visualization. When students corrected the code, they often counted spaces the bunny would move to determine if the number in the code should stay the same or change. We classified students based on whether they made a counting error on any of the three tests. For students who made any counting error, we identified on which test they made an error and whether they made an error on the *corrected* code (i.e., changed the first line of code to jump up 2) or when changing it to *new* code (i.e, changed the first line of code to jump up 1).

Results Positional and Directional Language

Table 1: Students' Generic and Non-Generic Uses of *Up* and *Right*

Students		Midtest		Posttest	
		Generic	Non-generic	Generic	Non-generic
Up	1st (n=11)	9%	73%	9%	64%
	3rd (n=12)	8%	83%	---	83%

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* St Louis, MO: University of Missouri.

Right				
1st (n=11)	82%	9%	55%	9%
3rd (n=12)	50%	42%	58%	25%
Up Explained-play (n=15)	13%	73%	7%	73%
Free-play (n=8)	---	88%	---	75%
Right				
Explained-play (n=15)	67%	27%	67%	13%
Free-play(n=8)	63%	25%	38%	25%

Overall, when describing the first line of code, students in both grades were more likely to describe the bunny as going *up* as opposed to describing thedirection with generic terms (see Table 1). On the other hand, the students were more likely to use generic terms, such as *go over* to describe the bunny's movements in the second line of code. Third graders were more likely than first graders to correctly describe this movement as going *right*, although across all students, fewer of them even referenced the direction on the posttest because some described and fixed the first line of code and then indicated the second line was okay without talking about it.

Interestingly, for students who played the game without explaining their code in the first three sessions, a higher percentage of them used the term *up* on the midtest than students who were forced to explain while they played. Further, students in this group also used less generic language for *right* on the posttest compared to the other group.

Counting

Overall, of the 23 students analyzed, 12 of them (five first graders and seven third graders; six free-play and six explained-play) made at least one counting error on this item. The majority of them, 80% of first graders who had errors and 71% of third graders who had errors, counted incorrectly on the pretest. In particular, these students changed the first line of code to have the bunny jump once from A1 to A3 and then had the bunny move right to C3 (see Figure 1). However, when counting from A1 to C3, they recounted the space A1 where the bunny would already be, suggesting the code should say *walk right 3* instead of *walk right 2*. Some students continued to double count the square the bunny occupied when adding on lines of code to walk up to C5 or over to E5. Fewer students miscounted on the midtest (none in first grade!) and posttest because they changed the first line of code to read *jump up 2*. Interestingly, they accepted the correct second line of code and did not double count in these situations (except for one third-grader who did this on the posttest). Only 33% of miscounters from the original freeplay group miscounted on the posttest compared to 67% of miscounters from the explained-play group.

Discussion

Similar to previous reports, we found that students were more likely to use the specific term *up* when describing vertical movement but less likely to use the term *right* (Sarama & Clements, 2009), choosing instead to use generic directions. Especially when giving directions to others, providing explicit directions is important. Therefore, the results suggest teachers should emphasize precise directional terminology as early as kindergarten (when the Common Core

Standards for Mathematics suggest students learn positional language), because playing the game without reinforcement of the specific language did not increase the use of *right* nor did being forced to explain their programming movements. On the other hand, students had fewer counting errors after playing the programming game because many of them more efficiently corrected the programming code and accepted the final direction to *move right 4* without experiencing the counting error they had when changing the code. This suggests that using worked examples could be used to scaffold their counting. There was a slight trend for students who initially had free-play to use more specific and less generic language as well as have fewer counting issues. If this pattern holds for the larger data set, it may suggest that having the opportunity to play before explaining helped students better attune to what they were explaining.

CAN PEER-LED TEAM LEARNING IMPROVE STUDENT OUTCOMES IN AN UNDERGRADUATE INTRODUCTORY STATISTICS COURSE?

Felice Shore
Towson University
fshore@towson.edu

This paper describes an intervention to improve student success in an undergraduate Introductory Statistics course. Research suggests that students' success in general education mathematics courses (such as Introductory Statistics) is a strong predictor of their eventual degree completion; thus, improving student outcomes in these courses has potential to influence overall retention. This paper presents the results of one effort to improve these outcomes, using a Peer-Led Team Learning structure. Peer coaches (former students in the course) led a series of voluntary, weekly structured tutoring sessions centered on inquiry-based lesson plans. Results indicate that students who attended the sessions outperformed their peers on several key indicators, including pass rate and course grade. We discuss the structure of the intervention, evidence of its success, and implications for undergraduate mathematics education.

Keywords: Data Analysis and Statistics; Policy Matters; Post-Secondary Education

A pressing problem in undergraduate mathematics education is student struggle in so-called "gateway" mathematics courses: those courses that satisfy a general education credit and are often required by students' majors. Research suggests that students who pass their first credit-bearing mathematics class are significantly more likely to complete their undergraduate degrees (e.g., Adelson, 2006). Therefore, interventions that target student success in these courses have the potential to increase overall student retention. The large number of students in these courses makes it difficult for faculty members to support students directly, but also provides an opportunity to shift outcomes for many students. One solution that has been extensively used and tested in other STEM disciplines, particularly Chemistry, is a structure for collaborative student tutoring called *Peer-Led Team Learning* (PLTL). In this paper, we describe one institution's efforts to construct a PLTL intervention to support student success in Introductory Statistics. This gateway course has a high historic failure rate (including students earning a grade of D or F, or withdrawing before course completion) at our institution. These failure rates have ranged up to 65% in some sections and have a historical mean of approximately 24%. Given that annual enrollment in the course generally includes 800 or more students, reducing this failure rate could meaningfully improve overall retention.

Perspectives and Literature Review

Both our choice of the course to include and structure of the intervention were informed by previous research on undergraduate student success. Our choice to study Introductory Statistics was based on our concern about the historical failure rates as described above, but also by nationwide calls to improve pathways to success for students in non-algebra intensive majors (e.g. Charles A. Dana Center, 2015). After a review of the literature, we noted that PLTL structures have been used successfully across the STEM disciplines and particularly in Chemistry courses (see, e.g. Grosser et al., 2008; Wilson & Varma-Nelson, 2016). Although less work has been done to study this model in undergraduate mathematics, there is some evidence that PLTL session can improve mathematics students' learning (Merkel et al., 2015) and attitudes toward mathematics (Curran, Carlson, & Celotta, 2013). In this paper, we attempt to extend these findings to the context of Introductory Statistics and investigate whether a PLTL structure can improve student outcomes in that course.

Methodology

Program Structure

Our intervention was based in part on descriptions of successful PLTL structures in the literature (e.g. Carlson et al., 2016). Each week, peer coaches led a set of weekly collaborative learning sessions. The peer coaches were selected from students who had earned an "A" in the course during the previous semester and chosen based on their performance in an interview. The peer coaches were trained weekly to implement inquiry-based lesson plans designed by a faculty member in mathematics education. These lesson plans aimed to deepen student conceptual understanding of the course ideas (e.g., distributions, sampling, and interpretation of inferential tests). Each coach conducted 1-2 sessions per week, each lasting approximately 2 hours. During these sessions, they would deliver the lesson plan and engage in collaborative problem-solving with up to 12 student participants. A total of 10 weeks' worth of sessions were held during the semester under study. Participation was voluntary for students, with a modest grade incentive offered based on the number of sessions attended.

Participants, Measures, and Data Analysis

During the semester under study, PLTL sessions were offered to all students (n = 682) that were enrolled in Introductory Statistics. We recorded the number of sessions which each student attended, which could range from 0 to 10. We also requested that instructors provide a percentage score on the first exam and the final exam for all enrolled students, and collected students' final assigned grade for the course. In this paper, we present the results from three different analyses of the data: *gain scores, course success,* and *course grade*. For all analyses, we tested two threshold levels for attendance, comparing students who had attended 2 or more sessions to those who attended 1 or fewer, and those attending 4 or more compared to 3 or fewer.

Our first method of data analysis was to examine students' changes from their first exam score to their final exam score (we refer to this change as a *gain score*, although the mean gains may be positive or negative). Examining students' gain from their first exam to the final exam allows us to reveal the effects of the intervention since the PLTL sessions began after the first exam. Note that the mean gains presented in the results are all negative in value, probably due to the increase in difficulty of the material between the first exam and final exam. For one section of the course, the instructor provided no exam data; students in that section are excluded from the *gain score* analysis. There were a further 131 students for whom either their first exam score or final exam score were missing. The majority of this missing data (128 students) was from students who did not take the final exam, generally because they had already withdrawn from the course. These students are also excluded from the *gain score* analysis. We compared the gain scores for the remaining 524 students using independent sample t-tests.

In contrast, the final two methods of data analysis include the entire population of 682 students in 24 sections. This allows us to examine the results of the intervention on all students, including those who withdrew from the course before the final exam. Indeed, since the primary purpose of the intervention was to improve overall student success and particularly to reduce the DFW rate, it is important to consider whether students who attended the PLTL sessions were more likely to earn a passing grade. For the second analysis, we compared the rates of course failure for students attending and not attending PLTL sessions using a chi-square analysis. This comparison is complicated by the fact that students who withdrew would certainly not attend any additional PLTL sessions, so attendance at more sessions is likely negatively correlated with withdrawal (even absent an effect on learning). Our final comparison takes into account not just whether students passed the course, but their final course grade. We computed each student's "quality points" (e.g. A=4.0, A-=3.7, B+=3.3, B=3.0, etc.) and compared the mean quality points for attenders vs. non-attenders using independent sample *t*-tests.

Results and Discussion

Results indicate that students who attended the PLTL sessions outperformed their peers on a variety of measures; however, it is difficult to generalize based on potential differences between the students who chose to attend and those who did not. This difficulty notwithstanding, results indicate that the program was successful in improving student outcomes. Below, we present our results for each of the three data analysis methods described above.

Gain Scores for PLTL Attenders vs. Non-Attenders

For each of the 524 students for whom first and final exam data was available, we computed their score *gain* as their final exam score minus first exam score. For students who attended at least two of the PLTL sessions (n = 62), the mean gain score was -4.40 (S.D. = 13.51), whereas for students who attended 0 or 1 session (n = 462), the mean gain score was -8.51 (S.D. = 13.83); this difference was statistically significant with $p < .05$. To better understand the difference in mean gain between the two groups, we computed Hedge's g to be 0.3491. The Hedge's g statistic measures the difference in means in units of pooled standard deviation. In our case, the mean gain for students who attended two or more PLTL sessions was 0.3491 pooled standard deviations higher than the mean gain for students who attended one session or none. Similarly, students who attended four or more sessions (n = 44) had significantly higher mean gain scores (mean gain = -3.26 with S.D. = 15.1) than those who attended three or fewer sessions (n = 480; mean gain = -8.46 with S.D. = 13.66; $p < .05$). It appears that students who participated in the PLTL sessions thus outperformed their classmates, at least in terms of the change between their performance before the sessions started and at the conclusion of the semester.

Course Success for PLTL Attenders vs. Non-Attenders

Our second method of data analysis compared course outcomes (pass vs. fail, with fail defined as students receiving a D or F grade or withdrawing). Table 1 presents passing rate date for students who participated in four or more PLTL sessions, compared with those who attended three or fewer; this comparison was near significant with $X^2(1, n = 682) = 4.53$, $p = .09$. This data indicates that attendance at the PLTL sessions might have somewhat improved students' course outcomes, but some of this effect is likely an artifact of the correlation between withdrawal and session attendance (because students who withdrew stopped attending sessions).

Table 1: Course Passing Rates by Attendance at PLTL Sessions

	Attended 3 or Fewer Sessions	Attended 4 or More Sessions	Total
Students (Percent) who passed the course (grade of A, B, C)	431 (69%)	43 (80%)	474
Students (Percent) who failed the course (grade of D, F, or W)	197 (31%)	11 (20%)	208
Total	628	54	682

Final Grade and GPA Comparisons for PLTL Attenders vs. Non-Attenders

Our final comparison takes into account not just whether students passed the course, but their final course grade. We computed each student's "quality points" (e.g. A=4.0, A-=3.7, B+=3.3, B=3.0, etc.) and compared the mean quality points for attenders vs. non-attenders. This comparison was near significant for students attending four or more sessions (n = 54; mean grade = 2.49; S.D. = 1.27) compared to those attending three or fewer (n = 628; mean grade = 2.15; S.D. = 1.36; p = .068). However, a statistically significant difference was revealed for students who attended five or more sessions (n = 44; mean grade = 2.56; S.D. = 1.21) compared to those attending four or fewer (n = 638; mean grade = 2.16; S.D. = 1.36; $p < .05$). This adds to the data indicating that students who attended PLTL sessions outperformed their classmates on a variety of comparisons, thus suggesting that the intervention was helpful to student success.

Other Differences Between Groups

Participation in PLTL sessions was voluntary, which raises the concern that factors other than PLTL session attendance could explain the observed difference in gain between the two groups. We proceeded to check for large differences in other factors between the group of students who attended one or fewer PLTL sessions and the group of students who attended two or more PLTL sessions. We investigated GPA prior to the Fall 2017 term and first exam score. We normalized differences in each factor by computing the Hedge's g statistic. For GPA prior to the Fall 2017 semester, we observed a Hedge's g of 0.1250. This shows that the mean GPA for students attending one or fewer PLTL sessions was 0.1250 pooled standard deviations higher than the mean GPA for students who attended two or more PLTL sessions. For first exam grade we observed a Hedge's g of 0.4474. This indicates that the mean first exam score for students who attended one or fewer PLTL sessions was 0.4474 pooled standard deviations higher than the mean first exam score for students who attended two or more PLTL sessions. These comparisons suggest that the students who attended the PLTL sessions were overall weaker in mathematics compared to those who did not. Although this limits the generalizability of our results in some ways (because we cannot infer what the effect of the intervention might have been on the students who did not attend), it does suggest that the program was successful in recruiting students who were at risk of failure and improving the outcomes of students who chose to attend.

Conclusion

These data indicate, on the whole, that students who attended the PLTL sessions outperformed their peers on several key indicators, including their final course grade, pass rate, and their final exam score (in comparison with their first exam score). These results indicate that the intervention was successful in improving individual student outcomes. However, our comparisons were complicated by the fact that attendance at the PLTL sessions appeared to be correlated with students' backgrounds as well as other factors not related to their learning (such as students who stopped attending sessions because they had already withdrawn). These complications limit the generalizability of our results, but are expected in any intervention study including an optional opportunity. The finding that students who attended the PLTL program began the semester somewhat weaker but still showed significant growth suggests that the program was successful. Given that faculty were involved only in the creation of the lesson plans and training the peer coaches, this provides evidence that the PLTL model can provide a sustainable path for supporting student learning and success in gateway mathematics courses.

COMBINATORICS PROBLEMS: A CONSTRUCTIVE RESOURCE FOR FINDING VOLUMES OF FRACTIONAL DIMENSION?

Erik Tillema

Jinqing Liu
Indiana University
jinqliu@iu.edu

Pavneet Kaur Bharaj
Indiana University
pkbharaj@iu.edu

Volumes of fractional dimension are a 7th grade standard in the Common Core State Standards in Mathematics (CCSS-M). Relatively little research has been conducted on how students' reason about volumes with fractional dimension. To address this dearth of research, we designed a teaching experiment based on a central conjecture that combinatorics problems could be a constructive resource in the development of volumes with fractional dimension. In this paper, we outline the reason for this conjecture. In our presentation, we elaborate on this conjecture by providing four cases of how pre-service secondary teachers (PSSTs) reasoned first with combinatorics problems, and then with volumes of fractional dimension. One contribution of the study is it expands and combines in novel ways empirically grounded theoretical constructs.

Keywords: Fraction Scheme, Combinatorics Problems, Volume, Multiplicative Concepts

Fractions and rational number knowledge is regarded as one of the most challenging domains at both the elementary and secondary levels (e.g., Behr, Wachsmuth, Post, & Lesh, 1984; Hackenberg, 2013; Norton, Wilkins, & Xu, 2018; Steffe, 2003) in part because many problems involve coordinating multiple units and multiple wholes (Lamon, 2007; Steffe & Olive, 2010). At the same time, the results of large-scale assessments (e.g., NAEP, TIMSS) also indicate that geometry and measurement are complex for both elementary and secondary students (Battista, 2007; Smith & Barrett, 2018). Fractions and volume initially come together in the Common Core State Standards in Mathematics (CCSS-M) in the 7th grade where students are asked to explore the volume of rectangular prisms with fractional dimensions.

To date, relatively little research has investigated how students reason about volumes of fractional dimension. The majority of research on fractions has focused on reasoning with one-or two-dimensional models (e.g., length, number line, circles, or rectangular area) (Lamon, 2007), while the majority of research on volume has been conducted in whole number contexts (Smith & Barrett, 2018; e.g., Clements, Sarama, & Van Dine, 2017). To address the dearth of research, we designed a teaching experiment for pre-service secondary teachers (PSSTs) whose purposes were to investigate: a. how they reasoned about volumes of fractional dimension; and b. how they would use what they learned to design lessons during their student teaching placement.

A central conjecture of the study was that combinatorics problems could support the PSSTs to develop discrete three-dimensional units as the product of three one-dimensional units (Tillema & Gatza, 2016, 2017), and that doing so would serve as a constructive resource in the development of volumes of fractional dimension. This conjecture was grounded in two results from prior research: a. students find it challenging to establish a "unit cube" as a multiplicative composition of one length, one width, and one height unit (Battista, 2007; Smith & Barrett, 2018); and b. students' multiplicative schemes for discrete quantity can be a constructive resource (rather than distractor) in their construction of fraction schemes (Hackenberg & Tillema, 2009; Steffe & Olive, 2010). The following research question guides this paper: How do PSSTs reason about volume of fractional dimension after they have used combinatorics problems to establish 3-D arrays?

Theoretical Framework

Broadly speaking, we use operations, schemes and concepts to provide an account of students' reasoning (Piaget, 1970; Von Glasersfeld, 1995). An operation is a mental action (e.g., iterating or partitioning) where operations are the "motor" of schemes. Schemes consist of three parts, an assimilated situation, an activity, and a result. The assimilatory mechanism of a scheme involves a person making an interpretation of a problem situation; the activity of a scheme entails a person using operations that transform the assimilated situation to the result. A person has constructed a concept when he or she no longer has to implement the activity of a scheme to take the result of the scheme as given in a problem situation.

Multiplicative Concepts, Volume, and Combinatorial Problem Situations

To investigate students' reasoning about volume, we build on Hackenberg's (2015) work in which she identifies three qualitatively distinct multiplicative concepts students use (see also, Steffe, 1992); the primary difference among each multiplicative concept is the number of embedded units that students take as a given prior to reasoning about problem situations. Cullen et al. (2017) have used these differences in their analysis of how students reason about volume problems involving whole numbers. They found that some students conceptualize volume as composed of individual unit cubes (i.e., units of one, akin to Hackenberg's first multiplicative concept); other students conceptualize volume as composed of rows of units cubes (i.e., treat five unit cubes as one row, akin to Hackenberg's second multiplicative concept); while other students conceptualize volume as composed of layers (i.e., treat four rows of five cubes as one layer, akin to Hackenberg's third multiplicative concept). Cullen and colleagues (2017) have also stressed the importance of students establishing a spatial structure in their construction of volumes of rectangular prisms with whole number dimension (see also, Battista, 2004). Here a spatial structure means a mental organization of volume units so that there are no gaps or overlaps.

The analysis of embedded units in Cullen and colleagues as well as in Hackenberg's work takes the "basic unit" as a unit of one. Smith and Barrett (2018) have pointed out that this elides the issue that individual volume units are themselves supposed to be a multiplicative composition of one length, one width, and one height unit. This distinction is theoretical in nature, but empirical findings suggest that students may not treat volume units as if they are a multiplicative composition of one length, one width, and one height unit (Battista, 2007). The CCSS-M approaches this issue by defining one cubic unit of volume as a unit that is one length unit by one width unit by one height unit. In our work, we have contended that this definition is appropriate for people who have already constructed a cubic unit of volume but is insufficient for supporting a person's construction of it (Tillema & Gatza, 2016). Thus, for this study, we followed an approach that we have used previously with high school students in which we presented them with combinatorics problems to help them establish discrete three-dimensional units from three discrete one-dimensional units (Tillema & Gatza, 2016, 2017). We have called these discrete three-dimensional units triples where, for example, one triple might be an outfit that a student has created in the Outfits Problem.

> *Outfits Problem*. You have 4 shirts, 3 pants, and 2 belts. An outfit is one shirt, one pants, and one belt. How many outfits could you create?

In creating outfits to solve this problem, a student might first pair one shirt with one pants, and then pair the shirt-pant outcome with one belt to create what we call a triple. We call such a unit a triple because it contains three units, but is considered a single unit, one outfit. We consider these operations to entail students in establishing discrete three-dimensional units from three discrete one-dimensional units.

Moreover, in prior studies, high school students have used such problems to establish a spatial structure for 3-D arrays by locating individual triples and regions (e.g., all triples that have the first shirt) (Tillema & Gatza, 2016, 2017). The reason combinatorics problems can be conducive for establishing a spatial structure for 3-D arrays is that they can involve ordering the units within a composite unit (e.g., a first shirt, a second shirt, etc.), and ordering the triples (e.g., shirt in the first position; pants in the second position; belts in the third position). Ordering the units within a composite unit can result in an order for the units along a single axis of an array and ordering the positions in a triple can result in an order for the axes of an array.

Fraction Schemes with Length Quantity

Our analysis also uses two key constructs from research on students' fraction schemes—their construction of iterative fraction schemes and their construction of fraction composition schemes. Steffe and Olive (2010) have found that students using the third multiplicative concept can construct an iterative fraction scheme with length quantities (see also, Hackenberg, 2015). Students who have constructed an iterative fraction scheme (IFS) with length quantities can, for example, partition a length into five parts, disembed (remove from the whole) one of those parts, and iterate it four times to create four fifths as a length. IFS students interpret the relationship between one fifth of a length and four fifths of a length to be multiplicative (four fifths is four times one fifth). Moreover, IFS students are able to establish this multiplicative relationship for improper fractions like six fifths; a length that is six-fifths is six times one fifth. This conceptualization of improper fractions is not easy for students to establish and is a hallmark of students who have constructed an IFS with length quantities (Hackenberg, 2007).

Steffe (2003) identified that a central operation in students' construction of fraction composition schemes with length quantities is recursive partitioning. He defined recursive partitioning as partitioning a partition in service of a non-partitioning goal. For example, a student who engages in recursive partitioning might respond to a request to find one third of one half by partitioning one unit of length into two parts, and then partition each part into three mini-parts. She might then respond that one mini-part is one-sixth because she could iterate it six times to make one unit of length. These constructs were central to our analysis of students' reasoning about volumes of fractional dimension.

Methods and Methodology

The data for this study was collected using teaching experiment methodology (Confrey & LaChance, 2000; Steffe & Thompson 2000). This methodology involves a researcher engaging students in problematic situations aimed at helping them in the construction of schemes and operations (Hackenberg, 2010). A researcher designs initial problems for students based on her prior experience working with students in the domain, and her understanding of prior relevant research. This initial design work is supported by guiding conjectures. Once a researcher begins interactions with students her goal is to develop working models of students' reasoning (Steffe & Weigel, 1994). Throughout the experiment, the researcher refines these working models by establishing conjectures about the affordances and constraints of students' current reasoning and designing problem situations to test these conjectures. A researcher can establish these conjectures both in between teaching episodes and in the moment of interacting with students.

The broad goal of the teaching experiment was to investigate how the PSSTs developed a combinatorial understanding of common algebraic identities (e.g., $(x+y)^3 = x^3 + 3x^2y + 3xy^2 + y^3$). As part of supporting this work the researchers used a quantitative approach in which students represented sets of outcomes in combinatorics problems as 3-D arrays, and subsequently represented volumes of fractional dimension for these algebraic identities. The PSSTs used snap cubes as a representational tool throughout the teaching episodes (Figure 1).

The four participants for the study were enrolled in the second semester of a secondary mathematics methods class at a Midwestern university during the fall of 2018. They were selected based on willingness to participate in regular meetings over the course of the 2018-2019 academic year. During Fall 2018, they worked as a pair in 13 teaching episodes; each episode lasted for 60-90 minutes and was video recorded using three cameras—one to capture the interaction between the researcher and the PSSTs and two to capture student work.

For data analysis, all three authors watched relevant video from the entire data set. They used a four-column table as a guide for analysis. The four-column table included timestamp, brief characterization of 3-D reasoning, low inference description of what happened, and inferential analysis of the PSSTs' reasoning (Saldana, 2013). Each row in the table was a single utterance, a turn of talk, or a period of talk focused around a specific idea. The authors met weekly to discuss ongoing conjectures and reconcile differences in their interpretations of the data. These discussions were aimed at developing internal consistency and coherence with the data, and for consistency and coherence with prior research findings.

Findings

The PSSTs' solution of combinatorics problems revealed differences in the way they established discrete three-dimensional units. All four of PSSTs entered the teaching experiment having constructed a recursive scheme for the solution of three-dimensional combinatorics problems. The recursive nature of their schemes meant that they could take the result of their scheme as input for a further application of their scheme; for example, they were able to take each pants and pair it with all shirts to produce all shirt-pants outcomes, and then take each shirt-pants outcome and pair it with all belts to produce the set of all possible triples.

However, not all of them produced the same multiplicative relationships in this process. One PSST had interiorized a multiplicative relationship that can be symbolized as, for example, 1 x 4 = 4. This can be thought about as one discrete 1-dimensional unit times four discrete 1-dimensional units produces four discrete 2-dimensional units. She could then iterate these operations to produce all of the possible 2-dimensional units in her solution of a problem. Once she produced all possible 2-dimensional units, she took each individual 2-dimensional unit (i.e., a 1 x 1), and paired it with all 1-dimensional discrete units from the third composite unit. This can be symbolized as (1 x 1) x 5 = 5, where the 1 x 1 in the statement symbolizes a pair. These operations were sufficient to establish a row in a 3-D array as a unit of three dimensional discrete units. The other three PSSTs established different multiplicative relationships as they created three-dimensional discrete units, which will be discussed in the presentation.

During their solution of combinatorics problems all four PSSTs worked to coordinate the multiplicative relationships that they produced with a spatial structuring for a 3-D array. None of the four entered the teaching experiment able to locate points and regions in three-dimensional space in situations where they needed to coordinate orthogonal "planes" to determine the location of a point or region. This issue, along with how these problems supported students to construct volumes of fractional dimension, will be discussed in the presentation.

PROMOTING AN AUTHENTIC EXPERIENCE OF STATISTICAL PRACTICES IN STATISTICS EDUCATION

Layla Guyot
Texas State University
l_g244@txstate.edu

Alexander White
Texas State University
whiteale@txstate.edu

The demand for statistical skills is growing in many different fields and sectors, and the employment of statisticians is expected to increase drastically. However, employers are experiencing difficulties in hiring mainly because there is a misalignment between the skills acquired in academic settings and the skills required of a statistician at the workplace. Indeed, statisticians develop practices that grow out of experience (Pfannkuch & Wild, 2000). In order to investigate these practices, statisticians engaged in a reflection on their experience. Preliminary results revealed predominant skills from the perspective of the practitioners and can inform how to develop curriculum materials that better promote authentic practices in statistics education.

Keywords: Data Analysis and Statistics, Curriculum

From actuarial science to zoology, the field of statistics has applications in many diverse disciplines and in the era of big data, statistical skills are increasingly valuable on the job market. Even though the number of students seeking degrees in statistics have been increasing over the past few years, the supply of professionals with statistical skills still does not match the thriving demand (American Statistical Association, 2015) and employers are experiencing difficulties in hiring statisticians across disciplines and sectors. In addition, most employers are looking for experienced statisticians which makes the transition is even more challenging for graduates in statistics.

Purpose

The purpose of this research study is to promote an authentic experience of statistical practices in education to ease the transition to the workplace. Previous research has shown that the transition to the workplace is challenging for graduates in general (Grosemans, Coertjens, & Kyndt, 2017), and in particular for graduates in statistics because there is a misalignment between what they learn in academic settings and what is required of them at the workplace (Van der Berg, 2017). Indeed, statisticians develop practices that grow out of experience and are relevant to their discipline and context (Pfannkuch & Wild, 2000). We need to understand how statisticians develop these practices at the workplace and what practices should be included in academic settings to facilitate the transition. The role of mentors was found to be crucial to support recent graduates in their transition (Grosemans et al., 2017) that is why mentors of statisticians such as managers, senior statisticians or educators, need also to be involved. More specifically, the following questions guide this research:

1. What practices are important for the role of statistician?
2. How do statisticians learn and develop these practices while in transition to the workplace?
3. What key statistical practices should be included in statistics education as recommended by statisticians and their mentors?

Background and Theoretical Framework

The transition to the workplace often presents challenges because it involves adapting to a new environment, with a new role, different rules, and learning new practices. An example of difficulties encountered by individuals in transition is the misalignment between the learning outcomes in academic settings and the expectations of the workplace.

Transition to the Workplace for Statisticians

Harraway and Barker (2005) followed 913 recent bachelor's, master's and doctoral degree holders into their early career and identified discrepancies between statistical techniques taught at the university and the ones used at the workplace. Graduates agreed they needed more training in particular for regression, multivariate methods, research design, and power analysis.

Through a survey, Van der Berg (2017) investigated the transition experienced by 95 interns at the end of their training. Most interns agreed that they acquired the appropriate *statistical knowledge* before entering the workplace but did not acquire the appropriate *statistical skills* needed at the workplace. Therefore, practices acquired in academic settings do not align with practices required at the workplace. Interns listed 21 skills required at the workplace that were not taught: for example, data collection, questionnaire design, communication, writing skills, and using statistical software. In addition, mentors who accompanied interns during their transition agreed that even though interns had some theoretical knowledge, they were lacking practical skills and had to learn how to perform most of the statistical tasks. In particular, they recommended that statisticians should primarily develop skills before entering the workplace.

Therefore, a misalignment between statistical practices acquired in academic settings and statistical practices required at the workplace has been identified. We need to understand how statisticians develop practices to adapt to the workplace.

Theoretical Framework

To understand how statisticians develop practices at the workplace, this study draws on activity theory (Vygotsky, 1978; Engeström, 1987; Konkola, Tuomi-Gröhn, Lambert, & Ludvigsen, 2007) and more precisely on the concept of boundary crossing and boundary objects (Akkerman & Bakker, 2011; Star & Griesemer, 1989). Academic settings and the workplace can be conceptualized as *activity systems* whose goal is to develop statistical practices (the *object* of the activity). The activity is mediated by *tools* and regulated by *rules*, and the *division of labor* ensures the distribution of tasks and authority within a *community* and a *subject*, or individual of focus. For example, in academic settings, a student (*subject*) develops statistical practices (*object*) using curricula materials (*tools*). The *community* of students, teachers, and advisors work together ensuring that the student meets the degree requirements (*rules*). The teacher defines the responsibilities (*division of labor*) of each participant. At the workplace, a statistician (*subject*) performs statistical practices (*object*) using statistical software (*tools*) for example. The collaboration between statisticians, managers, and clients forms a *community*, following regulations (*rules*) and a specific organization of the different tasks (*division of labor*). Thus, statistical practices are considered from different perspectives (student and statistician) and are not necessarily aligned between the two activity systems of academic settings and the workplace.

The misalignment between practices acquired in academic settings and statistics required at the workplace creates challenges that statisticians learn to overcome. The concept of *boundary crossing* represents the process of establishing continuity between two activity systems and the involved challenges, or boundaries. *Boundary objects* can function as bridges between systems (Akkerman & Bakker, 2011; Star & Griesemer, 1989) and assist boundary crossing. In the context of this study, statistical practices are characterized as boundary objects because they could be utilized to facilitate the transition boundary crossing and should be coordinated between the two activity systems. Figure 1 represents academic settings and the workplace as activity systems and statistical practices as boundary objects.

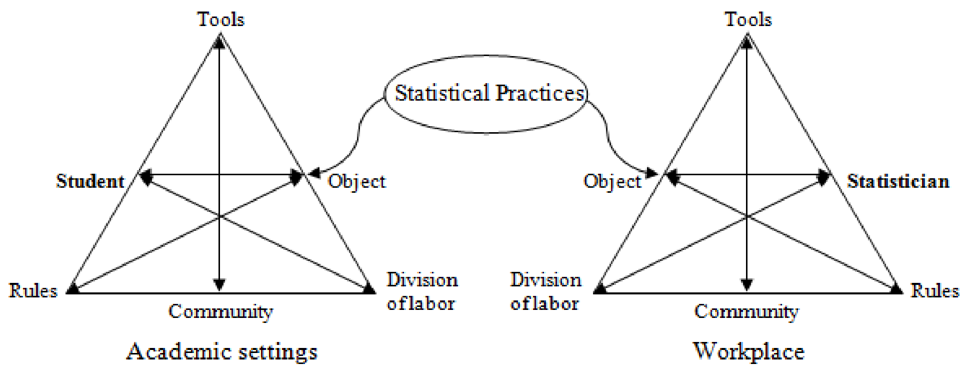

Figure 1: Activity Systems and Boundary Objects

Through the lens of activity theory with the concepts of boundary crossing and boundary objects, this study explores the transition experienced by statisticians as they move between the activity system of academic settings and the activity system of the workplace. We need to analyze how participants identify and coordinate practices from each activity system, and how they can eventually transform practices. The collaboration of statisticians, mentors, and educators will help build boundary objects, namely statistical practices, to facilitate the transition between academic settings and the workplace.

Methods

In order to investigate what important statistical practices are performed at the workplace, statisticians and their mentors reflected on their own experiences. Statisticians and mentors were recruited during a workshop presented at conferences focusing on statistical practice. During the workshop, participants engaged in a sorting task, derived from Q-methodology which aims at exploring inner perspectives and the possible differences and similarities of perspectives within a community (Brown, 1980). Participants sort a list of 24 practices into an array of 9 columns (see an example of the shape in Figure 2) from the least (rank 1) to the most (rank 9) important according to their own perspective of the role of statistician. The list of practices is based on a review of the literature about what statistician do and a review of required skills on job offers (Table 1). Participants could add up to 6 practices relevant to them.

Table 1: List of 24 Practices Classified in 5 Categories

Process of data analysis			Traits	
Design	Focus on data	Techniques	Interpersonal skills	Personal skills
- Using knowledge of the context - Translating a real problem into a statistical form - Designing studies - Preparing sampling frames	- Collecting data - Creating / Maintaining databases - Cleaning data - Using statistical software - Producing visual representations - Interpreting data	- Researching appropriate statistical methods - Developing new statistical methods - Applying statistical methods - Using advanced mathematics	-Working independently - Participating in teams / Collaborating - Communicating in writing - Communicating orally - Consulting with a client - Communicating interpretations of statistics to non-statisticians	- Being curious / willing to learn - Being skeptical / critical - Meeting deadlines - Considering ethical issues

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

At the time of writing this paper, the sorting task had been conducted at four conferences in the US, France, and Japan. Overall, a total of 63 completed sorting tasks were collected from participants with different experiences (statisticians, educators, students). Each sorting task represents a perspective from a participant, arranging practices in a specific order. The analysis of sorting tasks in Q-methodology is based on data reduction, reducing all of the perspectives to identify patterns of thought. To reduce the data we used principal component analysis (PCA) where participants are correlated instead of correlating variables as it is the case in regular PCA. The results give a smaller number of perspectives that summarize different patterns of thoughts among the participants.

Preliminary Results and Discussion

We identified 3 different perspectives among our participants (Figure 1). Perspective 1 summarizes the sorting tasks of 24 participants who emphasized the importance of traits, in particular on interpersonal skills (dark orange) with "Communicating interpretations of statistics to non-statisticians" ranked as the most important (rank 9). The 24 participants contribute positively to this perspective, meaning that they all shared similar views.

The sorting tasks of 20 participants were summarized by Perspective 2 which focuses on the process of data analysis, in particular on techniques (dark blue) with the practices of "Researching" and "Applying statistical methods" being ranked as 8. One participant contributed negatively to this perspective, meaning that their view opposed the views of the other 19 participants which are represented by Perspective 2.

The third perspective is a contrast between the process of analysis (shades of blue) and traits (shades of orange). There are 7 participants contributing to this perspective, 3 contributing negatively and 4 contributing positively, meaning that they have opposite views for the importance of the process of analysis (in particular, focusing on data and designing studies) versus traits (especially personal skills).

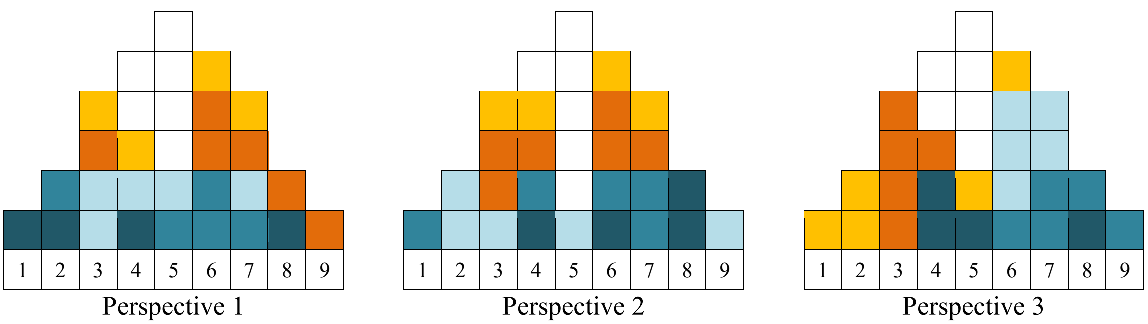

Figure 2: Statistical Practices Ranked from Highest to Lowest Mean

Additional practices mentioned by the participants included: training constantly and reading articles (added by 10 participants), mentoring junior statisticians and providing feedback (added by 10 participants), and managing projects (added by 9 participants).

Conclusion

As educators of future statisticians, we need to be aware of practices required at the workplace. In particular, we need to develop curricula materials that give students an authentic experience of important practices as identified by statisticians.

Next, interviews of statisticians and their mentors will reveal how the important practices identified through the sorting task were developed at the workplace. The tools, rules, community, and division of labor involved for each practice will be identified and will help define how these practices can be included in academic settings to ease the transition to the workplace for statisticians.

TEACHERS' STRATEGIES FOR GENERATING A MATHEMATICAL DEFINITION FROM A LIST OF ATTRIBUTES

Susanna Molitoris Miller
Kennesaw State University
smolitor@kennesaw.edu

Writing definitions is a useful tool for mathematical learning. This study examines pre-service and in-service teachers' responses to an interview task which asks them to generate a mathematical definition based on a given list of attributes rather than providing a memorized definition for a named shape type. The strategies employed by participants reveal three main kinds of informal reasoning used when synthesizing multiple pieces of information into a single concise definition; identifying and defining, building-up attributes, and attribute thinning. These strategies were used by various participants either as exclusive approaches or in conjunction with one another. Findings provide implications concerning the role participants' concept images may play in the defining process.

Keywords: Geometry and Geometrical and Spatial Thinking, Reasoning and Proof, Teacher Knowledge

Writing mathematical definitions has been identified as a useful tool for the professional development of teachers (Leikin & Wimicki-Landman, 2001). However, it may be challenging to provide an authentic defining experience for concepts such as quadrilateral types because most teachers enter professional development programs with pre-existing ideas about these shapes. This study explores how teachers in professional development settings employ strategies to generate an accurate mathematical definition based on a list of attributes which are true of an unnamed shape type.

Literature and Theoretical Framework

Tall and Vinner (1981) describe two ways of knowing a mathematical concept, *concept image* and *concept definition.* The *concept definition* is "a form of words used to specify that concept" (p. 152, Tall & Vinner, 1981). The *concept image* is "the total cognitive structure that is associated with the concept, which includes all the mental pictures and associated properties and processes… built up over the years through experiences of all kinds, changing as the individual meets new stimuli and matures" (p. 152, Tall & Vinner, 1981). Students rely more heavily on their concept images rather than concept definitions when solving problems (Tall & Vinner, 1981), but textbooks often introduce geometric concepts with a concept definition rather than opportunities to develop rich concept images (Usiskin & Griffin, 2008). The act of defining is considered an important component of geometric reasoning that precedes formal proof (Burger & Shaughnessy, 1986). Preservice teachers have demonstrated a mismatch between their concept images and concept definitions (Cunningham & Roberts, 2010).

de Villiers, Usiskin and Patterson, describe a mathematical definition as having, *necessary*, *sufficient*, and *minimal* conditions (p. 193, 2009). *Necessary* conditions "appl[y] to all elements of the set," (de Villiers, Govender, & Patterson, 2009, p. 193). *Sufficient* conditions describe "indications of the concept," (Winiki-Landman & Leikin, 2000, p.17). And *minimal* conditions do not include any "redundant properties" (de Villiers, Govender, & Patterson, 2009, p. 196). While a definition may function containing only necessary and sufficient conditions, definitions which are also minimal are considered “economical,” (de Villiers, Govender, & Patterson, 2009, p. 196).

Methods

The ideas of concept image and concept definition suggest students should learn about many different aspects of a geometrical concept before being presented with a definition. The challenge of teaching a topic in light of previous exposure is not specific to teacher education as the presence of shape types spans the entire PreK-12 curriculum. Thus, the majority of learners arrive in geometry classrooms with some pre-conceived notions about the content In this study I explore what kinds of informal reasoning may be employed to deduce a mathematical definition of an unknown shape type from a list of known attributes. I also consider what role, if any, the learner’s pre-existing concept image may play in this process.

Participants included thirty-two pre-service teachers majoring in early childhood education, two pre-service teachers majoring in secondary mathematics education, and five in-service teachers pursuing a master’s degree in mathematics education. All were enrolled in one of two geometry content courses being taught by the investigator. All students received instruction which unpacked the necessary, sufficient, and minimal characteristics of a mathematical definition as described by de Villiers, Govender, and Patterson (2009) as well as opportunities to become familiar with all attributes included in the task. The data were collected in one-on-one task-based interviews which were video recorded and transcribed, including gestures, for analysis. Participants were given a pen, paper, and a set of sample quadrilaterals they may use when completing the defining task. Data from all participants were combined for analysis because the limited sample size and no observed differences across groups.

The task began by providing the participant with a list of attributes for “Shape Type 1.” The participant was told that all attributes were true for a specific group of shapes and that this group of shapes may be a new or a familiar group. The properties given were: is simple, is closed, is a polygon, is a quadrilateral, has two pairs of opposite congruent angles, has two pairs of parallel sides, has two pairs of opposite congruent sides, has two pairs of adjacent congruent sides, has at least one line of reflectional symmetry, and has at least 180° rotational symmetry. Collectively, these properties describe members of the rhombi family. This particular shape was chosen because it was identified as one of the quadrilateral types with which students were least familiar (Molitoris Miller, 2018).

Participants were asked to read the list and invited to ask clarifying questions about the given properties. Next the participant was asked to write a “best approximation” of a definition for “shape type 1.” Participants were reminded of the tools at their disposal, as well as the opportunity for revisions as their thinking evolves. Participants were encouraged to talk through their thinking out loud. The interviewer offered no guidance in completing the task but would note things the student said and ask for clarification or elaboration in order to better understand the participant’s thinking.

After composing a definition, participants were asked to verify if that was their final response and then allowed to make revisions as desired until they felt they reached a final answer. The interviewer asked them to once again briefly describe their thought process as they wrote the definition. After this description, the interviewer repeated back a summary of her understanding of the described solution process for the participant to verify or provide clarification. Interviews lasted ten to thirty minutes.

Interview data was analyzed and a-priori coding was preformed to describe the strategies employed by participants as they completed this task. Initial inspiration for the codes developed as the investigator noticed trends during data collection, and more detailed consideration of each individual interview ultimately revealed three main strategies for developing a definition from a list of attributes.

Results

Participants exhibited three primary strategies for developing a mathematical definition from the given list of attributes; identifying and defining, building-up, and attribute thinning. Some participants used exclusively one strategy for the entirety of their interview, while others created their final answer using a combination of techniques.

Identifying and Defining Strategy

Some participants approached the task by attempting to determine what the mystery shape type was, name it, and provide a known definition of this named type. This approach had mixed results. Some participants read through the list and almost immediately declared the same was a square. When asked how they knew it was a square, participants drew or located an image of a square and verified that all of the properties given were true for a square. One such student stated "If you draw a square and you were to label each part, then you can see by labeling it, and showing your students physically how you found this out, and being like, 'it is,' you have to physically show it." Next they provided what seemed to be a commonly known definition for a square, most often a variation of "a quadrilateral with all right angels and all sides equal." Other participants correctly identified the "Shape Type 1" as rhombi. Some of these students did not articulate the thought process that lead to this conclusion. Other participants identified that mystery shape type as a rhombus by using a sieve sorting and then provided a correct definition for a rhombus, such as, "A quadrilateral with all sides equal."

Building-Up Strategy

Students who employed the building-up strategy crafted their definition by adding properties to the definition one-by-one and considering which other properties could be deduced from the property they put into the definition. Participants most often used this strategy for condensing properties such as "quadrilateral," "simple," "closed," and "polygon." In these cases, such as the work done by Macy, participants added "a quadrilateral that…" to their definition and then crossed out the other named attributes saying, "If it's a quadrilateral then it has to be a polygon [crossed out polygon from list]. And if it's a polygon then it must be simple and closed [crossed out simple and closed]." This first deduction is based exclusively on properties nested within one another's definitions and is therefore relatively straight-forward.

Deductions were also made for more complicated relationships. These represented very informal reasoning which seemed to be based on intuition and gut feelings rather than formal mathematical rigor. For example:

> I'm thinking that these two also have to have something to do with each other. With if they have opposite congruent angles and they have opposite congruent sides like they would have to be the same length here and here [noting opposite pairs of sides on sketch of rhombus] so they would join at the point here [showing a pair of opposite congruent angles] and make two of the same angles [gesturing toward other pair of opposite angels] if they are oppositely congruent.

A participant engaging in the building-up strategy would continue adding properties to their definition until they felt all the properties in the list had in some way been accounted for by one or more of the properties in their definition.

Property Thinning Strategy

Some participants began the task by writing a long and complicated definition which was basically a litany of all of the properties provided on the sheet. The participant then considered each property on the list and if or how the definition would function differently if that property were removed. This strategy often employed very similar logical arguments to those unpacked in the building up strategy: some removed properties based on their inclusion as part of anther property's definition, and some removed properties based on some intuitive reasoning or feeling about the relationship between two or more seemingly unrelated properties.

There were two notable distinctions between the enactment of these strategies. (1) The property thinning strategy seemed to be more effective for removing properties which were not directly related to others, such as those concerning symmetry which were not needed in the definitions but were harder to logically connect to the other side and angle based properties. (2) On the other hand, the property thinning strategy did not lend itself to situations where more than one related property could be synthesized into a third shorter, but not previously listed property. One such example is the combined effects of "two pairs of opposite congruent sides" and "two pairs of adjacent congruent sides," which can be combined to deduce that all sides must be congruent.

Combinations of Strategies

As noted earlier, not all participants' solution strategies conformed strictly to one of the strategies described above. Some participants named the mystery shape as a square, but rather than providing a definition of a square from memory, they returned to the given list of attributes and employed one of the other strategies for condensing the property list into a definition. Others began by building up the definition as best they could, and then wrote a definition which contained the built-up properties as well and any that were not yet accounted for and thinned that. The majority of participants engaged in some form of property thinning when revising their definitions before settling on a final submission.

Implications and Conclusion

These results provide a few insights into the defining process experienced by the participants. The majority of definitions produced contained more than a minimal final list of attributes. This suggests that the relationship between the complex collection of attributes which are true about a particular shape family and the concise concept definition which names that shape family is not always obvious to learners. For example, some learners may not realize that having all congruent sides implies that the shape must have two pairs of parallel sides. This challenge would undoubtedly also hinder the recognition of hierarchical relationships among shape type such as the fact that all rhombi are parallelograms, a noted challenge in the study of geometry among both teachers and students (Fujita, 2012). Likewise, participants who struggled to condense, "two pairs of opposite congruent sides," and "two pairs of adjacent congruent sides," by recognizing that they collectively imply that all sides must be congruent, would likely struggle to fully grasp the relationship between parallelograms and kites, namely that their intersection forms the group known as rhombi.

We also see the powerful role played by participants' pre-existing conceptions of shape types and their attributes. The identifying and defining strategy highlights a strong urge to name the shape being considered. Naming the shape type was not a required or prompted part of the interview task, yet many participants began their work by attempting to name the shape type which in turn seemed to elicit strong ideas about what that shape should be and distracted from the list of properties.

All strategies rely on the characteristics of mathematical definitions requiring a necessary, sufficient, and minimal set of attributes. Elements of these structures of definitions drive each of the individual approaches. When employed effectively, the identifying and defining strategy depends on the given list of properties as a necessary and sufficient collection of attributes in order to identify the shape type. The building-up strategy seeks to create a minimal definition by strategically assembling a short set of properties. And the attribute thinning strategy strategically removes attributes from the given necessary and sufficient set to achieve a more minimal set of properties in the final result. All three of the strategies used rely on these key characteristics of mathematical definitions and thus engaging with these strategies promises to effectively support and develop further understanding of both the nature of shapes being defined and that of mathematical definitions in general.

Keywords: Measurement; Cognition; Elementary School Education

When measuring with nonstandard, discrete units, some early elementary students will leave gaps between the units (Clements & Sarama, 2009). When measuring with rulers, some students report the number at the end of the object as its length regardless of the starting position of the object (Bragg & Outhred, 2004; Nunes, Light, & Mason, 1993), interpret the numbers on the ruler as points as opposed to accumulating units, and count from one instead of zero (Bragg & Outhred, 2004; Clements & Sarama, 2009). One method that can illuminate students' conceptions about mathematics problems and potentially help them confront their confusions is analyzing incorrect worked examples (e.g., Booth, Lange, Koedinger, & Newton, 2013; Durkin & Rittle-Johnson, 2012). Therefore, in this study, we investigated the following research questions: When analyzing worked examples of incorrect measurements, what did third graders identify as incorrect? How did this relate to their ability to identify the correct measurements?

Participants included 37 third graders who saw pictures of items incorrectly measured with broken rulers (or cubes) and were asked to identify and correct the mistakes: (#1): egg spanning 4 to 7 on the ruler, incorrect answer: 7 units; (#2): screwdriving spanning 2 to 4, incorrect answer: 4 units; (#3): screwdriver spanning 1 to 9, incorrect answer: 9 units; (#4): screwdriver spanning the edge of ruler to 4.5, incorrect answer: 4.5 units; (#5): screwdriver measured with four blocks with gaps, incorrect answer: four blocks long. The starting points of the objects on the rulers were varied to probe students' conceptions of where to start measuring. We recorded the mistakes they identified and their reasoning for what the measurements should be.

Students' performance in identifying the length of the objects improved as the starting point of the object being measured was positioned closer to zero on the ruler. Students who thought measurements should start at one on the ruler thought the answer for (#2) would be three units, because if the screwdriver had started at one on the ruler, it would end at three. However, students who originally said the object should start at *one* or *the edge* (which never aligned with zero) when measuring, changed their answer when they saw a screwdriver positioned at one; in these cases, they said it should be positioned at zero. Surprisingly, 54% of students, many of whom said the screwdriver positioned at one should start at zero in the previous problem (#3), thought the screwdriver in (#4) correctly showed a measurement of 4.5 units. With the blocks, only 54% of the students were able to correctly determine that the screwdriver would be longer than four blocks once the gaps between the four blocks were removed; six students said that after the gap or alignment problem was fixed, the screwdriver would still be four blocks long, and surprisingly, four students said it would be less than four blocks long! Overall, students' conceptions of zero seem tied to the ruler's edge even when it was not marked at the edge.

ESTRATEGIAS CUALITATIVAS EN LA RESOLUCIÓN DE SITUACIONES DE COMPARACIÓN DE PROBABILIDADES

Maribel Aguas-Hidalgo Ricardo Quintero-Zazueta
Centro de Investigación y de Estudios Avanzados (Cinvestav-IPN, México)
aguashidalgomm@yahoo.com.mx quintero@cinvestav.mx

Palabras clave: números racionales, probabilidad

En problemas de comparación de probabilidades están implicadas las proporciones. Para Piaget e Inhelder (1969) "…la noción de proporción se inicia siempre de una forma cualitativa y lógica, antes de estructurarse cuantitativamente". Por lo expuesto, consideramos que al tratar situaciones de probabilidad clásica con o sin proporcionalidad en un contexto de urna es necesario analizar no sólo las estrategias cuantitativas como las presentadas por Piaget e Inhelder (1951), Falk (1980), Green (1988) o Alatorre (1994), sino también las estrategias de corte cualitativo que se derivan de componentes lógicos que subyacen en las comparaciones cuantitativas para la toma de decisiones.

Las formas de razonamiento cualitativo usadas en la resolución de problemas son medios alternativos a los procedimientos cuantitativos (López, 2003). Estos medios alternativos, de corte cualitativo, son los que nos proponemos analizar desde los argumentos lingüísticos que estudiantes de educación secundaria ofrecen en la resolución de problemas de comparación de probabilidades, y que incluyen connotaciones como: 'más que', 'menos que', 'mayor que', 'menor que', 'más grande que', 'más pequeño que', sin explicitar por cuánto o cuántos. Es decir, desde un análisis de los componentes lingüísticos planteamos hacer una valoración del pensamiento cualitativo que ponen en acción estos estudiantes.

Para el desarrollo de esta investigación educativa se adopta un método cualitativo con un caso instrumental (Stake, 1999). El caso lo conforma un grupo de 35 estudiantes de tercer grado de educación secundaria. Para el diseño de las actividades, además de incluir el modelo de urna, se analizaron los tipos de problemas de razonamiento proporcional. En cuanto a la clasificación de Lamon (1993), los problemas diseñados corresponden a los de parte-parte-todo, que Özgün-Koca (2009) incluye en su estudio dentro de los de comparación numérica. Para el análisis de los resultados, una vez determinadas las relaciones de orden que se establecen con las variables que se implicaron: casos favorables, casos desfavorables o casos posibles, se identificaron las estrategias "dentro" o "entre" de solución para hacer la elección, centrando nuestra atención en los argumentos lingüísticos que no denotaban la cantidad sino la cualidad (más que, menos que,…) de los conjuntos comparados.

Con los resultados que arroje el estudio de las estrategias cualitativas queremos sustentar la pertinencia de incluir problemas de tipo cualitativo en la educación secundaria que, si bien subyacen a los problemas cuantitativos, no se contemplan en los Programas de estudio de este nivel educativo. En otras palabras, consideramos necesario valorar al razonamiento cualitativo como una herramienta de análisis, distinta a la numérica pero complementaria, que puede llevar a la simbolización algebraica de la expresión verbal, más allá del pensamiento aritmético mediático y que se podría favorecer; por ejemplo, desde situaciones de comparación de probabilidades cualitativas.

QUALITATIVE STRATEGIES IN THE RESOLUTION OF SITUATIONS OF COMPARISON OF PROBABILITIES

This paper analyzes the influence of qualitative thinking and its relevance in decision-making in situations involving the comparison of probabilities. To this end, classic probability scenarios were designed with the urn model. In each situation two ballot boxes were raised with simple extraction, involving or not relationship of proportionality, to third-degree students of secondary education. The analysis was carried out through the categorization of the results based on the relationships established between the components of the ballot boxes (favorable, unfavorable and possible cases). The study showed that, when comparing probabilities, students not only resort to quantitative comparisons, but to other relationships where a qualitative thinking is involved influencing the decisions they take.

IDENTIFYING U.S. ELEMENTARY STUDENTS' STRENGTH AND WEAKNESS IN GEOMETRY LEARNING FROM ANALYZING TIMSS-2011 RELEASED ITEMS

Jinqing Liu
Indiana University
Jinqliu@iu.edu

Keywords: Geometry Learning, U.S. Elementary Students, Strength and Weakness, TIMSS

Rather than focus on results showing that U.S. elementary students have consistently fallen behind East Asian students in in geometry based on the Trends in International Mathematics and Science Study (TIMSS) (Mullis, Martin, Foy, &Hooper, 2016), this poster session focuses on identifying the U.S. students' strengths and weaknesses in geometry as shown in TIMSS scores so as to use their strengths to leverage their achievement in areas in which they need support.

The major data in this study are the 24 Grade 4 TIMSS released items that fall in the geometry content domain (retrieved from https://timssandpirls.bc.edu/timss2011/international-released-items.html). To define U.S. students' strengths and weaknesses in geometry, I employed the International Average percent correct and the percent correct of Hong Kong students (consistently ranked in the top 3 in TIMSS) as benchmarks, with which I compared the U.S. percent correct. I then grouped the 24 items into three categories: items on which U.S. students performed weakly (lower than the international average percent correct or below 50%), items on which they performed normally (slightly higher than the international average correct percent, 50% to 70%), items that U.S. students performed strongly (slightly lower than Hong Kong student' performance, 70% to 100%). At last, I analyzed the content and cognitive domain of each item in each group to identify emerging themes.

Initial results indicate that U.S. students performed weakly on five geometry items, three that assessed application of knowledge and two that assessed reasoning. These items involved measurement, such as figuring out the length of a folded string (item ID: M031004; 20% correct), the distance Ruth walk around the edge of a square land (Item M041155; 43% correct, compared to the international average of 50% and the Hong Kong average of 82%). U.S. students performed normally on 10 geometry items, six testing for knowledge and the rest application of knowledge. These items assessed students' knowledge of 2-D and 3-D shapes, such as identifying shapes in a given picture (Item M041143) or drawing according to specifications (e.g., Item M031325: drawing an obtuse angle). U.S. students performed strongly on nine items that focus on testing students' knowledge about symmetries and locations, five of which assessed their knowing and the rest assessed application of these knowledge. Among these items, U.S. students far surpassed the international benchmark and nearly matched Hong Kong students' performance on items such as justifying which line is a symmetry line (Item M031093), describing the movement of Jamie's counter on a board game (Item M031088). U.S. students performed best (92%) on Item M0411608 where they were asked to mark the location of a house on a map. In general, results indicate U.S. students preferred practical geometrical knowledge and were challenged by abstract geometric concepts and reasoning.

Based on these initial findings, I suggest that U.S. math teachers and educators should focus on promoting U.S. students' conceptual understanding of measurement (e.g., length, angle) and their flexibility in applying such geometrical knowledge. We should also explore the factors that contribute to U.S. students' strengths in location and symmetries related knowledge to see if we can extend these strengths to other geometrical topics.

CORRESPONDING COLOR CODING FACILITATES LEARNING OF AREA MEASUREMENT

Understanding formulas for area measurement requires making connections between the symbols in a formula and the corresponding elements of a pictorial diagram. Unfortunately, many geometry textbooks do not provide explicit links between these two representations (e.g., Kennedy, Charles, & Bragg, 2005). The absence of explicit connections between two representations combined with the instructional emphasis on algorithmic computations (e.g., plugging numbers into a formula *area*=*base*×*height*; Zacharos, 2006) may lead to misconceptions and incorrect formula applications, such as using a side instead of height to find the area of an obtuse triangle (Fuy, Geddles, & Tischler, 1988). Previous studies have shown that using colors to highlight corresponding components of text and illustrations supports learning of complex science concepts in high-school and college students (Ozcelik et al., 2009; Kayuga et al., 1999). Here, we propose that using distinct colors to highlight corresponding elements of diagrams and formulas during instruction may help students make connections between the two representations, and we test the effects of corresponding color-coding on learning of triangle area measurement.

Using a pretest-lesson-posttest design, we assessed 38 sixth-grade students' knowledge of area measurement before and after a video lesson on calculating area for an obtuse triangle. For half of the students, corresponding elements of the formula and the diagram were highlighted in distinct colors during the lesson (e.g., the base was highlighted in green in both representations). The other half of the students viewed an identical lesson without the color coding (e.g., the base of the triangle in both representations were in black).

Overall, students improved in identifying both base (pretest: 41.5%; posttest: 62%) and height (pretest: 22.5%, posttest: 43.5%) of obtuse triangles from pretest to posttest, *p*s< .001. The effect of condition emerged only in students' performance on base items. Specifically, students in the color-coding condition improved more in identifying bases (pretest: 48%; posttest: 72%) than students in the control condition (pretest: 35%; posttest: 52%), $F(1, 37) = 4.46$, $p = 0.04$. The findings suggest that corresponding color-coding of diagrams and formulas may be an effective instructional approach to promoting learning of area measurement.

INCLUSIVELY RESPONSIVE INSTRUCTION TO ADVANCE SPATIAL REASONING AND NUMBER SENSE

Rebecca Ambrose
University of California-Davis
rcambrose@ucdavis.edu

Keywords: Geometry and Geometrical and Spatial Thinking, Elementary School Education, Design Experiment

Geometry continues to be overlooked in elementary school mathematics despite its potential to support spatial reasoning which has been shown to have a role in overall mathematics performance (Sinclair & Bruce, 2015). Moreover, when it is taught, the focus tends to be on classifying 2-dimensional shapes according to their sides and angles. To address these short-comings, I have been designing and testing activities that engage children in building polyhedra and measuring their volumes. I hope that combining attention to shape and number within the same lessons will make it more likely that geometry will be addressed with greater frequency in elementary school classrooms. The work has taken place in a 5th grade classroom with 27 11-year-olds. The class is ethnically diverse with a range of mathematical abilities and achievement levels.

Lesson design was informed Murata's model of Inclusively Responsive Instruction (2013) which assumes that students' zones of proximal development will differ. This diversity of thinking can be an asset to the classroom when students have access to the thinking of their classmates giving them opportunities to incorporate new ways of thinking with their own. When this occurs "each learner will feel valued for his or her own thinking as different ideas interact to become something collectively meaningful" (Murata, 2013, p. 18). My previous work in the domain of 3D geometry (Ambrose & Kenehan, 2009) and my understanding of the ways in which children coordinate units (see Ulrich, 2015 for example) helped me to anticipate the levels of thinking that might be evident in the class enabling me to be strategic about the student work to bring up during the class discussion.

Activities tended to include children building polyhedra using polydrons and measuring the volume of their constructions. An ample supply of cubic centimeter manipulatives was available to measure the volume of polyhedra. Children varied in what they built and their strategies for as determining the volume differed and reflected the degree to which they spatially structured (Battista, 2007) their polyhedron. Whole class discussions were crafted to ensure that different levels of thinking were available to the students so they could learn from one another. Spatial structuring emerged from the analysis of shapes as well as discussions of volume. In particular students varied in terms of attending to the number of cubes in a row, the number of rows in a "layer" and the number of layers in the shape.

In all lessons the children were positioned as knowers, builders and designers, giving them a sense of agency. Ball, Goffney and Bass (2005) argued, "mathematics instruction can be designed to help students learn that differences can be valuable in joint work, and that diversity in experience, language, and culture can enrich and strengthen collective capacity and effectiveness (p 5)." In this way the lessons provided children with an opportunity to participate in a democratic discussion space where all individuals' contributions were valued.

EXPLORING THE DISCURSIVE DIFFERENCES OF MATHEMATICS COACHES WITHIN ONLINE COACHING CYCLE CONVERSATIONS

Ryan Gillespie
University of Idaho
rgillespie@cdaschools.org

Julie Amador
University of Idaho
jamador@uidaho.edu

Jeffery Choppin
University of Rochester
jchoppin@warner.rochester.edu

We present the results of our analysis regarding the discursive tendencies of four mathematics coaches during planning and debriefing conversations within online coaching cycles. Guided by the Content-Focused model of coaching (West & Cameron, 2013), the coaching cycles are a single component of a larger online professional development model for middle school mathematics teachers in rural areas (Choppin, Amador, & Callard, 2015). This paper explores the different ways coaches talk with teachers during coaching conversations. Building on prior studies from literacy coaching (Ippolito, 2010), we found five different discursive moves for how coaches talk with teachers: invitation, suggestion, explanation, description, and evaluation. We use these moves to identify similarities and differences in the discursive tendencies of coaches. The implications of these discursive tendencies are provided.

Keywords: Inservice Teacher Education/Professional Development, Online Learning, Coaching

Introduction

Coaching teachers to support their mathematics instruction is a promising practice to improve pedagogical implementation and content knowledge (Campbell & Griffin, 2017). However, not all coaching processes are the same. There are three commonly referenced models: Content-Focused Coaching (West & Cameron, 2013), Instructional Coaching (Knight, 2007), and Cognitive Coaching (Costa & Garmston, 2016). Although each model approaches the process of coaching differently, they all articulate the same three sequential cycle components: a) a pre-conference discussion to plan a lesson, b) a collaborative lesson implementation, and c) a post-conference discussion to debrief the lesson (Bengo, 2016). The three-part coaching cycle is a prominent professional learning activity mathematics coaches use when working with individual teachers to improve their practice (Mudzimiri, Burroughs, Luebeck, Sutton, & Yopp, 2014). Despite the use of a similar three-part cycle, the way these cycles are delivered varies depending on the type of coaching and the personnel involved.

The research on literacy coaching highlights two competing stances for how coaches talk with teachers: reflective or directive (Deussen, Coskie, Robinson, & Autio, 2007; Ippolito, 2010; Sailors & Price, 2015). Coaches using a *reflective* stance facilitate improvement of teaching practices and student learning through collaborative inquiry (Ippolito, 2010). Coaching moves associated with this stance include probing questions and low-inference, non-evaluative observations as means to catalyze teacher thinking (Costa & Garmston, 2016). In contrast, a *directive* coaching stance involves the use of advice, suggestions, and evaluative feedback to support teachers to implement new teaching practices (Ippolito, 2010). Because these different coaching stances can have significant impact on the teacher's learning and uptake of new practices (Costa & Garmston, 2016), it is crucial for researchers within mathematics education to explore the existence and impact of these stances during coaching.

We examined the existence of reflective and directive stances of four middle school mathematics coaches during their coaching cycle conversations with teachers. Specifically, the study was guided by the question: What were the different discursive tendencies of four mathematics coaches within the planning and debrief conversations of a coaching cycle? This question is relevant to mathematics education as variability within coaching has been a dominant theme in existing literature. Although coaching and coaching cycles have been shown to have the potential to improve teaching practices and student learning, results have been inconsistent (Gibbons & Cobb, 2016). Variability in coaching experience, the types of activities coaches use, and the context surrounding the coaching activities often vary dramatically (Ellington, Whitenack, & Edwards, 2017). This variability has been attributed to the inconsistent impact of coaching on improving teaching and learning (Campbell & Griffin, 2017). The purpose of this study is to open up an examination of coaching discursive tendencies to explore the variability of coaching stances.

Methods

In this study, experienced coaches, all guided by the Content-Focused Coaching model (West & Staub, 2003), took part in coaching activities as part of a larger online professional learning project (Choppin et al., 2015). The project paired coaches using Content-Focused Coaching with middle grades teachers and was designed to improve teacher practices for implementing high cognitive demand tasks and facilitating mathematical discourse (Smith & Stein, 2011). Using a cohort model, nine teachers from grades 5-8 participated in a two-year online professional development program. The fully online professional development program was specifically created for mathematics teachers working in rural areas and provided teachers with an online course, online teaching labs, and video-assisted online coaching cycles.

Participants

Three of the four coaches (see Table 1) working with the cohort teachers had more than ten years of prior coaching experience and had worked collaboratively using the Content-Focused coaching model (West & Staub, 2003) for at least three years. Each coach was assigned one to three teachers, with whom they each engaged in five total online coaching cycles over the course of two years. The data for this inquiry were collected from the planning and debrief conversations of the four project coaches and their assigned teachers.

Table 1: Coach Demographics

Coach	Years of Classroom Experience	Years Coaching	Teaching and Administrative Certifications
Alvarez	28	21	Permanent Certification in K-5, 6-8 and 9-12 Mathematics
Bishop	28	14	Secondary Mathematics State 1, Secondary Mathematics State 2
Lowery	14	13	Special Education (N-12); Elementary Education (PreK-6); Reading (N-12)
Reiss	15	0	Elementary (N-6), Special Edu (K-12), Mathematics (7-12)

Context: Coaching Cycles

Each online coaching cycle was designed to support successful implementation of new discourse practices (e.g., Smith & Stein, 2011) learned during the online course and teaching labs. Each cycle followed the same structure. First, the coach and teacher had a planning discussion using video conferencing technology, Zoom, around a proposed lesson. Based on the Content-Focused Coaching model, the focus of this planning meeting was on the mathematical lesson goals, the tasks that would be used in the lesson, anticipated student thinking, and instructional practice goals for the teacher (West & Staub, 2003). The coach used a variety of discursive moves to support the teacher during this planning discussion. Following the planning meeting, the teacher video- and audio- recorded themselves teaching the lesson using Swivl Technology (automated video camera and recording). After the lesson was taught, the coach and teacher asynchronously watched and annotated the lesson video. Annotations included written comments to the other person about the contents of the video. The coaching cycle concluded with the coach and teacher having a debrief discussion that utilized the annotations to reflect on student thinking in relation to the lesson goals and the teacher's goals for instructional practice. The planning and debriefing discussions were the focus for analysis for this project and typically lasted forty to sixty minutes.

Data Collection and Analysis

For this study, we collected and analyzed the planning and debriefing conversations of one coaching cycle for all coaches and their assigned teachers. This resulted in the analysis of 15 conversations (eight planning and seven debriefing), which were transcribed verbatim. Transcripts were parsed into stanzas which we defined as including both the coach's discursive move and the teacher's response, as well as text needed for context (Saldaña, 2013). A stanza served as the unit of analysis. We then used a comprehensive codebook created by the research team to analyze all stanzas. To create the codebook, we first open-coded coaching transcripts for our data set using constant comparative methods (Corbin & Strauss, 2008). We then synthesized our initial open codes with the discursive moves associated with reflective and directive coaching stances described in the three primary coaching models (Costa & Garmston, 2016; Knight, 2007; West & Cameron, 2013). For example, Cognitive Coaching strongly promotes a reflective coaching stance using the discursive moves of invitational questioning and descriptive paraphrasing (Costa & Garmston, 2016). Similarly, Instructional Coaching leans towards reflective coaching stances by encouraging coaches to collect and share observation data using descriptive but non-evaluative discursive moves (Knight, 2007). Finally, Content-Focused Coaching suggests a fluid balance of both coaching stances through the use of reflective questioning moves as well as directive suggestions and explanations when appropriate (West & Cameron, 2013).

The open codes, combined with the literature on coaching, resulted in a broad codebook that accounted for the discursive moves and the content of the conversations. The coaching discursive moves section accounted for five broad categories within this codebook (see Figure 1). Then we connected each of the five discursive moves to either a reflective or directive coaching stance by again returning to the coaching literature. Suggestions, explanations, and evaluations connected to a directive coaching stance as those moves all involve the coach sharing their thinking and opinions with the teacher which in turn positions the coach as an expert (Sailors & Price, 2015). Invitations and descriptions connected to a reflective coaching stance because those moves position the teacher as the thinking authority since neither move contains the thinking or opinion of the coach (Ippolito, 2010).

Coaching Stance	Discursive Move	Description	Example
Reflective	Invitation	Statement or question that invites the teacher to reflect or respond	"What might be some strategies we could use to increase student participation?"
	Description	Statements that share a direct observation and do not contain inference, interpretation, judgement or opinion	"I noticed that during the turn-and-talk, Alex did not say anything to his partner."
Directive	Suggestion	Statement that recommends an action	"I think we should use a turn-and-talk prior to the whole class discussion."
	Explanation	Statements that provide an interpretation or rationale of an event, interaction, or mathematical idea	"Turn-and-talk is a powerful strategy to use prior to a whole class discussion because it increases student participation."
	Evaluation	Statements that offer praise or critique	"I think it was a great idea to use a turn-and-talk."

Figure 1: Excerpt from the Larger Codebook Focusing on Coaching Discursive Moves

To analyze the planning and debriefing meetings between the coach and teacher, the stanzas from the transcripts were coded by pairwise teams of researchers for the discursive moves of the coach, the discursive moves of the teacher, and the content being discussed within each stanza. (Note that only the discursive moves of the coach are considered for this study.) The researchers then calculated Kappa to determine consistency with coding and met to reconcile disagreements. Kappas ranged from 0.39 to 0.65, considered moderate to strong reliability (Landis & Koch, 1977).

Two examples are provided to clarify the ways the five discursive codes were used to analyze how the coach talked to the teacher. The following is an excerpt from a coach:

> One of the really nice moves you can do if the group shares a thought about something, and it's somewhat ambiguous, is you can turn to the class and say, "Can someone else use their own words to explain what Dave is saying?"

This comment from the coach was coded as a suggestion because the coach recommended the teacher use a question to promote additional student discourse. In this instance, the suggestive discursive move implied the coach held a directive coaching stance.

It is also possible that multiple discursive moves were used by a coach within one stanza. To illustrate this, the following is an excerpt from a transcript in which Reiss (pseudonym) uses a descriptive move (lines 1 - 4) followed by an invitational move (lines 5 - 6):

> I kept hearing kids saying, "No, four, no five. You need four, you need five."
> You asked the question well, how many boxes do you need to take the bagels home
> was the question you asked.
> I heard the answers four and five come out from kids.
> What mathematical idea is at play here, and where do we think the kids understanding
> is for that idea?

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

In this example from a debriefing interview, Reiss recalled the contents of the lesson and details what she heard the teacher and students say without inference or evaluation. She then questioned the teacher about the mathematics and students' understanding. Since she first described student and teacher actions and then invited dialogue, this was coded as both a description and an invitation. Both of these discursive moves suggested the coach was operating from a reflective stance at that moment in the conversation since no interpretation or opinion was provided by the coach enabling the teacher to construct their own meaning from the situation.

After we coded the transcripts, the total number of each of the five discursive moves used by a coach within a conversation was calculated. For example, during a planning conversation containing 31 stanzas, Reiss used a total of 15 invitations, nine descriptions, three suggestions, 11 explanations, and zero evaluations. These counts indicate the coach held both reflective and directive stances during the conversation. However, the higher combined frequency of invitational and descriptive moves (24 total) when compared to suggestive, explanation, and evaluative moves (14 total) suggested the coach favored a reflective coaching stance. Because coaches were assigned different numbers of teachers and thus had different numbers of total coaching conversations, we calculated an average for each move by dividing the total number of discursive moves used in all conversations by the total number of conversations. For example, Reiss used a total of 52 invitational moves during four conversations resulting in an average of 13 invitational moves for a single coaching conversation (see Table 2).

To characterize reflective coaching stances using the discursive moves, we divided the sum of the number of invitational and descriptive moves by the number of coaching conversations. This provided the average number of moves in a conversation associated with a reflective coaching stance. Similarly, we determined the average number of directive stance moves by combining suggestions, explanations, and evaluations. For example, during a single conversation, Reiss averaged 22.5 combined discursive moves connected to a reflective stance and 17 combined moves associated with directive coaching (see Table 2).

Results

In total, we analyzed 594 stanzas from 15 total conversations (eight planning and seven debriefing meetings). When examining the frequency of the five discursive moves used by each coach, we found both consistency and variability. As an example of a consistency, each of the four coaches was similar in their use of descriptive moves as the average ranged from 7 to 9.5 moves per conversation. The coaches were also relatively consistent in their use of explanation moves. However, there existed larger variability within the coaches' use of invitational, suggestive, and evaluative moves. To illustrate this variability within invitational moves, Alvarez had the highest average of 22 invitational moves per conversation compared to Reiss who averaged the lowest with 13 moves per conversation. For suggestions, Bishop had the highest average with 13.7 moves per conversations whereas Alvarez used only 3 suggestive moves per conversation. Bishop also had the highest level of evaluation moves with an average of 6.5 per conversation compared to Reiss who averaged only one evaluation move per conversation.

Reflective and Directive Stances by Coach

The differences in the number of directive (invitation and description) and reflective (suggestive, invitational, and evaluative) moves suggested the existence of variability in how the four coaches balanced the two stances during the conversations (see Table 2). For example, Alvarez averaged 29 discourse moves associated with a reflective stance compared to only 12 directive moves during a single conversation. This finding suggested the coach strongly favored a reflective stance. In contrast, Bishop averaged more directive moves per conversation (32.2) than reflective moves (25.8) indicating the coach favored a directive stance. The discursive moves for Lowery and Reiss were more evenly balanced but implied both coaches slightly favored a more reflective stance.

Table 2: Average Number of Discursive Moves Per Coaching Cycle Conversation

	Reflective		Directive			Combined Reflective Moves	Combined Directive Moves
Coach	Invitation	Describe	Suggest	Explain	Evaluate		
Alvarez	22	7	3	7	2	29	12
Bishop	18	7.8	13.7	12	6.5	25.8	32.2
Lowery	18.7	7.7	11	9.3	4.3	26.4	24.6
Reiss	13	9.5	7	9	1	22.5	17

Reflective and Directive Stances Based on Planning or Debriefing

To further explore the discursive tendencies of coaches, we separately examined the data based on the conversation type. Specifically, we analyzed the frequency of discursive moves used by coaches during planning and debriefing conversations. For example, Lowery averaged 13 suggestive moves during a planning conversation and seven during a debriefing conversation (See Table 3). Again, this analysis revealed a small number of additional consistencies and further highlighted distinct differences in discursive tendencies between coaches. As an example of one such consistency, all coaches used more descriptive moves during debriefing conversations than in planning conversations suggesting each coach made a potential shift to the use of more reflective coaching stances during debriefs.

Reflective and Directive Variability

To illustrate the additional variability in discursive tendencies, Table 3 shows the average number of discursive moves per coaching cycle conversation for each coach.

Table 3: Average Number of Discursive Moves Per Coaching Cycle Conversation

	Planning Conversation					Debrief Conversation				
	Reflective		Directive			Reflective		Directive		
Coach	Inv	Desc	Sugg	Exp	Eval	Inv	Desc	Sugg	Exp	Eval
Alvarez	20	0	3	8	1	24	14	3	6	3
Bishop	21.7	6.7	19.7	11	4	14.3	9	7.7	13	8.3
Lowery	21.5	2	13	10	1	13	19	7	8	13
Reiss	16.5	6	5	9	0	9.5	13	9	9	2

Note: Invitation (Inv), Descriptive (Desc), Suggestive (Sugg), Explanatory (Exp), Evaluative (Eval)

Bishop's highest combined frequency of suggestive, explanatory, and evaluative moves in both the planning and debrief conversations portrayed a more directive coaching stance when compared to the other three coaches. In contrast, Alvarez's low frequency of suggestive and evaluative moves combined with a higher total frequency of invitational and descriptive moves suggested this coach held a highly reflective coaching stance during planning and debrief conversations. The more balanced discursive moves of Reiss and Lowery provided evidence of an evenly balanced coaching stance. We provide three examples of the variability with the discursive moves. First, Bishop and Alvarez varied greatly with their use of suggestions during planning conversations. Bishop provided 19.7 suggestive moves per planning conversation yet Alvarez only offered three per planning conversation. As a second example from debriefing conversations, Reiss and Lowery differed greatly with their use of evaluative moves. Reiss averaged only two evaluative moves per debrief conversation compared to Lowery's 13 evaluative moves per debrief conversation. As a final example, Alvarez averaged 24 invitational moves during debriefing conversations whereas Reiss averaged only 9.5 per debrief conversation. These three examples regarding the differences in discursive moves further demonstrates the existence of variability in how each coach balanced reflective and directive coaching stances. Additionally, the examples highlight large potential differences in the learning experiences of the teachers based on their coach.

Discussion

Our findings suggest the existence of certain common discursive tendencies within the four coaches. For example, all four coaches were relatively consistent in their use of descriptive moves. All four coaches also used more descriptive moves during debriefing conversations than during planning conversations. This finding is consistent with Knight's (2007) recommendation that coaches should collect, share, and examine descriptive, low-inference data with teachers during a debrief conversation. This finding is significant as it suggests each of the four coaches enacted a coaching practice identified by existing coaching literature as productive in supporting teacher learning. However, our findings were consistent with prior literacy coaching studies (e.g. Heinke, 2013) and highlighted many substantial differences in the coach's discursive tendencies. These differences could have a significant impact on the learning experiences of the teachers (Costa & Garmston, 2016). For example, a teacher planning with Bishop received many more suggestions than a teacher planning with Alvarez. Similarly, a teacher debriefing with Lowery encountered far more evaluative moves than a teacher debriefing with Reiss.

Extant research indicates that most coaches tend to use both reflective and directive stances during coaching conversations (e.g. Deussen et al., 2007). The differences in discursive tendencies also suggest variability in how each of four coaches balanced reflective and directive coaching stances despite the fact that each coach was operating within the Content-Focused Coaching model. In fact, authors of the Content-Focused Coaching model advocate for the use of both stances (West & Cameron, 2013). However, neither the coaching model nor prior research on coaching provide guidance on how to properly balance these differing stances to best support teacher learning. Additionally, these works have not closely examined the actual discursive moves coaches are using with considerations about how this may influence teacher learning. Now that we know the types of discursive moves the coaches in our project are using, it would be beneficial to examine how this relates to teachers' responses in the moment of coaching.

Future Directions

Building from the variance in mathematics coaching described by Campbell and Griffin (2017), these findings expose an additional source of variability. Our data show that even with highly experienced coaches drawing from the same coaching model, there existed considerable variability in the discursive tendencies of coaches. Likewise, although our intent was not to compare coaches based on demographics, the coach with the least coaching experience (Riess) showed tendencies similar to Lowrey who had been coaching for over a decade. These discursive differences imply the coaches used distinct coaching stances which, like other forms of variability found within coaching, likely have an impact on teacher learning (Costa & Garmston, 2016). Further exploring the possible relationship between experiences and coaching practices could reveal interesting insights that would provide information on how to best support both coaches and teachers.

These findings are also significant in that they generate new questions for coaching in mathematics education. The existence of discursive variability between coaches, even within the favorable context found in our study, warrants further exploration into the underlying causes of these differences. It is possible that the diversity in coaching discourse is due to the coaches being responsive to the varying needs of the individual teacher. However, it also plausible that these differences result from beliefs, preferences, or personal interaction styles that are inherent of the coach. Prior research on literacy coaching has highlighted that coaching discursive patterns are primarily static and not adapted based on the varying learning needs of the teacher (Collet, 2012). However, research on the adaptive nature of coaching discourse is scarce within literacy coaching (Collet, 2012) and, to the best of our knowledge, non-existent within the specific context of mathematics coaching. To fill this gap, our future analysis will use data from additional coaching cycles to compare both the discursive moves of a single coach across multiple teachers and the way in which coaches shift their discursive tendencies across multiple coaching cycles with the same teacher.

Future studies should also build on these results to examine the relationship between the discursive tendencies of coaching and teacher learning (Heinke, 2013). Although certain coaching models make claims about the affordances and drawbacks of certain types of discursive moves (e.g. Costa & Garmston, 2016), further research is needed to better understand the how different discursive tendencies affect the teacher being coached. This understanding, combined with the results of our study, can provide practicing coaches with sound guidance about how to strategically balance and employ different discursive moves. This understanding could also lead to more strategic partnering of coaches and teachers by matching the discursive tendencies of a coach to the unique learning needs of a teacher.

MATH TEACHERS' SENSEMAKING AND ENACTMENT OF THE DISCOURSE OF "PERSEVERANCE"

Patricia Buenrostro
Vanderbilt University
patricia.m.buenrostro@vanderbilt.edu

Nadav Ehrenfeld
Vanderbilt University
nadav.ehrenfeld@vanderbilt.edu

Students' opportunities to struggle with mathematical ideas have long been considered paramount to learning. However, there's little research on how teachers (1) draw on and make sense of the discourses of perseverance, (2) enact it in classroom, and (3) develop an expansive view of perseverance. To contribute to these lines of research, we build on a case study featuring a veteran mathematics middle-school teacher across two settings: his classroom where he facilitates students' engagement with a classical mathematical task, the Tower of Hanoi, and in a subsequent video-based debrief with his colleague and our research team. We propose a conceptualization of perseverance as upholding three dimensions of (a) persistence (b) sensemaking and (c) problem solving heuristics. We argue for its potential as a conceptual resource for operationalizing perseverance more comprehensively.

Keywords: Mathematics Teaching, Perseverance, Video-based coaching, Problem-solving

Objectives

Perseverance, grit, and productive struggle are a few of the descriptors signaling the importance of fostering students' sustained engagement in math classrooms to support mathematical sensemaking. Mathematics educators, researchers, and policymakers agree that cultivating students' dispositions towards seeing mathematics as a worthwhile and *effortful* pursuit supports students' success in engaging with conceptually-rich mathematics in flexible and fluent ways. Indeed, *make sense of problems and persevere in solving them* is the first of eight mathematical practices deemed essential for teachers to champion in their classrooms as outlined in the Common Core State Standards for Mathematics (National Governors Association, 2010). Similarly, in the influential document *Adding It Up* (Kilpatrick et al., 2001), mathematical proficiency is defined as the amalgamation of five strands, one of which is *productive disposition*, or the "habitual inclination to see mathematics as sensible and useful, coupled with a belief in one's own efficacy" (p. 5). In short, perseverance is one of the noncognitive factors that is highly consequential for academic success (e.g. SRI International, 2018, p. 1).

Despite a burgeoning discourse within education broadly and mathematics classrooms specifically, little research investigates how mathematics teachers interpret these discourses of perseverance. Yet these interpretations matter for how they take them up in their classrooms. Accordingly, inspired by Naraian (2011), we explore questions such as: What discourses do teachers draw on as they aspire to promote perseverance? How do teachers design for and enact perseverance in math classrooms? What discursive dilemmas emerge in this process? How can teacher educators support teachers' expansive view of perseverance?

In this analysis, we present an illustrative "best case" of a teacher, Ezio (all names of teachers and the school are pseudonyms), who identified perseverance as an explicit goal for his class. We analyze the discourses he drew on, his enactment of a lesson designed to support perseverance, and the discussion we conducted three days later as part of our research project. We identify the Opportunities To Learn (OTLs) that emerged in our debrief that supported the teacher's thinking about perseverance more expansively while also pinpointing where we fell short as teacher educators in our own limited understanding of perseverance, the same discourse to which we aim to contribute in this paper.

Theoretical Framework

Situating Teachers as Sensemakers

Despite strong efforts to shift teachers towards ambitious instruction, the field continues to struggle with effectively translating research-driven visions and practices so they might be taken up more frequently and more seamlessly by practitioners. We address this problem in our research, as well as in our practice as teacher educators, by taking a situated view on teaching (Greeno & MMAP, 1998; Horn & Kane, 2015). A situated view on teaching (and on teacher learning) highlights that teachers do more than simply implement pedagogical discourses, but rather they constantly make sense of their classroom context as it is negotiated by institutional norms and practices and wider socio-historical discourses (Horn & Little, 2010; Narian, 2011). In this vein, we take a situative approach in examining teachers' Opportunities To Learn (OTLs) by considering the various discourses teachers draw on such as the state standards, professional development organizations, and their own epistemic stances or beliefs about what can be known, how to know it, and why it matters (Horn & Kane, 2015). In this study, we are interested in the conceptual resources made available for teachers and teacher educators in their attempts to operationalize discourses around productive struggle. We view the two settings of classroom and video-based coaching session as informative in drawing out the discursive dilemmas in each other. In other words, classroom dilemmas inform teachers' OTLs, and pedagogical conversations with colleagues, at their best, inform classroom dilemmas. In light of that, we aim to conceptualize perseverance in a way that might support teachers and teacher educators in conceiving and enacting perseverance more expansively.

Research on Perseverance

To conceptualize perseverance, we draw on several studies (Bass & Ball, 2015; Hiebert & Grouws, 2007; Sengupta-Irving & Agarwal, 2017; Stein et al. 2017), and propose a rich and productive conceptualization of perseverance as upholding the three conditions of (a) *persistence* (b) *sensemaking* and (c) problem solving *heuristics*.

Hiebert & Grouws (2007) documented the ways that certain forms of *persistence* or student struggle can be a key enabler for math learning. However, persistence alone is an insufficient condition for learning mathematics conceptually. For example, the results of a recent study by Stein et al. (2017) revealed that teachers disproportionately create conditions for students to struggle unproductively, with little explicit attention to and few opportunities for building conceptual understanding. For students to develop conceptual understanding, they need opportunities to *make sense* of mathematical ideas, construct new knowledge, and make connections. Consequently, teachers are tasked with finding challenging problems that require the right amount of struggle within students' conceptual reach or within their zone of proximal development (ZPD; Sengupta-Irving & Agarwal, 2017; Vygotsky, 1978). Less productive challenges were described by Sengupta-Irving and Agarwal (2017) as either "unnecessary struggle" or "no struggle" (see Figure 1).

Bass & Ball (2015) add a dimension to our understanding of perseverance related to problem solving *heuristics*. Analyzing a 5th grade class engaged in collective problem solving, they presented a macro-analysis of the lesson identifying (1) six stages of students' collaborative work; and (2) the teacher's instructional moves that oriented students engagement across the

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

stages. Through their analysis of how teachers made perseverance “visible and learnable,” they underscored how the teacher made explicit for students the different heuristics they exercised in making sense of the task, identifying adequate approaches and generating possible solutions. Indeed, research has shown heuristics to be an important tool for successful problem solvers (Schoenfeld, 1985).

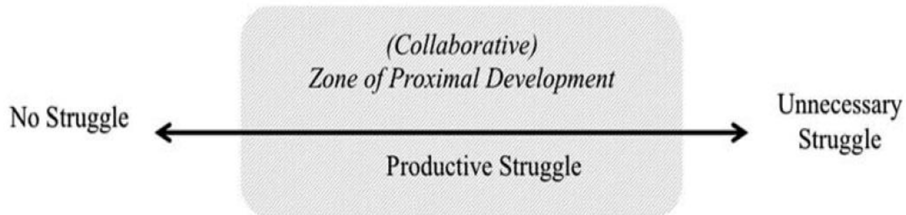

Figure 1: Productive Struggle and the ZPD (Sengupta-Irving & Agarwal, 2017)

Methods

Research Context

This analysis comes from a larger research-practice partnership aimed at understanding how video-based coaching, tied to teachers’ instruction, can support urban mathematics teachers’ development of ambitious instruction. To support and document teacher learning, our research team developed a Video-based Formative Feedback (VFF) cycle, a 4 step co-inquiry into practice. First, we prompt teachers about their goals and specific inquiries related to the class to be filmed, identifying a question we can use to inform our observation. Second, we film one classroom session using two cameras, a classroom wide-angle camera and teacher point-of-view camera. Additionally, we place four audio markers at different student groups to capture group-level conversations. These video and audio records serve as rich representations of teachers’ practice from which to focus coaching conversations. Next, our team analyzes the captured footage to identify moments of interest that may address the teachers’ inquiry questions. Finally, typically within two days of filming, we meet with the teachers to debrief the lesson, focusing on the identified video moments as a springboard for discussion. The debrief session is filmed for our research purposes.

Data sources. Primary data sources for this analysis include: (1) Focal teacher’s email describing the lesson activities and teacher’s goals; (2) the 90-minute video-taped classroom session; (3) the 81-minute videotaped debrief of the lesson with three members of the research team—the two authors of this paper and the project Principal Investigator, Ilana Horn. Patricia Buenrostro facilitated the conversation with the focal teacher, Ezio, and a collaborating teacher, Veronica. The other researchers were primarily filming (Ehrenfeld) and taking field notes (Horn) but on occasion participated in the debrief conversation. Because our relationship with Ezio extends beyond this focal event, we draw on other conversations, observations, and interviews as secondary data in confirming or disconfirming evidence for tenuous claims.

Focal participant. The VFF cycle analyzed represents a debrief with Ezio Martin, a veteran, middle-school teacher with over 17 years of experience, and his colleague, Veronica Kennedy. Ezio demonstrated strong content knowledge during his teaching and in professional development workshops, underscored by his undergraduate and graduate math degrees. His participation in a 5-year professional development program showed his commitment to his professional growth. In addition, he had strikingly warm rapport with his students, who show respect and admiration for him. As a teacher with a strong math identity, the classroom was decorated with mathematical phrases, posters and books. The class episode under study featured animated talk, boisterous laughter, and wooden manipulatives in action. In short, it appeared a vibrant environment in which to learn and do math. Ezio's queries prior to filming centered around student dynamics (e.g., status issues). Notwithstanding, in the debrief, Ezio identified perseverance as an explicit goal for the featured task, the Tower of Hanoi.

Focal task, "Tower of Hanoi." The Tower of Hanoi activity consists of three poles and varying number of rings in different sizes (see Figure 2), arranged on one pole. The goal of the task is to move all the rings, one at a time, from the initial-pole to either of the two remaining poles, while avoiding the placement of a larger ring onto a smaller one *in the least number of moves*. For example, 3 rings can be transferred in only 7 moves. The task is to find the general rule for determining the minimal number of moves for any given number of rings [$f(n) = 2^n-1$]. Ezio wanted to expose students to a nonlinear function and to experience a challenging problem with which to persevere.

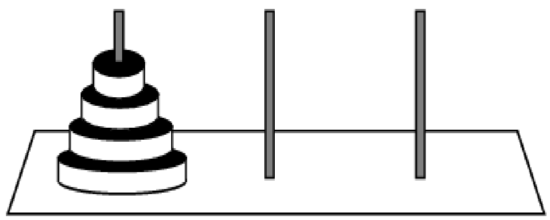

Figure 2: Illustration of Tower of Hanoi Kit with Three Poles and Four Rings

Methods of Analysis

To be clear, the centrality of Ezio's goal to have his students persevere emerged during the post-class debrief. Our overall methods represent an iterative process of analyzing both the debrief and classroom session to understand how Ezio made sense of, designed for, and enacted *perseverance*.

We looked across the data from both settings and used interaction analysis (Jordan & Henderson, 1995) with both sets of transcripts to examine the complementary and contradictory discourses that emerged. For the classroom, we looked at Ezio's design and enactment of perseverance with an eye towards the macro-analysis of lesson phases presented by Bass and Ball (2015) and expanded our definition of perseverance. For the debrief, we analyzed Ezio's conceptualization of perseverance as he discussed his teaching. Comparing the emergent views of *perseverance* arising from these analyses, we explored the discursive dilemmas (e.g., asking questions students are unable to answer) in both events—the classroom and debrief—which ultimately led to our expansive understanding and proposed characterization of perseverance described earlier.

Results

To understand the discourses that Ezio drew on in making sense of perseverance, we examined his epistemic stance on perseverance as corroborated from his email and the debrief conversation. Next, we report on the classroom events from the filmed lesson, followed by an analysis of the debrief conversation. Finally, we look across the two settings and reflect on how, in our role as coaches, we supported Ezio in re-imagining perseverance in his classroom, while also underscoring where we needed a richer conceptualization of perseverance.

Ezio's Epistemic Stance on Perseverance: "I want them to learn how to persevere"

During the debrief, Ezio interrupted the start of a video clip viewing to share the significance of having his students engage with a complex problem such as the Tower of Hanoi. He stated, "I think the Tower of Hanoi is complex enough, at least in middle school [that] I want them to learn how to persevere. It is one of the standards." He was not quite sure how to teach perseverance ("I don't know how to do it"), but he believed that posing a challenging task would create the conditions for his students to persevere. This notion is corroborated by the email Ezio sent us the day prior to filming his class in which he briefly laid out his goals and plans for the class. He noted that "most will not be able to determine the equation for Tower of Hanoi even with the hints I give them...I am willing to leave the problem 'unsolved' for those who are not able to figure it out." Ezio anticipated that "most" students would struggle, thereby, creating a situation in which they would persevere.

We learned in the debrief about Ezio's epistemic stance regarding the importance of perseverance in math learning. Ezio shared his "personal belief" that all students will experience a potentially insurmountable challenge in mathematics. He described this experience as "hit[ting] a wall," one that "everybody hits." Ezio described all math learners, including himself and the greatest of mathematicians, as eventually "hit[ting] a breaking point" but that the key is to "[learn] how to overcome [it]." Ezio distinguished those that "reach that breaking point and...give up" from those "who continue the struggle…[those] who will succeed in math." For Ezio, *hitting the wall* is a defining moment where one decides to either concede to not being capable enough or, contrastingly, persevere and "overcome that breaking point." While he said that he does not "do a good job of teaching [students] how to persevere over those obstacles," the Tower of Hanoi gives him "the opportunity to focus in on that."

Classroom Excerpt: "Maybe you haven't tried hard enough"

To understand how Ezio designed for and enacted perseverance in his classrooms, we describe what we termed as Ezio's "cycles of perseverance" in light of his epistemic stance. The cycle begins with a challenge beyond students' conceptual reach, in essence directing them to a "wall," and concludes with Ezio's scaffolding them over the wall of struggle.

The 90-minute lesson was replete with intensive mathematical work by 31 eighth graders. It was built around two mathematical tasks: a warm up with visual patterns representing a linear function (around 30 minutes), and the Tower of Hanoi (around 60 minutes). The episode discussed here is focused on the second task. It began with a playful introduction from Ezio, where he teased students about being "a bunch of babies" necessitating the use of toys to which students responded with smiles and baby voices.

Two cycles of perseverance. Students were seated in seven groups of four to six but working primarily in pairs. Ezio systematically circulated between the seven groups, conversing with students about their work, occasionally teasing them ("Maybe you haven't tried hard enough"). In our analysis of classroom events, we identified that Ezio designed for and enacted perseverance in his classroom in two cycles, each consisting of "a wall" and a scaffold (see Table 1). We highlight here two cases in which Ezio paused the groupwork to scaffold the whole class: first, to supply them with "a cheat", and second, to aid them in synthetically manipulating their empirical results to arrive at the function, $f(n) = 2^n-1$.

Table 1: Two Cycles of Perseverance, Each Consist of a "Wall" and a Scaffold

Cycle	The "wall"	The scaffold
Cycle 1	Ezio asking students repeatedly, how they know their result is the minimal possible number of moves?	"the cheat" - explains the recursive rule (i.e. how to find the answer for n rings according to the answer for n-1 rings).
Cycle 2	Ezio asking students, what would happen if they had 100 rings? (i.e. the recursive rule does not help)	the table - manipulate results to find the general function f(n)

Cycle 1. Ezio introduced the Tower of Hanoi and ensured all student pairs understood the task. As students began to collect and annotate their initial empirical results, Ezio circulated to six of the seven groups asking them "how do you know that's the fewest [number of moves]?" He repeatedly asked this question without waiting for or following up with students for a response. Moreover, the students continued to explore it empirically (i.e. trying to move rings in less moves) without discussing the question posed. We account for this question as the first "wall". Ezio followed this up with a whole-class scaffold where he explained "the cheat". The cheat represents the recursive nature of the task which allows one to easily solve for any number of rings n, given the result for n-1. For example, one can determine the least number of moves for 4 rings by building on the least number of moves for 3 rings. (we do not bring the full explanation for lack of space). We want to be explicit regarding the assumptions under which we consider this teaching move to be an over-scaffold: explaining to students the recursive rule is over-scaffolding *if* the teacher aims for student discovery of mathematical ideas. In the case where the teacher's goal is to directly teach the idea of recursive functions (which is not the case in hand), we do not consider this move to be an over-scaffold but rather an instantiation of direct instruction. Upon explaining "the cheat," Ezio prompted several groups to replicate the "cheat" or recursive rule by asking questions such as "If you know [the number of moves for] 4 [rings] can you show me 5?".

Cycle 2. After having students demonstrate the recursive rule, Ezio introduced them to the next wall: how could they determine the minimal number of moves for 100 rings? Here the recursive rule only works if students have generated the minimum for 99, 98 etc. Ezio followed up with another scaffold in the form of a table (distributed on a hand-out) where they could determine the number of minimal moves for n rings, into the function $2^n - 1$, only by way of a synthetic manipulation. As one example, for n=3 rings, students were instructed to: (a) find the minimal number of moves (7); (b) add one (8); (c) do prime factorization (2^3); and (d) write the final power form [$f(n) =2^3$]. Students were then asked to find a relationship between the final power form [$f(n) =2^n$] and the function [$f(n) =2^n - 1$]. Again, we view this as an over-scaffold in the sense that it does not center sense-making but rather guides students almost directly to generating the function.

Conclusion of classroom analysis. Our analysis shows that students moved back and forth between both edges of their collective ZPD as described by Sengupta-Irving and Agarwal (2017) as moments of "unnecessary struggle" and "no struggle" (see Figure 3). Ezio's questions (the "wall") placed students to the right edge of the ZPD students creating unnecessary struggle as students appeared to have few, if any, conceptual resources to answer the questions. Following their struggle, students were strongly scaffolded either directly by Ezio's whole-class explanation of "the cheat" (rooted in his enactment of the task) , or by the table on the handout (rooted in the design of the task). To conclude, Ezio's design and enactment of the Tower of Hanoi placed his *perseverance as persistence* at odds with sensemaking, all the while leaving out problem solving heuristics as a potential avenue for aiding students in discovery and sensemaking.

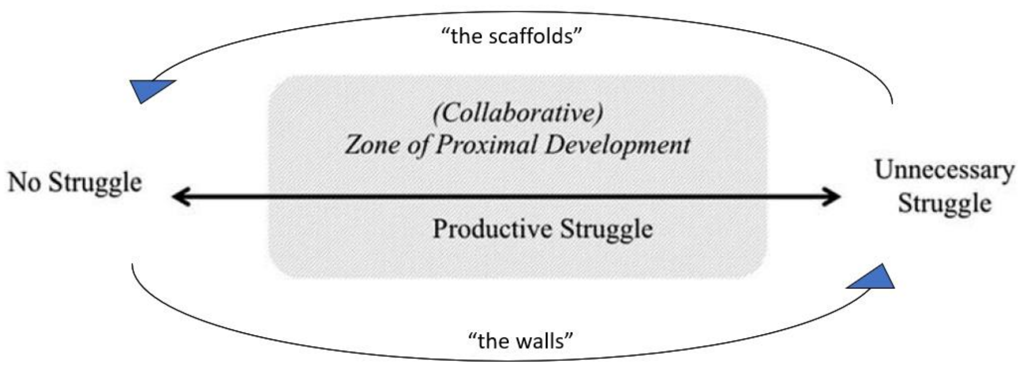

Figure 3: Cycles of "Walls" and Scaffolds Outside of Students' ZPD (adapted from Sengupta-Irving and Agarwal, 2017)

VFF Debrief Conversation

While we posit that Ezio's enactment of perseverance fell short of engaging students' sense-making in the task, we also acknowledge our own shortcomings, as teacher educators, in unpacking perseverance. During the debrief we did mention all three dimensions of perseverance, albeit in isolation from one another. For example, the coach (author one) confirmed that, in her view students were persevering (read: persisting), an observation supported by the partner teacher and the other researchers present. Secondly, she recognized that students were persisting through the activity but not verbalizing their thinking of how to reproduce the same number of (minimal) moves from one trial to the next. Consequently, the coach offered Ezio the heuristic of "solve a simpler problem first" (Polya, 1945/2004) strategy as a possible scaffold to center students' sensemaking in the lesson. The coach suggested this heuristic to Ezio as a scaffold to have students think about how and why they can consistently reproduce the transfer of 3 rings in 7 moves. By understanding the logic of the simpler problem, students could then discuss with their peers how to reproduce the transfer in the fewest moves and apply it to 4 rings, 5 rings, and so on. Essentially, they would be discovering and making sense of the "cheat."

As Ezio reflected on his "fear [that] they would waste so much time on the counting…[and not get] in-depth with anything else," he acknowledged the suggested heuristic as an important scaffold that would have accomplished students going "in-depth" with the problem. Veronica also acknowledged the value of giving challenging problems, as a first step, and the importance of teaching students problem solving heuristics. Ezio returned to the suggested heuristic several times as his big takeaway from the debrief in thinking about future ways to aid his students discovery of the "cheat" on their own.

Discussion

In the debrief, we discussed all the units of persistence, sense-making, and heuristics but did not explicitly connect the dots between them as constituting what we now propose as a conceptualization of perseverance. As researchers, we have the privilege to grapple in-depth with the in-vivo problems of practice we encounter as teacher educators. The discursive resources our analysis has generated were not available to us at the time of the debrief. Without an elucidated conceptualization of perseverance, we were also conflating perseverance as persistence as we too noted students not giving up in the absence of sense-making. Although the coach suggested a heuristic scaffold, it fell short of addressing the full mathematical practice of *make sense of problems and persevere to solve them,* by not connecting persistence to sensemaking.

Interestingly, as Ezio described the "wall" and hitting that breaking point, he reiterated that those that make it (i.e., persevere) in mathematics "learn *how* to overcome it" as opposed to those who "mentally give up on math." It bears noting here that Ezio is wondering how to help students overcome that breaking point. Learning *how* to overcome is distinct from pushing through (persistence). Overcoming a breaking point implies being able to access some internal or external resources that could shed some insight into the given hurdle, a resource such as a problem solving heuristic. Moreover, his comment about "mentally giv[ing] up on math" implicates the cognitive demand of mathematics which is more than the will and heart to continue--more than persistence. "Mentally giv[ing] up on math," seems to suggest a person not making sense of the mathematics or hitting a wall in which a path forward seems insurmountable. Although Ezio is unable to tease this out, and we are unable to support him in doing so, he does have the initial instinct and foresight to know that he wants to offer students some type of tool or heuristic that they can use in a general sense to overcome mathematical challenges.

In sum, a deeper analysis of Ezio's stance on perseverance merited more attention. As coaches, we were limited by an insufficient conceptualization of perseverance beyond persistence much like Ezio in his design and enactment of it in the classroom. While the coach was able to suggest a scaffold that served as a heuristic for the sake of making sense of the task, we were limited in explicating a formidable relationship between persistence, sense-making, and problem solving heuristics as constituting perseverance, his long term goal for his students.

Acknowledgments

Both authors contributed equally to the paper. We are thankful to the participating teachers and to Darryl Yong and the research team for their feedback on different stages of work: Ilana Horn, Grace Chen, Brette Garner, Lara Jasien, Samantha Marshall, Katherine Schneeberger McGugan. SUPPORTING BEGINNING TEACHERS TO ENGAGE IN RELATIONAL INVESTIGATIONS OF TEACHING AND LEARNING

Mallika Scott
California State University, Fullerton
malscott@fullerton.edu

This paper examines a social design-based approach to supporting beginning elementary school teachers toward ambitious and equitable mathematics teaching. First-year teachers were enlisted as co-designers of a learning community aimed at supporting participants to build classroom math communities that leverage students' diverse mathematical resources. Findings show that teachers collectively moved from thinking about teaching as fixing local problems to engaging in relational investigations of teaching and learning that centered students' mathematical experiences. This shift supported teachers to take up and make progress toward complex problems of practice in their classroom teaching. This study has implications for how we conceptualize, analyze, and design for equity-oriented learning for beginning teachers.

Keywords: Mathematics education, Instructional Vision, Equity and Diversity

> "I just feel like I have this huge moral dilemma. The math benchmarks are coming up and I have to cover all these things…it's just weighing on me. And there have been a couple periods where I haven't been the math teacher I want to be."
> Kara, Elementary School teacher, October 2016

Kara, a recent graduate of a highly-regarded teacher preparation program, is not alone in facing the moral dilemma of being committed to a vision of teaching that does not yet exist in schools on any wide scale. Schools in the US tend to be organized to sort students by various measures of "achievement" (standardized tests, "math benchmarks" etc.), searching out what students do not know rather than building on the reasoning evident in what students *are* doing (McDermott & Raley, 2011). This fixation on sorting produces winners and losers in ways that intersect with social hierarchies and inequities, resulting in students from some nondominant communities continuing to be constructed as "struggling" or "failing" (Martin, 2003, 2009). Given the high status of mathematics in the US and the ways mathematics achievement is often conflated with intelligence, math classrooms can be fertile ground for perpetuating the inequities endemic in systems of schooling preoccupied with finding deficits (Martin, 2009; Shah, 2017).

Scholarship on equity and mathematics teaching has helped to paint a picture of alternative classroom arrangements that can support robust learning for all students. In these classrooms, students are supported to make sense of complex ideas and to recognize and learn from the diverse strengths each student brings to mathematics (Boaler, 2008; Cohen, Lotan, Scarloss, & Arellano, 1999). Kara shares with other members of her cohort a deep commitment to this vision of ambitious, equity-oriented math teaching. Yet the pressure of having to give her 3rd grade students a "math benchmark" assessment led Kara to sometimes focus more on whether students were producing correct answers on pages of multiplication problems than on noticing and building on the diverse ways they were making sense of multiplication.

It is often assumed that a reasonable goal for new teachers like Kara is to "survive" their first year, not to take up an ambitious agenda. In line with this assumption, the support offered to beginning teachers tends to be geared toward generic teaching topics (Ingersoll & Strong, 2011; Mehta, Theisen-Homer, Braslow, & Lopatin, 2015). New teachers are often left entirely on their own to figure out how to navigate the "huge moral dilemmas" that arise when they attempt to counter the culture of deficit that dominates systems of schooling, leading some teachers to either give up on their commitments or to give up on teaching (DeAngelis, Wall, & Che, 2013).

This paper reports on the learning that can become possible when support for new teachers is intentionally designed to provide opportunities to take on the challenges of equity-oriented mathematics teaching in a community oriented toward a shared vision. Specifically, I investigate how a learning community, named Math Crew by participants (of which Kara was a member and I was facilitator), supported first year teachers to engage in relational investigations of teaching and learning that centered students' mathematical experiences.

Theoretical Perspectives and Prior Research

In this section I describe the vision for mathematics classrooms that formed the foundation of Math Crew. I then explain the ways that research on social design and teacher learning informed the design of this teacher learning community.

Ambitious and Equitable Mathematics Teaching

Math Crew was formed to support teachers to create classroom math communities that are both ambitious and equitable. I join other scholars in using the term "ambitious" to refer to math teaching that provides students with opportunities to engage in cognitively demanding math tasks and considers the ways students make sense of these tasks to be central to instruction (Jackson & Cobb, 2010; Kazemi, Franke, & Lampert, 2009). Further, I use the phrase "ambitious and equitable" mathematics teaching to point to a particular conception of equity underlying the shared vision held by Math Crew participants. In line with scholarship that interrogates the ways that our educational system continues to perpetuate disparate outcomes for different populations of students, I consider equity in mathematics teaching to mean not merely improving access to learning opportunities for all students, but also disrupting dominant hierarchies of power and privilege (R. Gutiérrez, 2008, 2013; Gutstein, 2003; Leonard & Martin, 2013; Martin, 2003). The vision underlying the Math Crew community is one that considers ambitious and equitable mathematics teaching to entail working toward a more just educational system where students from nondominant communities are assumed to have rich and diverse mathematical resources that benefit everyone's mathematical learning.

A Social Design Approach to Teacher Learning

Organizing classrooms to build on diverse mathematical strengths runs counter to the common discourse and practices of math schooling. Design responses to this challenge must therefore provide teachers with robust support that honors the complexity and dilemmas inherent in this work. Social design-based research approaches focus on designing activity systems that consider the tensions and contradictions participants encounter in their work to be resources for learning, rather than obstacles to be overcome (Engeström, 2011; Gutiérrez & Jurow, 2016; Gutiérrez & Vossoughi, 2010). In these approaches to design, participants are actively involved in co-constructing the supports they need to navigate the tensions they encounter (Gutiérrez & Jurow, 2016). By focusing on systems rather than individuals, social design-based research attends to the ways different aspects of design, such as the tools and artifacts provided and the participant structures used, work together to mediate learning toward a shared goal. Drawing on these principles, Math Crew was co-designed with participants to support teachers to navigate the tensions of attempting to enact ambitious and equitable math teaching while working in contexts where that vision was not widely shared.

In taking the activity system as the unit of analysis, I conceptualize teacher learning as changes in participation in teaching activities over time (Rogoff, 1994). I consider "teaching" to include classroom teaching with students as well as the planning, reasoning, and reflection that shape what happens in classrooms. For the design of Math Crew routines and my analysis of learning over time, I draw on in-depth studies of teacher learning communities that have identified generative activities for learning. These studies have found that conversational routines (e.g. replays and rehearsals of actual teaching) that support teachers to make connections between teaching choices and underlying principles of ambitious teaching can be productive sites for teacher learning and for analyzing changes in teachers' participation (Horn, 2005; Horn & Little, 2010). This line of research has also highlighted the importance of interactional norms that govern teacher activities, by noting, for example, the extent to which discussions function to either open investigation into "problems of practice" or close conversations to further analysis (Horn & Little, 2010; Little, 2002). Drawing on this research, the intention of the design of Math Crew was to create a space that invited deep collective investigations of problems of practice and supported participants to make connections to their shared vision of teaching.

In this paper, I analyze teacher learning in Math Crew by examining changes in participation over time. I find that participants moved from approaching teaching by trying to fix local problems to engaging in relational investigations of teaching and learning that centered students' mathematical experience as it connected to different aspects of the classroom learning ecology. As participants shifted to investigating from this relational perspective, they took up complex problems of practice in their classroom and worked on them over time in ways that were consequential for their students. Their learning coevolved across the Math Crew activity system and their classroom activity systems, with the travel across systems providing new resources for learning toward ambitious and equitable mathematics teaching.

Methods

This study grew out of my experience teaching prospective elementary teachers in a math methods course at a large public university. During their preparation, many of these teacher candidates developed a deep commitment to organizing their classrooms to build on students' diverse mathematical strengths. At the same time, they were daunted by the realities of working toward a vision for math classrooms that differed substantially from the focus on finding and fixing deficits present in many schools. With the aim of learning more about how to support beginning teachers toward ambitious and equitable math teaching, I invited six of these teachers to join me in creating a teacher learning community to provide support during the first year of teaching. These teachers were selected because they had each expressed commitment to equity-oriented math teaching during the methods course and would be teaching in local K-5 classrooms during the 2016-2017 school year. All six enthusiastically accepted, and Math Crew was created.

Table 1: Participants, Schools, Districts (all pseudonyms)

Math Crew Design

The design of Math Crew was grounded in two structures: monthly learning community meetings and classroom visits (4-6 over the course of the year) by me as group facilitator. Underlying both structures was a set of design principles drawing from literature on social design and teacher learning communities: 1) Participants must be actively involved in design decisions, 2) Tools, artifacts, routines, and participation structures should be oriented toward student and teacher strengths rather than deficits, 3) Conversational routines and participation structures should support collective investigation of problems of practice.

As participants were actively involved in shaping and reshaping Math Crew, monthly meetings and classroom visits were responsive to the needs of the community. Different routines developed over the course of the year, including sharing success stories and dilemmas from the classroom, doing math together to support our thinking about specific content, choosing focal students and discussing questions about these students, and looking for strengths in student work and discussing how to build on them. During the first two Math Crew meetings, we worked together to formulate our shared vision for ambitious and equitable math teaching. Out of these discussions, the group articulated their shared commitment as “building a classroom community where every student meaningfully contributes to the mathematical work of the classroom.”

Data Collection

Primary data sources include monthly two-hour, video-recorded community meetings, ethnographic field notes from classroom visits, audio-recordings of a focus group interview mid-way through data collection, and audio-recordings of individual closing interviews with each participant. For the purposes of this paper, video-recordings of Math Crew meetings serve as the primary data source, with field notes serving as a supporting data source.

Analytic Methods

To reduce the data, I created activity logs for the nine Math Crew meetings, breaking them into 8-10 minutes episodes and writing a summary of the activity with observer comments. During this process, the routine of starting each meeting with one participant sharing a teaching story about their classroom math community (suggested by a participant at our first meeting) emerged as an activity to investigate for changes in participation over time. This routine happened at six of the nine meetings and followed the same protocol. I created more detailed activity logs for these stories, chunking them in 3 to 5 minute episodes and writing detailed notes about the content of the episode and observer comments about emerging patterns. These conversations were transcribed and coded using an open coding process to capture teacher participation. I worked with a research assistant to begin to group codes and to identify patterns in the ways conversations evolved over time. Through this process we decided on a subset of

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

codes that best captured the changes we were seeing in the video-recordings. This analysis revealed two phases of activity marked by substantial differences in participation. The table below shows our condensed coding scheme.

Table 2: Coding Scheme to Capture Change Over Time

Code	Description	Example
Sharing students' mathematical actions	Describing mathematical participation of students	"He was able to, you know, interpret his own data and then come up with a question which is really hard and then answer his own question."
Connecting learning ecology with math participation	Relating how students are participating to an aspect of the classroom learning ecology	"It reminds me of Kara's story about Ahmed, like having different content kind of opening up different kinds of opportunities for kids."
Connecting to ambitious and equitable math teaching	Relating a teaching action to their shared commitment	"At the end of the day the kids are out of my room, I can take a breath and then I can actually look at their work and look at what they are doing and notice their strengths"

Findings

Over the course of the school year, participants brought different teaching stories to discuss in Math Crew as they tried to enact their commitment to ambitious and equitable math teaching. Analysis of the activity of making sense of teaching stories over the course of the school year revealed two phases of the activity: Phase 1 in which teaching was minimally investigated, where relatively simple solutions were offered to complex teaching issues with little connection to a broader vision for teaching, and Phase 2 in which Math Crew teachers began to investigate students' mathematical experiences as part of a complex classroom learning ecology. As teachers engaged in these relational investigations of teaching and learning, they increasingly connected their choices in the classroom, what they saw students doing in response to these choices, and their shared commitment to creating ambitious and equitable classroom math communities.

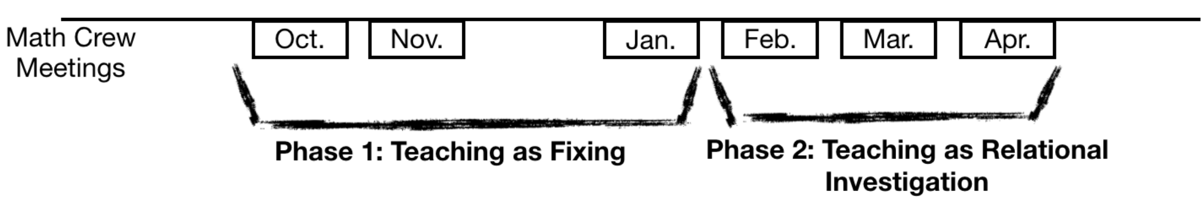

Figure 1: Change Over Time in Math Crew

During Phase 1, when teachers engaged in the routine of sharing a teaching story, both the telling of the story and the conversation that followed focused on relatively simple ideas or solutions. Teachers tended to talk mainly about the perspective of the teacher and to minimally investigate the reasons students may be acting in particular ways or to connect their actions to aspects of the classroom learning ecology. During Phase 2, stories or issues were still sometimes initially framed from the teacher perspective, but subsequent discussions of the classroom began to include investigating students' mathematical experiences and making connections between student actions and the classroom learning ecology. These discussions touched on many larger themes of teaching related to the Math Crew shared commitment to ambitious and equitable math teaching and often led the group to consider complex problems of practice such as how to support students to see value in each other's mathematical contributions or how to support students to recognize many different ways to be good at mathematics.

To provide a more detailed look at the changes in these conversations over time, I examined the ways teachers participated in these conversations, analyzing how teachers talked about mathematical participation and the connections they made to the learning ecology and to their shared vision. Table 3 shows the frequency and nature of these discursive practices during the story telling routine.

Table 3: Discursive Practices over Time

	Phase 1			**Phase 2**		
	Oct.	Nov.	Jan.	Feb.	Mar.	Apr.
Sharing students' mathematical actions	1	3	1	6	5	6
Connecting learning ecology with math participation	0	2	0	1	5	10
Connecting to ambitious and equitable math teaching	0	0	1	7	9	11

As is evident in the table above, during the first three Math Crew meetings, discussions of teaching stories were not well connected to students' mathematical actions, to how their actions related to the classroom learning ecology, or to their shared commitment to ambitious and equitable math teaching. The conversations during phase 2 included many more instances of connecting to the specifics of what students were doing in the classroom as well as connecting to themes and questions related to the Math Crew shared commitment of building a math community where every student meaningfully contributes to the mathematical work of the classroom. These discussions led to different articulations of teaching issues. Whereas in early meetings issues tended to remain local problems related to a particular classroom or lesson or to particular students, in later meetings even if issues were initially framed in local terms, participants made connections to larger problems of practice related to the shared vision of Math Crew and considered the issues from the perspective of how they might shift aspects of the classroom learning ecology.

Phase 1: Teaching as Fixing Local Problems

An example of this early form of discussing teaching stories where complexity was left relatively unexplored, occurred in the October Math Crew meeting when Tina shared a story from her 5th grade math classroom. She described a moment when a student shared an incorrect answer to a division problem, commenting, "another student turned around and said, 'WHAT?!?' And so right there and then I was like 'okay we need to refocus, this is not the way we talk to each other in math.'" Tina continued, "I had to remind myself just cuz I tell my students once, they are not going to immediately change their mindset and be able to be the kindest and nicest people in the world." In Tina's telling of this story, she described the issue as students not being kind to each other, with no exploration of why students might be responding critically to incorrect answers. Kara responded, "it kind of takes on this icky feeling of kids like really being critical of each other's thinking…And I really get on them for that, but I feel like there hasn't been a full change of attitude." Here, Kara continued with Tina's description of the issue as students being critical and then described her insufficient attempts to solve that problem.

The conversation lasted for nine minutes and the teaching responses generated were to "keep repeating yourself" because it takes time and to "write out our norms" so that everyone has an explicit visual reminder. These ideas are sensible, but they are limited and these limitations are directly related to how teachers made sense of Tina's story. The conversation focused on the perspective of the teachers, with the issue being understood as getting students to be kinder to each other. If the issue had been investigated in more depth and teachers had considered possible reasons *why* students might be responding negatively to incorrect answers such as students not seeing what they can learn from incorrect answers or not seeing value in each other's ideas (as were discussed in later Math Crew meetings), very different sorts of conversations about teaching could have been possible. These conversations might have made space for teachers to consider issues of status or of narrow cultural notions of what math is, which may have led to inquiry and teaching ideas more responsive to the complexity of the issue.

Phase 2: Teaching as Relational Investigation

During the February Math Crew Meeting, Tina brought a different story to the group that led to relational investigation and the identification of a complex problem of practice. Tina explained to the group that one of her students, Albert, had asked her if the reason they did math at the end of the day was because it wasn't important. She then decided to have her students respond to the writing prompt, "Do you think math is important? When do we use math outside of math class?" Albert was the only student who wrote that he didn't think math was important. She read his response to the group, and then commented, "so I have the question now of how I can continue to show the class that I do value math and that it is very useful…a lot of it has to do with growth mindset too with this particular student, if he's willing to open himself up to liking math." In Tina's initial description of the issue, she described it as a relatively simple issue of showing her students that "I do value math" and of Albert being "willing to open himself up."

In the 15-minute conversation that followed, participants investigated Tina's initial framing to consider possible reasons why Albert might not yet name math as important. Lauren commented, "What stood out to me was that the one reason he gave for being good at math was because he wanted to be smart which means he associates being good at math with being smart. And since he doesn't associate himself with math then he doesn't think he's smart." Maritza added, "Yeah, I kinda thought that he only associates math with calculations. He seems to think calculating numbers is boring so therefore, math is boring." Marie picked up on the theme of math and smartness, adding "what's so sad is that sometimes they are not the ones that told themselves they are dumb… just like recognizing that it is a bigger issue that we have in our culture about math and the value of it…It's just like a symptom of a larger problem." Here Marie pushed on what Tina offered as an issue of showing that she valued math and Albert being "willing" to like math by suggesting that Albert's writing could be understood as sensible given pervasive cultural narratives about what mathematics is and what it means to be good at it. The conversation then turned to how teachers might support their students to see math as a broader more inclusive space that is not just about calculation and how they might support individual students like Albert to be recognized as competent within that broad space. This problem of practice of upending cultural notions of what math is and what it means to be good at it is a much more generative space for equity-oriented teacher learning than the local problem of Tina needing to show she values math or of Albert needing to be willing to like math.

Summary of Shift to Relational Investigation

In Phase 1 of the activity of making sense of teaching in Math Crew, classroom stories were shared and discussed in ways that offered some new teaching ideas. These conversations provided teachers with space to make sense of teaching together and offered new resources for classroom teaching such as posting norms and giving students new ways to respond to each others' thinking. In Phase 2, as teachers dug deeper into teaching stories from a relational perspective that centered students' mathematical experiences, they participated in ways that created many more opportunities for equity-oriented learning. Lauren and Maritza analyzed the specifics of what Albert was saying and then connected his writing to broader issues of teaching and learning. Marie connected Albert's perceptions about himself and about mathematics to dominant cultural narratives about mathematics. Participants suggested teaching responses to shift the classroom learning ecology toward their shared vision such as providing students with opportunities to recognize each other's mathematical strengths. Throughout this conversation, participants considered Albert's perspective and connected his mathematical experience to different aspects of the learning ecology and to ambitious and equitable mathematics teaching. These ways of participating were generative for the conversation in that they led to new ways of understanding the issue and they were generative for ongoing teacher learning in that analyzing and problematizing what we think we see in the classroom is integral to creating a classroom math community that functions very differently from what is currently typical in schools.

This shift toward relational investigation supported teachers to try out new practices in their classroom teaching that were responsive to the complex classroom learning ecology. For example, the story described above about Albert was part of Tina's investigation over time into the problem of practice of expanding students' conceptions of mathematics and mathematical competence. The investigation of Albert's experience both during this conversation and during my visits to the classroom prompted Tina to implement new routines to provide students with structured opportunities to recognize each other's mathematical strengths. After the conversation described above, Tina drew on ideas offered from different participants to try out a new routine of having students write down each other's mathematical strengths at the end of partner math tasks. By the end of the year, Tina reported, and I observed, that students were spontaneously noticing and naming each other's mathematical strengths using specific mathematical language (e.g. "finding easier ways to count the cubes using multiplication and arrays", field notes 4/12/17) even when she did not use this routine. This indicates that Tina's relational investigation led to shifts in her teaching that were consequential for her students.

The shift from engaging with teaching as fixing local problems to engaging in relational investigations of teaching and learning supported Math Crew teachers to think deeply about their classroom learning ecology, to take up complex problems of practice, and to work on them over time in ways that were responsive to students' experiences of mathematics. This new equity-oriented learning became possible because participants were part of a community oriented toward a shared vision that fostered new forms of activity such as supporting teachers to come to see the mathematics classroom from their students' perspective.

Conclusion

In Math Crew, first-year teachers moved beyond focusing on the overwhelming list of day-to-day concerns that tend to dominate for most first-year teachers to dig into complex problems of practice and to consider how their teaching choices might shift the classroom learning ecology to support each student to meaningfully contribute to the mathematical work of their classroom.

The first year of teaching is often talked about in terms of "survival" rather than in terms of possibility. I offer Math Crew as a counter story to deficit narratives about the first year of teaching with the aim of raising both our sense of possibility and our sense of responsibility about supporting beginning teachers toward ambitious and equitable math teaching. If we hope to support this type of equity-oriented learning, this case suggests that it can be productive to move beyond thinking about the knowledge and practices we want teachers to master to think about the systems teachers are working within and how those systems can make available new forms of activity. Future work could build on these beginnings to investigate how we might design and support teacher communities oriented toward a shared vision across different pre-service and in-service contexts to support robust teacher learning.

Technology-mediated simulations of teaching practice are becoming a more common way to introduce teachers to the dilemmas of teaching during professional development. In this paper, we show that the inclusion of markers of student emotions in cartoon-based scenarios of teaching changes teachers' appropriateness rating of the actions that the teacher took in the storyboard. Our results show that the inclusion of markers of student emotions in representations of practice could cue teachers into a particular judgments of action.

Keywords: Instructional activities and practices; Affect, Emotions, Beliefs, and Attitudes; Technology

Computer-based virtual environments, using avatars to represent students, have grown in popularity in both teacher education and educational research (Gibson, 2007; Herbst, Chazan, Chen, Chieu, & Weiss 2011; Ma et al., 2016; Straub, Dieker, Hynes, & Hughes, 2014). While such environments have been used to engage teachers in the cognitive and rational aspects of teaching, they are not frequently used to elicit teachers' reasoning related to more affective aspects of teaching (Lehtonen, Page, Miloseva, & Thorsteinsson, 2008). However, similar technology, using avatars in virtual environments, have been shown to be effective in helping individuals gain increased understandings of social situations (e.g. Cheng & Ye, 2010; Tettegah, 2005). This suggests the potential for such environments for supporting teachers' engagement with the more emotional aspects of teaching.

This is good news, given that emotions arguably play an important role in teachers' decision making (Demetriou, Wilson, & Winterbottom, 2009; Hargreaves, 1998; Zembylas, 2005). For some time now, we have known that emotional intelligence —the ability to perceive one's own emotional state—has evident value in professional circumstances (e.g. Jaeger, 2003; Lopes et al., 2006), including playing an important role in teacher's job satisfaction and organizational commitment (Naderi Anari, 2012). Beyond the many studies on teacher's emotional intelligence, there is reason to believe that the broader construct of emotional competence—the ability to recognize and understand the emotions of others—may be highly related to improved outcomes for student learning (Jennings & Greenburg, 2009). This hypothesis seems reasonable in light of recent findings that the relational aspects of teaching are as important as the cognitive aspects for student outcomes (Battey & Neal, 2018). Knowing how teachers' emotional competence shapes their work is particularly important given they often have to know what people are feeling without having to directly probe them to report their feelings—e.g., reading students' emotions when in the midst of teaching. However, learning to effectively read facial expressions is non-trivial and particularly challenging during instructional transactions where there exists a power differential between the individuals, as is the case with teachers and students (Galinsky, Gruenfeld, & Magee, 2003). Yet, little work in the field has aimed to gauge or support teachers in gaining such competencies (Hargreaves, 1998).

We see the work we describe in this paper as adding to this literature about the role of emotions, in particular teachers' emotional competence, in teaching. We have been designing scenario-based assessments to understand teachers' reasoning about mathematics instruction. In that work, we have been cautious about using facial expressions because of our own lack of certainty about how facial expressions might impact the ways in which participants' judge the instructional actions represented within such items. More specifically, we have been uncertain whether the addition of facial expressions might bias the items for individuals more capable of reading facial expressions (in both human faces as well as within cartoon representations). In that context, we have been wondering whether and how emotions represented on cartoon-based representations of students in classroom scenarios of practice play a role in the ways that teachers appraise the scenarios of teaching.

Theoretical Framework

Digital simulations of teaching use a variety of semiotic resources to represent the individuals and settings of practice. Icons, language, and dashboards (e.g., in SimSchool, Gibson, 2007) are three kinds of semiotic resources frequently used for students to respond to instruction, but for each of those a limited variety of systems of choice are available. Herbst et al. (2011) argue that graphic representations of teaching practice using two-dimensional, nondescript icons to represent teacher and students can display nonverbal aspects of teaching practice. They argue that comic-based representations can represent the same meaning as, for example, textual accounts of practice. Herbst and Chazan (2015) suggest that ***lean***, ***nondescript*** graphic elements allow the designer to easily represent practice as emergent in mathematics classroom interactions and enable viewers to project into those characters their own settings and clients—in contrast with avatars whose graphical features are used to mark high individuality. In a follow-up study, Herbst, Boileau, Clark, Milewski, Chieu, Gürsel, and Chazan (2017) show that this lean cartoon-based semiotic system can be expanded to include signifiers for complex social constructs such as race and ethnicity. In their comparison of the written story and the storyboard for the Case of Mya (Chazan, Herbst, & Clark, 2016), Herbst et al. (2017) conclude that the storyboard representation encouraged a plurality of interpretations of the same case, both expected and unexpected.

Following this line of inquiry, our lab has begun exploring whether emotions can be encoded using a similarly lean semiotic system when representing professional scenarios of teaching. One crucial foundation for that work is the well-established line of research from Ekman and colleagues who developed the facial action coding system (FACS) (Ekman & Friesen, 1978)—an analytic scheme for precisely describing various configurations of human faces as functions of muscle movements. The FACS has made possible the cataloging of human facial expressions for reliably representing human emotion interpretable by humans across cultural boundaries (Ekman & Friesen, 1986). The reliable interpretation of emotions based on facial expression representations suggests that the ability to interpret facial expressions is an important aspect of emotional intelligence (Keltner, Sauter, Tracy, Cowen, 2019). The FACS has also been used to inform the development of animated and cartoon facial expressions (McCloud, 2006; Thórisson, 1996; Spindler & Fadrus, 2009).

In this paper, we leverage the FACS to modify the default expressions of a set of cartoon characters we call the Thexpians B (Herbst & Chieu, 2011) to include lean semiotic markers of emotions (Dimmel, Milewski, & Herbst, 2015). For example, Figure 1 shows the affordances of the facial expression semiotic system to represent student emotions. In both panels of Figure 1, a student disagrees with a peer who has critiqued his shared solution. In the left panel, the student's eyes and mouth express a neutral state. In the right panel, we added to the eyes triangular-shaped eyebrows that slope inward and changed the shape of his mouth from round to triangular to represent the emotional state of anger. These changes are meant to communicate the emotions associated with that specific moment.

In previous work, we have compared these kinds of lean renderings of facial expressions with that of facial expressions as represented by human actors and demonstrated that participants are, in fact, able to interpret the cartoon-based representations of emotion with similar levels of accuracy to that of photos (see Dimmel et al., 2015). Here, we build on that work to ask how the addition of such expressions into scenarios of teaching make a difference for participants' judgment of the instructional actions taken within such scenarios. To that end, we ask: To *what extent* and *how* does the representation of emotions on student avatars in a cartoon-based representation of practice change the way that practicing teachers judge the appropriateness of instructional actions of teacher avatars?

Neutral Character	**Emoted Character**

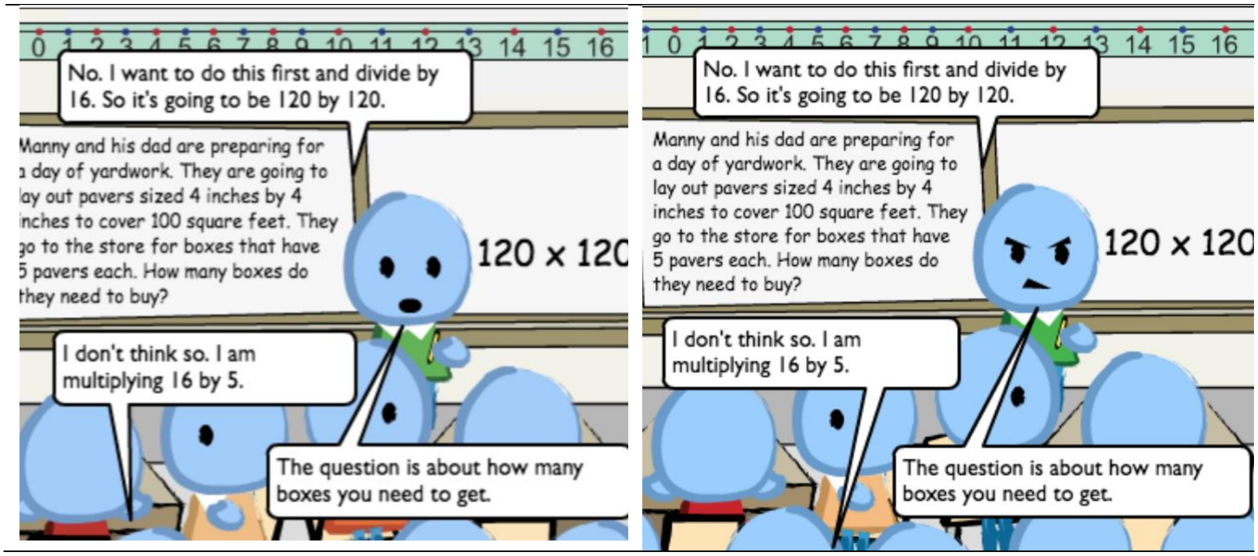

Figure 1: Neutral and Emoted Characters

Methods

Participants

In this study, we use a randomized control trial design to assess the extent to which representations of emotions impact teacher interpretations of scenarios of teaching. We recruited 69 participants from the respondent pool for the validation study of the PROSE instrument (Herbst & Ko, 2018). We randomly assigned participants to either the emoted or neutral experimental conditions. For the emoted condition, we edited the original PROSE items to include relevant facial expressions at the scenario turning point (as shown on the right pane of Figure 1). For the neutral condition, we removed all facial expressions from the original PROSE items. Instead, we represented all characters in the scenario using the neutral eye and mouth shapes (as shown on the left pane of Figure 1). Intuitively, comparing the responses to the emoted and neutral scenarios allows us to assess the extent to which the explicit representation of facial expressions in scenarios of teaching has an impact on teachers' interpretation of instructional actions.

Outcomes

The main outcome for this study is teachers' reactions to scenarios of instruction. To this end, we adapt the PROSE instrument (Herbst & Ko, 2018) to include facial expressions. The main outcome of interest of the unadapted PROSE instrument is teachers' recognition of professional obligations as a source of justification of instructional actions. In that instrument, teachers are asked to assess the extent to which a teacher instructional action was justified on the grounds of professional obligations (Herbst & Chazan, 2012). In the adaptation of this instrument to our study, we selected nine items[1] from the overall battery of twenty-four PROSE items for two possible reasons. First, following Milewski and Erickson (2015), we located items where a sizable number of participants indicated that their rating of the item depended on some assumptions they needed to make about the scenarios—we call these *high construal items*. We scanned teachers' responses to high construal items to locate items for which participants professed needing more information about the emotions of the student avatars—we call these *high emotional construal items*. For example, participants indicated their rating depended on whether or not a student in the scenario was upset. Accompanying these responses, we also found many participants that assumed that the represented student was in fact upset (even though the expression on the student's face was neutral in the item). That said, not all responses contained references to emotion and presumably some participants did not construe emotion into the item and thus the inclusion of emotional cues into the item might alter the way that participants respond to the item. Using this heuristic, we located seven items for inclusion in the study. Second, some items in the original PROSE instrument included some facial expressions which participants could have interpreted as emotions. We call these items *PROSE emoted items* and for the purposes of this study selected two such items. For all of these items, either the data or the original design of the item led us to believe that emotion may have been part of the way that participants were reasoning about their judgments. Our main outcome of interest with these adapted items from the PROSE instrument was to understand more about how the inclusion of facial expressions as markers of emotion was affecting the ways in which participants' rated the items. Figure 2 reports a brief synopsis of each item and whether it was selected for its high emotional construal or PROSE emoted items.

Participants also completed an emotion recognition questionnaire (Keltner et al., 2019). This instrument shows participants photographs of trained actors displaying emoted facial expressions and asks participants to identify the corresponding emotion. We also administered a parallel version of this instrument (developed by Dimmel et al, 2015) that uses our cartoon characters—using cartoon-based shapes for eyes, eyebrows, and mouth as well as changing their location in relation of the overall face to reproduce the facial expressions in the photographs. These two instruments allowed us to measure the extent to which our participants are able to recognize emotions in both photographs and cartoons. We use this information as a robustness check of our results.

Table 1: Description of Selected PROSE Items

Item	Description	Type
a1012	A/n (embarrassed) student shares a solution to a problem on the board. The teacher asks others to build on that solution strategy.	High Construal

[1] One item was removed from these analyses because of a mistype in the question prompt.

a3012	A student is sharing her/his solution on the board. Another student in the classroom suggests another solution strategy and the student at the board responds (with anger). The teacher compliments the students handling the disagreement.	High Construal
a3022	The teacher is asking questions to the class. One student answers all the questions, while other (frustrated) students look on. The teacher calls on students by pulling names from a cup.	High Construal
a3032	A (confused) student privately asks the teacher a question. The teacher asks the student to ask the question out loud to the class.	High Construal
a3102	A student tells the teacher that she/he is done with her work. The teacher asks her/him to help other students instead of working on the homework and she/he (begrudgingly) complies.	High Construal
a3112	A teacher ignores volunteering students to cold-call a (confused) student to publicly share a definition of a term.	High Construal
a3152	A student is solving a problem on the board. The teacher asks her/him to start over because other (frustrated) students cannot read the writing.	High Construal
a3162	Teacher offers magnets to (excited) students. When many students volunteer, the teacher decides to raffle the magnets.	Emoted PROSE

Analysis

Our data is nested both within respondent and item. That is, we asked the same participants to answer multiple items. As we are interested in the effect of facial expressions on the overall evaluation of the instructional action, we use a multilevel linear model to account for the nesting of responses within participants and items. In detail, we use a mixed effects model (Raudenbush & Bryk, 2002) with crossed participant and item random effects. We fit the equation

$$Y_{pi} = \beta_0 + \beta_1 \cdot Emoted_{pi} + u_p + u_i + e_{pi}$$

where u_p is the participant-level random effect accounts for participant-level differences in the assessment of the instructional action that is unrelated to our experimental condition, u_i is the item-level random effect accounts for item-specific differences in the assessment of the instructional action that are due to contextual factors embedded in the specific PROSE instrument. The coefficient of interest is β_1. This coefficient estimates the causal effect of including facial expressions (i.e., the difference between seeing an emoted item versus a neutral item) on participant assessment of the instructional action represented in the PROSE items.

Results

Effect of Emotions on the Assessment of Instructional Actions

Table 1 reports the estimates of the effect of facial expressions on teachers' assessment of instructional actions. Column 1 reports the results of the unconstrained mixed effects model, column 2 reports the effect on the raw assessment score (1-6 Likert scale), column 3 reports the same effect in standard deviation units. Columns 4 and 5 report the results of robustness checks testing whether our main results are sensitive to participants' recognition of emotions in photographs or cartoons.

We find that the inclusion of facial expressions in scenarios of teaching has an impact on teachers' assessment of instructional actions of, on average and in absolute value, 0.356 points on a 1-6 Likert scale or 0.280 standard deviation units. This result appears to be robust against participants' recognition of emotions in photographs or cartoons. That is, the magnitude of the effect does not change after controlling for participants' emotion recognition in photographs and cartoon images. This allows us to conclude that participants' change in their assessment of the instructional actions in emoted items is due to the emotions that are represented in the characters facial expressions. If this was not the case, we would observe a change in the estimated effect once controlling for participants' emotion recognition.

Table 2: Average Effect of Facial Expressions on the Assessment of Instructional Actions

	(1) Unconditional	(2) Pooled	(3) STD	(4) STD + Cartoon Rec	(5) STD + Photo Rec
Emoted		0.356^{**}	0.260^{**}	0.262^{**}	0.267^{***}
		(0.111)	(0.081)	(0.082)	(0.081)
Constant	1.798^{***}	1.583^{***}	0.000^{*}	0.022	0.121
	(0.239)	(0.247)	(0.063)	(0.185)	(0.213)
Var(Resp)	0.014	0.000	0.000	0.000	0.000
Var(Item)	0.430	0.430	0.000	0.000	0.000
Var(Residual)	1.633	1.617	0.844	0.841	0.840
Observations	544	544	544	544	544

Note. The unconditional model reports the results of a cross-effect mixed model that controls fro respondent- and item-level variance components. Pooled results report the difference between treatment and control groups on raw item scores. Standardized results use the control group mean and standard deviation to center the raw scores. Standard errors in parentheses. * $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$

How Facial Expressions Affect the Assessment of Instructional Actions

We explore how facial expressions affects teachers' assessment of instructional actions by estimating the effect of the inclusion of facial expressions on each individual PROSE item. Figure 3 visually presents the differences between the emoted and neutral conditions in their assessment of the instructional actions in each of the eight PROSE items.

We note three main findings. First, in three items (a3022, a3012, a3101) the emoted scenarios received higher agreement with the normative actions than the neutral items. For the rest of the items, participants agreed less with the normative actions in the emoted items than in the neutral items. This finding suggests that facial expressions can both increase and decrease agreement with instructional actions. Second, we notice that all the 95% confidence intervals cross the red line at zero. This suggests that none of the differences that we observe are significant at the 95% level. This result likely indicates that our experiment was underpowered to detect significant differences in participants' assessment on each individual item. Third, even if these differences are not significant, we can still make inferences about the direction of these differences. That is, most of the confidence intervals for the negative point estimates are to the left of the dashed vertical line and most of the confidence intervals for the positive intervals are to the right of the dashed vertical line. This gives us evidence that the direction of the effect of emotions on participants' assessment of instructional actions is in the same direction as the sign of the point estimate for most items.

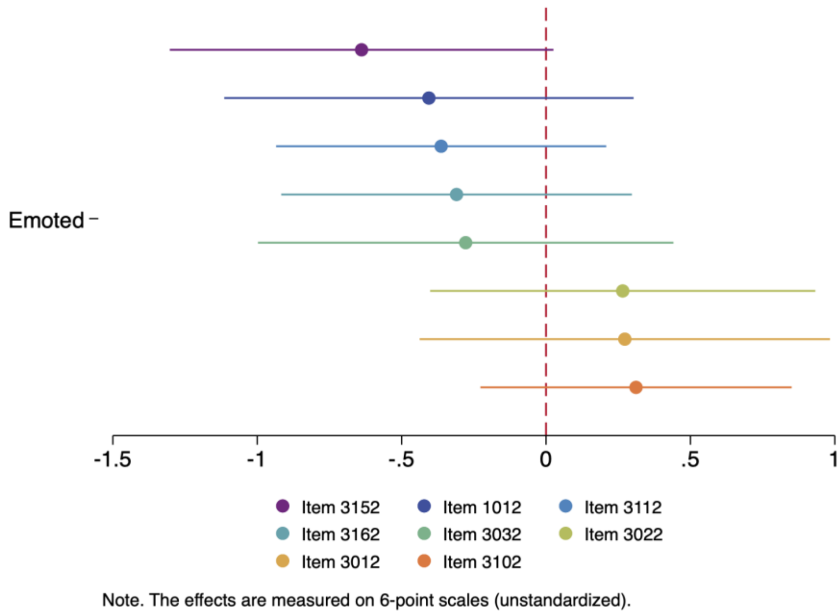

Figure 2: Effect of Facial Expressions on Each PROSE Item

Future Directions

Together these two analyses suggest that: (1) the inclusion of facial expressions for representing emotions can impact the overall participant agreement with instructional actions and (2) the direction of that effect is not uniform—that is it can cause participants to agree with the actions of the teacher more or less favorably. With that, we suggest that more work will need to be done to understand exactly how the addition of emotions makes a difference for participants overall rating of an item. To begin this work, we examine some of the more qualitative differences between the items for which the addition of emotional cues had differing effects. To frame our quantitative results, a positive difference between the emoted and neutral items means that participants who saw emoted items deemed the teacher resolution of the teaching dilemma as more appropriate than the teacher's normative (expected) action. Conversely, a negative difference between the emoted and neutral conditions means that the inclusion of emotions in the items made participants view less favorably the teacher's follow-up action.

With this in mind, we notice that the emotions in items where we have a negative difference are the direct result of the teacher's initial action, either (1) the teacher ignoring or being insensitive to a student's emotions (a1012, a3032, a3112) or (2) failing to anticipate students' emotions (a3152, a3162). For these items we see participants casting judgment on the represented teacher's actions. For example, after viewing a scenario in which a teacher overlooks students who are volunteering and cold calls a non-volunteering student with a confused expression, one participant reacted by saying "I prefer to acknowledge those who are willing to contribute *rather than embarrass those who are not. The students who did not raise their hands in this scenario look confused*." (*emphasis ours*, a3112, 4356). Similarly, after witnessing the teacher offer mementos to volunteers only to change her mind and draw sticks once students demonstrate excitement about the mementos, one participant commented "Teacher should have *planned in advance* to draw sticks, and told the students that's how they would determine who gets one" (*emphasis ours*, a3162, 5095).

For the items for which we observed a positive difference, student emotions are a consequence of other students' own actions and the represented teacher could be understood as resolving these situations (a3012, a3022, a3102). For these items, we see participants' responses supporting the teacher's actions, in spite of the students' emotional state. For example, in the context of an item in which a student prefers to move on to other homework rather than help his peers and the teacher insists he help his peers, one respondent said, "*This student is also being rude* by being bold enough to state that they are sure they are correct. I have had students like this is[sic] the past and they have often benefited from checking answers when they thought they had done all their work correctly. The idea of working in groups is so that everyone can benefit." (*emphasis ours*, a3102, 4571). These differences across the teachers' reactions to emotions in the items makes us wonder whether the source of the emotional reaction plays a role in how teachers develop an agreement with instructional actions. We plan to explore this insight in future work.

Discussion and Significance

With the increase in interest in student non-cognitive outcomes (Battey & Neal, 2018), it has become more important to understand the role of emotions in teacher decision-making (Hargreaves, 1998). In this paper, we explored how emotions play a role in teacher decision-making. We found that facial expressions communicate emotions in scenarios of teaching and that teachers are responsive to these emotions when reacting to a scenario of teaching. While the effect size of the inclusion of emotions in PROSE items is small to moderate (a quarter of a standard deviation), this effect is non-negligible. Unaddressed emotions in items, either construed or represented, could bias participants' assessment of instructional actions in ways that are difficult to predict a priori because facial expressions can both increase and decrease the direction of these assessments.

Our previous work suggests these facial expressions perform as well as photographs of emotions (Dimmel et al., 2019) This highlights the affordances of the semiotic system (composed of eyebrows, eyes, and mouths) in enabling the reading of facial expressions while dramatically reducing the number of tokens used for such denotation. This can help in designing new instruments to assess teachers' emotional competence. with the goal to support teacher professional development around the role of emotions in teaching.

These findings have important implications for the use of cartoon-based scenarios of teaching in teacher professional development. We can use facial expressions to include the role of emotions in instructional decisions. Different teachers might interpret the emotions differently. This could help in describing the variation in instructional actions due to response to emotions.

PROFESSIONAL GROWTH IN THE MATHEMATICS TEACHER AS AN INTERCONNECTED NETWORK OF CHANGE

James C. Willingham
James Madison University
willinjc@jmu.edu

This exploratory case study investigated interactions among internal and external factors and an elementary mathematics teacher's classroom practices and learning outcomes during a longitudinal professional development program. Data from the critical case of a teacher engaged in professional change supported an examination of the interaction of these domains and provided a rich narrative regarding the importance of these interactions in sustained teaching change. The model of professional change evidenced by this case adds to an expanding body of knowledge regarding the Interconnected Model of Teacher Professional Growth.

Keywords: Affect, Emotions, Beliefs, and Attitudes; Instructional Activities and Practices; Instructional Leadership; Teacher Education-Inservice/Professional Development

Introduction and Background

Three decades ago, an important transition in the study of mathematics teacher change began when the largely ignored question of how teachers' conceptions of mathematics affected their instructional practices was first widely considered (Thompson, 1984). Questions such as this expanded the focus on effective mathematics teaching from teachers' knowledge of mathematics to their conceptions of mathematics and its teaching (Ernest, 1989; Guskey, 1986; Philipp, 2007; Thompson, 1984). This shift highlighted that constructs including teachers' beliefs, views, and attitudes about mathematics were essential components of their teaching practices, that these practices slowly evolved in response to a myriad of other factors, and that teachers in transition operated in a dual reality between their espoused and enacted conceptions (Clark & Hollingsworth, 2002; Ernest, 1989; Guskey, 1986; Pajares, 1992; Philipp, 2007).

Recently, research has considered how these dispositions impact professional development in four important ways. First, the models examining the influence of teachers' conceptions on their classroom practices have grown increasingly sophisticated and begun to account for the nonlinear relationships among the factors involved in these relationships (Clarke & Hollingsworth, 2002; Wilkins, 2008). Second, a variety of professional development programs have supported long-term changes in teachers' conceptions of teaching mathematics and their associated practices (Garet, Porter, Desimone, Birman, & Yoon, 2001; Loucks-Horsley, Love, Stiles, Mundry, & Hewson, 2003; Wilson & Berne, 1999). Third, researchers have presented a diverse range of models to describe the stages through which teachers transition as their conceptions and practices evolve (Andreasen, Swan, & Dixon, 2007; Farmer, Gerretson, & Lassak, 2003). Finally, research has explored the impact of a multitude of other factors, such as the school setting, the teacher's perspective concerning professional development activities, and the types of learning activities implemented in the classroom, on teachers' conceptions and implementation of teaching practices (Clarke et al., 2013; Opfer & Pedder, 2011).

Purpose

A complete model of mathematics teacher development must describe the teachers' motivations and dispositions for their teaching as well as the influence of these factors on areas such as the teacher's implementation of learning activities, interactions with students and the classroom environment, and interpretations of professional development experiences (Goldsmith & Shifter, 1997; Opfer & Pedder, 2011; Wagner & French, 2010). The principal purpose of this study was to explore the interaction of these factors in an elementary teacher engaged in the process of mathematics teaching change during a longitudinal professional development program. This intent led to the primary research question of the study reported here: How do factors including a mathematics teacher's knowledge, beliefs, and attitudes influence her engagement in professional development and ultimately interact with her classroom teaching practices and student outcomes?

Theoretical Framework

A well-developed model of teacher change, the Interconnected Model of Teacher Professional Growth (IMTPG, Clarke & Hollingsworth, 2002), provided a lens through which to view teacher change throughout this study. In this theoretical model (see Figure 1), four domains identified by Guskey (1986) were expanded, and the relationships among them were described in terms of enactment and reflection similar to those posited by Ernest (1989). The domains of this model included the personal domain (knowledge, beliefs, and attitudes), the external domain (outside sources of information), the domain of practice (enacted classroom experiences), and the domain of consequence (salient outcomes involving student learning). Two processes, *enactment* and *reflection* mediated interactions among these domains. Enactment is the active process of operationalizing ideas from one domain into another, while reflection is a determined consideration of the experiences of one domain as they influenced another. The authors posited that interactions within these domains occurred within a specific *change environment* consisting of a particular set of elements, unique to each teacher, that would facilitate or inhibit experiences within each of the model's domains (Clarke & Hollingsworth, 2002).

Within this change environment, two types of teacher shifts arise as specific interactions occurred between the domains (Clarke & Hollingsworth, 2002). The first of these, termed a *change sequence*, occurred any time one domain exerted influence on another. These changes were often temporary and typically enacted in some form of professional experimentation quickly abandoned by the teacher. However, change sequences occasionally lead to further interactions between the domains, resulting in a more permanent transition. These extended interactions are part of a *growth network* and represented the product of teacher development.

Figure 1: The Interconnected Model of Teacher Professional Growth

Methodology

An exploratory, holistic single-case design (Yin, 2014) supported consideration of modeling teacher change with the IMTPG. The study focused on Gale Martin, a second-grade teacher, deemed significant as evidence from her engagement in an ongoing professional development project, Project Influence, indicated that she represented the critical case of a teacher displaying strong growth mindset characteristics and engaging in the processes of teaching change.

Data Collection

The data collected throughout the study focused on how Ms. Martin's experiences, beliefs, and practices influenced her described and observed mathematics teaching practices and her adaptation of a demonstration lesson for use in her classroom. Data sources included historical records of her mindset and beliefs, semi-structured interviews, classroom observations, artifacts of the observed and enacted demonstration lessons, reflective journal entries, and artifacts from Ms. Martin's lessons. The researcher collected this data across four stages, including a participant selection process, baseline classroom observations, Ms. Martin's engagement in the demonstration lesson through her professional development project, and her adaptation and enactment of the demonstration lesson in her own classroom.

Data Analysis

The researcher then organized this body of data in chronological fashion, corresponding approximately with the data collection stages described above, and completed a simple time series analysis (Yin, 2014). A holistic analysis of themes, "not for generalizing beyond the case, but for understanding the complexity of the case" (Creswell, 2012, p. 101), was performed for each stage of data through open coding with reduction of these codes into themes consistent with the theoretical framework. Themes emerging from each stage of analysis guided interpretation and coding of the next stage, with all stages revisited for completion.

The Participant

The researcher selected Ms. Gale Martin, a Caucasian female in her mid-thirties, as the critical case for the study. Rationales for this selection included historical survey data indicating persistent growth mindset characteristics, a positive record of changes in beliefs regarding the teaching and learning of mathematics, and observational records indicating a change in classroom teaching practices consistent with the mindset and belief data. Ms. Martin was an elementary mathematics teacher in her second year of teaching second grade and her fifteenth year of teaching elementary school who taught in a rural elementary school of approximately 330 students in a southeastern state, who was engaged in her third year of ongoing professional development for mathematics teaching.

The Demonstration Lesson

As part of the study, Ms. Martin observed a second-grade demonstration lesson conducted by the faculty of Project Influence with a lesson goal of "engaging students in thinking about subtraction with regrouping, while potentially representing the process symbolically" (Demonstration Lesson, October 28, 2015). The lesson involved students interacting with the following task in a problem-solving format.

> On Thursday, Tara was at home representing numbers with base-ten blocks. The value of her blocks was 304. When she wasn't looking, her little brother grabbed two longs and a flat.

> What is the value of Tara's remaining blocks? Use pictures, words, and/or symbols to describe how you solved the problem.

Students worked in pairs to solve the problem and participated in mathematical discussions across pairs, small groups, and the whole group under guidance of an expert teacher.

Results

The unique strength of a teacher's classroom practices exists in their ability to mediate the outcomes of their students' learning (Hiebert & Grouws, 2007). The IMTPG suggests that a variety of interactions among the domains described previously mediate both the practices the teacher selects and their students' outcomes, and a complete description of these interactions would be impossible in a report of this scope. Instead, this section contains a detailed description of the interactions between two sets of specific domains, the external domain to the domain of practice and the domain of practice to the domain of consequence. These exemplars then support a general description of the manner in which the IMTPG summarizes the teacher's experiences throughout Project Influence.

External Domain to Domain of Practice

Ms. Martin cited her involvement with immersion activities as one of the most impactful experiences of Project Influence and attributed much of the change she had implemented to these opportunities to experience effective teaching and learning practices first hand.

> I've told people this, and I'll continue to tell people this. Project Influence is the best professional development I've ever had, because it's so useful and it's so purposeful. It helps me be a better teacher, because I see it in action, I'm immersed in it. So it's not somebody standing in the room telling me all of these things I need to do, I'm in the middle of those practices. Us being the student with the teacher, helps us come back to our classroom and know how we need to do that with our kids. That's just been the most meaningful thing. (Selection Interview, September 9, 2015)

This description suggested that in addition to highlighting effective teaching practices these experiences provided opportunities to return to the classroom and experiment with new methods of instruction and to evaluate their success with elementary students. In addition to the practices she encountered, Ms. Martin also cited the influence of the project faculty who modeled these instructional techniques.

> [The Project Influence facilitator], just her enthusiasm and the way she ran the classroom, I really thought, "Hey, this is definitely something that I can do, I'm already doing a lot of this." So I guess it just fed into what I was kind of already doing. (Selection Interview, September 9, 2015)

This enthusiasm and affirmation of her teaching practices, both those that were effective and in place prior to involvement with the project and those adopted from the project itself, appeared to have provided continued motivation for change for Ms. Martin.

When asked to identify specific teaching practices that modeled during these activities, Ms. Martin described the facilitator allowing learners to have their own ideas and guiding conversations about mathematics from those ideas rather than toward solutions.

> The way she facilitated the classroom, the way she let us have our own ideas and never shot anybody down. That's another thing that I really like, we don't talk about answers. That was another thing that I had to change, because yeah, they want to know the answer, I want to know the answer, that's just something that you've always done. I've changed that also. (Selection Interview, September 9, 2015)

In this quote, Ms. Martin once again attributed specific changes in her classroom practices to her experiences during Project Influence and alluded to a belief about mathematics teaching, allowing learners to do the thinking about mathematics, which appeared to have evolved during her experiences with the project.

Domain of Practice to Domain of Consequence

Ms. Martin described the biggest change that had occurred in her classroom in recent years as involving a shift from problem performing to problem solving (Rigelman, 2007). She elaborated on how her changes in instruction had impacted her students' learning and described the importance of problem solving for her students.

> It is a big shift. It's probably the biggest shift that I have just seen, the impact that it has on their learning. They are learning, like the whole of problem solving is so important. . . for them to be able to have their own ideas and me not say, "Oh, this is how we're going to do it," or, me give them a thought or an idea and let them cling to that because they will. If they think that this is Ms. Martin's way, they want to do what Ms. Martin is doing. (Background Interview, September 18, 2015)

In describing this change in learning, Ms. Martin emphasized the independent problem-solving ability that had developed in her students. She contrasted this independent thinking with that of problem performers, who she described as focused on the solution to a problem rather than understanding the process of solving it.

> If you're just performing you're just giving an answer. Maybe you really don't know why you got that answer or how you came to that answer, you're just giving the answer because that's the final result. Problem solving involves so many more life skills that these kids are going to need, not just finding a solution, but there are just many different ways that problems can be solved and there's not just one right path and one right answer. (Background Interview, September 18, 2015)

The combination of independent thinking, a focus on deep understanding, and the ability to recognize that problems are solvable in more than one way formed the basis of the life skills Ms. Martin associated with her students' transition to problem solving over problem performing.

Later in the school year, Ms. Martin referenced how these changes in problem-solving approaches had caused other changes in her students' abilities to see connections between their thinking. She also described the reasons for this success.

> Well, for example today in math, I had them sharing out their examples or their solutions strategies to the test that we did at the end of class. And you would have certain kids say, "Well, my strategy looks a lot like Sarah's strategy." So they're mirroring or they're

> recognizing that their strategies looks similar to another strategy in the room. And here it is November, so we're moving along on that trajectory. And as far as continuing that, I think you just still tell them, pulling those cards and making everybody responsible for an answer. And they know that they're going to have to provide some sort of answer and some sort of discussion. (Point of View Interview, November 4, 2015)

In this quotation, Ms. Martin recognized that her students are progressing toward the goal of recognizing and connecting different mathematical ideas and attributed this success to her classroom practices related to accountability. She also expressed a desire to continue utilizing these practices in order to encourage and support these changes.

Support for the Interconnected Model of Teacher Professional Growth

The description of Ms. Martin presented here suggested a reflective practitioner deeply invested in the process of transitioning to reform-oriented instruction. However, the multitude of connections between Ms. Martin's conceptions of teaching and learning mathematics, mathematics teaching practices, experiences in Project Influence, and insights into her students' mathematical development offer substantial evidence that these change processes do not occur in isolation and require an extensive support network to initiate and maintain. Based on evidence regarding these factors and their relationships, I present a generalized growth network for Ms. Martin's change environment in Figure 2.

This growth network presents a model of the incremental changes Ms. Martin described experiencing throughout her time in Project Influence combined with the processes observed as she adapted a demonstration lesson from Project Influence for use in her classroom. In this generalized network, some conception of the teaching and learning of mathematics, such as Ms. Martin's valuation of students' thinking and communicating about mathematics or her ideas regarding the manner in which a specific piece of mathematics content should be taught, influenced her interpretations of and interactions during an activity from Project Influence (Arrow 1). Examples of these activities included immersion in a problem-solving task or the observation and debriefing of a demonstration lesson. Ms. Martin's reflections on this experience (Arrow 2) then served to either confirm or incrementally reshape the conception in question. Under the recent influence of this conception, Ms. Martin then adapted some aspect of the Project Influence experience, such as a new classroom norm, questioning practice, or mathematical task, for enactment in her classroom (Arrow 3). Reflecting on this enactment's outcomes, such as the success of a lesson or changes in her students' affect or mathematical understanding (Arrow 4), served to further reinforce or extinguish the conception (Arrow 5) and reinitiate the cycle through external interactions or further classroom experimentation. Although specific examples of this process appear later in this discussion, the current example serves to explain the general processes in play as Ms. Martin's beliefs and classroom practices changed.

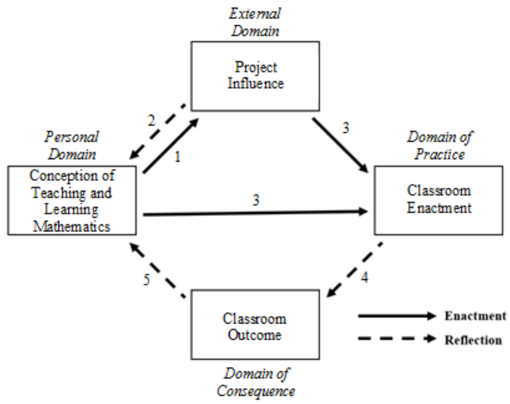

Figure 2: The Generalized Growth Network for Ms. Martin's Change Environment

Discussion and Conclusion

The generalized growth network for Ms. Martin's change environment models specific descriptions of her experiences in Project Influence combined with evidence collected as she adapted the demonstration lesson she observed as part of the study for use in her classroom. Three examples of the specific evidence for this growth network, one related to each of Ms. Martin's goal layers (Willingham, 2017), are provided here in order to illustrate their impact on the process of teacher change (see Figures 3, 4, and 5). These models each share a common pathway (Arrow 1 in each diagram) representing the influence of Ms. Martin's personal domain characteristics on her interpretations of her professional development experiences. Additionally, as the examples provide evidence of the same growth network pathways across different domain characteristics, the diagrams share common labeling of these pathways tailored to each diagram (e.g., 2a, 2b, 2c represent reflective pathways between domains at three different goal levels).

The first example, situated at the level of Ms. Martin's global goals, involves changes in Ms. Martin's beliefs and teaching practices regarding the value of students' thinking and communicating about mathematics (see Figure 3). Although the primary evidence for this growth network developed from Ms. Martin's descriptions of her changes in practices based on her earliest experiences with Project Influence, the network parallels the reinforcement of these beliefs and practices during her implementation of the demonstration lesson. In this growth network, Ms. Martin became involved with Project Influence due to her desire to continue improving her abilities as a mathematics teacher, which she attributed to her own growth mindset and love of mathematics (Arrow 1).

During her first experiences with Project Influence, Ms. Martin became aware of reform-oriented teaching practices related to the value of students' thinking and communicating about mathematics due to the modeling of Project Influence's faculty and witnessing these practices in use in a demonstration lesson. Based on these experiences Ms. Martin developed goals for her classroom aligned with these practices (Arrow 2a). Operationalizing these goals, Ms. Martin described adopting the norms and problem-solving approaches she had experienced in Project Influence to her own classroom (Arrow 3a), and noted the influence that these practices had on her students' abilities in this area, which she later described as students' classroom maturity (Arrow 4a). Ms. Martin described these changes as transformative to both her way of thinking about (Arrow 5a) and teaching mathematics (Arrow 3a) and elected to continue her involvement with Project Influence when given the chance (Arrow 1), initiating a cyclic process.

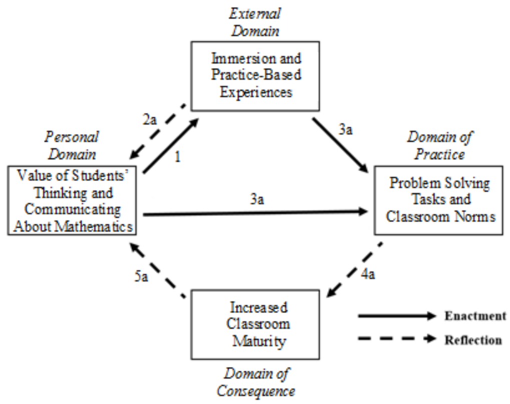

Figure 3: The Growth Network for Ms. Martin's Beliefs and Practices Regarding the Value of Students' Thinking and Communicating About Mathematics

In other iterations of this growth network, Ms. Martin's goals at different levels were involved. As an example, during her activities involving the demonstration lesson of this study, she described considering how the lesson matched with her envisioned mathematics learning trajectory (see Figure 4). Her reflections on aligning this lesson involved finding an appropriate place in the trajectory for its use (Arrow 2b) and planning for the lesson by preparing her students to engage with its content by referencing concepts from earlier in the year. She then considered the types of interactions she would use to address struggles she had witnessed from students in the observed demonstration lesson (Arrow 3b). Once the lesson was enacted, Ms. Martin reflected on its specific outcomes (Arrow 4b), and considered these outcomes in terms of the sequence of lessons and unit in which it was situated (Arrow 5b).

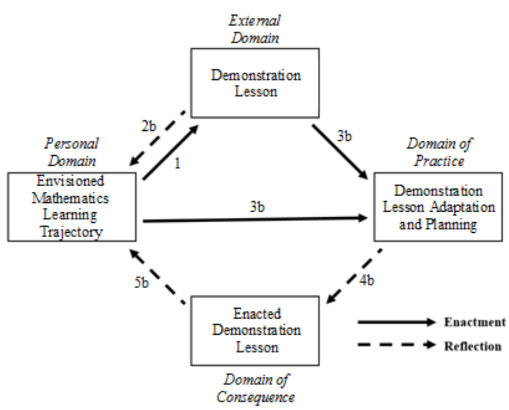

Figure 4: The Growth Network for Ms. Martin's Envisioned Learning Trajectory

The same set of contexts provide insight to the changes to the demonstration lesson Ms. Martin made based on her specific content goals for her enacted lesson (see Figure 5). In this case, her reflections from the demonstration lesson focused on the manner in which she would prepare her students to examine how different representations of numbers support thinking about numeric operations such as subtraction (Arrow 2c). These reflections, along with the core activity from the demonstration lesson, helped Ms. Martin prepare her students to work with this idea during the enacted demonstration lesson by scaffolding the idea in the lesson immediately preceding it (Arrow 3c). Immediately following this lesson Ms. Martin described monitoring her students' progress with the content goals of the enacted lesson (Arrow 4c) in order to determine the course of the remaining lessons in the sequence (Arrow 5c).

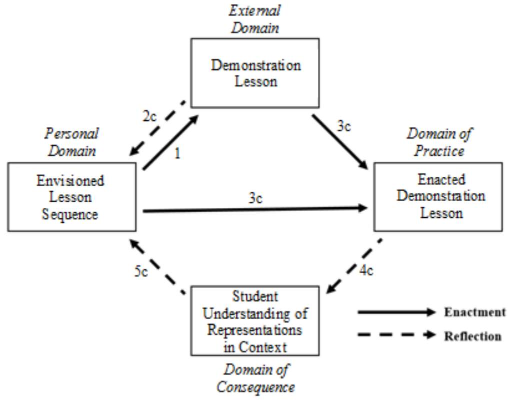

Figure 5: The Growth Network for Ms. Martin's Lesson Goals for Her Enacted Demonstration Lesson

Ms. Martin's descriptions supported interpreting the first example given here as reinforcing her current beliefs and practices due to her experiences with the demonstration lesson in this study. In this case, all three of the examples shown share the same form of initial change sequence as their first enactment pathways (Arrow 1 in Figures 3, 4, and 5). In these shared pathways, a goal-dependent conception of the teaching and learning of mathematics, each at a different goal level, influenced Ms. Martin's interpretations of the demonstration lesson. These layered change sequences then lead to unique connected growth networks in which the mediating pathways are identical while the specific domain foci are dependent on Ms. Martin's pedagogical goals. This highly connected, multidimensional growth network offers a potential explanation for why Ms. Martin's experiences in Project Influence were so influential on her beliefs and teaching practices.

Although Ms. Martin's circumstances are obviously unique, her case provides an exemplar for the manner in which a growth-oriented mindset mediates the internal and external factors of teacher change. For those involved in the development of mathematics teachers, two features of this mediation are the most instructive: the layering of mathematical goals at a variety of pedagogical levels, and the incorporation of explicit reflection in the translation of the activities and practices of professional development programs to the classroom. For Ms. Martin, these layered goals involved the personal growth of her students, the intentionality of her learning trajectory, and the core intention of a single mathematics lesson. Well-designed professional development programs should consider opportunities for participating teachers to define their own goals along similar levels, and then use these goals to frame explicit conversations regarding the manner in which key features of the program translate to the classroom to support their attainment.

EXAMINING OBSTACLES TO MATHEMATICS GRADUATE STUDENTS' DEVELOPMENT AS TEACHERS

Mary Beisiegel

Alexis Rist
Oregon State University
delonga@oregonstate.edu

As the field of professional development for mathematics graduate students evolves, there is a need for research studies that examine how mathematics graduate students develop as teachers. This study aims to fill this gap in the research by studying mathematics graduate students' experiences with teaching as they progress through their graduate programs. Mathematics graduate students were recruited from a large university mathematics department. They were responded to surveys and were interviewed semi-annually for two or more years. We analyzed their responses using thematic analysis and a framework that captured their development as teachers. In this report, we describe a framework for teachers' development and context and methods of the study. We present findings on how the framework elucidated mathematics graduate students' development as teachers and illustrate obstacles to their development.

Keywords: Professional Development; Post-Secondary Education; Affect, Emotions, Beliefs, Attitudes; Instructional Activities and Practices

As is common in most graduate programs in the sciences in the United States, mathematics graduate students (MGSs) receive funding to support the time they spend in their master's or doctoral programs. In exchange for this funding, they spend between 12 to 16 hours each week working for mathematics departments as instructors or teaching assistants. In some graduate programs, MGSs have the opportunity to teach their own courses for the duration of their graduate programs. In other programs, MGSs do not teach their own courses but instead have the opportunity to lead recitations or workshops that support larger lecture sections which are taught by faculty members. During a two-year master's degree program, mathematics graduate students might have the opportunity to teach as many as seven classes or lead as many as 24 recitations, and in a six-year doctoral program 15 classes or 60 recitations. This means that during their graduate programs, MGSs contribute to the learning experiences of hundreds, if not thousands, of undergraduate students. Their contribution to undergraduate students' learning experiences extends past their graduate programs, with more than 60 percent of new mathematics PhDs finding employment in post-secondary education settings in which teaching makes up a significant portion of their work (Golbeck, Barr, & Rose, 2016). Thus, in their roles as graduate students and later as faculty members in mathematics departments, MGSs exert a significant impact on undergraduate learners' trajectories in STEM fields (Belnap & Allred, 2009; Ellis, 2014).

Despite their contact with and impact on undergraduate students, MGSs receive very little preparation for teaching (Deshler, Hauk, & Speer, 2015; Ellis, 2014). Experts in MGS professional development have not yet reached consensus on the breadth and depth of PD programs that prepare MGSs to teach. Programs vary from a few hours, to an intensive week, to a seminar that spans a full academic year. Few programs extend beyond MGSs' first year in graduate school (Deshler et al., 2015; Ellis, 2014; Harris, Froman, & Surles, 2009; Kung & Speer, 2009; McGivney-Burrelle, DeFranco, Vinsonhaler, & Santucci, 2001). Several researchers who aimed to change MGSs' teaching practices over an academic semester or year discovered that their professional development (PD) programs did not improve the MGSs' practices (Belnap, 2005; DeFranco & McGivney-Burrelle, 2001; Speer, 2001). Preparation for a broad scope of evidence-based teaching practices (e.g., inquiry-based learning, active learning, equitable instruction) is crucial as most MGSs' teaching practices remain rooted in lecturing, with lecture-based mathematics courses causing significant problems for undergraduate students (Deshler et al., 2015; Miller et al., 2018; Stains et al., 2018).

Prior to developing and implementing a two- to three-year PD program for MGSs, our research team sought to understand how MGSs think about teaching, what they learn about teaching, and what type of PD might be relevant at different stages of MGSs' development. We had in mind the question – how might MGSs' needs for professional development be different in their second year of teaching compared with their fourth year of teaching? Looking to the literature, we observed that little is known about MGSs' development as teachers. In an attempt to characterize the types of research conducted regarding MGSs' growth as teachers, Miller and colleagues (2018) completed a review of the literature of professional development for MGSs. The review identified 26 peer-reviewed articles since 2005 that investigated MGSs' teaching development, only 17 of which attended to growth. Thus, the authors concluded that "[mathematics teaching assistants'] growth as teachers is a largely unexamined practice" (Miller et al., 2018, p. 2) and suggested that this area of study would benefit from longitudinal studies that make explicit a model of growth.

With this in mind, the purpose of the study described in this proposal is to investigate MGSs' development as teachers, what and how they learn about teaching, and changes in their thinking about teaching and learning longitudinally as they progress through their degree programs. The research questions that guide this study are: (1) How does an existing framework of teacher development elucidate mathematics graduate students' growth as teachers? (2) What kind of experiences do MGSs have with teaching and what impact(s) do those experiences have? (3) What features of their graduate school and teaching experiences support or hinder their learning about teaching and their development as teachers?

Theoretical Framework

Because research has not yet addressed MGSs growth as teachers, we looked to the K-12 literature, where researchers have studied schoolteachers' experiences in order to gain an understanding of teachers' growth over time. Katz (1972) described four developmental stages, which include: (1) *survival* of the first year of teaching, with particular focus on classroom management and the routines of classrooms and schools; (2) *consolidation*, in which teachers begin to understand which skills they have mastered, and what tasks they still need to master; (3) a period of *renewal*, when teachers become tired of their routines and start to think of how things might happen differently; and (4) reaching *maturity*, where teachers think more broadly about the contexts of schools and students' learning (p. 52-53). We aimed to use this lens to see whether and how MGSs might progress from thinking of teaching as lecturing (survival and consolidation) to thinking about incorporating active learning into their practice (renewal and maturity).

Context and Methods of the Study

At the beginning of the academic years in 2015-2018, participants were recruited from the mathematics department at a large, doctorate-granting institution. Approximately 5,000 undergraduate students enroll in courses such as Pre-calculus, Differential, Integral or Vector Calculus, Business Calculus, or Differential Equations each year. Most of these courses are structured as three hours of lecture with 150-250 students per class and are taught by an instructor. MGSs are generally assigned to run recitations (60-80 minute workshops each week) of smaller groups of students from the large lecture sections. MGSs are not assigned to courses based on knowledge, skill, or experience; their assignments to courses mostly depend upon scheduling.

When new MGSs first arrive to this graduate program in mathematics, they receive two to three days of professional development for their teaching assignment, with a focus on how to support active learning and student engagement in mathematics during recitations. In the first term of their graduate program, they attend a seminar for one hour each week that addresses teaching-related concerns such as grading papers, student conduct issues, and lesson planning. In the summer after their first year, they have the opportunity to teach their own course, then they return to the main MGS duty of leading recitations. Only informal mentoring happens before and during the summer sessions and into the MGSs' subsequent years.

We developed two beginning-of-the-academic-year surveys, one for new and one for experienced MGSs, and protocols for mid-year and end-of-year interviews. Surveys are used at the beginning of the year because of logistical issues. They include open-ended questions that inquire about MGSs' thoughts about teaching and learning mathematics, how they would describe a well-taught mathematics lesson, and what influenced the way they think about teaching. Mid- and end-of-year interviews allow a deeper investigation of MGSs' teaching practices, their most recent teaching experiences, whether they feel that they are receiving adequate support, and what other support they feel they need to grow as teachers. The intention of the study is to survey and interview participants for the duration of their graduate programs to study their development over time. Table 1 illustrates participation in the study.

Table 1: Study Participants

Recruitment Year	Number of Participants
2015-2016	11 new participants: 4 first year, 2 second year, 4 third year, 1 fourth year
2016-2017	11 continuing participants; 6 new participants: 4 first year, 1 third year, 1 fourth year
2017-2018	11 continuing participants; 10 new participants: 8 first year, 1 third year, 1 fifth year
2018-2019	14 continuing participants; No new participants

Our research team analyzed participants' responses to survey and interview questions in two rounds of coding using thematic analysis (Braun & Clarke, 2006). Thematic analysis has six stages which include: (1) familiarization with the data; (2) coding interesting features of the data in a systematic way and collating data that is appropriate for each code; (3) possibly combining codes into themes and collect data for each them; (4) reviewing the themes and supporting data for each theme; (5) continuing to analyze the themes, generating a clear definition for each; and (6) producing the report of the themes with selected data to provide evidence of each theme. In the first found of coding, we applied a deductive approach (e.g., using a pre-existing coding frame) where we looked for instances of the participants' experiences that could be elucidated with Katz's (1972) four-stage model of teacher development. In the second round of coding, we used an inductive approach that focused on codes we developed through the first round of analysis, when we observed issues that either provided explanation for the stages or weren't captured by Katz's framework. These codes included what had an *impact on their views about teaching* (graduate course work, their students, the instructor they are assigned to, the course they are assigned to, their previous experiences as learners, office hours, their MGS peers, and the resources they use for teaching), *issues of identity* (being a teaching assistant versus being an instructor, resignation), and *teaching* (descriptions of their teaching practices, the transitions they have made in their teaching, what changes they would make to their teaching, and what is important for their teaching).

Findings

Using Katz's Framework to Elucidate MGSs' Development as Teachers

We have found Katz's (1972) framework to be a useful lens to view MGSs' development as teachers. First-year MGSs struggled to survive as they adjusted to their roles as teachers. In the quote below, a first-year MGS described his initial experience teaching:

> By that point the quarter [midterms], it was just getting really hectic and I wasn't able to plan as much as I usually like to plan for courses. Sometimes I was looking at the material for about two hours before I started that day whereas usually I like to look at it the day before or during the weekend or something. And so sometimes, though, the classes that I went to where I was kind of doing it on the fly, where I was literally looking at it like an hour or two before class. A lot of times it's just more like get the notes done, go in, and do it.

We discovered that after they gained some experience teaching, MGSs could reflect on their teaching and think about how their teaching might evolve:

> I think previously, I was more focusing on, "I just want to survive my first teaching experiences." So, now that this is my fourth time [leading a recitation], I feel a little bit more comfortable trying to incorporate more active learning in my classroom, and trying non-traditional techniques whereas previously, when I taught, for example, my first time teaching my own class and I taught Calculus, I did mostly lecture because I just wanted to do what I felt most comfortable with – what I felt I could be successful at.

We found that a few MGSs reached the *renewal* stage after a couple of years of leading recitations and were ready to grow their teaching practices:

> Because I've already gone through three years now teaching. So I'm already comfortable with coming up to class and writing things down and grading things in a reasonable enough fashion and in good time. But, yeah, it would be really great to be able to like just take it another step further.

A participant in their third year of the graduate program acknowledged that they could now better understand what active learning meant: "maybe even if I heard the same thing, it would carry more weight now. It might be good to hear [about active learning] in the context of now having three years' experience. I would have a better understanding for the context it would fit in." We observed that a small number MGSs began to think about incorporating active learning strategies in their third and fourth years of teaching.

Out of 38 study participants, we observed that only a few reached the *renewal* stage, and only one or two of the MGSs spoke of teaching in ways that Katz (1972) would categorize as *maturity* even in their sixth year of teaching. Most MGSs appeared to be stuck in the *consolidation* stage and their descriptions of teaching were remarkably unchanged year after year. We have also found that MGSs do not pass through Katz's (1972) developmental stages linearly. In fact, they sometimes returned to the *survival* stage if their new teaching assignment varied significantly from their prior teaching assignments. Based on these findings, we investigated further what was having a significant impact on the study participants development as teachers.

Always a Teaching Assistant, Never a Teacher

The role of teaching assistant stood out as significantly problematic for the research participants. Some of the participants felt that being an instructor and a teaching assistant were very different things, with a second-year MGS stating, "Because [working as a teaching assistant] is totally different than teaching. And I didn't realize that until I got in there." She did not think her work as a teaching assistant (helping individuals or groups of students during class time) did not count as teaching:

> I guess I don't feel like I've taught yet. Right now in [instructor's] class where I just walk around and answer individual questions. And so I don't really feel like I've taught yet but I have ideas for what I'd want in my own classroom. But as a teaching assistant, like you can't tell them no cell phones. Really it's up to the instructor. And so it kinda sucks when you get super frustrated that all these students are on their cell phones and you can't do anything about it. Or you wanna be able to say, you have a week to turn in late work instead of everyone handing you stuff in the final week of classes and you have to take it because that's the instructor's policy. So, stuff like that I don't really have control over.

Several of the MGSs expressed dissatisfaction at the amount of communication they had with the instructors of the courses they were assigned to. One participant said: "I just had like zero interaction with the instructor. So, it just would have been nice to be on the same page about things that the students were learning and things that he wanted, that kind of thing." This lack of communication led to feelings of uncertainty about what mathematics they should offer students:

> I mean I'm often happy to or at least, you know, I've always taken the approach that if the instructor wants something done I'll just do it their way. Which can sometimes be hard. I guess with you know with giving concepts I go back and forth on you know if you're teaching a concept should you teach it the same way the teacher does to reinforce thinking about it a certain way. Or should you teach it in the way that you think about it so a student can see these two different ideas and maybe they'll pick up one instead of the other. And I think I have a tendency to follow the instructor if I know what they're doing and not if, well if I don't know what they're doing then it's a tossup.

Others experienced a sense of ineffectiveness in the role of teaching assistant, with little input into or control over the class:

> But I have no power over what happens in the recitation hour. There is a quiz that was written up, there's an activity that was written up. That's nice, because I appreciate the standardization, and I know that the people who were making these things care a lot, or think a lot about it. So I'm not grumpy about that, necessarily. It's the instructor's course. That's fine. But it means I'm not choosing any of the problems, or anything like that. So what can I do?

Some MGSs' experienced some detachment, disinterest, and frustration in what happened in the role of teaching assistant:

> But I haven't, you know it's not my problem I didn't put it together. I didn't it just. Yeah. I don't know I'm just less invested and then it's coupled with the material just being very difficult and the students struggling. It's hard to, it can be a lot to overcome. You know just when you just have a very small window.

The perceived lack of contribution to students' learning led some MGSs' to feel as though it didn't matter who they were:

> For the impact on their learning, I think I'm interchangeable with all the other graduate students. Every once in a while, there'll be a problem that everyone's asking questions on, and I'll be like, "Okay, let's review something that you all might enjoy having a small review of." And that's fine, but they could get that in the tutoring center. They could get that from going to anybody's office hour.

One MGS expressed the pain that resulted in being a teaching assistant and feeling forced to work with students in ways she didn't agree with: "When I am forced to overwhelm my students or otherwise have no freedom in teaching and consequently get cruel reviews... I take things personally… negative feedback is painful."

A MGS in the fourth year of his graduate program had started to see the value in teaching mathematics in ways that he felt most comfortable with, and that he might even become assertive in his thinking about the recitations he would lead:

> Things that I learned? Probably just re-emphasizing that I should probably be a little bit more assertive about how I think the class should go. Because to some extent, now that I think about it, it probably depends on me as a leader for that recitation. Rather than just you know the instructor wants it done a certain way. If there's a way that I'm comfortable doing it probably works better than what someone else would do.

Discussion and Conclusion

Given the obstacle that the role of teaching assistant played in MGSs' development as teachers, we propose that mathematics departments reconsider how the role is portrayed to MGSs and instructors. Specifically, we recommend that departments fully define the role and make explicit how teaching assistants are valued and how they contribute to students' learning. We also recommend that instructors are offered their own professional development in what and how they communicate with their teaching assistants (e.g., valuing their contributions, providing space for MGSs to contribute to the course, helping MGSs to learn about teaching). Finally, we recommend that professional developers keep in mind the obstacles to MGSs' growth as teachers that we have described in this paper. In particular, professional development programs that aim to teach MGSs about teaching should inform and empower MGSs in their roles as teachers.

BEING A PD OPPORTUNIST: LEVERAGING TEACHERS' IDEAS TO BUILD MATHEMATICAL KNOWLEDGE AND CHALLENGE BELIEFS

Richard Kitchen
University of Wyoming
rkitchen@uwyo.edu

In this paper, I describe a process used in professional development sessions to leverage participating teachers' mathematical ideas as a means to further develop their mathematical knowledge and potentially modify beliefs teachers may hold about instruction and their students. I use an integrated theoretical framework that incorporates noticing, Whiteness and positionality. Sample instructional vignettes are provided that demonstrate how I employ teachers' solutions to mathematical problems as a means to support their mathematical thinking, challenge beliefs they may hold about teaching and their students, while also validating the mathematical ideas that they bring to the learning process.

Keywords: Equity and Diversity, Teacher Knowledge.

In my work as a Mathematics Teacher Educator (MTE), I teach content and methods courses for prospective teachers as well as lead professional development (PD) sessions for practicing teachers. One of my goals during PD sessions for practicing teachers is to leverage their mathematical ideas as a means to support them developing deeper mathematical knowledge and to potentially examine beliefs they may hold about instruction and their students. This involves noticing teachers' mathematical ideas and having them share these ideas with their peers (Sherin & van Es, 2009; van Es & Sherin, 2008). More than just noticing teachers' mathematical ideas, a primary focus of instruction in the PD sessions *is* their ideas and much of my instruction is constructed based on participating teachers' ideas. This entails working to both highlight and build on teachers' mathematical ideas during instruction as a means to support teachers reflecting on and potentially revising their mathematical thinking (Schoenfeld, 1985).

In this paper, I describe a process that I use in the "Institute," PD sessions for P-12 teachers to leverage their mathematical ideas as a means to extend teachers' mathematical knowledge and potentially modify beliefs they may hold. During the 2016-17 and 2017-18 academic years, I led monthly full-day professional development sessions for more than 30 primary and secondary-level teachers of mathematics who teach in culturally and linguistically diverse, rural schools in northern New Mexico, USA. The vast majority of the participating teachers are culturally and linguistically diverse women, primarily of Hispanic and Native American descent. In each Institute session offered, teachers regularly engaged in problem solving activities, shared their solution strategies with one another and the whole group, and examined other teachers' solutions. I work to make teachers' mathematical ideas central in PD sessions I lead for the following three reasons: (1) To champion the notion that we all bring mathematical knowledge and ideas to bear to solve problems (Schifter, 2005); (2) To endorse teachers' knowledge and ideas as mathematically valid and important; and (3) To distribute the mathematical authority in our sessions (Cobb, & Yackel, 1996). In 2016-17, the problems assigned in the sessions were aligned with the Common Core State Standards for Mathematics (CCSSM) Domain, "Operations & Algebraic Thinking" (National Governors Association Center for Best Practices [NGA] &

Council of Chief State School Officers [CCSSO], 2010). During 2017-18, problems assigned aligned with the CCSSM Domain, “Number & Operations—Fractions.”

An important consideration for me in designing the Institute sessions is the fact that many of the participants are elementary school teachers who are culturally and linguistically diverse women whose ideas have historically been marginalized in the mathematics classroom (Becker 2003). As an MTE, I work to notice what Louie (2018) refers to as “students smartnesses” (p. 59). This is an intentional strategy in which I work specifically to showcase the mathematical work of women and teachers of color who are part of the Institute. Noticing, Whiteness and positionality informed the theoretical framework that informed my moment-to-moment decision-making about how to leverage teachers’ ideas during the Institutes. Noticing and making teachers’ mathematical ideas central in PD shifts the focus away from me as the sole mathematics authority. Since the vast majority of Institute participants are culturally and linguistically diverse individuals, noticing these participants’ ideas is a means to work against my white privilege and toward the building of an inclusive professional development community. An important part of my work as a PD provider is considering white privilege and how it operates to provide differential educational opportunities based upon race and class (Battey, 2013; Martin, 2013). Whiteness in mathematics education has historically subjugated culturally and linguistically diverse students, while reproducing privilege for white students (Battey, 2013; Joseph, Haynes, & Cobb, 2016; Martin, 2013).

Through noticing and taking teachers’ ideas seriously, they begin to view themselves as more capable mathematics learners (Wager, 2014) and this is reinforcing and cyclical in nature. This leads to more academic risk taking over time in which the teachers become more willing to attempt to solve more difficult problems (Kitchen, DePree, Celedón-Pattichis, & Brinkerhoff, 2007). In addition, noticing and making culturally and linguistically diverse participants’ ideas central in our work as MTEs contests instruction in which culturally and linguistically diverse students are constructed as mathematically deficient, while positioning students from the dominant culture as the most mathematically qualified (Kitchen, et al., 2007). Hence, another goal in the Institutes was to position teachers, particularly culturally and linguistically diverse teachers, as competent problem solvers from the outset. An individual’s positionality is determined via rights and duties acquired, assumed or that are imposed upon the individual (Redman & Fawns, 2010; Varela & Harré, 1996). Once positioned, one begins to view the world from a particular perspective (Davies & Harré, 1990). It is also the case that positionality is fluid and dynamic, responsive to shifting contexts as people occupy multiple positions (Tait-McCutcheon & Loveridge, 2016).

Lastly, noticing and making the teachers’ mathematical ideas a focus of instruction was also intended to encourage teachers to consider how their students may have mathematical ideas worthy of incorporating in their instruction as well. As students become more confident participating in mathematical activities and expressing their ideas, teachers begin to place greater value on their students’ ideas (Hiebert & Carpenter, 1992). In addition, I wanted teachers to consider the value of their students’ developing positive mathematical identities. By developing their own positive mathematical identity, they will want the same for their students (Kitchen, et al., 2007). A potential result is that teachers begin to position their students as competent problem solvers (Kitchen, Burr, & Castellón, 2010; Tait-McCutcheon & Loveridge, 2016).

Research Methodology

I provide one example of how I work to leverage teachers' ideas as a means to develop their mathematical knowledge. Given the space limitations of a Brief Research Report, I do not provide examples of how I leverage teachers' mathematical ideas to explore beliefs teachers may hold. For the sample teacher solution offered below, I describe how I leveraged these solutions to further develop teachers' mathematical knowledge. The example came from copies of collected teacher work samples and from photos taken of teachers' solutions to tasks posed during Institute sessions. Throughout the Institutes, I engaged in my own journaling about what transpired during sessions, which helped me reconstruct the instructional decisions that I made at particular moments. I also examined teacher evaluations of sessions. This served to inform me about how teachers were responding to my pedagogy in general, and to my focus on their mathematical ideas in particular. All these data subsets were analysed using interpretive methods (Creswell, 2014). Each data subset was read or viewed as a whole, followed by a period of clarifying learning goals that emerged as I worked to notice, center the teachers' mathematical ideas, and then construct instruction based upon these ideas. An iterative process of reflecting upon and then clarifying my learning goals and resultant instruction followed (Miles, Huberman & Saldana, 2013). This process went through multiple revisions as the data were repeatedly read and reviewed to check the consistency of findings. After I had established how to characterize instruction that took place during the Institutes, I searched for commonalities and differences across instructional vignettes to further examine how as well as why I made particular in-the-moment instructional decisions during the Institutes.

Using Teachers' Ideas to Enrich Their Understanding and Attend to Their Beliefs

I now offer an example to address how I noticed and then leveraged teachers' ideas in-the-moment as a means to further develop their mathematical knowledge. In each example cited below, culturally and linguistically diverse Institute participants created the solution strategies shared.

In this example, I built on a participating teacher's idea to develop notions of number sense through examination of a mathematical property. The following problem was offered to participating teachers that approximates a fifth-grade CCSSM Algebra Standard: Judy says that to find 5 times 26, she can find 10 × 26 (260), and then divide this number by 2 to get 130. Write an equation that demonstrates her mathematical thinking.

As teachers worked on the problem individually and then with group members, I walked around observing and listening to how teachers explained their solutions to one another. I then selected one of the participating teachers to share her solution strategy on chart paper for the whole group to view. My goal was to then further examine her solution with the whole class and derive mathematical insights about a mathematical property. After writing her solution strategy on the chart paper, she shared this strategy with the entire class:

$(5 \times 2) \times 26 =$
$\vee$
$10 \times 26 = 260$
$260 \div 2 = 130$

In her solution, the teacher noted that multiplying 5 by 2 was equivalent to multiplying by 10. She also argued that after multiplying 26 by 10, it was necessary to divide this product by 2 to arrive at the appropriate result since 10 ÷ 2 equals 5. The teacher then proceeded to produce the following equation for the whole class that synthesized the solutions that she had previously presented:

$$5 \times 26 = (10 \times 26) \div 2$$

During the whole class discussion that ensued, I worked to validate and made an in-the-moment decision to build on the teacher's initial solution to demonstrate how she had used the transitive property of equality, namely that if a = b and b = c, then a = c. To do this, I circled the first expression (5 × 2) × 26 and labeled it as expression "a". I continued by circling expression b, 10 × 26, followed by expression c, 260. I concluded by reviewing how a = b, b = c, and finally that a = c.

$$\underbrace{(5 \times 2) \text{ X } 26}_{a} = \underbrace{10 \times 26}_{b} = \underbrace{260}_{c}$$

Next, I asked whether 10 × (26 ÷ 2) = (10 × 26) ÷ 2? The realization that these expressions are equal led a participating teacher to share how she teaches GEMA (grouping symbols, exponential operations, multiplicative operations, and additive operations) rather than PEMDAS (parenthesis, exponents, multiplication and division, addition and subtraction) to support student understanding of the order of operations since with PEMDAS, students may learn to multiply before they divide and to add before they subtract.

Discussion and Implications

In this paper, I have shared a process that I have developed for use in PD sessions in which teachers' mathematical ideas are leveraged to develop their mathematical knowledge and potentially challenge particular beliefs teachers may hold about mathematics instruction and their students. This process involved making in-the-moment decisions about how to teach mathematics in a manner that supports the mathematical learning and pedagogical development of teachers. Using an integrated theoretical framework to make these decisions incorporates noticing, Whiteness and positionality, culturally and linguistically diverse participants' mathematical ideas were continually on display throughout the Institute. In their evaluations of the Institute, teachers wrote that they liked having their ideas highlighted throughout. Some teachers also shared that they needed to provide more space in their classrooms for greater inclusion of their students' mathematical ideas because they have come to believe through our work that their students also have important mathematical ideas to share, just like they do.

In the example provided, I deliberately selected a teacher's solution that incorporated the transitive property of equality; a powerful property that I knew would be beneficial to examine together. Inspired by the teacher's final equation, I also decided that we would collectively examine order of operations. I knew from experience this was worthy of consideration since application of PEMDAS may lead to miscalculations (Dupree, 2016). An intentional strategy here was to take advantage of participating teachers' mathematical ideas to organically push their thinking to consider ideas that most certainly will emerge in their instruction. From participating teachers' responses to their colleagues' mathematical solutions and from information gleaned from evaluations completed, teachers frequently offered how the Institutes helped them learn mathematics and become more confident in their mathematical abilities. As previously mentioned, culturally and linguistically diverse teachers created all three of the solutions shared here. Intentionally having women and culturally and linguistically diverse teachers publicly share their mathematical solutions to problems removed me as the sole mathematical authority in the room. Though I decided whose solutions were on display and what mathematical ideas to develop further, the teachers' ideas were always in the forefront of discussions.

An implication of the research findings of this study is that making diverse teachers' ideas a focal point of instruction is a practical approach to incorporate equity and access to mathematics in one's teaching. Such instruction is equitable for the simple reason that it validates the ideas of members of underrepresented groups in the learning process, erasing the notion that one's competence in mathematics can be predicted by one's race, class, sex, ethnicity, and English proficiency (Gutiérrez, 2002). In the case of the Institutes, teachers' learning from other participants is an example of what Boaler (2008) has referred to as "relational equity."

The SunBay Digital Mathematics Project promotes the use of a curricular activity system (CAS) in which professional development (PD), curricular materials, and dynamically-linked virtual representations help teachers engage in student-centered instruction. Here we describe a district-university partnership that resulted in a unique model for PD focused on supporting teachers to implement technology-based units and adopt effective mathematics teaching practices. We examine teachers' perceptions of the PD model and how it impacted their practice. Data sources were qualitative in nature (e.g., observations, interviews); preliminary analyses suggest the implemented model resulted in relevant, impactful, effective, and empowering PD.

Keywords: Teacher Education, Professional Development, Inservice Teachers, Technology

The initial preparation of mathematics teachers as well as the type of ongoing professional learning provided to them throughout their career has received much attention (Sowder, 2007). Initial preparation is traditionally the responsibility of teacher education programs and as they progress through their careers, the responsibility for their professional development (PD) falls within the purview of school districts. This dichotomous approach brings to light the challenges many districts across the U.S. are facing, where teachers are leaving the profession at alarming rates and at earlier points in their career (CERRA, 2019). Among the factors that predict the attrition and migration of mathematics teachers is useful content-focused PD (Ingersoll & Perda, 2010). One way to share responsibility for ongoing PD is through university-district partnerships (Roschelle, et al., 2010; Roy, Fueyo, & Vahey, 2017; Vahey, Knudsen, Rafanan, & Lara-Meloy, 2013; Vahey, Roy, & Fueyo, 2013).

The SunBay Digital Mathematics Project promotes the use of a curricular activity system (Roschelle et al., 2010) in which focused PD, realistic curricular learning progressions that address state-defined college and career readiness standards, and dynamically-linked representations (Moreno-Armella, Hegedus, & Kaput, 2008) are aligned to assist mathematics teachers as they engage in a student-centered approach to instruction. Curricular materials that incorporate dynamic technology have been shown to support teachers' middle school mathematics content knowledge (Roy, Vanover, Fueyo, & Vahey, 2012). By allowing teachers to initially "do the math" and explore the dynamic representations while participating in the PD as learners they can make mathematical connections and broaden their own content knowledge. These PD experiences can lead to different classroom environments when similar curricular learning units (Vahey, Werner, Roy, Fueyo, & Collier, 2013). Here, we describe a partnership in which university faculty collaborated with district-based leadership and middle school teachers to build on that prior research to explore the intersections among pedagogy, technology, and mathematics to address both the practice of mathematics teachers and student achievement. This paper provides a concrete example of how to successfully support teachers so they will implement effective teaching practices and innovations.

We developed a three-year PD that was research-based, high-touch, responsive, and collaborative (CBMS, 2012). We examine the impact of this four-pronged PD approach on quality implementation and teacher change by investigating the following research questions:

What are middle school teachers' perceptions of this professional development model?
In what ways has the professional development model impacted teacher practice?

Methods

Participants and Setting

During the intervention, middle school teachers across a large, suburban school district (NCES, n.d.) were provided PD to explore the SunBay curricular units as learners, and then later implement those same units with their middle school students. More than half of the students are non-white and two of the ten public middle schools are classified as Title 1 schools. Forty school teachers from the eight middle schools received PD. Teachers were provided with PD on at least two curricular units specific to the grade level they taught. Although students are not the focus of this paper, it is worth noting that approximately 1,700 students were served in year 1; 3,300 students in year 2; and 2,100 students in year 3.

Data Sources and Analysis

Data sources include field notes from classroom observations, audio transcripts from end-of-year focus group interviews, surveys, and notes from team meetings. As data were collected, the first author engaged in open coding (Cresswell & Poth, 2017; Hatch, 2002) to identify themes, which were revised as more data were analyzed. She also engaged in constant comparison to cross-check data for inconsistencies and nonexamples. The codes and associated findings were shared with other authors and participants, and further revisions were made. Illuminating quotes were then selected and presented in this paper.

Intervention

Elements of the curricular activity system include (a) six total curricular units; two units per grade level emphasizing the mathematics content in each respective grade, and each of the units was aligned to the state standards and served as replacement for state adopted textbook lessons; (b) dynamic technology emphasizing multiple mathematical representations; and (c) focused teacher PD exploring the implementation of technology within the unit. Each element of the curricular activity system will be described in the following sections.

The SunBay units. Six units and four web-based apps were developed by curriculum specialists with feedback from district personnel and teachers who would be implementing the units. These were designed as replacement units for 'business as usual' units and covered the same standards. Each of the units: (a) addressed important content identified in both research and the state standards; (b) incorporated web-based dynamically linked representations; (c) incorporated the Predict, Check, and Explain instruction routine (Roy et al., 2016); and (d) emphasized purposeful instructional lesson structures.

Our professional development model. Our framework emphasized teacher's own mathematical content development; attention to students' interaction with the curriculum; teacher beliefs that middle school students can learn deep, rich mathematical concepts; and building a network of teachers who can support each other and attend to their collective learning throughout implementation (Doerr & Lerman, 2010). We also sought to support teachers to implement SunBay units with fidelity and to affect student achievement. We developed a three-year PD model aligned with principles described by the CBMS (2001) by creating a PD that was:

- *High-touch.* The PD was deep and iterative, not the single-session experiences that the teachers reported they regularly receive. We provided multiple-day PD for new and returning teachers prior to the implementation of each SunBay unit, with a minimum of two sessions per academic year. Teachers benefited from individual correspondence with PD facilitators, classroom coaching observations and feedback, and participation in the end-of-year Teacher Forum at which they reflected on successes and challenges (Blank & de las Alas, 2009). This high-touch model allowed the teachers opportunities to reflect on what they learned after each session, implement the units in class, troubleshoot issues that arose with their peers and PD leaders, and make changes for the next implementation (Garet et al., 2010; Demonte, 2013; Tarr et al., 2008).
- *Responsive.* Topics varied depending on teacher and district needs. Initial training always focused on learning both the content and the curricular materials. New-to-SunBay teachers typically received two days of PD that included opportunities to "do the math" in the same manner their students would. Returning and new SunBay teachers also received PD specifically addressing issues of SunBay curriculum implementation identified by teachers and the authors during interviews, observations, surveys, and PD discussions. Sessions focused on Productive Struggle, Student Talk (year 2), and NCTM's (2014) Eight Effective Teaching Practices (year 3).
- *Collaborative.* In planning, the PD developers worked closely with curriculum developers and district personnel, including the Math Curriculum Specialist. This ensured we fulfilled the vision of the developers and met district needs.
- *Research-based.* In addition to the research-based SunBay materials themselves (Vahey et al., 2013), we drew on teacher education research about best practices for teaching mathematics as we made decisions about how to deliver the PD (e.g., NCTM, 2014; Smith & Stein, 2011). We actively engaged the teachers with the content and highlighted sense-making by asking them to "do the math", explain their thinking, and justify mathematical solutions as we hoped they would do with their students.

Findings

When considering teachers' perceptions of the PD model and how that PD impacted their practice, we identified several themes, described below. These findings are preliminary and will be refined after future analysis of questionnaires and interviews of the teachers.

Teachers Believed in the SunBay Technology, Materials, and Pedagogical Approach

Teachers mentioned the use of technology itself, the real-world applications, and the visual nature of the way concepts were displayed as some of the greatest rewards of SunBay. They noted that students took ownership of their own learning and "were encouraged to challenge themselves to think through problems."

Teachers Found the PD Model to Be Relevant, Useful, Responsive, and Impactful

They commented that "this is the best PD we have ever had," and "it's not like other PD where you don't want to go … I wanted to come to this PD." They found the facilitators supportive and responsive, and felt well-prepared to teach each of the units.

Relationships Built with the PD Team Were Critical

The PD facilitators and district personnel involved with SunBay worked hard to build rapport and demonstrate care for participating teachers, and the teachers noticed. They felt that facilitators "were always available and listened to us as they planned PD" and "that if I need anything, it's a phone call away."

The Curriculum and Pedagogy Were Challenging

For most of these teachers, the SunBay approach was a shift in how they were used to teaching. It was challenging to think on their feet, to manage classroom discussions well, as well as to not give away answers to students but to instead allow students time to work things out on their own. Teachers struggled with time management and pacing, especially during the first year of implementation. The curriculum developers responded to this feedback by shortening units and providing better-suited materials for both teachers and students. For instance, the teachers were provided more guidance regarding how to integrate the curriculum materials along with other the mathematics activities (e.g., warm-ups) they use in their class. The teachers were grateful, and reported their timing issues were "much better" due to their exploration regarding how effectively integrate the material without cutting or modifying it.

The PD Was Effective for the Teachers and Their Students

Teachers reported that during their instruction of the SunBay units, their students were more participatory, more actively engaged with content, seemed to enjoy themselves more, and better understood the mathematics as compared to business as usual. Their students "were eager to understand the concepts behind the math." Some teachers used pedagogical strategies learned at the PD when teaching non-SunBay units.

Opportunities for Empowerment Result in Empowered Teachers

Though participation was technically voluntary, many Year 1 teachers expressed being "volun-told" to participate. Over time, this perspective shifted, with participants becoming SunBay advocates and using the SunBay lessons for their formal school-based observations and evaluations. Two teachers presented at their state-level Council for Teachers of Mathematics conference, and four volunteered to serve as Teacher Leaders and carry on SunBay trainings with others in the district after the study was completed.

Concluding Remarks

When adopting new curricula and encouraging teachers to change their thinking and modify their instruction, PD has the potential to make a great impact on teacher practices and student achievement, but many times fails to do so. We offer an alternative. The PD model we implemented and relationships we built with teachers resulted in relevant, impactful, and empowering PD for teachers. This high-touch, responsive, collaborative, and research-based approach may serve as a model for providing PD to mathematics teachers adopting a curriculum and pedagogical approach aligned with best practices for teaching mathematics. We encourage PD providers to offer long-term and responsive PD to teachers, focusing especially on building both content knowledge and relationships with teachers. It is worth noting that when our grant concluded, some of the teacher leaders we trained continue to provide PD to other teachers in their district and the SunBay units continue to be one of the curricular choices for teachers to implement. For these reasons we believe this approach to be sustainable in large districts.

We discuss our three-part online synchronous and asynchronous professional development model for online video coaching for rural middle grades mathematics teachers and share results of an analysis of teachers' and coaches' noticing. We report on one aspect of this model, an online version of Content-Focused coaching (West & Cameron, 2013). We engaged practicing teachers in repetitive cycles of coaching, which involved co-planning, teaching, annotating video, and debriefing, all through distance technologies. In this study, we focus on the noticing of both teachers and coaches as they watched the recorded lessons and annotated lesson video. Findings indicate that coaches and teachers focused on both the teacher and students in their annotations. Coaches were specific more often in their annotations and made more connections than teachers. Coaches' annotations were more often interpretive whereas teachers were descriptive.

Keywords: Middle School Education, Teacher Education, Technology

Teachers in rural areas face constraints in terms of accessing the expertise and resources required for high-quality professional learning experiences, often because of lack of proximity to such resources as institutions of higher education and critical masses of teachers required to collectively reflect on problems of practice (Howley & Howley, 2005). The innovative online professional development experiences in our project focus on the development of teacher capacity to enact the Five Practices for Orchestrating Mathematics Discussions (Smith & Stein, 2011), with a specific focus on supporting teachers to notice students' mathematical thinking (i.e. van Es & Sherin, 2008; Jacobs, Lamb, & Phillip, 2010). Recognizing the critical need to prepare all teachers to implement rigorous instruction, especially teachers who are not geographically proximate to in-person trainings or coaching resources, we engaged participants in online courses, online lesson labs, and online video coaching over a two year period.

The use of coaching to foster teacher learning and improve students' mathematical understanding has become a popular strategy for schools, districts, and states in the US (Gibbons & Cobb, 2017). Prior studies have shown that coaching can improve certain aspects of teaching (Kraft, Blazar, & Hogan, 2018; Sailors & Price, 2015). In this paper, we focus on one component of our larger model—online coaching—and particularly the use of video annotations made by both coaches and teachers in response to video-recorded lessons. This was completed through the use of an innovative online Content-Focused coaching model (Authors, 2015; West & Cameron, 2013) to stimulate coaching interactions and the development of professional noticing (Jacobs et al., 2010; van Es & Sherin, 2008). The purpose of this study was to better understand the content of the annotations and the interactions of the coach and teacher in the online space. Specifically, we were interested in understanding the subject focus of the annotations (whether the coach noticed student or teacher actions), the specificity of the noticing (whether general or specific), and the analytic stance (how noticing was communicated). Given the dearth of research on coaches' noticing, we consider it valuable to focus on coaches' noticing, in addition to teachers' noticing. We answered the following research question: When annotating lesson video as part of an (synchronous and asynchronous) online coaching model, how is the noticing of coaches and teachers similar and how is it different?

Method

Using a cohort model, we engaged 8 middle-grades teachers in an intensive two-year professional development model focused on supporting teachers to engage in ambitious, responsive instruction. The four coaches on the project were all experienced in coaching teachers using in-person Content-Focused coaching (West & Staub, 2003).

Online Content-Focused Coaching Model

As a component of the overall professional learning model, participants took part in Content-Focused coaching delivered synchronously and asynchronously. To facilitate this online coaching, we used video conferencing software (Zoom), and video capturing/annotating software (Swivl). The online video coaching was purposely designed with features analogous to West and Staub's (2003) in person Content-Focused coaching cycle. First, the teacher and coach met synchronously via Zoom to plan the lesson; second, the teacher video recorded the lesson implementation using Swivl; third, the teacher and coach asynchronously viewed and annotated the video of the enacted lesson; and finally, the coach and teacher met synchronously via Zoom to reflect on the lesson using the annotations to anchor their discussion.

Data Collection

The focal aspect of this study is the lesson annotation component. After teachers taught and recorded their lesson, the coach and teacher each independently watched the video of the lesson and wrote comments (annotated) about the lesson through the online Swivl platform.To enter the comments, the coach or teacher paused the video and typed their comments, which were then synced to the video by a time-stamp. This allowed for the teacher or coach watching the video to connect a comment to a specific moment in the video. The unit of analysis for this study was the annotations from the coach-teacher pairs, with each coach-teacher pair completing two or three coaching cycles over the course of one year.

Data Analysis

We considered each annotation comment a separate data unit for analysis. Given the focus on understanding coach and teacher noticing, we created a codebook with three main categories: subject (who), specificity, meaning the extent to which the comment made connections, and analytic stance (how noticing was communicated) (see Figure 3). We based the subject category on the work of van Es and Sherin (2008) and van Es (2011), with the focus on either the teacher or student(s). We based the specificity component on the work of Author (date) to describe how participants drew connections between teaching and learning in their comments. We based the analytic stance category on the work of van Es and Sherin (2008) and van Es (2011). Categories for analytic stance included tag, describe, evaluate, interpret, suggest, and question. Based on the literature, we considered the codes of *tag* and *describe* to reflect less advanced noticing and *evaluate* and *interpret* to reflect more advanced noticing. We consider *suggest* and *question* to be deliberate types of moves that do not reflect more advanced or less advanced noticing directly, but represent a stance participants took. The code for *tag* was only used in the absence of any other code for analytic stance. Each annotation could receive any number of codes from each of the categories. After several rounds of testing and validating the codebook, coding commenced with two researchers independently coding all annotations from a given coach-teacher coaching cycle. We then calculated Kappa for each coaching pair and the two researchers met to reconcile differences in codes, resulting in final codes for each coach-teacher pair for each coaching cycle. Kappa ranged from 0.63 to 0.70, indicating good to excellent reliability (Landis & Koch, 1977). Following the assignment of codes, we conducted frequency counts related to all codes for the coaches and teachers individually. We then conducted frequency counts for the coaches as a group and the teachers as a group.

Results

In total, 197 annotations were made within the analyzed coaching cycle; of these 60.9% (n=120) of these were from the coaches and 39.1% (n=77) were from the teachers.

Subject (Who)

Coaches focused on the teacher in 73.3% (n=88) of their annotations and students in 68.3% (n=82). The teachers focused on the teacher in 55.8% (n=43) of the annotations and students in 55.8% (n=43). Teachers had fewer annotations that mentioned both the teacher and the student(s) (20%) as compared to the coaches (40.6%). The teachers' annotations commonly focused on only one subject, a teacher or student, rather than two subjects. In contrast, it was more common for the coaches to include a focus on both teacher and students in a given annotation.

Specificity

The coaches were more specific in their annotations than the teachers. The annotations from the coaches were coded as specific 75% of the time and the annotations of the teachers were coded as specific 20.2% of the time. In other words, the teachers were much more likely to make a general annotation when compared to the coaches. For example, one teacher wrote, "Used a fraction bar to start figuring out inches to pounds…" (Hopkins, June 19) A coach wrote, "Good wait time." (Lowrey, June 19) In these examples, the annotations were general because there was no connection drawn between the teacher and student or another person or aspect (see Figure 3). In contrast, the following was a specific annotation from a coach, "Bringing the conversation back to what was important information about the problem provided a bridge between the two days and supported students to re-engage in the problem." (Lowrey, June 19) In this example, there was a connection between the teacher's talk move of "bringing the conversation back to what was important" and student learning by supporting them "to re-engage in the problem" because of this move.

Analytic Stance (How)

In considering the analytic stance of the coaches and teachers, there were differences with respect to the type of stance taken. Table 1 shows the percentage of each type of analytic stance, meaning *how* the annotation was written.

Table 1: Percentages of Annotations by Analytic Stances

	Tag	Describe	Evaluate	Interpret	Suggest	Question
Coaches	3.14	17.28	15.71	24.61	23.04	16.23
Teachers	15.56	25.56	15.56	17.7	16.67	8.89

The frequencies of evaluative annotations was similar for both groups, with interpreting and suggesting being more common for the coaches. In other words, the coaches were more likely to make meaning or make an interpretation through the annotation. The following is an example of an interpretation from a coach:

> "What do you mean by that?" provides opportunity for the student to think through their own process and for the rest of the group to understand the information better. This also provides an opportunity for students to engage in the mathematical practices. (Lowrey, June 19)

In this example, the coach referred to teacher move (describe) and then unpacked the outcome of this move with respect to student opportunity for engagement in the lesson (interpret).

Coaches provided suggestions for the teachers more often than teachers wrote comments to themselves about what they should do differently. The following is an example of a coach providing a suggestion, "After posing the question about 50 people, I wonder if a few minutes of independent think time would have given all of the students a chance to make sense of the question you asked." (Reiss, June 6) The teachers gave themselves pointers in some instances, "Have the student explain how/why." (Sandoval, June 4) In this case, the teacher wrote herself a note that that she should have had the student explain. Approximately 20% of the annotations (irrespective of participant type) contained some type of suggestion for how something could have gone differently in the lesson.

Discussion and Implications

Knowing that the coaches focused on students in their annotations to a greater extent than the teachers raises questions about practices that would better support teachers to notice children's mathematical thinking (e.g. Jacobs et al., 2010; van Es, 2011). To increase teachers' focus on students, coaches may consider how they could encourage teachers to make an intentional shift to focus more heavily on students' mathematical thinking in their annotations.

Another difference in the results concerned the level of specificity of the coaches' annotations as compared to the teachers' annotations. In many instances, the coaches identified student thinking, made interpretations, and made connections to broader principles of teaching and learning, all components of the van Es and Sherin (2008) definition of noticing. This often involved identifying a moment in the lesson and then elaborating on this moment with some interpretation, which is a heightened form of noticing (van Es, 2011). These findings raise questions about how we support teachers to develop more specificity and increase the frequency at which they make interpretations with their own noticing.

An additional question for future investigation would be to connect the coaches and teachers' noticing, evidenced in their annotations, with the content of the post-coaching cycle debrief meetings. As a part of the online Content-Focused coaching model, the coach and teacher met following their completion of the annotations for an hour-long debriefing meeting. Connecting the annotations to the actual conversations the participants have about the lesson would provide further insight into their noticing.

These findings provide an opportunity for professional development providers to understand how teachers notice as they participate in the online learning experience. At the same time, the annotations provide insight about how the teachers focus on students' thinking, which may relate to their ability to monitor student thinking in their teaching (Smith & Stein, 2011). We contend that the annotation analysis is one minute component of the larger project and additional studies are needed to fully understand the noticing practices of the participants.

IN-SERVICE TEACHERS' NOTICING OF MATHEMATICAL IDEAS IN AN ANONYMOUS PRESCHOOLER'S REPRESENTATION OF COUNTING

Madhuvanti Anantharajan
Stanford University
madhuvan@stanford.edu

This study examines twelve in-service early math teachers' noticing of mathematical ideas in an anonymous preschooler's representation of counting. The findings suggest that stand-alone representations offer a generative opportunity for teacher-learning about student-thinking.

Keywords: Number concepts and operations, Early childhood education, Teacher-noticing, Mathematical representations

Objectives

Literature on the early math activity of Counting Collections suggests that asking children to represent their counting on paper can provide teachers valuable information about children's mathematical strategies and understanding (Franke, 2017; Johnson & Gaxiola, 2018; Schwerdtfeger & Chan, 2007). However, the independent potential of children's representations as evidence of their mathematical thinking has not been studied empirically. The current study examines how, in the absence of other information about the student, teachers who implement Counting Collections make sense of a student's mathematical thinking through a representation of counting. The results can inform professional development and teacher-learning opportunities.

Theoretical Framework

The broad research question that guides this paper is: What do in-service preschool and kindergarten teachers who implement Counting Collections learn about students' mathematical thinking from an anonymous preschool student's representation of counting? The sub-questions are (1) What mathematical ideas do participants notice in the representation, and to what degree is teacher-noticing of mathematical ideas in the representation consistent across participants? (2) How do the constraints of the anonymous representation affect participants' noticing of mathematical ideas? The study is informed by the research in math education discussed below.

Teaching Based on Student-thinking

Researchers and practitioners agree that teaching grounded in student-thinking effectively supports children's mathematical learning (Ball, 1997; Carpenter, Fennema, & Franke, 1996; Lampert, 2003). The current study is based on an activity called Counting Collections, where children count collections of objects and record their counting on paper. Teachers make sense of children's understanding by observing them count, having them explain their thinking, and asking them questions about their counting (Carpenter, Franke, Johnson, Turrou & Wager, 2017; Franke, Kazemi & Turrou, 2018; Schwertfeger & Chan, 2007). Teachers' moves when engaging with students' thinking are conceptualized as teacher-noticing and include attending, interpreting, and responding (Jacobs et al., 2010; Sherin, Jacobs & Philipp, 2011). The current study examines teacher-noticing of a preschooler's representation of counting.

Teacher-learning About Children's Mathematical thinking from Student Work

Research suggests that young children's written work is valuable evidence of students' mathematical strategies, reasoning, and confusions (Brizuela, 2005; Carruthers & Worthington,

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

2005, 2006; Johnson & Gaxiola, 2018; Kamii et al., 2001; Schwerdtfeger & Chan, 2007). In the current study teacher-noticing is elicited through an artifact of practice (Ball & Cohen, 1999), namely a representation made by a preschool student during Counting Collections. The study evokes "productive disequilibrium" (Ball & Cohen, 1999, p.15) in participants through a generative piece of student work chosen for rich mathematical details, while limiting external information about the child. The study also examines teachers' restraint in interpreting student work and how they verify their interpretations (Ball & Cohen,1999; Kazemi & Franke, 2003).

Early Math

The study focuses on the early math domain of counting and number sense. Counting involves the principles and strategies of counting (Carpenter et al., 2017; Clements & Sarama, 2009; National Research Council, 2001, 2009). A previous study of Counting Collections indicated that children need distinct understandings to *represent* counting, compared to counting objects (Anantharajan, in press). The current study examines teacher-noticing of all these mathematical ideas in an anonymous representation of counting by a preschooler (See Table 1).

Methods and Data Sources

The participants[1] were 12 in-service teachers based in California, who taught pre-K, transitional kindergarten, or kindergarten. The participants had implemented Counting Collections for between six months and four years. All participants looked at the same representation (Fig.2). They were told the student's grade level and that the student was counting coins. They did not observe the child's counting that preceded the representation and did not know the child. The representation provides the opportunity to notice *multiple mathematical ideas* including number sequence, one-to-one correspondence, cardinality and representing place value in the base ten system. It indicates the student's *strategies* (Schwerdtfeger & Chan, 2007; Franke et al., 2018), such as representing in rows, and associating each object with a numeral. The representation indicates a *problem* the child may be trying to solve (Carpenter et al., 1993), to represent the ordinal value of each object. Finally, the representation indicates a *partial understanding* of a math idea (Carpenter et al., 2017; Franke et al., 2018), representing place-value. Participants looked at the representation during individual semi-structured interviews. Questions focused on their noticing of mathematical ideas in the representation and interpreting what the student may understand or struggle with. Interview transcripts comprise the study data.

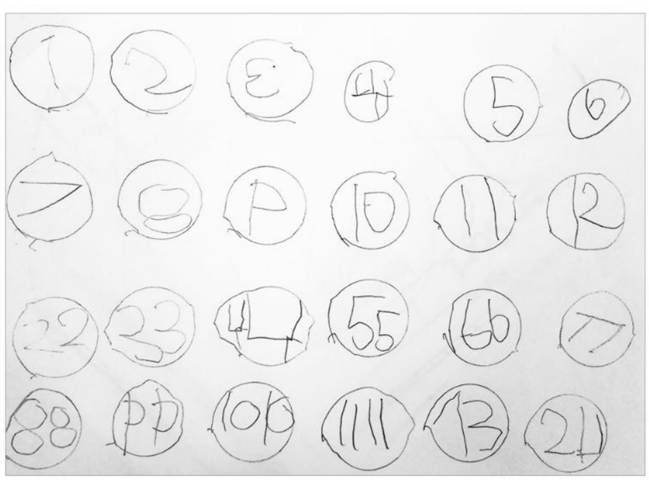

Figure 1: Anonymous Representation of Counting Made by Preschool Student

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

The coding framework consisted of three main codes: specific principles and strategies of counting, and understandings required to represent counting (Anantharajan, in press; Carpenter et al., 2017; NRC 2001). Each code was distinguished to indicate a strong understanding when teachers implied that the child's understanding of an idea is fluent or consistent; a partial understanding when teachers implied that the child is working on or has an inconsistent understanding of an idea; and uncertainty when teachers were unsure of how to interpret particular aspects of the child's thinking. Transcripts were coded line by line applying as many codes as needed to each line. Inter-rater reliability of 90 to 100% was achieved. Nvivo was used to code the transcripts. The analysis indicates the number of participants who noticed a mathematical idea or level of an idea and qualitative patterns across participants' noticing.

Results

Multiple Participants Noticed Certain Mathematical Ideas in the Representation

Table 1 shows that teachers noticed some mathematical ideas consistently in the representation. All twelve teachers noticed one-to-one correspondence and knowing how numerals look and how to write them. Eleven teachers noticed number sequence. Ten teachers noticed the use of visual configurations. Seven teachers noticed an understanding of cardinality, the association of number with object to count, and the symbolic strategies used by the student.

Table 1: **No. of Teachers Who Noticed Mathematical Ideas in an Anonymous Representation**

		No. of teachers
Principles and strategies of counting	One-to-one correspondence	12
	Number sequence	11
	Cardinality	7
	Abstraction principle	0
	Order irrelevance	0
	Other mathematical ideas	9
	Grouping	4
	Visual configurations	10
	Keeping track	1
	Associating number with object	7
	Other mathematical strategies	0
Understandings distinct to representation	Counting can be shown on paper.	2
	Marks on paper can be counted independently	0
	Representations can show what objects are counted	2
	The total number of objects in the collection determines the number in the representation	3
	Using symbolic strategies for representation of counting	7
	Utilizing space on paper	1
	Knowing how numerals look and how to write numerals	12

Participants also commented on the degree to which the student understood the ideas. For instance, eleven of the twelve participants who noticed one-to-one correspondence in the

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

representation perceived a strong understanding of it. All eleven participants who noticed an understanding of number sequence, noticed a partial understanding of the principle. Similarly, ten participants noticed a partial understanding of writing numerals and all twelve expressed uncertainty about what the child may know about writing numerals.

Participants Spontaneously Attended to Specifics and Details of the Representation

All participants paid special attention to the third and fourth row of the representation. Participants spontaneously went beyond broad assessments of right or wrong answers to both *specifics* and *details* of what they saw. Consider Betty's observations:

> "They definitely know the counting sequence up here [end of the second row] …[I]t's interesting they counted correctly up to twelve but then started doubling their numbers but then ended with the correct number at the end. That's pretty fascinating." (Betty)

Participants pinpointed the specific place where they saw a shift in the child's understanding – the beginning of row three. They further articulated specifics of what followed – that the student "doubles" the digits, that the last number in the representation seems to reflect the correct total number. The teachers also moved back and forth between what they noticed and their interpretation of what the child may know or struggle with.

Participants Proposed Multiple Explanations for the Same Aspect of the Representation

Each participant proposed between three and eight explanations for the apparent shift from the third row onwards. For example, Amanda used details of the representation to consider multiple possibilities: the student may be struggling with number sequence; trying to invent a system of numerals; represent a counting strategy of grouping; or struggling to remember how to write numerals after twelve. Amanda is one of the participants who relates the representation to a common struggle that young children have with the number sequence, the transition from twelve to the 'teen numbers.' In interpreting such details, seven participants made the distinction between the child knowing number names and sequence and knowing how to write numerals.

Participants Were More Uncertain About Their Interpretations of the Child's Partial Understandings Than About Their Interpretations of the Child's Strong Understandings

In contrast to participants' confidence regarding their perception of strong understandings, more participants expressed uncertainty about their perception of partial understandings in the representation. Eleven out of twelve participants said that the representation indicates a *strong* understanding of one-to-one correspondence. Only three of the eleven indicated that they may need to confirm whether the child has a strong understanding of one-to-one correspondence. Similarly, ten out of twelve teachers felt that the child had a strong understanding of visual configurations to aid and represent counting, but only two expressed uncertainty about their interpretation. In contrast, eight of the eleven teachers who indicated that the child had a *partial* understanding of the number sequence past twelve also indicated that they were uncertain of the child's understanding of the number sequence. Similarly, ten out of twelve teachers felt that based on the representation, the student had a partial understanding of how numerals look and how to write them. All twelve teachers however expressed their own uncertainty about the student's understanding of how numerals look and how to write them.

Significance

The results of this study suggest that the use of representations in professional learning may help teachers develop the habit of attending to specific details in the work; exploring multiple explanations for what students do; perceive a broader range of abilities, struggles and confusions in students; and remain aware of the limitations of what student work alone can reveal about student thinking. These habits and attitudes may help teachers explore alternative explanations for the work of students that they believe they know very well. Teachers can also share their students' work with colleagues and invite fresh insights into their students' thinking.

Endnotes

All participants' names have been changed.

Acknowledgments

I thank the study participants for their insights and enthusiasm. I thank Profs. Deborah Stipek, Hilda Borko, Jennifer Langer-Osuna, and members of MERGe for their valuable inputs.

PUBLIC SENSEMAKING OF NON-REHEARSING TEACHERS DURING DEBRIEFS OF REHEARSALS

Jen Munson
Northwestern University
jmunson@northwestern.edu

Erin E. Baldinger
University of Minnesota
baldi013@umn.edu

Rehearsals have become a common way to support mathematics teacher learning. Primarily, research on rehearsals has focused on the experience of the rehearsing teachers, and we know much less about the experiences of non-rehearsing teachers. In this study, we investigate non-rehearsing teachers' public sensemaking about rehearsals during debrief discussions following rehearsals. We use the lens of professional noticing to capture the ways in which non-rehearsing teachers made sense of the rehearsals and positionality to account for the dual roles of student and teacher that non-rehearsing teachers take on in rehearsals. We found that non-rehearsing teachers primarily attended to and interpreted their experiences from the position of student, and made connections beyond the rehearsal from the position of teacher. These findings have implications for considering the experiences of all rehearsal participants.

Keywords: Teacher Education-Inservice/Professional Development, Instructional Vision, Instructional Activities and Practices, Classroom Discourse

Recent literature in mathematics teacher preparation focuses on how coached rehearsals can be used to support the learning of complex instructional practices (e.g., Ghousseini, 2017; Lampert et al., 2013). In these approximations of practice, one person typically takes on the role of teacher, while the rest of the group takes on the role of student. The rehearsal is usually facilitated by a teacher educator (TE) who takes on the role of coach (Kazemi, Ghousseini, Cunard, & Turrou, 2015). As these approximations of practice have gained prominence in both pre-service and in-service professional development, research has focused on the learning of participants who take on the role of teacher (e.g., Ghousseini, 2017; Lampert et al., 2013). However, we know much less about the experiences and learning opportunities for those who take on the role of student. In this paper, we examine the experiences of secondary mathematics teachers taking on the role of student in rehearsals during a summer professional development institute. In particular, we describe how these non-rehearsing teachers (NRTs) using noticing to make sense of their experiences during the reflective debrief discussions that follow each rehearsal.

Prior Literature

Often, after a rehearsal, all participants (rehearsing teachers [RTs], NRTs, and TEs) engage in a debrief discussion. This type of discussion could take many forms based on the learning goals for the rehearsal. For instance, a debrief could serve as a venue for RTs and NRTs to reflect on and discuss their experiences during the rehearsal (e.g., Baldinger, Selling, & Virmani, 2016). This kind of reflective post-rehearsal discussion, facilitated by the TE, represents an opportunity for public sensemaking, or "collaborat[ing] on sensemaking as a shared group goal" (Ruef, 2016, p. 16). Through public sensemaking, RTs, NRTs, and TEs all have a chance to learn from one another and reflect on the rehearsal experience. Public sensemaking is also valuable from an analytic perspective, because it gives insight into some (but not all) of participants' sensemaking about a given experience. In this kind of reflective debrief structure, we wonder about what sensemaking NRTs share publicly.

One way to describe public sensemaking analytically is through the lens of professional noticing. We draw on the framework for the professional noticing of children's mathematical thinking (Jacobs, Lamb, & Philipp, 2010). When engaging in the work of noticing, teachers *attend* to specific details, *interpret* those details, and finally *decide how to respond*. In the context of a debrief discussion, NRTs might attend to and interpret an event that occurred during the rehearsal. However, in this context, the NRT would not be deciding how to respond to student thinking, but rather might describe implications or connections that extend their thinking beyond the specific context of the rehearsal itself. This noticing framework provides a lens through which we can describe the public contributions made during debrief discussions.

NRTs spend rehearsals acting as students, and then they are asked to apply what they learn from rehearsals to their work as teachers. In other words, NRTs are asked to change their positionality, moving between the positions of teacher and student during the rehearsal and debrief. How a person positioned themselves in an interaction can influence the obligations they feel (Aaron & Herbst, 2012; Herbst & Chazan, 2012). In particular, being positioned as teacher versus being positioned as a student can change how people react to the same contexts (Baldinger & Lai, 2019). Positionality is thus an important consideration that might help explain how NRTs engage in public sensemaking. Given this, we ask the following research questions: (1) How do NRT use debrief discussions to publicly make sense of their experiences during rehearsals? (2) How do NRT position themselves during debrief discussions? (3) In what ways is positioning related to NRT noticing?

Methods

Setting and Participants

This study took place in the context of professional development for early-career (2nd-7th year) secondary mathematics teachers serving lower-income schools. This two-year fellowship included two-week summer institutes and ongoing online coaching during both school years. Our research considers the second summer institute, which focused on facilitating collaborative group work. Participants included 22 high school mathematics teachers from comprehensive public, magnet, and charter schools across the US.

Design

The summer institute culminated in a full day during which all participants had the opportunity to rehearse leading collaborative group work. Participating teachers were randomly assigned to one of two rehearsal rooms. Four rounds of rehearsal were conducted in each room, so that each teacher had the opportunity to rehearse the focal practice once and participated as a NRTs three times. Additional math teachers were recruited to participate as NRTs to increase the class size in each room. After each rehearsal, the facilitating coach prompted the group to discuss the experience, beginning by asking RTs to share "some of the things in your head right now" and then pose any questions they had for the NRTs. Debriefs then pivoted to NRTs addressing any RT reflection questions and segued into general reflection. All debriefs ended with "final thoughts" from the RTs.

Data Sources and Analysis

This study draws on audio and video recordings of the debrief discussions following each of the eight rehearsals at the end of the second summer institute. Debrief discussions ranged in length from 14 to 23 minutes. Each was professionally transcribed for analysis.

Each talk turn (n = 454) was coded by participant type (RT, NRT, TE) and then segmented based on the component of noticing represented in the speech, (i.e., attending, interpreting, implicating), where *attending* and *interpreting* were defined by prior research (Jacobs et al., 2010) and *implicating* was defined as making connections beyond the rehearsal (e.g., to the speaker's own classroom) or considering alternative pathways for the rehearsal itself. Emergent coding was used to classify any remaining utterances. Each talk turn segment was then coded for the positionality the speaker took in the utterance (e.g., teacher, student). If a single utterance took more than one position, it was further segmented such that each utterance could be given a single position and noticing code pair (n = 780). Emergent codes were developed to further classify utterances coded as *attending* based on *to what* the NRTs were attending. Code matrices were developed within and across the eight rehearsals to explore patterns of participation. Initial patterns and descriptive statistics are provided in the findings. A chi-square test was performed to test for independence of positionality and noticing type.

Findings

Through our analysis, we found that *public noticing* was inherent to the sensemaking of NRTs in debrief discussions of rehearsals. Of the 762 talk turn segments in the data, 560 segments (73.5%) were NRTs attending to, interpreting, or implicating the rehearsal experience. The remaining segments were either affirming (n = 132) or connecting to (n = 33) others' contributions. Predominantly, NRTs made sense of rehearsals by attending to and interpreting their experiences. Of the 560 noticing utterances, 34.3% were attending, 45.7% were interpreting, and 20.0% were implicating.

Positionality and Noticing

The positionality of NRTs during debriefs played a role in their noticing. When NRTs reflected on their experiences during rehearsals, they most frequently took the position of students (80.5% of noticing utterances). This pattern was most pronounced when NRTs attended to or interpreted their experience, and NRTs' positionality often switched to teacher when implicating (see Table 1). We used a chi-square test for independence to examine the relationship between the noticing component NRTs engaged in aloud and the position they took when doing so. The relationship between these variables was significant, χ^2 (4, n = 560) = 183.23, $p < 0.0001$. When NRTs were attending to or interpreting their experiences they were more likely to do so as students, but when implicating, they were more likely to do so as a teacher.

Table 1: Contingency Table of Positionality and Noticing Component of NRT Utterances

	Positionality			
Noticing	Student	Teacher	TE	Total
Attending	187	5	0	192
Interpreting	225	31	0	256
Implicating	42	66	4	112
Total	454	102	4	560

Attending To

Looking more closely at NRTs' attending talk turn segments (n = 192), we found that what they attended to during debrief discussions spanned 8 categories: (1) the presence of RTs, (2) the moves RTs used, (3) the outcome of the moves used by RTs, (4) the structure of the activities as planned by RTs, (5) the physical materials used in the rehearsed lesson, (6) NRTs' own mathematical work and decisions, (7) NRTs' mathematical struggles, and (8) the moves TEs used to facilitate the rehearsal. Talk turn segments could be coded for more than one attending category.

NRTs primarily focused their attending on the moves the RTs used with them during collaborative work and the mathematical work and decision-making their own group engaged in (see Figure 1). This split points toward the ways that NRTs juggle attending to themselves and the RT during debriefs, while staying nearly entirely in the stance of student. In the five instances where NRTs engaged in attending from the position of teacher, they primarily attended to RT moves or presence.

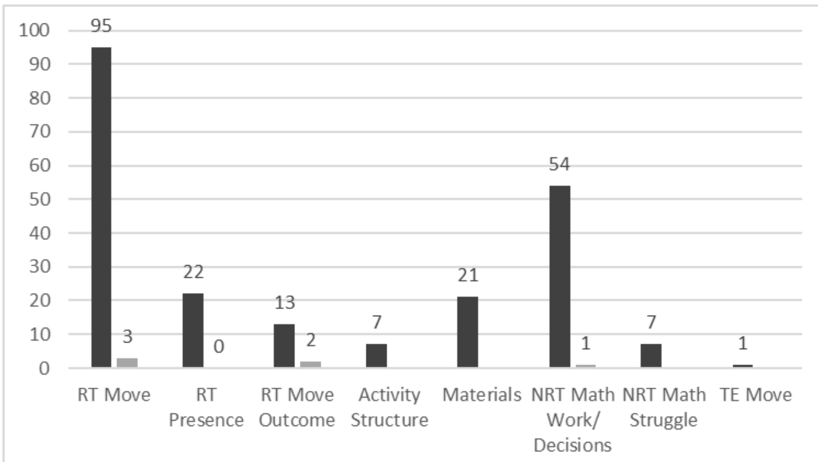

Figure 1: Distribution of What NRTs Attended to During Debrief Discussions When They Positioned Themselves as Student (darker gray) or as Teachers (lighter gray).

Significance

Debriefs of rehearsals created a space for NRTs to publicly make sense of their experiences through noticing, with an emphasis on attending to and interpreting the details of the rehearsal from their position as students. Rather than "deciding how to respond" as the third component of noticing, as it is in the professional noticing of children's mathematical thinking (Jacobs et al., 2010), this study found a third component of noticing in debriefing rehearsals appears to be drawing implications for practice. Responding to student thinking is not the goal of rehearsals as it is in classrooms; rather learning in, from, and for practice is what is called for in the rehearsal setting (Lampert, 2010). This finding contributes to the body of literature on teacher noticing by considering how noticing is used to make sense of learning settings other than the classroom. This study suggests that there is a cognitive shift NRTs make when attending and interpreting from the position of student to implicating in the position of teacher. Further analysis is needed to understand the conditions that foster this shift and how it contributes to the learning goals of rehearsal. In facilitating rehearsals, mathematics teacher educators may need to consider structuring venues for NRTs to make this shift, and debriefs of rehearsals can serve this function.

NETWORKED PROFESSIONAL DEVELOPMENT: AN ECOLOGICAL PERSPECTIVE ON MATHEMATICS TEACHER LEARNING

Robin Anderson
North Carolina State University
randers6@ncsu.edu

Teacher learning does not happen only during planned traditional professional development programs. In this study, I situate teacher learning within a complex learning network where learning happens amongst and in-between multiple communities of practice. Using survey data from 322 teachers who participate in an online learning community, I argue that teachers draw upon multiple parts of their learning network to respond to the needs of their students. This study seeks to broaden what counts as mathematics teacher professional development.

Keywords: Inservice Teacher Education/Professional Development, Technology

Access to supportive learning communities is critical for the continued professional development of mathematics teachers and the subsequent learning opportunities they provide to their students. With new standards every decade, new students every year, and new technology seemingly adopted every month, teachers must continually learn to keep up with change. Yet, only 25% of teachers report satisfaction with the professional learning that their schools offer (Bill and Melinda Gates Foundation, 2014). Teachers report dissatisfaction with the insufficient time included for professional development during the school year, and the content of professional development often not contextually relevant. To combat inadequate professional development offered by their employers, teachers look for support elsewhere. In this research I examine the complexity of teacher learning networks as they expand beyond traditional forms of professional development.

Framing

Responsive teaching requires teachers to adjust their teaching to meet the needs of their students. Often teachers find themselves modifying or developing new lesson plans overnight in response to their student's needs. Teachers learn in and from practice in multiple ways to become responsive teachers (Ball & Cohen, 1999). Some teachers find value in traditional professional development guided by research based best practices (Desimone 2009; Borko, Jacobs & Koellner, 2010). While others look to informal learning communities, such as online networks, to become responsive teachers (Moore and Chae, 2007; Smith Risser, 2013). But often, teachers are attending to the needs of their students by seeking professional development from multiple learning communities both formal and informal.

In their pursuit to respond to the needs of their students, teachers learn among multiple communities. Often times teachers move between communities to develop a more complex understanding of the teaching and learning of mathematics. Learning among multiple communities is motivated by both necessity and desire. Teachers might find a lack of support in one learning community and therefore turn to another to find the desired knowledge. An ecological perspective on learning allows for a multi-dimensional approach to investigating how teachers learn about teaching and learning within and across multiple communities. Barron (2004) defines "a learning ecology as the accessed set of contexts, comprised of configurations of activities, material resources and relationships, found in co-located physical or virtual spaces that provide opportunities for learning" (p. 6). This framework legitimizes types of teacher learning that are often overlooked within traditional studies on teacher professional development. Within the framework, learning within structured professional development is valued alongside non-traditional forms of teacher learning like blogging or online forums. Researchers have investigated the learning opportunities with an ecological perspective within multiple contexts: youth technology learning (Barron et al., 2009), adult amateur astronomers (Azevedo, 2013), film fans (Sheridan, 2008), and youth summer learning (Akiva, Kehoe, & Schunn, 2016). In this research I seek to add to the examination of mathematics teacher professional development by using an ecological perspective which highlights learning across multiple communities.

Methods

Setting

This report will include initial findings of a survey, which comes from a larger study that examines teacher learning networks. The participants of the study are members of a Facebook group that was started in the summer of 2017 by Youcubed, a mathematics education research group at Stanford University. The group was created to provide a space where teachers, and other individuals interested in mathematics education, could network around reform oriented mathematics education.

The group has new, member-generated, content daily. Members of the group often post questions, share struggles, success stories, and less frequently post links to articles around mathematics education. On average the group has seven original posts a day, 95 comments on existing posts, and 209 reactions. Reactions are the way group members can react to a post, or comment, without writing anything. Members can react by clicking the like, love, haha, sad, or angry emojis at the bottom of the post or comment. In general, activity on the group occurs daily through multiple forms of participation.

Participants

The survey participants are a subset of the Youcubed Facebook group. The survey was posted in the Facebook group and members of the group took it at their convenience. The survey was solicited as a general survey about their professional learning experiences. 322 completed surveys were collected. Because the sampling of the survey was based on convenience, the results are not assumed to be generalizable.

There were 300 female (93.1%), 20 males (6.2%), 1 non-binary/third gender (.3%), and 1 prefer not to state (.3%). The majority of teachers self-identified as being White or Caucasian (86.6%). 3.7% self-identified as Asian, 2.5% self-identified as Hispanic, and .3% identified as Black/African American. The remainder of the respondents self-identified as two or more races.

The majority (97.2%) of respondents have a teaching credential. There was a variety of levels of teaching experience with a majority of teachers having at least 16 years of teaching experience.

Data Sources and Collection

A survey was designed based on a previous learning ecology survey (Barron, 2004) to measure teacher learning networks. The survey was intended to measure, through learning topics and learning partners, the complexity of teacher professional learning networks. The survey included three parts: 1) general demographic questions about the teacher and the school in which they teach, 2) professional development habits through questions around time spent on learning activities, 3) The final part of the survey aims to measure the complexity of the network by collecting data on learning topics and learning partners.

This report will focus on the third part of the survey that intended to measure complexity in the learning networks. The teachers were asked, through a multiple choice question, which topics they learn about when they seek new knowledge about the teaching and learning of mathematics. The topics included: assessment practices, facilitating classroom discussions, scope & sequence of your subject, classroom management, mathematical content knowledge, interpreting student work, unit/lesson design (plans, tasks, activities, etc.), groupwork strategies, math games, strategies for interacting with stakeholders (parents, community, administration, etc.), technology ideas, supporting second language learners, grading practices, supporting students with special needs, classroom routines, questioning, and mindset/brain science. Respondents were also given fill-in-the-blank fields labeled “other” to type in topics that were not covered in the above list.

With the intention of understanding how teachers learn about the above topics, teachers were asked to select learning partners. For each topic that the teacher selected to learn about, a list of 15 learning partners were provided to the teachers to select. The list of learning partners included: colleagues, administrator, coach, in-person learning community (fellowships, conferences, district-sponsored network, etc.), family, university course, websites (blogs, teachers-pay-teachers, Wolfram-Alpha, etc.), online networking community (twitter), online networking community (Facebook), online networking community (other), online webinars, online course, newsletters, books, and journals. The learning partners come from both existing literature on teacher learning networks (Baker-Doyle, 2014) and personal conversation with mathematics education researchers and educators. Thus, for each topic the teachers indicated they wanted to learn about, they also indicated their learning partners. These selections produced a learning network.

Analysis

The survey was constructed to measure the complexity of teacher learning networks. The complexity will be measured based on average number of learning topics, average number of learning partners, and visualization of learning network. While visualizations do not quantify the complexity of the networks, it will help the readers appreciate the interconnected nature of learning within a teacher learning network.

Results

The 322 teachers responding to the survey reported on average they were interested in learning about eight different topics in mathematics education. The top five topics were mindset/brain science (n=254), assessment practices (n=245), unit/lesson design (n=218), facilitating classroom discussions (n=215), and mathematics content knowledge (n=210).

When selecting learning partners, the survey respondents on average elected 7 different learning partners across their desired learning topics. This does not mean that respondents turned to seven different learning partners for each of the topics, but rather between all topics they selected on average seven different learning partners. The top five learning partners were colleagues (n=288), websites (n=273), online networking community/Facebook (n=247), books (n=246), and in-person learning community (n=242).

Complete learning networks of the 322 teacher respondents were built to illustrate the complexity of teacher learning networks. Figure 1 is an example of one respondents learning network. This visualization shows that teachers learn about specific topics within multiple communities. For example, this teacher learns about mindset/brain science from six different learning partners (colleagues, Facebook, websites, coach, university course, and books).

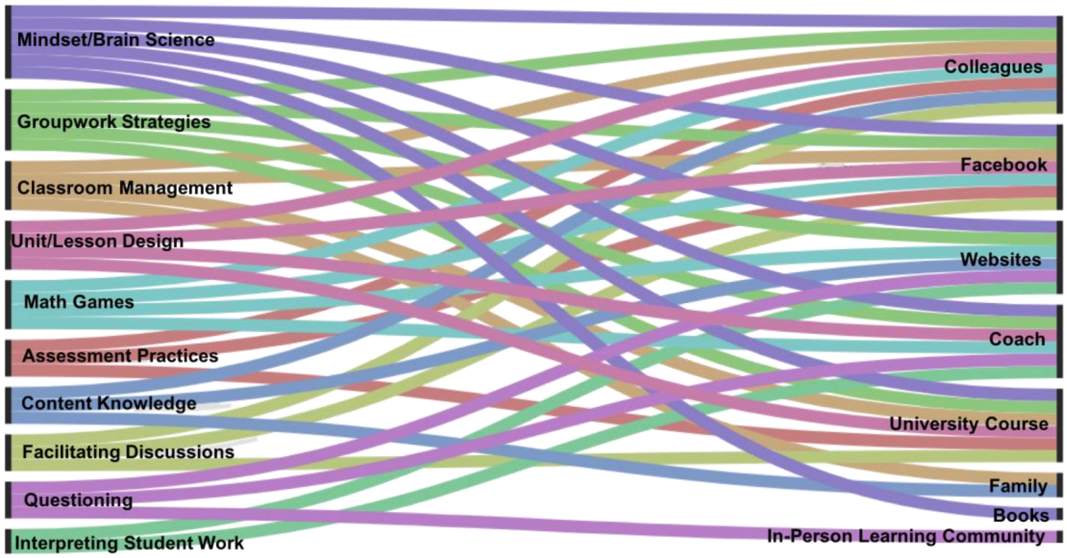

Figure 1: Teacher Learning Network Visualization Example

Discussion

Teachers that responded to this survey desired to learn about multiple different mathematics education topics with multiple different learning partners. As teachers seek out new knowledge to respond to the needs of their students, they are learning about individual topics within multiple learning communities. By moving knowledge between learning communities, mathematics teachers have the potential to develop a more complex understanding of the topic they desired to learn about. With membership in multiple learning communities, teachers experience "boundary encounters" in which they share the practices—new, or augmented, knowledge—between their multiple learning communities (Wenger, 1998). It is during the "boundary encounters" that innovated ideas are shared and teachers have the potential to develop a more complex understanding of their desired learning topic.

An ecological perspective on teacher professional development allows researchers to highlight the complexity of a teacher's learning network. Using a learning ecology survey, data was collected that proved teachers are not just learning from traditional forms of professional development, but rather they report to have multiple learning partners. Further analysis of both the survey data, and also interview data from the larger study, will provide a more complete understanding of how teachers are using their complex networks to make sense of new knowledge of mathematics teaching and learning.

MATHEMATICS TEACHERS' PERCEPTIONS OF THE INSTRUCTIONAL QUALITY ASSESSMENT AS A REFLECTIVE TOOL

Amber G. Candela
University of Missouri – St. Louis
candelaa@umsl.edu

Melissa Boston
Duquesne University
bostonm@duq.edu

This brief research reports details a professional development using the Instructional Quality Assessment rubrics (Boston, 2012) as the frame for teachers reflecting on their selection and implementation of tasks. The purpose was to find teachers' perspectives of how an observation protocol typically used by researchers could be used as a professional learning tool with teachers. Through case study, we found themes related to teachers finding the rubrics to support their reflection on teaching with cognitively demanding tasks, their ability to provide feedback to colleagues, and their desire for more direct feedback from researchers and instructional leaders.

Keywords: Teacher Education, Inservice/Professional Development

In order to provide students with the opportunity to engage in cognitively challenging mathematical tasks, teachers must regularly select and implement tasks that promote reasoning and problem solving (NCTM, 2014). As such, one of a teacher's most important decisions is choosing the tasks to be used during instruction (Lappan & Briars, 1995). Teachers need knowledge of the characteristics of tasks that have the potential to engage students in high quality mathematics. Once a teacher has selected a cognitively challenging task, they also need to implement that task at a high level to support students' mathematical thinking (Henningsen & Stein, 1997). Teachers can implement cognitively challenging tasks, but not maintain the cognitive demands, depending on how the task is implemented (Son & Kim, 2015; Tekkumru-Kisa & Stein, 2015). Hence, it is not enough to select cognitively challenging tasks, the implementation of the task matters.

A way to provide opportunities for teachers to learn about selecting and implementing cognitively challenging tasks is through professional development (Boston & Smith, 2009, 2011; Stein, Grover, & Henningsen, 1996). The challenge for those designing and providing professional development is to identify a format that adequately supports teachers in enhancing their instruction. This study builds off a previous study on professional development aimed at supporting teachers' selection and implementation of high cognitive demand tasks (Candela, 2017) by using the Instructional Quality Assessment (IQA) rubrics (Boston, 2012) as a frame for supporting teachers' selection and implementation of tasks. In the original professional development, the IQA rubrics were used to rate teachers' implementation of tasks, but teachers were not introduced to and had no interaction with the IQA rubrics. In this pilot study, we intended to use the IQA rubrics as a tool *with* teachers, so teachers could become familiar with the rubrics, use the rubrics to support their selection and implementation of cognitively demanding tasks, and be empowered to direct their own instructional change. In this brief research report, we describe a yearlong professional development utilizing the IQA rubrics as a frame to support teachers' selection and implementation of cognitively demanding tasks and the teachers' perspectives on using the rubrics to support mathematics instruction.

Methodology

In order to understand the teachers' perspectives, we utilized case study (Yin, 2003) to develop thick descriptions and answer questions about teachers' perspectives with respect to the phenomenon of selecting and implementing high cognitive demand tasks, using the IQA as a frame for assessment and reflection. The case was defined as the set of school participants. We collected multiple data points including the individual teacher interviews and final group interview presented in this brief report to gain teachers' voices on the professional development. We analyzed data to find common themes among participants with particular interest in teachers' perceptions of using the IQA rubrics as a tool to support their selection and implementation of tasks, with the following research question driving the research: What aspects of the IQA rubrics and professional development did teachers identify as affecting the implementation of high cognitive demand tasks?

The research took place at a K-8 public charter school in a large Midwestern city. The school population has around 900 students with diverse student body: 44% of the students are White, 26% are Black, 17% are Hispanic, 7% are Asian, and 6% are multi-racial. Sixty-eight percent of students receive free or reduced-price lunches, 22% of students are English Language Learners and 20% receive special education services. The participants (n = 10) included two teachers from grades three through five to provide each with a collaborative partner, each mathematics teacher from grades six through eight, and the mathematics instructional coach. The intention was to create a core of teachers (along with the instructional coach) who could then share and support other teachers with what they learned. Building administrators also attended sessions so they could be familiar with the rubrics and use the rubrics in observations to support mathematics instruction based on cognitively challenging tasks.

The Instructional Quality Assessment and Professional Development

The IQA rubrics to assess students' opportunities to learn mathematics with understanding based on the premise that, in order for students to engage in rigorous mathematics, they need access to tasks that allow and promote such engagement. The Levels of Cognitive Demand (LCD) and the MTF (Stein et al. 1996) inform the IQA's set of Academic Rigor rubrics (e.g., Potential of the Task, Implementation of the Task, Teacher's Questions, and Students' Discussion rubrics). These rubrics measure students' work, the level of the task, and the level of implementation. The work of Michaels, O'Connor, Hall, and Resnick (2010) provides the basis for the IQA's Accountable Talk rubrics (e.g., Teacher and Student Linking, Teacher Press and, Student Providing rubrics). These rubrics capture talk that is accountable to the learners in the classroom community and accountable to mathematics in the classroom. Previously, researchers have used the IQA to observe and rate teachers (e.g., Boston & Wilhelm, 2015) but not in conjunction *with teachers* (Candela, 2017).

As professional development can impact teachers' knowledge in ways that impact their instructional practices (Desimone, 2011), the intent was to increase teachers' knowledge around selecting and implementing cognitively demanding tasks using the IQA rubrics for the professional learning activities. The professional development started with two half-day sessions before school started on using the Potential of the Task rubric to select and modify tasks to engage students in high-level mathematics. Seven times throughout the year, teachers participated in 2.5-hour after-school sessions. Each session was based on a different IQA rubric with the general format of introducing the rubric, watching videos at various score levels, and discussing and rating the videos using the rubric. Between sessions, the teachers then practiced using the rubric to support instruction by reflecting on their own instruction and by offering feedback to colleagues. In the following session, teachers reflected on using the rubric and how it affected their practice and repeated the sequence with a new rubric. A few times throughout the year, teachers videotaped lessons and watched and rated the videos using the IQA rubrics and reflected on their instruction with their peer.

Results

Two themes emerged during analysis from the individual and group teacher interviews. The first theme related to teacher reflection and intentional thought. The teachers claimed the IQA rubrics provided a space for intentional thought in their planning of lessons, reflecting on their instruction, developing a vision of instruction, and providing feedback to peers. The teachers claimed the rubrics supported their planning of cognitively challenging tasks because the rubrics helped teachers think through a lesson in depth, to the point where they felt comfortable implementing a high cognitive task. One teacher commented "I enjoyed thinking about my lessons. In thinking about your task and really knowing the ins and outs before you actually teach something. Really being thoughtful." The teachers also commented on how the IQA rubrics provided a space for reflection. Another teacher said, "When you were reflecting on your own lessons, being able to think back to the rubrics was really helpful." The teachers reflected back on their lessons using the IQA rubrics and then used their reflection to inform instruction.

The teachers thought the instructional activities around using the IQA rubrics to rate lessons, of their peers or of example lessons, provided a good model of instruction. The teachers said these activities helped them visualize maintaining high-level tasks and gained a better idea of what their instruction could look like. One teacher claimed "We have always known it was important for [students] to be discussing, but what I've learned, is how to make that come together. We knew what we needed to do, but now we know how to do it." The teachers also claimed that watching their peers teach helped them see other ways of teaching, and because it was in their school, it was more relatable than some of the videos of outside classrooms. By watching example videos of teachers in mathematics classrooms and watching their peers' videos in conjunction with using the IQA rubrics to rate the lessons, it supported their ideas of what it meant to maintain or lower the cognitive demand of a task. The teachers claimed the peer reflection was also beneficial in hearing others' perspectives on their lesson using the IQA rubrics. The teachers discussed how it is difficult critiquing peers' teaching, but the IQA rubrics helped them by being able to point to specific aspects of the rubrics as evidence.

The second theme that emerged was around the structure of the professional development. The teachers wanted more direct feedback on their teaching and a quicker pace of being introduced to the rubrics. The teachers commented they wanted an expert opinion, as they were unsure if they were implementing tasks well in their own classrooms. One teacher commented:

> I felt like there was a lack of immediate feedback. It doesn't help to come and talk about something I did two months ago when I've still been trying to do it. I didn't just do tasks on the days you asked us to do a task and record it. I was still trying to do them along the way and I kind of felt floundering at times, not knowing am I even doing this right.

While the goal of the professional development was to familiarize teachers with the IQA rubrics and how those rubrics could support practice, we should have provided immediate, ongoing feedback based on the IQA rubrics. This may have supported the teachers with their confidence in implementing tasks and their confidence with the tool. The teachers also commented on the pace of the professional development. In its conception, the plan was to introduce a new rubric each month and give the teachers time between sessions to practice what was learned in the session. The thought was to give teachers smaller bits of information each month in order to not overwhelm them with information and give time each month to practice using a new rubric. The teachers remarked they would have rather learned all the rubrics up front, in the first half of the year, and had the second half of the year to practice using all the components. While the intention was to give smaller sections at a time, it was clear the teachers wanted the rubrics all up front, and then more time to practice.

Discussion

One goal of using an observation instrument, originally designed for research, in a professional development setting with teachers was to provide teachers with a tool that could provide focused feedback and direction to promote growth and improve instruction (Boston, Bostic, Lesseig, & Sherman, 2015). While we looked specifically at the IQA rubrics, there are other observation protocols used in mathematics classrooms to assess instruction. These include The Reformed Teaching Observation Protocol (RTOP; Sawada et al., 2002), The Mathematical Quality of Instruction (MQI; Hill et al., 2008), the Elementary Mathematics Classroom Observation Form (Thompson & Davis, 2014), and the Mathematics-Scan (M-Scan, Walkowiak et al. 2014). For more resources on these observation protocols see Boston and colleagues (2015) or Charalambous and Praetorius (2018). Future research could look at how other observation protocols could be used as tools support teachers' instruction of mathematics.

In recent review of literature, Darling-Hammond and colleagues (2017) found teachers who participated in professional development that involved modeling of the instructional practice enabled those teachers to create the vision they needed to reflect on their own practice. This collaborative aspect aligns with effective elements of professional development (e. g., Darling-Hammond, et al., 2017; McGee, Wang, & Polly, 2013). By providing the teachers time to collaborate and learn from each other with the IQA rubrics, they found the professional development to be more effective in supporting their selection and implementation of high cognitive demand tasks. In regards to providing more feedback, Darling-Hammond and colleagues (2017) claim feedback by an expert and teacher reflection should go hand in hand during professional development to supports the effective implementation of new instructional practices. Desimone and Pak (2017) found integrating coaching into cohesive professional development structures enhance the effectiveness of that professional development. This suggests integrating coaching and feedback into professional development supports teachers and provides an opportunity for teachers to immediately incorporate the feedback into their practice. The professional development in our study had an embedded peer feedback and reflection component, which could be strengthened with an expert feedback and reflection component.

While aspects of the IQA rubrics rate students' engagement with the task, such as students' ability to link their ideas to their peers or justify and explain their mathematical solutions, the IQA does not measure student outcomes related to their performance in mathematics. Future research could collect student data in classrooms where teachers use the IQA rubrics and determine if ratings on the rubrics correlate to student outcomes in mathematics.

In this case study, the goal of using the IQA rubrics with teachers was to support their ability to attend to the cognitive demands of instructional tasks, how tasks are implemented during instruction, and the level of mathematical discussion (teachers' and students' contributions) that occurs around the task. The IQA rubrics provided an accessible way for teachers to reflect on their practice and implementation of high cognitive demand tasks. More generally, this professional development indicates that teachers responded well to begin provided with a platform that allowed for self-assessment and self-reflection and to collaboratively assess and reflect on instruction with colleagues.

This study investigates teachers' understandings of teacher student relationships (TSRs), and mathematically productive relationships (MPRs). Seven elementary teachers were coached to increase their teaching quality. Semi-structured interviews were conducted at the end of the coaching program to find out how teachers described the core features of TSRs and MPRs, and the factors that influenced students' mathematics achievement. Safe, mistake-friendly environment, trust and respect, establishing and maintaining clear and high expectations, and consistency were considered as core features of TSRs and MPRs across teachers. However, these features did not align with what teachers considered important for deep mathematics learning.

Keywords: Teacher Professional Development; Teacher Attitudes; Teacher-student Relationship

Ensuring that schools are safe, nurturing spaces is critical for children's cognitive and social development (Brophy, 1998; Davis, 2001). In particular, adult-child relationships play a significant role in supporting children's development (Pianta, 1999). In this regard, positive teacher-student relationships (TSRs) are considered essential for quality learning to occur. In this paper, we investigated (i) teachers' perceptions of strong teacher-student relationships (TSRs), (ii) how they should unfold in the mathematics classroom [referred to as mathematically productive relationships (MPR)] and (iii) the extent to which teachers see these relationships as fundamental to students' mathematics learning.

Teacher-Student Relationships (TSRs)

Healthy TSRs promote higher academic achievement and behavioral adjustment and are associated with pleasant student peer relationships (Hughes & Kwok, 2006), better connections with school and engagement in the classroom (Furrer & Skinner, 2003), and higher overall achievement (Crosnoe, Johnson & Elder, 2004). When TSRs are positive, students are more likely to work hard and persevere, to risk making mistakes, and seek help when needed (Murray & Greenberg, 2000) – dispositions essential to being powerful mathematical thinkers. Thus, they tend to have a positive influence on students' achievement, often mitigating the negative effects of socio-economic status (Hattie, 2009). When teachers are unable to develop and sustain these kinds of relationships, students often show lack of focus, low levels of on-task behavior and performance, and engage in disruptive behavior (Marzano, Marzano & Pickering, 2003), thereby negatively influencing learning that occurs in the classroom. As such, how a teacher conceptualizes her teacher-student interactions in the mathematics classroom is important. We refer to these interactions as mathematically productive relationships.

Building Mathematically Productive Relationships (MPRs)

We consider MPRs to be healthy teacher-student interactions that foster mathematical caring, and an emotionally safe environment that encourages intellectual vulnerability, problem solving and academic risk-taking. Similar to TSRs, maintaining healthy MPRs involve communicating positive expectations, engendering feelings of belongingness and pride in the classroom community through warm and responsive interactions, demonstrating caring, and attending to emotional needs that arise personally and for students (Boynton & Boynton 2005; Davis, 2004). However, although there is significant overlap, these features may unfold differently in the math classroom as the primary goal of MPRs is to develop strong mathematical thinkers.

Communicating (and Acting On) Positive Expectations

In the math classroom, acting in ways that help students meet high expectations means selecting worthwhile and rigorous tasks that are developmentally appropriate, then scaffolding students' productive struggles in ways that build ideas. Shaping MPRs may unfold differently than TSRs. Boynton and Boynton (2005) suggest communicating positive expectations by calling on students equitably as a key aspect of promoting positive TSRs. However, two essential practices for supporting mathematical learning is to be selective about the student responses showcased and to sequence these tasks in ways that extend students' thinking (Stein & Smith, 2011).

Relationship Building and Demonstrating Caring

Expressing sincere acts of care towards students will create a positive learning climate, engender trust, and encourage students to achieve the high expectations set by their teacher. Mathematical caring relations "conjoins affective and cognitive realms in the process of aiming for mathematical learning" (Hackenberg, 2010, p. 237). Focusing on productive struggle, where students will experience unpleasant emotions, the mathematically caring teacher may not try to relieve these unpleasant emotions (which is the typical approach of general caring); rather, focus on helping the student channel these emotions in ways that encourage perseverance, and focused and divergent thinking.

Reducing Your Own Frustration and Stress

Teachers' emotional experiences are core aspects of their daily work, particularly in relation to instruction, TSRs, and educational change (Schutz & Zembylas, 2009). In this regard, the continual experience of unpleasant emotions (e.g. anger, frustration) tends to have detrimental effects on teachers' decision-making and instructional practices often leading to attrition (Cross & Hong, 2009). Unless regulated appropriately, heightened unpleasant emotions can interfere with teachers' abilities to develop or maintain an environment that prioritizes the features of productive TSRs and MPRS.

Methods

This study involved seven elementary (K – 5) teachers from three school districts in the Midwest serving high populations of students of color and eligible for free and reduced lunch.

Data Sources and Analysis

The data came from three-hour, semi-structured interviews at the end of the coaching cycles. The questions focused on a range of topics including teacher identity, emotions, beliefs, as well as teachers' definitions of TSRs and their importance, factors that supported positive TSRs, factors that supported mathematical success and teachers' perceptions of productive struggle. The interview transcripts were coded and coded statements were closely examined and categorized to identify overarching themes that captured teachers' perceptions (Saldana, 2005).

Teachers' Descriptions of Factors That Support Positive TSRs And MPRs

Safe, mistake-friendly environment

Several participants foregrounded the importance of trust and building a safe environment where students could be themselves and not be embarrassed to make mistakes. These perspectives were expressed in Wilma's descriptions of the important elements of healthy TSRs. She stated, "It's OK to make mistakes. And we talk about that a lot-- whether it's behavior, whether it's math. yeah, it's OK to make mistakes and using those mistakes as learning platforms." She responded similarly when describing the qualities of MPRs. She emphasized the importance of students feeling comfortable in the environment to share their ideas, ask questions and attempt multiple approaches without ridicule.

Trust and Respect

Two of the teachers emphasized the role of trust and respect in establishing and maintaining TSRs and MPRs. In order to achieve positive TSRs, there needs to be mutual respect between the teacher and student. Linda shared her insight explaining, "[It depends on] trust that is built there. The utmost important thing is that the student respects you and to gain and earn that respect, you have to delve into those relationships - you have to share pieces of yourself." She reiterated later, when asked to describe the core features of MPRs, "Well, I think it's kind of the same thing. I think it's that trust between the student and the teacher. To be able to get down to the nitty-gritty." For Linda trust and respect were fundamental to productive TSRs and establishing this creates and open, safe atmosphere to share.

Establishing and Maintaining Clear and High Expectations

In addition to engendering trust and respect, Julie also underscored the importance of teachers having high expectations "Establishing that safe environment, establishing a personal relationship, a high relationship, where they know their boundaries. They know their expectations. And they know that they are high expectations and that they will be challenged." Julie described the importance of ensuring that the teacher defines the relationship making sure students know the parameters. Both Julie and Anderson were explicit about ensuring that students know what the expectations are, that the expectations are high, and they are there to support them in achieving their goals.

Consistency

There was general sense that these core features of both MPRs and TSRs were to be applied consistently – they should be core pillars of the relationships. Bradley, a third-grade special education teacher, in addition to the attributes mentioned above highlighted the importance of consistency. He captured it well in his statement, "No matter what happens the teacher will most likely react in the same way as they did the day before… consistency is really important for kids…that they know that when you say something that you're going to follow through." Embedded in the teachers' responses was that for both TSRs and MPRs to be healthy, teachers need to be committed to ensuring their classrooms were consistently safe spaces – mistake-friendly, engendering mutual trust and respect with high expectations.

Teachers' Descriptions of Factors That Promoted Mathematical Success

Working with the Student Over Time

All the teachers thought that learning occurred over time through building knowledge of students, how they think and what approaches best support them in advancing that thinking. It's critical that the teacher is "taking time, having the time with them to explore their little mind"

(Sam, post interview). It was important that teachers have opportunities to understand students as learners to best support them mathematically.

Developing a Partnership Around Learning

In addition to time investment, both teacher and student should have similar goals of their interactions - learning. In this regard, teachers found that it was important that this shared goal be enacted in the form a partnership, “like a partnership, like we both learned, [like we] came to this point together.” The invest of time and work should be mutual, Wilma shared that “there's not one particular thing. I think it's a whole body of work on the teacher's part- on the student's part.” For success, it’s important that both parties are committed to doing that work toward a successful end.

Knowing the Basics and Using Manipulatives

Many of the teachers stated that they thought that “a key factor [for] success was knowing the basics” (Anderson, post interview). Similarly, Julie described how she supported a student, highlighting “… just really spending time with her and going back to the basics and using the manipulatives.”

Persistence

In conjunction with the investment of time, teachers also talked about the importance of persevering and being persistent, that is “it was just-- just that constant persistence with them and just trying different ways and they finally got it, but that's what I think of when I think of the success.” Persevering is essential for success because engaging in worthwhile mathematics involves challenge and struggle and sometimes “it takes a long time to get through before you get to this new way” (Bradley, post interview).

Discussion

Alignment Between MPRs, TSRs, And Existing Research

Features of healthy MPRs and TSRs overlapped in teachers’ descriptions suggesting these elements may be grounded in their beliefs about beneficial ways to interact with students. We are cautious here in making connections to their instructional practices as we did not include analysis of the teachers’ instruction. In addition, the relationship between teachers’ thoughts and their actions is not linear (Cross Francis, 2014). The participants expressed that strong TSRs and MPRs involved a safe psychological environment for students, where teachers demonstrated care, one of the characteristics identified in the literature as key to mathematical caring relations (Hackenberg, 2010). Establishing and maintaining clear and high expectations, for both learning and behavior, was important - letting students know they are capable thereby warranting high-quality work was a common thread across the teachers’ responses. The teachers considered maintaining trust and respect to be critical to having a safe space. However, absent from the teachers’ descriptions is the need for the emotional fortitude and skill to consistently provide and sustain opportunities for students to think deeply about mathematical ideas. In order to maintain healthy MPRs teachers must help students navigate through productive struggle, and the emotional fluctuations that accompany this process (Hackenberg, 2010), while maintaining the cognitive demand of the task (Smith, 2000). Teachers did not identify any significant distinctions between healthy TSRs and MPRs, perhaps indicating a lack of awareness of the importance of being able to effectively manage the affective and cognitive realms as students engage in learning (Hackenberg, 2010).

Factors That Contribute to Mathematical Success and Their Descriptions of MPRs

The teachers' descriptions of MPRs did not align with the factors they identified as contributing to mathematical success. This would suggest that they considered the factors that support mathematical success to be direct teacher actions supporting mathematical thinking. Although they did not make this distinction directly, it appeared that the teachers perceived MPRs as more distal to student learning than working with the student over time, developing a partnership around learning, persistence, and knowing the basics and using manipulatives. Although the factors the teachers identified are clearly important, we found this disconnect problematic as it seemed to indicate low awareness of how these elements are integrated to facilitate high quality learning. Let's consider the notion of a mistake-friendly environment - mistakes are fundamental to learning and learning is maximized when students are able to leverage their mistakes to extend thinking. If students do not feel safe to make mistakes and do not appreciate their learning potential, then it's unlikely they will persist in "learning the basics" or be open to working alongside the teacher over time. This disconnect between the elements of MPRs and factors supporting deep learning may explain outcomes of research (e.g., Kane et al., 2013) that show that the nature and quality of both the instructional and emotional/social aspects of TSRs tend to be low generally. Although teachers identify healthy TSRs as important, they may not mentally integrate these features with content-specific instructional practices which may help explain research results that do not show improvement in teachers' instructional practices leading to comparable positive shifts in student outcomes (Kraft, 2019)**.**

This paper reports on examining teachers' beliefs about the nature of mathematics and their confidence in enacting mathematical modeling in the elementary classrooms after a school-university partnerships institute focused on designing and implementing (MM) tasks. We found high correlation between teachers' Process of Inquiry and their Confidence in MM Competencies. Some of the key findings from the analysis of the lesson studies and teacher design memos revealed that teachers posed MM questions that related to a) student lived experiences drawing on their personal, school and community events that had MM potential; b) situations that connected to their grade level standards; and c) opportunities to use mathematics for decision-making using descriptive, predictive and optimizing models. The study provides promising pathways to work with elementary teachers as designers of MM tasks.

Keywords: Modeling; Affect, Emotion, Beliefs, and Attitudes; Instructional Activities and Practices; Teacher Knowledge

Objectives/Purpose of the Study

Using design research as a method of inquiry, we collaborated with school district leaders to investigate ways to support elementary teachers design and enact mathematical modeling(MM) as a means to promote problem posing and problem solving in the classroom. The district identified a cohort of twenty teachers who were immersed in a weeklong summer institute to experience MM first-hand and improve their content-specific knowledge of MM. In the second phase of the study, in the fall, teacher designers engaged in Lesson Study and collaborated with the research team on designing MM tasks. Through our study we wanted to better understand how teachers learned to problem pose and design early modeling experiences in the elementary grades. As we studied this ambitious practice, we wanted to assess how teaching with an inquiry stance through mathematical modeling impacted teachers' beliefs about mathematics and their confidence in posing real world problems. The following research questions guided this study:

1. Are teachers' beliefs about the nature of mathematics different before and after participating in a PD on MM? Is there a correlation between teachers' beliefs about the nature of mathematics and their confidence in orchestrating MM in the elementary grades?
2. How do elementary teachers develop their ability to pose MM tasks and design early modeling experiences for elementary students?

Theoretical Framework

In the recent years Mathematical Modeling (MM) has gained attention as a comprehensive and dynamic cyclic process that supports the problem posing and the translation of real-world problems into a mathematical language (NGA & CCSSO, 2010). Problem formulation is one of the critical first steps in MM (MM) which includes posing the real-world problem, making assumptions and defining variables, which then leads to developing a mathematical model, analyzing and assessing the solution, and refining the model (COMAP & SIAM, 2016). In examining research on how MM problems are formulated, Galbraith, Stillman, and Brown (2013) reported on turning ideas into modeling problems where “a nucleus of an idea” is developed into a modeling problem and extended by a related problem closer to the “personal experience of adolescents” (p. 133). Zbiek and Connor (2006) investigated the role of contexts and how modeling can “motivate students to study mathematics by showing them the real-world applicability of mathematical ideas” (p. 89). When posing a MM problem, it is important to choose a context familiar to students because “the formulation of the real-world situation itself requires demanding a priori knowledge” (Caron & Bélair, 2007, p. 127). Based on research on professional development around mathematical modeling, we positioned teachers as designers of MM learning experiences for young learners with the support of a six-month professional development design institute.

Methods

Participants

Participants were 19 in-service, K-6 mathematics teachers and one middle school teacher, in a large mid-Atlantic school district, involved in a professional development (PD) initiative focused on mathematical modeling (MM), between August, 2017 and June, 2018.

Data Collection

To assess teachers’ belief about mathematics, we administered teachers’ Beliefs about the Nature of Mathematics (Tatto, et al., 2012) before they participated in the PD and after. We used the Nature of Mathematics to capture teachers’ attitudes about the nature of mathematics, as well as how the subject is best learned and taught. This survey was made up of two scales: (a) mathematics as a set of rules and procedures - “Respondents who score highly on this scale tend to see mathematics as a set of procedures to be learned, with strict rules as to what is correct and what is incorrect” (Tatto et al., 2012, p. 154); and (b) mathematics as a process of inquiry - “Respondents who score highly on this scale see mathematics as a means of answering questions and solving problems” (Tatto et al., 2012, p. 155). Items on this survey are scored on a Likert scale from 1 - Strongly Disagree to 6 - Strongly Agree. We used these scales to see how posing problems in MM would capture attitudes that may be important to the modeling process.

All of our participants completed a survey at the end of the PD and Lesson Study to gauge their level of confidence orchestrating MM with their students. This survey was created by the project team to assess teachers’ confidence in five processes involved in modeling: posing problems, making assumptions and defining variables, building a solution, analyzing and creating a model and finally revising, refining and reporting on the solution. In this survey, teachers self-reported their level of confidence in orchestrating MM in their own elementary classrooms on a 5-point Likert scale. Each Likert scale item was followed by two open-ended questions asking teachers about their successes and struggles with that competency. 19 teachers had complete survey data at all timepoints. Data were also collected from lesson studies and teacher interviews exploring the processes of MM. We focused on better understanding how teachers involve elementary students in the problem formulation process as they co-construct the problem, how they work through making assumptions, building a solution or a model and revising their model as they relate back to their problems.

Data Analysis

For our first research question, we conducted a paired samples t-test to compare teachers' beliefs on the two factors (Rules and Procedures and Process of Inquiry) before and after participating in the PD. In addition, we examined Pearson's correlations between Rules and Procedures and Confidence in Teaching MM, as well as between Process of Inquiry and Confidence in Teaching MM, all at post. For the second research question, we used Dedoose Version 7.5.9 to code our Lesson Study and interview data and dissect the text into text segments. These text segment were analyzed qualitatively for emergent themes and patterns.

Findings

For our first research question, the results of the t-tests indicated statistically significant differences for Rules and Procedures, $p < .05$, and Process of Inquiry, $p < .001$. Means and standard deviations are presented in Table 1. In addition, through the Pearson's correlations. we found that the correlation between Rules and Procedures and Confidence in Teaching MM was non-significant, $p = .59$, but that the correlation between Process of Inquiry and Confidence in MM Competencies was statistically significant, $p < .001$, and also very high, $r = 0.80$.

Table 1: Means and Standard Deviations of Teachers' Beliefs about the Nature of Mathematics and Confidence in MM Competencies

		Pre	Post
Rules and Procedures	M (sd)	3.72 (0.80)	3.26 (0.76)
Process of Inquiry	M (sd)	4.86 (0.73)	5.50 (0.50)
Confidence in MM Competencies	M (sd)	--	3.74 (0.59)

For our second research question, we analyzed responses to open-ended items on the Confidence in MM Competencies survey, lesson artifacts and memos. Qualitative survey data revealed that teachers focused on authentic contexts; finding everyday situations that provided access to familiar contexts and service learning "opportunities [that presented] themselves out of *real need*." In this way, teachers reported that students' engagement was extremely high. Teachers described students as "excited" and "invested in their learning." They described seeing "emotion and empathy" and "ownership investment" from students in math classes engaged in MM. They also described that students "became risk takers" as a result of their participating in MM. These reflections help illustrate why finding local contexts for MM problems is so critical in problem posing. One common challenge with problem posing and content alignment is in finding age appropriate contexts. Teachers found that it could be challenging to find authentic contexts, relevant to their students, that aligned to mathematical content. When contexts were too complex, teachers found that, “students not connecting with the context leads to struggle with assumptions.”

The video analysis of enactment of problem posing for the teachers who reported highest confidence also helped us better understand ways to promote productive problem posing, and the effectiveness of engaging students in problem-posing activities. Some of the key findings from the analysis revealed that teachers tapped into a) student lived experiences drawing on familiar and meaningful contexts from their personal, school and community happenings; b) mathematical situations that related to their grade level standards; c) opportunities to use mathematics for make decisions using descriptive, predictive and optimizing models. For example, one lesson study team focused on getting students to use mathematical modeling to answer the question, “How can we organize and maintain our supplies to last us all year?”. It took the students awhile to get to the point where they decided to count and inventory their supplies. Students then tracked their usage and how many supplies they had over the course of the next couple months. Once they had multiple data points, students then tried to find trends so that they could predict how much supplies they would have by the end of the year. This was a very interesting point in the lesson and students approached this is varying ways. Some groups looked for patterns and did repeated subtraction and division while others used self-invented ways to try to find the average amount used in a month. Some groups found that they predicted they would have supplies left over at the end of the year (pencils), while others found they would run out of supplies before the end of the year (glue sticks). This lead the glue stick group to determining they had to adjust the use of glue sticks to last longer or find a way to raise money to purchase more glue sticks.

Discussion/Conclusion

An important contribution of this study is finding the positive relationship between teachers' beliefs about the Process of Inquiry and their confidence in MM competencies. Respondents who score highly on this scale see mathematics as a means of answering questions and solving problems. They see mathematical procedures as tools of enquiry, as means to an end, but not as ends in themselves. This inquiry stance helps teachers appreciate the nature of mathematical modeling that involves posing problems, allowing students to make assumptions to narrow their investigation to a focused problem and help facilitate the building solution phase without doing the math for the students. They value the need to provide time and space to facilitate discussion with students around the model they developed so that they can revise, refine and report their model so that they learn to critique and revise their models to maximize learning.

SHIFTS IN SELF-EFFICACY FOR TEACHING ENGLISH LEARNERS: EMERGENT FINDINGS FROM MATHEMATICS TEACHER PROFESSIONAL DEVELOPMENT

Jill Neumayer DePiper	Johannah Nikula	Josephine Louie
Education Development Center	Education Development Center	Education Development Center
jdepiper@edc.org	jnikula@edc.org	jlouie@edc.org

Supports for access and mathematical communication are essential components of mathematics instruction for students who are English learners (ELs), but many mathematics teachers are not adequately prepared to support ELs. The Visual Access to Mathematics project developed and studied teacher professional development (PD) focused on visual representations (VRs) and language strategies in middle grades mathematics. This paper reports on shifts in teachers' self-efficacy for using VRs and for teaching ELs based on participation in the PD. The findings have implications for understanding how PD can affect teacher self-efficacy in these areas.

Keywords: Equity and diversity, Instructional vision, Teacher education, Teacher knowledge.

The Visual Access to Mathematics (VAM) project is engaged in a multi-year effort to develop and study teacher professional development (PD) designed to build teacher knowledge of teaching with visual representations and language access and production strategies to support mathematical reasoning and communication among students who are English Learners (ELs). We recently conducted a cluster randomized trial of the PD to investigate self-efficacy and learning outcomes for participating teachers. Self-efficacy—or one's belief or perceptions about their abilities—can support an individual's incentive to act (Usher & Pajares, 2009) and may lead to change in their instruction. This report presents findings related to participating teachers' shifts in self-efficacy and discusses connections from self-efficacy to specific PD components.

Perspectives and Theoretical Framework

Visual representations (VRs) in mathematics, such as tape diagrams and double number lines, can support student understanding of quantities and relationships (Siegler, Thompson, & Schneider, 2011) and foster students' mathematical problem solving while supporting access to critical mathematical content and processes. Students who are ELs particularly benefit from VRs as VRs support making sense of problems and selecting solution strategies (Ng & Lee, 2008). However, many U.S. teachers are neither experienced nor skilled in understanding and using VRs in mathematics (Orrill & Brown, 2012; Stylianou, 2010), frequently relying on algorithmic thinking, such as the cross-multiplication algorithm in proportional situations, without the ability to demonstrate conceptual understanding or use a VR (Orrill & Brown, 2012).

Additionally, teachers are not consistently provided training for how to support ELs to meet mathematical content standards (Bunch, 2013; Darling-Hammond, Wei, & Adamson, 2010; Samson & Collins, 2012). The integration of language and content during lessons is linked to opportunities for ELs to learn mathematics, and regular participation in "explaining solution processes, describing conjectures, proving conclusions and presenting arguments" both orally and in writing is imperative for ELs (Moschkovich, 1999, p.11). Mathematics teaching practices must "specifically address the language demands of students who are developing skill in listening, speaking, reading, and writing in a second language while learning mathematics"

(Celedón-Pattichis & Ramirez, 2012, p.1). Attention to language is especially important as current mathematics standards emphasize communication and academic language (Bunch, 2013).

The VAM PD was developed to build teachers' knowledge and self-efficacy for planning and implementing mathematics lessons focused on ratio and proportional reasoning content for ELs. The project focuses on ratio and proportional reasoning content because proportionality has been called the "cornerstone of higher mathematics and the capstone of elementary concepts" (Lesh, Post, & Behr, 1988, p. 98). The PD aims to promote teachers' skills in learning and teaching mathematics with VRs because VRs are valuable tools that students developing English skills can use to reason through challenging tasks and to communicate their thinking. The PD also supports teachers in learning how to integrate language access and production strategies into mathematics lessons to support students' mathematical reasoning and communication. The 60-hour VAM PD starts with a four-day face-to-face summer institute, followed during the academic year with eight two-week long asynchronous online sessions, two face-to-face workshops, and four synchronous online meetings. A hybrid face-to-face and online learning approach may promote teacher pedagogical content knowledge and practice as related to student outcomes (Dede, 2006; Treacy, Kleiman & Peterson, 2002). The VAM Theory of Change (Figure 1) identifies key PD activities, hypothesized teacher outcomes, and envisioned classroom and student outcomes. The VAM PD design derives from the research perspective that deep understanding of content is important for teacher practice, and PD that aims to change classroom practice should be embedded in classroom practice and content (e.g., Cohen, 2004). Through insight into students' understandings, teachers can more effectively target math instruction to the concepts, practices, and skills that remain to be learned (Darling-Hammond, et al., 2010).

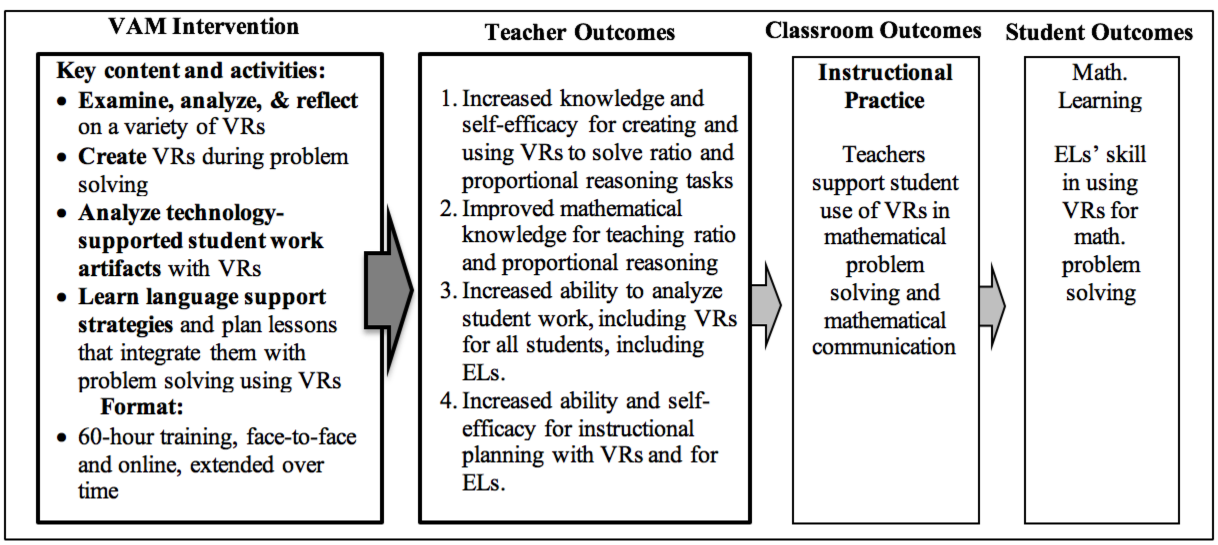

Figure 1: VAM Theory of Change

Methods and Modes of Inquiry

After two years of design and development, a cluster randomized trial involving 101 middle grades teachers across 47 schools in New England was used to examine whether teachers who participate in the VAM PD demonstrate stronger learning outcomes – including higher measures of teacher self-efficacy – than teachers in a control group. This paper addresses the research question: *Compared to control teachers, do VAM PD treatment teachers demonstrate greater* *self-efficacy for planning and implementing instructional activities that integrate support for ELs' language and use of VRs?* A self-efficacy instrument was adapted from items focused on teaching ELs and teaching mathematics (Ross, 2014; Siwatu, 2007; Wright-Malley & Green, 2015). The final instrument included 19 items with a 7-point Likert-type rating scale (Strongly Disagree to Strongly Agree) addressing three areas: using VRs in mathematics (5 items), including, "I am confident I can translate quantitative information into a visual representation to solve a ratio and proportional reasoning task;" teaching with VRs in mathematics (5 items), including "I am confident I can help students learn to create visual representations, such as double number lines and tape diagrams, to solve ratio and proportional reasoning tasks;" and teaching students who are ELs in mathematics (9 items), including, "I can describe strategies that help ELs get started on mathematics tasks in my class."

Treatment and control participants completed the self-efficacy instrument pre and post VAM PD. Based on exploratory factory analysis of the 19 items in our self-efficacy scale, we identified two strong subscales: self-efficacy related to using and teaching with VRs in mathematics, or "self-efficacy-VRs" (10 items, α=0.96; possible score range 7-70), and self-efficacy related to teaching ELs in mathematics, or "self-efficacy-ELs" (9 items, α=0.98; possible score range 7-63). Participants also completed other measures of teacher knowledge that are not reported here.

The effects of VAM PD on teachers' scores on the two self-efficacy subscales were estimated with two-level hierarchical linear models using HLM 7.03 software (Raudenbush, Bryk, & Congdon, 2017). Teachers were clustered within schools (between 1 and 7 teachers per school) with random assignment at the school level. In the final analytic sample after attrition (2% at the school level, 5% at the individual level), pre- and post-test self-efficacy data was collected from 98 teachers (24 treatment schools with 52 teachers; 23 control schools with 46 teachers). Baseline equivalence between our treatment and control groups was established by estimating a two-level model for each subscale with pretest score as the outcome and treatment status entered at Level 2. For self-efficacy-VRs, mean treatment and control group pretest scores differed by an effect size of Hedges $g = |0.10|$; for self-efficacy-ELs, treatment and control group scores differed by $|0.19|$. These statistics suggest baseline equivalence when acceptable statistical adjustments are included in analyses (WWC, 2017.). This study's research question was answered by fitting a sequence of models to predict posttest scores for each self-efficacy subscale; first fitting an unconditional model to estimate the variability at each level, and then a second model that included treatment status at Level 2 and pretest scores (a statistical adjustment, grand-mean centered) at Level 1.

Results

Analysis showed that participation in VAM PD had a positive effect on how teachers scored on the two self-efficacy subscales (Table 1). The mean posttest self-efficacy-VR score was 55.85 points for the control group and 62.34 for the treatment group, or an effect size of g=0.79, controlling for pretest scores. The mean posttest self-efficacy-EL score was 44.74 points for the control group and 54.22 points for the treatment group, or an effect size of g=1.14. Both of these effects are statistically significant at $p<.001$ and may be considered large. The ICC or proportion of variance in teachers' posttest scores that is explained by schools is 0.11 for self-efficacy-VRs and 0.22 for self-efficacy-ELs. The proportion of variance in self-efficacy-VRs posttest scores that is explained by a model that includes both treatment group and pretest scores compared to a model that includes only pretest scores (not shown) is 0.05 at Level 1 and 0.88 at Level 2. The proportion of variance in self-efficacy-ELs posttest scores that is explained by the same model comparison (again not shown) is 0.04 at Level 1 and 0.88 at Level 2.

Table 1: HLM Results for Models of Teacher Self-efficacy in Using VRs and Teaching ELs

	Self-efficacy-VRs		Self-efficacy-ELs	
	Model 1	Model 2	Model 1	Model 2
Fixed effects: Coefficients (SE)				
Model for posttest intercept (β_{0j})				
Intercept (γ_{00})	59.31*** (0.96)	55.85***(1.13)	49.62*** (1.15)	44.74***(1.01)
Treatment Intercept (γ_{01})		6.49***(1.55)		9.48***(1.40)
Model for pretest slope (β_{1j})				
Intercept (γ_{10})		0.28***(0.07)		0.58***(0.07)

Discussion

Findings from this study suggest that VAM PD holds promise for improving the self-efficacy of teachers of ELs in mathematics more broadly. A next step is to explore how specific components of VAM PD may have worked to promote greater teacher self-efficacy, and how these components may be scaled. Teacher responses to VAM PD exit surveys indicate course components they found most helpful for their own learning: doing mathematics tasks and analyzing solutions with other teachers; focused work with tape diagrams and double number lines; and interactions with course instructors and teacher peers at face-to-face workshops. In addition, the project team is examining reflections participants wrote in online notebooks to identify possible paths within the PD experience to increased self-efficacy. For example, one teacher wrote: “Doing the tasks myself increase[d] my repertoire of visuals and the value I place on them for both ELs and increasing students’ conceptual understanding.” This comment suggests that under certain conditions, teachers may come to value the use of specific mathematical tools in instruction more highly as they develop a deeper understanding of these tools. Similarly, another participant noted that being “challenged to apply the various [language support] strategies in different ways in our classroom” supported her ability to implement the strategies routinely, even when not part of a course assignment. The positive impact of VAM PD on teachers’ self-efficacy encourages further study of how the components of the PD may have contributed to teacher change as well as the potential for effective scaling of the PD.

In this paper, the authors present preliminary findings on an exploratory study about the experiences of three in-service mathematics teachers who were participating in a mathematics professional development (PD). Because the authors believe that mathematics classrooms (and PDs) are racialized spaces that can leave room for teachers to position each other and themselves, the authors use Critical Race Theory and positioning theory as the theoretical frameworks to analyze an interaction among three teachers. The authors briefly describe the context of the PD, the backgrounds of the teachers, and the episode to be analyzed. Preliminary findings show how Wanda, a white woman, and Deirdre, a Black woman, position and reposition themselves and each other as more-experienced teacher and less-experienced student. Implications for future research will be discussed.

Keywords: Teacher Education-Inservice/Professional Development; Equity and diversity; Algebra and Algebraic Thinking

Rationale and Background

Recent investigations into the professional development (PD) of mathematics teachers focuses on ways to improve the effectiveness of teachers' experiences. PD that introduces teachers to new pedagogical strategies must center on the mathematics content because there is evidence that content-oriented PD is impactful for teachers; (Marra et al., 2010). Yet there can be issues during PD that may arise among teachers and facilitators, which are similar to what teachers and students experience within the classroom (Adler, Ball, Krainer, Lin, & Novotna, 2005). For example, some facets of PD reflect the dynamics of a mathematics classroom, such as an instructional triangle consisting of interactions among the nodes representing the PD instructors, the participating teachers, and the mathematics content (Borko, 2004). Teachers in PD also consider their own students as they attend to their own learning, which creates an instructional rhombus with a fourth node representing the teachers' real or hypothetical students (Nipper et al., 2011). Moreover, the dynamics of power and status relationships (a perceived social ranking among members) can play a role among teachers in a PD just as they do in the classroom with their students (Cohen & Lotan, 2014). In fact, in PD, these relationships can become even more fraught, because experienced teachers can be positioned (by themselves, by each other, and by those orchestrating the PD) as less-experienced learners. The power behind each of these identities (e.g., as being the more- or less-experienced learner) can shift quickly during a PD and can affect the mathematical learning of each participant in profound ways. Therefore, it is imperative to investigate the ways mathematical identities, power, and status operate for teachers within in a PD so that more teachers learn to notice and address issues of status in their own practice and with their own students.

This paper described in this proposal presupposes that PD workshops, like K-12 mathematics classrooms and the rest of the world, are racialized spaces (Martin, 2009) where participants' experiences are based on racial, gendered, and experiential identities (whether self-imposed and/or imposed by their fellow teachers and the facilitators). The authors use the theoretical frameworks of Critical Race Theory (Delgado & Stefancic, 2017) and positioning theory (van Langenhove, & Harré, 1990) with the analytical framework of whiteness to analyze how three teachers negotiate their shifting identities while solving a task during a PD. Preliminary findings from this study continues the research about teacher identities in an environment (PD) that needs more attention in the field.

Theoretical Framework

As first described by van Langenhove & Harré (1990), positioning theory "refer[s] to cognitive processes that are instrumental in supporting the actions people undertake particularly by fixing for this moment and this situation what these actions mean" (Harré et al., 2009, p. 6). Wood (2013) describes in her seminal paper an example of students positioning themselves and each other: Rebecca (a white girl), Daren and Jakeel (two Black boys), and how Rebecca positions Jakeel as knowing less mathematics while Jakeel repositions himself (and attempts to adopt a positive mathematical identity) as someone who knows mathematics. When people use language to position each other, there are an associated meaning, storyline, and identities with that language and the interaction(s) (Harré et al., 2009; van Langenhove & Harré, 1990). By understanding the meaning behind the language used and how the language can serve a specific purpose for positioning oneself and another, researchers can understand the ways in which language and meaning inform identity formation within mathematics classrooms (Wood, 2013).

When teachers collaborate in PD, they are forming identities while also negotiating multiple hierarchies of positions. Teachers can position each other by using status-laden language regarding their mathematical knowledge, expertise, and potential to contribute to the PD experience. For example, more experienced teachers might position novice teachers as knowing less mathematics and might take control of a task or react to the novice's contributions with condescension. But there is another layer of positioning that happens in PD: teachers who are participating in PD are positioned by the teacher educators (or facilitators) as knowledgeable learners (yet still learners in their own right). In each situation, the teachers in PD are also negotiating their own identities of themselves and of each other as they position (and seek to position) while making sense of the PD interactions.

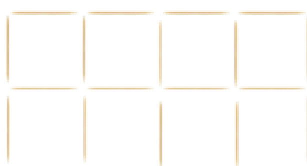
Critical Race Theory (CRT) serves as our second foundational theoretical framework. As summarized by Delgado and Stefancic (2017) and described in more detail by others (e.g., Dixson, Rousseau & Anderson, 2006; Langer-Osuna, 2011; Martin, 2009; Tate, 1997; Taylor, Gillborn & Ladson-Billings, 2015), educational researchers use CRT to examine the ways that race and racism play a role in oppressing and suppressing the voices and success of Black, Brown, and Indigenous people, among others. Martin (2009) argues that mathematics classrooms are racialized spaces in which messages are communicated to students, about students, and for the purpose of positioning students. Martin outlines that:

> Issues of identity—racial, cultural, gender, mathematical—and agency become centrally important when seeking to better understand how students make sense of, and respond to, their mathematical experiences (p. 324).

Similar to Martin, Shah (2017) also argues that "societal narratives about topics like race matter because of how they can become consequential in positioning" (p. 7). Researchers can use CRT to examine the interactions of teachers in PD as they negotiate their identities, especially as related to the notion that PD spaces are also racialized and there are societal narratives in formation. Therefore, given the presumption that learning as a social activity, researchers should examine how race and racism play a role when teachers form their identities within the context of a PD. In this exploratory case study (Merriam, 1994), we explore a single incident from a PD and ask the following research questions: How do teachers in a PD exercise moves of positioning in the context of solving a groupworthy (Lotan, 2003) mathematics task? And how do the teachers' racial identities play out (and become complicated) while solving a task?

Methodology

The authors used critical discourse analysis (Fairclough, 2013) to analyze one episode from a PD workshop facilitated by Prasad. Middle- and high-school mathematics teachers participated in a three-week-long summer institute in which Prasad modeled teaching through problem-solving and using Complex Instruction (Cohen & Lotan, 2014) strategies like assigning group roles. Because all participating teachers planned to teach algebra in the following school year, Prasad presented them with the problem shown in Figure 1 (Driscoll, 1999).



The picture shows a rectangle made up of two rows of four columns and of squares outlined by toothpicks. How many toothpicks would be needed to make a rectangle with R rows and C columns?

Figure 1: Toothpick Task

This episode featured three teachers named Wanda, Deirdre, and Frances (all pseudonyms). All three teachers were experienced, mid-career, self-identified female high-school mathematics teachers of similar ages who taught in the same high-needs, high-density district. Deirdre and Frances were Black, while Wanda was white. The facilitator, Prasad, is Indian-American and is younger than the teachers in the group. Kalinec-Craig is white and the same age as Prasad, and she had worked with the three teachers and Prasad in previous sessions, but was not present for this particular session. Prasad introduced the idea of using group roles to structure equitable participation (Featherstone et al., 2011), but many of the groups in the workshop took up this idea in ways that best suited their own goals. For example, Wanda used Frances' designation as the group's "Presenter" to externalize her struggle to understand Deirdre's solution. Because the interactions and work were recorded using a LiveScribe pen, Deirdre took up her role as the assigned "Recorder." In the preliminary analysis, the authors looked across the transcript of the entire interaction to understand how each participant positioned herself and was positioned by her peers. Preliminary findings focus on the experiences of Wanda.

Preliminary Findings

After the teachers worked individually on the problem, Prasad directed the teachers to discuss their solutions. The following interaction occurred when Deirdre, Frances, and Wanda began talking amongst themselves. Deirdre had developed the expression of "$2CR+C+R$" to express the number of toothpicks in a given rectangle with C columns and R rows. Deirdre attempted to explain her solution (to strategically count the horizontal and vertical toothpicks separately, but in a related way) to Wanda and Frances. For example, each row contained $C+1$

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* St Louis, MO: University of Missouri.

vertical toothpicks, making the total number of vertical toothpicks in the rectangle is $R(C+1)$; similarly, there are $C(R+1)$ horizontal toothpicks in the rectangle.

At one point in the episode, Deirdre attempted to position herself as having a correct solution. However, Wanda, who had not yet developed a viable expression at this point, attempted to position Deirdre as having an incorrect or incomplete solution by stating, "so that's why what [Deirdre]'s talking about might work per se, but I don't understand it the way she's trying to explain it to me." As Wanda tried to replicate Deirdre's solution, she stated, "…so now if I go (oops), I shouldn't have done that, I should have gone over to this one…" to which Deirdre defended the validity of her solution by replying, "…that's why I said one of them [C*R] has to be two." Still unsure of Deirdre's solution, Wanda stated, "...but this isn't going to work for *all of* [the toothpicks] if you're going to multiply by two" (italics added for emphasis). Deirdre persisted and repositioned her solution and herself when she said, "... really? Because what I said was, 'so then my formula became however many rows I have.'" Wanda's insistence that Deirdre (re)justify her solution using Wanda's mathematical constraints and assumptions helped Wanda position herself as the "teacher" and to position Deirdre as a "student" who should mimic the teacher's justification for the solution.

At multiple points in the interaction, Deirdre resisted Wanda's moves to position her as being a learner who is less knowledgeable. Deirdre also positioned herself as a conciliator when Wanda assessed her expression by testing it against a two-column table Wanda generated. Deirdre asked Wanda, "So, do you want to try some more to see if it fits all of them, or do you think it just fits that one? Or are you good with that?" Wanda, in response, positioned herself as being the one who would confirm the group's progress by saying, "Well, I see what you're doing and I think it will work," yet immediately follows by saying, "We just have to get the labeling down so when Frances ... goes up to explain, she can explain [the solution to the class]..." In this moment, Wanda accepted Deirdre's attempt to position herself as a "teacher," and then moved to position Frances (and Frances' assigned role of presenter) as the student who needed to articulate the solution. Wanda implicitly acknowledged Deirdre's solution as valid without confirming the solution herself nor acknowledging that Deirdre displayed a mathematical solution that Wanda was not yet ready to explain in her own words.

Wanda's initial positioning of Deirdre and eventual positioning of Frances seemed to highlight how she exercised the notion of whiteness (Harris, 1993) to maintain her relative high, more-knowledgeable status with respect to the two Black teachers in her group. When Deirdre solved the problem quickly and successfully, Wanda resisted being positioned as a "student" and insisted that Deirdre's explanation conform to her own thinking about the problem. As the group was to present their solution to the whole class, Wanda (serving as teacher) positioned Frances as a student who needed to be knowledgeable about the solution prior to presenting. Wanda's resistance to being positioned as a student was important to note, given that in the context of PD, the teachers were all, explicitly and intentionally, positioned by Prasad as "learners." Prasad's framing of teachers-as-learners was purposeful: to help teachers experience small-group learning through problem-solving, before they unpacked their experience as "teachers", as they had done in the previous problem-solving experience in this PD.

Next Steps

As evident in the brief excerpt of the interaction, Wanda seemingly repositions Deirdre and Frances as students whereas she avoids a learner position in the context of this particular task. Wanda's stance may have subverted the opportunity for her to learn another approach (Deirdre's approach) to the problem because of this insistence. The initial analysis of this interaction offers some insight into how teachers can position each other and themselves in the course of solving a groupworthy task. Moreover, the group's experiences suggest that the notion of racialized identities and whiteness were at play during the task. The next phase of the analysis will use a finer-grain critical discourse analytic approach (Fairclough, 2013) to examine the *micro*positioning moves that highlights each teachers' racialized identities (Wood, 2013).

AN INVESTIGATION OF TEACHERS' SENSEMAKING AROUND FACILITATING MATHEMATICAL ARGUMENTATION

We report on a study that aims to understand how elementary teachers' thinking and sensemaking may support or constrain their learning to promote disciplinary argumentation. The study context is a professional development model organized around a sequence of learning cycles in which teachers collectively investigate and enact teaching. We share results related to teachers' engagement in the model and their sensemaking around the work of facilitating classroom mathematical argumentation.

Keywords: Classroom discourse, Instructional practices, Practice-based professional development

Whole class discussions that focus on mathematical argumentation are central events of inquiry-oriented environments (Staples & Newton, 2016), and important for promoting conceptual understanding and developing mathematically proficient students (Osborne et al., 2019; Rumsey, 2012). Mathematical argumentation engages students in a collaborative process where they make claims and justify them using reasoning that is based in disciplinary practices and in their existing knowledge and cultural and linguistic resources. Argumentation-based discussions, however, are uncommon in U.S. classrooms (Cazden, 2003). Research has revealed teachers' roles and responsibilities in these socially and intellectually demanding environments, and highlighted teaching practices that support mathematical argumentation (Lampert, 2001; Staples, 2007). However, this research also suggests that implementing these complex practices is not trivial. Teachers must judge how to elicit and respond to student thinking and how to facilitate students' engagement with each other's ideas around disciplinary content. To accomplish these goals, teachers must draw on specialized professional knowledge, which entails taking individual student thinking seriously and learning about the cultural resources and assets that students bring (Bartell et al., 2017) as well as the nature of disciplinary learning in schools for creating a more just society (Gutiérrez, 2008). Understanding how teachers learn to make these judgments and how they reason about when and how to take up these goals and practices is the aim of this study.

Research on teacher learning about facilitating disciplinary argumentation has to date focused for the most part on how teachers socialize students into this process (Forman et al., 1998), teacher noticing of situations for argumentation in the classroom (Ayalon & Hershkowitz, 2018), and design aspects of professional development that support learning about and facilitating argumentation (Osborne et al., 2019). Less is known about teacher learning and sensemaking about disciplinary argumentation in the course of their professional development. In this brief report, we examine teacher learning about facilitating mathematical argumentation within a practice-based professional development model that engages teachers in investigating and enacting practice. We highlight two preliminary findings related to teacher learning: the relationship between descriptive and explanatory talk and supporting student participation.

Theoretical Framework

We frame teacher learning from a sociocultural perspective as a process of changing participation in a community of practice (Rogoff, 1995). This process entails the development of principled goals, commitments, and ways of thinking valued by this community, as well as the continual refinement of a set of principled practices for supporting mathematical argumentation in the classroom. Consonant with this perspective on teacher learning, we use a practice-based design of professional development (PBPD), which centers teacher learning on the activities that characterize their daily work (Ball & Cohen, 1999). In this context, PBPD facilitators support teacher learning using interactive structures that promote teachers' sensemaking with each other and make teacher thinking visible through methods such as video analysis (van Es & Sherin, 2010), problem solving cycles (Koellner et al., 2007), rehearsals (Kazemi, Ghousseini, Cunard, & Turrou, 2016), and teacher time out (Gibbons, Kazemi, Hintz, & Hartmann, 2017). Three key commitments, central to facilitating productive classroom discourse, orient our work with teachers: attending to student thinking (striving to hear students, attending to who they are and the knowledge they bring (Bartell et al., 2017); attending to the integrity of the content (promoting dispositions and practices central to learning disciplinary content); and attending to a classroom community where students learn to articulate their thinking and to listen to and represent others' ideas, even those with whom they disagree (Ball & Bass, 2003).

Context and Professional Development Model

The context of our investigation is a professional development (PD) initiative across two locations in the U.S. We recruited from partner schools three instructional leaders and 13 teachers with varying experience in leading classroom mathematical argumentation. Both schools serve richly diverse student populations with respect to language, race, and ethnicity. We are co-designing and co-facilitating the PD with the instructional coaches from each site. The PD takes place at the school site during the school day, and consists of 12 Learning Labs implemented over two years (6 cycles/year, with a projected cycle every other month). Each Learning Lab begins with new learning during which teachers may engage a reading or analyze artifacts of practice to identify new ideas with respect to students' mathematical thinking as well as elements of teaching that support productive argumentation. In the next phase, teachers collaboratively prepare a lesson to enact in a classroom. Next, teachers rehearse small portions of their lessons in front of other study participants, exhibiting and sharing their understanding and decision making about how to promote classroom communication focused on argumentation and seeking feedback from colleagues. The teachers then collectively enact the lesson in one of the participant's classroom, collect records of their enactment, and debrief what they learned in the last phase of the Learning Lab. The day comes to a close with teachers setting goals for next steps in their ongoing work with argumentation in their own classrooms. New ideas and insights from these trials are then brought back to the subsequent Learning Lab.

Data Collection and Analysis

Currently in our first year of this project, we are collecting data in each cycle in the form of video records of teachers' participation, fieldnotes from each phase of the cycles, copies of teachers' reflections and artifacts of practice (including plans and videos of their teaching), and one-on-one interviews with both teachers and instructional coaches/mentors. For the purpose of this report, we thematically analyzed (Boyatzis,1998) data from fieldnotes and teachers' written reflections to capture (a) what teachers attend to when they debrief the collectively planned and enacted lessons, and (b) the problems of practice that arise for teachers and what knowledge they use to address them. Looking across these dimensions over time allowed us to identify teacher insights that were suggestive of emerging aspects of their sensemaking about facilitating mathematical argumentation.

Results

We focus our results on two themes that emerged from our analysis: student participation and the relationship between descriptive and explanatory talk in argumentation-focused discussions.

Student Participation

Attending to student participation was a key problem of practice for teachers in facilitating argumentation-based discussions, and addressing it leveraged two major understandings about this work for teachers: the way language can function as an enabler and barrier for participation in discussions, and the way classroom culture can invite or constrain participation. Teachers noticed the centrality of language in classroom discussions. In one Lab debrief, for instance, several teachers noted that those not speaking up were the students whose first language is not English. They related this lack of participation to the task structure which appeared to promote quick responses and privilege students who have the mathematical language to verbally communicate their ideas over others. As one teacher elaborated, "you have to take information, process it, translate it . . . I see kids open their mouth to say something and then someone else jumps in." These conversations allowed teachers to consider pedagogical moves that encourage broader participation. Teachers indicated a need for different scaffolds that make language in discussions more accessible. They suggested providing students with sentence stems to support their engagement with the content and using a student-generated word bank based on small group discussions to better support sharing within a large group.

In another respect, teachers stressed how the classroom culture needed to be inviting for participation to occur. In one Lab debrief, the teachers noticed students' hesitation to share until one student contributed a starting point for an idea. This led to a examination of the sort of norms that encourage confidence. One teacher shared that she tries to solicit responses that are not always right, " I like to acknowledge [their] thinking to show the other kids this is what we do, and that usually lowers the risk for other kids to take a guess." These insights led to the identification of several teacher moves that help make the environment more friendly for sharing, including an initial question of "who can get us started?" and stressing that the discussion is aimed at thinking about ideas and not having the right answer.

Relationship Between Descriptive and Explanatory Talk

Teachers engaged in unpacking two aspects of the relationship between descriptive and explanatory talk in mathematical argumentation and considered how understanding this relationship might impact task design and instructional moves. In one respect, teachers recognized that descriptive and explanatory talk are not the same and require different work on the part of students. In one Lab, for instance, teachers considered how students could use talk to describe calculations that prove why a mathematical equation (4x6=2x12) is true. In their discussions, they realized that explaining why the equation was true without calculating produced a more rigorous demand for creating an argument. As a teacher expressed it, "you take [the mathematical work] to the next level by not calculating." This insight led teachers to begin to experiment with how to redesign mathematics discussion tasks to support more explanatory talk. For instance, in relation to the equation task described above, teachers tried removing the need for calculation by stating up front for students that the equation was true and asking students to create models and representations to explain relationships instead of calculating results.

In another respect, teachers realized that descriptive talk sets an important foundation for explanatory talk, especially in generating conjectures or claims. Through experimenting with student discussions, teachers observed that giving students time to notice and describe patterns in a mathematical task supported them in noticing regularity in their descriptions of mathematical reasoning. Students then used their initial descriptive talk to generate and justify claims. This led teachers to experiment with how to facilitate a discussion structure around this realization. In one case, the teachers first had students describe how they would explain that each fraction comparison in a series of statements are true (e.g., $\frac{1}{8} < \frac{3}{8}$; $\frac{3}{5} > \frac{2}{5}$). As students described their thinking, teachers created a public representation of their strategies. The teachers then asked students to look across their thinking for multiple problems and begin to generate a conjecture about how to compare fractions. One teacher explained that the goal was to support students to see "the patterns in the way [they] are thinking about it. Making that obvious to them...that is their conjecture." Hence, teachers' deeper understanding of the relationship between descriptive and explanatory talk in mathematical argumentation influenced their design of instructional tasks and moves.

Conclusion

The preliminary findings we share suggest aspects of the sensemaking that teachers experienced in the context of the PBPD focused on enactment and investigation. These insights related to broadening student participation and the coordination of descriptive and explanatory talk are grounded in the commitments that frame our view of teacher learning: attending to the integrity of the content and to the promotion of a classroom community where students learn to articulate their thinking. The findings suggest the way teachers reason pedagogically about such commitments. Additionally, the emergence of these insights was enabled by the structure of the PBPD model which afforded teachers time to experiment collectively with leading argumentation-based discussions and to reflect and notice aspects they were likely to miss in their own classrooms.

Teacher shortages have created an influx of alternatively certified teachers, which raises questions about the effect these teachers are having on classrooms. This study explored potential differences in mathematics teachers' beliefs based on their path to certification. An ANOVA revealed differences in beliefs among the four certification pathways explored, such as teachers certified through a traditional mathematics education program self-reported significantly higher levels of mathematics identity and mathematics teacher identity than teachers certified through a traditional education program that was not mathematics specific. These findings have implications for educational stakeholders and policy makers when considering the certification pathway options available for potential teachers.

Keywords: Affect, Emotion, Beliefs, and Attitudes; Teacher Beliefs

Over the past seven years, there has been a decrease in the percentage of teachers who are entering the teaching profession through a traditional teacher preparation program. During the 2017-2018 school year, less than half of new hires in the state of Oklahoma were holding a standard teaching certificate. Even more striking, between 2012 and 2018 the number of emergency certifications increased from 32 to 2,915 (Lazarte Alcala, 2018). This increase is partly in response to the shortage of teachers in the state across all content and grade levels. With an influx of teachers who are emergency and alternatively certified in Oklahoma, it is important to study the impact these teachers are having on students and the education system in general, particularly with evidence that teachers who are emergency or alternatively certified have lower levels of retention, both in Oklahoma (Lazare Alcala, 2018) and in other states (Zhang & Zeller, 2016). One way to begin to address this concern is to explore potential differences between teachers based on their certification pathway. Other researchers have begun to explore these differences, noting that alternatively certified teachers tend to feel less prepared than teachers certified through a traditional education program (Kee, 2012).

Research indicates that teacher beliefs play an important role on teachers' practice (Stipek, Givvin, Salmon & MacGyvers, 2001; Wilkins, 2008). In particular, a number of specific mathematics related beliefs have been connected to teachers' instructional practices and behaviors including self-efficacy and anxiety (Ghaith & Yaghi, 1997; Trice & Ogden, 1986), mindset (Good, Rattan, & Dweck, 2007), and identity (Jong, 2016). Therefore, the purpose of this study is to explore differences in mathematics teachers' beliefs based on their pathway to certification.

Methods

In late spring of 2018, a survey was sent to all potential mathematics teachers in Oklahoma based on contact information provided by the State Department of Education. 17,444 emails were sent to elementary, middle grades, and secondary teachers; 1,385 of these were bounced emails. Additionally, elementary teachers, some who did not teach math, were included in this initial email, as we had no way of determining which teachers did or did not teach math. After eliminating 155 teachers who elected the option of not being a math teacher and removing 233 surveys that were missing a significant number of responses, we were left with 1,543 completed surveys. As this study focuses on comparing certification pathways and this option is primarily open to secondary teachers, elementary teachers were removed from the sample leaving 217 secondary teachers (6th-12th) that responded to the survey.

The respondents were 85% female and 15% male. In terms of race and ethnicity, respondents were 85.7% White, 6.5% Asian, 3.7% African-American, 3.7% Multicultural, and .5% Other, with only 2.3% of the participants identifying as Hispanic. The age of participants ranged from early 20s to 70 years, with them holding degrees ranging from a Bachelors to a Doctorate. The years of experience reported by participants ranged from 1 year to 49 years with an average of 13.4 years.

The survey included items related to participant demographics (e.g., gender, paths to certification), and mathematics specific beliefs (e.g., mathematics identity, mathematics mindset). In order to determine teachers certification pathway, participants were asked to select one of the following options: (1) traditional undergraduate teacher education program with certification in secondary mathematics, (2) traditional undergraduate teacher education program with certification in a field other than secondary math, (3) master's degree with certification in secondary mathematics, (4) bachelor's degree in mathematics and pursued alternative certification, (5) bachelor's degree in a field other than mathematics and pursued alternative certification, (6) traditional undergraduate teacher education program with certification in elementary, (7) bachelor's degree in field other than education and pursued alternative certification, (8) Troops to Teachers, (9) Teach for America, and (10) other. We removed participants selecting option 8 and 9 as the sample size was small. For the purpose of this study, we grouped similar pathways in the following way:

A. Pathway 1 and 3 - traditional mathematics teacher education pathway (*n* = 49);
B. Pathway 2 and 6 - traditional non-mathematics teacher education pathway (*n* = 58);
C. Pathway 4 - alternative certification with bachelor's degree in math (*n* = 27); and
D. Pathway 5 and 7 - alternative certification with bachelor's degree in field other than math (*n* = 83).

The survey also included measures for mathematics identity (MID, 11 items, 5-point Likert scale) using items developed and tested with adults in prior research (Cribbs, Hazari, Sadler, & Sonnert, 2015). This scale is comprised of three sub-constructs including interest, recognition, and competence/performance. The higher the mean the more a person identifies with being a "math person." Math mindset items (MS, 4 items, 5-point Likert scale) drew from prior research (De Castella & Byrne, 2015; Degol, Wang, Zhang, & Allerton, 2018). Mean scores range from 1 (fixed mindset) to 5 (growth mindset). Mathematics teacher identity (MTID, 13 items, 5-point Likert scale) drew from a study with secondary preservice mathematics and science teachers (Thamotharan & Hazari, 2017) and includes the same three sub-constructs as mathematics identity but focused on mathematics teaching. The higher the mean the more a person identifies as being a mathematics teacher. The 5-point Likert scaled self-efficacy for teaching mathematics instrument (SETMI) was used to measure efficacy for pedagogy in mathematics (EPM, 7 items) and efficacy for teaching mathematics content (ETMC, 15 items) (McGee & Wang, 2014). The higher the mean score the more efficacious the teacher was towards teaching mathematics. The 5-point Likert scaled mathematics anxiety rating scale revised (MARS-R) with two sub-constructs – learning mathematics anxiety (LMA, 8 items) and mathematics evaluation anxiety (MEA, 4 items) - was used in this study (Hopko, 2003). A higher mean score indicates a higher level of anxiety. The 5-point Likert scaled constructivist teaching scale (TP1, 6 items) was used in this study (Woolly & Benjamin, 2004). A higher mean score indicates beliefs that align more with a constructivist teaching philosophy. Finally, a nine-item researcher developed instrument was used to measure the teachers' mathematics teaching philosophy (TP2). This instrument used a semantic differential scale to measure teachers' beliefs about effective mathematics practices as described in the *Principals to Actions* text published by the National Council of Teachers of Mathematics (NCTM, 2014). Mean scores can range from 1 (teacher centered) to 5 (student centered). A higher mean score indicates a more student-centered rather than teacher-centered teaching philosophy. Internal consistency values using Cronbach's alpha ranged from .71 to .95 across all scales. One-way analysis of variance (ANOVA) was performed to determine if there were differences in mathematics and teaching beliefs between the four (A, B, C, and D) certification pathways.

Results

Results for the one-way ANOVA exploring differences in mathematics and teaching beliefs based on certification pathways for mathematics teachers are shown in Table 1.

Table 1: ANOVA Results Comparing Across Four Different Certification Pathways

Measure	A	B	C	D	*F*	*p*
	Mean(SD)	Mean(SD)	Mean(SD)	Mean(SD)		
MID	4.42(.61)	4.05(.74)	4.12(.93)	4.18(.67)	2.473	.063†
MS	4.26(.62)	4.32(.68)	4.39(.56)	4.39(.59)	.553	.646
MTID	4.69(.36)	4.37(.71)	4.23(.60)	4.42(.65)	4.252	.006**
EPM	3.88(.57)	3.76(.70)	3.58(.72)	3.94(.60)	2.548	.057†
ETMC	4.38(.54)	4.24(.67)	4.09(.73)	4.26(.62)	1.280	.282
LMA	1.41(.51)	1.47(.47)	1.58(.72)	1.57(.56)	1.210	.307
MEA	1.72(.83)	1.84(.76)	1.99(.73)	2.07(.82)	2.251	.084†
TP1	3.93(.62)	3.84(.60)	3.88(.59)	3.88(.65)	.199	.897
TP2	3.74(.69)	3.78(.62)	3.88(.69)	3.85(.59)	.507	.678

Note. MID = math identity; MS – mindset; MTID – mathematics teacher identity; EPM - efficacy for pedagogy in mathematics; ETMC - efficacy for teaching mathematics content; LMA - learning mathematics anxiety; MEA - mathematics evaluation anxiety; TP1 – teaching philosophy measure 1; TP2 - teaching philosophy measure 2
†$p < 0.10$. **$p < 0.01$.

Results indicate a marginally significant difference between certification pathway groups, $F(3, 213) = 2.473$, $p = .063$ for Mathematics Identity. A Tukey HSD post hoc test found significant differences ($p = .042$) between groups A and B. A significant difference~~s~~ was found between certification pathway groups, $F(3, 213) = 4.252$, $p = .006$ for Mathematics Teacher Identity. A Tukey HSD post hoc test found significant differences between group A with groups B ($p = .033$) and C ($p = .009$), and a marginally significant difference between group A and D ($p = .062$). Results also indicate a marginally significant difference between certification pathway groups, $F(3, 213) = 2.548$, $p = 0.057$ for Efficacy for Pedagogy in Mathematics. A Tukey HSD post hoc test found significant differences between group C and D ($p = .050$). Finally, results indicate a marginally significant difference between certification pathway groups, $F(3, 213) =$

2.251, $p = 0.084$ for Mathematics Evaluation Anxiety. A Tukey HSD post hoc test found marginally significant differences between group A and D ($p = .063$).

Discussion

Our findings indicate that there are some differences in beliefs between the four different certification pathways explored in this study. Specifically, teachers who were certified through a traditional mathematics education program self-reported significantly higher levels of mathematics identity and mathematics teacher identity than teachers who were certified through a traditional education program that was not mathematics specific. Teachers certified through a traditional mathematics education program reported higher levels of mathematics teacher identity and efficacy for pedagogy in mathematics than teachers who had a mathematics bachelor’s degree and were alternatively certified. Teachers certified through a traditional mathematics education program also reported higher levels of mathematics teacher identity and lower levels of mathematics evaluation anxiety than teachers who had a bachelor’s degree in a field other than mathematics and were alternatively certified. Lastly, teachers who had a bachelor’s degree in a field other than mathematics and were alternatively certified reported higher levels of efficacy for pedagogy in mathematics than teachers who had a mathematics bachelor’s degree and were alternatively certified. It is also worth noting that teachers who were certified through a traditional mathematics education program reported higher means, even if not statistically significant, for all but one factor measured than all other certification pathways. These findings contradict some prior research noting no differences in beliefs between teachers who are alternatively and traditionally certified. For example, Fox and Peters (2013) found no significant differences between teachers’ self-efficacy based on certification pathway. It is also important to note that alternatively certified teachers may not be able to accurately assess their own instruction as compared with traditionally certified teachers (Naugaret, Scruggs, & Mastropieri, 2005). With this in mind, participants self-reporting on their teaching philosophy, where they reflect on their own instructional methods, may be skewed for alternatively certified teachers as they have not observed, reflected, and practiced implementing instruction that is student-centered as is often the focus of traditional education programs. This may account for the lack of significance for the teaching philosophy factors (TP1 and TP2) not having a higher mean for the traditionally certified teachers than the other certification pathways. Given the importance that teachers’ beliefs have on their classroom practice, these results speak to the added benefit a traditional, content-specific education program has in preparing teachers for the classroom. These results could inform policy makers and educational stakeholders as they consider certification pathways for future prospective teachers. Future research should be examined that accounts for differences in years of teaching experience and other demographic differences.

USING COMPUTER GENERATED ANIMATIONS TO EXAMINE PEDAGOGICAL CONTENT KNOWLEDGE IN STSTISTICS TEACHING

Dhimitraq Duni
Eastern New Mexico University
dhimitraq.duni@enmu.edu

In this study, I examine the nature of pedagogical content knowledge (PCK) (Shulman, 1986) that teachers exhibit while observing computer-generated animations of statistics lessons that bring up pedagogical issues in middle school classrooms. In-service teachers were asked to view different animations and react to different prompts about the animations. Later, teachers were interviewed to stimulate further discussion of pedagogical issues with the intention of clarifying their stance and their knowledge of pedagogy. The computer animations were utilized as a surrogate for classroom teaching, highlighting issues that could be otherwise overlooked during live teaching observation.

Keywords: Data Analysis and Statistics; Computer Generated Animations; Pedagogical Content Knowledge; In-service Teacher Knowledge

In understanding teachers' knowledge of content and pedagogy, researchers have used classroom observations, as well as pen and paper assessment instruments. The next step in this endeavor was the introduction of animations (comics) to help understand teachers' knowledge (Chazan & Herbst, 2012; Herbst, Chazan, Chen, Chieu, & Weiss, 2011; Herbst & Kosko, 2014). These authors have argued that animations present a unique opportunity in understanding teacher's knowledge, because of the inherent concentration on the desired topics afforded by animations, compared to classroom observations.

The purpose of this study was to examine the use of computer-generated animations (CGAs), in lieu of classroom vignettes, for understanding aspects of teachers' pedagogical content knowledge. The topic of "measures of central tendency" was chosen because of the importance of statistics in the curriculum as well as the importance of its first introduction to students in middle school (Franklin et al., 2007; NCTM, 1989, 2000, 2006; NGA & CCSSO, 2010).

The goal of this research report is to present an initial effort in creating several computer-generated animations CGAs that helped assess teachers' knowledge of pedagogy. My research questions concentrated on characterizing teachers' knowledge as it related to the components of PCK put forth by Hill, Ball, & Schilling (2008).

Theoretical Framework

It is a model that has endured and has been used and adapted by other researchers in the study of statistics (Burgess, 2009; Groth, 2013, 2014). In this framework, PCK is partitioned into three categories: knowledge of content and students (KCS), knowledge of content and teaching (KCT), and knowledge of curriculum (KC). This model gives me the ease of understanding how to classify given responses into statements about students, teaching, and curriculum. Within each part, I have introduced components that are advocated for in research about what this knowledge should look like (Duni, 2018). The Expected Statistical Knowledge for Teaching Measures of Center framework (Duni, 2018) is designed and supported by research conducted in the teaching and learning of statistics, as well as the curriculum documents put forth by NCTM (1989, 2000, 2006) as well as CCSSM (2010).

Methodology

Videos as tools to be analyzed have been used since the Third International Mathematics and Science Video Study (1999; Hiebert et al., 2004), which gave video evidence of different teaching styles around the world. Herbst, Chazan, Chen, Chieu, and Weiss (2011), argued that comic-based representations of teaching can be powerful substitutions of videos, in seeing the mathematics taught in the lessons that were observed, allowing PST's to explore decisions made in the classroom while teaching. Furthermore, Herbst et al. (2011) argued that comics could enable a high degree of control over the content as well as the possibility of highlighting issues that might not show up in most videos. As Herbst advocated, I am using animations because it gives me the opportunity to control the narrative and what mathematics teachers pay attention to. These CGAs concentrate on eliciting different aspects of teachers' PCK when introducing the measures of center in middle school statistics.

Development of Computer-Generated Animation Protocol

The first step in designing the CGA's was the creation of the vignettes, the dialogue taking place in each CGA. The vignettes were designed with the idea that the teacher in the animation would pose a question or an activity, and the students would respond to the questions. The prompts that are used after each vignette were specifically designed to assess different aspects of teacher knowledge with regard to the teaching and learning of measures of center. The problems posed, as well as the students' comments, were typical of examples from research on students' knowledge of statistics (Cai, 1998; Russell & Makros, 1990; Strauss & Bichler, 1998).

For brevity's sake; I will give a description of just one vignette. The content of the second vignette was created to discuss measures of center as "typical" instead of the traditional "mean, median, mode". The teacher starts by introduces data gathered from the students (shoe weight) and ask students to find the typical weight. The data are not ordered, and at the end, there is a piece of data that seems like an outlier. The first students, using the algorithm, finds the mean of the data. The second student eliminates the supposed outlier (with no comment on identifying the outlier) and using the algorithm finds the mean. A third student eliminates the smallest and largest data points and then finds the mean. The fourth student, who considers the outliers, chooses to use the median (wrongly identified since the data was not ordered). Lastly, the first student comments on his confusion about always using the mean without consideration of distribution. Student responses and issues with the content were consistent with previous research (Tarr & Shaughnessy, 2003; Zawojewski & Shaughnessy, 2000). The corresponding prompts were:

1. Please identify which student or students seem to be struggling with the idea of measures of center and explain why.
2. How would you help these students improve their conception (please talk about each child individually)?

Table 1 shows which component of the expected framework knowledge was solicited from each vignette. Keeping with vignette 2 as an example, finding typicality from data of weight of shoes, the vignette could have solicited teachers to discuss their students' understanding of the mean as well as which measure of center to choose, depending on characteristics of the distribution. The second vignette could have also prompted teachers to discuss their students understanding of outliers, issues with finding median, and the idea that students tend to ignore the mean when it is not part of the data.

Table 1: Vignettes to Framework Chart

Vignettes	V1	V2	V3	V4	V5	V6	V7
C1 – Median as a central point	✓					✓	✓
C2 – Conceptual understanding		✓		✓	✓	✓	✓
C3 – Representing data with a single number			✓		✓		
C4 – Relate choice to shape & context		✓					✓
C5 – Connect center to variability							
S1 – Min, Max outliers		✓					✓
S2 – Ignore 0			✓				
S3 – Fail to order data		✓					
S4 – Mode to represent typical		✓					✓
S5 – Ignore mean when not part of data		✓	✓				
S6 – Difficulty with Weighted Mean					✓		
S7 – Mean only procedurally		✓	✓		✓	✓	✓
T1 – Investigative process	✓					✓	✓
T1a – Formulate questions							
T1b – Collect data							
T1c – Analyze data		✓	✓				
T1d – Interpret							
T2 – Connect to mathematics			✓		✓		
T3 – Explore real data	✓	✓	✓	✓		✓	✓
T4 – Use technology and assessment							

Note. Tick marks mean that that component of the framework was solicited by the corresponding vignette.

Results

Knowledge of Content and Curriculum

The fourth CGA, which directly asked teachers to connect a concept to a given activity, was the only question that was a source of most of the codes for curriculum. With respect to the concept of mean as fair share or leveling off data, the teachers made comment about it; however, almost all (14 of 15) comments came after the animated teacher (in CGA 4) demonstrated a fair share activity to the classroom.

Thinking of the measures of center as representing the data using a single number, the comments that were offered discussed the idea by mentioning that all measures of center gave different information about the data. As far as relating the choice of the center to the shape and the context of the data, comments were mostly concentrated on singular points (outliers) and did not mention, nor discuss, the shape or the context of the data. Even though the components of the framework were based on curriculum documents and research, participants did not show evidence indicating that their knowledge matched what had been recommended by researchers. Similar findings were observed by Watson (2001), who reported that even though there were a lot of activity-based lesson plans at the primary level, there was almost no evidence a uniformity of curriculum. Watson also found that the major curriculum document, was only used by a quarter of the secondary teachers.

Knowledge of Content and Students

There were numerous prompts that asked teachers to discuss topics that would reveal their knowledge of students; however, only half of the teachers specifically identified a challenge that students have that was also identified by the research. Most comments were not about making a choice about which measure of center to use but were about differences in definition and computational algorithm, between the three measures of center. The other comment about challenges came from one teacher recognizing that students do not see the need to have ordered data when finding median.

Three participants made at least three comments coded as S1 (min max as outliers), two of those teachers took the acknowledging of an outlier by a student as a given and commented on whether the elimination of said outlier was correct or not. One teacher commented that students should not just eliminate outliers and find the mean, whereas the other recognized that the outlier can skew the data. The third teacher acknowledged what the student was doing without passing judgment; interestingly though, this third teacher also recognizes that the students are eliminating what they "thought was an outlier." Watson et al. (2008) reported that, at the low content knowledge level, teachers were not successful at responding to student work or questions. Similarly, Hashweh (1987) found that low content knowledge teachers tended to reinforce preconceptions and incorrectly criticized correct student answers.

Knowledge of Content and Teaching

The one component, about knowledge of content and teaching, that participants gave plenty of evidence about was T3—*relying on exploration of real data*. Of the six teachers who commented on T3, only two tried to recognize the actual context of the real data that they were using, and the rest of the teachers merely mentioned the use of real data. From the comments pertaining to KCT, only 8% corresponded to one of the codes created in the framework; the rest of the comments were attributed to other ideas about general teaching.

It was evident that participants mainly employed direct instruction, a finding corroborated by Ijeh (2013), who reported that most teachers taught the topic in a step-wise and mostly procedural fashion. As with Watson et al. (2008), who reported teachers giving generic suggestions to students work, my participants gave such vague suggestions that they did not even pertain to statistics. Similar, to the comments that a participant made, that she did not feel comfortable teaching because of her missing knowledge, Batanero and Diaz (2010) also reported that their teachers did not feel prepared to help their students. Hashweh (1987) and Carlsen (1993) also reported that teachers with low knowledge of content tended to not deviate from activities presented in books, showing that they were not comfortable teaching the subject.

In submitting this research report, I wanted to add to the conversation about the validity of the data received by conducting research with Computer-Generated Animations being used as an assessment tool. As can be seen from the results introduced in these pages, CGA's are a good way of getting teachers to open up about their knowledge of pedagogy in a comfortable setting. These participants were given a week to go online, at their convenience, and respond to several prompts on seven animations. The animations allowed teachers to concentrate on the statistics discussed in the classroom, and not be distracted by environmental polluters.

CONVERSATIONAL PATTERNS AND OPPORTUNITIES FOR TEACHER LEARNING IN COLLABORATIVE PLANNING CONVERSATIONS

Grace A. Chen
Vanderbilt University
grace.a.chen@vanderbilt.edu

Samantha A. Marshall
Vanderbilt University
samantha.marshall@vanderbilt.edu

Although many researchers have studied teacher collaboration, few have focused on what and how experienced teachers learn when they co-plan daily lessons. This study examines how mathematics teachers' conversational patterns in co-planning meetings shape their opportunities to learn. Preliminary findings suggest that different features of collaborative conversations, such as their agreements and disagreements, their use of students as conversational resources, and their methods of justifying their suggestions, support teacher inquiry about specific lessons or about teaching more broadly. This has implications for teachers' professional growth.

Keywords: Teacher knowledge; Curriculum; Instructional activities and practices

High-quality teacher collaboration has been linked to improved student outcomes (Ronfeldt, Farmer, McQueen, & Grissom, 2015) and research on one such form of collaboration—co-planning daily lessons—has primarily studied the processes of lesson planning (e.g., Lewis, 2002). Despite evidence suggesting that teacher collaboration is crucial for teachers' professional learning (Horn & Little, 2010), research that links co-planning and teacher learning skews toward individual cognitive processes (e.g., Shavelson & Stern, 1981) or novice teacher learning (e.g., Feiman-Nemser & Beasley, 1999). Because teachers' conversational routines shape their opportunities for examining problems of practice (Horn & Little, 2010), we examine the learning opportunities found in experienced teachers' conversations as they engage in co-planning daily lessons. This is a common and time-consuming activity for many teachers; thus, it is important to understand what and how teachers have opportunities to learn during these conversations.

Theoretical Perspectives

Taking a situated view of teacher learning as being embedded in a community of practice (Lave & Wenger, 1991), we draw on the concept of teachers' opportunities to learn as "affordances [within contexts] for changing participation and practice" (Greeno & Gresalfi, 2008, p. 172). As Grossman, Wineburg, and Woolworth (2001) point out, not all forms of teacher community are generative for improving instructional practice. In pseudocommunities, teachers act as if they agree, but this "illusion of consensus" reduces the likelihood for teachers to experience intellectual renewal, professional growth, and learning (p. 955). By contrast, teachers' opportunities to learn are enabled by processes of inquiry (Ball & Cohen, 1999), which in turn are shaped by, among other things, the norms and expectations that teachers co-construct, the conceptual resources available to them, and the conversational routines in their teacher communities (e.g., Horn, 2010; Horn & Little, 2010; Little, 2003).

Specifically, we focus on "how conversational processes differentially support teachers' professional learning" (Horn, Garner, Kane, and Brasel, 2017, p. 41). We hypothesize that engaging in different forms of inquiry—such as inquiring into a specific lesson versus inquiring into broader problems of practice—opens up different opportunities for teacher teams to learn in ways that would not be possible if they simply agreed on what to teach and how to teach it.

Therefore, this analysis aims to answer the research question: *How do teachers' conversational patterns in co-planning meetings shape their opportunities to learn?*

Data Collection and Analysis

Study Context

This study analyzes data from a 4-year research-practice partnership between our university and a professional development organization (PDO) in which we collect ethnographic field notes, audiorecordings, and artifacts from teachers' collaborative meetings and classroom teaching, among other data, to study teacher learning. PDO teachers are competitively selected and have between 5 and 20 years' teaching experience. As a result, their conversations often involve sophisticated pedagogical reasoning compared to novice teacher conversations, which are more likely to, of necessity, prioritize classroom and time management.

Participants and Data

For this preliminary analysis, we selected transcripts from two co-planning meetings with teachers teaching the same course at the same pace in the same school. We selected these particular transcripts because PDO leaders recommended these teams as high-functioning and these conversations offered analytically interesting contrasts; they both involved planning for the next day and their structure and goals were entirely up to participants, but conversational patterns were noticeably distinct. At Noether High School, Greg and Abigail planned an Algebra 2 lesson about the fundamental theorem of algebra as it relates to polynomial functions. At Banneker High School, Amanda, Clark, and Franck planned an Algebra 1 lesson on writing algebraic rules for visual patterns representing arithmetic sequences.

Analytic Methods

To answer the research question above, we examined the questions teachers asked, how (if at all) they justified what they said, and the processes of consensus-building in their co-planning conversations. We identified continuous half-hour excerpts from each transcript, beginning when teachers started designing the upcoming lesson, and coded the transcripts using methods from critical discourse analysis (Wodak & Meyer, 2001). First, we looked for the modes expressed in each turn-by-turn utterance, coding for questions, declarative statements, justifications, direct and indirect suggestions, and expressions of agreement and disagreement (Fairclough, 2015). We also considered patterns in turn-taking and the types of justifications that teachers provided, when they provided any at all, to support their suggestions or expressions of dis/agreement.

Preliminary Findings

We found three differences in the two transcripts of co-planning meetings: 1) the nature of suggestions, agreements, and disagreements; 2) the use of students as conversational resources; and 3) the explicitness of justifications. We illustrate these differences using transcript excerpts and then describe the consequences of these differences for teachers' opportunities to learn.

Suggestions and Dis/agreements

Teachers in both teams made both direct and indirect suggestions about the next day's lesson. We coded statements of what "we should" do as direct suggestions, even if they were non-imperative (e.g., "maybe we should..."); most of the suggestions at Noether were direct suggestions. Indirect suggestions, on the other hand, merely implied what the group should do; these were more common at Banneker, where teachers often described their personal practice or preferences as an offering to the other teachers. For example, Clark said that in his previous lesson, he posted questions one at a time rather than all at once, "so that was helpful, I think."

The teachers at Noether regularly agreed vocally with each other's suggestions, responding with utterances like "yes, okay," "I agree," "yes that's true," and "got it." However, they also often disagreed. For example, Abigail disagreed with Greg's suggestion to save fourth-degree polynomials for homework; Greg disagreed with her disagreement.

> Greg: ... Should we just do quadratics and third and for homework do degree four?
> Abigail: Umm—I don't think they're going to be able to make a—ah—an interesting statement between the degrees and the number of zeroes if they don't do degree four. You know? Maybe.
> Greg: Okay. For example. I'm trying to—so if they don't do degree four—
> Abigail: So if we ask the question 'what's the relationship between the degree and the number of zeroes,' I don't know if they'll really have enough information to answer the question. What do you think?
> Greg: I think they already know it, in my mind. Like 50% of the class?

At Banneker, we coded only one instance in which teachers openly disagreed. This disagreement was less direct than disagreements at Noether: Clark had proposed giving students individual whiteboards for a problem. Franck offered, "or paper." Clark responded, "whiteboards I think is helpful for this because it's so easy to make a mistake..." without rejecting Franck's suggestion.

Students as Conversational Resources

At both schools, students became resources for teachers' sensemaking in lesson planning. At Banneker, teachers tended to narrate individual students. For example:

> Amanda: ... This girl is an expert picture-drawer, so she had shaded that. Then the kid next to her had done this, and so he was ... We were talking about, 'Well, why is it minus three?' She was like, 'Because this one got counted three extra times.' So it was like we counted it once, but then we counted again and again and again. So we have to take off the three that got triple-counted. [Clark says "yeah."] Then other kids were like, 'You take off one to get this and multiply it by four and add the extra one back in.'

In the next 13 turns, Amanda and others continued animating students; Franck, for example, noted that a student who often struggled also completed the annotations that Amanda described.

At Noether, on the other hand, teachers referenced students to support their proposals. For example, Abigail said, "Okay, I have another idea? …in my third period… they're not thinking about how the equation connects with the graph." Most references a) were in generalized terms, citing an entire class or "students" more broadly, and b) described what students had found or might find difficult (e.g., "they're still having a hard time graphing quadratics").

The different patterns of invoking students across the two high schools led to qualitatively different learning opportunities for each group of teachers. Banneker teachers' narration of individual students left open a range of interpretive possibilities, letting teachers explore what students might understand about sequences. At Noether, referring to students collectively and in terms of their challenges instead narrowed teachers' learning opportunities to focus on specific ways of responding to specific student difficulties in this specific mathematics lesson.

Justifications

Both teams justified suggestions, but the Noether teachers did so less frequently. Justifications occurred mostly when there was disagreement, and tended to refer to tacit principles of teaching. For example:

> Abigail: …Because what I worry about is if we just go straight into solving with complex they may not make the connections.

Abigail referred to an idea that she seemed to take as shared: that it is good for students to make connections between graphs and algebraic work. She appealed to this idea several times.

Banneker teachers, by contrast, commonly justified their suggestions explicitly, often without being prompted to do so. After Clark proposed giving students individual whiteboards instead of using a shared whiteboard, he added, "because then they could show each other." After Franck disagreed, however, Clark justified his preference with a value statement, declaring that work feels less permanent on whiteboards than on paper (and presumably, that this is a good thing).

Abigail's appeal to tacit principles as justification, occurring mostly when there was disagreement, opened opportunities to consider how these principles could be embedded into tomorrow's lesson and led to more articulated consensus on the Noether team. The Banneker team offered more frequent justifications and did so by appealing to broader values, providing opportunities for teachers to consider less-settled ideas without necessarily arriving at consensus.

Discussion

Although both teams' conversations provide rich learning opportunities by developing teaching concepts directly related to future work (Horn et al., 2017), differences in teachers' suggestions and dis/agreements, use of students as conversational resources, and justifications may nevertheless have implications for teachers' opportunities to learn. Greg and Abigail seemed to share an expectation of reaching consensus but were willing to disagree in order to do so, justifying their reasoning with observations about students' general challenges. Achinstein (2002) stresses the importance of conflict in "creat[ing] the context for learning and thus ongoing renewal of [teacher] communities" (p. 412), so Greg and Abigail's conversational pattern, with clear dis/agreements and few tangents, likely opened up opportunities for them to inquire into and learn specifically about how to integrate connections between algebraic and graphical representations into teaching polynomial functions to Noether High School students.

The teachers at Banneker High School expressed less direct disagreement; they offered more animations of individual students and justifications based on values. In this conversational pattern, teachers played with ideas, allowed room for their colleagues to draw different conclusions, and left questions unanswered, supporting a stance of adaptive expertise (Horn, 2010). We wonder whether this pattern opens up for discussion more ideological commitments, laying the foundation for the type of generative conflict that can challenge the status quo of teaching (Achinstein, 2002). The opportunities for teacher learning afforded by Noether and Banneker's different conversational patterns are both important: learning about teaching specific mathematics content to specific students supports teachers' effectiveness and is efficient, and critical reflection about teachers' philosophies of teaching is also central to professional growth. Ideally, we imagine that high-functioning teacher teams probably engage in both.

To continue this analysis, we will code more co-planning meetings for these and other teacher teams. Given our interview data, we wonder whether the observed differences might be caused by different social histories among teacher teams or whether they might be consequential for outcomes other than teachers' opportunities to learn. We hope that this analysis can shed light on whether the conversational patterns we found in these initial meetings are typical or unusual across teacher teams, school contexts, and situations, contributing to a deeper understanding of how teachers collaboratively plan curriculum and the consequences of such conversations.

GRADUATE STUDENT INSTRUCTORS' CONCEPTUALIZATIONS OF PEDAGOGICAL EMPATHY

Karina Uhing
University of Nebraska – Lincoln
karina.uhing@huskers.unl.edu

In this study, I explore the phenomenon of pedagogical empathy, which is defined as empathy that influences teaching practices. Specifically, I examine how graduate student instructors (GSIs) conceptualize empathy as it relates to the teaching and learning of mathematics. The findings presented in this paper emerged from interviews with 11 GSIs in which they were asked questions to elicit their thoughts about empathy. The participants provided complex and diverse notions of how empathy relates to teaching mathematics. Conclusions drawn from this paper may help inform professional development efforts targeted at novice and experienced instructors at the post-secondary level.

Interpersonal relationships are central in the teaching and learning of mathematics. One way that teachers relate to their students is through experiencing empathy in an educational setting. However, little research has been conducted at the intersection of teacher and student affect, where empathy is often situated. Exploring how empathy influences and shapes teaching interactions can lead to a better understanding of teaching practices and have far reaching implications for the broader education community.

This study aims to explore how mathematics graduate student instructors (GSIs) conceptualize empathy as it relates to the teaching and learning of mathematics. The conclusions drawn from this study will add to the emerging body of literature about math GSIs' knowledge, beliefs, and teaching practices. In addition, this research can be used to inform professional development efforts for both novice and experienced instructors.

Theoretical Perspective

Empathy is a multifaceted construct. Researchers have described empathy in various ways and have developed different characterizations depending on the context in which empathy is referenced (Cuff, Brown, Taylor, & Howat, 2016). Therefore, it is important to provide a working definition of empathy as it relates to the context of teaching. In this paper, I use the term *pedagogical empathy* to refer to the empathy that a teacher experiences for a student or a group of students. This empathy has the potential to influence teaching decisions and directly impact the actions that are taken in the classroom. Thus, pedagogical empathy involves how teachers use their understanding of students' perspectives and experiences to inform their decisions. The terms empathy and pedagogical empathy are used interchangeably in the remainder of the paper.

The findings presented in this paper also build on Zembylas's (2007) framework, which establishes a connection between pedagogical content knowledge and emotional knowledge. Zembylas (2007) contends that "teacher knowledge is a form of knowledge ecology – a system consisting of many sources and forms of knowledge in a symbiotic relationship" including "content knowledge, pedagogical knowledge, curriculum knowledge, knowledge of learners, emotional knowledge, knowledge of educational values and goals and so on" (p. 356). Specifically, Zembylas (2007) narrows in on emotional knowledge and defines the construct of emotional ecology to connect emotional knowledge to PCK. Building on his work, I argue that teachers experience pedagogical empathy when pedagogical content knowledge and emotional knowledge (along with other types of knowledge) are funneled through a filter of empathy, which consequently influences teaching decisions. The findings presented in this paper help demonstrate how pedagogical empathy can be conceptualized as this filter.

Purpose

This paper stems from a larger study that explores how pedagogical empathy might influence the feedback that mathematics graduate student instructors (GSIs) provide to their students. As a first step, it is important to consider how GSIs define empathy within the context of teaching mathematics and how that definition relates to their conceptions and beliefs about empathy. Thus, this paper focuses on the following research question: *How do GSIs conceptualize pedagogical empathy?*

GSIs are an important and unique population to study because they are not only instructors of undergraduate mathematics courses, but also students in graduate mathematics courses. Having these simultaneous roles may make it more likely for GSIs to experience pedagogical empathy for their students as they may have recently had similar or shared experiences as students themselves, an important factor that has been shown to be associated with empathy (Eklund, Andersson-Stråberg, & Hansen, 2009). In addition, many of them are future mathematics faculty members who will continue teaching at institutions of higher education after they graduate. The insights gained from this study can be used to inform GSI professional development efforts and design activities to increase instructors' awareness of pedagogical empathy.

Methods

Eleven mathematics GSIs at a large Midwestern university participated in this study. Each GSI was the instructor of record of a precalculus course (either Intermediate Algebra, College Algebra, Trigonometry, or Precalculus) and had varying levels of teaching experience. None were international GSIs. Participants selected their own pseudonyms, which are used below. Data was collected during the summer and fall of 2018 through multiple interviews and classroom observations of the GSIs. The findings in this paper emerged from the initial interview with each participant, which was designed to explore how GSIs conceptualize empathy as it relates to teaching mathematics.

Interviews were transcribed and analyzed using MAXQDA. Since pedagogical empathy is a novel theoretical construct, open coding was initially used to generate a set of preliminary codes (Strauss & Corbin, 1998). Each interview was coded, and short summaries were then generated for every coded segment. These segments were then categorized and sorted using axial coding (Strauss & Corbin, 1998). During this process, codes were refined and further clarified until a robust understanding of each category was reached. These codes were then organized into three main themes that characterize how GSIs conceptualize pedagogical empathy.

Findings

Three main themes emerged from the interviews: accounting for contextual factors, enacting and experiencing empathy for students, and considering empathy along a trajectory of development. These themes contribute to an understanding of how GSIs conceptualize empathy as it relates to teaching and learning mathematics. Due to space constraints, only the contextual factors are discussed in depth below.

Context

The context in which a class is situated has the potential to influence how teachers conceptualize and experience pedagogical empathy. This context includes a broader disciplinary perspective and a more localized course format that takes into account specific course constraints and affordances to pedagogical empathy. These two components, which are described in detail below, help explain how the content and the structure of a course might mediate empathic interactions between teachers and students.

Mathematics perspective. Several participants discussed mathematics from a disciplinary perspective and referenced how past experiences with math can shape the way that students feel and think about mathematics as a discipline. It was widely acknowledged that teachers and students might have opposing beliefs about mathematics and that it is important to consider these different perspectives as they have the potential to influence how teachers empathize with their students.

A few GSIs discussed how students might feel or think about math and the resulting impact that might have on their experience in the course. Aaron brought up empathizing with a student in his class who was "hesitant" and "scared." He talked about "trying to think of ways to figure out more about how this student is feeling about math" and how he could "bring her more confidence while she approaches problem solving." Another participant, Mark, emphasized the importance of knowing that "students come in from a lot of backgrounds, many in which they're taught to hate math or to think of themselves as bad at math" and remarked that in order to "reach all students" instructors need to consider the perspectives of their students.

In addition to reflecting on how their students might feel about math, a few of the GSIs referenced their own perspectives and experiences with mathematics. Beth talked about how she wants her students to "appreciate math and appreciate that they can do it" because she wants them to feel the way that she feels about math. Mark brought up his history with math and how he had experienced mixed feelings about it: "I did go through a few years in high school where I didn't like my math classes, but even then I didn't really feel like I disliked math. I just disliked the math class because it was boring." He went on to share how his experience with Calculus had changed his perspective and how that influenced his view of the course as an instructor:

> Calculus, for me, had been just such a joyful class. It was sort of like what reignited my interest in math, reminded me that math class was a cool thing. So when I was teaching it the first semester, it didn't really even occur to me that my students could legitimately be worried about this and frightened about this.

Some GSIs openly discussed their negative experiences with math. Aaron explained how he shares a personal story with his students to tell them about his "perspective on the culture of math and how there's a fear-based culture of math in many cases." Aaron's story involves being a student in an undergraduate math class where he was handed a sheet of problems to solve:

> I didn't know how to even start any of them because I hadn't taken the necessary class prerequisites. So I was just sitting there waiting, not really able to do anything, and the professor stood in front of me and just started staring at me, at my blank sheet of paper for like five minutes. He finally broke the silence by asking, "Do you understand?" And it made me feel really bad.

By sharing this story with his students, Aaron hopes that they will be able to recognize and acknowledge their own fears and anxieties about math and can better relate to him as an instructor.

Course format. The format of a course is another contextual factor that can mediate how teachers and students interact with each other. This format influences the ways in which teachers interact with their students, including how often teachers see their students, how many students are in a course, and what types of interactions are possible. The position and level of authority that teachers have within the course structure can also affect how they view their role in the classroom and their perceived instructional responsibilities. These structural elements of courses can either support or deter opportunities for experiencing pedagogical empathy in the classroom.

A few participants discussed how it was easier to experience empathy for students when the format of the course allowed for direct interactions with them. For example, Chris discussed how teachers are more likely to experience empathy "when they're not just lecturing at them [students] the whole time and then telling them to beat it." He went on to describe how empathy can be more easily elicited in courses where "two-way communication is heavily encouraged" and the teacher is not the only person who is allowed to talk. Amanda felt similarly, stating:

> The way that our classes are set up, at least in the precalculus level with active learning, I think that also makes it easier to experience empathy because you have a lot more one-on-one interaction with your students in class.

Similarly, Mark discussed the affordances of being able to "sit down one-on-one" with a student who needs help or is feeling overwhelmed. However, he also mentioned how it is often difficult to "avoid time constraints" and ensure that all students understand a concept before moving on to the next topic and identified the number of students in his class as being a potential barrier to experiencing empathy:

> In an ideal world where I have time to actually make sure each student gets the help they need, I would try to figure out where the disconnect begins and then work from there. But again, I say this in the context of a classroom where I've got time to do this. In a classroom where there's one teacher and 42 students, corners have to be cut unfortunately.

In addition to contextual factors like the structure of a course and the number of students in a class, GSIs' roles and responsibilities might also influence the way that they empathize with their students. In particular, Jane talked about the difference between being a recitation leader and being an instructor of record. As the instructor of record for a precalculus class, Jane felt "a lot more of an emotional burden on my students to do well and for me to teach them the material," whereas leading a recitation comes with less "responsibility for their education and what they learn." She also suggested that GSIs might have more opportunities to feel empathy when they are the instructor of record, as compared to being a recitation leader, because having that responsibility for helping students learn is "another way that you can feel empathy."

Discussion

The findings above dissect one facet of how GSIs conceptualize pedagogical empathy. Specifically, they highlight how perceptions of mathematics as a discipline can influence teachers' experiences of pedagogical empathy and how the format of the course might elicit or suppress this empathy. These findings also help illustrate how pedagogical empathy can be conceptualized as a filter through which different types of knowledge pass: as teachers interact with their students, they draw on their knowledge and use pedagogical empathy as a filter to decide what actions are most appropriate for the situation. After examining this perspective, we can begin to consider how to structure professional development to increase teachers' awareness of this phenomenon and help them become better decision-makers in the classroom.

INVESTIGATING MATHEMATICS GRADUATE STUDENTS' GROWTH AS TEACHERS: THE UNIQUE CASE OF EMMA

Mary Beisiegel	Claire Gibbons	Alexis Rist
Oregon State University	Pierce College	Oregon State University
mary.beisiegel@oregonstate.edu	cgibbons@pierce.ctc.edu	delonga@oregonstate.edu

The need for research-based professional development programs for mathematics graduate students is significant, yet few studies have investigated their development as teachers. This study aims to fill this gap in the research by studying mathematics graduate students' experiences with teaching as they progress through their graduate programs. Participants responded to surveys and were interviewed semi-annually for two or more years. We analyzed their responses using thematic analysis and a framework that captured their development as teachers. In this report, we describe the developmental stages for teaching and context and methods of the study. We present general findings on the experiences that mathematics graduate students did not move past a certain developmental stage and we present specific findings about one mathematics graduate student who experienced significant growth in her teaching.

Keywords: Professional Development; Post-Secondary Education; Affect, Emotions, Beliefs, Attitudes; Instructional Activities and Practices

At graduate institutions in the United States, mathematics graduate students often receive funding from mathematics departments to support their time working on master's or doctoral degrees. In return, they teach courses as instructors or they work as teaching assistants, supporting faculty instructors of large lecture courses by leading weekly, small-group recitations. Over the course of their graduate programs, mathematics graduate students contribute to the learning experiences of hundreds of undergraduate students. Their contribution to undergraduate students' learning experiences extends beyond their graduate programs with more than 60 percent of new mathematics PhDs finding employment in post-secondary education settings in which teaching makes up a significant portion of their work (Golbeck, Barr, & Rose, 2016). Thus, mathematics graduate students exert a significant impact on undergraduate learners' trajectories in STEM fields (Belnap & Allred, 2009; Ellis, 2014).

Despite the amount time they interact with undergraduate learners, mathematics graduate students receive little professional development (PD) for their teaching (Deshler, Hauk, & Speer, 2015; Miller et al., 2018). The PD they do receive varies greatly across institutions – programs range from a few hours, to an intensive week of PD, to a seminar that spans a full academic year (Deshler et al., 2015). The field of mathematics graduate student PD is relatively new and experts in the field have not reached consensus on the depth and breadth of PD programs that prepare mathematics graduate students to teach. This lack of consensus might be due to the fact that mathematics graduate students' growth "is a largely unexamined practice" (Miller et al., 2018, p. 2). Miller and colleagues (2018) suggest that this field of study would benefit from longitudinal studies of mathematics graduate students' growth as teachers.

Our primary long-term goal is to develop an extended PD program for mathematics graduate students. Prior to developing and implementing such a program, our research team sought to understand how mathematics graduate students think about teaching, what they learn about teaching, and what type of PD might be relevant at different stages of their development. We wondered – how do mathematics graduate students develop as teachers? What are salient, transformative experiences and what are experiences that might hinder mathematics graduate students' growth as teachers? In this report, we describe a longitudinal study of mathematics graduate students growth. We focus on one specific participant who illustrated significant growth in her teaching.

Theoretical Framework

Because research has not yet addressed MGTAs growth as teachers (Miller et al., 2018), we looked to the K-12 literature, where researchers have studied schoolteachers' experiences in order to gain an understanding of their growth over time. Katz (1972) described four developmental stages, which include: (1) *survival* of the first year of teaching, with particular focus on classroom management and the routines of classrooms and schools; (2) *consolidation*, in which teachers begin to understand which skills they have mastered, and what tasks they still need to master; (3) a period of *renewal*, when teachers become tired of their routines and start to think of how things might happen differently; and (4) reaching *maturity*, where teachers think more broadly about the contexts of schools and students' learning (p. 52-53). Based on the literature, we posit that mathematics graduate students' teaching practices in the survival and consolidation stages will be lecture-based, and in the renewal and maturity stages, more focused on teaching practices that support student engagement in mathematical work during class time (e.g., active learning, inquiry).

Context and Methods of the Study

Our study takes place in a mathematics department in which mathematics graduate students receive two to three days of professional development when they first arrive, as well as a year-long, introduction-to-graduate-studies-in-mathematics seminar part of which is focused on teaching. Mathematics graduate students are most often assigned to teach recitations for large lecture courses, but they also have the opportunity to teach their own courses. Sometimes they work as a grader for upper-division or graduate courses. Mathematics graduate students were recruited for the study in 2015, 2016, and 2017. They are asked to complete a beginning-of-the-year survey, a mid-year interview, and an end-of-year interview. Three mathematics graduate students have participated in the study for its duration (currently in its fourth year), five have participated for three years, and other mathematics graduate students in their second year of participation in the study. We are using the six steps of thematic analysis (Braun & Clarke, 2006) as a method for analyzing surveys and transcripts of interviews.

Findings

We have found Katz's framework (1972) to be a useful lens to study mathematics graduate students' growth. We have observed that mathematics graduate students do not pass through Katz's (1972) developmental stages linearly. They sometimes returned to the *survival* stage if a new teaching assignment varied significantly from their prior teaching assignments. Most mathematics graduate students appeared to be stuck in the *consolidation* stage and their descriptions of teaching were remarkably unchanged year after year. In addition, out of the nine mathematics graduate students who have participated in the study for three or more years, only two of the participants spoke of teaching in ways that Katz (1972) would categorize as *maturity* – and none so profoundly as one participant, Emma (pseudonym).

Focusing on Emma's Growth as a Teacher

Emma began participating in the study in 2015 as a second year graduate student. Emma has had several different teaching assignments over the years of the study. She has worked as a teaching assistant in both in-person and on-line courses, as a grader for graduate courses, and as an instructor for a course. These positions were determined by the department based on Emma's schedule. Early in the study, Emma expressed her belief that a goal of teaching mathematics is to impart knowledge – not only mathematical knowledge but also "the knowledge of how to gain more knowledge, how to be a student, how to be a mathematician, how to think like a mathematician." Whether and how she felt she had an impact on students (in their learning and what they thought about mathematics) was very important to Emma. Her role as a teaching assistant made her feel that she had very little impact on students.

Difficulties of Being a Teaching Assistant Instead of Instructor (Survival, Consolidation)

Like many participants in the study, Emma found the role of teaching assistant to be "less than ideal" because she did not have control over the classroom dynamic or over the work the students were assigned. This feeling continued into the third year of the study, where Emma described the instructor of the course as the decision-maker who has the biggest impact on student learning. Emma explained that the instructor chooses the content for recitation, which meant that she had "No power over what happens in the recitation hour" which made her feel ineffective: "It's the instructor's course. That's fine. But it means I'm not choosing any of the problems, or anything like that. So what can I do?" Because she saw the instructor as having total control over both the lecture and her own work with students, Emma felt like she had "such little power to actually impact [students'] learning."

Eventually, her role as teaching assistant began to have a negative impact on how she saw herself and what she felt she could contribute to students' learning:

> For the impact on their learning, I think I'm interchangeable with all the other graduate students. Every once in a while, there'll be a problem that everyone's asking questions on, and I'll be like, "Okay, let's review something that you all might enjoy having a small review of." And that's fine, but they could get that from going to anybody's office hour.

Teaching Her Own Course for The First Time (Consolidation With Hints of Renewal)

When Emma had the opportunity to teach her own course, she very much wanted to have an impact on students and aimed to do so through detailed, planned lectures. She spoke in detail about how she planned for her lectures:

> So I worked so hard on that class. Oh, my God. It was a full-time job for me. I was preparing lectures, and I supplemented the text in all these ways, and I spent boatloads of time coming up with awesome examples and activities. So I spent all this time and energy into the activities, and I do think that I had a big impact on people's enjoyment of it, and I got personal notes from students saying as much.

Even though Emma emphasized lecturing, we observed evidence that the message of active learning was having an impact on Emma. She described "full on lecture" as "easier" than leading recitations. But she also remarked that she wanted to include both group work and direct instruction. She vocalized some uncertainty of how successful she would be: "Having never done this before, I don't know how effective it's going to be."

In the interview following her first experience teaching her own class, Emma reported using strategies that supported student engagement in mathematical work. She lectured during most class periods, but had students working on problems three or four times per class. Her goal was to talk for no more than several minutes before letting students work on an example:

> I would introduce a concept, try to put it in the big picture. This was my whole thing, was like, "Okay, fundamental theorem of calculus. Let's put it in the big picture. Why am I even talking about this? 'Why is it called fundamental'? What makes this worth studying?" And then instead of doing example, I would do a simple example on the board, and then I would make them do an example on their own.

Unfortunately, Emma saw students' exam performance as the most important measure of her impact as a teacher and she reflected on her lecturing:

> But my students got the exact same average on the midterm as every other instructor who was teaching this course over the summer. That made me think, "Maybe I'm not having as big an impact as I thought." […] I would like it to be, "I just nailed all of my lectures," and I want that to have a measurable impact on student performance. I think [lecturing] doesn't have as big an impact as I used to think it did.

In a later interview, Emma remarked: "I have started to see the in-class lecture as a colossal waste of time, and not as big an impact."

Emma's Move Away from Lecturing (Renewal, Maturity)

Recently, we observed Emma reach the renewal and maturity stages through a unique experience in which she had the opportunity to design and teach a course. With some advice from the department, she chose the curriculum, lesson formats, and assignments. She incorporated many things that were important to her about mathematics, including a focus on deep mathematical reasoning (e.g., *Why* would a mathematician think about a problem in a particular way?). She made the choice to not lecture and instead had students engage in mathematical activities. When asked about her transition from lecturing to active learning and whether it was difficult, Emma admitted her love of "performing" and stated, "I like being center of attention and look like I know everything." Reflecting on her choice to not lecture, Emma said, "It bums me out because I like lecturing. I think I'm good at it. But now, I'm convinced that people don't learn by lecturing." She later said, "So I did feel a sense of loss at first. And then by the end of that class, it totally changed me. I maybe got more out of the class than the students did because I got to the end of that class and I said, 'I am never ever lecturing again, ever.'"

Conclusion

What can we learn from Emma's experiences and her growth as a teacher? What prompted Emma to make the changes to her teaching practices? Emma noted that some events in the mathematics department influenced her. For example, the department that had selected a few courses to be more focused on active learning and Emma had exposure to an active learning classroom in her first year as a graduate student, a visiting colloquium speaker provided examples of active learning and some of her peers were incorporating active learning into their classes. However, we acknowledge that not all mathematics graduate students will have the same exposure to active learning and opportunities to grow in their teaching practices. Thus, we see as Emma's desire to feel that she had an impact on students and how she reflected on her own learning experiences for more guidance critical to her growth as a teacher. We suggest that PD programs be designed such that mathematics graduate students understand the contributions they make to students' learning. We also propose that PD programs include a reflective component that prompts mathematics graduate students to consider their most meaningful learning experiences. Our study will continue and it remains to be seen whether Emma will continue to develop as a teacher after this unique experience. What might happen to her views about active learning should she be assigned to an instructor who wants her to lecture mathematics to students and/or if she feels that her role does not allow her to contribute to student learning?

The modeling literature offers insights on student learning but remains scarce on teachers' instruction of mathematical modeling. We investigate the efforts of a team of secondary teachers, teacher leaders, and mathematics and science teacher educators to co-design and use instructional tools for mathematical modeling. We adopt formative interventions (Engestrom, 2011) to understand how the team coalesced around a shared problem rooted in modeling and uncover the ways that the team respond to contradictions in the activity system. This study contributes a view of professional learning that deeply connects research, design, and enactment fostered by the team's agentic actions.

Keywords: Professional Development, Modeling, Instructional activities and practices

Professional development (PD) designed by educational researchers to change instruction is often developed outside of the educational setting for teachers and districts inside the educational setting. With the aim to impact knowledge, instruction, and student achievement, researchers often cite the complexity to affect change within the time span of typical research (Koellner & Jacobs, 2015). This brief report investigates efforts of secondary teachers, teacher leaders, and mathematics and science teacher educators (hereto called the TLE team) to co-design and use instructional tools for mathematical modeling to impact teachers' knowledge, instruction, and student achievement.

Modeling researchers provide insights on student learning, but there are limited details on teachers' mathematical modeling practice associated with student learning. Even though modeling is a part of many state's K-12 standard (NGA, 2010), research on modeling instruction has not kept pace (Kaizer, 2017). The questions driving this study are: How are modeling instructional tools co-designed by the TLE team in ways that support co-production of learning? How does tool use uncover further complications of modeling enactments and foster agentic action? To consider the co-production of learning, we examine the TLE team's efforts in design summits, two-day events in which the TLE team learned about modeling and designed and refined instructional tools. This study contributes a view of professional learning that deeply connects research, design, and enactment, to tool-design and use for mathematical modeling.

Framework

Literature on professional learning, with an eye toward reimagining practitioner/ researcher roles and redesigning systems of working in partnerships of research, design, and enactment are theoretical rooted of design-based research (Bevan & Penuel, 2018). This growing scholarship offers insight on the typical divisions between researchers' and practitioners to re-negotiate the research hierarchy and share roles in research, design, and enactment.

We adopt Engestrom's (2011) formative interventions as a starting point for design and research with a focus on shared problems in a system. Modeling, as a mathematical activity, is demanding and merges STEM disciplines and real-world questions, in novel ways of reasoning with no pre-designed pathway to a solution (Barquero, Bosch & Romo, 2018). In this study, modeling instruction was identified as a problem of practice by the TLE team due to the lack of instructional supports and the complex layering of human activity in which school mathematics and modeling coexist. Engstrom's construct allowed us to examine the contradictory motives that emerged and subsequent responses both unpredictable and agentic.

Mathematical modeling is a cycle of activity iterating across real world situations, promoting problem formation, mathematizing problems, and coordinating a mathematical model and justification to make meaning within the real world (Bliss, Fowler, & Galluzo, 2014). Researchers posit to build students' modeling competence they need wholistic opportunities to engage in the modeling process *and* specific opportunities to build new skills with particularly demanding aspects of modeling (Schukajlow, Kaiser, & Stillman, 2018). This atomized approach was catalyst for instructional tool designs that establish classroom routines for modeling reasoning. Across three design summits, TLE team members advanced two instructional tools to resolve shared problems of enactment.

Context and Methods

Eleven math and science teachers and four teacher leaders working in rural, suburban, and urban districts in the western United States and five math and science teacher educators from two campus of the University comprised the TLE team. Data were collected from the TLE team activities in three design summits taking place across seven months. The summit goals were two-fold, to advance the TLE team's capacity to enact modeling with learners and to identify or design tools in support of enactments.

Many in the TLE team had teaching experience using routines as instructional tools. Although the genesis of the summits was initiated by teacher educators, teachers were seen *and became* co-developers in considering issues and designing solutions. Across the summits, responsibility for facilitating shifted to teachers and teacher leaders. In the first summit, the TLE team designed two instructional routines focused on key elements of the modeling cycle, defining assumptions and variables (called Donkey Ume) and iterating, refining and defending a model (called Is it Good Enough). In the second summit, enactments of the routines were discussed and further refined. In summit three, the routines were rehearsed to further the revision of the two instructional tools. The agentic actions of the team are the focus of our analysis to further understand how PD can link research, design, and enactment.

Methodology

Data were collected to trace meaning making that took place in design summits. Data reduction was accomplished by identifying *design/re-design* and *enactment discussions* in each summit. Data included: (1) teacher created design cycle documents in summit one, (2) post-summit one enactment reflections and classroom artifacts, (3 & 4) fieldnotes and design cycle documents from summit two and three.

Our analysis drew upon Engestrom's (2011) formative interventions to pinpoint starting points, processes and outcomes. Starting points were the ways in which the TLE team identified problematic and potentially contradictory goals essential to teaching mathematical modeling. Claims were inventoried and themed (Saldana, 2012). After an exhaustive list of themes were identified, we clumped themes into larger categories that captured the initial starting points, catalysts for action, and mediating artifacts. Documenting the claims chronologically, we could parse how issues emerged and shifted activity post modeling routine-design. We discuss how themes resulted in the layered character of a formative intervention, tracing the starting point, process, and outcome.

Findings & Discussion

Our analysis identified themes we conjecture are the main contradictions that the TLE team worked to overcome.

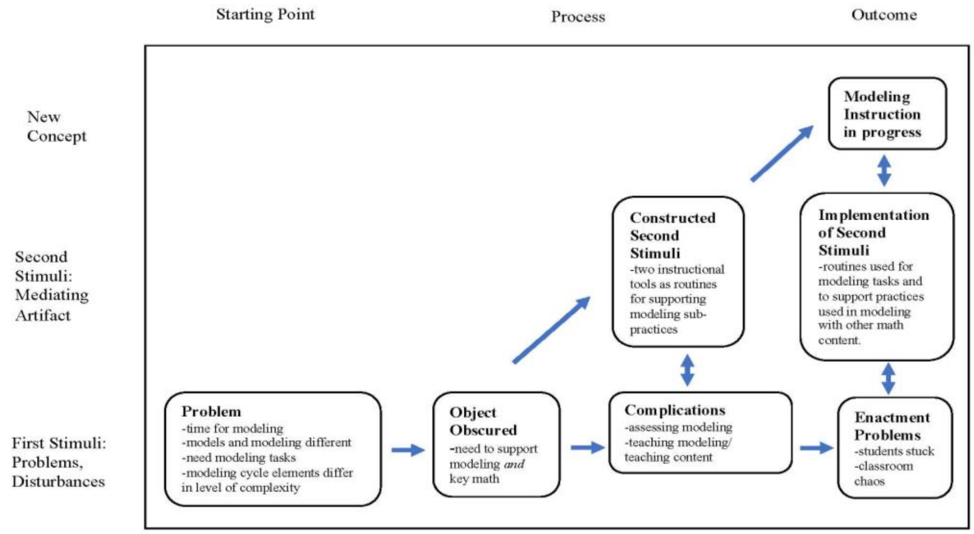

Figure 1: Formative Intervention with TLE Team (adopted from Engestrom, 2011)

In Figure 1, we share our conjectures on learning. Our aim was to document how instructional tools for modeling were co-designed in ways that supported co-production of learning across stakeholders. Due to space limitations we limit the discussion to highlights of the analysis.

The TLE Team saw a contradiction between the modeling practice-standard and the act of modeling and were aware that not all features of the modeling cycle were easily navigated. The six elements of the modeling cycle became a tool to talk about where instructional "chaos" erupted because of "cognitively demanding" mathematics. We saw efforts here similar to calls for atomizing modeling to support students' reasoning (Schukajlow, et al., 2018). Team members readily agreed that it wasn't because students weren't capable of doing the mathematics, but rather their instruction hadn't adequately supported students.

These enactment problems didn't hampered enthusiasm for modeling, rather theTLE team honed in on the elements of the modeling cycle that were more demanding. Via two tools for defining assumptions and variables and iterating, refining and defending a model, they conjectured that students would be better equipped to engage in all the elements of the modeling. After designing the tools, members gathered in two subsequent design summits to examine and refine the tools.

Summit data analysis identified two central agentic actions of TLE members. The first was an assessment question of capturing students' improvement on modeling and the second was a tension between teaching modeling verses teaching content. Assessment questions emerged from almost all members in enactment discussions relating the tools' role in learning of math content, math modeling, and specific focal practices. The assessment ideas coalesced into an action plan for an "experiment" alternating "full modeling cycle" tasks and "hard stop" tasks. They thought that strategically alternating types of tasks would allow team members to know if student were able to "transfer" thinking.

The second theme was a tension between modeling and content that the TLE team felt compelled to reconcile. One member's comment summarizes this idea when she said, "does it have to be modeling OR content?" noting the tension between the two and pushing back. TLE team members discussions lingered on "what was *not* being taught" by focusing on modeling. We marked this tension between content and modeling and saw it transform in interesting ways.

A number of teachers had shaped tasks and lessons to use the routines in ways that were supportive of the focal practice and were doing so on a semi-regular basis. They conjectured that this allowed students more agency to engage in learning and supported building norms for reasoning. As the third summit approached, teachers shared online video, tasks, and student work. From these data we saw team members use the routines with non-modeling tasks to leverage justification of a different representation and consider assumptions and variables when working with functions.

In the third summit, discussions of enactments led to TLE team members advocating for rehearsing with the tools to resolve instructional complications they had encountered. The collective agency for rehearsal resulted in iterating the tools to refine the instructional sequence, develop clarity of mathematical aims, and to generate two tools for each routine, one for teachers to use in planning and one as a public record for students. Also notable was that TLE members were thinking about how other teachers could use the tools modifications for non-TLE members.

Conclusion

Often in research on PD, the researcher looks to intervene on practice to improve it. As researchers, we did not have a full-proof design and as Engestrom (2011) suggests, formative interventions do not have one end point in mind. Rather, we are interested in the agentic actions of the TLE team and how they resolve contradictions. This report documents the TLE team's commitment to resolving contradictions that emerge by bringing the real world of modeling into the world of school mathematics. Unlike other studies of PD aimed at documenting impact of a predetermined treatment, this research attempts to document the agentic actions of professionals and the unfolding responses to contradictions that are part and parcel of human experience.

Acknowledgments

The authors sincerely thank the TLE team members who are teachers, teacher leaders and teacher educators engaged in ambitious instructional designs, leadership, and instruction.

TEACHER LEADER LEARNING THROUGH PARTICIPATION IN AND FACILITATION OF PROFESSIONAL DEVELOPMENT ADDRESSING PROBLEMS OF PRACTICE

Research on facilitation of professional development (PD) has been limited. Further limited is our knowledge of how learning to facilitate PD takes place and how PD gets adopted or adapted, once disseminated to different school contexts. As part of a district and research university research-practice partnership (RPP), a PD model was developed to help teachers implement a new mathematics curriculum and center discussions around addressing problems of practice. This study examined how teacher leaders from different school sites learned to facilitate site-based PD focused on discussions about mathematics group tasks and video clips from their own classrooms. Teacher leader learning and enactment of facilitation was analyzed throughout this ongoing and adaptive RPP PD model.

Keywords: Teacher Education-Inservice/Professional Development, Teacher Knowledge

Introduction and Research-Practice Context

This study examined teacher leader learning while participating in and then subsequently facilitating professional development (PD) aimed at addressing persistent problems of practice within their school contexts. The professional development was part of a larger ongoing research-practice partnership (RPP) between an Urban Unified School District (UUSD) and a research university. UUSD re-designed their curriculum and aimed to implement *group-worthy tasks* (Lotan, 2003) to address the CCSS-M. In addition, the district developed interdisciplinary Dimensions of Teaching and Learning, inspired by the Teaching for Robust Understanding (TRU) Framework (Schoenfeld, 2013, 2014). These dimensions include visions of equitable teaching and learning around three main components: assessment; access to content; and authority, agency, and identity. A central goal of the RPP is to support UUSD in implementing the new curriculum and the vision of teaching and learning represented by these dimensions.

Teacher leaders (TLs) from middle school sites within UUSD participated in a program led initially by the university research team and district mathematics personnel. The program incorporates the Problem-Solving Cycle (PSC) model of PD and Teacher Leadership Preparation (TLP) model of PD leader preparation (Borko et al., 2015), as well as adaptations to these models developed within the RPP (cf. Borko et al., 2017).

The Teacher Leadership Preparation model prepares teacher leaders to plan and lead Problem Solving Cycle workshops with the math teachers at their school sites (see Figure 1). The central component of the TLP is a series of Leader Support Meetings (LSMs) that provide ongoing, structured guidance for the TLs as they prepare to lead the PSC workshops. The first LSM activity (LSM: Modeling and Debriefing Discussions) is the modeling of mathematics task-based or video-based discussions (VBDs). During these discussions, teacher leaders participate as teacher learners within the project-team-facilitated PD. For the debrief, the partnership team invites TLs to ask questions during the "pulling back the curtain" component, where intentional planning, facilitation, and focal question choices are made explicit.

The final activity of each Leader Support Meeting is the LSM: Rehearsal and Planning portion. Mirroring the math discussions or VBDs from earlier in the day, TLs plan and rehearse facilitating discussions to be enacted at their school site. TLs engage in these rehearsals as an opportunity to develop discrete components of complex practice in settings of reduced complexity (Grossman, 2009; Grossman et al., 2005). Grounding the PD in artifacts such as videos of practice makes practice available to peer review, opens opportunities to learn new practices and pedagogical strategies, and allows deep analysis of the complexities and richness of teaching and student learning (Ball & Cohen, 1999; Borko et al., 2008; Sherin, 2004; Sherin & Han, 2004; Sherin & van Es, 2009).

PSC workshops that follow the LSMs are facilitated by the TLs, and are enacted at their respective school sites. Non-TL colleague mathematics and support services teachers attend as teacher learners. When a VBD is the focus of the PSC, the video clip is taken from the classroom of an attending TL or colleague teacher.

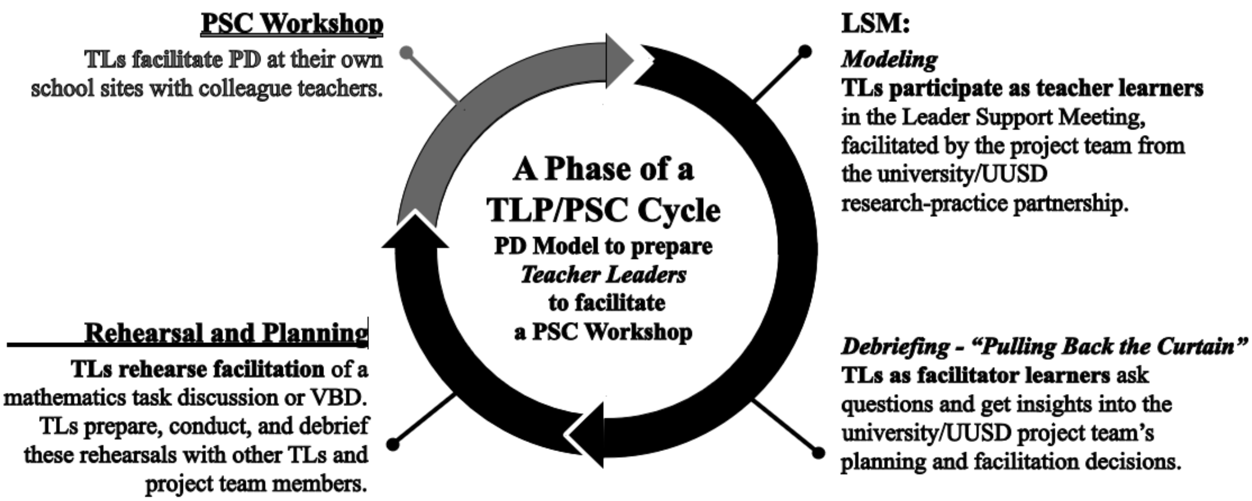

Figure 1: Teacher Leader Roles During Each Phase of a TLP/PSC Cycle. Three Interconnected Phases Occur Per Semester, Which Comprises One TLP/PSC Cycle.

Purposes of Study

This study examined the impact of TLs' participation in TLPs on their facilitation moves when conducting corresponding PSC workshops at their respective school sites. Little attention has been given to how leaders learn to facilitate PD, and even less research considers how teacher leaders learn from the facilitation of other PD providers (Elliott et al., 2009; Goldsmith & Seago, 2008; Roesken-Winter, Schüler, Stahnke, & Blömeke, 2015). As such, we investigated each layer of the teacher leaders' participation in the LSM and PSC -- as teacher learners in the LSM: Modeling and Debriefing Discussions, as facilitator learners during LSM: Rehearsal and Planning, and as TLs during PSC PD workshops enactment at their respective school sites. This investigation was particularly focused on how teachers are learning and enacting facilitation of VBDs focused on problems of practice.

A central goal of the partnership was to support implementation of the new curriculum and incorporation of the dimensions of equitable teaching and learning into classroom practice. Thus, it was important to consider the ways in which TLs were supported in developing facilitation skills to conduct site-based PD that addressed these partnership goals. With these aims in mind, this study sought to analyze the relationships between and within the following: (1) the activities, practices, and facilitation moves that were adopted or adapted during LSM: Rehearsal and Planning, and (2) the TLs' facilitation of PSC workshops at their own school sites.

Theoretical Perspective

We adopt a situative perspective to study teacher learning supported by participation in and facilitation of discussions addressing problems of practice (Putnam & Borko, 2000). A situative perspective asserts that a purposeful progression of activities provides opportunities for learning, and that all learning occurs in a situation (Greeno, 1998). This perspective emphasizes the social interactive development of understanding and individual identity development during participants' engagement in activities. It views knowledge as distributed among participants and their context, including the artifacts, tools, materials, and their communities (Greeno, Collins, & Resnick, 1996). In addition, this perspective highlights the activities and problems of practice that arise from participating in various learning communities and interrogates how those activities and problems can change with changes in context.

For this study, we observed the TLs in multiple spaces of learning and facilitation. During LSMs, TLs engaged with problems of practice as well as learning activities to promote inquiry and sense-making among their colleagues. The school site contexts varied across TLs, presenting situations where TLs first considered the individual and collective goals of their colleagues and departments, and then examined how the focus of VBDs and their facilitation could be adapted to address these differentiated goals. A situative perspective acknowledges the possibility that different school settings may give rise to different kinds of learning. Therefore, we analyzed TL facilitation moves during LSM: Rehearsal and Planning as well as during their own school-site PSC workshops, considering how TLs adopted or adapted facilitation moves and activities as they moved between LSM and PSC contexts.

Methods

Data Sources

This study focuses on the LSMs and PSC workshops conducted during the 2016-2017 school year, which was the first year of full implementation of the four-year university/UUSD research-practice partnership. Sixteen TLs from seven different middle schools within UUSD were involved in the RPP during the 2016-2017 school year. The data sources for the analyses reported in this study include video and audio recordings from the six LSMs and corresponding TL-facilitated PSC workshops conducted that year. Records represent four different school sites. Three sites were omitted based on missing video recordings from either the LSM: Rehearsal and Planning or corresponding PSC workshop. Thus, we examined video records from 24 rehearsals (one rehearsal by TLs from each school during each LSM) and 24 PSC workshops.

Analysis

Video and audio data sources were coded using a video-analysis software called Angles (fulcrumtec.com). Initial codes from frameworks for facilitation and orchestration of video-based discussions by Borko and colleagues (2014) and van Es and colleagues (2014) were adapted by the first and second authors. These frameworks include a total of seven main practices: orienting group to the video analysis task; eliciting teacher's thinking about the lesson segment; probing for evidence of their claims; sustaining an inquiry stance; maintaining a focus on the video and the mathematics; supporting group collaboration; and helping the group to connect their analyses to key mathematical and pedagogical ideas. Additionally, moves and activities that did not precisely fit in this framework were identified, discussed and categorized by a larger research team of mathematics educators. This process resulted in the addition of two practices: debriefing the facilitators, and TL adaptation for own context.

Results

The following results are preliminary in nature and offer broad themes found across each TL facilitation context. TL participation in the debriefs of VBDs modeled during Leader Support Meetings increased over the course of the school year. Early debriefs consisted primarily of one project team member asking questions of the LSM: Modeling facilitators to "pull back the curtain" on their thinking. Later sessions included more questions by TLs and fewer by LSM leaders. During LSM rehearsals, most TLs practiced using focal questions to launch their video-based discussions. We observed a shift in the nature of TL participation during rehearsals from "walking through their presentations" more toward approximation of practice.

Not all the facilitation moves rehearsed transferred to the PSC workshops. Shortened time for VBDs seemed to limit TLs' enactment of facilitation moves that the foster high-quality discussion (e.g. connecting ideas, distributing participation). Time constraints affected each site in our sample; every site had at least one PSC workshop limited to 30 minutes because of various context-related constraints such as shortened department meeting times, mandated testing discussions, and other school/district goals for the department. Differences were also found in the nature of facilitation across PSC workshops. Regardless of context-based constraints, some PSCs included more facilitator-directed whole-group discussions during the VBDs, limiting the time that participating teachers had to respond or share insights with their colleagues, and using pair-share or small group participation in a limited manner. The TLs in these situations also had varying patterns of facilitation participation; some TLs would take turns facilitating rather than co-facilitating, while other TLs participated as a colleague teacher rather than facilitator. Other PSC workshops had more participant-centered VBDs and used a variety of participation structures. TLs at these sites typically co-facilitated more; for example, one TL facilitated a discussion while another TL recorded responses and occasionally asked clarifying or follow-up questions. Some of the PSCs also included intentional connections to problems of practice in their VBDs to elicit colleague teachers' ideas that could address the needs of their students.

Discussion

This study contributes to the growing number of research projects that are focused on what PD leaders should know and be able to do, and how to best prepare and support them (Elliott et al., 2009; Even, 2008; Koellner et al., 2011). More specifically, it builds on the call to researchers to develop Mathematical Knowledge for Professional Development (MKPD) proposed by Borko, Koellner, and Jacobs (2014) and the framework for organizing and categorizing facilitation moves during video-based discussions developed by van Es and colleagues (2014). We extend this work by examining the nature of novice facilitators' activities, practices, and moves enacted during rehearsals and then incorporated into their PD workshops. Our findings support using rehearsals as an approximation of practice (Grossman et al., 2005) for novice facilitators. They also highlight the importance of considering how facilitation can be affected by contexts such as school-based constraints when preparing novice facilitators. Future research should address both adapting to school-based constraints and facilitation that fosters discussions of equitable teaching practices.

Acknowledgments

This work is supported, in part, by the National Science Foundation under Grant No. DRL 1417261. We also extend our gratitude to the district mathematics coordinators, the teacher leaders, and all other teachers who participated in this project and continue to use the PSC model of mathematics professional development in their schools.

A LONGITUDINAL STUDY OF INSERVICE TEACHERS' VISION FOR TEACHING WITH TECHNOLOGY

Suzanne R. Harper
Miami University
HarperSR@MiamiOH.edu

Dana C. Cox
Miami University
Dana.Cox@MiamiOH.edu

Keywords: Instructional Vision; Teacher Beliefs; Technology; High School Education

For almost two decades, Miami University has prepared preservice secondary mathematics teachers (PSMTs) to teach with technology. PSMTs take a required course where they revisit their own learning of secondary mathematics and investigate concepts by way of problem solving with various technological tools. In previous work, we sought to understand the impact of this course on future teaching practice. We defined *vision of teaching with technology* as "an imagined state wherein PSMTs are able to translate their technological beliefs into principles on which they will base future instructional decisions and practice," (Cox & Harper, 2016, p. 169). We found that as a result of participation in this course, PSMTs develop a vision of teaching with technology that is better aligned with that expressed in modern policy documents (i.e., National Council of Teachers of Mathematics, 2000) (Cox & Harper, 2016). We also found that PSMTs draw heavily on their index of personal experiences to illustrate their visions and that descriptions of curricular experiences were central of what PSMTs referred to as "responsible use of technology" (Cox & Harper, 2016).

The current study is a longitudinal examination of the development of a vision of teaching with technology. Since beliefs and practice are dialectic (Thompson, 1992) it is likely that an individual's vision has been impacted by actual teaching experience. Given the importance of indexing personal experiences when articulating a vision, we will likely be able to discern key professional events and activities that point to both continued evolution and devolution of beliefs. No longer limited by imagined states, we have an opportunity to answer the questions: (1) What are seminal teaching experiences that impact an individual's vision of teaching with technology? (2) What is the longitudinal value of collegiate curricular experiences in shaping teachers' vision of teaching with technology?

Participants in this study are recent graduates of Miami University who have been teaching secondary (6-12) mathematics since graduation. Participants were asked to complete an online survey. The survey includes three lines of inquiry. First, we invite participants to narrate their experiences with teaching mathematics with technology. Second, we provide participants with their original vision statements written at the conclusion of the technology course and invite them to identify passages that still represent their thinking as well as passages about which they now think differently. Lastly, we ask participants to identify experiences such as graduate study, professional development, or classroom episodes as well as the impact (or lack thereof) they have had on their developing vision of teaching with technology. A complete analysis of data with findings will be included on this poster.

While meaningful mathematics for all students is the expectation stipulated by leading organizations, the noted opportunity and achievement gaps between students with and without disabilities remains. Given the current climate based on accountability, rigorous standards, and increased student diversity, professional development is a necessity for teachers. We present a practical, three component framework design to in-service professional development for general and special educators for improving inclusive mathematics instructional practices. The framework hinges on the use of high-quality mathematics tasks, differentiation strategies, and effective co-teaching to create a change in both instructional and collaborative practices.

Keywords: Co-teaching, Differentiation, High-quality mathematics, Professional development

The growing number of students with identified disabilities served in general education classes (Mayrowetz, 2009) necessitates the need for lessons to be differentiated to provide meaningful learning experiences for all students (National Council of Teachers of Mathematics [NCTM], 2014). To do this, teachers need support as they work to meet these high expectations for a diverse student population. We present a practical professional development framework that was developed across a three-year service delivery project.

Conceptual Framework

The components of the conceptual framework included opportunities for growth with (a) co-teaching strategies, (b) differentiated instructional strategies, and (c) implementing these high-quality mathematics tasks. The initial emphasis of our conceptual framework centered on increasing the rigor and engagement through the use of high-quality tasks (Stein, Smith, Henningsen, & Silver, 2001). This was followed by the inclusion of differentiation strategies to meet the diverse student needs (Tomlinson, 2017), and then effective and efficient co-teaching models (Friend & Cook, 2010) were of focus to ensure a collaborative atmosphere was in place and that the expertise of both general and special education teachers were capitalized. The relationship of the components of the presented framework were critical for successful teaching and learning of mathematics. The use of high-quality tasks provided the basis of meaningful mathematics instruction. However, without differentiation strategies for the task, some students may not have access to the mathematics. Coupled with the support of both the general and special educators, all students can be supported in their problem-solving approaches, meaning-making, and solutions of the high-quality task.

Acknowledgments

This project was funded by a 2015 Mathematics and Science Partnership grant from the Alabama State Department. Dr. Jim Gleason is the principal investigator on this grant.

ACTIVIDADES DIDÁCTICAS DEL LÍMITE DE UNA FUNCIÓN PARA PROFESORES DE EDUCACIÓN MEDIA SUPERIOR USANDO TEORÍA APOE

José Javier Guerrero Maldonado
Benemérita Univ. Autónoma de Puebla
jjguerre@unet.edu.ve

Lidia Aurora Hernández Rebollar
Benemérita Univ. Autónoma de Puebla
lhernan@fcfm.buap.mx

Múltiples investigaciones enfocadas en el concepto de límite permiten concluir que los estudiantes presentan dificultades que retrasan su proceso de aprendizaje. La investigación presentada se enfoca en docentes de preparatoria como integrantes del triángulo didáctico. Basado en la Teoría APOE se plantea el diseño de una secuencia de actividades didácticas que contribuyan a enfrentar de manera óptima situaciones problemáticas donde dicho concepto se encuentre involucrado. Las actividades se organizaron en dos bloques, el primero a manera de diagnóstico y el segundo de desarrollo de las estructuras y mecanismos mentales necesarios para la construcción del concepto de límite de una función.

Palabras claves: Pensamiento matemático avanzado, Conocimiento del profesor, Actividades y prácticas de enseñanza.

Con este trabajo se busca contribuir, a través del diseño de una secuencia de actividades didácticas basadas en la Teoría APOE (Acción, Proceso, Objeto y Esquema), a la promoción del nivel estructural de un concepto fundamental del cálculo diferencial como lo es el del límite de una función en un grupo de profesores. El método a seguir está basado en la Teoría APOE (Arnon, Cottrill, Dubinsky, Oktaç, Fuentes, Trigueros, & Weller, 2014) en cuanto al análisis de las descomposiciones genéticas existentes (Cottrill, Dubinsky, Nichols, Schwingendorf, Thomas & Vidakovic, 1996) y el diseño de las actividades, tomando como inspiración las propuestas por Tomás (2014).

Estas actividades utilizan las representaciones analítica, tabular y gráfica del concepto de función y se aplicaron a doce profesores asistentes a un curso de 20 horas con la finalidad de favorecer en ellos la concepción métrica y de aproximación del límite de una función. En algunos casos los docentes observaron la aproximación de las imágenes de una función mientras los valores del dominio se aproximan a un número dado en una tabla y, en otros casos, observaron este proceso gráficamente. Teóricamente, la coordinación de estos procesos lleva al docente a la concepción de aproximación. Otras actividades semejantes se proponen para efectos de la concepción métrica. Se espera que la coordinación de los procesos de estas dos concepciones favorezca la concepción Proceso del límite de una función en el docente. A continuación, se presenta el contenido de una de las actividades con parte de su análisis:

Dada $f(x) = \begin{cases} 2x+1 & x<0 \\ -2x-3 & x \geq 0 \end{cases}$ Se pide completar la tabla siguiente:

x	-0.1	-0.01	-0.001	-0.0001	0	0.0001	0.001	0.01	0.1
$f(x)$									

Para realizar esta actividad el docente debe realizar la acción de evaluar una función definida por partes en algunos valores del dominio que se aproximan a cero. También se solicita describir el comportamiento de la variable dependiente respecto a la independiente, para determinar si hay

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

coordinación o no en el proceso de aproximación en el dominio cuando *x* tiende a cero por la izquierda con la aproximación en el rango cuando *f(x)* tiende a 1 o cuando tiende por la derecha, con el proceso de aproximación en el rango cuando *f(x)* tiende a -3.

En este trabajo se muestra cómo se corresponden dos bloques de actividades con la teoría y, en un estudio posterior, se reportará el impacto de su aplicación en los participantes. Por lo que concluimos que la actividad de enseñanza del concepto de límite puede ser modificada al aplicar la Teoría APOE para promover el desarrollo de estructuras mentales más elaboradas en los profesores.

lhernan@fcfm.buap.mx

Multiple investigations focused on the concept of limit allow us to conclude that students present difficulties that delay their learning process. The presented research focuses on high school teachers as members of the didactic triangle. Based on the APOS Theory, is considered the design of a sequence of didactic activities that contribute to optimally deal with problematic situations where this concept is involved. The activities were organized in two blocks, the first in a diagnostic manner and the second in the development of the structures and mental mechanisms necessary for the construction of the concept of the limit of a function.

SEEING MATHEMATICAL LEARNING: TEACHER NOTICING AND GESTURE

Caro Williams-Pierce
University of Maryland, College Park
caro.williams@gmail.com

Janet Walkoe
University of Maryland, College Park
jwalkoe@umd.edu

Keywords: Teacher Knowledge, Communication, Technology

Students gesture while learning mathematics, and will often gesture new concepts before they can verbally communicate their budding understanding (Alibali & Nathan, 2012). In addition, gestures can complement spoken or written language, communicating additional and unique mathematical information (Pier et al., 2019; Williams et al., 2012; Williams-Pierce et al., 2016). Given that gestures play such a crucial communicative role, an equally crucial question is: how do teachers notice gestures when evaluating student learning?

Teacher noticing has been identified as an important construct of teacher knowledge (Sherin, Jacobs, Philipp, 2011). There is consensus that teachers' attention to the substance of students' ideas has important implications for instruction (e.g., Ball, Lubienski & Mewborn, 2001; Fennema et al., 1996). Oftentimes, however, the focus has been on teacher noticing of students' verbal or written expression of ideas (e.g., Sherin & van Es, 2009). Our motivation for examining teacher noticing of gesture is two-fold: 1) teachers may be missing crucial mathematical information when not attending to gesture that could otherwise greatly improve student mathematical learning; and 2) attending to spoken and written language means privileging those who are adept with English mathematical language – by supporting teachers in noticing gesture, we lessen that privileging. To that end, this poster will report on a pilot study that has been designed and will be conducted with up to 30 in-service teachers in April, 2019.

In Phase 1 of the study, participants will view three videos of students talking and gesturing about mathematics from the second author's previous research, which we chose specifically because these students communicate unique mathematical information in gesture. These videos will be viewed on LessonSketch, an online platform that allows viewers to drop timestamped "pins." They can drop pins of two different colors: red when they see powerful evidence of mathematical learning; and blue when they wish they could step into the video and ask the student a question. After each video, participants will be presented with text boxes that ask them to describe the mathematics learning that they noticed in the video, and to elucidate what questions they still have about the student's learning.

In Phase 2, the participants will read a short paper by the first author (Williams-Pierce et al., 2012), which specifically addresses the role that gestures can play in communicating mathematical learning. They will follow this by Phase 3: similar to Phase 1, but with an additional question about what they noticed differently this second time watching the videos. We hypothesize that participants will be unlikely to notice – or be explicitly aware of what they are noticing about – what the gestures communicate about student learning during Phase 1, but that the brief article will serve as a small intervention that will increase their ability to notice relevant mathematical gestures in Phase 3. This pilot study will serve to confirm or disconfirm these intuitions. Alongside reporting on the results of this study, we plan to share our plans for a larger follow-up study, and look forward to gaining additional advice and insights from the poster session attendees.

REFLECTION, CASE STUDIES, AND DISCOURSE: COMPONENTS FOR TRAINING NEW UNDERGRADUATE MATHEMATICS TUTORS

Joseph Antonides
Ohio State University
antonides.4@osu.edu

Carolyn Johns
Ohio State University
johns.125@osu.edu

Keywords: Undergraduate-level; Instructional activities and practices

Introduction and Rationale

Almost all colleges and universities in the United States house a mathematics tutoring center, most often staffed by undergraduate students majoring in STEM disciplines (Johnson & Hanson, 2015). Altogether, these tutoring centers cater to nearly 20 million undergraduate students annually (National Science Board, 2018). These tutors, while typically prepared mathematically, often have had little to no pedagogical training or teaching experience. This trend raises important concerns regarding the preparation of tutors, an issue rarely studied rigorously in the literature.

In this study, we analyzed four 55-minute tutor training sessions to capture specific ways that "apprentice" mathematics tutors' pedagogical capacities were developed. Particular focus was on the teacher's decisions in facilitating the training sessions and the ways in which the teacher attempted to raise mathematical knowledge for teaching among tutors. Our study was guided by the following research question: what are the major approaches used to develop apprentice undergraduate mathematics tutors' pedagogical capacities during these training sessions?

Context, Methodology, and Framework

This study was conducted at a large, public university in the Midwest region of the U.S. The researcher observed four 55-minute sessions during which newly-hired "apprentice" tutors were trained to perform as undergraduate mathematics tutors. The range of courses tutors were expected to support included: remedial mathematics, college algebra, trigonometry, Calculus I, II, and III, differential equations, as well as mathematics courses for business and biological sciences. Audio recordings were collected and analyzed through a sociocultural framework (Smagorinsky, 2007, 2018).

Findings and Implications

The sessions promoted reflection and discussions regarding what it might mean to know mathematics and how student learning might be traced. The most prominent approach in successfully gauging discussion and reflections on effective pedagogical moves included a reliance on an examination of case studies of student-tutor interactions that depicted both effective and problematic tutoring practices. This approach promoted not only the greatest level of engagement by the tutors, but also allowed the facilitator to identify effective pedagogical moves that could be utilized by the tutors in their future work.

INFLUENCES ON THE USE OF INSTRUCTIONAL FRAMEWORKS IN MATHEMATICS CLASSROOMS

William S. Walker, III
Purdue University
wswalker@purdue.edu

Signe E. Kastberg
Purdue University
skastber@purdue.edu

Keywords: Instructional Frameworks, Professional Development, Practical Knowledge

Instructional frameworks can provide teachers with a vision for research-based instruction and a guide to support changes (e.g. National Council of Teachers of Mathematics, 2014). Three such frameworks were used in a mathematics professional development program. The frameworks included *Launch, Explore, Summarize* (Lappan, Fey, Fitzgerald, Friel, & Phillips, 2002); *Math Talk* (generated within the program) and *Positive Norms for Math Class* (Boaler, 2017). These frameworks addressed needs identified by the teachers. This research investigated the question, how do teacher practical knowledge and the situated context of the school relate to the use of instructional frameworks in participants' classrooms?

The concepts of practical knowledge and the situated nature of the school were central considerations in the design of the professional development program for this research. Practical knowledge includes the knowledge teachers have of instructional techniques, students' learning styles, classroom management skills, and the appropriate place and time to use this knowledge (Chapman, 2011; Elbaz, 1983). A situated perspective recognizes knowledge as the product of the context and culture where it is used (Brown, Collins, & Duguid, 1989) and allows researchers to view actions as part of the larger system of social practices (Cobb & Bowers, 1999).

Subjects for this study were eight teachers at a Midwestern middle school who completed a 14-month mathematics professional development experience. Teachers were interviewed to learn how practical knowledge and school context influenced the use of instructional frameworks. Data consisted of field notes from the interviews with researcher reflections and artifacts from the professional development. An inductive approach of comparative pattern analysis was used to create a category system for the data (Merriam, 2009). For example, the statement "I feel free to use or not use different activities" was categorized as "autonomous decision-making."

Findings

Elements of teacher's practical knowledge and the situated context of the school supported and constrained the use of the instructional frameworks. *Math Talk* and *Positive Norms* were widely used because they were consistent with ways the teachers understood their classroom learning environment, like including group work and having multiple solution methods. At the same time, short class periods (45 minutes) and planning time needed to create lessons aligned with the frameworks limited their use. Similarly, the situated context of the school influenced the use of the instructional frameworks. The teachers stated that support from school leadership allowed them to make autonomous decisions about instructional strategies. Additionally, teachers noted a lack of a school-wide curriculum, which made it difficult to integrate aspects of the instructional frameworks. The professional development providers worked with participating teachers to select the instructional frameworks, yet constraints on the use of the instructional frameworks could not be anticipated. This finding suggests that having prior long-term relationships with the teachers and spending extended time as a participant in the school may be necessary conditions for the development or selection of productive instructional frameworks.

When teachers work to improve their instruction following professional development (PD), the tensions they encounter often undermine the positive effects of PD (Kennedy, 2005). To begin to explore this phenomenon, we documented and categorized the tensions articulated by 92 teachers who participated in our design study focused on the teaching and learning of fractions in grades 3–5. The study included 3 years of PD that used research-based frameworks of children's thinking and instructional practices to encourage a vision of instruction that is responsive to children's mathematical thinking (Jacobs et al., in press; Richards & Robertson, 2016).

Based on a thematic analysis of 72 focus groups across the 3 years of PD, we identified "not enough time" as a significant tension teachers encountered, but this tension had many faces, as illustrated by the following two categories. First, teachers identified time tensions linked to their *instructional contexts*. Some of these tensions were general in nature (e.g., school or district policies that reduced instructional time) while others were mathematics-specific (e.g., pacing guides that controlled use of instructional time). Second, teachers identified time tensions linked to the *instructional vision* in the PD. Some of these tensions focused on time-consuming instructional practices that centered children's ideas (e.g., whole-class discussions based on children's strategies) while others reflected teachers' understanding that supporting children's mathematical sensemaking often takes longer than showing procedures. (Figure 1 exemplifies the two categories.) Our overarching goal is to better understand the tensions teachers encounter when working to implement what they learn in PD so that we can help them view these tensions as manageable, even necessary, rather than as roadblocks (Braaten & Sheth, 2017).

Tensions Linked to Instructional Contexts	Tensions Linked to Instructional Vision
"We are getting more district mandated things. We lose 40 minutes a day for intervention and then we lose 40 minutes a day for [a language program] and so the amount of time that we have to teach is a lot shorter. So I mean, like the district is saying you have got all these opportunities and everything, but as far as how much teaching we get to do, it is less and less each year."	"This whole philosophy of students sharing strategies and things like that. A typical math lesson—those things take time. Just fitting it all in and still having time for reading and writing and everything else because this type of math is wonderful but it does take a lot longer than the traditional "turn to page 51 and do the"— you know."

Figure 1: Sample Teacher Comments Illustrating Two Categories of Time Tensions

SECONDARY MATHEMATICS TEACHERS OVERCOMING DIFFICULTIES IN AN ONLINE REAL ANALYSIS COURSE

Kanita DuCloux
Western Kentucky University
kanita.ducloux@wku.edu

Keywords: Teacher Education - Inservice/Professional Development, Advanced Mathematical Thinking, Instructional Activities and Practices

Topics in real analysis such as understanding and constructing proofs and creating counterexamples have a history of being important yet difficult topics for many students (Doruk and Kaplan, 2015; Weber, 2001). The current ways, however, in which these topics are taught, may not be helpful to prospective secondary mathematics teachers when they begin teaching. Thus, a team of researchers (Wasserman, Fukawa-Connelly, Villanueva, Mieja-Ramos, & Weber, 2017) proposed an alternative model to teach an analysis content course for secondary teachers. The model contains 12 modules that are closely aligned with Abbott's *Understanding Analysis* (2nd edition). The goal of this exploratory study was to examine the difficulties that secondary mathematics teachers experienced while engaging in real analysis teaching modules. Any of the 12 modules could be used to examine the teachers' difficulties but given the online setting and time constraints only nine modules were used. Chapters 1 and 6 each had one module aligned with the content, thus both modules were selected. Chapters 2 and 4 each had three modules, so two were chosen from each chapter. There were no modules for Chapter 3. Chapters 5 and 7 each had two modules. Only one was selected from chapter 5 (both addressed differentiation) and both from chapter 7 (Riemann Sums and the Fundamental Theorem of Calculus).

Four secondary mathematics teachers enrolled in the researcher's analysis course for an online master's program participated in the study. During nine weeks, the teachers completed the modules and textbook problems and participated in required asynchronous discussions. They also completed reflection questions where they discussed important concepts, difficulties encountered, and the relevance of the modules. The reflection question concerning difficulties, from each module, was coded using Doruk & Kaplan's list of seven types of student difficulties. The findings revealed that all four teachers struggled with writing convergence proofs, integrating the bell curve, as well as distinguishing among various concepts and definitions. The teachers reported relying heavily on the textbook, online discussion boards, and videos to overcome difficulties encountered while engaging in the modules. This study has implications for the teaching and learning analysis to increase its relevance for teachers.

MIDDLE LEVEL TEACHERS' ENGAGEMENT IN THE STATISTICAL PROBLEM-SOLVING PROCESS

Christopher Engledowl
New Mexico State University
chriseng@nmsu.edu

Tracey Gorham Blanco
New Mexico State University
tgblanco@nmsu.edu

Mohammad Al-Younes

mmigdadi@nmsu.edu

Keywords: Data Analysis and Statistics; Teacher Education–Inservice/Professional Development

An important component of professional learning of statistics content is engagement in the statistical problem-solving process (Burgess, 2011; Franklin et al., 2007)—also referred to as the practice of statistics (Watson et al., 2018). This cycle involves formulating a question, collecting data, analyzing data, and interpreting results (Franklin et al., 2007). The research base is relatively weak for studies that involve the entire cycle, with very few including the component of formulating questions (Watson et al., 2018), and even fewer that document this process among practicing teachers (Burgess, 2011). Burgess and Watson et al. both call for more research in this area, with Burgess (2011) proclaiming that "part of the core work of teachers involves responding to students' questions, and evaluating students' responses to questions or tasks. Without appropriate teacher knowledge, such work can be compromised" (p. 267). This study aims to contribute to this research base by documenting middle level teachers' engagement in the entire statistical problem-solving process within a professional learning context.

This qualitative study involved 7 middle school mathematics teachers of statistics, who all taught in diverse settings in 3 districts in the Southwestern United States. Teachers exhibited a range of teaching experience (1–40+ years) and were observed to be at both beginner (Level A) and intermediate (Level B) levels of statistical literacy level, according to the levels in the GAISE report, as measured by the Levels of Conceptual Understanding in Statistics (LOCUS) assessment (Jacobbe, 2016)—administered prior to the start of the professional learning sessions.

This study is part of a larger project examining these teachers' engagement in the statistical problem-solving process across all three days of the professional learning session, which was facilitated by the authors. This study focuses on teachers' whole class discussion as they engaged in all components of the process during the Raisins task which took place across 4 hours during the first day of professional learning. During the Raisins task, teachers were provided with small boxes of raisins. They then engaged in formulating statistical questions about the boxes of raisins, making predictions about the answer to their questions, collecting data, analyzing data, and interpreting results. Data comes from a video-recording of the session and teachers' written work. Video data was analyzed by first identifying the moments when each component of the problem solving process, as described in the GAISE report (Franklin et al., 2007), was occurring. Then, teachers' talk was coded for which statistical literacy level (A, B, or C) it most fit within.

Analysis is currently on-going and full results will be shared on the poster. However, preliminary results indicate that, across all components, teachers mostly were observed to be within Level B. Moreover, it appears that the formulating questions component of the task enabled teachers to participate in higher levels of statistical literacy in later components. For instance, discussion about specific words to include in the statistical question allowed teachers to analyze data drawing on multiple statistical summaries of the data—such as using a broader term like *typical* rather than *mean*. Results of this study respond to calls for more research on teachers' engagement in the statistical problem-solving process (Burgess, 2011; Watson et al., 2018).

ANALYZING DESIGNS FOR TEACHER ONLINE DISCOURSE AROUND VIDEOS OF PRIMARY STUDENTS' MATHEMATICAL THINKING

Sarah Larison
Northwestern University
slarison@u.northwestern.edu

Jennifer Richards
Northwestern University
jrichards@northwestern.edu

Miriam Sherin
Northwestern University
msherin@northwestern.edu

Keywords: Teacher Education-Inservice/Professional Development

Discussing classroom video, with a focus on students' mathematical thinking, can be a generative forum for teacher learning (e.g., Cohen, 2004; van Es & Sherin, 2008, 2010). However, in online settings, opportunities and challenges arise in supporting productive discourse (Falk & Drayton, 2009). This study explored primary mathematics teachers' discourse around video from each other's classrooms during a six-week online course, asking: How might different designs engender productive teacher conversation around video, particularly about student thinking?

We analyzed teachers' contributions within two different designs: comments teachers made about peers' videos and reflections on a discussion board (N=39) and tags teachers made directly on peers' videos (N=112). We drew on conceptions of substantive discourse from prior work (van Es & Sherin, 2008, 2010) coding contributions where teachers described and/or interpreted specific students' mathematical thinking and provided evidence for their statements as "substantive." We also coded for two emergent dimensions of productivity: whether contributions were "connected" (meaning explicitly tied to preceding contributions) and "expansive" (went beyond the bounds of the video).

Table 1 compares teachers' contributions across the two designs.

Table 1: Percent of Productive Dimensions of Teacher Contributions Across Designs

	Comments	Tags
% Substantive	36% (15/39)	50% (56/112)
% Connected	36% (14/39)	11% (12/112)
% Expansive	69% (27/39)	10% (11/112)

More tags were coded as "substantive" than comments. In contrast, comments extended beyond the video more frequently, often to teachers' own classroom settings. While few contributions met criteria for productivity across all dimensions (5% of comments, 0% of tags), 26% of comments (10/39) were coded as *both* substantive and expansive, representing occasions when teachers noticed specific moments of students' mathematical thinking in a peer's artifact and compared to what they saw from their own students — which did not occur when tagging.

Thus, both designs for teacher discourse used in this study supported some productive teacher discourse around student thinking, but in different ways. We envision each design serving a different niche in online teacher learning using video as a tool. Moving forward, we will explore relationships between productive discourse, the nature of classroom mathematical tasks, and the substance of the videos and reflections shared.

SCHOOL-BASED PROFESSIONAL DEVELOPMENT TO ADDRESS EQUITY IN MATHEMATICS INSTRUCTION

Sara Birkhead
George Mason University
sbirkhea@gmu.edu

Keywords: Equity and Justice, Instructional activities and practices, Teacher Education-Inservice/Professional Development

High-quality professional development (PD) is often provided through university-based partnerships and requires teachers to attend sessions in the summer or in evenings after school. While this PD does have positive impact on teacher practice (Desimone, Porter, Garet, Yoon, & Birman, 2002), it is not available to all teachers, nor does it take into account the contextual differences of teachers' work sites. This poster will present a PD model utilizing teacher inquiry as well as a video coaching platform to provide school-based PD that is responsive to teacher contexts and can be implemented with minimal input of both human and monetary resources.

Professional Development to Address Issues of Equity

The distribution of teacher quality in the United States is notably inequitable. Students who are most in need have the least qualified teachers (Goldhaber, Quince, & Theobald, 2018). Impacting this distribution requires that all teachers, especially those in under-resourced schools, have access to high-quality PD. School-based PD models are more accessible to teachers and thus offer a greater potential for instructional change than traditional off-site centers of expertise.

School-based PD Using Facilitated Teacher Inquiry

Teacher research has been found to have a positive impact on teacher practice (Cochran-Smith & Lytle, 2009). The PD model shared here uses a teacher inquiry structure and a video coaching platform to facilitate teacher reflection as well as interaction with video of teachers' practice as data (see Figure 1). The model described is centered in individual classrooms, making it responsive to all elements of context.

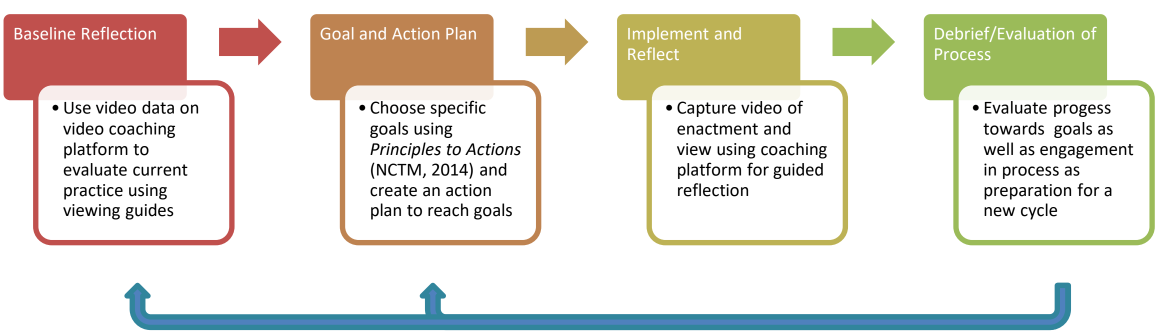

Figure 1: Teacher Inquiry Cycle Supported by Use of a Video Coaching Platform

The goal of this model is both to provide effective PD with minimal investment of resources and also to create a sustainable focus on instructional improvement in the classrooms of

participating teachers. By participating in the teacher inquiry, it is hoped that teachers will continue the cycle, setting new goals and reflecting on their practice.

Keywords: Teacher Education-Inservice/Professional Development; Teacher Beliefs; Affect, Emotion, Beliefs, and Attitudes

Mathematics teacher education is emphasizing a greater need to understand the relationship between mathematics teachers and the resources they use in their instruction (Lee, 2012). Particularly, more impoverished schools within rural contexts are recognized as lacking in resources and needing to close the gap to retain mathematics teachers in these areas (Roberts, 2004; Yarrow, Ballantye, Hansford, Herschell, & Millwater, 1999), but further research is needed to understand current teachers' perceptions of themselves and their mindsets in approaching mathematics instruction in their rural contexts.

In a multiple summer professional development for mathematics teachers in a rural county, K-8 mathematics teachers participate in three two-week summer mathematics institutes that emphasized the learning of math pedagogy and content in the context of their rural setting. This professional development institute recognized the needs of these rural teachers and provided both pedagogical and physical resource support on current research-based mathematical methods in K-8 classrooms, including STEM literature and other manipulatives. Data was collected via surveys, daily reflections, and interviews concerning the teachers' pedagogical methods before and after the institute and their mindsets about themselves as successful math teachers and math people. Through a situated learning lens (Lave & Wenger, 1991), this study examines the development of these rural math teachers' conceptualizations of resources and their view on access to resources in the data analysis, particularly as they considered their own identities as math teachers and math people. The professional development institute itself adopted an approach of focusing the teachers' views of resources on the students learning so that they could consider the modification of certain tasks when resources were not accessible to them in their rural contexts, as well as the conceptualization of what a resource is to be successful in mathematics teaching in these rural contexts. Thus, research questions in this study were:

How do rural teachers conceptualize resources in the mathematics classroom?
How does access to and mindsets about access to resources affect rural mathematics teachers' identity as mathematics teachers?

Findings indicate that teachers in rural contexts began to conceptualize resources as necessary characters in the mathematics classroom to successfully implement research-based mathematics methods. Further, their qualitative responses indicate a direct connection between these teachers' conceptualizations and attempts for implementation of these teaching methods.

These findings have implications for future research to understand how to support rural teachers' access to resources, as well as how to assist rural teachers in reconceptualizing different resources to change their views and identities of themselves as math people and math teachers.

DESIGNING FLEXIBLE, WEB-BASED FORMS OF PROFESSIONAL DEVELOPMENT FOR SUPPORTING MATHEMATICS TEACHER LEARNING

Angela Knotts
WestEd

nseago@wested.org

Keywords: Teacher Education-Inservice/Professional Development; Technology

Incorporating video in the professional development (PD) environment offers great potential for teachers to unpack the relationships among pedagogical decisions and practices, students' work, and the disciplinary content (Borko, Koellner, Jacobs, & Seago, 2011). However, research on video-based PD focuses on face-to-face formats, which do not capitalize on the benefits of digital platforms for professional learning (e.g., scalability, flexibility to tailor to individual needs, financial/logistical accessibility). Research to date in online professional development has shown positive effects for teachers, even when compared to face-to-face (O'Dwyer, Masters, Dash, De Kramer, Humez, & Russell, 2010). For example, teachers who are reluctant to share ideas in face-to-face settings can be more comfortable doing so in digitally-mediated interaction (Dede, Jass Ketelhut, Whitehouse, Breit, & McCloskey, 2009). However, significant questions still remain for how to adapt professional learning programs from face-to-face to digital formats, especially in terms of the social dimensions of professional learning.

This study adapts the Learning and Teaching Linear Functions face-to-face PD materials (Seago, Mumme, & Branca, 2004), which support improvement in teacher and student knowledge of functions. The digital adaptation includes multiple self-contained modules that can be experienced in two-hour time frames, varied sequences, and in flexible collaboration formats. The modules place a video clip at the center, or "in the middle," of a professional learning experience as teachers take part in an online experience of mathematical problem solving, video analysis of classroom practice, and pedagogical reflection. Usability research, conducted in two phases, was completed with 15 mathematics teachers and teacher educators. The participants completed the activities in one digital module, and were surveyed about their experiences and the potential for the modules to support teacher learning. Participants' comments from the surveys were qualitatively analyzed to identify emergent themes (Glaser & Strauss, 1967) about positive experiences with design elements and individual suggestions for improvement.

Preliminary findings indicate that the adapted digital materials show promise for engaging teachers in similar learning as the face-to-face PD. Participants found two new design elements most useful: the lesson graph and comparing solution methods. The lesson graph gives context for the video clip by showing a sequential overview of the lesson the video comes from, which is chunked by the main activities. Comparing solution methods shows teachers a variety of solution methods uploaded by other participating teachers, similar to what they might experience when solving the math task in a face-to-face format. The results from the upcoming feasibility study, which will be shared in the poster, will allow us to compare teachers' experiences in three different settings: independent, locally-based facilitated, and project-facilitated.

HOW TEACHERS REASON WITH THEIR MATHEMATICAL MEANINGS WHEN MAKING CURRICULAR DECISIONS

Keywords: Geometric Reflections, Mathematical Meanings, Curricular Reasoning

Teachers' curricular decisions are important in mathematics classrooms because they determine the learning opportunities for all students. Students do not learn that which they are not given the opportunities to learn (Hiebert, 1999). Researchers have identified a number of influences on teachers' curricular decisions. For example, we know professional development, the written curriculum in the form of the district-adopted textbook or supplementary materials, and teachers' content knowledge all influence curricular decisions (Ball, & Cohen, 1996; Ball, Thames, & Phelps, 2018; Desimone, Porter, Garet, Yoon, & Birman, 2002). Despite our knowledge of influences on curricular decisions, few researchers have investigated *why* teachers make these decisions. In this poster I provide evidence addressing the following research question: *In what ways do middle grades teachers reason with their mathematical meanings when making curricular decisions about the definition for geometric reflections?*

Teachers' mathematical meanings (Thompson, 2016) provide insight into their reasoning about curricular decisions. Two teachers who make different curricular decision may have more in common than not. They may have graduated from similar universities or colleges and received a similar education. Both teachers may have similar mathematical knowledge, based on completing similar course work and scoring similarly on required state content assessments. However, these similarities may obfuscate the genesis for teachers' curricular decisions. By studying teachers' mathematical meanings we gain insights into teachers' reasoning and can identify similarities and differences across teachers as we study their curricular decisions.

Using data collected through our National Science Foundation study (NSF #1561542, #1561554, #1561569, #1561617), I created models of two middle grades mathematics teachers' mathematical meanings. By using these models I predicted concepts teachers would emphasize while teaching geometric reflections and I could accurately explain the teachers' reasons for their curricular decisions. Some of the curricular decisions that I investigated and explicate in this presentation concerned whether the teachers would emphasize the orientation of a figure in relation to reflections, if they would use perpendicular bisectors in defining reflections or merely rely on the concept of equidistance, if they would emphasize reflections on the coordinate grid or off the coordinate grid, and if they would seek to have the students learn coordinate rules for reflections.

TEACHERS' VIEWS OF STUDENTS WITH DISABILITIES AS MATHEMATICALLY CAPABLE

Erica N. Mason
University of Missouri
ericamason@mail.missouri.edu

Keywords: beliefs, instructional vision

The majority of students with disabilities receive the majority of their instruction in general education settings, which positions general education teachers as the daily instructional decision-makers for these students. However, general education mathematics teachers report feeling instructionally unprepared to support students with disabilities in inclusive settings (DeSimone & Parmar, 2006), or view instruction as ineffective for these students (Jordan, Schwartz, & McGhie-Richmond, 2009). Two factors that may influence teachers' instructional decision making are their visions of high-quality mathematics instruction (VHQMI; Munter, 2014; Wilhelm, 2014) and their views of students as mathematically capable (VSMC; Jackson, Gibbons, & Sharpe, 2017). What then is the relation between these constructs and a student's disability status?

Data for this study come from interviews conducted with grades 3-8 general education mathematics teachers whose classes included students with disabilities, in one urban school district (n = 15) and one suburban district (n = 15), both in the Midwest U.S. Using a semi-structured interview protocol, I asked teachers about their instructional vision and then asked them to order students in one of their classes from "most struggling" to "least struggling" based on their own conception of "struggling". Teachers articulated what they considered the underlying reason for a student's learning struggle and described any instructional adjustments they made for that student including their rationale for doing so. All interviews were audio recorded and transcribed. I used Munter's (2014) VHQMI rubrics to characterize the level of sophistication of each teacher's instructional vision. I also used the VSMC coding scheme (Jackson et al., 2017) to characterize teachers' views of their individual students as mathematically capable and to characterize the instructional adjustments teachers reported making for those individuals. Responses about individual students were analyzed in relation to the student's disability status, and patterns within and across teachers were identified.

This poster will share findings and implications for in-service teacher development and learning.

ANALYZING THE MEDIATED EFFECT OF ELEMENTARY MATHEMATICS SPECIALIST CERTIFICATION ON JUSTIFICATION OPPORTUNITIES

Christopher Austin
University of Southern Maine
christopher.austin@maine.edu

Keywords: Reasoning and Proof, Elementary School Education, Teacher Beliefs, Teacher Knowledge

It is critical that elementary teachers be prepared to support their students in developing the mathematical practice of justification. In a classroom, shared understandings of both the need to justify and what counts as a justification are important as members of the classroom community communicate mathematical ideas (Cobb, Wood, Yackel, & McNeal, 1992). This demands that elementary teachers possess knowledge of the mathematics involved, the practice of justification, and their students' understandings (e.g. Ball, Thames, & Phelps, 2008). Furthermore, teachers' beliefs about teaching and learning mathematics (e.g. Hill, 2011) and the nature of mathematics itself (Raymond, 1997) influence their instructional decisions. Given historical concerns about elementary teachers' preparedness, multiple states have developed elementary mathematics specialist (EMS) graduate certificate programs to improve elementary teachers' ability to provide high-quality mathematics instruction. Calls to study EMS graduates as classroom teachers (e.g., National Mathematics Advisory Panel, 2008) are only recently beginning to be answered. The purpose of this study was to investigate the relationship between elementary teachers' EMS status (i.e. certified, not certified), knowledge, beliefs, and attitudes, and the opportunities they provided students to engage in justification during typical classroom instruction.

Data for participating EMS (n = 28) and non-EMS (n = 33) teachers in Grades 3-5 included four subscales of the Learning Mathematics for Teaching instrument (Hill, 2011) as a measure of mathematical knowledge for teaching, and surveys utilizing 29 beliefs items and 30 attitudes items from existing instruments (Banilower et al., 2013; White, Way, Perry, & Southwell, 2006). Three teaching observations were also conducted, resulting in scores for eight elements of the classroom environment based on rubrics adapted from an existing observation protocol (e.g., Tarr & Soria, 2015). For analyses here, the average of the three scores for the element "Students created and defended mathematical justifications" is used as measure of teaching practice.

Quantitative analyses were informed by an existing framework for relationships between teachers' background characteristics, knowledge, beliefs, attitudes, and teaching practice (Ernest, 1989; Wilkins, 2008). Exploratory factor analyses resulted in belief and attitude factors which were included in a path analysis with directly measured variables for EMS status, knowledge, and teaching practice. Multiple mediation analysis revealed a significant indirect effect of EMS status on teachers' practice, mediated by teachers' knowledge and beliefs. Furthermore, the only significant direct effects on teaching practice were from two belief factors: *mathematics should be a meaningful challenge* (β = .47, p < .01), and *mathematics lessons should be highly structured experiences* (β = -0.31, p < .01). Implications of the role of these factors in mediating effects of EMS status and knowledge on teaching practice will be discussed.

ccook19@gmu.edu

This research report will discuss mathematics specialists and the way in which they communicate ideas of equity and social justice within a master's program that leads to a state endorsement in mathematics education leadership. Many mathematics specialist programs focus on developing their mathematical content knowledge for teaching, but these specialized leaders also need to learn about curriculum, assessment, pedagogy, and leadership for school change. This research describes one mathematics specialist program's initial efforts in developing mathematics teacher leaders who take action within their K-12 school contexts. Preliminary findings suggest that the mathematics specialists within this program are aligning their views of equitable mathematics instruction with Principles to Actions (National Council of Teachers of Mathematics, 2014) and the Teaching for Robust Understanding *Framework (Schoenfeld, 2015). Implications for the program are that we are still exploring how to incorporate these ideas and facilitate critical conversations as teacher educators within our classrooms.*

Keywords: Mathematics specialists, Online learning, Equity, Social justice

Mathematics education researchers are called to view equity as a collective professional responsibility (Aguirre et al., 2017). While recent research publications related to our online mathematics specialist program have contributed to the field in the arenas of self-study (Baker & Bitto, under review), online teaching (Hjalmarson, 2015; Baker & Hjalmarson, 2019), and field experiences (Baker, Bitto, Wills, Galanti, & Eatmon, 2018), we recognize that we have more to do to improve our professional practice and to turn our research lens toward inequities in education. As reflective mathematics teacher educators, we strive to advance our master's students' understanding of equity and their readiness to advocate for more socially just educational structures in their contexts.

Our research journey began in Summer 2017 as we purposefully reflected on national equity conversations in our field within position papers and conference strands. Our emerging knowledge informed our interactions with one another and with our students. We questioned whether our program substantively engaged our master's students in ideas of equity and social justice. We further recognized that we needed to be intentional in creating learning experiences which would challenge their thinking and build their awareness as they worked toward becoming agents of change in their school communities.

This study captures our theorized entry points for making equity more explicit in our courses and our analysis of our students' evolving descriptions of equity. Our work is motivated by the tenets of the National Council of Supervisors of Mathematics (NCSM)/TODOS position statement (2016) titled *Mathematics Education Through the Lens of Social Justice:*

Acknowledgment, Actions, and Accountability. We place our work in the "acknowledgement" phase, and the results of this study drive our movement toward the "action" phase in our own practice and in our candidates' practice as emerging mathematics teacher leaders. The implications of this work are especially important as our we move toward a 100% synchronous online program design which extends our sphere of influence beyond in the state of Virginia and builds an increasingly diverse community of learners. We seek to build a program that both respects their current thinking yet challenges their perspectives of equity and social justice in ways that make all of us more accountable.

Research Question

How do candidates in a synchronous online K-8 mathematics specialist master's program describe equity and social justice?

Theoretical Framework

Equity and Social Justice in Mathematics Education

As White female mathematics teacher educators in a highly-resourced suburban mid-Atlantic community with diverse public school populations, we acknowledge both our positionality and our own pursuit of deeper understandings of equity and social justice. We have collaboratively contemplated entry points into broader conversations about equity in our master's level courses for aspiring mathematics teacher leaders. Gutiérrez (2007) placed access and achievement together on a *dominant axis* in her framework for equity in mathematics education. This dominant axis reflects "the status quo" and privileges a "static formalism" which equates resource allocation and access for historically marginalized students. It further creates an achievement-driven pipeline which defines societal economic participation (p. 39). Gutiérrez also theorized a *critical axis* of equity in which "mathematics… squarely acknowledges the position of students as members of society rife with issues of power and domination" (p. 40). She offered a window/mirror metaphor for identity as a precursor to building power through mathematics to challenge marginalization in society. "Students should have the opportunity to see themselves in the curriculum as well as to have a broader view of the world" (Gutiérrez, 2012, p. 20).

The tensions between these two axes (Gutiérrez, 2012) orient our research community toward a broader agenda of social justice in which mathematics education evolves to effect change. This tension is deeply embedded in our own instructional decisions as we facilitate conversations about equity which both value and challenge the contexts that our experienced teachers bring to their graduate work. Rubel (2017) categorized standards-based teaching and complex instruction as "equity-directed instructional practices" (p. 69) within the dominant axis and culturally-responsive teaching and mathematics for social justice within the critical axis. Yet, we wonder if situated instructional moves which are intended to build mathematical competence (Berry, 2018; Gresalfi, Martin, Hand, & Greeno, 2009) are so clearly categorized. We believe that instructional practices can be highly contextualized and actually place our teachers at the uncertain intersection of achievement as the dominant axis and identity as the critical axis of equity in mathematics education.

We are asking our aspiring teacher leaders to operate in this tenuous space as we seek to understand how their views of equity evolve with the use of reflective tools designed to foster student identities as productive learners and doers of mathematics (Aguirre, Mayfield-Ingram, & Martin, 2013, Aguirre et al., 2017) and change student and teacher beliefs about mathematics

(Berlin & Berry, 2018; Horn, 2007). In our mathematics specialist courses, we engaged our students in the National Council of Teachers of Mathematics (NCTM) (2014) *Principles to Actions* effective teaching practices and the Teaching for Robust Understanding (TRU) framework (Schoenfeld, 2015) pedagogical moves as tools which promote equity in classrooms. We also facilitated conversations around the calls to take a social justice stance in the joint position paper from NCSM and TODOS. These tools and papers were a starting point for broader conversations among our faculty as we prepare our mathematics specialist candidates to understand all four dimensions of equity (Gutiérrez, 2007) and to become agents of change.

Mathematics Specialists

Mathematics specialists, also called mathematics coaches or mathematics teacher leaders, are recommended to, "enhance the teaching, learning, and assessing of mathematics in order to improve student achievement" (Association of Mathematics Teacher Educators (AMTE), Association of State Supervisors of Mathematics, NCSM, & NCTM, 2010, p. 1). To be prepared for varied contexts and responsibilities, specialists need expertise that includes deep knowledge of mathematical content and pedagogy (Ball, Thames, & Phelps, 2008) as well as the ability to develop teaching peers' mathematical knowledge for teaching (AMTE, 2013). It is recommended that credentialing and certificate programs develop content knowledge for teaching mathematics, which includes deep understanding of mathematics for grades K-8 and further specialized mathematics knowledge for teaching; pedagogical knowledge for teaching mathematics, which includes learners and learning, teaching, and curriculum and assessment; and leadership knowledge and skills (AMTE, 2013). NCTM *Principles to Actions* (2014) acknowledges the critical role of mathematics specialists in enhancing teacher capacity to enact research-based teaching practices.

Potential agents of change. Mathematics specialists can act as agents of change to implement policy initiatives related to standards, curriculum, assessment, and professional development within their K-12 school contexts (AMTE, 2013; Fennell, 2017). However, mathematics specialists face many challenges, including meeting the expectations of multiple stakeholders in the school system (e.g., teachers, administrators, and parents) (Chval et al., 2010), while teaching the learning of mathematics to those involved (Felux & Snowdy, 2006). Therefore, they require guidance and support to become experts (Borko, Koellner, & Jacobs, 2014; Chval et al., 2010) as experience and time are needed for both developing their leadership abilities and changing the mathematics practice within their schools (Campbell, 2012).

The mathematics specialist master's program at George Mason University is developing specific teacher leader skills and dispositions (Baker et al., 2018) which prepare our specialist candidates to become agents of change. But as we, as faculty, reflect upon the candidates' ability to take action to reform and advance their educational settings to be equitable and accessible, we wonder: How do candidates describe equity and social justice in a mathematics specialist advanced program?

Methods

Context

The George Mason University K-8 Mathematics Specialist Leader program, established in 2005, is comprised of ten 3-credit graduate courses (five content, four leadership, and one capstone internship course) based on current coaching leadership frameworks (Bitto, 2015) and national standards for mathematics specialists (NCTM, 2012; AMTE, 2013). Over the past decade the program has transitioned from traditional face-to-face to an online format. In Fall

2017, the first iteration of a 100% synchronous online program began. All coursework was delivered using a synchronous online format that utilized Blackboard Collaborate Ultra for communication (audio, video, and text) along with interactive Google slides in which candidates had editing rights allowing for simultaneous engagement with their instructors and peers on slides.

Participants

There were 16 mathematics specialist candidates in the first synchronous online cohort, including female (87%) and male (13%); a combination of White (69%), African American (19%), and Indian American (6%) educators. All of the candidates were employed in K-12 schools, with the majority (81%) in elementary schools (K-5) and 19% who taught at the secondary level (6-12). The candidates represented varied educational settings, including 81% who resided in districts in Virginia, which does not use Common Core State Standards; others were outside of Virginia in Common Core states (13%) or in international schools (6%). Prior to the beginning of the cohort, 25% of the candidates were already working in mathematics specialist positions without formal preparation coursework.

Data Collection and Analysis

Data was collected via identical surveys that were given at the beginning of the program and midway through coursework. Consisting of 23 questions total, initial questions centered on participant demographics such as job title and K-12 setting. Eight questions utilized a Likert scale (1-5), were taken from the EMC survey (Yopp, Burroughs, & Sutton,, 2010), and delved into one’s comfort facilitating leadership activities such as modeling instructional practices, collaborating with stakeholders, providing feedback, and identifying gaps in their peers’ knowledge. Six questions aimed at understanding participants’ perceptions of high-quality mathematics instruction and collaborating with various K-12 stakeholders (e.g. teachers, administrators). Five questions were open-ended and centered on each of the dimensions of the TRU Framework (Schoenfeld, 2015).

Responses were analyzed qualitatively. An in vivo coding (Saldaña, 2016) scheme was used in order to capture the specific language of the participants. Categories shared by the participants were aligned and the reduction of these categories led to the emergence of a few prominent themes (Maxwell, 2005). These themes will be elaborated on and discussed in the following sections.

Results

Preliminary findings indicate our mathematics specialist candidates’ descriptions of equity within mathematics education evolved during their program in the following ways: 1) changing their descriptive language; 2) increasing understanding of a teacher’s responsibility; and 3) developing knowledge of facilitating rich mathematics experiences.

Advancing Their Perspectives of Equity

At the beginning of the program, mathematics specialist candidates characterized equity as differentiation. In the pre-program survey, they spoke about “meeting students’ needs” 27 times and used the term “differentiation” 10 times. More specifically, they described “differentiation” and “meeting the needs” as a function of resource allocation. That is, if teachers and mathematics specialists provided the right combination of tools, access, and resources, they were being equitable in their instructional approaches. Participants articulated a critical role for differentiation in achieving equitable mathematics instruction. They also recognized that many factors contribute to ensuring each student has access to meaningful learning.

The math specialist candidates discussed how differentiation in mathematics instruction was a way to "level the playing field" for low-performing students. One candidate said, "Each student enters a mathematics classroom with a different skill set. Collectively, they possess a variety and multitude of levels and deficiencies." They also communicated a commitment to access for all students by "making content available to all and treating all students with dignity regardless of their level is important." Furthermore, they described equity as teachers utilizing multiple formats to meet the needs of students, either collectively or individually, as demanded by the differences in student readiness.

This focus on providing access for the purpose of higher achievement was aligned with the dominant axis (Gutiérrez, 2007) of equity. They viewed equity as addressing mathematical weaknesses instead of fostering the identities of students of varied cultural backgrounds as productive doers of mathematics. The mathematics specialist candidates talked about the (lack of) prior knowledge as a deficit rather than communicating a mindset that views potential in each student.

However, in the mid-program survey the language the specialist candidates used to discuss students and their understandings shifted. There were fewer references to differentiation and meeting students' needs and a deeper recognition of the value all students bring to classroom learning experiences. Their language also shifted from viewing (lack of) prior knowledge as a deficit to an opportunity for meaningful learning. For example, one candidate wrote:

> Equitable math instruction means that all students have access to high quality math instruction. All students need to have a voice in the classroom with lots of opportunities to share their thinking. Teachers need to hold all students to high standards and provide support to them. By using best practices, all students can have a deeper level of math understanding and be problem solvers and think critically.
