Pamela's science lesson was an introduction to tectonic plate boundaries. The driving question of the lesson was "what happens when plate boundaries meet?" She gave students time to discuss the different possibilities of plate interactions. Students mentioned a few boundary interactions, such as "a plate going underneath the other one", or that plates "rub up against each other, and kinda shear" After the initial discussion, Pamela used student's responses to introduce the appropriate discipline-specific words (i.e., divergent, convergent, and transform). Pamela encouraged students to use these discipline-specific terms during the follow-up activity, where students used a graham–cracker-and-frosting model to mimic and further investigate the plate interactions. Pamela's science teaching shows an intentional choice of lesson structure and ongoing support for the acquisition and use of key terms. She used the earth- and space-science terms that are used to describe tectonic plate interactions: divergent, convergent, and transform. Pamela's familiarity with the science discourse meant that her approach to elicit students' learning of these terms started with eliciting colloquial descriptions of plate interactions. Pamela then linked these descriptions to discipline-specific words and facilitated students' adoption and use of these discipline-specific words to describe plate activity throughout the cracker-and-frosting modeling activity.

Learning Mathematics through Word Use

Pamela's mathematics lesson was a part of an ISTEM unit that she and three of her classmates collaborated on designing. The unit was eventually implemented in an eighth-grade classroom, where students were to design a scale-model prototype of a zoo enclosure. Pamela started the micro-teaching session by attempting to find a scale factor by exploring the relationship between a scale drawing of a building footprint and its footprint in real life. As an inquiry-based approach, Pamela worked to build interest by using the footprint of the building containing our classroom. She handed out an image of the building's footprint (see Figure 1).

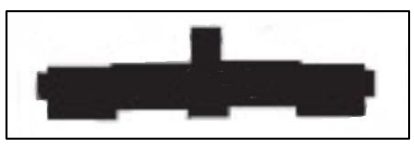

Figure 1: Image of the Building Footprint

To elicit learning of the term scale, Pamela considered approaching the concept by establishing the proportional relationship between the building's footprint on the map, and its actual footprint. The following excerpt includes Pamela's initial question:

> Pamela: Using your ruler, I would like you to measure, um luckily, we are in a building that is kinda shaped like a rectangle, so your best approximation of how long and how wide it is in centimeters
> [gives a minute for students to find the measurements]
> Pamela: So can one group tell me on the map, how many centimeters long the building is?
> Audrey: one!
> Pamela: and how wide is it?
> Audrey: well, the skinniest part is 0.2 but the widest part is 0.3
> Pamela: okay, so let's say it's 0.25, and you guys have a class set of calculators, so can someone tell me what the area of the building is on our map, in centimeter squared?

In this excerpt, Pamela's request for the dimensions of the building reflects her association of the discipline-specific term *area* with a formula for computing the area of regular figures: length × width. Approaching area using the computational formula of length times width has been identified as a constraint that prevents connecting area to the measurement of space (e.g., Baturo & Nason, 1996; Kamii & Kysh, 2006). Pamela's approach to finding scale factor resulted in her use of the discipline-specific term area. Yet calculating area through the length times width algorithm constrained her flexibility when students suggested multiple measures for a dimension of the building. Her move was intended to find dimensions and compute a number to represent area on the map that could be related to the area of the building footprint in real life. In this move she shared her view of area as a computed quantity rather than a word whose use in relation to scale could be discussed.

After finding an approximate area of the building's footprint using the map, Pamela encouraged the students to find the relationship between the building's footprint on the map and its actual footprint. The following excerpt illustrates how that conversation played out:

> Jesse: It's 400 times bigger [referring to the building's footprint being 400 times bigger than its footprint on the map]
> Pamela: How did you get 400? What did you do to the numbers to get 400?
> Jesse: I guess, I don't know, I think I did 0.25, one-fourth of one, and then somehow, I got to 400, from there to 1600
> Pamela: okay, okay, so, 400 times 4 is 1600, and 0.25 is one-fourth, so there's something maybe with 4 there? and that's how you got 4, one-fourth, 400, okay, any other thoughts on how we might be able to relate these two numbers [the building's footprint on the map and in real life]?
> Leona: I divided the 1603.6 [the footprint of the building in square meters] by 0.0025
> Audrey: shouldn't be 0.000025
> Leona: Oh, let me do it one more time then. It's much bigger, it's like 6 million.
> Jesse: Okay that makes more sense, it's much bigger than 1600
> Pamela: and how is this number related to our map? [pointing at the 6 million]
> Rosie: So the actual building is that many times bigger than the measure on the map

Ultimately, the computation of a scale factor became difficult for Pamela, making her micro-teaching of the mathematics lesson less structured compared to the intentional structure of her science lesson. However, this excerpt shows Pamela embracing uncertainty and allowing the discussion to continue. By letting the students converse, Pamela became a learner in the exploration of area. There was room for students to share their ideas and strategies. While the discussion did not lead to an exact number, it did lead to a discussion about the meaning of the relationship between the two numbers, thus leading to the concept of scale.

Discussion

This case study aimed to examine a PST's experience when teaching outside her area. Pamela showed expertise in designing and micro-teaching a lesson from her own discipline. When she crossed the disciplinary boundaries, her performance could be considered equivalent to that of a novice PST (Baturo & Nason, 1996). However, Pamela is not a novice PST. Her familiarity with science led her to identify the discipline-specific key terms prior to micro-teaching the lesson, purposefully integrating these terms in the structure of the micro-lesson for students to adopt and utilize. However, when micro-teaching the mathematics lesson, Pamela's unfamiliarity with that discourse led to a less direct approach to elicit learning of the term *scale*. As the lesson progressed, Pamela embraced uncertainty and positioned herself as a participant in the discussion, and the structure of the lesson became more open and flexible to the students' negotiations about the meaning of scale. If teachers teaching outside their areas do not have to position themselves as knowledge providers or expert participants (Sfard, 1998), there is more potential for learning to occur if they negotiate their authority and position themselves as learners in the discourse. This was evident during Pamela's last episode. Teachers implementing ISTEM curricula need to be aware of how they use and discuss the use of discipline-specific words (Stohlmann et al., 2012). It is especially important for teachers to participate as learners in the discourse, to allow the discourse change and for learning to take place.

The paper describes 19 pre-service secondary teachers' (PSSTs) responses on a pre-assessment that elicited their meanings for subtracting a negative number. We found several references in their responses that built upon these meanings and here we report on four prominent categories: 1. Subtraction and the negative sign are explained through movement and direction on the number line, 2. Subtraction and negative are the same, and they often cancel each other, 3. Subtracting a negative is the same as adding, and 4. Subtraction is an action. The paper elaborates on these meanings, with examples and a possible reasoning for their emergence.

Keywords: Subtracting integers, Meanings of integer subtraction, Secondary preservice teachers

Operations with integers is a standard part of the secondary math curriculum. Although initial instruction happens in 6th and 7th grade (CCSSM, 2010), many students struggle with operations with integers throughout high school. Consequently, all secondary teachers need a deep understanding of operations with integers to effectively support student success.

Research with pre-service secondary teachers (PSSTs) on operations with negative numbers is less common. The ones that exist deal with different aspects, like representation on the number line, models of teaching, and use of contexts (Cunningham, 2009; Steiner, 2009). These studies make a call for research to bring forward the meanings associated with subtracting integers. In this paper, we focus on what meanings PSSTs associate with subtracting a negative number, which we believe has a bearing on how they will make sense of the representations and contexts and use them in their future teaching.

Subtracting a Negative Number: Meanings and Frameworks

Researchers have recently begun discussing pre-service teachers' efforts to make sense of integer subtraction (e.g. Almeida & Bruno, 2014; Bofferding & Richardson, 2013). The difficulty of subtracting negatives is not only the concern of school mathematics (Schindler et al, 2017) but is seen among adults and university students. They suggest that many concerns with subtracting a negative are associated with the continuum conjectures that students make based on their decade of experience in subtracting positive numbers.

To understand the difficulty in subtracting a negative, researchers have developed frameworks that emphasize the "meaning" of the negative sign. Vlassis (2004, 2008), emphasizes the symbolic aspect and focuses on three uses of meanings of the minus sign: the unary, the binary and the symmetric functions. In the unary function, the minus sign is attached to a number to form a negative number, as in "– 6". A binary use of the minus sign refers to the subtraction operation in arithmetic or algebra, as in "5 – 3". The first two uses correspond to the distinction emphasized in other studies between the use of the minus sign to indicate a signed or directed number and the use of the minus sign to indicate the subtraction operation (Glaeser, 1981). The symmetric use of minus sign is less frequent and refers to taking the additive inverse of a number, as in $-(-6)$. Our study brings out additional details of these meanings that are attached to the symbols, rather the quantities.

Study Design, Participants, Analysis

Data for this study was collected within a math elective course tailored to deepen preservice secondary mathematics teachers' understanding of secondary mathematics topics. The study participants were 19 undergraduate students enrolled in a single section. One participant was an elementary mathematics preservice teacher; eighteen participants were secondary mathematics preservice teachers in the secondary education program. Three students presented as men; the rest presented as women. We refer to all students as preservice secondary mathematics teachers (PSSTs).

During a recent fall semester, the first and second authors co-taught the aforementioned course, beginning with a three-week unit on operations with integers. Before starting the unit, they administered a preassessment to gain information about PSSTs understandings of subtracting a negative integer. The assessment contained a single, open-ended question: "How would you support a student who is struggling to understand why $4-(-3)=7$?" The PSSTs' mathematical responses included diagrams, models, and written explanations. Using a grounded theory approach (Corbin & Strauss, 1990), each author open-coded the responses, marking and commenting on aspects of each response that seemed to portray a meaning the PSST held. One author then collected and analyzed what the others had identified, coming up with 23 references to meanings from the collection. These meanings were then brought to consensus and categorized to portray PSSTs' understandings of subtracting a negative number.

The findings we report here are part of a larger study that examines how PSSTs' understanding of integers and operations with integers has significance to their meaning making process with different contexts and representations and how that changes throughout instruction. This paper specifically addresses the research question: What meanings do preservice secondary mathematics teachers bring for subtracting a negative number?

Results: Meanings and Representations

Given the nature of the question on the assessment, words like "subtraction", "subtract", and "subtracting" pervaded PSST responses as well as phrases like "take away" and "minus(ing)". Here we describe the four meanings we found among the PSST's responses.

Meaning 1: Subtraction and the Negative Sign are Explained Through Movement and Direction on the Number Line

In this collection of responses, we see three uses of direction, usually in reference to a number line. In the first, which we categorize as *subtraction is going backwards*, PSSTs suggest that when one sees a subtraction sign one moves "backwards" on the number line. One description suggested that "all the operations are about which way to go" on the number line, and subtraction is to go backwards. In these elaborations, we assume, consistent with the responses, that moving right is going forward and moving left is going backward.

In the second use, *subtraction and negative both means going backwards*, PSSTs identified subtraction and negative as two separate entities, but they assigned the same direction to both, with language like "If one (-) sign makes you go backwards then 2 (-) makes you go backwards and then turns you around again." This reference to "backwards" is slightly different than the first use; this is a relative "backwards". In the context of $4-(-3)$, a beginning forward direction is assumed, the first subtraction sign suggests move backwards, the second negative sign suggests “backwards again” and that would mean “turning around”.

In the third use, *subtraction says moving left, negative say flip direction*, the PSSTs say things like “The minus sign says to go to the left (←) negative direction, but the negative sign says to flip that direction and go the other way, right (→) positive direction”. All three uses suggest a procedure, or journey on the number line, to arrive at the result of 7, rather than attending to the meaning of the terms and symbols in $4 - (-3) = 7$.

Meaning 2: Subtraction and Negative Are the Same, and They Often Cancel Each Other

We see PSSTs talking about two negatives making a positive in three ways: by canceling, by analogy and by drawing. The first two ways are seen in the literature (Bofferding & Richardson, 2013), but not the last one. PSSTs talk about canceling as a way of manipulating the symbols using language like “when we have two negative signs, they cancel each other out.” Second, the PSSTs appeal to an analogy with the English language where “a double negative turns out to be positive”. In the third example, the PSSTs describe a drawing process they would use to literally turn the two negative symbols into an addition symbol. They describe this with language like “the two negatives make a plus sign” and a picture similar to Figure 1. These responses indicate a reliance on a visual mnemonic rather than a separate meaning for subtraction and the negative sign, which could be problematic when trying to convey meanings to students.

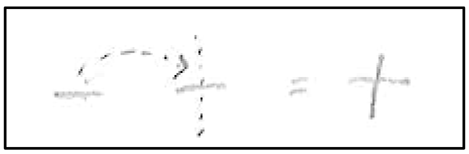

Figure 1: Two Negatives Make a Plus Sign

These teachers did not attend to the meaning of subtraction as an operation nor the meaning of a negative integer as a signed number. Rather, they had non-mathematical strategies for dealing with two negatives when they occur sequentially in an expression.

The language of canceling is common in algebra when students are simplifying algebraic expressions, so the language of canceling is not surprising. What may have started for these PSSTs as a mnemonic to help them remember how to subtract a negative has, at some level, become a meaning for them. The drawing method could be considered a visual mnemonic for remembering the phrase “two negatives make a positive.” What is particularly striking about this meaning is the lack of attention to the difference in the meaning of “-” as a subtraction symbol and as an indication of the sign of a quantity.

Meaning 3: Subtracting a Negative is the Same as Adding

We consistently saw the phrase “subtracting a negative number” in the PSSTs’ responses, although sometimes they use “minusing” or “take away” instead of subtracting. However, the completion of the phrase “subtracting a negative number” is ambiguous in all but one case: “subtracting a negative quantity from another quantity would yield the same result as if you were to add the positive amount of that quantity.” This is the only statement observed that refers to the minuend and language of quantity. The other 4 statements end in a phrase similar to “is the same as adding it” where what “it” is is ambiguous, and which likely refers implicitly to the quantity aspect of the negative number being subtracted.

What’s notable about this meaning is that students are attending to what is being subtracted, whether they use the language of “negative number” or “negative quantity”. Unlike in meaning

2, these PSSTs are distinguishing between when the symbol “-” denotes subtraction and when it is associated with a negative number. In the statement involving quantity, we see an important distinction between the process of the subtracting one number from the other and the result of the process.

Meaning 4: Subtraction as Action

PSSTs portrayed four different meanings for subtraction: take-away, negative direction, going backwards, and adding a negative. The take-away meaning was apparent in one PSST’s use of an integer chip model in which the PSST equated crossing out three negative chips in a picture with “take(ing) away 3 negative chips”. A PSST discussed subtraction, or the minus sign, as going left or in the “negative direction” on a number line. Similar to the negative direction meaning, a PSST stated that “when we subtract, we go backwards on [a] number line”. One PSST chose to redefine subtraction as “adding a negative” to facilitate the rewriting of $4 - (-3)$ as $4 + -(-3)$.

By explicitly assigning an action meaning to subtraction, PSSTs provided a glimpse into how they think about the act or process of subtracting. The first three meanings: take away, negative direction, and going backwards, are closely tied with representations. Researchers have shown that representations assist in reasoning about and making sense of mathematical situations, facilitating student learning (Mitchell et al., 2014), and in communicating thinking (Janvier,1987; Schwartz et al., 1993/94).

Conclusion and Implications

In this study we see PSSTs use a range of language, mnemonics, and representations to describe an understanding of why $4 - (-3) = 7$. As language plays an important role in meaning making and communicating meaning (Vygotsky, 1962), the unstable, inconsistent and ambiguous language across these responses suggests a need for pre-service secondary mathematics teacher programs to include intentional opportunities for PSST to develop rich, consistent meanings of operations with integers. The meanings represented here, if teachers teach these meanings, generally do not distinguish enough between the meaning of subtraction and the meaning of a negative for students to be able to construct their own meaning and make sense of subtracting a negative number.

We hoped that the PSSTs would use the meaning of the symbols in the expression $4 - (-3)$ to explain why the result is 7. Instead, they had a variety of ways to justify switching subtracting a negative three $[4 - (-3)]$ to adding a positive three $[4 + (+3)]$ without attending to the meaning of subtraction or a negative number. That is, they treated $-(-3)$ as a procedure, but they did not attend to $4 - (-3)$ as a process. Unfortunately, some curricula (EngageNY, 2015) do not attend to the meaning of subtracting a negative because they define subtracting a quantity as adding the inverse or the opposite of the quantity. In order for our PSSTs to effectively teach their students the meanings associated with operations with integers, they need to develop those meanings for themselves and understand how their discussion of the pre-assessment task focuses on procedures instead of meanings.

We believe one of the reasons the PSSTs explanations were so varied is due to the nature of the prompt which positioned the PSSTs as teachers, not doers of mathematics. That is, they were not called on to determine what $4 - (-3)$ equals, but to support a struggling student to understand why $4 - (-3)$ is 7. For that specific purpose, they created representations which gave us access to the meanings they have for themselves and which they think might be useful for teaching. By incorporating representations into their responses, the PSSTs recognized the importance of utilizing representations for communicating meanings. This shows promise for the PSSTs establishing meanings closely tied with representations.

INDIRECT REASONING TASK FOR PROSPECTIVE SECONDARY TEACHERS: OPPORTUNITIES AND CHALLENGES

Orly Buchbinder
University of New Hampshire
orly.buchbinder@unh.edu

Sharon McCrone
University of New Hampshire
sharon.mccrone@unh.edu

We describe an instructional module aimed to enhance prospective secondary teachers' (PSTs') subject matter knowledge of indirect reasoning. We focus on one activity in which PSTs had to compare and contrast proof by contradiction and proof by contrapositive. These types of proofs have been shown to be challenging to students at all levels and teachers alike, yet there has been little research on how to support learners in developing this knowledge. Data analysis of 11 PSTs, points to learning opportunities afforded by the module and the PSTs' challenges with indirect reasoning.

Keywords: Teacher Knowledge, Reasoning and Proof, Instructional Activities, Indirect Proof.

Introduction and Theoretical Perspectives

Reasoning and proof have been at the center of substantial research efforts in the last decades, yet, very few studies have focused on indirect reasoning, proof by contradiction and by contrapositive (Stylianides, Stylianides & Weber, 2017). By indirect reasoning, we mean any instance in which a person makes an argument of the form: "it is not possible because otherwise …". Students use indirect reasoning informally, when checking for errors (Thompson, 1996), and formally, when proving by contradiction or by contrapositive. A proof by contrapositive relies on the logical equivalence between a conditional statement S and its contrapositive $(P \Rightarrow Q) \equiv (\sim Q \Rightarrow \sim P)$. A proof by contradiction assumes the negation of S: $(P \wedge \sim Q)$ and proceeds directly to obtain $r \wedge \sim r$ (where r is any statement), which is a contradiction, implying that S is true. Despite the similarities, (e.g., both have $\sim Q$ in the assumption, and contain direct steps), there are also differences, for example, a contradiction can take many forms, but a proof by contrapositive necessarily ends with $\sim P$ (Yopp, 2017).

The studies on indirect proof suggest that students view these types of proof as less convincing and particularly difficult to construct (Harel & Sowder, 1998; Leron, 1985; Antonini & Mariotti, 2008), specifically struggling to construct negations (Lin, Lee, & Wu Yu, 2003). Recently, more research attention has been directed towards studying students' understanding of proof by contrapositive (Yopp, 2017) and proof by contradiction (Brown, 2018). However, almost nothing is known about what types of interventions or pedagogical supports could help to mitigate students' challenges in this area.

Indirect proof is important in both tertiary and secondary mathematics. For example, proof of congruency of alternate interior angles created between parallel lines and a transversal, or proofs of sums and products of rational and irrational numbers are done by contradiction. Thompson (1996) asserts that teachers can support secondary students' understanding of indirect proof. But to do that, teachers themselves, must have robust knowledge of indirect proof and of pedagogical strategies for teaching it. Our review of educational literature found no studies on whether pre-service secondary teachers (PSTs) have such knowledge, or how to support its development.

To address this gap, we designed and systematically studied an instructional module that aimed to enhance PSTs' knowledge of indirect reasoning, as a part of a larger design-based research project, *Mathematical Reasoning and Proof for Secondary Teachers* (Buchbinder & McCrone, 2018). In this paper we examine the research question: "What challenges and learning opportunities arose from the PSTs' interactions with one of the tasks in this module?"

Methods

Indirect Reasoning Instructional Module (IR Module)

The IR module was the last in the series of four modules in the capstone course, preceded by modules on: direct proof and argument evaluation; conditional statements, and quantification and the role of examples in proving. By the time the PSTs reached the IR module, they had already refreshed and strengthened their knowledge of conditional statements and contrapositive which are critical for indirect reasoning (Buchbinder & McCrone, 2018).

The IR module comprised two in-class activities followed by planning and enacting a lesson in secondary classrooms integrating indirect reasoning. The objectives of the *Indirect Proof Structure* activity were to help PSTs understand the relationships between proof by contradiction and proof by contrapositive. For each of six given proofs, the PSTs were asked to identify the P and Q of the statement, the assumption and the conclusion of the proof, determine if the proof is by contrapositive or contradiction, and if so, identify the contradiction (see Table 1 for examples). To highlight the differences in the logical structure, we included of a proof by contradiction and by contraposition for the same statement (Statements 4 & 5, Table 1).

Table 1: Three Out of Six Items in the *Indirect Proof Structure* Task

Items	Proof Structure
Statement 2: *Let a and b be two real numbers. If ab = 0, then a = 0 or b =0* Proof: Suppose that $ab = 0$, and $a \neq 0$ and $b \neq 0$. Since $a \neq 0$ and $b \neq 0$, we can divide both sides of $ab = 0$ by a and by b. This will result in 1= 0. Therefore, if $ab = 0$, then $a = 0$ or $b=0$.	Proof by contradiction P: $a,b \in \mathbb{R}$; $ab = 0$ Q: $a = 0$ or $b = 0$ Assume: $P \wedge \sim Q$ Contradiction: $1 = 0$ Infer: $P \Rightarrow Q$
Statement 4: *For all integers n, if* n^2 *is even, then n is even.* Proof: Suppose n is an integer, such that n^2 is even, and n is not even. Since n is not even, it is odd, that is, $n = 2k + 1$ for some integer k. By substitution and algebra: $n^2 = (2k+1)^2 = 4k^2 + 4k + 1 = 2(2k^2 + 2k) + 1$. Now, $(2k^2 + 2k)$ is an integer, since the products and the sums of integers are integers. So, $n^2 = 2(integer) + 1$. By definition of odd, n^2 is odd. Therefore, n^2 is both even and odd. Therefore, if n^2 is even, n is even.	Proof by contradiction P: $n \in \mathbb{Z}$; n^2 is even Q: n is odd Assume: $P \wedge \sim Q$ Contradiction: $P \wedge \sim P$ Infer: $P \Rightarrow Q$
Statement 5: *For all integers n, if* n^2 *is even, then n is even.* Proof: Suppose n is an odd integer. By definition of odd $n = 2k + 1$ for some integer k. By substitution and algebra $n^2 = (2k+1)^2 = 4k^2 + 4k + 1 = 2(2k^2 + 2k) + 1$ Now, $(2k^2 + 2k)$ is an integer, since the products and the sums of integers are integers. So, $n^2 = 2(integer) + 1$. By definition of odd, n^2 is odd.	Proof by contrapositive P: $n \in \mathbb{Z}$; n^2 is even Q: n is odd Assume: $\sim Q$ Obtain: $\sim P$ I.e.: $(\sim Q \Rightarrow \sim P) \Rightarrow (P \Rightarrow Q)$

The PSTs worked on the activity in groups of 3 to 4, followed by a whole class discussion, led by the course instructor, the first author of this paper. Next, the PSTs summarized similarities and differences between proof by contrapositive and by contradiction on posters.

Participants, Data Sources, and Analytic Techniques

Participants in the study were 11 PSTs in the capstone course *Mathematical Reasoning and Proof for Secondary Teachers*. All PSTs were in their senior year and had completed proof oriented coursework. Data sources were video recordings of the whole class and of each small groups' work captured with 360° table-top cameras, the PSTs' worksheets and posters. The data were analyzed using open coding (Wiersma & Jurs, 2005) to identify learning opportunities and challenges experienced by the PSTs. Challenges were identified as moments in which the PSTs went back and forth between mathematically correct and incorrect ideas, or verbally expressed their confusion. Learning opportunities were defined as instances where the confusion was resolved in a manner that aligns with conventional mathematical knowledge.

Results

Challenges

Here we identify a few a few challenges that the task elicited.

"A proof by contrapositive is a proof by contradiction." After correctly identifying Statement 4 (Table 1) as proof by contradiction, a group of three PSTs: Jane, Emily and Kelly moved on to Statement 5. They recognized it is the same statement, and correctly identified its P and Q. However, when trying to identify the type of proof a disagreement arose.

Jane: So, it [the proof] follows the contrapositive, but it ends with a contradiction.
Emily: This proof is proving $\sim Q$ implies $\sim P$, which is equivalent to P implies Q.
Jane: How is it not a contradiction at the very last line?
Emily: Contradiction is you start with P and then you come up with $\sim Q$ contradicting what you would expect to happen, right? I would expect n^2 to be odd. We assumed $\sim Q$ so we want $\sim P$. It is equivalent to P implies Q.
Jane: So this [proof] ends with the false statement? n^2 is odd? I think it's a contradiction.
Emily: Contrapositive.

Emily correctly identified the proof as a proof by contrapositive. On the other hand, Jane noticed that the proof ends with $\sim P$ (n^2 is odd) and juxtaposed it with P of the given statement (n^2 is even), perceiving it as a contradiction of the form $(P \wedge \sim P)$. In our analysis we identified several instances of this phenomenon, but a more common confusion was the following.

"A proof by contradiction is a proof by contrapositive." The following example comes from a group of four PSTs: Erick, Abby, Phil and Joel, discussing Statement 2.

Erick: This is probably proof by contrapositive.
Abby: Contrapositive is $\sim Q \Rightarrow \sim P$ … where's the $\sim P$ part, though?
Erick: Right there [points to the paper, see Figure 1], the result would be like 1=0, which I think is kind of the idea that ab can't equal 0.
Joel: For a contrapositive we would need to start by saying if $a \neq 0$ and $b \neq 0$, then $ab \neq 0$, and prove that it is true. In this case, however, they say "suppose $ab = 0$ and $a \neq 0$ and $b \neq 0$, this is "if P and $\sim Q$". So there is no contrapositive whatsoever in this proof.
Erick: I think that they prove the contrapositive true. Because they use the fact that $a \neq 0$ and $b \neq 0$ to show like $ab \neq 0$. […] If you just take out "suppose $ab = 0$", and you get rid of the last line [in the proof], then you have showed that the contrapositive is true. They just put extra things in [the proof] so it would be easier to understand.

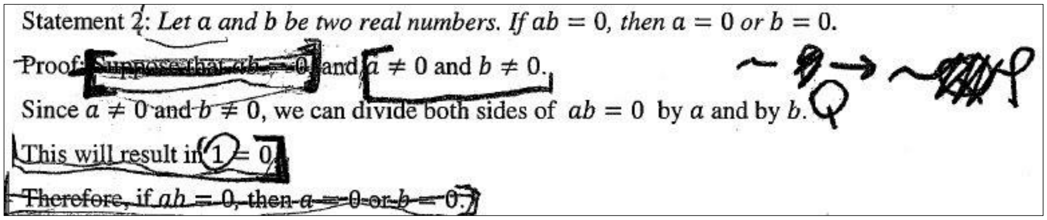

Figure 1: Erick's Worksheet with Crossed Out Portions of the Proof

In this excerpt Erick seems to selectively ignore existing parts of the proof, such as P in the assumption $P \wedge {\sim}Q$, and the conclusion: therefore, $P \Rightarrow Q$, while mentally inserting a non-existing proof line "1 = 0 implies $ab \neq 0$ which he interprets as ${\sim}P$ (Fig. 1). Joel's opposition and correct explanation did little to move Erick away from his conviction. It seems that Erick had a pre-existing assumption that a proof by contradiction is essentially a proof by contrapositive and he sought a way to confirm this. Although Erick was the person who most actively expressed his position, the data shows that other PSTs had similar challenges.

Evidence of Learning

Despite these challenges, the task generated multiple learning opportunities for PSTs to clarify and strengthen their knowledge of indirect reasoning, both in the small group and whole class discussions. The culmination of the activity was PSTs creating posters summarizing main features of proof by contradiction and by contrapositive (Figure 2).

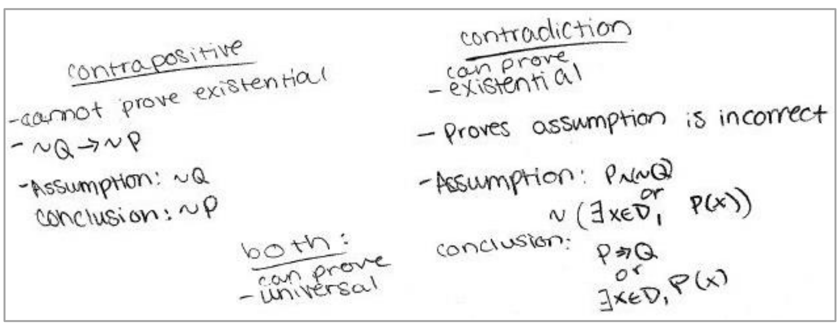

Figure 2: PSTs' Poster Comparing Proof by Contradiction and by Contrapositive

Discussion

The results presented above highlight some of the conceptual challenges and learning opportunities elicited by analyzing the structure of given proofs. These results concur with the literature suggesting that PSTs struggle to distinguish between proofs by contradiction and by contrapositive. We add to the literature by clearly identifying the challenges as confusing these two types of proofs by either: (a) interpreting the conclusion ${\sim}P$ of a proof by contrapositive as contradicting the hypothesis P in the statement, or (b) interpreting a proof by contradiction as a contrapositive proof due to the presence of ${\sim}Q$ in the assumption of both types of proofs. The overarching theme underlying these challenges seems to be "selective noticing" of certain aspects of the proof's logical structure, such as fixating on ${\sim}P$ in ${\sim}(P \wedge {\sim}Q)$, while ignoring other critical aspects such as P in the assumption of the proof by contradiction.

Our data illustrate the pedagogical potential of the *Indirect Proof Structure* task to evoke rich conversations that resulted in multiple instances of learning for the PSTs. We attribute this to the careful selection of the types of proofs, the focus on proof comprehension rather than proof production, comparing across multiple proofs, and summarizing the differences on a poster

(Brown, 2018; Mejia-Ramos, et al. 2012). Going back to Thompson's (1996) aspiration that teachers support students' understanding of indirect proof, we assert that the *Indirect Proof Structure* task in particular and the IR module in general bear the potential to prepare PSTs to carry this practice into secondary classrooms.

PRE-SERVICE TEACHERS' CONCEPTIONS OF MATHEMATICAL ARGUMENTATION

Hyejin Park
Marquette University
hyejin.park@marquette.edu

Marta T. Magiera
Marquette University
marta.magiera@marquette.edu

Drawing on a situated perspective on learning, we analyzed written, open-ended journals of 52 pre-service teachers (PSTs) concurrently enrolled in mathematics and pedagogy with field experience courses for elementary education majors. Our study provides insights into PSTs' conceptualizations of mathematical argumentation in terms of its meanings. The data reveals how PSTs perceive teacher actions, teaching strategies, classroom expectations, mathematics content, and tasks that facilitate student engagement in mathematical argumentation. It also shows what instructional benefits of enacting mathematical argumentation in the elementary mathematics classroom they perceive.

Keywords: Teacher Education-Preservice, Teacher Beliefs, Reasoning and Proof

Background

For more than two decades, standards documents (e.g., National Council of Teachers of Mathematics, 2000; National Governors Association Center for Best Practices & Council of Chief State School Officers, 2010) continue placing a great deal of emphasis on the practice of mathematical argumentation in the mathematics classrooms across all grade levels. Previous studies have shown that by engaging in this practice, students develop their mathematical understanding and improve their mathematics achievement (e.g., Cross, 2009; Francisco, 2013). Mathematical argumentation is an important aspect of developing mathematically proficient students, but teachers often view curricular expectations about engaging students in mathematical argumentation as challenging. Graham and Lesseig (2018) noted that "teachers—both novice and experienced—have difficulty incorporating argumentation in the classroom" (p. 173).

Research-based understanding of elementary practicing and pre-service teachers' (PSTs') interpretations of mathematical argumentation is limited. The existing studies on mathematical argumentation have focused predominantly on teachers' perceptions of mathematical argumentation from the perspective of proof (e.g., Martin & Harel, 1989; Stylianides & Stylianides, 2009), teachers' classroom discourse practices in argumentation (e.g., Brown, 2017; Yackel, 2002), or teachers' evaluations of student arguments (e.g., Morris, 2007; Shinno, Yanaginomo, & Uno, 2017). Our work adds to this body of research. We provide a window into PSTs' conceptions of mathematical argumentation by answering the following research question: *How do PSTs conceptualize mathematical argumentation as a pedagogical practice in the context of elementary mathematics classrooms*? Our study builds a foundation for professional development efforts that aim to help PSTs meet the challenges of teaching elementary mathematics with a focus on mathematical argumentation.

Conceptual Framework

This research is grounded in a situated perspective on learning (Lave & Wenger, 1991; Peressini, Borko, Romagnano, Knuth, & Willis, 2004). Using the situated perspective to frame our work allowed us to explore PSTs' pedagogical conceptions of mathematical argumentation in elementary school mathematics as they positioned themselves as future teachers. Consistent with this perspective, we believe that PSTs build their views about mathematical argumentation by negotiating and renegotiating its meaning for themselves as they participate and reflect on their experiences with mathematical argumentation within and across different contexts. In our analysis then, we considered multiple contexts (i.e., mathematics and teacher preparation courses, field experiences) to include PSTs' experiences as both learners and apprentice-teachers.

Methods

Our study draws on data from a larger project conducted in a midwestern university in the United States. The overarching project was designed to explore K-8 PSTs' knowledge development about mathematical argumentation and proof in a teacher preparation program. The data were collected in two different semesters. Participants were two cohorts of PSTs (n = 52) concurrently enrolled in two courses for elementary education majors: a mathematics content course and a first of two mathematics-oriented pedagogy with field experience courses. Curricula of both courses were coordinated and addressed fundamental to elementary school mathematics topics and their teaching. For this paper, we purposefully selected PSTs' written responses to open-ended reflective journals which they completed throughout the semester (see Table 1), and in which they shared their views on mathematical argumentation. Using the qualitative content analysis and constant comparative methods (Glaser & Strauss, 1976; Mayring, 2014) we analyzed 380 responses in total (some participants did not consistently respond to all prompts).

Table 1: Journal Information

Timeline	Journal Prompts & Number of Responses
4th and 9th week of the semester	Thinking about yourself as an elementary school teacher define the term *mathematical argumentation*. How would you explain its meaning to a parent, for example? (J1, P1, 48 responses; J6, P1, 46 responses)
4th, 9th and 14th week of the semester	Describe the practices that characterize an elementary mathematics classroom in which a teacher engages students in mathematical argumentation. What practices could a visitor (e.g., a parent) see observing that teacher? How these practices can support students' argumentation skills. (J1, P2, 45 responses; J6, P2, 45 responses; J10, P2, 48 responses)
5th week of the semester	Are there any areas or topics of study in elementary mathematics that you view as more or less suitable for engaging students in mathematical argumentation? If so which one. Why? (J2, P1, 50 responses)
5th week of the semester	Describe characteristics of mathematical tasks that have high potential to engage students in mathematical argumentation. How are the tasks you described different from tasks that do not encourage mathematical argumentation? (J2, P2, 50 responses)
14th week of the semester	Describe how your experiences this semester influenced your ideas about teaching elementary mathematics with a focus on mathematical argumentation. (J10, P1, 48 responses)

Results and Discussion

Table 2 gives a summary of outcome space that describes PSTs' pedagogical views on mathematical argumentation. Given the space limitation, we only discuss selected results.

Table 2: Results Summary

Major Category	Sub-Category	Number of PSTs
1. Notion of the term mathematical argumentation	Individual perspective	38
	Social perspective	10
2. Benefits of the use of mathematical argumentation in teaching mathematics	For students	26
	For teachers	22
3. Teacher actions that support argumentation	Teacher questioning	33
	Teacher encouragement	13
4. Teaching strategies that promote argumentation	Discussion	38
	Concrete manipulatives or visual representations	19
5. Mathematics content where argumentation can be implemented	Selective topics	30
	All topics	14
6. Tasks that can be used with argumentation	Call for justifications	30
	Open to multiple solution strategies	21
7. Classroom expectations	Student actions	31
	Classroom environment	13

Note. Some of the participants shared more than one view.

While defining mathematical argumentation, the vast majority of our PSTs discussed argumentation from the perspective of an *individual.* They focused on a person's ability to explain and justify the thinking and reasoning used to solve a problem. We illustrate this perspective with an excerpt from PST A38's journal: "Mathematical argumentation is the ability for a student to reach mathematical conclusions through logical reasoning" (J6, P1). A much less prevalent interpretation of mathematical argumentation stemmed from perceiving argumentation as a *social* activity. PSTs with the *social* perspective conveyed the view of mathematical argumentation as a process of communicating mathematical ideas to others to justify, convince, or to provide a challenge. We illustrate this view using PST A19's response:

> Mathematical argumentation is the process of explaining and justifying to others clearly how you got an answer to a particular mathematical problem or question…When questions from others arise, one must be able to answer those questions and must also be able to answer questions of others based on their work if they are unsure about how someone else goes about their answer. (J6, P1)

Across the analyzed journals, 36 PSTs discussed teacher actions which they viewed as essential for engaging students in mathematical argumentation. Most frequently, they attended to teacher *questioning* and teacher efforts of *encouraging* students to participate in argumentation. With a focus on teacher questioning, PSTs often shared that teachers who regularly ask the "*how*" and "*why*" questions engage students in mathematical argumentation by having them to explain and justify their thinking. PST A1's journal entry exemplifies this view:

> A classroom that fosters mathematical argumentation should contain a teacher who is constantly asking his/her students to explain how they reached their answers and why they think it [the answers] make sense… Teachers should be asking their students questions like "how did you come to this answer?," "why does that make sense?," and "how did you know where to start in this problem?" (J1, P2)

PSTs who focused on teacher encouragement discussed that teachers foster mathematical argumentation by prompting students to present their thinking, inviting students to critique each other's reasoning, or correcting misconceptions. PST A29, for instance, wrote:

> A teacher who fosters mathematical argumentation should…encourage students to share their methods of thinking through a problem with the class. [This] promote[s] mathematical argumentation within the classroom and will help students to build their skills in math by getting them to talk to one another and figure out what methods do and do not work for solving math problems. (J1, P2)

Summary Discussion and Conclusions

Our PSTs' largely individual-focused perceptions of mathematical argumentation was clearly visible when PSTs discussed teacher actions in support of argumentation. In their descriptions, only a few PSTs considered how a teacher might support *collective* efforts in which students jointly build on each other's ideas and collectively establish a mathematical claim. The vast majority of our PSTs concentrated on how teachers might encourage individual students to explain and justify their thinking for themselves, to other students, or to teachers. Even while discussing how a teacher might support a group of students, our PSTs painted pictures of individual students developing their own arguments drawing on ideas from others.

We hypothesize that PSTs' experiences with mathematical argumentation in their mathematics content and pedagogy courses could possibly contribute to their largely individual-focused views on mathematical argumentation. Even though in their mathematics content and pedagogy courses instructors frequently engaged PSTs in sharing, analyzing, critiquing, and building arguments collectively, the social aspects of argumentation or any instructional decisions in support of collective argumentation were not explicitly discussed. While mathematical argumentation was also a focal aspect of PSTs' field experiences, culminating activities in which PSTs engaged consisted of one-on-one interactions with students. It might be, then, that in their field experience classrooms most PSTs saw mathematical argumentation from the perspective of individual students focusing on each student's ability to generate arguments.

Drawing on past research which established the relationship between teachers' beliefs and their instructional practices (e.g., Stipek, Givvin, Salmon, & MacGyvers, 2001; Thompson, 1984), it appears reasonable to expect that PSTs with mostly individual-focused views of mathematical argumentation might less likely use argumentation as a pedagogical tool for constructing meaning of mathematics collectively. That is, they might not routinely consider engaging their students in collective examination of assertions and provide them with opportunities to build on and critique each other's ideas. To help our PSTs develop a richer perspective on mathematical argumentation we are now more explicitly draw PSTs' attention to both individual and social aspects of mathematical argumentation in both courses (i.e., mathematics content and pedagogy). Research needs to further examine PSTs' views on mathematical argumentation in relationship to their experiences with mathematical argumentation to provide directions for learning activities that can help PSTs develop richer perspectives on mathematical argumentation.

CHALLENGING A NEW HORIZON IN MATHEMATICS TEACHER EDUCATION WITH CRITICAL CONVERSATIONS OF EQUITY

Alesia Mickle Moldavan
Fordham University
amoldavan@fordham.edu

Facilitating opportunities for preservice teachers to develop the knowledge, skills, and dispositions necessary to support equitable mathematics instruction, recognize systems of inequity, and advocate for all learners can be challenging. This study reports on the various efforts of mathematics teacher educators to engage preservice teachers in critical conversations of equity in their methods courses. Dominant conversations addressed equity in terms of access, achievement, and identity, while issues pertaining to power, privilege, race, and other systems of oppression called for increased attention. Suggestions for advancing critical conversations in mathematics teacher education are discussed.

Keywords: Teacher Education-Preservice, Equity and Diversity, Classroom Discourse, Instructional Activities and Practices

As mathematics teachers prepare their preservice teachers for today's diverse mathematics classrooms, they must consider ways to embed critical conversations of equity into initial teacher preparation curriculum. Recent initiatives led by professional organizations (e.g., Association of Mathematics Teacher Educators [AMTE], National Council of Teachers of Mathematics [NCTM]) have offered solutions to create, support, and sustain a culture of access and equity in school mathematics (e.g., AMTE, 2017; NCTM, 2000, 2014a, 2014b). With research suggesting that effective mathematics teachers have a comprehensive understanding of equity-based teaching practices (Chao, Murray, & Gutiérrez, 2014), mathematics teacher educators are exploring ways to equip preservice teachers with the knowledge, skills, and dispositions necessary to support equitable mathematics instruction, recognize systems of inequity, and advocate for all learners. This study reports on the various efforts of nine mathematics teacher educators to engage preservice teachers in critical conversations of equity in their methods courses. The following research question is examined: How do mathematics teacher educators address equity in mathematics teacher education?

Theoretical Framework

I used Gutiérrez's (2007) equity framework to guide my inquiry and examine where efforts were made (or not) to engage preservice teachers in critical conversations of equity in mathematics teacher education. The framework describes equity as a complex notion that is comprised of four dimensions (i.e., access, achievement, identity, and power) mapped onto two axes (i.e., the dominant axis and the critical axis). The components of the dominant axis include concepts of access and achievement. Gutiérrez refers to access as the resources provided that enable participation in mathematics (e.g., high quality teachers, rigorous curriculum, inviting classroom environments, appropriate texts and technology). Cautious efforts must be taken to ensure that access does not mean equal resources as such actions perpetuate sameness. Instead, resources must fairly support students' mathematical, cultural, and linguistic needs. The other dimension addresses achievement and how outcomes that historically measure ability (e.g., course grades, course-taking patterns, standardized exams) need to be critiqued as structures that routinely disadvantage marginalized students. Thus, the dominant axis recognizes the dominant, Eurocentric mathematics that enables participation in society and the need to critique society's status quo to understand and interpret other ways of knowing and practicing mathematics.

To challenge the static notions of the dominant mathematics, Gutiérrez (2007) addresses concepts of identity and power, which encompass the critical axis. Identity recognizes the need for students to self-identify with mathematics and draw on personal experiences as well as cultural and linguistic resources (Gutiérrez, 2009). This dimension not only draws attention to students' assets but also recognizes ways students have been (and still are) racialized, gendered, and classed. A close look at power can also assist with examining who is privileged (and silenced) in the classroom and in what ways mathematics can be used to explore injustices and advocate for all learners. Thus, the critical axis acknowledges the need for self-identification in mathematics to self-empower and exercise mathematics as an analytical tool to critique societal norms.

Methods

I used a qualitative case study to critically examine how nine mathematics teacher educators from nine institutions (i.e., public, private, and Historically Black Colleges and Universities) in the southeastern United States addressed equity in their methods courses. The participants identified as mathematics teacher educators responsible for preparing preservice teachers in initial teacher preparation programs. They also indicated that they were knowledgeable (to some extent) of the recent initiatives led by professional organizations to advocate for equity in mathematics teaching and learning (e.g., AMTE, 2017; NCTM, 2000, 2014a, 2014b). Participants were selected using stratified purposeful sampling to offer information-rich cases from varying contexts and settings to facilitate meaningful comparisons (Patton, 2002).

For each participant, I conducted two semi-structured interviews and a follow-up interview for member-checking. I also collected artifacts (e.g., syllabi, course readings, activities, assignments, work samples), which served as corroborating sources of evidence and discussion topics for the second interview. Data sources were coded using in vivo and descriptive code (Saldaña, 2016) and interpreted using Kvale's (1996) meaning-making methods to capture the participants' shared experiences. I also performed analytic memo writing to assist with my reflection and extraction of relevant information to guide my synthesis.

Results

Findings revealed that mathematics teacher educators made intentional efforts to address critical conversations of equity in their methods courses. While concepts of access, achievement, and identity primarily dominated the participants' equity conversations, participants disclosed how they addressed (some more than others) issues of power in terms of privilege, race, and other systems of oppression. Using Gutiérrez's (2007) equity framework to organize the findings, I share examples of the various ways the participants engaged preservice teachers in equity conversations through activities and assignments. The varied efforts reaffirm that equity is a multifaceted concept that is communicated differently based on understanding and experience of how issues of access, achievement, identity, and power can be addressed in initial teacher preparation curriculum.

Access

When asked to describe equity in terms of access, several participants defined access as tangible resources, supports, and self-differentiated tasks that position learners for participation in the mathematics classroom. To illustrate how access is communicated in methods courses, one participant shared how she models a situation in which preservice teachers are asked to complete computations using a non-Western numeral system. Some preservice teachers receive access to supports (e.g., translation charts), while others do not. Following the activity, she engages her preservice teachers in a discussion about the way supports can be used to break down cultural and language barriers to ensure all learners have access to the mathematics. Another participant has her preservice teachers review national and local data reports on homelessness, poverty, hunger, crime, and health status. Preservice teachers create a resource handbook for parents and students in their community to aid with locating agencies and services to assist with homelessness and hunger. The other participants shared how they work with their preservice teachers to create self-differentiated tasks that allow for multiple entry points. The tasks communicate high expectations focused on individualized learning with appropriate supports for all learners.

Achievement

In terms of achievement, several participants commented on the dangers of tracking and how success in mathematics can be used as a gatekeeper to career opportunities. To assist preservice teachers in recognizing the dangers of tracking, one participant has his preservice teachers discuss how school systems are structured in ways that are inequitable for marginalized students. His preservice teachers critique tracking from observations of White students at one end of the hall and Black students at the other. Similarly, a participant facilitates a debate among her preservice teachers that examines how success in mathematics can be used as a sorting mechanism to provide access into colleges and high-paying careers. Another participant assigns an equity report that requires preservice teachers to analyze data from the National Assessment of Educational Progress database for discrepancies in student achievement. Preservice teachers reflect on the ways race, class, and performance attribute to the "achievement gap" and how anti-deficit counternarratives of student success can be used to challenge the discourse.

Identity

The participants also shared specific ways they engaged preservice teachers in equity conversations related to identity. Most of the activities and assignments focused on identifying growth mindsets; incorporating inclusive and culturally responsive mathematics instruction; and recognizing students' mathematical, cultural, and linguistic strengths and resources. For example, one participant has her preservice teachers draw a model mathematician. The preservice teachers talk about ways to picture themselves and their students as mathematicians. Similarly, three participants assign a mathematical autobiography. The activity requires preservice teachers to reflect on their mathematical identity, experiences, and biases. Another participant has her students analyze mathematics textbooks and critique how the word problems relate (or not) to students in the community. Other conversations include reflections on readings about culturally responsive pedagogy and strengths-based thinking.

Power

Not all of the mathematics teacher educators were able to share how they addressed concepts of power in their methods courses. Some participants did not see mathematics as a political activity, while others were hesitant to get into heated debates or were still looking for activities that would help them facilitate a productive discussion. For example, one participant said, "Some of these ideas about equity and social justice in math are things I'm just now learning about more deeply." Another participant shared: "I don't specifically talk about race in my classes, but I do talk about how many people have been neglected and refused opportunities." Another participant communicated his wishes to teach preservice teachers to "recognize that power is a perpetuation of White privilege or White supremacy," but he asserted, "I don't have a nice lesson that's digging into that well yet."

A few participants shared their efforts to engage preservice teachers in conversations pertaining to issues of privilege, race, and other systems of oppression. One participant engages her preservice teachers with an activity called "Race Cards." Preservice teachers are organized in groups where they pull cards of different themes (i.e., attributes, grade-levels, mathematics courses, race, and gender). The attributes describe socioeconomic status, mental and physical health, family dynamics, club involvement, behavior, and sexuality. The groups discuss which students might be more privileged in school based on the descriptors on the cards. The activity assists preservice teachers with identifying stereotypes and challenging the status quo. Four other participants disclosed how they facilitate discussions, often times haphazardly, that encourage preservice teachers to notice privilege, including what mathematics is privileged in society and who is recognized for the mathematics.

Discussion

Mathematics teacher educators are influential in fostering preservice teachers' consciousness of equity-based teaching practices. For preservice teachers to acquire the practices necessary to enable all learners to participate in meaningful mathematics learning that supports the development of positive mathematical identities and challenges oppressive norms, mathematics teacher educators must consider ways to engage preservice teachers in critical conversations of equity. This study provides insight into the various efforts of mathematics teacher educators to address concepts of equity in their methods courses. Mathematics teacher educators used specific activities and assignments to facilitate conversations of equity in terms of access, achievement, and identity. When sharing ways to engage preservice teachers in conversations pertaining to issues of power, privilege, race, and other systems of oppression, most efforts were addressed in vague terms, which is similarly reported by other researchers (e.g., Civil, Bartell, Bullock, & Fernandes, 2018). With awareness that Gutiérrez's (2007) dominant (i.e., access and achievement) and critical (i.e., identity and power) axes are equally important to address equity, mathematics teacher education must look for ways to advance preservice teachers' knowledge about the historical context of mathematics education, including the roles of power, privilege, and oppression that result in inequitable learning experiences for marginalized students. When preservice teachers acquire the critical consciousness to question inequities and advocate for access to high-quality mathematics instruction for all learners, they can serve as role models and leaders challenging a new horizon in mathematics education.

In this empirical study, we report data from 44 elementary PTs' talk about linear functions in a simulated teaching context and our analysis of this talk in terms of the representations involved (i.e., graphs, equations, and tables) and whether it conveyed conceptual understanding or errors. Drawing on two complementary definitions of conceptual understanding from educational psychology and mathematics education, we examine descriptive results about the kinds of conceptions PTs revealed as well as results about the relationship between understanding evident in utterances and types of representations invoked. PT talk about an equation or table alone tended to be more strongly associated with errors than talk about a graph both alone and with other representations. Implications are discussed.

Keywords: Teacher Knowledge, Teacher Education-Preservice, Algebra and Algebraic Thinking

The field of mathematics education has increasingly identified the potential and promise of addressing algebraic ideas in the elementary grades, and this trend has important implications for elementary teacher education (e.g., Soares, Blanton, & Kaput, 2006). The wide adoption of the Common Core State Standards for Mathematics (CCSSM) and inclusion of algebraic thinking as one of the strands in Grade K-5 is a recent milestone. Moreover, the Grade 6 CCSSM standards include algebraic equivalence and graphing linear function (e.g., 6.EE.B & 6.EE.C) and many states license elementary teachers through Grade 6.

There is little published work about elementary prospective teachers' (PTs) understanding of linear functions and their representation in equations, graphs, and tables, perhaps because algebra has been restricted traditionally to the middle and secondary grades. Even for those elementary teachers who do not teach the Grade 6, knowledge of algebraic ideas provides insights for teaching more central content in the elementary curriculum. First, teachers can anticipate and support mathematical connections students will make in the future (cf. horizon content knowledge; Ball, Thames, & Phelps, 2008). Second, knowing algebra provides elementary teachers with "mathematical peripheral vision" (p. 4) that can support interpretations of students' understanding of arithmetic and instructional responses (Cho & Tee, 2018).

To address this gap in the literature, we asked PTs to discuss connections within and between multiple representations of linear function in a simulated teaching task. As teacher educators, we were also interested in the relationship between different representations of linear function and mathematical errors—a key indication of low mathematical quality of instruction (Hill et al., 2008). Drawing on a framework that defines understanding as connected knowledge and using statements rather than individuals as the unit of analysis, we sought to answer the following research questions. (1) *How is elementary PTs conceptual understanding of linear function* *related to the representations they invoke?* (2) *Are statements involving more representations less error-prone than those involving fewer representations?*

Theoretical Framework

Algebraic expertise involves the flexible use and coordination of powerful conceptual tools including functional thinking, graphing, and symbolic notation. Our work is informed by the definition of conceptual understanding provided by Hiebert and Lefevre (1986): "a connected web of knowledge, a network in which the linking relationships are as prominent as the discrete pieces of information" (p. 3). Lesh (1979) and Lesh and Doer (2003) refine this definition by distinguishing five types of representations and identifying conceptual understanding as the ability to move flexibly between representations. We refine further by distinguishing between transformations between representations of the same type (e.g., equivalent equations) and translations between different representations (e.g., equations and graphs, c.f., Duval, 2006).

A complementary definition of conceptual understanding is the explicit knowledge of the general principles in a domain that underlie routine procedures (Crooks & Alibali, 2014). For example, one general algebraic principle is that linear functions describe two quantities changing at a constant relative rate. Translation rules (e.g., “Equivalent representations describe the same rate of change.”) and transformation rules (e.g., “Adding the same value to both sides of an equation maintains equivalence.”) are principles that underlie equivalent representation procedures. We designed our analysis to attend both to flexible use of multiple representations as well as to explicit knowledge of general principles.

Figure 1: Transformation Task, Q1 (a) and Translation Task, Q2 (b).

Data and Methods

This study was part of a larger project conducted at a large Midwestern public university. Participants (n = 44) were recruited from an elementary math methods course and participated in a 2-hour research procedure that included pre-assessment, intervention, and post-assessment. In this paper, instead of making claims about individual PTs or the intervention, we combined data from both pre and post occasions and use an *utterance* (defined below) as the unit of analysis to provide descriptive insights pertaining to PTs conceptual understanding of linear equations.

Data

The data from the pre- and post-test conceptual understanding assessments were used in this report. Each assessment involved two tasks and had two versions with slightly different numbers. The two versions were counterbalanced so everyone answered both versions, but half did so in the opposite order. In the Transformation Task (Q1; Figure 1a) the PTs were asked to use graphs or tables to convince three students that three equations in different forms were equivalent. In the Translation Task (Q2; Figure 1b) the PTs were asked to discuss the rate of change and intercepts across three different representations of linear function.

Coding

To analyze the assessment data, the videos of the PTs' responses were transcribed and divided semantically into *utterances*: a one-to-several sentence unit of talk expressing a single main idea. Transcription data from a total of 43 PTs were obtained with data for 42 PTs having both pre and post occasions. (Some data were missing because of equipment failure.) The researchers used a constant comparative method of qualitative coding to define codes for each utterance. Two team members read through the data for each PT in succession, identifying new ideas with new codes and using the growing code book to mark previously identified ideas. New codes were discussed with the full team each week until agreement was reached. The final codes consisted of 36 codes for the Transformation Task (Q1) and 40 codes for the Translation Task (Q2). Each code was further categorized by conceptual understanding and by representation type.

Analysis and Results

As stated earlier, the unit of analysis for this study is a PT utterance. Out of 1470 utterances, we coded 607 utterances related to equations, graphs, and table representations. The rest of the utterances were either too imprecise to code (n = 85, 42 for Q1 and 43 for Q2) or non-mathematical (e.g., reading the task aloud, n = 778). To address the research questions, we first illustrate codes for each task then present statistical tests of distributional independence.

Transformation Task

We used four codes to capture conceptual understanding related to graphs on Q1. These codes reflected different levels of understanding among the PTs. First, "Graphs are the same" (0221LH.q1.1, n = 25) was used when PTs clearly stated that the graphs for the equations in Q1 would be the same without articulating how or why the graphs would be the same. The second code "Equal slope means equivalent" (0222MS.q1.3, n = 9), was used when PT's argued that graphs of the equations would be the same because they have the same slope; the PT might say "all the graphs have the same slope and that's why they look the same." The third code "Graphs will be same as slopes and intercepts will be same" (0228MD.q1.2, n = 4) reflected a deeper understanding of graph equivalency, because it included an explicit check of an additional feature of the graphs: the intercepts. The fourth code, "The graphs are the same because they have the same points" (0228MS.q1.1, n = 7) was used for an even more precise claim. One PTs justified by saying, "we will get the same point value on the graph each time".

Last, we discuss an error code that occurred when PTs were only discussing the equation representation. For Q1, two of the equations were in the slope-intercept form, while the third eq. was in the point-slope form. The code "Unclear ideas about point-slope equation" (0227MY.q1.1, n = 4) captured PT confusion when comparing the point-slope and slope-intercept forms. One PT stated for the third equation that "I don't know how this one goes with the first two." In another example, a PT said that the "first two are the same but the third equation is not similar". While the PT was able to see that the first and second equations are the same, the PT did not see how the third equation could also be equivalent.

Translation Task

We used several codes for Q2 that were related to graphs and understanding linear function in the context of graphs. Many PTs described graphs as a good visual representation of the relationship between two variables (0224MS.q2.2, n = 12). Another set of codes captured the observations that graphs demonstrate the rate of change between two variables as well as the point where the line intersects either of the axes (0221MH.q2.1, n = 29; 0228AE.q2.1, n = 18; 0228MS.q2.2, n = 44; 0222MS.q2.2, n = 40; 0224MS.q2.3, n = 8; 0410EL.q2.3, n = 1). By contrast, PTs exhibited numerous misconceptions when talking about the meaning of coefficients. For example, some PTs stated that coefficient of x (or y) in an equation represents the x (or y) intercept (0331VL.q2.2, n = 6, 0331VL.q2.7, n = 4), or considered the coefficient of x as the value of slope even when an equation is given in a standard form (0303LB.q2.1, n = 3). Although talking about equations alone often revealed errors, utterances that coordinated equations and graphs provided strong evidence of understanding. For example, PTs connected the coefficients of variables in an equation with a feature of the graph related to slope or intercept (0222MS.q2.6, n = 6, 0310TM.q2.1, n = 2, 0228MD.q2.1, n = 4). These utterances were relatively rare, yet they substantiated clear cases of the effective use of multiple representations while discussing the concept of linear equations.

Table 1: Code Frequency, Error Rates by Task and Representation

	Transformation (Q1)		Translation (Q2)			Error Rates		
Representation	CU	Error	CU	Error	Totals	Q1	Q2	Total
Equations Only	56	4	44	23	127 (21%)	7%	34%	21%
Graphs Only	47	10	148	0	205 (34%)	18%	0%	5%
Tables Only	24	3	34	0	61 (10%)	11%	0%	5%
Equations & Graphs	8	1	11	0	20 (3%)	11%	0%	5%
Equations & Tables	24	4	26	12	66 (11%)	14%	32%	24%
Graphs & Tables	3	0	31	0	34 (6%)	0%	0%	0%
All Representations	6	0	88	0	94 (15%)	0%	0%	0%
Total	168 (28%)	22 (4%)	382 (63%)	35 (6%)	607	12%	8%	9%

Tests

Table 1 shows code distribution by task, representation, understanding and error rates. We used Pearson's Chi-squared test with Yates correction to draw conclusions from these data. First, there were utterances for all possibilities of representation use, but the distribution between these categories was not uniform ($\chi^2 = 276.63$, $df = 6$, $p < 0.00001$). Second, there was no evidence in our data that error rates significantly differed for the Transformation versus the Translation Task ($\chi^2 = 1.205$, $df = 1$, $p = 0.273$). Third, utterances involving a single representation did not differ significantly in error rates from utterances involving multiple representation ($\chi^2 = 0.571$, $df = 1$, $p = 0.450$). Finally, utterances involving graphs had significantly fewer errors than those not involving graphs ($\chi^2 = 37.288$, $df = 1$, $p < 0.00001$).

Implications & Conclusions

The results of this study contribute in at least two ways. First, we provide a descriptive account of major themes of elementary PTs' knowledge for teaching linear function in the context of equations, graphs, and tables. This is the only such study of which we are aware, and the more than 30 distinct qualitative codes for each task therefore contribute by providing detailed evidence of the breadth and range of how elementary PTs in one program talk about linear function. Second, we provide results about the relationship between erroneous teacher talk and its representational content. No errors were evident in utterances linking all three representations, yet these data suggest that it is not simply more representations that support accuracy (Finding 3) but rather that one specific representation—graphs—may play a particularly powerful role in supporting accurate talk about linear function (Finding 4). More research is needed to understand how universal both the descriptive coding and the relative importance of graphs are among other populations of preservice elementary teachers.

TOWARD A PRACTICE-BASED FRAMEWORK FOR DEVELOPING PRESERVICE ELEMENTARY TEACHERS' MATHEMATICAL AUTHORITY

Priya V. Prasad — University of Texas at San Antonio — priya.prasad@utsa.edu
Victoria J. Barron — Boerne-Champion HS — victoria.barron@boerneisd.net
Raquel Vallines Mira — University of Texas at San Antonio — raquel.vallinesmira@utsa.edu

To be mathematically empowered, preservice teachers (PSTs) must rely on their own sense-making in mathematics in order to develop robust mathematical understandings. They must have an internal sense of mathematical authority with which to reason and justify. Mathematics teacher educators (MTEs) must support PSTs in establishing their own sense of mathematical authority. In this brief report, we present our preliminary work on building a practice-based framework to help MTEs assess how mathematical tasks can contribute to PSTs' mathematical empowerment.

Keywords: Teacher Education-Preservice, Algebra and Algebraic Thinking, Teacher Knowledge

Introduction

For students (and preservice elementary teachers) to be mathematically *empowered*, they must rely on their own sense-making in mathematics in order to develop robust mathematical understandings; that is, they must have an internal sense of mathematical authority to reason and justify. Thus, it is of particular importance for mathematics teacher educators (MTEs) to support pre-service teachers (PSTs) in establishing their own sense of mathematical authority. This goal is twofold: 1) to support PSTs to trust in their own mathematical self-efficacy they will need as teachers, and 2) to give PSTs opportunities to experience a mathematics class in which mathematical authority is shared, and not concentrated in the instructor or a textbook encouraging them to develop such dynamics in their own future classrooms. However, many college students are likely to depend on an external mathematical authority to validate their own thinking (Povey & Burton, 2003; Schoenfeld & Sloane, 2016).

In addition, while work has been done to define PSTs' content knowledge (e.g. Thanheiser et al., 2013) or develop their mathematical habits of mind (e.g. Magiera, van den Kieboom, & Moyer, 2017), there is little evidence in the literature that can help MTEs explicitly support PSTs' to rely on internal mathematical authority. We present our preliminary work on building a practice-based framework to assess the extent to which mathematical tasks for PSTs can contribute to their mathematical empowerment.

Theoretical Framework

When students are doing mathematics, they rely on a mathematical authority that drives their decisions about their course of action when solving a problem. Depending on where that authority is located in a classroom or how students confer (or defer to) it, the exercise of mathematical authority, that is, "'who's in charge' in terms of making mathematical contributions" (Gresalfi & Cobb, 2006, p. 51), can vary greatly. Schoenfeld and Sloane (2016) describe that, when mathematical authority is situated within the learner (i.e. internally), it results in a "personal ownership of the mathematics they can certify" (p. 62). In other words, learners and instructors co-create the knowledge they are exploring (Povey and Burton, 2003). Reinholz (2012) proposes three mutually supportive skills that make up the exercise of an internally situated mathematical authority: students who rely on an internal mathematical authority (1) *explain* their reasoning, (2) *justify* their conjectures, and (3) *assess* their work once they find a solution, just as “mathematicians use these skills to derive authority from the logic and structure of mathematics, rather than relying on some other authoritative source” (p. 242). However, students can potentially rely on an external authority by seeing mathematics as outside their control. In this case, the learner views mathematics as a subject that is fixed and unchangeable. Such students leave mathematics to the “experts”. In addition, the “authority for the learner rests in the content,” rather than internal judgement (Povey & Burton, 2003, p. 244).

When students view instructors as the sole arbiter of mathematical correctness, they are surrendering their authority to the instructor, which detaches them from the material they are learning. In order to decrease students’ reliance on external mathematical authorities and foster their dependence on internal ones, instructors must shift their roles in the classroom (Gresalfi & Cobb, 2006; Stein et al, 2008; Webel, 2010). Rather than having instructors present themselves as a “‘dispenser of knowledge’ and arbiter of mathematical ‘correctness,’” they should take on the role of the facilitator or “engineer of learning” while allowing students to construct their own understanding of the mathematics they are learning (Stein et al., 2008, p. 4).

It is imperative for PSTs to understand how to support their future students in exercising mathematical authority, but they must first develop their own robust internal senses of mathematical authority. PSTs need to be mathematically empowered in multiple ways, with mathematical authority and self-efficacy, as well as with an understanding of how and when to cede mathematical authority to their students in their own future classrooms. Thus, it is a task of mathematics teacher education to provide models of teaching for mathematical empowerment. In this paper, we present preliminary work on a framework for analyzing and revising mathematics tasks for elementary PSTs so that they better support PSTs’ mathematical empowerment.

Methodology

This preliminary framework is being developed on data collected about a visual patterns task implemented in a mathematics content course for elementary PSTs at a large, Hispanic-serving southwestern university. This task was within the context of a larger project based on the Continuous Improvement (CI) model for course improvement developed by Berk and Hiebert (2009). This model maps out the following steps for task design and revision: (1) design a task that targets a specific mathematical concept and identify the learning goal, (2) develop hypotheses about anticipated student responses to the task, (3) implement the lesson and observe the implementation, (4) collect and analyze student data on pre- and post-assessments, and (5) revise the task for future implementation. While designing the visual patterns task, the research group identified a specific learning goal: “*PSTs will be able to use a variable to represent an index/input in a sequence of visual patterns and build an expression in terms of the variable to represent an arbitrary step in the sequence”.* After administering a pre-assessment based on the work of Warren and Cooper (2008; see Figure 1), the research group designed a groupworthy mathematical task (Lotan, 2003) to address the learning goal (see Figure 2).

Consider the following growing pattern:
1. Using a variable, write a general expression that tells how many tiles are in a step of the pattern.
2. Justify your pattern by describing the growing pattern in words and explaining what the variable represents.

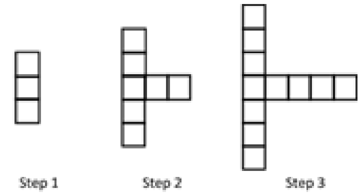

Figure 1: Pre- and Post- Assessment to Visual Patterns Task

The lesson was implemented in two classes by two different instructors. As they worked through the task, PSTs' small-group interactions were audio-recorded and synchronized with the group's written work. The task was followed by a post-assessment that was identical to the pre-assessment.

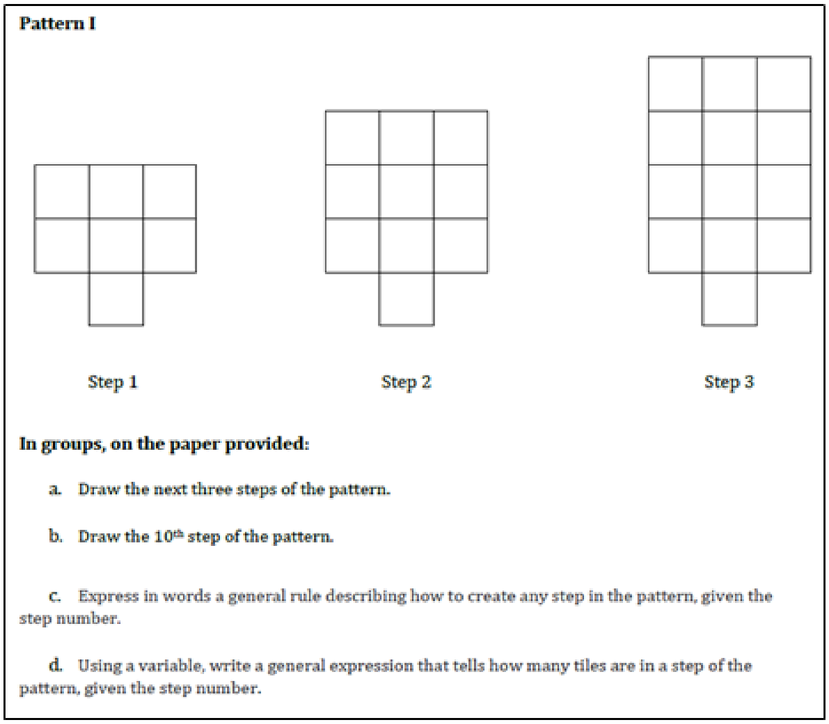

Figure 2: Visual Patterns Task Given to PSTs, from Boaler (2015)

Findings from Classroom Implementation

As anticipated by the pre-assessment results, most groups of PSTs used one of two strategies during their exploration of the task: (1) building a linear relationship by first generating table of values or (2) plugging in the values of the initial step and the difference into the formula for arithmetic sequences. Although both strategies led most groups to develop correct expressions (see Table 1), the PSTs largely relied on the authority of the arithmetic sequence formula or the familiarity of the procedure for developing a linear equation from a table of values to justify their reasoning. Thus, in the first iteration of the task, most groups of PSTs were not fully exercising their mathematical authority by explaining, justifying, and assessing for themselves, even though the structure of the task created opportunities for all three (Prasad & Barron, accepted).

Table 1: Pre- and Post-Assessment Outcomes

	Pre-Assessment ($N = 49$)	Post-Assessment ($N = 49$)
$x + 4$	17	3
$3x + 4$	6	1
Different incorrect expression	6	6
Only preliminary numerical/verbal investigation shown	8	3
Correct expression (e.g. $4x - 1$, $3 + 4(x - 1)$, etc)	12	36

Discussion: Developing the Framework

Despite most PSTs developing correct expressions on the post-assessment, the task did not meet the larger course goal of mathematically empowering PSTs by supporting them to rely on an internal mathematical authority. After observing the initial lesson, the research group revised the task in the following ways: (1) introduce the concept by giving PSTs an expression and the description of a pattern, and multiple choices of patterns that numerically fit the expression but not the description to encourage them to attend to the visual attributes of the patterns, (2) prompt PSTs to investigate only one linearly growing pattern whose visual attributes were clearly growing with respect to the index, taken from Beckmann (2008), (3) extend the ideas by including a quadratically growing pattern, challenging PSTs to move beyond previous understandings and the reliance on their knowledge of linear relationships, and (4) prompt PSTs to develop a growing visual pattern that fits a given linear expression.

The researchers noticed that, while the pre- and post-assessments effectively assessed how well the task met the content standard outlined in the expressed learning goal, they did not provide any information for assessing how and when PSTs relied on an internal mathematical authority in order to reason about the task. In order to better evaluate the revised lesson, we propose a preliminary framework based on the work of Reinholz (2012). It is our intention that this framework be *practice-based*, that is, based on data collected during the practice of teaching and of potential use to MTEs while planning and facilitating lessons, since not every MTE can collect and analyze data for every lesson they teach. This preliminary framework is decomposed into three phases:

1. *Planning:* Does the task provide opportunities for exercising all three of the mutually supportive skills that make up mathematical authority? In other words, does the task motivate students to explain their thinking, does it have opportunities built into it for students to assess conjectures for themselves, and does it require students to justify their thinking?
2. *Implementation:* Does everyone engage in exercising the three mutually supportive skills that make up mathematical authority? This can be addressed at the group level and at the individual level. Group-level assessments can be made easily as MTEs circulate around the classroom engaging with different small-groups. In cases where groups are not explaining, assessing, and justifying for themselves, it becomes important to identify to what forms of external authority the students are turning.
3. *Reflection*: Once the potential sources of external authority have been identified, the task can be revised to mitigate their influence.

An important underlying assumption to this framework is that PSTs can only become mathematically empowered when they have the opportunity to work in small groups on groupworthy tasks (Lotan, 2003). Moreover, some portions of the framework can be addressed by establishing classroom norms that expect students to explain their thinking and utilize questioning practices that expect and motivate students to justify their conjectures.

The next steps in developing this framework is to use it to assess the data collected from the revised visual patterns task that the research group wrote and implemented. We hope to refine the broad recommendations so that they can be of practical use to MTEs.

Elementary and special education preservice teachers (PSTs) were given an assignment to create lesson plans that included anticipated student solutions that were incorrect or partly correct, as well as planned questions that would help students overcome those errors. Authors categorized preservice teachers' anticipated errors and types of planned questions. Results showed most PSTs focused on procedural errors without considering underlying conceptual understanding. Authors concluded that methods courses need to be explicit in discussing types of questions and focus on questions that require students to clarify and justify their reasoning.

Keywords: Instructional activities and practices, Teacher knowledge

Introduction

Association of Mathematics Teacher Educators (AMTE, 2017) and National Council of Teachers of Mathematics (NCTM, 2014) recommend writing lesson plans that include anticipated student responses to assigned tasks along with the teacher's own responses, because anticipating student responses allows teachers to tentatively plan follow-up questions and instructional moves. Anticipating student responses was included in the first-ever comprehensive Standards for Preparing Teachers of Mathematics (SPTM) put forth by AMTE in 2017. SPTM built on existing standards and research about mathematics teacher preparation and are intended to motivate researchers to investigate areas that are not well understood. According to the standard, C.3.1. Anticipate and Attend to Students' Thinking About Mathematics Content, instead of demonstrating their approaches to a problem or correcting errors, teachers should first try to see problems through their students' eyes, anticipate, understand, and analyze students' varied ways of thinking, and respond appropriately (AMTE, 2017). Anticipating both correct and incorrect solutions to mathematical tasks is emphasized as a key strategy to successfully implement effective mathematics teaching practices that were developed by NCTM (2014). In particular, anticipating both correct and incorrect responses is elaborated as a focal planning practice for three of the eight effective mathematics teaching practices in Smith, Steele, and Raith (2017), and Huinker and Bill (2017): (1) implement tasks that promote reasoning and problem solving, (2) facilitate meaningful mathematical discourse, and (3) elicit and use evidence of student thinking. Elicit and use student thinking is closely linked to another effective teaching practice, pose purposeful questions, in NCTM (2014). Posing purposeful questions enables teachers to determine what students know and think, to adapt their instruction to meet students' different levels of understanding, and to help students make connections among ideas.

The value of anticipating student answers is recognized in mathematics education literature; however, little research has been done. The researchers that have explored the importance of anticipating student answers in teaching and learning of mathematics (e.g., Ball, & Bass, 2000; Hill, Ball, & Schilling, 2008; Thompson, Christensen, & Wittmann, 2011) found that preservice and beginning teachers have difficulty anticipating a variety of correct student solutions. Anticipating incorrect approaches, as well as correct approaches, and planning to include incorrect approaches in class discussions is discussed as an avenue to promote a classroom culture in which mistakes and errors are seen as important reasoning opportunities, to encourage a wider range of students to engage in mathematical discussions with their peers and the teacher (Smith, et al., 2017). Boaler and Brodie (2004) found that questions that encourage students to clarify and justify their reasoning were critical in allowing students to build understanding of the ideas. Likewise, Emerson (2010) found that higher level questioning activities were related to an increase in students' conceptual understanding of mathematical concepts and connections.

In this study, which is part of a larger study to analyze how PSTs plan to enact effective teaching practices, we explore the ways they anticipate incorrect student solutions and pose questions when planning to implement a mathematical problem-solving task.

Theoretical Foundation

In 2008, Stein, Engle, Smith, and Hughes proposed a pedagogical model for conducting whole-class discussions after students had completed work on cognitively challenging tasks. The model specifies five key practices: anticipating possible solution strategies students may employ to solve a high-level cognitively challenging task, monitoring student responses while they work on the task, selecting student work to be presented, sequencing selected student work in such a way to maximize the chance to achieve mathematical goals for the discussion, and making connections between student responses. Since then, anticipating student answers has been discussed as part of orchestrating productive classroom discussions as a crucial initial step for selecting and sequencing practices. Yet, researchers mostly focused on selecting and sequencing practices. For example, Meikle (2014) categorized preservice middle school teachers' rationales for selecting and sequencing choices, in an attempt to understand and improve their selecting and sequencing practices. Silver, Ghousseini, Gosen, Charalambous, and Strawhun (2005) examined teachers' transformation through a year-long professional development experience about the use of multiple solutions in the classroom discussions. Teachers noted that they had in the past always tried to suppress any discussion of wrong answers or flawed approaches, but now they came to an understanding that it is "really important to take a look even at wrong answers." Hallman-Thrasher (2017) investigated preservice teachers' responses to unanticipated incorrect solutions to problem-solving tasks in the enactment phase, and found that they all experienced difficulty in helping students question or leverage an incorrect idea toward a more productive strategy. For example, their response was often encouraging students with correct solutions to explain their ideas to students who had incorrect solutions or inefficient strategies. The authors indicated that PSTs did not treat student ideas as objects of inquiry.

All levels of questioning are important, as questions that gather information and probe thinking are necessary for teachers to determine what students know, while questions that encourage reflection and justification are important to reveal student reasoning. Effective questioning attends to students' thinking by asking students to explain and reflect on their thoughts (NCTM, 2014).

Our work with PSTs explored and characterized their anticipated wrong or flawed solutions, and analyzed the questions they planned to use to help students overcome those errors, in an attempt to inform mathematics teacher educators.

Data Analysis

The sample was comprised of 88 PSTs in a math methods course for a mix of elementary and special education majors. The analysis involved categorizing the erroneous solutions PSTs anticipated, as well as categorizing the proposed questions to help students evaluate and judge their own work, and eventually understand why it was invalid. One researcher reviewed the preservice teachers' work and proposed initial categories for the anticipated erroneous solutions and planned questions. Another researcher was asked to use those identified categories to categorize the preservice teachers' work. Any discrepancies between the researchers were discussed and categories and codes were revised as necessary. The process was repeated until 100% agreement was achieved.

Results

The problem-solving task assignment specifically required PSTs to identify difficulties their students may have that would cause them to not get started on the problem or lead them to incorrect or partially-correct solutions, and to plan questions they would ask to help students overcome those difficulties. Seven main categories of difficulties were identified: (1) student error not specified; (2) student makes a calculation error; (3) student chooses an inappropriate operation, formula, procedure or unit; (4) student incorrectly applies a formula or procedure; (5) student forgets to do something; (6) student cannot get started or is stuck; and (7) student's answer and explanation do not match. Questions were identified as focusing on (1) information and/or procedures, which asks students to identify numbers, shapes, key words or procedures to use in solving a problem; (2) context, which asks a student to identify information given in a problem; (3) meanings, which asks a student to explain the meaning of information or the reasoning for procedures; (4) representations, which asks students to use a different representation to explore a problem; or (5) general questions about concepts or procedures with no connection to the context of the problem. Note that many PSTs proposed more than one category of difficulty and question types.

Twenty-eight of 88 PSTs' work fell into the first category of anticipated difficulty, student error not specified. These PSTs planned questions to help a student overcome the difficulty without specifying the error or difficulty the student may have. Consequently, most questions they planned probably would not support student learning. PSTs primarily planned general questions (50%), such as "How did you get your final answer? Can you show me each step? Could you show me another way using manipulatives?", or questions that focused on information and/or procedures (57%), such as "What operation would you use to try to solve this?" PSTs also planned questions focused on meanings (18%), representations (21%), and context (25%).

Twenty-two PSTs anticipated that students would make a calculation error. For example, "Come up with incorrect factors [of number 56]" or "Started on the wrong number and/or counted incorrectly in the table." Accordingly, the majority (59%) of these PSTs had questions focused on correcting calculation errors that were coded as focusing on information and/or procedures, such as "Can you show me how you counted up from this number?" or "How did you figure out how much money the two items cost together?" Other categories included general questions (27%), and questions focused on meanings (18%), representations (18%), or context (9%).

The third category of anticipated difficulties, student chooses inappropriate operation, formula, procedure or unit, consisted of 56 PSTs' work. These PSTs predicted that students would, for example, "use addition instead of multiplication" (inappropriate operation) or "draws 7 groups of 5 instead of 5 groups of 7" (inappropriate representation) or "confused area and perimeter of a rectangle" (inappropriate formula). The questions these PSTs planned included, "what in the word problem made them think to add the two numbers together" (focus on information and/or procedures); and "Can you read your answer aloud?" (general question). Most (57%) PSTs proposed questions that were coded as focused on information and/or procedures, while about 43% of PSTs proposed general questions with no focus. Questions also focused on meanings (29%), such as "does dividing the angles we know make sense if we are trying to find one missing part?"; representations (29%); or context (25%).

Twenty PSTs predicted that students may make a mistake when applying a procedure or a formula. For example, "didn't carry out, didn't place decimal point correctly," "a mistake that might be made while using a factor tree would be circling a number/numbers that are not prime, like circling a 4 when really, 4 can be broken down further," or "performed equation wrong." The majority (95%) of these PSTs had questions that focused on information and/or procedures, such as "can you explain to me how you did your adding?" and "does the new fraction look like double the old fraction?" Seventy-five percent of these PSTs planned general questions, 55% planned questions focused on meanings, 50% planned questions focused on representations, and 10% planned questions focused on context.

Twenty-one PSTs anticipated that students would forget to do something. Examples include, "compared the numbers in the tens place first and stopped comparing the rest of the number," or "created table correctly, forgot to take into account subtracting the initial expense." These PSTs planned questions to remind students that there was something more that they needed to do. About 71% of these PSTs proposed questions that were focused on information and/or procedures, and 43% proposed general questions. Other questions focused on meanings (33%), such as "what made you conclude that the tens place comparison will correctly compare both multi-digit numbers?"; context (24%), such as "I would ask the student to tell me who ate all the cupcakes"; or representations (10%).

Only four PSTs anticipated solutions where the answer did not match the explanation. Two of those PSTs proposed questions coded as focused on information and/or procedures, including "which amount is bigger, $1.90 or $1.92?" and "what criteria are you using to round it to 55,000?" Finally, the majority of PSTs (82) planned questions for students who were stuck or could not get started. Those questions varied in type, such as those that asked students to focus on the context of the problem (proposed by 23%), such as "how much money does Oliver have in his pocket?", and questions that asked students to focus on information and/or procedures (57%), such as "do you group these numbers?" These PSTs also planned questions focused on representations (37%), such as "can you use one of your math manipulatives to help you solve the problem?"; general questions (57%); and questions focused on meanings (6%).

Overall, the majority of PSTs proposed questions that focused on information and/or procedures (86%). General questions were planned by 77% of PSTs, 42% proposed questions focused on meanings, 52% planned questions focused on representations, and 40% planned questions focused on context.

Conclusions

Authors found that PSTs realized many common procedural errors or mistakes students would make. However, the anticipated errors and the level of questioning indicate that most PSTs did not consider that students may have underlying gaps in their conceptual understanding. A focus on procedures without addressing conceptual understanding is in contrast to the recommended effective teaching practice of building procedural fluency from conceptual understanding, which notes that procedural fluency builds on a foundation of conceptual understanding (NCTM, 2014). Therefore, it is recommended that methods courses should be explicit in discussing types of questioning and focus on questions that support student learning by requiring them to clarify and justify their reasoning.

MATHEMATICS TEACHER EDUCATION IN THE AGE OF TWITTER: A CRITICAL TOOL IN ELEMENTARY MATH METHODS

Joanne Baltazar Vakil
The Ohio State University
vakil.30@osu.edu

Theodore Chao
The Ohio State University
chao.160@osu.edu

Higher education classes have gradually seen the rise in the use of Twitter for assignments and informal discussions. This paper describes recent research on the use of this platform as a pedagogical tool, demonstrating strategies instructors can implement to promote rich and engaging dialogue of mathematical topics. The potential for utilizing Twitter in Elementary Math Methods courses is illuminated with its use as a discussion board, a means to cultivate a math teacher identity, a forum for sharing classroom ideas, and a connection between pre-service teachers and the in-service teaching community. Data from student surveys and interviews of undergraduate and graduate education students who use Twitter in their classroom are shown.

Keywords: Math identity, Instructional activities and practices, Technology, Community

The landscape of higher education programs is rapidly changing as social media platforms permeate into the curriculum and are required for activities and assignments (Knowlton & Nygard, 2016) and used as a source of "push" technology for instructors to send out course information (Tang & Hew, 2017). One popular type of social media, launched in 2006, is the microblogging platform Twitter, which allows for the communication through posts that can be explored, followed, replied, and forwarded (Gao, Luo, & Zhang, 2012). Twitter's design of instantaneous interaction mimics real-time conversation (Fentry, Boykin, & Vickery, 2017), enabling instructors, through "pedagogical tweeting," (Menkhoff, Chay, Bengtsson, Woodard, & Gan, 2015, p. 1295) to assess students informally. Twitter has increasingly become a focal point of interest to researchers exploring the value and potential of social media in higher education classrooms (Tur, Marin & Carpenter, 2017).

A meta-analysis of fifty-one empirical studies assessed the potential interactions and challenges Twitter offers in an education context (Tang & Hew, 2017). They found that Twitter was beneficial for participants who realized the platform's potential, understood learning outcomes and expectations for its use, and proactively used it for class (Tang & Hew, 2017). A three-phase content analysis of twenty-one studies on microblogging identified classroom challenges such as unfamiliarity and reluctance in working with Twitter, an abundance of distracting information, and lack of participation of "lurkers" (Gao, Luo, & Zhang, 2012, p. 792)

The affordances and limitations of Twitter inform Pre-Service Teacher (PST) educators of how to help their students navigate the increasing societal norm of instantaneous communication. Promoting Twitter can cultivate a math teacher identity within elementary PSTs, provide a forum for sharing classroom ideas, and a connection between PSTs and the in-service teaching community. Disregarding this critical tool will leave students unprepared as they find themselves with 20th century skills in a 21st century world.

Theoretical Framework

With the ubiquity of Twitter and its options of sharing messages, images, and videos, it is necessary to incorporate such prevalent practices into academic coursework. Students, for the most part, are digital natives (Prensky, 2001), though not necessarily "inherently better versed in technology" (Lieberman, 2017). Studies have reported how widely adopted social media is with this generation (Arceneaux & Dinu, 2018), spending one to two hours per day on it (Ozen et al., 2018). Hence, students must be engaged with the technology they are familiar and comfortable with (Denker, Manning, Heuett, & Summers, 2018). Denker, Hermann, & Willits (2015) describe the phenomenon of the polymediated classroom, an extension of the physical college classroom into virtual space "where people are simultaneously communicating online and off" (p. 1). Drawing from Sociocultural Learning Theory (Vygotsky, 1978) and Situated Cognition Theory (Brown, Collins, & Duguid, 1989), we heed the caution against an "ersatz activity," an abstract task that does not align with 'ordinary practices of the culture'" (Brown, Collins, & Duguid, 1989, p 34). Retaining decontextualized classroom encounters that do not include social media may be considered irrelevant to students, and "as a result, students can easily be introduced to a formalistic, intimidating view of math that encourages a culture of math phobia rather than one of authentic math activity" (Brown, Collins, & Duguid, 1989, p. 34).

Our theoretical framework uses the additional lens of Communities of Practice (Wenger, 1998) wherein a community of PSTs and in-service teachers is fostered by using the Twitter domain. The shared interest of teaching and learning by education practitioners results in a dynamic, interactive exchange of ideas among participants, which can lead to connections and relationships in the virtual and real-world settings.

Dearth of Research of Twitter in Mathematics Teacher Education

Research on how higher education instructors utilize Twitter abounds, with studies on its use as a tool for scholarly practices (Veletsianos, 2012; Mollett, Moran, & Dunleavy, 2011; Alerpin, Gomez, & Haustein, 2018) and conference backchanneling (Risser & Waddell, 2018). Instructors who implement Twitter in the classroom tend to share common characteristics of being "reform-minded, open to change, and interested in restructuring their local communities environment to include web-based and social media tools" (Forte, Humphreys, & Park, 2012).

Though research has demonstrated how engaging (Hirsh, 2012; Alim, 2017) and motivating (Rico & Feliz, 2016) Twitter is as a tool for creating and sharing knowledge (Kassens-Noor, 2012; Junco et al., 2011) and collaboration (Tur, Marin, & Carpenter, 2017), limited studies have focused on its use in teacher education. Emerging research details the historical development of #MTBoS (Larsen & Liljedahl, 2017), a grassroots network of mathematics and science teachers which provides a space for nontraditional professional development and a community of practice (Risser & Bottoms, 2018; Willet & Reimer, 2018). Baucom, Ashe, & Webb (2018) report how they have "leveraged Twitter to support the statewide implementation of new mathematics standards" (p. 126). Goals of this investigation include analyzing the discourse engendered within Twitter as the forum for a weekly Math Methods discussion board, observing how this platform cultivates a math teacher identity. Additionally, this study addresses the perceptions PSTs hold concerning the mandatory use of Twitter for class as they employ it to access other forums that actively shares classroom ideas, connecting the PSTs to the in-service teaching community (Carpenter, J. P., & Morrison, S. A. (2018)

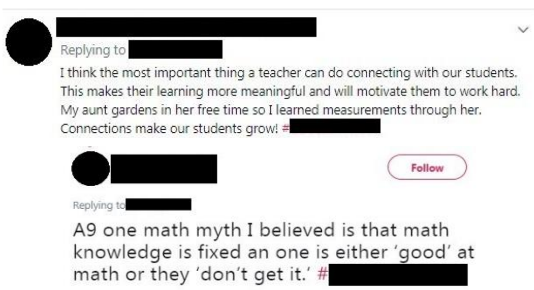
Methods and Data Sources

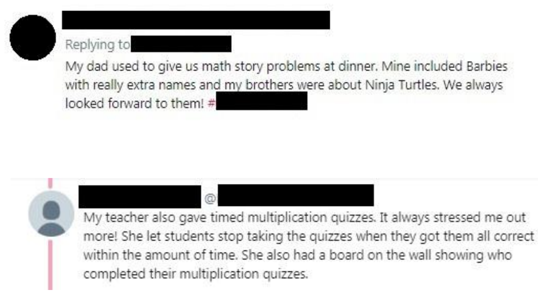
Participants (n= 4) for this qualitative study include undergraduate and graduate PSTs at a large, mid-Western university. Students were enrolled in an Elementary Math Methods course which required the use of Twitter. The students either tweeted directly to the professor's weekly questions about assigned article readings or to a group of 2 or 3 student moderators who tweeted the article questions directly to their classmates. Participants consented to allow the researchers to review the PSTs' Twitter feeds. They also completed a 9-question online Qualtrics survey and took part in a semi-structured, audio-recorded interview for 15- 30 minutes.

Sample Results and Discussion

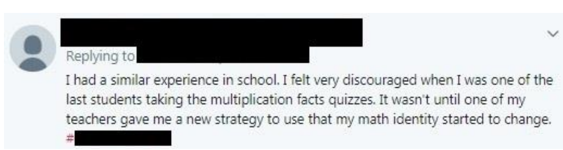
Class Assignment Twitter Feeds

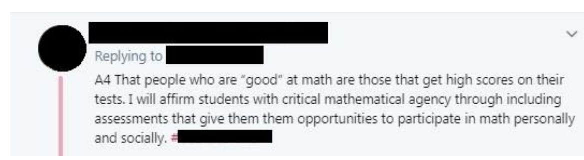
After reading chapters from Aguirre, Mayfield-Ingram, & Martin's (2013) text on identity, PSTs tweeted math stereotypes and assumptions they previously encountered. The response tweets acted as a springboard to deeper discussions asynchronously online and face-to-face.





PSTs addressed of their own informal math experiences, leading to a discussion on personal beliefs, as well as family support and involvement with their development of mathematical concepts. A conversation about math myths emerged and how some PSTs managed to overcome these initial conceptions.





By providing an opportunity for PSTs to share memories of their own experiences, a deep discussion about math anxiety tied into a class reading by Johnston (2010). The tweets exhibited an emerging understanding of mathematical agency (Aguirre et al., 2013) and provided a starting point for PSTs to begin unpacking issues of equity and social justice in the classroom.

Initial Survey Responses

The 9- question Qualtrics survey responses revealed that half of the participants did not previously have a Twitter account and that using this form of social media required at least 2-3 weeks for three of the participants to "feel comfortable in navigating Twitter." The instructor designated time during class to establish a course hashtag (Lowe & Laffey, 2011), model the tweeting process, guide students towards creating a professional account, and highlight hashtags of interest to PSTs such as #ElemMathChat, #iteachmath, and #MTBoS. Preparing students in this manner helped them "fully exploit the resources channeled through Twitter" (Tang & Hew, 2017, p. 111). Research by Rohr & Costello (2015) recommend addressing expectations for quality tweets by rewarding students higher marks for comments that build on other responses.

When asked if the participant felt if "tweeting for weekly discussions helped create ideas among you and your classmates?" and if they felt that "Twitter was an appropriate forum for discussing math problems or problem solving?" all but one participant agreed. Finally, all but one participant agreed that "Tweeting for weekly discussions works better than a traditional text-based discussion board" The participant who disagreed selected the answer "No, a combination would work better." The feedback from the participants enjoins future research to investigate the limitations of Twitter as an effective discussion board platform.

Individual Semi-structured Interviews

When asked "What aspects of using Twitter for weekly class discussions did you like during the course?" the following responses by participants (pseudonyms are used) were made.

> Megan: *I liked the fact that it's not completely cut off from the real world around us; people from education world can see our posts; the goal is not to prove that we read the article, it was to respond what we had read.*
> Andrew: *I like that it is easier to respond and post discussion post questions. It is kind of hard navigating and posting… There are more functions to Twitter, you can post a picture.*
> Jackie: *Examples everyone brought in; their experiences all their co-teachers would do… our mathematical experiences … I felt I came to realize there were mutual feelings.*

One participant noted her difficulties in responding to the Twitter assignments. Her concerns echo Tang & Hew's (2017) suggestions for further work into measuring student behavioral and performance patterns in order to "derive more meaningful lessons to design appropriate Twitter activity to engage different students" (p. 113).

> Hillary: *It was [pause]… fast; I feel like I could respond and forget about it…. Not normally my goal…I struggled to get …something out of the twitter discussion.*

Though she failed to see the benefits of using Twitter as a student, she understood the advantages of using it as a future teacher. When asked, "What are some reasons why you would or would not continue to use Twitter for math discussions after the course?" Hillary answered on a more positive note.

> Hillary: *I don't know if I would stop it… I like how you can make connections with other teachers around world… it's like the new research… getting advice from them.. what you can do differently if or giving advice back.*

Feedback for the course use of Twitter was addressed in the final interview question, "Can you elaborate on your survey question answer to #9, what recommendations do you have concerning the use of Twitter in an online or face-to-face STEM classroom?

> Megan: *We should include [and] take note of posts by influential members the education field; experience more authentic, use Twitter as a means to advocate for things that are important; retweet posts by [Superintendent of local public school]…*

> Andrew: *I really like how we have been using it for math… it would be interesting to use it for ELA. It would be fun …book discussions… [about] science and math…*

Two students provided constructive criticism by pointing out the need for more organization and reducing class time for reviewing themes and ideas expressed during the online interaction.

> Jackie: *[Using Twitter for class was] Good and bad… each week a different group was in charge… confused…kind of told us too late; just trying it out; due dates making sure are set.*
> Hillary: *I would drastically reduce the amount of time used to discuss Twitter in class…. Bulk of time on own time and also in class [would be] cut back on that and only pose one question at a time on Twitter and give students another way to discuss it if not their preferred learning style.*

Significance

The samples of student tweets in this study exemplified how Math teacher educators can weave topics of math identity and equity into Twitter conversations, as will be further elaborated in the presentation. The interviews offered insightful perspectives of PSTs which can inform Math teacher educators designing future courses incorporating Twitter as a weekly discussion board. The reflections demonstrated that overall, PSTs held positive perceptions of Twitter as a critical tool connecting them to a community of practice including stakeholders in the education field and that its feature of making "connections with other teachers around [the] world" could be extended as a forum to "advocate for things that are important."

This paper reports on the results of an intervention targeting prospective teachers' (PTs') noticing of high leverage mathematical practices (using precise mathematical language, giving mathematical explanations, using students' mathematical contributions, and remediating student errors). PTs completed a pre-post video assessment in which they watched a short clinical interview and answered prompts about what they attended to, how they interpreted the student thinking and instructional moves, and how they would respond if they were the teacher. Results indicated that the changes PTs' overall noticing skills from pre to post was approaching statistical significance, but that they still did not reach high levels of sophistication.

Keywords: Teacher Education-Preservice; Instructional activities and practices

Objectives/Purposes of the Study

The complexity of the classroom requires teachers to process a cacophony of stimuli. Sifting through these stimuli, determining which need immediate response, which can be addressed later, understanding what these stimuli mean in terms of student understanding, and determining the best response to move students towards instructional goals are the sophisticated noticing skills that expert teachers employ constantly throughout the day. Researchers have theorized a learning to notice framework (van Es & Sherin, 2002) which outlines levels of sophistication of what and how teachers notice. Part of the skill of noticing involves choosing which instructional practices to employ when responding to stimuli. Some researchers have advocated the teacher education programs should focus on teaching prospective teachers (PTs) certain "high leverage practices," or practices that have the most impact on student learning so that they are prepared to implement these practices effectively (Grossman Hammerness, & McDonald, 2009; Lampert et al., 2013).

In order to prepare PTs to sift through the complexity of classrooms, develop more sophisticated noticing skills, and learn about high leverage practices, we developed five lessons to specifically instruct them in these skills. The purpose of this study is to evaluate if the PTs' noticing skills improved after participating in these lessons. The following research questions guided this study:

1. If PTs receive explicit instruction in the skills of noticing (attending, interpreting, and responding), do their noticing skills improve?

2. After participating in the intervention, which instructional practices do PTs notice most?

Theoretical Perspective

Our study is framed by two main areas of prior research: teacher noticing and high leverage practices. Research on PTs' noticing often examines what they attend to in the classroom and how they interpret those events (van Es & Sherin, 2002; Mitchell & Marin, 2015). Sometimes research on PTs' noticing has also examined how they would respond to specific classroom events (Jacobs, Lamb, & Philipp, 2010). Research on using high leverage practices with PTs has mostly focused on helping PTs decide which responses to make in the moment, focusing on developing PTs' knowledge of specific instructional practices (Ball, Sleep, Boerst, & Bass, 2009). We see a need to first teach PTs how to notice and then give them the tools of the high leverage practices to support their responding.

Noticing

Experts within a profession notice different aspects of their environment (Mason, 2002). Noticing has been conceptualized slightly differently by different researchers (Jacobs & Spangler, 2017). For the purposes of this study, we follow Jacobs and colleagues' (2010) conceptualization of noticing as a nested model wherein teachers must first attend, then interpret, and then respond to classroom events. We combined this conceptualization of noticing with the Learning to Notice framework (van Es & Sherin, 2002) as we created the lessons for this study. The Learning to Notice framework posits that there is a predictable trajectory through which teachers progress as they learn to notice (van Es & Sherin, 2002): (1) teachers describe literal events in the classroom and make judgmental statements; (2) teachers make some comments at level 1, but begin to highlight noteworthy events in the classroom, without providing specific evidence for their interpretations of these events; (3) teachers identify important events and can interpret those events; and (4) teachers make connections among the important events they noticed and important principles of teaching and learning and begin to "offer pedagogical solutions based on their interpretations" (p. 581). Lastly, we integrated the ideas of Barnhard and van Es (2015) that PTs can engage in attending, interpreting, and responding at different levels of sophistication when viewing video of their own instruction (Figure 1).

Skill	Low sophistication	Medium sophistication	High sophistication
Attending	Highlights classroom events, teacher pedagogy, student behavior, and/or classroom climate. No attention to student thinking.	Highlights student thinking with respect to the collection of data from a scientific inquiry (science procedural focus).	Highlights student thinking with respect to the collection, analysis, and interpretation of data from a scientific inquiry (science conceptual focus)
Analyzing	Little or no sense-making of highlighted events; mostly descriptions. No elaboration or analysis of interactions and classroom events; little or no use of evidence to support claims.	Begins to make sense of highlighted events. Some use of evidence to support claims.	Consistently makes sense of highlighted events. Consistent use of evidence to support claims.
Responding	Does not identify or describe acting on specific student ideas as topics of discussion; offers disconnected or vague ideas of what to do differently next time.	Identifies and describes acting on a specific student idea during the lesson; offers ideas about what to do differently next time.	Identifies and describes acting on a specific student idea during the lesson *and* offers specific ideas of what to do differently next time in response to evidence; makes logical connections between teaching and learning.

Figure 1: Levels of Sophistication for Noticing Skills (Barnhard & van Es, 2015).

Expert teachers notice more than novice teachers (Huang & Li, 2012; Jacobs et al., 2010). Furthermore, PTs can learn to notice (Hiebert, Miller, & Berk, 2017; Mitchell & Marin, 2015; van Es & Conroy, 2009). For example, Mitchell and Marin (2015) created a video club in which four PTs viewed video of their own instruction over the course of 10 weeks. In advance of each video club meeting, the PTs viewed and scored a video of either their own or of their peers' instruction using the Mathematical Quality of Instruction (MQI) rubric (Hill et al., 2008). During the meetings, an MQI-trained rater facilitated a discussion of their scores. After participating in these sessions, Mitchell and Marin found that the PTs were more likely to notice aspects of mathematics as well as specific aspects of the MQI. The PTs were also less evaluative and judgmental regarding what they noticed. Our study builds on this work by using the MQI to frame the high leverage practices, but differs in how we organized the lessons, with attention to four specific practices and with all lessons structured around supporting PTs' skills in attending, interpreting, and responding.

High Leverage MQI Practices

The High Leverage Practices were born out of the desire for a shared professional curriculum that focuses instruction for prospective mathematics teachers on the essential knowledge and skills needed for practice (Ball et al., 2009). The goal of this instruction is to engage PTs in doing these practices, rather than simply hearing and talking about them. The in-depth teaching and learning of these practices in methods courses allows for PTs to practice and develop these skills in a low-risk environment, prior to enacting them in a classroom with students (Ball & Forzani, 2010). However, even with a shared curriculum, it can be difficult to distinguish when a PT's practice has reached a level that is appropriate to enact in a classroom. The Mathematical Quality of Instruction (MQI) framework was created to be able to identify and analyze mathematical features of the work of mathematics teaching (Learning Mathematics for Teaching Project, 2011). The MQI framework consists of seven constructs, which include: richness and development of the mathematics, responding to students, connecting classroom practice to mathematics, language, equity, and presence of mathematical errors, all of which are pivotal skills in enacting practices that engage students in meaningful learning of mathematics. Each construct has between four and seven individual instructional practices which represent important mathematical qualities of teaching. Based on our previous research with using the MQI with PTs (Gallagher & Suh, under review), we decided to focus on four instructional practices: mathematical language, mathematical explanations, using student mathematical contributions, and remediating student errors and difficulties.

Methods

This mixed methods study integrated qualitative and quantitative analysis of PTs' noticing. For the first research question, qualitative analysis techniques were employed first to stay close to the data in determining the levels of sophistication of the three noticing skills, and quantitative techniques were applied subsequently to explore whether there were changes in the sophistication of PTs' noticing after participating in the intervention. To answer the second research question, we employed qualitative techniques to investigate which aspects of the MQI were noticed most by the PTs after participating in the intervention.

Context and Participants

Participants from this study were sampled across three different university sites (the Pacific Northwest, the South and the Mid-Atlantic). All were enrolled in an elementary mathematics methods course (which range from a one to two semester sequence) at their respective universities. At the conclusion of the semester, five PTs (who agreed to participate in this research) were randomly selected from each of the three university sites for a total of 15 PTs in this sample.

Noticing Lessons

The authors designed five lessons all of which included an activity to activate prior knowledge, a short discussion of the high leverage practice of focus (e.g., mathematical language) and video or transcript analysis using the noticing framework (with the high leverage practice of focus as a lens for noticing). The first lesson introduced PTs to the noticing framework and the three noticing skills: attending, interpreting and responding. The subsequent four lessons focused on the following MQI practices: using precise mathematical language, giving mathematical explanations, using students' mathematical contributions, and remediating students' mathematical errors.

Data Collection

A week or two before the first noticing lesson, PTs completed an online module in which they watched a video of a clinical interview of a student converting a mixed number ($3\frac{3}{8}$)into a fraction greater than one (San Diego State University Foundation, Philipp, Cabral, & Schappelle, 2011). After the video, PTs answered the following prompts in writing: (a) "Please describe in detail what you noticed", (b) "Please explain what you learned about Rachel's understanding.", (c) "Please explain what you learned about the teaching", and (d) "If you were the teacher, what would you do next? Be specific and give your rationale." PTs completed this same task within a week of the last noticing lesson.

Data Analysis

To evaluate the first research question, we began by defining what it would mean for noticing skills to improve. Using the learning to notice framework (van Es & Sherin, 2002) and the levels of sophistication for noticing (Barnhard & van Es, 2015) as a starting point, we began to consider what it would mean for PTs to attend, interpret, and respond at different levels of sophistication. After reading through those frameworks, we then compiled the PTs' responses to the pre and post assessment in a spreadsheet, separating responses to each of the four prompts. We then read through the responses for six PTs and began to level them as low (1), mid (2), and high (3), adding comments justifying each level. We met regularly through this process, comparing our levels and justifications in order to build a rubric (Table 1). We realized that we were asking the PTs to attend to and interpret both teacher and student actions and utterances, so we created categories for each of those in addition to a category for responding.

Additionally, through these discussions we realized that there were particular moments to which we were expecting the PTs to have attended, interpreted, and responded. While focusing on the student, these moments seemed to be related to important mathematical ideas the student shared or a key mathematical error that she made. Thus, we termed the moments we expected the PTs to have attended to with respect to the student as *critical mathematical moments*, or moments in which important mathematical ideas (both understandings and misunderstandings) arose in the student's work or talk. When we focused on the teacher, we realized that the corresponding moments were focused on the pedagogical moves the teacher used in response to the student's critical mathematical moments. We called these *critical pedagogical moments*, which we define as teacher moves in response to the student's critical mathematical moments.

Once we created the rubric and agreed upon the scoring of the six PTs' responses, three of the authors scored the remaining nine PTs' responses. To establish reliability, two participants scores were double-coded by pairs of researchers; 90% of researchers' codes were in agreement. The codes that differed were decided by the third researcher. We then calculated the average of PTs' scores across the five categories of noticing (i.e., attending to the teacher, interpreting the teacher's actions and utterances, attending to the student, interpreting the students' actions and utterances, and responding) for their pre and post lesson assessment. Lastly, we used a paired samples t-test to examine whether there were differences in the PTs' noticing from pre to post.

With regard to the second research question, in order to determine which of the four high leverage MQI practices were noticed most, two of the authors coded the post-assessments of all participants with four a priori codes: mathematical language, mathematical explanations, uses student contributions, and remediating student errors. The two authors met to discuss how they planned to code the data and decided that the practice must be explicitly mentioned by the PTs in order to be coded. After these decisions were made, they divided the assessments and coded them independently. Once all data were coded, they examined each other's coding to be sure they had applied codes consistently.

Table 1: Rubric for Scoring Levels of Noticing

	Low	**Mid**	**High**
Attending - Teacher	No mention of teacher moves OR Describing teacher actions in general terms (i.e., "asked questions")	Describing teacher actions/utterances specifically, but they may not be related to the critical pedagogical moment	Describing teacher actions/utterances specifically, including those related to the critical pedagogical moment
Interpreting - Teacher	Interpretation without evidence, either because they didn't attend or because they were interpreting about something outside of the video	Interprets teacher actions/utterances but they may not be related to the critical pedagogical moment	Interprets teacher actions/utterances and how they contributed to student thinking around the critical pedagogical moment
Attending - Student	Did not attend to mathematical aspect of student thinking (i.e., critical moment around a misconception/partial understanding/thinking) OR attended to critical mathematical moment but very generally (i.e., not in detail)	Attended specifically to students utterances/actions AND attended to critical mathematical moment but did so vaguely (i.e., noticing that there was an error and describing it in general terms)	Attended to critical mathematical moment with details and examples capturing exact student actions and utterances
Interpreting - Student	Interprets st thinking but not around the critical mathematical moment with a general explanation (i.e., "student is confused about the process")	Interprets st thinking around the critical mathematical moment with a general explanation (i.e., "student misapplied the steps in the procedure, but she does have conceptual understanding of fractions")	Accurately and specifically interprets student thinking with regard to the critical mathematical moment (i.e., "student misapplied the steps in the procedure, but she does have conceptual understanding of fractions, including 8/8 in one whole and 3 wholes in 3 3/8")
Responding - Teacher response to student	General, future action without rationale or that does not address the critical mathematical moment	One general response that addresses the critical mathematical moment but doesn't necessarily connect conceptual and procedural understanding	Multiple ways to respond with rationales that make sense to address critical mathematical moment OR one in-depth and specific response with a rationale that addresses the critical mathematical moment and makes connections between procedural and conceptual understanding

Findings

For the first research question we investigated whether or not there were statistically significant differences from pre to post on PTs' overall noticing. Means and standard deviations for each category of noticing are included in Table 2. A visual examination suggests that PTs improved in their attending skills to both the teacher and the student, but that their interpreting and responding skills may not have improved. Furthermore, only three PTs scored a 2 (mid-level sophistication) on interpreting the teacher's actions at post, and the rest scored a 1 (low-level sophistication). This indicates that they were either not interpreting the critical pedagogical moments at all or making superficial, vague interpretations not connected to the pedagogical moves or mathematics, even though many of them were able to attend to those moments (four students scored a 3 or high-level sophistication, on attending to the teacher at post, indicating that they had correctly attended to the critical pedagogical moments). We also found that when discussing what their next instructional move or response to the student would be if they were the teacher , their plans were likely to be general and not provide concrete next steps (e.g., "I would give Rachel another number to change into a number greater than one, before moving on."). The paired samples t-test examined whether there were differences from pre to post assessment on the PTs' overall noticing scores, as overall noticing was the only continuous variable. This test indicated that differences on overall noticing were approaching statistical significance, $t(14) = 2.06$, $p = .059$, from pre ($M = 1.29$, $sd = 0.31$) to post ($M = 1.52$, $sd = 0.28$).

Table 2: Means and Standard Deviations of Levels of Noticing at Pre and Post (N= 15)

	Pre-Assessment Scores	Post-Assessment Scores
Attending-Student	1.27 (0.46)	1.80 (0.86)
Interpreting-Student	1.27 (0.46)	1.20 (0.41)
Attending-Teacher	1.20 (0.56)	1.73 (0.59)
Interpreting-Teacher	1.40 (0.51)	1.47 (0.52)
Responding	1.33 (0.49)	1.40 (0.51)
Overall	1.29 (0.31)	1.52 (0.28)

With regard to the second research question, we found that remediation of student errors and misconceptions was the high leverage MQI practice noticed most often by the PTs in the post-assessment (Table 3). This makes sense as the video was chosen because it illustrates a student who had a procedural misconception but was able to leverage her strong conceptual understanding to complete the conversion of $3\frac{3}{8}$ to a fraction greater than 1. When we examined the PTs' comments regarding remediation of student errors and misconceptions, we found that they were divided on whether to provide conceptual or procedural remediation in response to the student's misconceptions. This seems to have stemmed from difficulty interpreting the critical mathematical moments; no PTs scored at a 3 (high-level of sophistication) for interpreting the student's actions or utterances. An unexpected finding from the analysis of the post-assessment was that not all of the PTs had the mathematical content knowledge, even by the end of the course, for converting a mixed number to a fraction greater than 1. In particular, two of the PTs thought that the problem in the video was $3 \times \frac{3}{8}$.

Table 3: Frequency of MQI Practices Noticed in the Post Assessment

High Leverage Practices	Frequency
Mathematical Language	10
Mathematical Explanations	8
Uses Student Mathematical Contributions	11
Remediation of Student Errors and Difficulties	17

Discussion/Conclusion

An important contribution of this study is the development of the rubric which examines levels of sophistication of the skills of noticing in mathematics, building off the work of Barnhard and van Es (2015), and extending this work by adding criteria for attending to and interpreting the actions and utterances of both the student and teacher. Also, in comparison to other learning to notice frameworks (Barnhard & van Es, 2015; van Es & Sherin, 2002), this rubric focuses on how PTs attend, interpret, and respond to the critical mathematical and pedagogical moments. Within the complexity of the classroom, teachers need to sift through all the stimuli and determine what is most important to attend to. They must then interpret and respond to these critical moments. After participating in this intervention, more of the PTs noticed these critical moments. Supporting PTs' ability to attend to these critical moments is an important first step in developing effective and responsive practitioners. We found that it was essential for us, as researchers, to identify the critical mathematical and pedagogical moments before we began coding. In spite of the fact that the critical mathematical and pedagogical moments will vary for every teaching episode that is viewed, we believe this rubric can nevertheless be applied across different teaching episodes, so long as those moments are identified at the start.

Although the PTs did seem to improve in their overall noticing skills, particularly in attending, and they did notice the high leverage MQI practices which were explicitly taught, we also found that their interpretations of what the student needed next or of the implications of the teacher's instructional decisions did not reach high, or even mid-level, sophistication. We also found that their responses were likely to be general and not offer concrete next steps. Thus, we are working to revise our lessons to include more emphasis on interpreting student thinking and interpreting teachers' instructional decisions. We are also making revisions that will push PTs to think more specifically about their instructional responses given these interpretations.

The findings of this study have important implications for teacher educators as well as researchers. Teacher educators should consider how they can explicitly teach PTs to attend, interpret, and respond to high leverage practices and students' mathematical thinking. This may involve helping the PTs to identify critical mathematical and pedagogical moments in teaching episodes in addition to unpacking each of these practices. Furthermore, although our findings were approaching statistical significance from pre to post for PTs after participating in the intervention, it is possible that these differences were due to the normal maturation of the PTs. In order to determine if differences could be attributed to the intervention, future research should compare the change in levels of noticing of PTs who participated in the intervention to those whose classes did not receive the intervention.

In order to support PTs in becoming effective teachers, they need to be able to determine what they should attend to amid the cacophony of classroom stimuli. They need to be able to interpret those critical moments in light of principles of teaching and learning, and they need effective instructional practices that they can implement in response to those interpretations. By explicitly teaching PTs to attend to and interpret critical mathematical and pedagogical moments, and by giving them specific high leverage practices that they can use to respond to those moments, teacher educators can support the development of effective teachers.

Herein we present some of the findings of a broader research study exploring students' lived experiences of learning mathematics in Canadian schools. In this paper we explore aspects of preservice teachers' mathematical literacy as revealed by their mathematical autobiographies. More specifically, our exploration is driven by the question: what forms of mathematical literacy, if any, are revealed by preservice teachers' mathematical autobiographies?

Keywords: Affect, emotion, beliefs and attitudes; Teacher knowledge; Instructional activities and practices.

Introduction

According to the National Council of Teachers of Mathematics (NCTM, 1989), the notion of mathematical power (or mathematical literacy) "is based on the recognition of mathematics as more than a collection of concepts and skills to be mastered; it includes methods of investigating and reasoning, means of communication, and notions of context" (p. 5). The NCTM (1989) determined 5 goals for students that reflect the importance of mathematical literacy: (1) learning to value mathematics, (2) becoming confident in their ability to do mathematics, (3) becoming mathematical problem solvers, (4) learning to communicate mathematically, and (5) learning to reason mathematically. These goals for students are all dependent and contingent on promoting students' access to the power of mathematics, thus, a crucial role for mathematics teachers is to engage students in doing and understanding mathematics to help them recognize its power and become mathematically literate. Fulfilling such a role "requires effective mathematics teaching in all classrooms" (NCTM, 2000a, p. 17) necessitating deep understanding of the field of mathematics, commitment to students as learners and human beings, and the development and use of a variety of pedagogical strategies. In addition, teaching that has the potential to promote students' mathematical literacy, "requires a challenging and supportive classroom learning environment" (p. 18), and a continuous seeking for improvement. Having this in mind, this paper explores preservice teachers' mathematical literacy as revealed by their mathematical autobiographies.

Literature Review

Mathematical literacy has been a domain of great interest for educational systems all around the world. In its 2003 Assessment Framework, the Program for International Student Assessment (PISA), which was launched by the Organisation for Economic Co-operation and Development (OECD) in 1997, defined mathematical literacy as

> an individual's capacity to identify and understand the role that mathematics plays in the world, to make well-founded judgements and to use and engage with mathematics in ways that meet the needs of that individual's life as a constructive, concerned and reflective citizen. (OECD, 2003, p. 15)

According to the PISA 2003 Assessment Framework, mathematical literacy refers to students' abilities and skills in analysing, reasoning, and communicating ideas effectively "as they pose, formulate, solve, and interpret mathematical problems in a variety of situations" (p. 24). We believe that the NCTM's (1989) goals associated with the transformative process of *becoming mathematically literate* are, ultimately, dependent on engaging students in processes of doing and understanding mathematics and that how students learn mathematics shapes their lived experiences of what it means to become mathematically literate. Our decades of experiences in the field of mathematics education have convinced us that two of the NCTM's (2000a) principles for school mathematics are critical in shaping students' development of mathematical literacy: *equity* and *learning*. The NCTM's (2000a) principles and standards document suggests that *equity*—high expectations and strong support for all students—and *learning*—learning mathematics with understanding, actively building new knowledge from experience and previous knowledge—are fundamental for high-quality mathematics education. Thus, in our analysis of the participants' mathematics autobiographies we focus on what these participants seem to understand about the conditions of the teaching environments that shaped their experiences and how these conditions map onto these two principles: equity and learning.

Methodology and Methods

This report is part of a broader research study, the main purpose of which is to gain a deeper understanding of students' lived experiences of learning mathematics in Canadian schools, and to help teachers and schools to understand their roles in shaping students' mathematical identities. To fulfil the objectives of the study, we adopted a narrative inquiry methodological framework. According to Clandinin and Connelly (2000), "narrative is the best way of representing and understanding experience" (p. 18).

We gathered 'mathematics autobiographies' from kindergarten to post-secondary students, as well as from members of the general public, in two Canadian provinces. In these autobiographical narratives participants described their feelings about learning mathematics, the images of mathematics as a discipline that they hold, the kinds of mathematics teaching they have experienced, and their dispositions and identities in relation to this important discipline. Some responses were gathered during face-to-face interviews and some were submitted anonymously via a website. Many of the latter type of submissions were in multimedia form (e.g., Powtoon, VideoScribe, etc.).

In this report we draw on data from 48 preservice teachers who were participating in one of two Bachelor of Education (B.Ed.) programs in Alberta and Ontario. In our analysis of the study's dataset we have used several approaches, including thematic analyses (e.g., Towers, Takeuchi, Hall, & Martin, 2017), application and/or development of new analysis techniques (e.g., Hall, Towers, & Martin, 2018; Plosz, Towers, & Takeuchi, 2015), and focused interrogations in which we use selected portions of our extensive dataset to shed light on particular issues and questions of relevance to the field (e.g., understanding the unique experiences of very young children in Canadian classrooms (Takeuchi, Towers, & Plosz, 2016; Towers, Takeuchi, & Martin, 2018). The analysis presented here results from addressing our dataset in the latter of these ways and explores the question: what forms of mathematical literacy, if any, are revealed by preservice teachers' mathematical autobiographies?

Findings

In this section we use examples from several preservice teachers' mathematics autobiographies to highlight what these participants seem to understand about the conditions of the teaching environments that shaped their experiences and how these conditions map onto two of the NCTM's principles for school mathematics: equity and learning.

Equity

As noted by the NCTM (2000a), excellence in mathematics education requires equity—high expectations and strong support for all students. The significance of this principle was evident in the narratives of many preservice teachers as they reflected on the importance of being a teacher who strongly supports all students and believes every student can learn mathematics and as they gave examples from their own histories as learners that showed why this principle had meaning for them. For example, one student, Amy, described a pivotal moment in her Grade 5 year when she summoned the courage to approach the teacher to discuss a poor grade she had received on a test. She recalled "his kind and encouraging words, along the lines of 'It's just one test, don't worry about it. I know that you can do much better.'" This participant noted the validation she felt by recognizing that her teacher knew (and communicated to her) that she had potential, even though she experienced some struggles.

Another participant, Carly, described being a successful student until Grade 11. She painted portraits of two of her early teachers and the environments they created that she felt contributed to her feelings of success. These environments included elements such as student choice, opportunities for success, making real life connections, use of manipulatives, encouraging multiple strategies, having high standards for all, and supporting student risk-taking. This is how she described her Grades 3 and 8 teachers:

> By asking interesting questions [my Grade 3 teacher] constantly had us engaged and thinking about math. With a large focus on asking questions ourselves, we felt comfortable and ready to take risks. The authentic relationships each of us had with [him] made us feel important and successful.
>
> [My Grade 8 teacher] set high expectations for his students while offering support. He saw the strengths in his students and believed they could all excel….He encouraged his students to become comfortable with a multitude of tools and strategies. [He] valued the learning differences of all his students. By expecting the best of his students and scaffolding where needed, fewer students gave up on themselves.

By contrast, when students felt unsupported or undervalued in the classroom, the effects were just as profound. Many described classroom environments where there was little opportunity for discussion, answers were dismissed as either right or wrong, there was no support, questions were discouraged, and only students perceived as 'strong' were valued. Here is how Carly described her encounter with such a classroom environment in Grade 11:

> [My Grade 11 teacher] didn't know my name. I was on my way to being a mathematician until I entered this classroom. Unlike my previous classes I dreaded going here. He seemed to favor the students that excelled in his class and cared little for the ones that did not….I was afraid to ask questions. When I fell behind, I gave up.

Learning

As noted by the NCTM (2000a), students must learn mathematics with understanding, actively building new knowledge from experience and previous knowledge. A student we heard from earlier, Amy, described realizing during her preservice teacher education program that the kind of mathematics teaching to which she had been exposed throughout her education followed a script common to North American classrooms (Stigler & Hiebert, 1998) wherein a preferred procedure was first demonstrated by the teacher and subsequently practiced by students. Reflecting on her learning in these classrooms she was now able to recognize that she "might have been able to understand the problem better if [she had been] given an opportunity to figure it out on [her] own" and that it might have been easier for her to "solve the problems in her own way as opposed to following the 'correct' procedure."

Another student, Sammy, reflected that after reading Stigler and Hiebert's (1998) piece on teaching as a cultural activity she "realized that [her] Grade 11 teacher did not take the time…to observe what [was] being taught from the perspective of the student [and instead] followed the 'show, tell, do' model where [students] were shown [a] few examples to grasp the basic concept and [then told to] practice with other given questions" resulting in the participant feeling she wanted to be "done with math" as soon as she reached the end of Grade 12.

Looking back over her history of learning mathematics, another preservice teacher, Jenny, reflected that she did not feel engaged by the majority of her teachers and they did not allow her to make sense on her own and understand what she was learning. For her, mathematical reasoning was not "encouraged or respected" for most of her educational journey. Only in Grade 10 did she encounter a teacher who engaged her and "allowed [her] to use [her] own creativity to solve math problems." This lament—the restrictive, procedural, and formulaic approach to mathematics adopted, and in some cases rigidly enforced, in school mathematics classrooms—was a common feature of many of the mathematics autobiographies we collected. Many participants reported on the recent recognition (during mathematics education coursework) that the mathematics they had learned in school was entirely memorized and rote rather than deeply understood and, in many cases, such as for Abigail whose comment is below, they reported feeling that something had therefore been taken from them in their formative experiences of learning mathematics.

> It became evident to me, that I don't ever remember being in a mathematical classroom environment such as this. I feel as though, had I been, my perspective on math may have been much different. I believe I would have benefitted from being able to discuss math with other students and learn about the different ways my classmates went about solving their math problems; ultimately building on our math skills together. As opposed to sitting at my desk on my own feeling confused and helpless.

Discussion and Conclusion

These participants' stories show that, often through coursework in their teacher education programs, these preservice teachers are developing sophisticated understandings of the kinds of classroom environments that reflect the NCTM's (2000a) equity and learning principles. Such classrooms are built on mutual respect, support for risk-taking, high expectations, and collaboration. These principled classrooms also honour students' own skills of analysing, reasoning, and communicating ideas effectively (OECD, 2003) and hence privilege the growth of mathematical understanding and foster mathematical literacy. "Research has solidly established the important role of conceptual understanding in the learning of mathematics" (NCTM, 2000b, p. 2) and developing such conceptual understanding enables students to "become competent and confident in their ability to tackle difficult problems and willing to persevere when tasks are challenging" (p. 2), two important goals for a mathematically literate citizenry. Our work shows that having preservice teachers explore, through mathematics autobiographies, their own histories of learning mathematics can help them to recognize and unpack important principles of learning and teaching mathematics and come to understand and be able to articulate aspects of their own mathematical literacy.

SECONDARY PRE-SERVICE TEACHERS' IMAGES AND INTERPRETATIONS OF STUDENT MATHEMATICAL THINKING

Dawn Teuscher
Brigham Young University
dawn.teuscher@byu.edu

J. Matt Switzer
Texas Christian University
j.switzer@tcu.edu

Teachers utilizing student mathematical thinking is important when teaching, yet many inservice teachers find it difficult to implement. The Standards for Preparing Teachers of Mathematics (AMTE, 2017) outline the knowledge, skills, and dispositions that beginning teachers should have after graduating including the importance of attending to and interpreting student mathematical thinking. In this paper, we present results from two focused video analysis assignments that our pre-service teachers engaged in to identify their images of student mathematical thinking and their ability to attend to and interpret student mathematical thinking.

Keywords: Teacher Education – Preservice, Instructional Activities and Practices, Noticing, Student Mathematical Thinking

Utilizing student mathematical thinking (SMT) is important when teaching mathematics, yet, it is challenging for many teachers to utilize SMT in ways that help students make sense of the mathematics. Mathematics teacher educators (MTEs) have used video clubs to improve in-service teachers' focus on SMT and researchers have found that video clubs help teachers refocus from teacher actions to student thinking (e.g., van Es & Sherin, 2010; Walkoe, 2015). Others have assisted inservice teachers to improve their ability to attend to and use SMT while teaching yet attending to and using SMT in-the-moment of teaching is still challenging.

The Association of Mathematics Teacher Educators (AMTE) recently released *Standards for Preparing Teachers of Mathematics* (2017) providing guidance of the knowledge, skills, and dispositions that beginning teachers should have upon graduating. One attribute emphasizes preservice mathematics teachers' (PSTs) ability to "anticipate and attend to students' mathematical thinking and mathematical learning progressions" (AMTE, 2017, p.18). We affirm this standard but wonder if changes in the types of activities that our PSTs complete during their programs might assist them in attending to and interpreting SMT.

We have goals in our undergraduate mathematics education program for PSTs to learn to anticipate, attend to, interpret, and use SMT. In each of our PSTs six mathematics education courses they spend time anticipating, attending to, and interpreting SMT with a focus on the importance of using SMT while teaching. Many activities (e.g., analyze authentic student work, watch video clips of real classrooms) that we use are common in other teacher education programs. However, we have found that our PSTs do not attend to or interpret SMT in productive ways (Teuscher, Switzer, & Morwood, 2016). Therefore, we deem it important to reconsider the types of activities our PSTs complete to assist them in learning to attend to and interpret SMT more productively.

Purpose of the Study

In this paper, we argue that the types of activities that PSTs engage in during their program may influence their images of SMT, which can assist them in attending to and interpreting SMT. We present results to answer the research question: *How do our PSTs attend to and interpret* *student mathematical thinking prior to student teaching?* We strive to make our PSTs' images of SMT explicit to illustrate how specific activities may afford PSTs opportunities to focus on SMT during their program, which we hope will assist them as they enter the teaching profession.

Theoretical Framework

Noticing is defined as being aware of something (Notice, 2019). Researchers have found that teachers, including PSTs, tend to notice classroom features that may not be important, yet were important to the teacher who noticed them (e.g., things on the wall, how the students were seated). Therefore, if we want PSTs to notice specific features, it is essential to guide PSTs' noticing so they become aware of important distinctions in the classroom. We frame our view of noticing with the professional noticing framework (Jacobs, Lamb, & Philipp, 2010) and focused video analysis (FVA) (Teuscher, Leatham, & Peterson, 2017); and our view of SMT with the *MOST* analytical framework (Leatham, Peterson, Stockero, & Van Zoest, 2015).

The professional noticing framework (Jacobs et al., 2010) is "a set of three interrelated skills: attending to children's strategies, interpreting children's understanding, and deciding how to respond on the bases of children's understanding" (p. 172). In our study, we focus on PSTs' attending to and interpreting of SMT. Jacobs et al. (2010) described *attending* to student's strategies as teachers' attention to the mathematical details of students' strategies and *interpreting* student's understanding as teachers' connection of student strategies with research on student understanding. For our study, we describe *attending* as PSTs' attention to the SMT in the video instances and *interpreting* as PSTs' inferred understanding of the attended SMT.

FVA is intentional and directed noticing (Teuscher et al., 2017) consisting of PSTs watching, identifying, and *analyzing* video instances using a specific coding framework that unpacks a targeted teaching practices (e.g. *Practice of Probing Student Thinking, MOST*). FVA differs from noticing in that PSTs do not respond only to what they notice in video clips, use guided questions to focus their attention, nor do they focus on broad teaching practices. Rather PSTs are given short video instances to analyze specific teaching practices, in this study instances of SMT.

We view SMT through the lens of the *MOST* Analytic Framework (Leatham et al., 2015). A **MOST** – "**M**athematically Significant Pedagogical **O**pportunity to Build on **S**tudent **T**hinking" (Leatham et al., 2015, p. 91) – is SMT that, if discussed with students in the class, could move SMT forward. For our study, we view the SMT identified by the PSTs as their written transcript of the student's words or actions in the context of the classroom discourse.

Methods

Participants consisted of seventeen PSTs, in a unique U.S. undergraduate program, who were enrolled in their capstone methods course prior to entering student teaching. The PSTs' take six mathematics education courses (17 credits) focused on connecting pedagogy and content (e.g., student thinking, assessment, task design, algebra, geometry). Upon entering their capstone course PSTs had completed four courses with various assignments analyzing written student work and discussing SMT in video clips as a class. At the beginning of the capstone course, the PSTs completed two FVA assignments about SMT within a week of each other. The FVA assignments were designed to gauge PSTs' ability to attend to and interpret SMT and make PSTs' images of SMT explicit for the instructor (first author).

FVA Assignments

FVA 1. PSTs analyzed seven pre-selected video instances (i.e., 10 - 20 secs) of SMT from various mathematics lessons that the authors selected. Prior to watching the instances, PSTs were provided the context and location in the lesson; the lesson goals; and the mathematics tasks that students in the video engaged for each instance. After watching the video instance PSTs transcribed the student mathematics and decided if they could infer the SMT. If PSTs inferred the SMT, they provided a written interpretation of the SMT. If PSTs could not infer the SMT, they wrote a question to ask the student to clarify the SMT.

FVA 2. PSTs analyzed five extended video instances from FVA 1 that included the teacher's responses. PSTs were familiar with the lesson context from completing FVA 1. After watching the extended instances, PSTs answered three questions: (1) What evidence do you see that the teacher attended or did not attend to the SMT, (2) How did the teacher press or not press SMT, (3) How did your initial inferences of SMT change based on the conversation in the classroom?

Analysis of Data

All 17 PSTs' written responses to FVA 1 and 2 were collected and analyzed to gauge the PSTs' ability to attend to and interpret SMT and make PSTs' images of SMT explicit. FVA 1 responses were analyzed to determine if the PSTs attended to SMT (i.e., did they accurately transcribe what the student said). The PSTs' interpretation of the SMT in FVA 1 were categorized as (a) valid and complete, (b) valid and incomplete, or (c) incorrect. The PSTs initial interpretation of the SMT were analyzed to determine if, and why, their interpretation changed after watching the extended video instances in FVA 2.

Results

We report results from one of the seven video instances to provide a sense of PSTs' ability to attend to and interpret SMT and provide an example of PSTs' images of SMT at the beginning of their capstone methods course. First, we introduce the context of the video instance and then we share the results for PSTs attending to and interpreting the SMT.

Context of Video Instance

This instance occurred near the end of a middle-grades mathematics lesson about quantities (i.e., measurable attributes of an object (Thompson, 2011)). The teacher had two boards in the front of the class that served as racetracks. One board was longer than the other and the boards were placed at different inclines. The teacher placed a car on each board, let them go, and asked the students, "*Which car went faster and how do you know? Can you prove to me that one car went faster than the other car?*" The lesson goals were for students to (1) identify different quantities and (2) coordinate two quantities to solve a problem.

Attending and Interpreting Student Mathematical Thinking after FVA 1

All 17 PSTs attended to the SMT by accurately transcribing the student statement "*If you times for each board, you could see how long it takes to get down at the end over how long the board is*." Three PSTs provided valid and complete interpretations that the student recognized the need for two quantities (time and distance) to find the speed and dividing time by distance would help her find the car's speed, which differed from how they calculated speed. Six PSTs provided a valid and incomplete interpretation by only interpreting that the student realized she needed to coordinate two quantities (time and distance) to find the speed of the car. Seven PSTs provided an incorrect interpretation, stating that the student understood speed as distance over time. One PSTs wrote that he could not infer the SMT and included a question to ask the student. Overall, only three PSTs (18%) provided valid and complete interpretations of the SMT.

Changes to PSTs' Initial Interpretation of SMT in FVA 2

Of the eight PSTs who interpreted the SMT in FVA 1 either incorrectly or did not infer the SMT, six changed their interpretation in FVA 2. Table 1 provides two PSTs' initial interpretation and their justification for changing their interpretation, which are similar to the other PSTs' responses. Five of the PSTs' justifications stated that the teacher's actions of recording the SMT on the board helped them recognize their interpretation of SMT was incorrect. Four of the PSTs' justifications implied that they made assumptions that resulted in incorrect interpretations. Therefore, we see in PSTs' initial justifications that they were not decentering (Piaget, 1955; Teuscher, Moore, & Carlson, 2015) to interpret the SMT.

Table 1: PSTs' Explanations for Change in Interpretation

PST	Initial Interpretation	Justification for changed interpretation
SD	The student is trying to get to *an inches per second kind of solution*, where the higher the number will tell which car was faster.	I originally though that the student was doing distance over time and trying to find the speed that way. *Here with the teacher writing exactly what she is saying on the board, it helps to see that she was thinking of setting something up like that but did not have a full understanding of how speed is calculated.*
KB	*This student understands the relationship s=d/t.* But you can't tell if she understands that that gives us an average speed of each car, not necessarily the fastest speed.	*I initially did not recognize that this student actually divided the time by the distance.* But having the student explain what she meant and put it up on the board made me realize more what the student was actually thinking. *I assumed the student understood that speed can be found by dividing distance by time, but she was not necessarily making a connection to speed.*

Of the six PSTs with valid and incomplete interpretations of the SMT only two changed their interpretation after FVA 2. These two PSTs extended their interpretation by building on their initial FVA 1 interpretation. One PST explained that she had assumed the student stated distance over time, yet after FVA 2 recognized that the student stated time over distance. The other PST explained that the student knew she needed two quantities to find speed but was unsure how to relate distance and time. Interestingly, most PSTs with a valid and incomplete interpretation did not change their interpretation after completing FVA 2.

Implications

These results suggest that the types of activities that PSTs engage in during their programs can influence their images of SMT. Although the PSTs had completed multiple courses focused on SMT prior to entering their capstone course, most did not provide a valid and complete interpretation of the SMT. Yet, after FVA 2, 65% of PSTs provided a valid and complete interpretation of the SMT. We hypothesize that separating videos into shorter segments for PSTs to attend to the SMT may allow PSTs to (1) focus on the SMT and (2) make sense of the SMT prior to watching the teacher response to that SMT. We hypothesized that having PSTs first transcribed SMT would help them interpret the SMT, yet we found that they interpreted the SMT by filtering it through their own way of thinking, rather than decentering.

Having PSTs transcribe and interpret SMT in the FVA assignments required them to analyze the video, which revealed their own thinking. Then having the PSTs view the video instances with the teacher response caused a natural dissidence for many PSTs because they had already decided the SMT from FVA 1. The FVA 2 and the PSTs' FVA 1 analysis became the teaching tool to assist them in decentering as they interpreted SMT. While the results of our study are optimistic, our PSTs did not meet the AMTE standard to attend to SMT even though they had multiple courses explicitly focused on SMT. Therefore, further research on the types of activities that will enhance PSTs' opportunities to attend to and interpret SMT during teaching are needed.

NOVICE ELEMENTARY TEACHERS' VISIONS OF THE TEACHER'S ROLE: A LONGITUDINAL COMPARISON OF TWO CASES

Temple A. Walkowiak
NC State University
tawalkow@ncsu.edu

Emily C. Elrod
NC State University
ekelrod@ncsu.edu

Frederique C. Yova
NC State University
fcyova@ncsu.edu

The purpose of this longitudinal study was two-fold: to compare the development of two novice elementary teachers' visions of the role of the teacher during mathematics instruction and to examine factors that might explain the variation in their vision trajectories. Data was collected for three years over the course of teacher preparation and the first year of teaching. The two participants were purposefully selected because their vision trajectories were similar early in their preparation program but then diverged during the latter part of the program and first year of teaching. Findings indicate differences in initial self-confidence in mathematics, mentor teacher relationships, and support in the form of curriculum and colleagues. Implications for teacher education and induction programs are discussed.

Keywords: Instructional vision; Affect, emotions, beliefs, and attitudes; Elementary education

Teachers' visions, as outlined by Hammerness (2001) are "a set of images of ideal classroom practice" (p. 143). When preservice teachers begin their teacher preparation programs, they certainly have a vision of classroom instruction, typically based upon their own experiences in school, also called the "apprenticeship of observation" (Lortie, 1975). Often, their experiences in school mathematics have not been aligned with the vision of the National Council of Teachers of Mathematics (NCTM, 2014) and the mathematics teacher educators who are preparing them. Therefore, we would expect their visions of their work as teachers of mathematics to evolve as they move through their teacher preparation program and into their teaching career. However, little is known about elementary teachers' development of instructional visions in mathematics during the preservice and induction years. Much of the past work has focused on experienced teachers in middle or high school settings (Hammerness, 2008; Munter, 2014) or in other disciplines such as science (e.g., Carrier, Whitehead, Minogue, & Corsi-Kimble, 2018).

Herein, we refer to preservice and first-year teachers as "novice teachers." The purpose of this study was to compare the development of two novice teachers' visions of the role of the teacher. Specifically, we examined two novice teachers over the course of three years, from the beginning of their teacher preparation program through their first year of teaching. The research questions guiding this study were: (1) For two novice elementary teachers, how did their visions of the role of the teacher in mathematics instruction develop as they progressed through the teacher preparation program and first year of teaching?; and (2) What factors might explain the differences between the two teachers in their visions trajectories?

Theoretical Perspectives

The current study draws on the framework proposed by Munter (2014) on a vision of high-quality mathematics instruction. Munter (2014) developed multiple rubrics for assessing vision, one of which focused on vision of the role of the teacher. Drawing on standards-based practices in the mathematics education literature, Munter's (2014) framework includes five progressively sophisticated levels: motivator, deliverer of knowledge, monitor, facilitator, and more knowledgeable other. As one moves up the framework, the descriptors are more aligned with a vision of standards-based teaching practices as advocated by NCTM (2014).

In their release of *Principles to Actions* (*P to A*), NCTM (2014) presents a “unified vision of what is needed to realize the potential of educating all students” (p. vii) in mathematics. In fact, much of this publication is devoted to the role of the teacher and the students in relation to a set of eight “Mathematics Teaching Practices.” The writers of *P to A* also suggest “unproductive beliefs” about the teaching and learning mathematics that may act as obstacles to achieving the vision outlined in the publication. By assessing novice teachers’ evolving visions as we undertake in the current study, we aim to surface, understand, and confront such obstacles that are part of teacher development early in the career.

Methods

Research Setting Context

This work is situated in the context of a larger research project designed to evaluate a STEM-focused elementary teacher preparation program. The larger investigation included tracking 245 novice teachers over time with more intensive data collection for 19 case study participants. During their junior and senior years, teachers enrolled in the program complete three full-time semesters of elementary education coursework accompanied with field experiences and one final semester of full-time student teaching in a classroom where they were placed the entire academic year (total hours for field experiences = 926 hours). The novice teachers take two mathematics methods courses (K-2 and 3-5) during the junior year. McIntyre and colleagues (2013) outline details about the teacher preparation program. In their methods coursework, there is an emphasis on the use of cognitively demanding tasks, mathematical representations, and discourse.

Participants

The two participants, Parker and Blake, were purposefully selected from the larger group of 19 case study participants (Walkowiak et al., 2015). Specifically, they were selected because their vision of the teacher’s role in mathematics instruction evolved differently over time. At the beginning and end of their first year of professional coursework (junior year), Parker and Blake had similar visions of the teacher’s role. However, at the end of their senior year and first year of teaching, their visions were different. Therefore, we purposefully selected Parker and Blake to investigate potential factors that might explain the variation in their visions trajectories. Table 1 displays the participants and the grade level of their classroom experiences. We utilize gender-neutral pseudonyms and female pronouns to protect the confidentiality of our participants.

Data Collection

Data was collected from Parker and Blake at four time points (five interviews), displayed in Table 1, about their vision of the role of the teacher in mathematics instruction (e.g., *What the teacher does and what the students are doing during mathematics instruction are really important. Describe what you think the teacher should be doing, and describe what you think the students should be doing most of the time.*)

We also collected interview data at each of the time points about the participants’ beliefs, contexts, and perceptions. We coded the questions that related to their confidence for teaching mathematics, contextual factors in their field placements and first-year-of-teaching schools, and their perceptions of the teacher preparation program (e.g., *Tell me your perception of how the math instruction at your school fits with the impressions you developed in your preparation program.*) Finally, at the conclusion of every semester in the program (n=4), Parker and Blake completed surveys about their field placement experiences.

Analysis

To code responses to the visions questions, we used one rubric (Role of the Teacher) from the Visions of High-Quality Mathematics Instruction (VHQMI) instrument (Munter, 2014). All responses were coded by two researchers who then discussed their codes. In cases of disagreement, discussion focused on reaching consensus. The rubric includes five levels (Levels 0-4) that correspond to how the participant described the role of the teacher. At the level of *motivator* (0), the primary role of the teacher is to entertain, to make learning fun, and/or to make emotional connections with students. The next level, teacher as *deliverer of knowledge* (1), indicates the role of the teacher is delivering the mathematical knowledge accurately and clearly, in a direct way. The teacher as *monitor* (2) is to provide demonstration on how to do a certain type of task but then give students time to work and talk together. The teacher monitors and redirects students if they are moving down an incorrect or nonproductive solution path. The teacher as *facilitator* (3) typically involves a teacher launching a task, students working in groups to figure it out, and the entire class discussing their strategies. The teacher asks probing questions to help them in their thinking, but the teacher does not directly tell the students what to do. Finally, when a teacher is described as a *more knowledgeable other* (4), the teacher and students share the mathematical authority, and the entire community of learners constructs the knowledge together.

For participants' responses to interview questions on beliefs, contexts, and perceptions and to field placement surveys, we utilized an open coding approach looking for themes across data sources for a participant.

Table 1: Participants, Data Collection Time Points, and Visions of Teacher's Role

Participant	TP1 Vision	Junior Year	TP2 Vision	Senior Year	TP3 Vision	1st Year of Teaching	TP4 Vision
Parker	1	Fall:1st Grade* Spring: 5th Grade*	2	3rd Grade*	3	4th Grade	3
Blake	1	Fall: Kindergarten* Spring: 5th Grade*	2	5th Grade*	1	2nd Grade	1

TP4: Math Lesson Interview & End-of-1st-Year Interview
*Field Placement Surveys every semester (n=4) during junior and senior years.

Findings

Vision Trajectories

Table 1 includes Parker's and Blake's visions of the teacher's role in mathematics instruction at each of the four time points using Munter's (2014) framework on a scale of 0-4. Both of the participants started their professional coursework at the beginning of junior year describing the teacher as the *deliverer of knowledge* (1), or as Blake stated, "the teacher should have a good example for [the students]." After the mathematics methods courses at the end of the junior year, they both described the teacher as a *monitor* (2). For example, Parker stated, "the teacher should be showing them why they're doing it….and making sure they really understand the concepts."

At the end of the senior year, Parker continued to progress in her vision of the teacher's role as she described the teacher's role as *facilitator* (3), and her vision remained at this level at the end of her first year of teaching. At that time point, Parker described the teacher's role to "guide [the students] by asking questions and pushing them further" while they "create their own ways to solve the problem." In contrast, Blake did not progress in her vision of the teacher's role at the end of the senior year and first year of teaching. Instead, her vision moved back one level to describing the teacher as the *deliverer of knowledge* (1) because "the teacher should always model at least once or twice what the concept is" (End of 1st year of teaching).

Potential Influencing Factors

Three factors emerged that could potentially influence variation in vision trajectories.

Mentor teacher relationships. Knowledge of the mentor teacher relationships during their student teaching is very limited; however, it is worth pointing to the complexity of these human relationships, particularly since both novice teachers emphasized the importance of the field experiences in their development. On her field placement survey, Parker complimented her mentor teacher for using "manipulatives and other hands-on activities" and for "keeping the students engaged" during math, but she also critiqued her mentor teacher's "negative attitude toward teaching." Blake provided only positive feedback about her mentor teacher at the end of her senior year, but during her first year of teaching, she stated that they "weren't the best fit." It is not clear how these complexities play out in their evolving visions, but their perceptions of the importance of field experiences suggest these relationships are likely pivotal.

Initial self-confidence in mathematics. One noticeable difference between Parker and Blake is their initial self-confidence in mathematics. In the initial interview, Parker says she is "high" in confidence in mathematics (and voices this confidence in subsequent interviews) while Blake indicates she knows she "needs to work on math" because she "was never the best math student." When considering their vision trajectories, perhaps Blake's background in mathematics that she perceived negatively impacts her progression in her vision (Valencia, Place, Martin, & Grossman, 2006).

Support in the form of curriculum and colleagues. Parker's and Blake's support during the first year of teaching seems to be an explanatory factor for Parker landing at *facilitator* and Blake at *deliverer of knowledge* at the end of the year. Parker mentions the "views and adopted curriculum" in her school are related to her confidence and interest in teaching math. The school uses *Investigations*, and the math coach's vision of instruction is aligned with standards-based instruction. She also talks repeatedly about the principal and math coach shared that she is obviously well prepared to teach math in comparison to other new teachers. In contrast, Blake points to her colleagues who have "done a lot of things one way for a long time" and many who follow the teacher-created district curriculum "closely." She verbalizes wanting "more professional development in science and math." It seems that Parker's level of support in relation to standards-based mathematics instruction is much stronger than Blake's; this difference could explain the variation in their visions at the end of their first year of teaching.

Discussion

Hammerness (2008) pointed to the importance of a teacher's instructional vision in the instructional practices actually utilized in the classroom. Therefore, allocating time and space in teacher preparation and induction programs for novice teachers to explicitly articulate and discuss their instructional visions seems important, particularly if we want to overcome or avoid some of the obstacles that may hinder progression of their visions. Furthermore, these perceived "obstacles" could actually become affordances (e.g., mentor teacher relationships) if we broaden our definition of teacher educator and include university-based *and* school-based teacher educators (i.e., mentor teachers, math coaches) in discussions about a novice teacher's evolving instructional vision toward one that is aligned with standards-based instruction (NCTM, 2014).

PROSPECTIVE MIDDLE SCHOOL TEACHERS USE OF DOUBLE NUMBER LINES IN A CONTENT COURSE

Eric Siy
University of Georgia
ericsiy@uga.edu

In this report, I describe how using double number lines shifted over the course of a year in a content course for prospective middle school teachers. I analyzed classroom data to characterize the relevant features of the double number lines the teachers used to solve division and proportion problems. The prospective teachers used three different sized units in their double number lines. I identify how the teachers created these units.

Keywords: Teacher Knowledge, Rational Numbers, Using Representations

Introduction

Researchers have echoed the importance of representations in mathematical thinking (Cuoco, 2001; Janvier, 1987). With representations, students can make sense of problems and the information in the problem, document solution strategies and concepts, monitor oneself (Lobato, Hohensee, & Diamond, 2014), communicate one's thinking (Roth & McGinn, 1998), and provide access to mathematics particularly if a student's language is not privileged in class (de Araujo, Roberts, Willey, & Zahner, 2018). In this study, I investigate the use of double number lines (DNLs), a type of representation that explicitly appears in the sixth grade Common Core standards. DNLs are introduced to help students solve rate and ratio problems (i.e., 6.RP.3). The DNL is an inscription where two number lines are drawn where each number line is partitioned into units of a quantity and students can coordinate two amounts of quantities.

Research on DNLs is sparse (Küchemann, Hodgen, & Brown, 2011; Orrill & Brown, 2012). Based on the few studies on DNLs, researchers have found DNLs are useful in supporting students' reasoning about situations involving scaling (Küchemann et al., 2011) and teachers' reasoning about proportional situations (Orrill & Brown, 2012). Partitioning and creating composed units, critical actions in understanding the multiplicative concepts can be supported by using DNLs (Orrill & Brown, 2012). Research on teaching with DNLs is more rare than controlled laboratory settings. In this study, I contribute to this body of work by describing how DNLs were used in a class for prospective middle school teachers to solve different multiplication, division, and proportion problems. Specifically, I identify how prospective teacher-generated DNLs changed over time and the conditions which the changes occurred.

Theoretical Framework

Definition of Representations

In this study, I frame representations as culturally and historically rooted artifacts whose meanings grow out of how communities have interacted with an inscription over time. Saxe's account (2012) of cultural forms and functions describe how historically rooted artifacts change over historical time. Forms are socially rooted artifacts perceivable by the community such as the base-27 system of the Oksapmin peoples (Saxe, 2012) or a number line (Saxe, de Kirby, Le, Sitabkhan, & Kang, 2015). Functions are how forms are used by the community. Over time, the community may preserve historical forms but may also change them in order to serve new functions. For example, as students use a number line form in earlier grades, the form shifts to accommodate rational numbers while preserving whole numbers. I focus on DNLs as representations although others were found in the data (e.g., equations).

Definition of Multiplication and Proportional Relationships

The class analyzed in this study used a multiplier-multiplicand definition for multiplication notated by equation $N \cdot M = P$ (Beckmann & Izsák, 2015). In this equation, the value N denotes the number of bases units in one group (the multiplicand), the value M denotes the number of groups (the multiplier), and the value of P denotes the number of units in M groups.

Data and Analysis

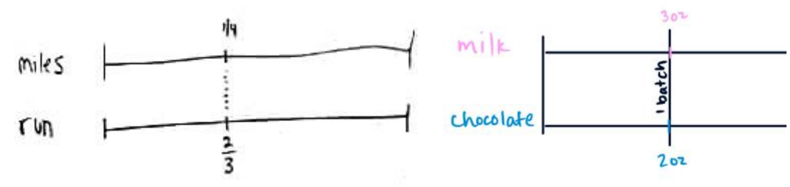
I analyzed fourteen lessons from a mathematics content course for prospective middle school teachers (PSMTs) focused on numbers and operations, including fraction operations. The 13 PSMTs in the course were predominantly white women. I also acted as a participant-observer and sat at one of the tables asking questions to support, extend, and connect PSMTs ideas. One stationary camera captured the whole class and another camera followed the teacher during small group work. Each table had an iPad where PSMTs can write notes and present their drawings. The primary analytical techniques were modified from Saxe et al., 2015 and focused on identifying forms and functions of the representations. To identify a form, I characterized the set of geometric inscriptions the PSMT used to explain their reasoning such as a tick mark or a line. I identified functions by using the PSMTs verbal explanations and annotations to explain what each form represented.

Results

In this section, I present the four forms PSMTs used to draw their DNLs. Each form corresponded to a different sized increment which relied on number choice in the word problems. The first form was used in order to establish relationships in the problem. Once the relationship was drawn, the PSMTs decided how to partition this correspondence in order to create a new correspondence to increment.

Correspondence Line

Each form began with a correspondence between two amounts of two different quantities. The PSMTs would draw a tick mark on both number lines and write down the corresponding amounts in the problem which PSMTs the product of a multiplication problem, the multiplicand, or a ratio. For example, consider Sophie’s initial DNL (Figure 1a) while explaining her strategy for Sue’s Run Problem, which reads “So far, Sue has run 1/4 of a mile but that is only 2/3 of her total running distance. Plot Sue’s total running distance and determine how many miles it is.” She drew a tick mark for one-fourth of a mile and two-thirds of a run and connected them with a line indicating correspondence between the two amounts showing the product or the amount of base units in M groups. Similarly, Molly began her DNL (Figure 1b) with a correspondence to begin her drawing for the Hot Cocoa Problem where PSMTs were told “A hot cocoa mixture has three ounces of milk and two ounces of chocolate. Draw a whole bunch of mixtures.” She connected two tick marks, one indicating three ounces of milk and the other indicating two ounces of chocolate, with each tick mark on a separate number line.



(a) **(b)**

Figure 16: Sophie's and Molly's Correspondence Lines

After the PSMTs drew the correspondence, they would either iterate this correspondence or partition the correspondence to create a new unit to iterate.

Composite Unit Increments

PSMTs incremented the correspondence they initially established during lessons on ratio and proportion similar to Lamon's (2007) building-up strategy. Consider the first lesson where the instructor posed the Hot Cocoa problem. After Molly drew her correspondence (Figure 1b), she then iterated this correspondence to show the mixture of required but also additional mixtures of the same flavor. She then showed amounts of one ounce on the corresponding number lines.

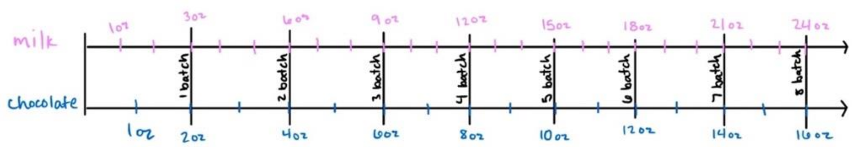


Figure 17: Molly's Drawing for the Hot Cocoa Problem

She also used this form while solving the Scooter Problem, a missing-value proportion problem, which reads, "A scooter is going 3/4 of mile every 4 minutes at a constant speed. How far does the scooter go in 12 minutes?" as seen in Figure 4. She initially drew the correspondence of three-fourths of a mile and four minutes. She then iterated the correspondence twice in order to get to 12 minutes. She explained she counted three-fourths three times in order to obtain two and one-fourth miles as the distance travelled in 12 minutes.

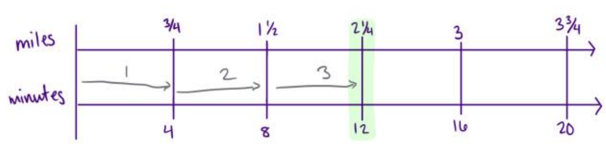

Figure 4: Molly's Drawing for the Scooter Problem

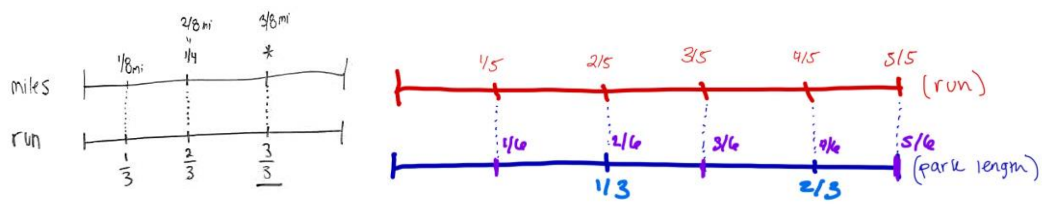
Lamon (2007) described this strategy as a building-up strategy where a PSMT creates a unit (i.e., unitizing) and built up to identify other correspondences. She noted this strategy as an entry point to proportion problems even for young PSMTs. In this study, I also note this strategy as an entry point to missing-value proportion problems where the amount given is divisible by the corresponding amount in the given ratio such as how twelve minutes is divisible by four.

Unit Fraction Increments

PSMTs created DNLs the initial correspondence is first partitioned to create a unit fraction amount which is subsequently iterated. Each unit fraction is paired with a corresponding amount in another quantity by partitioning the amount in the same number of partitions. This form emerged mostly during fraction division lessons and some ratio and proportion lessons.

To illustrate, Sophie used this form to complete her drawing for Sue's Run Problem early in the Fall. After drawing her unit correspondence Figure 16, she marked three-thirds on the run line and drew a line to an amount on the miles line, labelling it with a tick mark. She said she needed to find the amount at this tick mark and marked it with an asterisk. She partitioned the interval from zero to three-thirds in three parts. Knowing that one-third is half of two-thirds, she obtained the amount one-eighth as the corresponding amount on the miles line by getting half of two-eighths on the top number line. She finally iterated the resulting interval three times to obtain three-eighths as the amount represented by the asterisk (Figure 2a). She used a similar DNL in the Spring for a word problem, "If 2/5 of my total run is the distance of 1/3 of the length of the park, how far is my running distance in terms of the park length?" She began her DNL by drawing a Correspondence Line between two-fifths on the top and one-third on the bottom number line. She first identified that one-third was equivalent to two-sixths. She partitioned both the top number line and bottom number line further to show the correspondence between one-fifth of the run and one-sixth the park length. Finally, she iterated this correspondence five times in order to get five-fifths of a run and five-sixths the park length.



(a) (b)

Figure 18: Sophie's Drawing for Sue's Run Problem and 1/3 ÷ 2/5.

Unit Increments

PSMTs drew DNLs by partitioning the initial amount correspondence to create a new correspondence where one of quantities is one which is subsequently iterated. This form emerged during proportion lessons where PSMTs were solving missing-value proportion problems. In particular, the form emerged when the given value is not divisible by the corresponding amount in the ratio. Consider Andrew's work for the Hot Cocoa problem. Unlike Molly (Figure 3), Andrew wanted to draw more amounts and a general strategy (Figure 3). In his DNL, he chose to partition two ounces of chocolate in two and the corresponding amount of three ounces of milk to obtain three-halves ounces of milk. During small group, he explained partitioning something into two parts was "easier" than partitioning something into three. Once he obtained three-halves ounces of milk, he explained, "we can kind of build that up by one, every time an ounce of chocolate builds up, we get three-halves ounces of milk to go along with it each time." Notably, he incremented one ounce of chocolate to a generalized amount *n*. Correspondingly, he iterated the three-half ounces of milk to a generalized amount $\frac{n \cdot 3}{2}$.

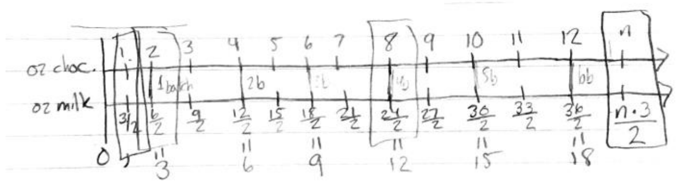

Figure 3: Andrew's Drawing for the Hot Cocoa Problem.

Discussion and Conclusions

In my analysis of the drawings, the forms for the double number lines provided me with a characterization of the different sized units to iterate. The PSMTs' forms followed a particular strategy. First, they established a relationship between two amounts of two quantities to begin the double number line. They used the product in partitive division problems and the given proportion in proportion problems to determine these relationships. They then identified a relationship they needed answer the problem. With a relationship, they selected the quantity and unit they wanted to use to increment. Orrill and Brown (2012) also found coordinating units and partitioning to be critical pieces of knowledge for teachers when engaging with double number lines. This report adds to Orrill and Brown's findings by identifying the conditions where the different size units emerge. Although there were three different-sized increments used by the PSMTs, a consistent strategy was to count up by "ones." In earlier grades, the number line is used to support the order of a counting sequence i.e., one, two, three. I argue that double number lines allow a coherent use of counting similar to earlier experiences especially when coordinating different amounts of quantities. The "one" in this case however where different size i.e., one batch, one of a quantity, one-*n*th of a quantity. This demonstrates the importance of working with number lines, particularly before middle school content and double number lines in order to imbue productive meanings for intervals on the number line.

PLANNING FOR EQUITY: ANALYZING THE CULTURAL RELEVANCE OF PRE-SERVICE TEACHERS' LESSON PLANS

Nickolaus A. Ortiz
Georgia State University
nortiz1@gsu.edu

Trina Davis
Texas A&M
trinadavis@tamu.edu

This scholarship is based on research conducted by members of the KATE Project, an NSF funded grant that employed strategies in the context of a mathematics problem-solving course. We utilized a rubric designed by KATE researchers to analyze 29 PSTs' lesson plans for their alignment with the tenets of culturally relevant pedagogy (CRP). Our findings indicated that most PSTs' lesson plans were identified in a superficial category, and that the PSTs did particularly well with indicators within the tenet of academic excellence and critical consciousness. Additionally, four themes were developed from the rationale provided by the PSTs detailing why they felt their lesson plans were aligned with CRP tenets.

Keywords: Teacher Education-Preservice, Equity and Justice

The current scholarship extends research conducted by members of the KATE (Knowledge for Algebra Teaching for Equity) Project, a 5-year NSF funded grant that employed strategies during a mathematics problem solving course to enhance preservice teachers' (PSTs') knowledge for algebra teaching for equity (Kulm et al., 2016). Participants in this study were given the directive to design a mathematics lesson, including a problem-solving scenario, that utilized a culturally relevant teaching scheme and would later be taught within a 3D virtual environment known as SecondLife. Also an element of this directive, we asked PSTs to articulate why the lesson plan fit the teaching scheme. Our goal here was to take a different approach from previous scholarship which has described examples of culturally relevant pedagogy (CRP) (e.g., Ladson-Billings, 2006; Tate, 1995), or those that solely evaluate lesson plans for evidence of CRP (e.g., Lemons-Smith, 2013; Leonard, Napp, & Adelke, 2009), and highlight the rationale provided by PSTs regarding why they felt their lesson plans aligned with this teaching scheme, in ways similar to how scholars have discussed PSTs' justification for using social justice oriented mathematics lessons (Felton-Koestler, 2017; Myers, 2015). We sought to understand how PSTs honored students' cultures, even in cases where the culture that teachers addressed was not exclusively predicated upon students' racial or ethnic identities. This contention does not insinuate that race must be addressed to make lessons culturally relevant, but it does infer that CRP would be diminished if discussions of race are consistently overlooked for more superficial and terse interpretations of culture, or in favor of more neutral terms such as diversity. The following research question guided the study: How successful were PSTs in implementing culturally relevant tenants into mathematics lessons designed for a virtual environment?

Literature Review and Theoretical Framework

Though a thorough discussion of the literature is beyond the scope of the present treatment, we rely on the scholarship of Ladson-Billings to explore academic excellence, cultural competence, and sociopolitical consciousness, the three tenets of CRP (1994, 2006), and assert that there are both similarities and differences within scholarship related to CRP and critical race

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

theory (Larnell, Bullock, & Jett, 2016; Tate, 1995). Scholarship related to CRP can be grouped into two major bodies of research, described here as manifestations. The first of these manifestations is related to a body of work focused on the teacher's delivery of the lesson. This scholarship describes how teachers are culturally relevant/responsive in the ways in which they engage their students and how they deliver instruction. For example, this was the case in Bonner and Adams (2012) and Johnson, Myamekye, Chazan and Rosenthal's (2013) descriptions of a culturally responsive teacher, one who expressed concern for their students and connected with them through forms of communication that were familiar and empowering, especially to Black children. The second manner in which CRP is manifested, and the focus of this current scholarship, suggests that culturally relevant tenets should be implicit in the lesson plans and mathematics activities. We offer, teachers must be intentional about using liberating and empowering curricula and tasks. This is an idea that was consistent in the work of Ares (2008) who insisted that the context of the problem and nature of the interaction that were facilitated in her classroom were both deliberate and culturally relevant for a classes of predominantly Black and Puerto Rican students familiar with traffic patterns in New York.

Nevertheless, the lesson plan informs delivery and delivery informs the lesson, thus, we argue, CRP tenets should be captured within the lesson plan, the very artifact that allows for a more nuanced and deliberate portrayal of ideas, activities, and goals. The contention of this study is that PSTs are more likely to honor the pedagogy when they put preconceived thoughts into these artifacts and how the concepts connect to students' lived experiences.

Methodology

Archival data used in this study were collected by the KATE Project members in the school year 2013-2014. We developed the Mathematics Rubric for Implementing Cultural Relevance (M-RICR) to analyze 29 lesson plans designed by the PSTs in this problem-solving course, and operationalized CRP in terms of 11 indicators across the three tenets, as seen in Figure 1.

Academic Excellence	**AE1: Teacher draws on issues or contexts that are meaningful to the student.** *Possible source of evidence: Rationale for context selected*
	AE2: Teacher indicates the purpose for students learning present content. *Possible source of evidence: Teacher introduction of the problem and the rationale for context*
	AE3: Teacher utilizes students' skills and/or acknowledges and builds on their initial knowledge. *Possible source of evidence: Devision of plan and looking back.*
	AE4: Teacher uses appropriate mathematical discourse. *Possible source of evidence: Understanding the probem and extension*
Cultural Competence	**CC1: Teacher draws on or uses cultural artifacts as learning tools.** *Possible source of evidence: Questions to probe*
	CC2: Teacher includes the role of family as a knowledgeable and capable source for support and learning. *Possible source of evidence: Questions to probe and extension*
	CC3: Teacher integrates or allows recognition of students' culture and embraces it. Possible source of evidence: Understanding the problem
Socio-Political Consciousness	**SC1: Teacher encourages the students to engage in the world critically to better understand their social position, as well as others.** *Possible source of evidence: Extension, rationale for context, looking back*
	SC2: Teacher highlights multiple mathematics perspectives or approaches. *Possible source of evidence: Looking back*
	SC3: Teacher encourages critical reflection and inquisitive or open-ended thinking. *Possible sources of evidence: Extension*
	SC4: Teacher engages students in mathematics problem solving, where they identify and investigate social problems, and plausible solutions. *Possible sources of evidence:*

Content validity for this instrument was established through review by three content experts in math and CRP, and revision among research members after a pilot study. For each lesson plan,

Figure 1: M-RICR Indicators

we recorded the presence of the 11 indicators by scoring each with a 1, 2, or 3, establishing what Thompson (2006) described as ordinal data; the scores denoted no, partial, or full implementation of the indicator respectively, with the biggest distinction between a score of 2 or 3 being the explicit attention PSTs dedicated to an indicator. The sum of scores across indicators produced the final score of CRP implementation, hereafter referred to as CR Score, and thus can be identified as intervally scaled data (Thompson, 2006). The CR score depicts a continuum that the PSTs are on and how they represent the tenets of CRP as a collective whole within their lesson plans. Borrowing from the work of Lemons-Smith (2013), we utilized categories which subsumed each of the 29 lesson plans based on this CR Score. Lesson plans with a score of 15 or less were categorized as absent level of cultural relevance. Similarly, superficial, moderate, and substantive levels of implementation were based on ranges 16-21, 22-27, and greater than or equal to 28 respectively. CR categories were based on lower (CR Score=11) and upper bounds (CR Score= 33) of the M-RICR. The cutoff score for the substantive level, for example, was 28 because PSTs could achieve this score by receiving a 3 on all but approximately half (i.e., 5) of the indicators, with the remaining indicators having a score of 2. The cutoff score for the other CR categories were similarly calculated. Descriptive statistics and ratios were utilized to see trends in CR category designation. Additionally, a content analysis was used to determine the justification that PSTs provided regarding why they felt their lessons were culturally relevant, and these responses were open coded and grouped into themes (Glaser & Strauss, 1978).

Findings

Most of the lesson plans (n=18) were placed in the superficial category and only one was identified as substantive. The range for the CR scores was 16 points with the lowest CR score being a 15 and the highest being a 29. Of the 29 total lesson plans analyzed, the average CR score was a 20.4, a score that is consistent with the superficial category. Cultural competence was found to be the least implemented among the three tenets of CRP, as evidenced by lower frequencies of full implementation on the M-RICR indicators illustrating this tenet.

Data from the content analysis led to the development of four themes (i.e., familiarity, age group, for all, and real-life) depicting the PSTs' justification of their lessons as culturally relevant. Perhaps the most prevalent theme (occurring in 23 of the PSTs' lesson plans) was based on familiarity. It was common for the PSTs to suggest that their students would be familiar with the context or the items that were referenced in the problem, and thus they would have no barriers to learning the concepts. Familiarity could be conveyed among school activities, food, national issues, nature, or even resources and activities within school. The second theme dealt with age group. Many of the PSTs said that their lessons were culturally relevant for a group of middle school students. Another theme that arose was that their lessons would be applicable to most, if not all, of their students. It was common for the PSTs to state that everyone in their class would have some knowledge or familiarity with the context that was used in the problem, and thus the lessons they created were culturally relevant for ALL of their students. Lastly, it was very common for the PSTs to say that the lesson was culturally relevant because it was a problem that was related to a real-life scenario, one that could or has occurred in students' lives.

Discussion

Our findings mirror those of Lemons-Smith (2013) in that most of the PSTs' lesson plans fell into the mid-range categories. Though the categories created by Lemons-Smith have qualitative descriptors by which group membership was determined, and our CR categories are numeric based cut-off scores, there are some overlaps in what we have described as substantive lesson plans. For Lemons-Smith, a substantive lesson plan used a variety of methods, such as using students' backgrounds, their families, communities, and both lived and out-of-school experiences, to draw upon their informal knowledge and to make connections. Gladys, the only PST in this study whose lesson plan was identified as substantive, demonstrated many of these characteristics in her lesson plan. The anchor, as described in her rationale, reflected the informal knowledge that students brought into the classroom about how to use the technology she referenced in the problem, as well as the reality that some of them may not be afforded the same access to these items or even the privilege of having allowance.

We leave the reader a few thoughts about these themes which will be further articulated in a forthcoming paper. First, familiarity as described by these PSTs, may be too large of an assumption, considering familiarity may differ greatly when we consider access. Regarding theme two, the very cursory way of thinking about students in middle school does not seem to have the ability to draw in or directly highlight the *needs* of middle grades students. Thus, it is easy to disregard more thorough understandings of culture, as well as the sociopolitical consciousness that might occur among middle grades students who frequent places such as a school cafeteria. We believe the notion of "for all" to be the exact opposite of what Ladson-Billings (2006) outlined in CRP. It appears that the PSTs were on a mission to make their lessons universal and to standardize the lesson, yet the impetus behind using CRP is not to dilute it beyond any personal identification that students have with the content, the idea is that students can see themselves, their questions, their interests, and their realities within the curriculum (Ortiz, Capraro, & Capraro, 2018). Lastly, by much of the rationales that were provided in this study, the greater portion of mathematics curricula would be perceived as culturally relevant, because one need not search far to find a mathematics context which occurs in real life.

Conclusion

We began this study by insinuating that ideas of diversity and equity tend to be much more neutral conceptualizations, and that those who are seeking to become more culturally relevant in their pedagogy are less often approaching it through a racialized lens (Milner, 2018). We also argued that though not necessary to implement CRP, if the PSTs in the current study were making no ties to culture from a racialized lens, we were interested in understanding which lens or conception of culture they were targeting in their lesson plan with the mathematics problems they developed. What is revealed in this work is that researchers and teacher educators may learn a great deal from acknowledging the ways in which PSTs make sense of CRP when given the opportunity to reflect on the way they have implemented it within at least one of two manifestations. Additionally, mathematics lesson plans can and should be developed with the intention to demonstrate attention towards each of the tenets associated with the scholarship, and this may allow for more substantive lesson plans to be developed. And lastly, contexts and lessons within mathematics that devote some attention to ideas of race and racism should not be avoided for the sake of circumventing difficult dialogue (Stinson, 2017); a racialized lens may help to better serve a more nuanced understanding of this pedagogy for PSTs, particularly related to cultural competence and sociopolitical consciousness, and may serve education in ways that discussions of diversity or equity are not adequately equipped to resolve (Martin, 2019).

EXAMINING SECONDARY MATHEMATICS AND SPECIAL EDUCATION PRESERVICE TEACHERS' ENGAGEMENT IN MATHEMATICS CONSULTATIONS

Samuel L. Eskelson
University of Northern Iowa
samuel.eskelson@uni.edu

Elizabeth K. Hughes
University of Northern Iowa
elizabeth.hughes@uni.edu

We engaged secondary mathematics and special education preservice teachers (PSTs) in mathematics-specific consultations as a way to prepare to teach students with special education needs. After engaging in the consultation process, the PSTs created lesson plans and reflected on the process. We analyzed the PSTs' lesson plans and reflections for evidence they attended to issues connected to mathematical knowledge for teaching (MKT), special education knowledge for teaching (SEKT), and a synthesized blend of MKT and SEKT known as mathematics special education pedagogical content knowledge (M-SEPACK). We found that despite being asked to focus on their students' mathematical and special education needs, PSTs tended to focus on general pedagogical issues. We discuss lessons we learned as mathematics teacher educators and implications for those who wish to engage their PSTs in similar work.

Keywords: Instructional Activities and Practices, Teacher Knowledge, Equity and Diversity

Study Purpose and Research Questions

Lawmakers and writers of educational policy have pointed to the need for equitable learning opportunities for students with special education needs (SEN) for nearly three decades (e.g., Australian Disability Discrimination Act, 1992; Individuals with Disability Education Act (IDEA), 2004; UNESCO, 2009). As a result of this emphasis in educational policy, teacher preparation programs are tasked with preparing their pre-service teachers (PSTs) with knowledge and skills to meet the distinctive needs of *all* of their students. Though the call for such teacher preparation is not new, teaching special needs students has been identified by teachers in several countries as their greatest need for professional development (Schleicher, 2012).

Recently, researchers and mathematics teacher educators in four countries have begun a collaboration to jointly explore possible methods for preparing PSTs to better meet the needs of their students with SEN (van Ingen et al., 2019). Their work has focused on engaging general education elementary PSTs with special education PSTs in mathematics-specific consultations as a way to meet the needs of students with SEN. We build on and extend the work of these collaborators by engaging secondary mathematics and special education PSTs in the consultation process and reflect on the process of facilitating this collaborative experience as mathematics teacher educators (MTEs).

This paper will address the follow research question: To what extent do mathematics and special education PSTs attend to issues connected to mathematical knowledge for teaching (MKT) (Ball, Thames, & Phelps, 2008), special education knowledge for teaching (SEKT) (van Ingen et al., 2019), and a synthesized blend of MKT and SEKT known as mathematics special education pedagogical content knowledge (M-SEPACK) (van Ingen et al., 2019) during consultations? We also provide lessons learned as MTEs and implications for those who wish to engage their PSTs in similar work.

Theoretical Framework

The Case for Teacher Consultations

There are several forms of teacher collaborations, one of the most common of which is co-teaching (Mastropieri et al., 2005; Weiss, Pellegrino, Regan, & Mann, 2015). Co-teaching can take on different forms (Sileo, 2011), but a common form is when the general education teacher and the special education teacher simultaneously assume instructional roles in the classroom with the intention of supporting one another in providing inclusive education to students with SEN. While this form of teacher collaboration can be effective, many schools do not have the resources to allow for co-teaching for all students with SEN. Consultations between general education teachers and special education specialists can serve as an alternative to co-teaching to support teachers in providing learning opportunities for students with SEN, particularly when resources do not allow for instances of co-teaching.

Teacher consultations can take varying forms and can follow different models (e.g., Richards, Hunley, Weaver, & Landers, 2003; Truscott et al., 2012; Wesley & Buysse, 2004). While these models differ, they do share some common elements. We use a synthesized model of the common elements of teacher consultations (van Ingen, Eskelson, & Allsopp, 2016). This model consists of: (a) initiate rapport building, (b) negotiate consultation relationship, (c) identify the problem, (d) develop recommendations, (e) finalize recommendations and solidify plan, (f) implement the plan, (g) evaluate the plan, (h) learn from results, (i) check back, and (j) re-engage.

M-SEPACK Framework

To evaluate the focus of the PSTs' consultations and reflections on their resultant teaching, we needed to gauge the extent to which they focused on thinking specific to mathematical knowledge for teaching as well as to teaching students with SEN. To do this, we utilized the M-SEPACK Framework (van Ingen et al., 2019). This framework differentiates between MKT, SEKT, and M-SEPACK. as well as identifies multiple sub-categories within each of these types of knowledge.

Methods

Participants

The participants of this study were 34 secondary mathematics and special education PSTs enrolled in a mathematics methods course and a special education methods course, respectively, at a mid-sized regional comprehensive university in the Midwest United States. This was the second of two mathematics methods courses for the mathematics PSTs and the second of two special education methods courses for their special education counterparts.

Consultation Process

As part of their methods courses, the PSTs were also participating in field experiences in local schools. For this study, the PSTs were asked to select one or more students in their field placement classrooms who had been identified as students with SEN. They engaged in two rounds of consultations. During the first round, the mathematics PSTs selected mathematical content to be addressed in an upcoming lesson to be taught to their focus student. After identifying the target student and choosing mathematical content, the mathematics and special education PSTs met in pairs. The mathematics PST shared the information about the target student and the mathematical content to be taught. We also asked them to ask the special education PSTs questions regarding how they could best meet the mathematical learning needs of the focus student, taking into account their specific special education needs, when teaching the selected mathematical content. The special education PSTs then responded to these questions and shared recommendations and information of what the mathematics PSTs could do to best support their students in engaging with the mathematical content. Based on these recommendations, the mathematics PSTs then modified their lessons to incorporate their colleagues' suggestions. The second round of consultations worked similarly, but this time the special education PST selected a focus student with whom they would work and mathematical content they would be teaching to this student. They then considered mathematical questions to ask the mathematics PSTs regarding the lesson in order to utilize their specialized mathematical knowledge for teaching. The mathematics PSTs then provide suggestions for teaching the content of the upcoming lesson.

Data Collection and Analysis

We collected the mathematics PSTs' final lesson plans as well as their written reflections regarding the consultation process. We specifically asked the PSTs to address the following as part of their written reflections:

- What ideas, strategies, and/or content knowledge did I incorporate into my lesson as a result of the consultative session?
- What was the outcome of the lesson, specifically related to ideas, strategies, or content that you incorporated as a result of the consultative session?
- What would you have done differently?
- What are the next steps for instruction?
- What are the Big Ideas you are taking away from this collaborative experience?

We coded the data from the lesson plans and written reflections using the M-SEPACK framework noting evidence of MKT, SEKT, and/or M-SEPACK. This analysis provided us with insights regarding the focus of the PSTs' consultation meetings and the resulting impact these conversations had on the mathematics PSTs' lesson plans.

Results

Our preliminary analyses found that while the PSTs were asked to focus their consultations on the mathematical aspects of their work with the target student and their specific special education needs their consultations tended to focus on students and teaching moves more generally. The majority of PSTs' lesson plans and reflections were focused on teaching in a more general sense. For example, one mathematics PST clearly identified a specific mathematical learning goal. However, none of the provided recommendations or dialogue during the consultation were connected to that goal. Additionally, the teaching strategies that the PSTs discussed were often not specific to working with students with SEN but would be seen as effective techniques for working with all students whether or not they had been identified as having special education needs. Below are samples of evidence we coded for the various categories of knowledge.

- General Pedagogy: "making sure handouts are not overwhelming, guiding students with options, intentional grouping, and being flexible." (mathematics PST 4)
- MKT: "I made a chart on the board with the numbers 1 through 12, those numbers squared, and then those numbers cubed. I thought having a table with all of the numbers

was a good way for the whole class to see how squared numbers and cubed numbers are different." (mathematics PST 12)

- SEKT: "getting students up and moving around, especially if you have students who have ADHD. It allows them to expend some energy while still working on math activities." (mathematics PST 13)
- M-SEPACK: "my consultant advised me that it is important to clearly articulate what is being asked from what is on the board and that it is important to also provide a visual clue to go along with it as well. This looked for me like reading math word problems out loud, highlighting both vocally and physically key terms and words in the problem for students to draw equations from." (mathematics PST 10)

Discussion and Significance

While the focus of the consultations, lesson plans, and reflections was not always as targeted as we would have hoped, the PSTs, did, however, feel that the collaborative experience was beneficial for their learning as part of a teacher education program. One mathematics PST commented, "My special education group mates helped me see that by analyzing my students' needs first and then creating a lesson around them, I could reach my students much more efficiently." (mathematics PST 6). As mathematics teacher educators, we concur that the consultation process was beneficial. From this experience and study, we have found at least two key lessons for mathematics teacher educators to take into account when engaging PSTs in consultations.

It is important to have a framework in which the PSTs can ground their discussions during the consultations. The mathematics PSTs were quite familiar with the Mathematics Teaching Practices from *Principles to Actions* (NCTM, 2014). When consulting with and reviewing the mathematics lesson plan of their special education PST partner, they were asked to focus on two of the eight Mathematics Teaching Practices which they felt were most relevant to the lesson and provide the special education PST with suggestions for modifications to the lesson with respect to those two practices. For example, the math PST might focus on "implementing tasks that promote reasoning and problem solving" during the consultation by suggesting ways to modify the task so that it promotes reasoning and allows multiple entry points and varied solution strategies. The special education PSTs also had a framework with which they came to the consultation, the Curricular Adaptations Decision-Making Process (Udvari-Solner, 1996). While both sides came prepared to the consultation and a guide with focus questions was provided, we find additional specific guidance and support for structuring the consultation conversation would be beneficial.

It is also critical to ensure that all PSTs are able to engage in each component of the consultation process. Due to scheduling issues, some mathematics PSTs used previously developed and taught lesson plans to discuss with the special education PSTs. Their reflections were noticeably weaker than their peers and did not contain much evidence of SEKT or M-SEPACK.

Mathematics education and special education experts have called for more collaborative experiences during teacher preparation for both general and special education PSTs (Boyd & Bargerhuff's, 2009; Karp, 2013). This study is a response to these calls and provides valuable insight for MTEs and educational researchers as they consider how to design and facilitate these valuable experiences.

TEACHER CANDIDATES' UNDERSTANDING OF EQUITABLE MATHEMATICS TEACHING

This exploratory study aims to unpack the equitable teaching practices that teacher candidates (n=55) attribute to their undergraduate elementary mathematics methods course at a four-year research-intensive institution, in the Mid-Atlantic region of the United States. We used a multiple-case approach which included the teacher candidates' end of course surveys and final project video data of mathematics teaching. We compared teacher candidates' understandings of and intentions for using equity focused practices to their actual teaching practices at the end of the course. Our findings demonstrate the need for ongoing support for enactment of equitable teaching practices which has implications for teacher preparation and teacher induction.

Keywords: Instructional activities and practices, Equity and diversity, Teacher knowledge

When preparing elementary mathematics teacher candidates to become high-quality mathematics educators, we challenge them to take a social justice stance that requires "fair and equitable teaching practices, high expectations for all students, access to rich, rigorous, and relevant mathematics, and strong family/community relationships to promote positive mathematics learning and achievement" (NCSM/TODOS Joint Statement, 2016). We do this by embedding equitable teaching practices that foster teacher candidates' development of research-based pedagogies to support culturally, socially, and linguistically diverse students in elementary mathematics classrooms, into our math methods course. Therefore, the following research questions guided this study:

1. What features of equitable mathematics teaching do teacher candidates attribute to having learned in their equity focused math methods course?
2. Do teacher candidates who earned a level "4" code for survey question 9 provide observable evidence of the practices described in their survey responses in their final project videos?

Related Literature and Framework

This study embraces sociocultural theories of learning, which consider the construction of knowledge occurring in and out of human interactions with one another and the world around them (Crotty, 1998). Therefore, we maintain that "what is learned cannot be separated from how it is learned" (Gresalfi & Cobb, 2006, p. 50). This work also incorporates a critical perspective aimed at disrupting the conditions many students from culturally and linguistically diverse backgrounds face in their mathematics courses. As such, we attribute achievement gaps to the "adverse conditions under which some children are often forced to learn, the privileged conditions afforded to others, and how forces like racism are used to position students in a racial hierarchy" (Martin, 2009, p. 300).

Methods

Our study investigates teacher candidates' interpretation of equitable mathematics teaching practices and how they planned to implement said practices in their mathematics teaching. The study took place at a large, predominantly White, research-intensive, 4-year university where pre-service teachers apprenticed in culturally and linguistically diverse teaching placements.

Equity Focused Elementary Mathematics Methods Course

This methods course, designed[1] by the third author, helps teacher candidates develop a set of practices for teaching mathematics that promote equitable access to the content, social justice, and positive mathematics identities. First, we incorporated Math Strong activities (Aguirre, 2018, with permission) which provided teacher candidates opportunities to confront negative stereotypes that dominate discourses around teaching multicultural students (Goffney, 2018). We used literature to introduce equity focused pedagogies that disrupt these negative stereotypes and corresponding status issues. Examples of status issues include: redefining "math smartness;" assigning competence; strategically positioning/repositioning students as math smart; creating purposeful groups that are heterogeneous, establishing and assigning student roles; incorporating group-worthy tasks; providing scaffolds for multiple entry points, and eliciting and interpreting student thinking (Teaching Works, 2018; Thames and Goffney, 2019) through the use of accountable talk and talk moves (Chapin, O'Connor & Anderson, 2003; Featherstone et al., 2011; Kazemi & Hintz, 2014). This literature helped them build a repertoire of equitable teaching practices while providing clear evidence of their necessity. Through pre-service teachers' enactment of these practices in their teaching placements, we provided a space for them to develop norms and structures aimed at disrupting status issues, such as heterogeneous grouping with assigned student roles, incorporating students' first language, and using complex instruction with multiple entry points (Featherstone et al., 2011; Kazemi, & Hintz, 2014; Moschkovich, 2007, and others).

Study Participants

Fifty-five teacher candidates enrolled in our elementary mathematics methods courses during the fall semester of their senior year of their initial certification program participated in this study. The majority of the participants were white females (*n=38*), and over half of them transferred from two-year or four-year institutions (*n=35*). More than 10% of them were age 24 or older (*n=8*), and they represented a variety of racial/ethnic backgrounds (two or more races, *n=1*; Black, *n=3;* Asian, *n=8;* Latinx, *n=14*).

Data Sources

To answer the research questions, we analyzed data collected from teacher candidates at the end of the course from two different data sources. The first source was a ten question, open-ended survey that was administered online via Qualtrics software (2016) from which we analyzed the responses to one specific question: *How has this course developed my practice to teach with an emphasis on equitable teaching practices that enable culturally and linguistically diverse students to develop knowledge and skills that promote mathematical proficiency?* The second data source was video data from recordings of teacher candidates' final project, where they led a whole class mathematics discussion.

Analytical Techniques

We employed qualitative research methods, starting with open coding of the survey responses to identify features of a high-quality response. These features included the use of specific language that referenced learned equitable teaching practices and referencing how these practices support mathematics proficiency among culturally and linguistically diverse students. We developed initial ratings of responses using values between 0 and 3 and conferred about data observations and individual ratings for each response, ensuring at least 80% inter-rater reliability. Data was ranked as "0," if there was no direct response to the question, as "1," if the response incorporated equitable teaching language but provided no specific examples of equitable teaching practices, as "2," if the response incorporated equitable teaching language with examples for equitable teaching practices but made no reference to the impact they have on student learning, and as "3," if the response incorporated equitable teaching language with examples for equitable teaching practices and discussed the impact they have on student learning. In the last phase of survey data coding, each member of the team re-coded all 3s as either a "3" or a "4" based on whether the responses were well developed, including detailed, specific, and observable practices. Again, we conferred to ensure at least 80% inter-rater reliability.

After identifying the most developed, detailed, and observable survey responses, we looked for alignment between survey responses ranked as "4" and the participants' actual teaching. We created unique video coding rubrics for each participant based upon the specific observable teaching practices they attributed to learning in the course. We calculated the percentage of alignment between survey responses and observed practices for each participant.

Findings

After analyzing the survey data, we found that of the 55 total participants, only 9 earned a level 4 rating. Four of the 9 had 100% alignment between their survey responses and actual teaching, and 8 of the 9 had over 50% alignment. However, one of the 9 had 0% alignment. It is important to note that the directions for the final project required participants to consider features of equitable mathematics instruction when designing and implementing their lessons but did not include assigning participants the task of aligning their teaching with their written survey responses. In Table 1 below, we present the findings from our analyses of participants. The table includes the exact wording used by each participant in their survey response and the percentage of alignment between their survey response and their teaching in the video.

Table 1: Percentage of Alignment between Written Responses and Video

Name	Individual Codes	Alignment
Kathy	Use multiple means of expression and delivery; manipulatives & hands-on experience	50%
Rose	Make classroom environment culturally diverse and accepting; use multiple means of expression to solve problems & manipulatives	0%

Karina	Teach math vocabulary through pictures and consistency; make math problems culturally relevant; student conversation and expressive learning through language is a math tool	100%
Mary	Create an environment of respect; equitable groupings; use talk moves and accountable talk; students answer questions and participate in discussions	100%
Angela	Use consistent math language; anchor documents and sentence starters; celebrate math smarts and attend to strengthening math identities; use peer/group work with assigned roles; include context that highlights a variety of cultures; build a classroom community	60%
Pavika	Differentiate instruction; use manipulatives; support positive identities	100%
Ellen	Use different instructional formats (whole group, pairs, small groups); multiple entry points in a task; assign roles in small groups	67%
Hope	Talk about different cultures in math class; connect students' culture and lived experiences to mathematical topics/ lessons; use multiple strategies for showing math smarts	67%
Adelina	Use strategies geared toward emergent bilingual students; shared mathematical experiences; informal dialogue (with movement into formal dialogue); mathematical representations and symbols	100%

Conclusion & Discussion

During the course, many teacher candidates produced high quality work, generating responses, reflections, and other written and oral productions that indicated substantial knowledge about issues of equity, features of equitable teaching practices, and the importance of equitable mathematics instruction in supporting culturally and linguistically diverse students' math proficiency. Nonetheless, only 9 of the 55 participants earned a level 4 rating. We are interested in examining these responses in greater detail to identify trends and patterns that might be useful for instructors of future sections of this course and school districts working with new and early career teachers.

The video data was most compelling. Of the 9 lessons we watched, 8 had over 50% alignment between the survey responses and the observed practices. Although 8 of the 9 participants were mostly aligned, the number of minutes and number of actual instances of equitable teaching varied considerably among these 8 lessons. Additional analyses will more closely approximate the amount of time spent enacting equitable mathematics teaching in each of these lessons to understand degrees of sophistication among these lessons better and further refine our ideas. Surprisingly, one of the teacher candidates who earned a level 4 rating on her survey response offered no evidence of any of those practices in their lesson. We hope to expand our knowledge on what factors might influence alignment by investigating in further detail the strongest case of alignment (Mary) and the case of misalignment (Rose). We are also interested in learning more about the degree to which our observations of their teaching align with their own observations of their teaching. In conclusion, our exploratory study on the alignment between our elementary mathematics methods teacher candidates' understanding of and intentions to incorporate equitable teaching practices and their actual practices demonstrate the need for ongoing support for enactment. These results have implications for teacher induction, given that our teacher candidates were in the senior year of their four-year certification program.

Endnotes

This course was developed by Dr. Imani Goffney as a part of her NSF grant, Mathematical Knowledge for Equitable Teaching, Award No. 1725551.

SUPPORTING PROSPECTIVE ELEMENTARY TEACHERS' NON-CIRCULAR QUANTIFICATIONS OF ANGULARITY

Hamilton L. Hardison
Texas State University
HHardison@txstate.edu

Hwa Young Lee
Texas State University
hylee00@txstate.edu

In this report, we (a) describe a lesson comprising a series of research-based tasks we designed to foster critical ways of reasoning about angle measure and (b) report upon the impact of these tasks on prospective elementary teachers enrolled in a geometry content course.

Keywords: Instructional Activities and Practices, Teacher Knowledge, Geometry and Geometrical and Spatial Thinking, Angle Measure, Quantifying Angularity

Angle and angle measure are pervasive topics in mathematics curricula from elementary school through higher education. Elementary students' (e.g., Lehrer, Jenkins, & Osana, 1998) and prospective teachers' (Akkoc, 2008) challenges with measuring angularity have been documented. In contrast, few researchers have examined how to foster productive conceptions of angle measure. We view angularity as a quantity—an individual's mental conception of a measurable attribute of an object or situation (Thompson, 2011). Quantities are mental constructions that exist in the minds of individuals, and the process of conceiving a quantity is referred to as quantification. The few researchers who have examined fostering productive quantifications of angularity have advocated measuring angles by measuring circular arcs (e.g., Moore, 2013), which we refer to as circular quantifications of angularity. For example, to say an angle, A, has a measure of $n°$ means A intercepts an arc that is $n/360$ the circumference of any circle centered at A's vertex. Although productive, we do not view circular quantifications of angularity as an appropriate starting point for elementary students' angle measure instruction. In the CCSSM (2010), angle measure is explicitly addressed in Grade 4, and many elementary students cannot yet coordinate these kinds of multiplicative comparisons (Steffe, 2017), much less generalize these comparisons as holding across all possible circles centered at an angle's vertex. In this report, we (a) present a series of research-based tasks we designed to foster critical ways of reasoning about angle measure that do not necessarily rely on multiplicative comparisons of arc lengths and (b) report upon the impact of these tasks on prospective elementary teachers enrolled in a geometry content course.

Previous Research and Task Design

In our research at the secondary level, we found students can develop powerful quantifications of angularity without necessarily attending to multiplicative comparisons of circular arc lengths (Hardison, 2018); these non-circular quantifications of angularity leverage partitioning or iterating (Steffe & Olive, 2010) the interiors of angles. For example, when we asked Bertin, a ninth-grader, how to make a one-degree angle he explained, "if you get a ninety-degree angle [*gestures a right angle*], you can divide that into nine so it would be like ten degrees each and then you can divide each one of those into ten." Bertin's description for making one-degree angles did not reference circles or arcs; instead, Bertin's reasoning involved positing a right angle as a 90-unit angular composite and recursively partitioning (Steffe & Olive, 2010) the interior of this angular template to produce 90 one-degree angles within the right angle.

From working with Bertin and other ninth-graders in a teaching experiment (Steffe & Thompson, 2000) informed by the principles of quantitative reasoning (Thompson, 2011) and focused on understanding, as well as fostering, students' quantifications of angularity (Hardison, 2018), we abstracted several critical ways of reasoning about angle measure, many of which had not previously been emphasized in extant empirical literature. These critical ways of reasoning include (a) attending to the object and attribute being quantified (i.e., the openness of an angle), (b) imagining motion throughout the interior of an angle model (e.g., opening a pair of hinged chopsticks), (c) using enacted or imagined superimposition to compare the openness of angle models, (d) establishing re-presentable templates for familiar angles (e.g., bringing forth a right angle in visualized imagination), (e) positing these familiar templates as composite angular units (e.g., a right angle is a 90-degree angle), and (f) applying extensive quantitative operations to the interior of angles (e.g., partitioning or iterating) to make and measure other angles in various units, including standard units like degrees.

Based on the aforementioned findings, we designed an introductory lesson comprising tasks to engender these critical ways of reasoning about angularity for use in our geometry content courses for prospective elementary teachers (PSTs). We thought working to engender these quantifications of angularity in PSTs would be productive in two regards. First, we observed ninth-graders could productively quantify angularity in these ways; therefore, it seemed promising that the PSTs had already developed or could develop similar quantifications. Second, we viewed these quantifications of angularity as instructional goals PSTs could productively work toward fostering in their future students.

Three of the tasks from our introductory lesson on quantifying angularity are shown in Figure 1. The Chopsticks Task was designed to allow for PSTs to enact motion through the interior of angle models through opening or closing hinged chopsticks and to engage in superimposition for comparing angularity; in this task, PSTs' worked with partners, and partners had hinged chopsticks of different lengths. The Right-Angle Task (in GSP) was designed to help PSTs conceive of familiar angular templates as composite units and insert angular units into these templates. The Making and Measuring Task involved using transparency paper to engage PSTs in partitioning and iterating the interior of angles to make and measure angles.

Pilot Study and Methods

In Spring 2018, we piloted the lesson with 31 PSTs in one section of a geometry content course at a large public university in the southern United States. One month after the lesson when PSTs took their first written exam, which contained Prompt 2 shown in Table 1, we noticed many PSTs explicitly referred to at least one of the tasks as an activity they would use to help a student better understand angle measure. For example, some PSTs described opening hinged chopsticks or using superimposition with transparency paper to verify angular congruence. Having found the lesson impactful, we implemented the lesson in Fall 2018 in three sections of the geometry content course with a total of 51 PSTs. Information regarding PSTs' initial ways of reasoning about angle measure at the onset of the course was collected via a first day Introductory Questionnaire. We taught the lesson, which contained the tasks shown in Figure 1, during the 2nd and 3rd days of class. Then, we gave a first test around the 5th week of the semester and a comprehensive final exam at the end of semester. We collected data from these and other written assessments throughout the semester. In this report, we foreground PSTs responses to two prompts on the assessments summarized in Table 1. Our goal was to determine the extent to which the lesson impacted PSTs' conceptions of angle measure.

Table 1: Prompts and Written Assessment Timeline

Prompt	Introductory Questionnaire (1st day)	First Test (~5th week)	Final Exam (end of semester)
1. Without a protractor, describe how you would make a 1° angle.	X	X	X
2. [Given a picture of two congruent angles A and B with different side lengths] Erica says angle A is bigger than angle B. Make sense of her reasoning—why might Erica think this? How might you discuss angles with her? (Modified from Beckmann, 2017)		X	

Findings and Discussion

In this report, we first focus on PSTs' responses to Prompt 1 (describe how you would make a one-degree angle), which was given on each written assessment shown in Table 1. We classified PSTs responses to Prompt 1 into five categories, which are exemplified in Table 2. A response was coded as *Blank/IDK* if the PST either left the question blank or wrote something to the effect of "I don't know;" as *Unclear/Other Attribute* if the process described was unclear to us or if the PST attended to an attribute other than angularity (e.g., length); as *Comparative* if the PST provided a comparative description without inserting angular units; as *Inserting Units Undefinitively* if the PST inserted angular units into a familiar template (e.g., right angle) through partitioning but the partitioning did not produce a one-degree angle from our perspective; and *Inserting Units Definitively* if the PST inserted angular units into a familiar template and produced a one-degree angle from our perspective.

Results are summarized in Table 3. From the majority of Introductory Questionnaire responses (55%), we inferred productive elements of quantifying angularity (i.e., Comparative or Inserting Units categories); however, only 18% of the PSTs considered inserting units into a familiar angular template on the Introductory Questionnaire, and only 10% definitively inserted units to produce a one-degree angle. In contrast, after the lesson, the majority of PSTs (79% on the First Test and 93% on the Final Exam) described inserting units into familiar angular templates when describing how to make a one-degree angle. Moreover, 59% and 74% of PSTs

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

definitively inserted units to produce a one-degree angle on the First Test and Final Exam, respectively.

Table 2: Categories and Examples of PSTs' Responses for Making a 1° Angle

Response Category	Example
Blank/IDK	"I would not know how to do this accurately."
Unclear/Other Attribute	"You would have to try to make it how you would think it looks and then label it."
Comparative	"I would make one horizontal line and start another line at one point going BARELY above horizontal."
Inserting Units Undefinitively	Inserting Units Definitively	
Table 3: PSTs' Responses for Making a 1° Angle Across Assessments

Response Category	Introductory Questionnaire	First Test	Final Exam
Blank/IDK	22%	4%	0%
Unclear/Other Attribute	22%	4%	6%
Comparative	37%	12%	0%
Inserting Units Undefinitively	8%	20%	19%
Inserting Units Definitively	10%	59%	74%

In their responses to Prompt 2 on the First Test (Table 1), over a third of the PSTs suggested enacting superimposition to verify angular congruence or suggested using motion throughout the interior of hinged chopsticks to help Erica understand angle measure. For example, one PST responded, "A way to discuss this problem with Erica would be to create a transparency of both angles and overlap the two to show they are equal and that the length of the rays have little to do with their degree measurement." Another PST responded, "…I would also demonstrate using different lengths of chopsticks, overlapping them to show their angle of rotation is the same." We took such responses as indications that the tasks may have impacted PSTs' future pedagogical actions in addition to influencing their quantifications. Looking across the assessments, we found the lesson had a productive impact on our PSTs' quantifications of angularity during the semester. In particular, these tasks supported PSTs' development of productive ways of quantifying angularity without foregrounding multiplicative comparisons of circular arc lengths. Further work is needed to investigate the permanence of the modifications

PSTs made in their ways of reasoning and what role, if any, these modifications play when PSTs enact future lessons on angle measure. In closing, we recommend educators (a) encourage non-circular quantifications of angularity by implementing tasks like those presented here and (b) celebrate individuals who develop non-circular, as well as circular, quantifications of angularity.

QUANTITATIVE REASONING WITH TRANSFORMING FRACTIONS

Eun Jung
University of Georgia
eunjung@uga.edu

The question of preservice teachers' knowledge of fractions warrants further investigation, since having a firm grasp of the different interpretations of fractions is a challenge for both students and preservice teachers. This study seeks to investigate the understanding of ten preservice teachers' of quantitative reasoning with fractions in the context of measurement division by making use of task-based clinical interviews. The results showed that preservice teachers' construction of different levels-of-units structures plays a crucial role in their reasoning regarding measurement division. The study shows that only the participant who constructed a unit-of-units-of-units structure understood measurement division tasks involving fractional quantities conceptually as the transformation of one quantity to another quantity.

Keywords: Cognition, Teacher knowledge, Rational numbers, Teacher education-preservice

In the past few decades, a growing number of mathematics education researchers—particularly those who hold to a constructivist theoretical framework—have approached students' construction of fractional knowledge in terms of schemes and operations. Students require not only the construction of fractional schemes but also the flexibility of interpreting fractions differently depending on their mathematical contexts. Since then, substantial research has further emphasized that there are multiple interpretations of fractions (e.g., Kieren, 1976; Behr et al., 1993, 1997), and numerous books have been written reflecting this point of view on teaching rational numbers (e.g., Charles & Zbiek, 2010; Lamon, 2012). Major work has been done studying the subconstructs of rational numbers (see Behr et al., 1993; Behr et al., 1997; Kieren, 1976), and this research has led to the division of rational numbers into the subconstructs of part-whole, ratio, quotient, measurement, and operator.

Different researchers have spoken of the operator role of fractions from various angles and with differing nuances. A few studies have already addressed some of the many factors that may be considered in regard to understanding fractions as an operator. Among these, some have dealt with students' algebraic reasoning (Hackenberg, 2010, 2013; Lee & Hackenberg, 2014), finding that only those students who had constructed the third multiplicative concept could use fractions as multipliers. At least two empirical studies have dealt with teachers' limitations in using fractions as an operator (Behr et al., 1997; Izsák, 2008), addressing the subject in the context of fraction multiplication. Few researchers have investigated teachers' and preservice teachers' limitations in conceptually understanding fractions as an operator (e.g., Behr, 1997; Ball, 1990; Ma, 1999), and still fewer researchers have investigated the underlying cognitive factors behind these limitations (e.g. Izsak, 2008). The current study concerns itself primarily with the former question, although with an eye toward the underlying cognitive factors as well (to the extent that the data and its analysis may offer insight in this area). In my usage, constructing fractions as operators requires that a student can abstract the operation involved in using a fraction as a "multiplier," and can on at least a conceptual level anticipate the outcome, if not the precise output of the operation, without first having to perform the mental operation itself. A measurement division task in this paper involving the transformation of one fraction into another fraction was designed to investigate preservice teachers' use and understanding of fractions as operators.

Quantitative Reasoning with Fractions

The Recursive Partitioning Operation

A recursive partitioning situation involves a partition of each part from another partition. When a child is asked to produce, say, one-third of one-seventh from a unit bar, and to determine the size of the result in terms of the unit bar, he or she can engage in the task in such a way that partitions the unit bar into seven parts, pulls one out of the parts, partitions this part into three parts, pulls one out of these parts, and determines that the part he pulled out is one twenty-first of the unit bar because he understands that partitioning one of the seven parts into three parts implies partitioning each of the seven parts into three parts without implementing the partitioning.

The Parts-within-wholes Fraction Scheme

The operation that involved this fraction scheme is only a partitioning operation, and a disembedding operation is not available for a child who has constructed this fraction scheme, which means that he or she cannot mentally take out parts from the whole without destroying the whole.

The Iterative Fraction Scheme

Children who have constructed the iterative fraction scheme use an operation that enables them to produce three levels of units to understand improper fractions, such as eleven-ninths. As a result, children comprehend that eleven-ninths is a composite unit containing a fractional whole (nine-ninths) and two-ninths and that each ninth of the eleven-ninths is both a part of the fractional whole and independent of the whole as well.

Research Design

The present research is designed to address the following questions: How does a middle grades preservice teacher reason with measurement division quantitatively?

1. What can her reasoning with measurement division reveal about her construction of fractional knowledge?
2. What is the nature of her struggles with measurement division tasks?

The study uses a case study design, examining how situations involving fraction division are represented (e.g., with drawn models, double number lines, etc.) by a preservice middle grades mathematics teacher in a mathematics education department at a major public university located in the southeastern United States. The primary data source is a series of clinical interviews conducted over the course of two semesters using 10 volunteer participants from a mathematics methods course. More specifically, data was collected through hour-long, one-on-one interviews as well as classroom observation notes and homework submissions.

Data Excerpts

I will present three of the 10 preservice teachers who participated in the study: Cassie, Jordan, and Morgan. The tasks used for this study were making a 1/4-bar using a 1/3-bar, a 1/4-bar using a 3/5-bar, and 1/5-bar using a 7/4-bar.

Task. How could you use a one-third bar to make a one-fourth bar?
Make a bar, and leave it on the left side of the screen. Copy the bar, and leave it on the right side of the screen. Make one-third of the right bar. Make one-fourth of the right bar. What could you do to the left bar to make it resemble the right bar?

The given task was how to use 1/3 of a bar to make 1/4 of a bar**.** Students use the computer program Java-bars, which allows students to make a bar, partition it, pull out a segment, and iterate it. Though not every three student coordinated three levels of units, they were able to state the size of a bar in terms of another given bar – if A is a 3-part piece and B is a 5-part piece, they would know A is three-fifths of B, and B is five-thirds of A – and also know that the numerical result of seven divided by five is seven-fifths.

Morgan used the 1/12-part as a co-measurement unit of both bars, and made a 1/4-bar by pulling out one part of the 4/12-bar and repeating it twice.

M: Okay. If I wanted to use one-third of the bar, of this bar, to make one-fourth, I would have to do, they have to be, okay. So, I have one-third and one-fourth, I think of making them into twelfths and making both unit bars into twelfths. So what I would do here [3/3-bar] is I would partition it from left to right four times [partitions each part of the 3/3-bar and the 1/3-bar into four parts horizontally] and what I would do here [4/4-bar] is partition it left to right three times [partitions each part of the 4/4-bar and the 1/4-bar into three parts horizontally].

Figure 1: Partitioning Each 1/3 into Four Parts and Each 1/4 into Three Parts

M: So that I know that at the end even though they're shaped differently, because I use the copy part of it, I know that really I just have to have one-fourth of this bar [the left 12/12-bar] just because they're shaped differently. I need for here, I had, this is one-twelfth, two-twelfths, and three-twelfths [indicates each part of the first column of the right 12/12-bar]. So that is three-twelfths, and that is equivalent to one-fourth. So here I have one-twelfth, two-twelfths, three-twelfths, four-twelfths [indicates each part of the 4/12-bar] and that's equivalent to one-third. So then I would pull this out [pulls out the first part of the 4/12-bar], and I would repeat it [copies it twice, resulting in making a 3/12-bar], so now right here [changes the color of the 3/12-bar from red to blue] is three over twelve, which is equivalent to one-fourth. So, yeah.

Figure 2: Pulling Out Three Parts from the 4/12-bar to Make the 1/4-bar

In sum, Morgan created a unit bar, copied it, and then pulled out one-third and one-fourth from each bar by partitioning two unit bars vertically into three parts and four parts, respectively, and pulling out one part from the 3/3-bar (the unit bar) and from the 4/4-bar (the copy of the unit bar). When she was asked to make the 1/4-bar using the 1/3-bar, her immediate response was to construct "a similar unit," one-twelfth. She partitioned each part of the 3/3-bar and the 1/3-bar into four parts horizontally, resulting in making a 12/12-bar and a 4/12-bar, and then partitioned each part of the 4/4-bar and the 1/4-bar into three parts horizontally, resulting in making a 12/12-bar and a 3/12-bar. Morgan counted the number of 1/12 parts in the 4/12-bar (originally the 1/3-bar) and in the 3/12-bar (originally the 1/4-bar). She then pulled out one part from the 4/12-bar and repeated this twice to make the 1/4-bar.

Discussion

Cassie only constructed a part-in-fraction scheme, which means that she could make sense of fractional parts in the fractional whole, but could not pull out the parts from the fractional whole without mentally destroying the whole. Thus, she could not discern the relationships among the fractional wholes and the parts she pulled out, the 1/3-bar and the 1/4-bar, from the identical fractional wholes. She tried to directly compare the parts, the 1/3-bar and the 1/4-bar, without referencing the wholes by using trial-and-error. Even when she pulled out three-fourths of the 1/3-bar, Cassie did not anticipate that three-fourths of one-third of the unit bar is the same as one-fourths of the unit bar. Only after determining the size of the two fraction bars to be the same through visual comparison could she explain why they were the same by using her procedural calculation of simplifying three-fourths of one-third, rendering it as one-fourth.

Jordan understood that the co-partition of two fractions can transform one fraction into another fraction. Jordan had constructed the operation to produce a two-levels-of-units structure, meaning she still needed to engage in an activity to conduct a recursive partitioning operation to figure out the result of her partitioning, rather than anticipating the result prior to the task. After solving the first task in thirty minutes, Jordan was able to solve the next task, making a 1/4-bar using a 3/5-bar, by using the result from the previous task and conceptualizing a 1/20-bar as the co-partition of one-fourth and one-fifth and partitioning the 1/5-bar into four parts rather than twenty. However, Jordan had not constructed an iterative fraction scheme and could not implement the reasoning she used to solve the previous task to solve the problem involving an improper fraction, making a 1/5-bar using a 7/4-bar, even though the structure of this task is the same as that of the previous two tasks she had solved correctly.

Morgan partitioned the 1/3-bar and 1/4-bar horizontally into fourths and thirds, respectively, resulting in the construction of differently shaped 1/12-bars from those two bars. However, her construction of a recursive partitioning operation allowed her to be able to determine the size of both parts, one part being one-third of one-fourth and the other being one-fourth of one-third, with both being one-twelfth. When moving on to the third task, making a one-fifth bar using a seven-fourths bar, her construction of an iterative fractions scheme and an equipartitioning scheme of connected numbers allowed her not only to anticipate the number of parts needed to partition the one-fourth bar and the one-fifth bar into fifths and fourths to find the co-partition of two bars, but also to determine the fraction of the seven-fourth bar that the one-fifth bar is.

Conclusion

To carry out these measurement division tasks successfully, prior to a given activity, preservice teachers need to construct various fraction schemes involving the splitting operations for connected numbers and the recursive partitioning operation. To help preservice teachers like Cassie and Jordan, we need to provide appropriate tasks so that they can engage in fractional operations—a disembedding operation for Cassie, and a recursive partitioning operation and for Jordan.

These findings may guide further research that could shed additional light on the construction of fractional reasoning, both in preservice teachers and in primary school students. Considering the foundational importance of being able to understand fractions as operators and transforming one fraction into another, at minimum we need to ensure that preservice teachers have a strong grasp of this fundamental fractional concept in order to teach middle school students effectively.

STEPPING UP INSTEAD OF STEPPING OUT TO TEACH ELEMENTARY MATHEMATICS DESPITE EXPERIENCES OF MATHEMATICS ANXIETY

Kathleen Jablon Stoehr
Santa Clara University
kstoehr@scu.edu

Keywords: Teacher Education-Preservice, Elementary School Education, Affect, Emotions

Mathematics educators agree that elementary teachers should possess confidence and competence in teaching mathematics (Beilock et al., 2010; Gresham, 2018). Yet many preservice teachers (PSTs) pursue careers in elementary teaching despite personal repeated experiences of anxiety when asked to learn or do mathematics or when asked to teach mathematics (Olson & Stoehr, 2019). This study analyzes how elementary PSTs who experienced mathematics anxiety (MA) during their K-12 years began to think about coping strategies to combat MA as they prepared for teaching mathematics in their future classrooms.

The participants were seventeen PSTs who were enrolled in a twenty-week elementary mathematics methods class. The PSTs selected for this study wrote a mathematics autobiography that spoke clearly about feelings of MA they experienced while learning mathematics. Other data sources included reflections written after course assignments, and a prompt that specifically asked PSTs to share how they would teach a mathematics lesson that created anxiety for them.

An iterative analysis (Bogdan & Biklen, 2006) of the data was performed followed by an emergent coding scheme (Marshall & Rossman, 2006) to demarcate the words and phrases that pertained specifically to MA in learning mathematics and teaching mathematics. Narratives within transcripts and text passages that included key words specific to MA, mathematics teaching anxiety, and possible coping strategies for dealing with mathematics teaching anxiety were identified. Analytic memos (Maxwell, 1996) were written to summarize key patterns.

Findings of the study revealed the types of coping strategies PSTs who have encountered MA while learning mathematics considered utilizing when confronted with teaching a content area that created anxiety for them. Examples included acting confident, reviewing the lesson standards, backwards mapping the lesson, asking other teachers, the mathematics coach or people outside of education for help, asking students to explain the content, being honest with students when feeling unsure, and knowing mistakes will happen and embrace them.

MEASURING CHANGE IN PRESERVICE TEACHERS' MATHEMATICS MINDSETS

Alexa W.C. Lee-Hassan
University of Illinois at Chicago
aleeha2@uic.edu

Keywords: Preservice Teacher Education, Measurement, Affect, Emotion, Beliefs, and Attitudes

Introduction

Research indicates that a teacher's fixed, deficit mindsets about their own mathematical abilities (Beilock, Gunderson, Ramirez, & Levine, 2010) and their students' abilities (Horn, 2007; Wilhelm, Munter, & Jackson, 2017) can undermine their attempts to support conceptual understanding and student equity. A key challenge for fostering change in teacher mindsets is that current tools treat the concept categorically—individuals are sorted as having fixed, growth, or neutral/unclear mindsets, ignoring the potential for gradations within categories. Thus, shifts in mindsets are invisible unless they cross category boundaries. This study proposes that measuring mindsets on a continuum is a more productive perspective when researching mindset change. Pre-service teachers (PSTs) completed surveys at the beginning and end of one of their first education courses, and a unidimensional Rasch model was used to rank questions and participant responses along a continuum: strength of fixed mindset.

Methods

The data used in these analyses were collected from 57 undergraduates enrolled in two sections of a mathematics content course for PSTs. The PSTs answered eleven multiple-choice questions adapted from the established mindset literature (Rattan, Good, & Dweck, 2012; Yeager et al., 2016), and three related, open-ended questions. The multiple-choice questions were fitted to a longitudinal Rasch model. Open-ended survey responses were analyzed using frame analysis to supplement the quantitative analysis.

Preliminary Findings and Implications

The Rasch analysis showed that both the survey questions and the PST mindsets could be mapped onto continuums, but there was a mismatch between the ranges of the two distributions. Almost all of the PSTs disagreed or strongly disagreed with almost all of the questions, especially the questions drawn from Rattan, Good, and Dweck (2012) which asked about a hypothetical struggling student. The misalignment could be ascribed to a difference in participant population—the 2012 study focused on graduate student teaching assistants, who may have had different attitudes towards teaching than the current study's PSTs. This explanation is supported by Gutshall (2014) in which almost all of the PST participants had growth or neutral mindsets, especially when considering a hypothetical student. This finding could indicate that the PSTs in the current study all have growth mindsets. Some of the PSTs' qualitative responses, however, echo fixed beliefs expressed by teachers in Horn (2007) and Wilhelm, Munter, and Jackson (2017), which indicates that they may hold fixed beliefs not addressed by the multiple-choice questions. Future work will examine whether adding questions based on those beliefs will result in a survey that better measures the range of PST mindsets.

PROSPECTIVE SECONDARY MATHEMATICS TEACHERS PROPOSED IDENTITIES AS ENACTED IN IMAGINED DISCUSSIONS

Eric Siy
University of Georgia
ericsiy@uga.edu

Jonathan Foster
University of Georgia
fosterjk@uga.edu

We describe the results of an analysis of how prospective secondary mathematics teachers imagine discussions play out and argue that imagined discussions are illustrate their identities. We found four roles they imaged a teacher may enact in discussion around tasks. This provides ways prospective teachers think about their identities as teachers prior to field components.

Keywords: Instructional Activities and Practices, Teacher Knowledge

Teacher education programs (TEPs) provide experiences where prospective teachers (PSTs) negotiate their identities or roles and enact them in interventions such as coursework and student teaching. In this report, we focus on an intervention where PSTs imagine a classroom discussion. Crespo, Oslund, and Parks (2011) argued using such interventions provides insight into PSTs' "developing mathematics teaching practice that would not have been possible to gain with other and more typical forms or representations" (p. 130). We present results from an analysis aimed at characterizing PSTs' identities as inferred through their practice in hypothetical situations. Although teacher educators may want to provide more "authentic" experiences (e.g., student teaching, field experiences), solely relying on or overplaying these experiences may "[interfere] with the opportunity to learn. Being situated in a classroom restricts attention to the sort of teaching underway in that particular class" (Ball & Cohen, 1999, p. 14). The data were collected from ten PSTs in a methods course in a TEP geared towards certifying mathematics teachers to teach grades 6-12. We collected two sets of assignments where the PSTs anticipate discussions based on prompts (Crespo et al., 2011). Based on their responses, we identified four roles as described below where there are two sub-roles within the second role.

1. **Teacher as the Source of Mathematics.** We found some PSTs placed the teacher's role as the thinker and doer of mathematics and the student's role is to question the teacher.
2. **Teacher as a Connector.** We found PSTs positioned the teacher's role as a presenter of data in order to make connections. We identified two sub-roles. First, the PSTs explained the teachers' actions of introducing new data was to "establish some common ground" or relate to or connect student's previous understandings. The teachers presented ideas they identified something they assume has been taught in the past. Second, some wrote about teachers presenting data in the form of an algebraic pattern meant to be generalized.
3. **Teacher as a Facilitator.** We found PSTs positioned the teacher's role as a facilitator of conversation between students where the main role was to elicit student thinking and select a focus to press student thinking.

Engaging PSTs in the activity of imagining how a conversation provides teacher educators to glean how PSTs view a teacher's role (c.f., Cooney, Shealy, & Arvold, 1998) We provided some ways PSTs positioned the teacher's role, and thus their identity, in discussions with students. Largely, the PSTs demonstrated a capacity to respond to student thinking and facilitate discussion. We note the PSTs' rationale for guiding the students are well-intentioned We note that although these discussions are not "authentic," we show that PSTs identities as mathematics teachers, for the most part, align with their images of "good" teaching and that the onus of expanding and reinforcing these images lie in the judicious selection of experiences mathematics teacher educators choose to provide.

ON THE JOURNEY TOWARDS EQUITY-BASED TEACHING: PRESERVICE TEACHERS' PERSPECTIVES ON GOOD MATHEMATICS TEACHING

Naomi Jessup
Georgia State University
njessup@gsu.edu

Latisha Jones
Georgia State University
ljones130@student.gsu.edu

Keywords: Teacher Education-Preservice, Equity and Diversity, Teacher Beliefs

Equity-based mathematics instruction is supported by policy documents and national reform efforts that includes responsiveness to students' backgrounds, experiences, and cultural knowledge (NCTM, 2008; 2014). Also, the Standards for Preparing Teachers of Mathematics (Association of Mathematics Teacher Educators, 2017) calls for preservice teachers (PSTs) to question practices that produce inequities for students' learning experiences and outcomes. These efforts recognize the importance of attending to students' identities and power dynamics within mathematics classrooms (Nasir, 2016) that are at the core of "good" mathematics teaching.

Good mathematics teaching that is equity-based ensures diverse students have access to the tools and resources needed to engage in high quality mathematics and rigorous curriculum which in turn provides measurable improvements in student achievement, classroom participation, and participation in the math pipeline (Gutiérrez, 2009). Additionally, good mathematics teaching attends to the cultural and linguistic identities of all students and power dynamics that shape children's mathematical identities and learning opportunities (Gutiérrez, 2009).

Promoting equity-based teaching notions of good teaching requires intentionality in methods course experiences. PSTs are encouraged to develop classroom environments where children can participate equitably (Yeh, Ellis, & Hurtado, 2016), challenge the traditional narrative of what it means to be good at math (Crespo & Featherstone, 2012), and critically examine inequities that shape the expectations, interactions, and the kinds of mathematics students experience (Battey & Leyva, 2016; Martin, 2006; Nasir, 2016). However, in planning meaningful experiences that propel PSTs on a journey towards equity-based teaching, little is known about PSTs perspectives towards good mathematics teaching and what it means to be a good math student. This study sought to understand PSTs perspectives on good mathematics teaching that attended to notions of equity-based teaching.

EXAMINING OUR QUESTIONS: DIFFERENCES IN RELATIONAL QUALITIES BETWEEN MATHEMATICAL AND PEDAGOGICAL QUESTIONING

Alyson E. Lischka
Middle Tennessee St. Univ
Alyson.Lischka@mtsu.edu

Signe E. Kastberg
Purdue University
skastber@purdue.edu

Susan L. Hillman
Saginaw Valley St. Univ
shillman@SVSU.edu

Keywords: Instructional Activities and Practices, Preservice Teacher Education

Questioning is a core practice in teaching that has been closely examined in the teaching of mathematics (e.g., Davis, 1997; Nicol, 1998; Parks, 2010), but is less closely examined in the teaching of teaching (Loughran, 2007). Because questioning in a mathematics methods class serves as an opportunity for prospective teachers (PTs) to learn from the instantiations of questioning practice (LaBoskey, 2007), examination of the questioning of mathematics teacher educators (MTEs) can lead to improving the practice of instructors and the experiences of PTs.

We work within self-study methodology, which is improvement aimed (LaBoskey, 2007) and characterized by openness, collaboration, and reframing of perspectives and ideas (Samaras & Freese, 2009). We explore our methods questioning practice through the lens of relational practice (Kitchen, 2005a, b) and examine ways our questioning contributes to relationships between MTEs and PTs. We take as a question any statement made by the instructor which generates a response from PTs (Dillon, 1981). We previously characterized our questioning according to the assumptions (Dillon, 1990) existing in our questions (Kastberg, Lischka, & Hillman, 2019). Building on that work, we explored differences between MTE's questions asked in teaching about learner's mathematical ideas and those asked in teaching about pedagogical ideas to explore: *What differences exist in our questioning as relational practice when the focus of the questioning situation is learners' mathematics versus teaching about teaching?*

Data gathered from this study include transcripts of audio recordings gathered during one semester of methods classes of each of the three authors along with recordings of our conversations in which we discussed our questioning in those classes. Analysis of our questioning across three different contexts, in which we coded our questions according to the Dillon (1990) framework and according to a relational teacher education framework (Kitchen, 2005a, b), resulted in findings of differences in MTEs' attention to and use of experiences of coming to know about learner's mathematics and mathematics pedagogy.

Two excerpts in Signe's data, drawn from the same lesson in October 2018, exemplify the differences we have found across our data. When questioning PTs about the mathematics in a video excerpt, Signe accepted and used PTs' ideas about learners' conceptions of mathematics (e.g. interpretations of the equal sign) to facilitate discussion of concepts. Signe did not reveal the complexity of her own process of coming to know about learners' mathematics. In contrast, within the same lesson, Signe shifted to a pedagogical discussion of giving written feedback in which she revealed her insecurities about and ongoing process of learning to give feedback. Signe further asked PTs for their advice about her feedback practice. Signe's mathematics focused questioning episodes were informed by her experience of becoming an MTE, but not revealing of that experience. In contrast, her experience of becoming an MTE was explicitly shared in pedagogical focused questioning episodes. Pedagogical episodes were longer and contained evidence of building relationships in the way Signe shared her ideas and the ways PTs responded to the discussion. We posit that MTEs' attending to and using their experiences of coming to know in mathematics and in pedagogy can mediate relationships with PTs.

TEACHERS MAKING MANIPULATIVES TO PROMOTE PEDAGOGICAL CHANGE

Jessica Davidson
Montclair State University

Keywords: Instructional Activities and Practices, Teacher Knowledge, Technology

Preservice elementary teachers have been characterized as coming to teacher preparation with a model of mathematics teaching that is not consistent with a pedagogy that supports learning mathematics with understanding. Consequently, they must be provided with opportunities that challenge this model. In this proposal, we present an investigation into a *Making-oriented experience* that tasks prospective mathematics teachers (PMTs) with designing, fabricating, and evaluating new manipulatives for use in teaching. We addressed the following question: *What forms of knowledge can be brought to bear on prospective elementary teachers' design activity as they Make new manipulatives to support the teaching and learning of mathematics?*

Constructivism and *constructionism* (Harel & Papert, 1991) frame this study and conjure an image of how learning works as one experiences it in the context of constructing a shareable artifact. In addition, we draw from the teacher knowledge literature (Ball, 1990; Borko & Livingston, 1989, 1990; Hill, Ball, & Schilling, 2008; Koehler & Mishra, 2009; Mishra & Koehler, 2006; Shulman, 1986) to characterize knowledge that might be brought to bear on PMTs' design work. Then, we take a *Learning by Design* approach (Koehler & Mishra, 2005) to advancing this knowledge by engaging PMTs with the task of designing manipulatives that are hypothesized to support learners' abstractions (Piaget, 1970; Pratt & Noss, 2010) of mathematical concepts from concrete tools.

The study took place in a specialized mathematics content course for prospective elementary teachers. Twenty-six students participated. The data consists of three written components, an "Idea Assignment," a "Project Rationale," and a "Final Research Paper." We took a case study approach (Yin, 2009) to analyzing this data, with purposeful sampling (Patton, 2002) to identify design cases whose reflections provide evidence of multiple layers of mathematical detail, knowledge of student thinking, or the use of technology during the project.

Harnessing the case study's virtue for evoking "images of the possible," (Shulman, 2004, p. 147), a poster session would provide an ideal venue for offering conference participants the opportunity to interact with the PMTs' 3D-printed manipulatives, and for sharing the narrative we crafted of Casey and Mia, who developed a tool called *Minute Minis*. Their narrative demonstrates how they drew on a breadth of knowledge domains to articulate the mathematical richness underlying their manipulative and the support it could provide a child to makes conceptual connections between a clock face and its underlying area properties as representations of fractions.

As researchers exploring how design experiences might catalyze new possibilities for pedagogical and curricular change, we positioned PMTs as knowledgeable designers of instruction in a space of technological possibilities. As PMTs assumed the multi-faceted role of teachers designing with technology, they created powerful and innovative tools, and their work demonstrated a rich and mature repertoire of knowledge domains that we are not typically afforded opportunities to see (AMTE, 2013). We propose that the identification and advancement of this knowledge, which is essential to effective mathematics teaching, suggest the promise of a Making experience within mathematics teacher preparation.

CHANGES IN ELEMENTARY PRESERVICE TEACHERS' UNDERSTANDINGS OF MATHEMATICAL PRACTICES AFTER AN APPROXIMATION OF PRACTICE

Christina Koehne
Texas State University
crz7@txstate.edu

Keywords: Teacher Knowledge, Instructional Activities and Practices, Informal Education

Quality classroom experiences centered around professional practices are essential for teacher education (Ball & Forzani, 2009; Grossman et al., 2009). However, the complexity of the classroom must be considered when introducing preservice teachers to such an experience (Doyle, 1977)), because preservice teachers (PSTs) do not focus on salient events, classroom practices, or student understanding unless taught about the events and practices on which to focus (Star & Strickland, 2007; Sherin & Han, 2004; Sherin & van Es, 2005; Jacobs, Lamb, & Philipp, 2010). Therefore, in working in a two-week summer math camp (MathKidz) for elementary and middle school students and professional development (PD) that focuses on and supports certain teaching practices, PSTs receive a unique opportunity that prompts them to view and explore these teaching practices.

National policy documents such as *Standards for Preparing Teachers of Mathematics* (AMTE, 2017), *Principles to Action* (NCTM, 2014), *Principles and Standards for School Mathematics* (NCTM, 2000), and *Common Core State Standards for Mathematics* (CCSSM, 2010) have listed various key teaching practices that every teacher, including novices, should be familiar with before entering the classroom. Several of these practices align with the *Guiding Principles* that MathKidz curriculum values. Thus, this poster will focus on elementary PSTs' noticing of the practices of supporting students' justification, the use of multiple representations, student autonomy, allowing students to make and self-correct errors, use precise language, and develop perseverance in problem-solving after their involvement in MathKidz.

Three elementary preservice teachers (ePSTs), each with 1, 2, or 3 years of experience with MathKidz, participated in a research study regarding their views, implementations, and justifications for supporting these practices. After the first day of camp, before the professional development seminar, the ePSTs responded to a written survey about their views and values of each teaching practice. At the end of the study, the ePSTs participated in a clinical interview involving four video tasks centered around these practices. During the tasks, the ePSTs were asked to comment on what they noticed in the videos and how the teacher supported the students. My analytic framework grounded on a corpus of research regarding these practices was then applied to the ePSTs responses. Examples of this will be presented on the poster. In applying the framework, I found that some categories of the framework remained unmentioned by some of the ePSTs, which could potentially mean that the ePST was not considering certain connections or moves when operationalizing and defining the practice. In addition, the ePSTs reviewed their pre-surveys and commented on how their knowledge of the practices had been changed.

This poster will report on the initial understanding of ePSTs views regarding the practices mentioned here, as well as their views and understandings of the practices after implementing and reflecting on them during a two-week summer math camp. This poster will highlight and match the relationship of the ePSTs initial and changed understandings to my framework definitions and categorizations operationalized in this study.

REHEARSALS AS A PLANNING TOOL IN PRESERVICE TEACHER PREPARATION

Robert J. Matyska, Jr.
Indiana University
matyskar@iu.edu

Keywords: Instructional Activities and Practices; Teacher Education-Preservice; Teacher Knowledge

It is a widely-accepted truth that quality teaching unlocks greater opportunity for all students to learn mathematics (Arbaugh, 2010). Professional knowledge and beliefs about teaching and learning are key components that determine a teacher's practice; fostering the development of this practice is a central component of teacher preparation (Ball & Forzani, 2009; McGraw, 2010; Stigler & Hiebert, 1999).

The heart of this work involves identifiable elements known as core practices that are connected to the aims of learning and consist of "strategies, routines, and moves that can be unpacked and learned by teachers" (Grossman, Kavanagh, & Pupik Dean, 2018, p. 4). This study targets one approximation of practice in preservice teacher education known as the rehearsal, a robust teacher education pedagogy for supporting novice teacher learning and practice (Grossman et al., 2009; Kelley-Petersen et al., 2018).

This study is guided by two research questions:

1. How do preservice teachers learn to launch lessons?
2. How are representations and approximations of practice useful in developing practice?

This poster will present findings from tasks stemming from a semester-long methods block taken by undergraduate students in an initial-licensure program. Comprised of three components—a course on middle-school mathematics methods, a supporting seminar course, and a field-based observation and teaching experience—novice teachers utilize the Lesson Planning Protocol (Smith, Steele, & Raith, 2017) and develop skills in establishing lesson goals, defining essential questions, and designing instructional activities targeting ambitious teaching (Lampert, et al., 2013). A typical lesson is designed in three phases: a launch, an exploration, and a summarizing discussion. Launches are targeted for rehearsal because they are seen as moves that can be unpacked and mastered by novice teachers, occur with high frequency in teaching, and have the potential to support both student and teacher learning (Grossman, Hammerness, & McDonald, 2009). Following the rehearsal, the preservice teachers enact their lesson as a component of their field experience in a local middle school classroom; after a debriefing session with the teacher educator/researcher, a written reflection by the preservice teacher completes the process.

Data sources include preservice teacher lesson plans, video recordings of the rehearsal session and ensuing discussion with peers, a second recording of the enactment in the field, the written reflection, and a one-on-one follow-up interview at the end of the semester to gain insight into the perceived usefulness of the rehearsal process in developing competency as a classroom teacher.

REFLECTION AS A TOOL FOR ENHANCING SELF-EFFICACY IN ELEMENTARY MATHEMATICS PRESERVICE TEACHERS

Brooke Becker
University of Northern Iowa
bkbecker@uni.edu

Keywords: Teacher education-preservice; Instructional activities and practices; Affect, emotions, beliefs, and attitudes

Although student-centered mathematics instruction, enhances students' deep understanding of mathematics (NCTM, 2014), many teachers fail to implement this approach due to the unexpected challenges they face and inability to overcome them (Marbach-Ad & McGinnis, 2009). One reason it may be difficult for teachers to shift towards student-centered instruction may be related to their teaching self-efficacy. Higher self-efficacy may increase the likelihood that teachers will implement student-centered instruction and try new strategies (Temiz & Topcu, 2013; Zee & Koomen, 2016). Wyatt (2016) emphasizes the importance of reflection in the development of teacher self-efficacy in that encouraging reflection in teachers may indirectly increase their use of student-centered mathematics instruction by increasing their self-efficacy. The purpose of this study is to investigate the effects of an intervention targeting preservice teachers' (PSTs') reflection with the intention of enhancing their mathematics teaching self-efficacy.

Research Questions and Methods

This qualitative action research study is guided by the following research questions: What is the nature of PSTs' reflections on mathematical tasks as they as they engage in the use of prompted reflection focused on students' understanding of mathematical content? How does PSTs' mathematics teacher self-efficacy change after the implementation of prompted reflections focused on students' understanding of mathematical content?

The intervention took place during an eight-week mathematics methods course in a small, Midwestern university with seven elementary PSTs. PSTs' engagement in reflection was measured through written responses to video prompts focused on student understanding and the role the teacher plays in this development. Reflection responses to videos, open-ended responses to questions adapted from the Mathematics Teaching Efficacy Beliefs Instrument (MTEBI), and interviews will be compiled separately and analyzed using open coding and analytic induction (Bogdan & Biklen, 1992; Merriam & Tisdell, 2015).

Results and Discussion

Similar to findings in other studies, preliminary results suggest there was a shift in PSTs' reflection to focus on student understanding (Santagata & Yeh, 2014; Sherin & Han, 2004; van Es et al., 2017; Wilkerson et al., 2018). Although a weaker association, a shift in mathematics teaching self-efficacy is observed, similar to findings in previous literature (Noormohammadi, 2014; Ross & Bruce, 2007; Yekyung Lee & Ertmer, 2006). This study promises to add literature to the mathematics education community as it can inform PST educators about the use of videos in mathematics methods courses. Specifically, the use of videos to develop PSTs' thinking through reflection prompts focused on student understanding and teacher interaction.

PRE-SERVICE SECONDARY MATHEMATICS TEACHER CANDIDATES' REFLECTION ON THEIR OWN TEACHING

Emily Elrod
North Carolina State University
ekelrod@ncsu.edu

Heather West
North Carolina State University
hmwest@ncsu.edu

Keywords: Teacher education – preservice; Instructional activities and practices; Teacher knowledge; Affect, emotions, beliefs, and attitudes

Research has shown that video analysis has helped teachers develop stronger mathematical content knowledge, instructional practices, and a deeper understanding of students' thinking (Sztajn, Borko, & Smith, 2017; van Es, 2012). Providing teachers with the opportunities to analyze videos of their teaching has been identified as a powerful tool to activate growth and facilitate change in their own classroom (Seidel, Stürmer, Blomberg, Kobarg, & Schwindt, 2011). In addition, integrating a reflection component not only helps teachers critically examine and think about their own mathematical practice, but also encourages them to take action in order to strengthen their instruction (Schön, 1983). In recognizing the benefits of video analysis, building these skills during teacher preparation programs may provide the springboard needed for life-long, reflective teaching practice. Analysis of video-recorded classroom lessons can support teacher noticing by providing explicit opportunities to focus on student thinking and discourse more deeply than is likely to occur in the moment of teaching (Santagata, 2009).

The purpose of this pilot study was to investigate the following research question: How does reflecting on video samples of their own teaching factor into secondary mathematics preservice teacher candidates' anticipation of student teaching experiences? As such, this study was situated around the conceptual framework of noticing, which is characterized by the following three key components: the ability to determine what is noteworthy during a teaching episode, connecting those events to the underlying conceptions and principles of teaching and learning, and utilizing context and experience to interpret the situations (Sherin & van Es, 2005). Research shows that noticing is imperative for teacher growth and demonstration of expertise, thus it is a valuable component of teacher preparation programs (Sherin & van Es, 2005).

An intrinsic case study design was utilized, focusing on two secondary mathematics pre-service teacher candidates (PST) to investigate their teaching reflections and development of noticing through interviews. As part of a senior methods course, the PSTs completed two micro-teaching assignments that required them to plan, teach, and video record lessons in their field placement classroom, a public high school mathematics classroom, then complete a written reflection after reviewing their own video recorded lesson. Document analysis was completed on the reflections through the lens of the conceptual framework, utilizing *a priori* coding, along with open coding. Furthermore, following each micro-teaching, one-on-one semi-structured interviews, focused on the affordances of the video-recorded lessons for reflection and the impact on future pedagogical decisions, were completed with each PST. The interview transcripts were analyzed using the noticing framework. Three themes emerged from data analysis: focus on teacher actions, student-teacher relationships, and events that inform future teaching practice. The data support how video provided explicit evidence for the PSTs, offering opportunities for noticing of and reflection regarding student engagement, teacher facilitation, and pedagogical decisions that can support future teaching. Further, PSTs desire to continue to obtain video evidence from their classrooms to help support their reflective teaching practice.

POST-LESSON DEBRIEF SESSIONS: WHAT PRESERVICE SECONDARY MATHEMATICS TEACHERS NOTICED

Raymond LaRochelle
University of Delaware
rlaroche@udel.edu

Michelle Cirillo
University of Delaware
mcirillo@udel.edu

Keyword: Teacher Education - Preservice

We share findings related to our efforts to implement a University Teaching Experience (UTE; Bieda, Visnawathan, McCrory, & Sikorskii, Accepted) for preservice secondary teachers (PSTs). In our implementation of the UTE, PSTs plan a lesson in pairs for a university pre-calculus course with guidance from the secondary methods instructor and the precalculus instructor. The pair then teaches the lesson while their peers observe and take notes about the student thinking that occurs as well as evidence related to two research questions identified by the PST pair. Afterwards, the teaching and observing PSTs debrief the lesson. Two cycles of the UTE are conducted so that each pair teaches twice. Herein, we discuss what the PSTs noticed during the UTE with respect to the issues of practice (i.e., research questions) that they selected.

Data for this study come from the first year of implementing the UTE model at a large mid-Atlantic public university. Fifteen PSTs participated in the study, which took place during their enrollment in the first of two methods courses. The UTE, which served as an on-campus field placement for the methods course, occurred in a university precalculus class.

To investigate what PSTs noticed with respect to the issues of practice, we analyzed video-recordings of the lesson debriefs using a professional vision framework (Sherin & van Es, 2009). Goodwin (1994) defined professional vision as "socially organized ways of seeing and understanding events that are answerable to the distinctive interests of a particular social group" (p. 606). Following Sherin and van Es's (2009) method of analysis, we first divided the debrief transcripts into idea units (i.e., sections of the discussion in which one particular idea was discussed). We then coded each idea unit for *what* the PSTs noticed. This involved coding for *who* they talked about (teacher, students, or other), and the *topic* of the conversation (classroom management, climate, pedagogy, or mathematical thinking). Finally, we coded for *how* the PSTs noticed, in particular, whether PSTs were descriptive, evaluative, or interpretive.

Results indicated that the opportunity to reflect on research questions during the debrief gave PSTs many opportunities to attend to and interpret the precalculus students' mathematical thinking that occurred during the lesson. For example, here, a PST reflected on the research question, "What were students' first thoughts when attempting to solve [$0.01=1{,}000^{2x+1}$]?":

> One table I saw tried to rewrite 1,000 as 0.01 because… I think some people want to take the smallest number and make that the base, like, for instance, with 5 and 125 [points at previous problem, $5^{x-2}=125$] you take the 5, so like, so there was one table that I went to that was like 'I don't know how to write 1000 as a base of 0.01.'

In particular, we noticed how this PST made interpretive comments about the math students' mathematical thinking, and even discussed underlying reasons for the students' question.

GRACE IN LEARNING: A NECESSARY CONDITION OF TEACHING MATHEMATICS METHODS AS AGAPE

Joel Amidon
University of Mississippi
jcamidon@olemiss.edu

Anne Marie Marshall
Lehman College
anne.marshall@lehman.cuny.edu

Rebecca Smith
University of North Alabama
rsmith27@una.edu

Keywords: Equity and Diversity

Teaching mathematics methods as agape, or teaching mathematics methods an as act of unconditional love (see Amidon, 2013), means acknowledging learning as happening in relationship with others (Lave & Wenger, 1991). This pedagogical ideal emerged from a study guided by the research question "What was learned in a elementary mathematics methods learning module designed to promote awareness and agency around issues of equity and diversity in the elementary mathematics classroom?"

In an attempt to identify what was learned in a module organized around data of disproportionate outcomes across racial/ethnic groups in the final course taken in high school (Battey, 2013) we identified and organized twenty-four learnings into four learning families. The learning families include technical learning, relational learning, critical learning, and learning bandwidth. Technical Learning describes instances where pre-service teachers (PST)s shared they had learned how to execute and/or create processes and products for student learning. Relational Learning described instances where PSTs shared what they learned about students and content to develop processes and products for student learning. Critical Learning referenced learning about equity in the teaching and learning of mathematics and the relationship of mathematics to the world. Finally, Learning Bandwidth, is defined as capacity related to the desire and sources of learning for the PST.

The culmination of this study, resulted in describing a kind of teaching that would foster this kind of learning, what we define as *teaching mathematics methods as agape*, with a necessary condition, and a product of such teaching, being *grace in learning*. Borrowed from Su's (2014) construct of *grace in teaching,* we define grace in learning as being undeserved favor in promoting an ideal relationship between PSTs and the equitable teaching of mathematics. Understanding learning to be the result of interactions between different degrees of knowers within a community of practice, *grace in learning* is both given and produced, by both PSTs and mathematics teacher educators in developing awareness and agency around issues of equity and diversity in the elementary mathematics classroom, or advancing toward being a more central participant within the community of practice (Lave & Wenger, 1991). In our poster we will illustrate both the necessity and production of *grace in learning* within the data from our study.

Keywords: Teaching and classroom practice; Preservice teacher education

The complexity of effectively orchestrating a whole class mathematical discussion is well documented as is the importance of developing this practice (Boerst, Sleep, Ball, & Bass, 2011). For a whole-class discussion to be mathematically meaningful, teachers need to purposefully select and sequence students' solutions to directly address the intended mathematical learning goals. (e.g., Smith & Stein, 2018). Learning to orchestrate such discussions is not trivial (Boerst et al., 2011). In describing their support of elementary PSTs learning to orchestrate discussions, Boerst et al. (2011) note the importance of learning through "doing practice" rather than just analyzing practice (p. 2849), but "doing practice" is difficult when methods courses do not include field experiences. To address this need, we designed a learning experience for an introductory methods course to support PSTs in developing skills needed to orchestrate effective whole class discussions.

To practice orchestrating a whole class discussion by breaking it into a string of "smaller and increasingly specified" pieces (Boerst et al., 2011), PSTs engaged in four sequential activities - 1) analyzing multiple samples of authentic student work, 2) selecting a specific sample of student work as their "favorite wrong answer" to be used to launch a whole class discussion, 3) scripting out a whole class discussion utilizing the student work they analyzed, and 4) creating an animation that captures the way they envision the whole class discussion would occur. Throughout this sequence of activities, PSTs' were expected to justify their choices based on a stated mathematical goal. The purpose of activities one and two was to set the stage by engaging PSTs in practices that would occur prior to launching a discussion, and given that by nature discussions are interactive, activities three and four provided progressively more detailed opportunities to *approximate* (Grossman, 2009) those interactions.

This study focused on PSTs' approximation of preparing for and orchestrating a whole class discussion for which the mathematical goal is to define function. The written responses, scripts, and animations of 21 PSTs were analyzed. Preliminary results showed all 21 PSTs focused on the learning goal in the planning of the discussion and made explicit connections to the learning goal throughout their approximations. Further analysis is being conducted using Boerst et al. (2011) Framework for Teacher Questions to examine the ways in which this series of approximations supports early PSTs in practicing orchestrating discussions. In addition, we plan to compare the findings between the script and the animation to better understand the ways the medium of the approximation of practice supports PSTs articulation of a whole class discussion. Findings from this study will be important for mathematics teacher educators designing effective tasks for developing this complex practice.

DEVELOPING TASKS FOR INVESTIGATING PRE-SERVICE TEACHERS' UNDERSTANDING OF RANDOMNESS

Nenad Radakovic
Joshua Hertel
College of Charleston University of Wisconsin La Crosse
radakovicn@cofc.edu jhertel@uwlax.edu

Keywords: Instructional activities and practices, Teacher knowledge

In this presentation, we investigate the informal notions of randomness held by elementary preservice teachers (PSTs). Understanding randomness is essential for developing a robust understanding of probability and statistics (Moore, 1990). However, studies suggest that most individuals do not possess a deep understanding of randomness (e.g., Ayton, Hunt, Wright, 1989). Historically, there has been a wide debate among philosophers and mathematicians on the meaning of randomness. In the literature, there is general consensus that random phenomena are the ones that cannot be explored and explained through deterministic or causal means (Beltrami, 1999). In the research reported here, we sought to gather information on the informal understanding of randomness held by PSTs with a focus on two ideas. First, although individual outcomes cannot be predicted, the set of all possible outcomes, as well as the long-term distribution of outcomes, can be determined. Second, a sequence of outcomes generated by a random process often appears "clumpy" in that similar outcomes are grouped together rather than evenly spaced. Our investigation was guided by two questions: 1) What intuitive ideas do preservice teachers hold about randomness? 2) How can an instructional task be developed to engage students in thinking critically about their own understanding of randomness?

Methods

We presented 18 PSTs enrolled in an elementary content course a task with the following structure: 1) Imagine a scenario using a generating device (e.g., a fair coin, six-sided die) and predict what a sequence of outcomes will be. There were two contexts provided: a well known coin-flipping task and lesser-used task in which students were asked to color a hexagonal grid; 2) run through the scenario using the generating device and record results; 3) compare the imagined sequence versus the experimental sequence; 4) judge whether or not a sequence was imagined or generated using a device. We analyzed student responses to identify patterns and themes using open coding (Corbin & Strauss, 2008). Common words, ideas, or phrases were assigned codes and an iterative process was used to refine these codes. A secondary analysis was then conducted to identify themes across the data.

Findings and Discussion

Two broad themes emerged: (1) student intuitive ways of reasoning about randomness and (2) student perceptions of structure in randomness. Within the first theme, we found three subthemes: judging randomness based upon frequency conflating and confounding theoretical and experimental probability, focus on determinism. Within the second theme, we found that the presence of structure was used as both a reason for judging something to be random as well as against judging something to be random. Judging the presence of structure as that is not random is consistent with Batanero, Arteaga, Ruiz, and Roa's (2010) findings that PSTs view randomness as unpredictability and lack of patterns. Using the presence of structure and patterns as indication of randomness has not been fully explored in the literature. With this study, we hope to describe the challenges of overcoming non-normative notions of randomness, and the feasibility of using such tasks to support students in developing conceptions of randomness.

THE UTE MODEL: DEVELOPING PRE-SERVICE TEACHERS' VISIONS OF HIGH-QUALITY MATHEMATICS INSTRUCTION

Kristen N. Bieda
Michigan State University
kbieda@msu.edu

Fran Arbaugh
The Pennsylvania State University
efa2@psu.edu

Michelle Cirillo
University of Delaware
mcirillo@udel.edu

Keywords: Secondary Teacher Preparation, Field Experience, Instructional Vision

The *University Teaching Experience* (UTE) model is a field experience where secondary mathematics PSTs teach in a first-year undergraduate mathematics course coinciding with their first methods course (Bieda et al., Accepted). Teacher educators mentor PSTs in planning and teaching in the UTE, supporting PSTs to enact ambitious teaching practices early in teacher preparation. We report results of our assessment of PSTs' vision for high-quality mathematics instruction (VHQMI) at the outset of the UTE, which inform mentoring of PSTs during the UTE.

Methods

We used the VHQMI protocol (Munter, 2014) in semi-structured interviews with participants during the first month of the semester in which they were participating in the UTE. The VHQMI probes PSTs' beliefs about the teacher's role, students' engagement, the nature of mathematical tasks, and the nature of classroom discourse in classrooms with high-quality mathematics instruction. We analyzed transcripts using Munter's (2014) rubric.

Results

In responding to the question "Can you describe what classroom discussion would be like if instruction was high quality?" all PSTs' responses scored in the top two levels of the rubric. Also, PSTs generally indicated high-quality mathematics instruction involves using tasks with opportunities for mathematical sense-making. When asked "What things should the teacher do for the instruction to be high quality?" PSTs indicated that teachers should be *knowledgeable others*, *facilitators*, or *monitors* (Munter, 2014) rather than imparting knowledge to students. However, when asked about what students' engagement would be like for high-quality mathematics instruction, their responses reflected norms of direct instruction. These findings suggest attention to students' engagement with tasks and evidence of students' learning may be particularly critical for PSTs as they reflect upon their practice in the UTE.

EXAMINING CREATIVITY IN A STEAMING HOT CAMP: IMPACT ON STUDENTS AND PRE-SERVICE TEACHERS

Keywords: Creativity, STEAM, Problem-based

Research states that STEAM problem-based learning increases student creativity (Pang 2015; Russo, 2013; Siew, Chong & Lee, 2015) and critical thinking skills (Russo, 2013). Creativity is described as an individual's thoughts, behaviors, and products that can be considered novel, effective and whole (Amabile, 1999; Henriksen, Mishra & Mehta, 2015). STEAM has been defined as, "the collective expertise from many disciplines to pose and solve problems in a manner which foregrounds the problem, not the discipline" (Quigley & Herro, 2016, p. 412). STEAM learning thus provides opportunities for creative thoughts and processes through incorporation of multi-sensory tools and a hands-on problem solving approach (Taljaard, 2016).

Additionally, the dynamic relationship between materials and the teacher can have a significant impact on student knowledge and creative performance. Myers & Torrance (1961) further state that a teacher's responsiveness directly influences the number of creative products and novel ideas generated in the classroom. Pre-service teachers (PSTs), training to be teachers, need to be aware and knowledgeable in the skills of developing lessons that foster problem solving, reasoning, and creativity. Motivated by these arguments the researchers sought to examine the creativity ideation of elementary school students after attending a two week summer STEAM camp and that of the facilitating PSTs working as camp counsellors. The researcher questions that provided focus to the study are: to what extend does elementary school students' creativity change as a result of attending a two week-long STEAM camp incorporating problem-based learning and what is the impact of facilitating a two week-long STEAM camp incorporating problem-based learning on pre-service teachers' self-efficacy?

Research Design

The study uses two research designs. The quantitative research design is used to assess school students' creativity using the Runco Ideational Behavior Scale (RIBS) self-assessment. This 23 item survey is administered at the start and the end of the 2-week STEAM camp and statistical analysis using one-tailed t-test is conducted. A parallel convergent research design is used to gauge the impact on PSTs creativity and self-efficacy through quantitatively analyzing the results from the RIBS self-assessment, Mathematics Beliefs Scale (Usher, 2008) and a Science Teaching Efficacy Belief Instrument or S-TEBI (Enochs & Riggs, 1990), and open and axial coding of the daily reflections.

Results

The results of the study show positive impact of STEAM camp on school students through self-assessing of their creativity. The results also show positive impact on PST's efficacy and creativity through cross examining the results from different surveys and reflections.

EXAMINING STUDENTS' SHAPE THINKING IN DIFFERENTIATING EXPONENTIAL AND QUADRATIC RELATIONSHIPS

Madhavi Vishnubhotla
Montclair State University
vishnubhotm1@montclair.edu

Despite the emphasis laid by national mathematical organizations (NCTM, 2000; CCSSM, 2010) on understanding exponential and quadratic relationships, there is limited research on students' meanings of these relationships. While a growing body of research has documented that middle school students can reason covariationally (Thompson, 2017) to construct meanings of quadratic (e.g., Ellis, 2011) and exponential relationships (e.g., Confrey & Smith, 1994, 1995; Ellis, Özgür, Kulow, Williams, & Amidon, 2015), there have been no reported findings on pre-service teachers'(PSTs) meanings of these growth patterns. In this study, I sought to gain insights into PSTs' meanings of these relationships and explore their ways of reasoning to differentiate between the two growth patterns when presented with graphs representing quadratic and exponential relationships.

I conducted one-on-one task based semi-structural clinical interviews (Goldin, 2000) with four undergraduate PSTs at a large university in the Northeastern United States who were chosen on a voluntary basis. Several tasks entailed half parabolas, exponential growth and decay graphs. I asked the students to describe the relationship represented by the graphs and justify their explanation. Each interview lasted for approximately 60 minutes. At the time of the interviews, the PSTs had completed at least two semesters of calculus courses. I analyzed the interviews with a goal of characterizing to what extent students conceptualized a graph as an emergent representation of two quantities' values varying simultaneously (Moore & Thompson, 2015) and reasoned about the amounts of change (Carlson et al., 2002) of one quantity for amounts of change in the other quantity.

I found that when attempting to describe the relationship or function the graphs represented, all PSTs engaged in static shape thinking. They tried to recall a shape from memory and conceived the graph as a picture rather than attending to the emergent trace and the covariational relationship. This finding is consistent with Moore and Thompson's (2015) description of static and emergent shape thinking. While two students employed other ways of reasoning, making a table of values from the graph, they inspected the physical properties of the shape of the curve to conclude that the graph could represent either a quadratic or exponential relationship. Students did not attend to the amounts of change in the two quantities to identify the graph as representing a quadratic or exponential relationship. Conclusively, all students' ways of reasoning relied completely on the shape of the curve and their reliance on shape thinking could not provide ways to differentiate between these two function classes.

EXAMINING PRESERVICE TEACHERS' USE OF MULTICULTURAL LITERACY IN ELEMENTARY MATHEMATICS INSTRUCTION

Alesia Mickle Moldavan
Fordham University
amoldavan@fordham.edu

Keywords: Teacher Education-Preservice, Instructional Activities and Practices, Culturally Relevant Pedagogy

When mathematical concepts are related to cultural experiences, students can engage in meaningful learning that promotes interest and appreciation for diverse cultures. Multicultural literature can be used to teach students about mathematics in culturally relevant contexts (Chappell & Thompson, 2000; Leonard, Moore, & Brooks, 2014). Teachers engaged in this work must recognize mathematics as a cultural construct and have opportunities to design and implement lessons with such texts (Iliev & D'Angelo, 2014; Sleeter, 1997). This study reports on preservice teachers' experiences participating in a microteaching activity that used multicultural literature to communicate mathematical concepts addressed in an elementary classroom. The following research question is examined: How do preservice teachers use multicultural literature in elementary mathematics instruction to foster culturally relevant mathematical connections?

Participants in the study included 30 preservice teachers enrolled in an elementary mathematics methods course at an urban university in the northeastern United States. In the beginning of the course, the preservice teachers were introduced to culturally responsive pedagogy and the notion of contextualizing mathematics teaching and learning to students' lives (Gay, 2002, 2009; Ladson-Billings, 1995a, 1995b). Next, the preservice teachers were grouped in pairs and tasked with designing a mathematics activity with reference to a multicultural text of their choosing. To guide the text selection and the design of the activity, the preservice teachers were asked to reflect on the ways in which the text and the activity: (a) portrayed cultural authenticity, (b) depicted cultural diversity as an asset, and (c) promoted culturally relevant mathematical connections (Harding, Hbaci, Loyd, & Hamilton, 2017). Following the submission of their written reflections, the preservice teachers taught their lessons to their peers. The peers gave constructive feedback to one another and assessed how the overall experience influenced their future use of multicultural literature in elementary mathematics instruction. The collected reflections and peer feedback were analyzed using in vivo and descriptive code (Saldaña, 2016).

Findings revealed that the preservice teachers used multicultural literature to design activities that empowered students to see themselves and their peers as mathematicians. The practice of using such texts to facilitate cultural connections also influenced preservice teachers' awareness of and confidence in using cultural practices to relate mathematical concepts. Several preservice teachers shared how prior to the microteaching activity they had not thought to use such texts to teach mathematical concepts, especially if the concepts depicted in the texts (e.g., numerical representations, computations) differed from the dominant mathematics studied. One preservice teacher described how her experience gave her the confidence to challenge other texts used in her field placement. Another preservice teacher disclosed how he planned to use multicultural literature in his mathematics classroom to help students identify cultural assets and remove potential barriers. Recommendations are shared for equipping preservice teachers with the knowledge and skills needed to select and use multicultural literature to recognize mathematics as a cultural construct practiced beyond what we see in the near horizon.

TEACHER PREPARATION PROGRAM OUTCOMES: A COMPARISON OF MATHEMATICS AND SCIENCE INSTRUCTIONAL PRACTICES

Temple A. Walkowiak	Heather M. West	James Minogue
NC State University	NC State University	NC State University
tawalkow@ncsu.edu	hmwest@ncsu.edu	jminogu@ncsu.edu

Keywords: Elementary school education, Instructional activities and practices

The National Council of Teachers of Mathematics (2014) has emphasized the importance of teaching for conceptual understanding through cognitively demanding tasks and rich discourse (2014). The Next Generation Science Standards (NGSS Lead States, 2013) call for teachers to utilize similar practices in science. As such, elementary teacher preparation programs aim to develop these practices among candidates, but little is known about whether instruction looks similar across disciplines. Typically, research on teacher candidates has focused on practices within a single discipline *during* the preparation program (e.g.,Spitzer et al., 2011), despite calls to conduct investigations after graduates enter their careers (Cochran-Smith & Zeichner, 2005). The current study fills these voids by examining instructional practices of second-year elementary teachers to understand whether practices in mathematics translate to science.

The participants in this study were purposefully selected from a larger group of 49 second-year elementary teachers who all graduated from the same teacher preparation program and provided videos of their mathematics and science instruction (three videos per discipline). The two participants, Dalton and Emerson, were selected because they taught the same grade level (fourth grade) and demonstrated above average facilitation of mathematical discourse (in relation to peers) as measured by an observational measure (Walkowiak et al., 2014). Videos were watched independently by three researchers who took detailed notes, wrote lesson memos, and met to discuss the discourse, tasks, and source of control of learning (teacher versus student).

Across disciplines, Dalton shared control with her students of their learning, whereas Emerson maintained a high level of control. Both teachers tended to use tasks of low cognitive demand in mathematics (Stein et al., 2009); however, Dalton's strong use of questioning heightened her instruction around these tasks. She probed students' thinking and encouraged them to make generalizations, thereby giving them some control over their own learning. Dalton's science tasks were inquiry-oriented, while Emerson's tasks focused on scientific facts and procedures. Across both disciplines, Emerson's instruction was often guided by videos (e.g., BrainPop). Emerson seemed to value student-to-student talk by giving students opportunities to talk to each other, but interestingly, assumed an extremely passive role during these interactions.

Findings from this study suggest some translation of practices across disciplines. Dalton and Emerson each demonstrated unique discourse practices that were encouraged in the program (e.g., probing, student-to-student talk). With the exception of Dalton's inquiry-oriented tasks in science, tasks tended to be lower level. A distinguishing characteristic in this study was the source of control of learning. Determining the factors that may influence control (e.g., teacher knowledge) is important for future research.

"GETTING BETTER AT STICKING WITH IT": EXAMINING PERSEVERANCE IMPROVEMENT IN SECONDARY MATHEMATICS STUDENTS

Joseph DiNapoli
Montclair State University
dinapolij@montclair.edu

Supporting students' in-the-moment perseverance is a vital objective in mathematics education because it promotes learning with understanding. Yet, little is written about if and how student perseverance can improve over time. I examine the specific ways in which secondary students improved their perseverance as they engaged with challenging mathematical tasks over six weeks. The results show that encouraging students to initially attend to their conceptual thinking can prolong productive effort upon impasse and explicitly improve selection of problem-solving strategies and affect regulation. These findings suggest learning environment designs that provide consistent opportunities for students to practice (and improve) their perseverance.

Keywords: Perseverance, Problem Solving, High School Education, Metacognition

In the context of problem-solving, perseverance is initiating and sustaining in-the-moment productive struggle in the face of mathematical obstacles, setbacks, or discouragements. The notions of tolerating uncertainty and overcoming obstacles have long been recognized as key processes supportive of learning with understanding (Dewey, 1910; Festinger, 1957; Polya, 1971). These ideas have been echoed for mathematics learning because students make meaning through productive struggle, or as they grapple with mathematical ideas that are within reach, but not yet well formed (Kapur, 2010, 2011; Hiebert, 2013; Hiebert & Grouws, 2007; Warshauer, 2014). Additionally, reconciling times of significant uncertainty (i.e., a perceived impasse) is critical for mathematics learning. The processes of struggle to approach, reach, and make continued progress despite a perceived impasse puts forth cognitive demands upon the learner that are conducive for development of conceptual ideas (Collins, Brown, & Newman, 1988; VanLehn et al., 2003; Zaslavsky, 2005). As such, supporting in-the-moment student perseverance has been made explicit as a way of improving teaching and learning in mathematics education, with the expectation that such support will nurture students' perseverance to improve over time (CCSS, 2010; Kilpatrick, Swafford, & Findell, 2001; NCTM, 2014).

Supporting and Improving Student Perseverance with Mathematics Tasks

Several research efforts have sought to make explicit classroom practices that support student perseverance with challenging mathematics, yet little is known about how such practices can help improve student perseverance in specific ways over time. Studies aiming to unpack the nature of productive struggle (DiNapoli, 2019; DiNapoli & Marzocchi, 2017; Kapur, 2009, 2011; Sorto, McCabe, Warshauer, & Warshauer, 2009; Warshauer, 2014) generally have found that providing consistent opportunities for students to engage with unfamiliar mathematical tasks encouraged more variability in problem-solving strategies and greater learning gains, compared to providing consistent opportunities to engage with more procedural mathematics. Other researchers (Bass & Ball, 2015; DiNapoli, 2016, 2019; Kapur & Bielaczyc, 2012; Stein & Lane, 1996) have explored the nature of perseverance by investigating the effects of implementing classroom tasks with familiar entry points yet a complex structure. In general, there is empirical support for students leveraging opportunities within such low-floor/high-ceiling tasks to persevere in their efforts despite challenge and seemingly make mathematical progress. Additional scholarship has focused on the role of teacher feedback to encourage in-the-moment perseverance (Freeburn & Arbaugh, 2017; Housen, 2017; Kress, 2017; Sengupta-Irving & Agarwal, 2017). A synthesis of the findings from these works suggests non-leading teacher questioning encouraging student metacognition can facilitate more independent thinking and creative problem-solving during times of confusion.

Building from the previously mentioned literature, a recent study (DiNapoli, 2018) developed an operationalization of perseverance called the Three-Phase Perseverance Framework (3PP) (see Table 1), an analytical perspective by which perseverance can be qualitatively described and measured. The 3PP reflects perspectives of concept (Dolle, Gomez, Russell, & Bryk, 2013; Middleton, Tallman, Hatfield, & Davis, 2015), problem-solving actions (Pólya, 1971; Schoenfeld & Sloane, 2016; Silver, 2013;), self-regulation (Baumeister & Vohs, 2004; Carver & Scheier, 2001; Zimmerman & Schunk, 2011), and making and recognizing mathematical progress (Gresalfi & Barnes, 2015).

Using the 3PP, this study (DiNapoli, 2018) investigated how prompting algebra students to create an artifact of their personal conceptualization of a mathematical task (Anghileri, 2006) could support perseverance at times of impasse. The results show how scaffolding tasks in this way encouraged making an additional attempt at solving via re-initiating and re-sustaining mathematically productive effort at impasse significantly more so than on tasks without such scaffolding. Participants articulated that the conceptual thinking recorded after engaging with the scaffold prompt acted as an organizational toolbox from which to draw a fresh mathematical idea, or a new connection between ideas, to use to re-engage with the task upon impasse and to continue to productively struggle to make sense of the mathematical situation. Participants were persevering in problem-solving cyclically, with each additional attempt as a new opportunity to productively struggle with a given task scaffolded by their own conceptual ideas (see Figure 1). Without recording their conceptual thinking on non-scaffolded tasks, participants felt frustrated after a setback and often gave up without making an additional attempt at solving.

Table 1: Three-Phase Perseverance Framework

Entrance Phase	
Clarity	Objectives were understood
Initial Obstacle	Solution pathway not immediately apparent
Initial Attempt Phase	
Initial Effort	Engaged with task
Sustained Effort	Used problem-solving heuristics to explore task
Outcome of Effort	Made mathematical progress
Additional Attempt Phase (after perceived impasse)	
Initial Effort	Engaged with task
Sustained Effort	Used problem-solving heuristics to explore task
Outcome of Effort	Made mathematical progress

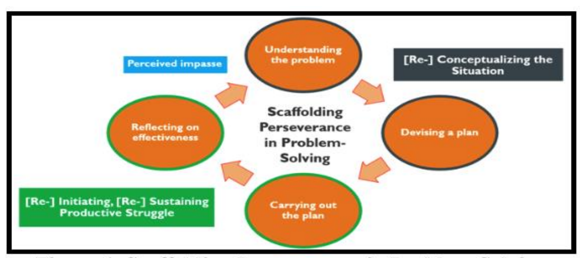

Figure 1. Scaffolding Perseverance in Problem-Solving

Despite the recent research on ways to support student perseverance in the moment, questions remain about whether these practices help nurture student perseverance to improve over time. There exists some work that shows evidence of student improvement in measures of grit (Polirstok, 2017) and time-on-task (Niemivirta & Tapola, 2007), however such work relies heavily on summative outcome variables that reveal little about the ways in which learners were challenged, overcame setbacks, and developed mathematical understanding, if they did at all (DiNapoli, 2018). Research on perseverance can produce insights into effective practices by which to learn mathematics with understanding, yet much of the empirical evidence of student

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

perseverance have been situated in single points of time with little or no exploration of how those perseverance experiences may be related or demonstrate signs of specific improvement. Thus, the present study aimed to address these lingering concerns about whether and how student perseverance, when supported properly, can improve over time.

Methods

The participants for this qualitative study were 10 ninth-grade students from one suburban-area algebra class in a Mid-Atlantic state. They were purposely chosen to have demonstrated, via pretest, the prerequisite knowledge necessary to initially engage with each mathematical task included in the study. Each participant was observed engaging with five tasks across six weeks, approximately one per 7-10 days. These tasks were rated as analogous by the Mathematics Assessment Project because of their low-floor/high-ceiling structure, two objectives, and generalization requirements. Three tasks were randomly chosen to be scaffolded with conceptualization prompts (Anghileri, 2006), and two tasks were randomly chosen to be non-scaffolded. The conceptualization prompt embedded into the scaffolded tasks was "*Before you start, what mathematical ideas or steps do you think might be important for solving this problem? Write down your ideas in detail*." Each participant worked on these set of five tasks in a random task order. The results of this paper unpack participant perseverance across the three scaffolded tasks: Cross Totals, Sidewalk Stones, and Skeleton Tower. For context, Cross Totals asked students to generalize rules about how to arrange the integers 1-9 in a symmetric cross such that equal horizontal and vertical sums would be possible or not possible; Sidewalk Stones asked students to generalize rules about an evolving two-dimensional pattern of different types of stones; Skeleton Tower asked students to generalize rules about an evolving three-dimensional tower of cubes. All tasks are available for view at www.map.mathshell.org/.

For each task and participant, I conducted think-aloud interviews while they worked on a task and video-reflection interviews immediately after they finished working. Additionally, once a participant had engaged with all five tasks (and thus all five think-aloud interviews and video-reflection interviews), I conducted an exit interview to elicit reflections on the overall experience working on the five tasks. In all, I conducted 11 interviews with each participant, or 110 interviews in total for this study. I adopted an inductive coding process (Strauss & Corbin, 1990) using the 3PP to capture the ways in which students were persevering, or not, across the five tasks (DiNapoli, 2018, Table 1). The 3PP considered if the task at hand warranted perseverance for a participant (the Entrance Phase), the ways in which a participant initiated and sustained productive struggle (the Initial Attempt Phase), and the ways in which a participants re-initiated and re-sustained productive struggle, if they reached an impasse as a result of their initial attempt (the Additional Attempt Phase). A participant was determined to have reached a perceived impasse if they affirmed they were unsure how to continue (VenLehn et al., 2003). Mathematical productivity was determined based on if the participant perceived themselves as better understanding the mathematical situation as a result of their efforts (Gresalfi & Barnes, 2015).

I used a point-based analysis with the 3PP to help inform deeper investigation of the ways in which participants persevered. Each participants' experiences with each task were analyzed using the framework, and each component in the Initial Attempt and Additional Attempt Phases were coded as 1 or 0, as affirming evidence or otherwise, respectively. Since each task had two objectives and six components per objective, there were 12 framework components to consider, per participant, per task. Thus, 3PP scores ranged from 12 to 0, depicting optimal to minimal demonstrated perseverance in this context, respectively. I conducted regression analyses to compare the ways in which 3PP scores were changing over time for participant work on scaffolded tasks and on non-scaffolded tasks. I also inductively coded interviews to uncover from the participant perspective how and why their perseverance may have been changing over time. I enlisted help from two independent coders to analyze participant perseverance and their reasons for doing so. Our inter-rater reliability was 93%.

Results

Overall, participants' perseverance across mathematical tasks improved over time, more so on scaffolded tasks than on non-scaffolded tasks. Participants' demonstrated perseverance on the three scaffolded tasks improved in quality over time as evidenced by increasing mean 3PP scores (see Figure 2). Participants' demonstrated perseverance on the two non-scaffolded tasks also improved in quality over time. However, the average rate at which scores on non-scaffolded tasks improved was three times less than the rate of improvement of scores on scaffolded tasks.

A simple linear regression was calculated to predict participants' 3PP scores on their second scaffolded task based on their first scaffolded task (see Table 2). A significant regression equation was found ($F(1, 8) = 58.593$, $p < .001$), with an R^2 of .880, indicating participants' 3PP scores on their first scaffolded task explained 88% of the variance in their 3PP scores on their second scaffolded task. Also, participants' 3PP scores on their first scaffolded task was a significant predictor of their 3PP scores on their second scaffolded task, with a one-point increase on their first scaffolded task predicting a .727-point increase on their second scaffolded task. A multiple linear regression was calculated to predict participants' 3PP scores on their third scaffolded task based on their first and second scaffolded tasks (see Table 2). A significant regression equation was found ($F(2, 7) = 10.741$, $p = .007$), with an adjusted R^2 of .684, indicating a participants' 3PP scores on their first and second scaffolded tasks, together, conservatively explained 68.4% of the variance in their 3PP scores on their third scaffolded task.

Table 2: Summary of Regression Analyses of Perseverance Scores

Task Type	Comparison	R^2	Adjusted R^2	B	SE(B)	Sig. (p)
Scaffolded	1st → 2nd	.880	.865	.727	.095	< .001
	1st/2nd → 3rd	.754	.684	.385/.234	.348/.449	.007 (.305/.618)
Non-Scaffolded	1st → 2nd	.553	.497	.680	.216	.014

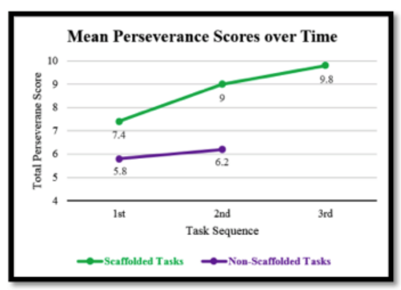

Figure 2. Mean Perseverance Scores Over Time

A simple linear regression was also calculated to predict participants' 3PP scores on their second non-scaffolded task based on their first non-scaffolded task (see Table 2). A significant regression equation was found ($F(1, 8) = 9.879$, $p = .014$), with an R^2 of .553, indicating participants' 3PP scores on their first non-scaffolded task explained 55.3% of the variance in their 3PP scores on their second non-scaffolded task. Also, participants' 3PP scores on their first non-scaffolded task was a significant predictor of their 3PP scores on their second non-scaffolded task, with a one-point increase on their first non-scaffolded task predicting a .680-point increase on their second non-scaffolded task. Thus, participants' 3PP scores were significantly improving over time, more so on scaffolded tasks than on non-scaffolded tasks.

During their exit interviews, participants revealed they noticed improvements, over time, in their engagement with the challenging mathematical tasks. Most participants (8 out of 10) mentioned they thought they were getting better, somehow, as they had more practice with these types of problems. Several participants (6 out of 10) mentioned their improved work on tasks specifically prompting them to conceptualize the situation prior to starting, i.e., the scaffolded tasks. Arguably the most noticeable improvement, from the participants' point of view, was affective in nature. Many participants (7 out of 10) explained in their exit interview that they felt like they were getting better at handling the stress of the situation as they reached impasses within their work on mathematical tasks they did not know how to solve. Some participants (4 out of 10) reported cognitive gains, believing the way they were thinking about the mathematics was changing for the better, over time, and that their problem-solving skills were improving.

Illustrative Case: Sandra's Perseverance Improvement across Scaffolded Tasks

Unpacking representative participant Sandra's experiences across her scaffolded tasks generally illustrates how perseverance improved over time, mostly by supporting participants to make a more quality additional attempt at solving. Sandra encountered Cross Totals first (first overall), then Sidewalk Stones (second overall), and then Skeleton Tower (fourth overall). Importantly, Sandra passed through the 3PP Entrance Phase on all three tasks by affirming she understood all of the objectives, but was not immediately sure how to achieve them. She earned a 3PP score of 6 for her perseverance on Cross Totals, a score of 9 on Sidewalk Stones, and a score of 12 on Skeleton Tower (see Table 3). Like her peers, Sandra made no additional attempt at solving while working on her first task, but progressively improved her perseverance after a setback in the Additional Attempt Phase as she had more experiences with tasks necessitating productive struggle. For comparison, Sandra earned 3PP scores of 6 for her work on both non-scaffolded tasks. She encountered non-scaffolded tasks third and fifth overall.

Table 3: Sandra's 3PP scores for Cross Totals, Sidewalk Stones, and Skeleton Tower

INITIAL ATTEMPT PHASE	Cross Totals (S, 1st)		Sidewalk Stones (S, 2nd)		Skeleton Tower (S, 4th)	
Evidence of Perseverance	Obj. 1	Obj. 2	Obj. 1	Obj. 2	Obj. 1	Obj. 2
Initial Effort	✓	✓	✓	✓	✓	✓
Sustained Effort	✓	✓	✓	✓	✓	✓
Outcome of Effort	✓	✓	✓	✗	✓	✓
ADDITIONAL ATTEMPT PHASE	Cross Totals (S, 1st)		Sidewalk Stones (S, 2nd)		Skeleton Tower (S, 4th)	
Evidence of Perseverance	Obj. 1	Obj. 2	Obj. 1	Obj. 2	Obj. 1	Obj. 2
Initial Effort	✗	✗	✓	✓	✓	✓
Sustained Effort	✗	✗	✓	✓	✓	✓
Outcome of Effort	✗	✗	✗	✗	✓	✓
Total Perseverance Score	**6**		**9**		**12**	

Notes: S = Scaffolded Task; Obj. = Objective; 1st = First task overall; 2nd = Second task overall; 4th = Fourth task overall

Cross Totals. Sandra began Cross Totals (her first scaffolded/overall task) by responding to the scaffold prompt and initiated her effort toward both objectives by stating her plan to reason about the magnitude of integers. She sustained her effort toward both objectives by exploring the logical ramifications of distributing different integers within the cross. Sandra perceived she was making mathematical progress in better understanding the situation by which cross totals may be possible or impossible. She found one example of a possible cross total (see Figure 3a), but soon after reported she had reached an impasse. During her think-aloud she said, "I know this one works, but it's just one example. These things aren't for all cross totals. It wants me to get it in general. I don't know." Although she recognized she had more work to do to better generalize the situation, Sandra decided to record two admittedly incorrect rules based on what she had found and not to make an additional attempt at exploring the problem. Sandra clarified this decision during her video-reflection interview: "In this moment I was just overwhelmed. I felt any other rules, general rules, would be more complicated to get and I just ran out of ideas."

Sidewalk Stones. Sandra's work on Sidewalk Stones (her second scaffolded/overall task) showed specific evidence of perseverance improvement compared to her work on Cross Totals. She similarly began by recording her ideas under the scaffold prompt about the mathematical relationships at play and ways to explore them. Importantly, Sandra revealed during her think-aloud that she was planning ahead when she said, "I was still stuck, or couldn't find a general rule, I could make up examples and check them." Sandra initiated her effort toward both objectives of the task by stating her plan to make a table of values representative of the different kinds of stones. She sustained her effort toward both objectives by searching for patterns within the table that could help her discern how the gray and white stones were changing. Despite some perceived progress, Sandra reached a perceived impasse about the generalization objectives. During her think-aloud she said, "How do I know about Pattern #*n*? This general stuff is hard." She clarified this moment during her video-reflection interview: "I was starting to see the gray pattern, but I had no clue about Pattern #*n*. I was thinking about quitting. I got farther than I thought, but general stuff, it's hard, like finding #*n*. I was stumped."

Despite the urge to quit, Sandra decided to keep working by amending her current plan and changing strategies. She said during her think-aloud, "Well, I guess I can make another example like I said I would." Sandra was referring to her scaffold work, in which she stated that if she "was still stuck" with the objective of generalization, she could "make up examples and check them." Thus, drawing from her earlier conceptualization work prompted by the scaffold, Sandra decided to make an additional attempt at solving Sidewalk Stones. She re-initiated her effort by choosing a different problem-solving heuristic, drawing a partial diagram of a new pattern of stones, and re-sustained her effort by amending her table of values and searching for a pattern amongst all available data (see Figure 3b). Sandra ultimately did not successfully find two general rules, and, by her own admission, she did not believe she better understood the mathematical situation as a result of her additional efforts. Yet, compared to her engagement with Cross Totals, Sandra's perseverance with Sidewalk Stones was much improved primarily because she included in her initial conceptualization work a plan for if she got "stuck." Sandra's backup plan helped her make an additional attempt at solving the problem upon a perceived impasse, an additional attempt she did not make one week earlier with Cross Totals.

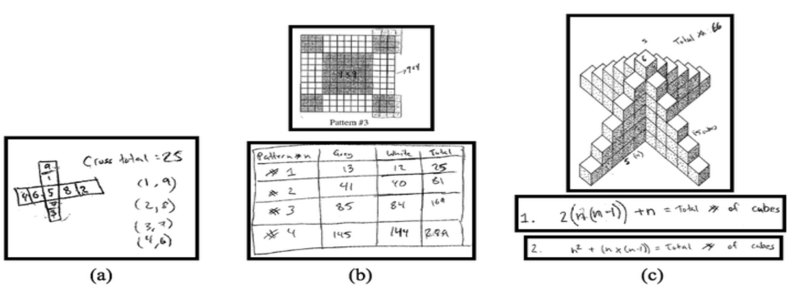

Figure 3. Samples of Work from Sandra's Engagement on Scaffolded Tasks

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

Skeleton Tower. Sandra's work on Skeleton Tower (her third scaffolded/fourth overall task) showed even further evidence of perseverance improvement compared to prior tasks. Under the scaffold prompt, she first recorded her mathematical ideas and problem-solving plans, which included "adding up all the cubes" and "knowing the area of a square, s^2, to maybe get an equation." During her video-reflection interview, Sandra clarified that she was preparing for the two generalization objectives: "I thought maybe the s^2 would help me get a general answer with an equation. Something I could just plug height into. The general stuff has been hard in all these problems so I thought using variables might help." Sandra initiated her effort toward finding one general rule by stating she would look for patterns in the diagram, and sustained this effort by counting the cubes in various parts of the tower and reasoning about how to algebraically represent these parts if the height of the tower was n. Sandra visualized piecing two legs of the tower together, stating in her think-aloud, "it's like two squares put together if you flip two of the legs." Eventually, she posited, "I think $(n\text{-}1)^2$ x 2 could be my rule for the total blocks because that's like two squares made up of the legs." Then, Sandra tested her equation and realized it was incorrect. Despite her ample perceived mathematical progress on this task, Sandra shared that she was "annoyed that it wasn't working" and was "stuck."

Despite the perceived impasse as a result of her first attempt to find one general rule, Sandra eventually decided to make an additional attempt by revisiting her past idea about the area of a square. During her video-reflection interview, she clarified, "Well I had that plan to use s^2 and I saw it here and really thought it was a good idea, so I decided to try it again, to maybe think about it another way." Sandra's earlier conceptualization work of Skeleton Tower helped her rethink about deconstructing the tower into squares and algebraically modeling the situation by considering the expression s^2. During this time when she was most "annoyed", it was revisiting her scaffold work that encouraged her to make an additional attempt at solving. From here, Sandra re-initiated her effort by deciding to draw parts of the tower separately, and re-sustained her effort by thinking-aloud about how to piece together the deconstructed parts of the tower. After diligent exploration she exclaimed, "Oh! It's not a square, it's a rectangle!" During her video-reflection interview, Sandra clarified these moments: "I wasn't sure that I was doing it right, but I kept going here. I knew I had a good plan and then, boom, it happened. I figured it out." Sandra went on to use algebraic expressions to model her discovery and ultimately wrote a correct rule that generalized the situation (see Figure 3c). While recapping her success during her video-reflection interview, Sandra cited the importance of incorporating a general equation in her initial conceptualization. She said, "Having an equation (Area = s^2) in mind from the start was a big help. It helped me keep going and helped me with the general part."

Unlike her work on Cross Totals and Sidewalk Stones, on which she worked toward both task objectives simultaneously, Sandra worked toward one objective at a time on Skeleton Tower. This meant that after her breakthrough above, she essentially started over to try to generalize the situation in a different way. Sandra used new strategies and a different point of view to persevere a second time on Skeleton Tower. As she did before, Sandra admitted she had reached another impasse during her first attempt toward the second objective, but ultimately changed her point of view to overcome the obstacle and make an additional, successful attempt (see Figure 3c). Compared to her work with Sidewalk Stones and Cross Totals, Sandra's perseverance with Skeleton Tower was much improved mainly because she planned to work with variables from the outset, during her scaffold work, to generalize the situation. Sandra's more-refined initial planning helped her make an additional attempt at times when she was most frustrated and go on to make progress and solve the problem.

Overall experience. Sandra's experiences with her scaffolded tasks helped illuminate the ways in which participants were improving in their perseverance. Sandra's perseverance gains were most noticeable in the improved quality of her additional attempt at solving a task after reaching an impasse. Sandra's scaffold work – recording her conceptualization of the mathematical situation at hand – played a role in why her perseverance changed because the types of ideas she recorded changed over time as well. During her exit interview, Sandra explained how she thought she was improving in the way she engaged with scaffolded tasks:

> I got better at writing out my ideas in those problems. When you keep doing it you get better at the planning stuff. All the problems ask for a general rule, and I started to learn about how to do that. I was ***getting better at sticking with it*** (emphasis added), too. Like after getting stuck or making a mistake. You just have to get into the problem and maybe even make some mistakes to figure it out. That got easier for me, not getting too annoyed after mistakes.

This perspective is indicative of how cognitive and affective changes impacted participants' perseverance improving over time for scaffolded tasks. Sandra was "getting better at sticking with it" because she better prepared strategies for generalization objectives and better regulated her frustration at key moments during problem-solving. All participants encountered impasses with the scaffolded tasks, yet, as they had more experience in situations requiring perseverance and requiring planning, they persevered more and noticed cognitive and affective improvement.

Sandra earned 3PP scores of 6 on both of her non-scaffolded tasks. She did not demonstrate any evidence of specifically preparing for mathematical generalization, nor did she report in any of her interviews specific ways she was changing how she prepared. Also, Sandra did not mention if she felt better about handling the stress during work on the non-scaffolded tasks, even though they were the third and fifth task with which she worked. Sandra's experiences with non-scaffolded tasks was illustrative of most participants in this study. This suggests that exposure to such tasks warranting struggle did not alone improve participants' perseverance in specific ways, but responding to the initial scaffold prompt, in which participants attended explicitly to conceptualizing the situation, played an influential role in perseverance improvement.

Discussion and Conclusion

Several effective practices for supporting student perseverance have been made apparent in recent research, yet there is little evidence to show if and how student perseverance can improve over time – a vital objective of most reform efforts. This study extends previous research by explaining how and why student perseverance improved over time, and by unpacking this process from the student point of view. These results suggest that developing students' perseverance for solving challenging mathematics tasks may be possible through the process of deliberate practice, a systematic effort to improve performance in a specific domain (Ericsson, 2016). Through this study's design, participants essentially deliberately practiced to improve their perseverance. They worked toward specific objectives of challenge, demonstrated appropriate prior knowledge, invested their full effort and attention to make progress on these tasks (relying heavily on self-control to not give up at moments of impasse and continue to persevere), were a self-source of feedback when recognizing a setback and modified their efforts accordingly, and had opportunities to repeat and practice working through these processes every week. With the scaffolded tasks, this repeated opportunity helped students refine their strategies over that time to learn to persevere in more effective ways. Although students also had a chance to repeat the processes of deliberate practice with non-scaffolded tasks, the data showed that they did not refine their strategies in the same high-quality ways as they did with scaffolded tasks.

Interpreting the apparent perseverance improvement in this study through a lens of deliberate practice makes clearer the process by which perseverance can be nurtured and developed, over time, in students. In mathematics education, deliberate practice has been studied primarily in the context of helping students learn specific skills and developing competencies in particular mathematical domains. Yet, findings in this study suggest mathematical practices like perseverance, in addition to domain-competencies, are malleable and able to improve through processes of deliberate practice, especially with support systems in place that encourage initial conceptual thinking. More work is needed to replicate these findings in different contexts. Still, teachers should take away from this study the key tenets of a learning environment conducive of developing more perseverant learners. No students are always perseverant, but regularly providing learning opportunities that encourage conceptual thinking and prize their productive struggle can support them "getting better at sticking with it" to make meaning of mathematics.

A design experiment with 18 students in a regular seventh grade math class was conducted to investigate how to differentiate instruction for students' diverse ways of thinking during a 26-day unit on proportional reasoning. The class included students operating with three different multiplicative concepts that have been found to influence rational number knowledge and algebraic reasoning. The researchers and classroom teacher tiered instruction during a 5-day segment of the unit in which students worked on problems involving speed. Students were grouped relatively homogenously by multiplicative concept and experienced different number choices. Students operating at each multiplicative concept demonstrated evidence of learning, but all did not learn the same thing. We view this study as a step in supporting equitable approaches to students' diverse ways of thinking, an aspect of classroom diversity.

Keywords: Rational Numbers, Instructional Activities and Practices, Middle School Education

Today's middle school mathematics classrooms are marked by increasingly diverse ways of thinking (National Center of Educational Statistics, 2016). Traditional responses to such diversity are tracked classes that contribute to opportunity gaps (Flores, 2007) and can result in achievement gaps. Differentiating instruction (DI) is a pedagogical approach to manage classroom diversity in which teachers proactively plan to adapt curricula, teaching methods, and products of learning to address individual students' needs in an effort to maximize learning for all (Tomlinson, 2005). DI is rooted in formative assessment, positions teachers and students as learners together, emphasizes engaging all students in creative thinking, and requires teachers to clarify big ideas for instruction in order to make effective adaptations.

One big idea in middle school mathematics is proportional reasoning (Lesh, Post, & Behr, 1988; Lobato & Ellis, 2010), and a great deal of research has been conducted in this domain (Lamon, 2007). One key finding is that computing to solve problems involving ratios (e.g., by cross-multiplication) does not indicate proportional reasoning and may mask it (Kaput & West, 1994; Lesh et al., 1988). A second finding is that students often double, triple, halve, etc., two quantities together as they learn to solve problems involving ratios (Kaput & West, 1994; Lobato & Ellis, 2010); in other words, students treat the two quantities as a *composed unit* (Lobato & Ellis, 2010) and operate on the quantities multiplicatively. For example, students who are creating mixtures of lemonade with the same flavor as 2 T powder with 3 cups water will double each quantity. A third finding is that operating multiplicatively on a composed unit is still different from thinking of the ratio as a *multiplicative comparison* (Lobato & Ellis, 2010), where students know, for example, that in the recipe the amount of concentrate is always 2/3 the amount of water. In this way of thinking, a person is measuring one quantity with the other, and doing so can lead to ideas about rates (Steffe, Liss, & Lee, 2014; Thompson, 1994).

One context for working on proportional reasoning with students is speed (Lobato & Siebert, 2002). In a teaching experiment with nine 8^{th}-10^{th} grade students, Lobato and Siebert gave a distance value and time value for one character to walk in a computer simulation and asked students to determine a different distance value and time value for another character to walk at the same speed. The researchers found that this problem engaged some students in constructing ratios. For example, ninth grade student Terry explained why traveling 2.5 cm in 1 s was the same as 10 cm in 4 s because he could see the 10 cm-4 s journey as made of up four 2.5 cm-1 s segments, and that each small segment was ¼ of the total journey. Similarly, in a teaching experiment with seven 7th grade students, Ellis (2007) found that such tasks supported students' construction of rate and slope in cycles of generalizing and justifying activity. Across both experiments students showed evidence of one hallmark of the construction of speed as a proportional relationship between distance and time, notably that "partitioning a traveled total distance implies a proportional partition of total time required to travel that distance" and vice-versa (Thompson & Thompson, 1994, p. 283).

The purpose of this paper is to report on this research question: What influences did tiering instruction with speed tasks have on a class of 18 regular seventh grade mathematics students during a unit on proportional reasoning? The report comes from a 5-year project to study DI and relationships between middle school students' rational number knowledge and algebraic reasoning. In the last phase of the project, the research team partnered with middle school mathematics teachers who had participated in a year-long study group to explore differentiation. In fall 2017 a seventh grade mathematics teacher and the project team designed to differentiate during a 26-day unit, and the teacher and first author co-taught the unit. The data for this paper comes from five episodes in which the students experienced tiered instruction focused on exploring speed to support reasoning with ratios. The instruction for these five days was adapted from Lobato's Math Talk project (mathtalk.sdsu.edu) and utilized the geogebra app Races developed by Bowers (https://www.geogebra.org/m/J434Kb54).

Theoretical Frame

In this section we present our definition of DI, our view of mathematical thinking, and a tool we use to understand students' diverse ways of thinking, students' multiplicative concepts.

Definition of DI

Our definition of DI is *proactively tailoring instruction to students' mathematical thinking while developing a cohesive classroom community* (cf. Tomlinson, 2005). For us, "tailoring instruction" requires posing problems that are in harmony with students' thinking and posing challenges at the edge of students' thinking (Hackenberg, 2010). We view a "cohesive classroom community" as students and a teacher who are working together to foster everyone's mathematical learning (Lampert, 2001; Tomlinson, 2005), who regularly talk about their ideas (Sherin, 2002), and who hold diverse points of view that are valued (Bielaczyc, Kapur, & Collins, 2013).

Mathematical Thinking and Interaction

As teacher-researchers we don't have direct access to students' mathematical thinking or points of view. So, we organize our experiences with students' thinking by describing and accounting for it using our constructs: operations, schemes, and concepts. *Operations* are the components of *schemes*, goal-directed ways of operating that involve a situation as conceived of by the learner, activity, and a result that the learner assesses in relation to her goals (von Glasersfeld, 1995). For us, mathematical learning involves a learner making reorganizations, or *accommodations,* in her schemes in on-going interaction in her experiential world.

Indeed, interaction is a core principle of our view of mathematical thinking and learning (Piaget, 1964; Steffe & Thompson, 2000). We find it helpful to think about two non-intersecting domains of interaction (Steffe, 1996): intra-individual interactions of constructs within a person, such as accommodations in schemes, and individual-environment interactions of which social interactions are a major part. Social interaction, such as student-student and student-teacher interactions, can open possibilities for accommodations and make operations and schemes apparent via verbalizations, non-verbal expression, drawn representations, or mathematical notation. Similarly, the construction of particular operations, schemes, and concepts can dramatically influence how a student interacts with others in a classroom (e.g., Hackenberg, Jones, Eker, & Creager, 2017). However, interaction of a particular kind in one domain does not directly cause interaction of a particular kind in the other (Steffe, 1996).

For us, *concepts* arise from re-processing the result of a scheme so that students can use it to structure a situation prior to acting (von Glasersfeld, 1982). Broadly speaking, students enter middle school operating with three different multiplicative concepts that significantly influence rational number knowledge (Norton & Wilkins, 2012; Steffe & Olive, 2010) and algebraic reasoning (Olive & Caglayan, 2008; Tillema, 2014). Transitioning between these three concepts requires substantial accommodations that can take two years (Steffe & Cobb, 1988; Steffe & Olive, 2010). Steffe (2017) estimates that at the start of sixth grade, 30% of students are operating with the first multiplicative concept, 30% with the second, and 40% with the third.

Students' Multiplicative Concepts

We view students' multiplicative concepts in terms of units coordination (Steffe, 1992). *Units* are discrete ones (Ulrich, 2015), lengths, or measurement units. As children progress in their construction of number and quantity, they organize units into larger units, such as composite units (units of units). A *units coordination* entails distributing the units of one composite unit across the units of another composite unit. For example, consider this problem: The length of the balance beam measures 8 skewer lengths. There are 7 toothpick lengths in a skewer length; how many toothpick lengths will measure the beam's length?

Students operating with the first multiplicative concept (MC1 students) solve this problem by counting on by 1s past known skip-counting patterns, tracking the total number of toothpick lengths and skewer lengths. For example, they might know that two 7s is 14. Then they count on by 1s to 21 for the amount of toothpick lengths in 3 skewer lengths. And they keep going. These students think of the result, 56 toothpick lengths, as a unit consisting of 56 units. But they don't see a multiplicative relationship between 1 toothpick length and the 56.

Students operating with the second multiplicative concept (MC2 students) do see a multiplicative relationship: The 56-unit length is 56 times 1 unit. These students also see the 56 toothpick lengths as eight 7s, or 8 units of 7 units of 1, which is three levels of units. However, as they work further, they think of 56 as a unit of 56 units of 1; the three-levels-of-units structure does not remain for them.

Students operating with the third multiplicative concept (MC3 students) can see what MC2 students see, but as they work further, they continue to view the 56 units as 8 units of 7 units of 1. This view is helpful if the number of skewer lengths is not a whole number. For example, if the distance were 8 ¼ skewer lengths, MC3 students are able to reason that to measure the distance in toothpick lengths they need eight 7s and ¼ of 7.

Method, Data Collection, and Data Analysis

To launch the experiment, we observed in two seventh grade pre-algebra classrooms: a participating class taught by Ms. W and a comparison class taught by a different teacher. Following observations, 38 students consented to participate: 18 out of 20 in the participating class, and 20 out of 21 in the comparison class. Before the unit began, we sought to develop initial understanding of students' multiplicative concepts and fractions knowledge and to select focus students: six from the participating class (1-3 operating with each multiplicative concept) and six from the comparison classroom. To gather initial information, we administered three written assessments of students' fraction schemes and operations (Wilkins, Norton, & Boyce, 2013) and multiplicative concepts (Norton, Boyce, Phillips, Anwyll, Ulrich, & Wilkins, 2015).

We used results of the written assessments, as well as our classroom observations, to select 30 students for 40-minute individual interviews prior to the start of the unit. In the interviews we developed deeper understanding of students' thinking, and sometimes we revised our assessment of a student's multiplicative concept. Following the interviews, we had 11 MC1 students (5 in the participating class), 17 MC2 students (9 in the participating class), and 10 MC3 students (4 in the participating class). We selected as participating focus students two MC1 students, three MC2 students, and one MC3 student, as well as six "matched" comparison focus students.

For this paper we have done two analyses. First, we developed second-order models of the six participating focus students; a second-order model is a researcher's constellation of constructs to describe and account for another person's ways and means of operating (Steffe & Olive, 2010). For each student, we repeatedly reviewed video of the student's three interviews; video of the student's activity during the targeted five days of class; and the student's written work, including a quiz on Day 17 and a unit test. To create the models we wrote summaries, interpretations, and conjectures, which we discussed at bi-weekly research meetings with a 6-member research team. We debated and questioned interpretations, coming to consensus through discussion. Each model is a description of the student's operations, schemes, and concepts, with accounts of accommodations that occurred and the individual-environment interactions (e.g., particular small group discussion) that were involved in the accommodations.

Second, we have engaged in close description and analysis of the classroom activity during the targeted five days. We have organized documents of the work of all 18 students across the five days in order to articulate trends and patterns in student ideas and responses.

Findings

Summary of Days 9-13

The unit consisted of three investigations: quantifying orangeyness (Days 1-8), quantifying speed (Days 9-18), and understanding percentages (Days 19-26). By Day 9 we had conducted formative assessment of students' reasoning with ratios during the quantifying orangeyness investigation. We found that MC1 students were not fluidly iterating two quantities as a composed unit (Lobato & Ellis, 2010), while MC2 and MC3 students were. So, we thought that tiering instruction at the start of the quantifying speed investigation would help us target students' current thinking with ratios and could support them to make advances. Students worked in small groups that were relatively homogenous by multiplicative concept from Day 9 to 13.

On Days 9 and 10 students articulated how to measure fastness and how they knew one car was going faster than the other in the Races app (Figure 1). Subsequently they worked on tasks where they were to make the red car go slower than the blue car if both traveled the same distance, and then if both traveled the same amount of time. On Days 11 through 13 students were given a distance value and time value for the blue car, and they explored how to make the red car go the same speed using a different distance value and time value. They were to justify their claims with pictures and explanations. Here we tiered instruction by selecting distance and time values strategically for different thinkers as shown in Table 1.

Now we show how students at each stage worked on the same speed task with a focus on members of the group that made the most progress: a group of three MC1 students in which we focus on Emily, a group of three MC2 students in which we focus on Lisa and Sara, and a group of two MC2 and two MC3 students in which we focus on MC3 student Joanna.

Figure 1: Races App with Blue Car (top) and Red Car (bottom)

Table 1: Students' Multiplicative Concepts and Numbers for Same Speed Task

MC	Same Speed Task (Blue car goes)
1	18 mi in 3 min; yields a whole number unit ratio (6 mi per 1 min)
2	15 mi in 6 min; yields a unit ratio that is a mixed number with ½ (2.5 mi per 1 min)
3	15 mi in 9 min; yields a unit ratio hard to work with as a decimal (5/3 mi per 1 min)

MC1 Students: Emily and Groupmates

When Emily and her two groupmates tried to find a distance and time for the red car to go the same speed as the blue car traveling 18 mi in 3 min, Emily suggested 9 mi in 6 min, 18 mi in 6 min, and 18 mi in 2 min. She seemed to be, primarily, halving or doubling either quantity but not operating on both together.

Then a groupmate suggested 36 mi in 6 min. Emily ran that race and was visibly excited when the cars kept pace with each other. She seemed suddenly subdued when the red car continued traveling after the blue car stopped, but the group concluded that the cars had gone the same speed and that doubling each number "worked."

The first author, Ms. H, asked the group to draw a picture to justify why traveling 36 mi in 6 min was the same speed as traveling 18 mi in 3 min. No one initially had ideas. Emily said, "I know how to tell, but I don't know how to show it." She explained that doubling each number (18 and 3) meant you could then divide each number (36 and 6) by 2, and "it's almost like they're the same number in a way." Ms. H acknowledged this idea but asked them to think about the quantities because that would help them develop stronger ideas about speed.

Ms. H asked if they could draw something to represent each journey. Emily's pictures evolved the most, so we focus on her. First Emily drew a segment to show each journey, identified by labels (Figure 2, left). When asked whether she could show the idea of doubling with the lengths, Emily drew a second picture (Figure 2, right).

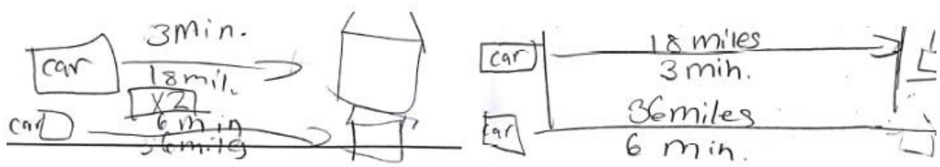

Figure 2: Emily's First Picture (left) and Second Picture (right)

Despite the discussion about doubling and Emily's emphasis on the importance of doubling, the second picture showed lengths about the same size. Ms. H asked whether the journeys were the same size, and Emily said no. She then extended the 36 mi-6 min segment but did not make it exactly twice as long as the 18 mi-3 min segment, in part because she reached the edge of the paper (Figure 3). She identified that there was supposed to be another 18 mi-3 min segment next to the first one, making up the 36 mi-6 min segment. She was about to draw a more exact picture when the period ended. So, Emily went from not knowing how to draw a picture to beginning to show how the 36 mi-6 min journey consisted of traveling the 18 mi-3 min journey twice. She presented this idea to the whole class the next day. In her follow-up interview on a similar question she began by showing two different journeys with equal lengths and then self-corrected to produce a picture showing relative size, which is evidence of learning for her.

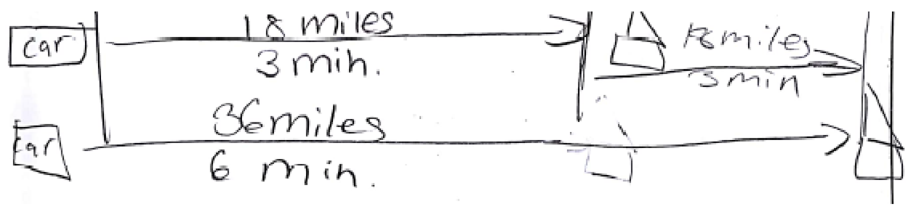

Figure 3: Emily's Third Picture

MC2 Students: Lisa and Sara

When Lisa and Sara tried to find a distance and time for the red car to go the same speed as the blue car traveling 15 mi in 6 min, Lisa suggested 14 mi in 5 min and then 15.1 mi in 6.1 min. When neither worked, both students said it was "impossible!" Ms. H asked them if it was really not possible for two cars to travel the same speed but different distances and times. Sara said: "They probably could, but I can't figure it out." Then she added, "unless you double it." They ran a race where the red car traveled 30 mi in 12 min, and they both seemed excited to find that doubling the quantities produced the same speed. "I figured the system out!" proclaimed Sara. Lisa added that it might be possible to triple both quantities or use other multiples.

Like Emily and her groupmates, Lisa and Sara found it challenging to explain why doubling would work. However, in contrast with Emily, Lisa's first picture showed that the 30-mi distance was twice the length of the 15-mi distance (Figure 4, left). In discussing the picture, Ms. H pointed out that in Lisa's picture it looked like the car traveling 30 mi went a trip of 15 mi in 6 min and then another trip of 15 mi in 6 min (tracing the trips with her pen).

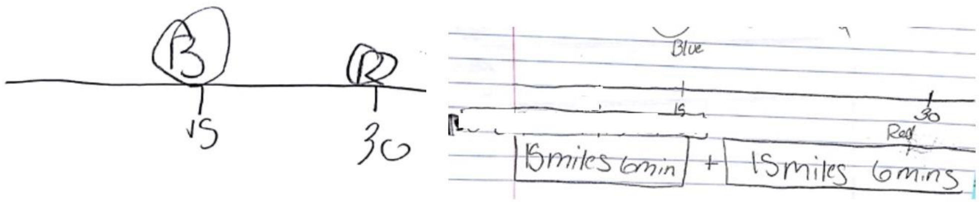

Figure 4: Lisa's First Picture (left) and Second Picture (right)

Lisa agreed and drew another picture (Figure 4, right) that showed the 30 mi-12 min trip as consisting of two "15 miles 6 min" segments added together. In a whole class discussion the next day, Lisa stated the idea that to go the 30 mi-12 min journey "first you'll need to do one 15 miles in 6 minutes and then you'll need to add another 15 miles in 6 minutes." Sara also used this multiple-trip explanation to explain solutions to this and other problems.

When Ms. H asked if they could find smaller distance-time pairs that would produce the same speed, they halved both quantities and indicated that they could continue to halve to find more same speed pairs. We note that Lisa and Sara did not consider dividing the distance and time values by numbers other than 2 without further teacher questioning. Nevertheless, during this instructional segment they went from not knowing how to generate same speeds to using at least whole number multiples and halving to do so, and from not knowing how to justify same speeds to using multiple-trip explanations. They sustained these ways of generating and justifying same speed pairs in their follow-up interviews.

MC3 Student: Joanna

When Joanna's group of four began discussing distances and times for the red car to go the same speed as the blue car travelling 15 mi in 9 min, Joanna quickly suggested 5 mi in 3 min. Her groupmate Mark suggested 16 mi and 10 min, adding one unit to each quantity. Joanna argued that 15 and 9 "reduced" to 5 and 3 but 16 and 10 "reduced" to 8 and 5, so 15 and 9 and 16 and 10 "wouldn't be the same ratio to each other." Using the app to test Mark's suggestion, the group determined that the red car travelling 16 mi in 10 min would actually go slightly slower than the blue car. Then Joanna stated that any numbers "where the miles would reduce to 5 and the minutes would reduce to 3" should work "because they're the same ratio to each other." She suggested 10 and 6 as another pair that would give the same speed.

To justify her claim, Joanna drew a distance line and time line (Figure 5). She partitioned the lines into three equal parts of 5 miles and 3 minutes. Then she used her picture to justify that when the red car travels 5 mi in 3 min, it goes the same speed as the blue car; it just stops earlier. Upon questioning, Joanna elaborated that 5 mi-3 min segment was 1/3 of the blue car's journey. To Joanna, the 15 mi-9 min trip was a unit that could be partitioned into 5 mi-3 min segments, and she saw that any trip made from a multiple of these segments would have to be the same speed as the blue car, a general way of thinking. She created this general way of thinking by determining the smallest whole number pair of numbers that could make the 15 mi-9 min trip.

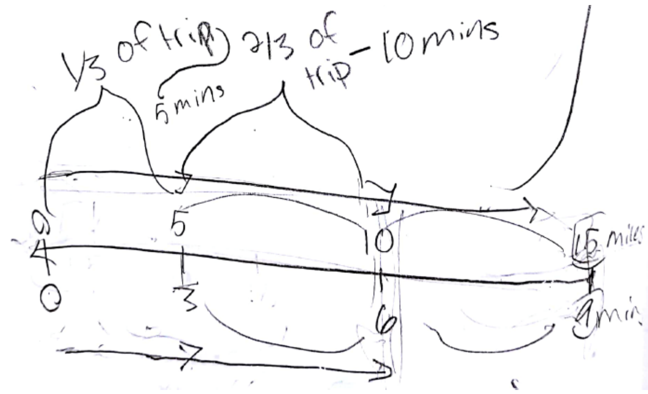

Figure 5: Joanna's Picture

Discussion and Conclusions

Now we point out some similarities in the students' ways of thinking, as well as differences that relate to students' multiplicative concepts. Notably, both Emily and Lisa were not sure how to create same speeds, and both took up groupmates' suggestions to double. However, Lisa's picture indicates that she conceived of doubling the quantities in a way that showed two smaller trips fitting into the larger trip. These relationships were not evident for Emily without interaction and support from a teacher to try to show relative size in her picture.

Students' multiplicative concepts are explanatory here. That is, both Emily and Lisa could repeat a distance and time to create a trip with double the distance and time. But Lisa appeared to have imagery of that larger trip as consisting of two smaller, equal trips—the smaller trip was both a part of the larger trip and also separate from it. This imagery is consistent with having constructed a disembedding operation where a unit (in this case, a segment representing a distance-time pair) can be both a part of a composite unit and also separate from it—a hallmark of the second multiplicative concept (Steffe, 2010). In contrast, Emily did not show obvious understanding of these embedded relationships. This phenomenon is consistent with MC1 students who conceive of a length as consisting of parts (smaller lengths), but once the original length has been separated into parts, they do not reunite the parts to create the original length or see the parts as being embedded in the original length (Hackenberg, 2013; Steffe & Olive, 2010).

In contrast to Emily, Lisa, and Sara, Joanna partitioned her distance and time quantities and seemed to view it as a logical necessity to partition each quantity proportionally (Thompson & Thompson, 1994). Her insight was that any numbers that were in a ratio of 5 to 3 would produce the same speed, so she saw more generally that 15 mi in 9 min was just one journey that was made from a multiple of 5 mi in 3 min. Her multiplicative concept can help account for her insight. That is, Joanna could view numbers and quantities as three-levels-of-units structures prior to working with them in a problem solving situation. So, she saw both 15 mi and 9 min as units of 3 composite units: 15 mi was a unit of 3 units of 5 mi, and 9 min was a unit of 3 units of 3 min. Being able to see both quantities in this way facilitated her thinking about how, since each 5 mi-3 min segment would have to be the same speed, then three of them strung together would be the same speed. Ultimately, she saw that any trip made from a multiple of this smallest whole number pair would produce the same speed.

Now we comment on the different numbers the students worked with. All distance-time pairs required taking thirds to get to the smallest whole number pair that could create the same speed (Table 1). Yet MC1 and MC2 students did not take thirds of their quantities: They doubled, tripled, and halved. We anticipated that many students initially would double and halve, and that is precisely why we gave pairs that could be “thirded” to produce the smallest whole number pair that could create the same speed. Thus, we learned that these number pairs were good choices in the sense of not being completely transparent to students. In addition, they supported MC3 students like Joanna to reveal the structural way she viewed and operated on both quantities.

Other researchers have used students’ ways of thinking about speed as an avenue for supporting the construction of ratios and rates (Ellis, 2007; Lobato & Siebert, 2002; Thompson, 1994), which are extremely important mathematical ways of thinking in secondary school. However, to our knowledge researchers have not investigated how students with different multiplicative concepts construct these ways of thinking, as well as how to differentiate instruction for these thinkers in the same classroom. In this seventh grade classroom tiering instruction was successful in supporting the learning of each of these three thinkers, although what each thinker learned was different. Thus, we view this study as a step in supporting equitable approaches to an important aspect of classroom diversity, students’ diverse ways of thinking. This kind of DI is an important component of inclusive, antiracist classrooms in which “equity is a priority” (Michael, 2015, p. 82) because all students are seen as mathematical thinkers and get what they need to learn.

BOB'S ADDITIVE REASONING: IMPLICATIONS FOR KNOWING FRACTIONS AS QUANTITIES

jhhunt5@ncsu.edu

Fractions are one of the most difficult areas of mathematics for all students and especially for students with learning disabilities (LD). An incomplete understanding of fractions during the elementary and middle school may be why some students view fractions as "really small" or "less than 1" compared to others who view them as multiplicative magnitudes. We analyzed how one student with LD worked on tasks involving both whole numbers and fractions using the framework of units coordination. Through our analyses of 14 teaching experiment sessions, we determined that he was operating on two levels of units with whole numbers, but only one level of units with fractions. We argue that this limited his ability to operate multiplicatively with fractions. However, his identified LD did not appear to impact his work with the fractions tasks he was given. Implications for future research and instruction are shared.

Keywords: (Dis)ability Studies, Rational Numbers

Background and Study Objectives

Fractions are one of the most relentless areas of difficulty in mathematics for all students (Siegler et al., 2010) and are especially for students with learning disabilities (LD) (Cawley & Miller, 1989). When asked to place fractions in order from least to greatest on two separate assessments, middle school students with LD answered only 47% and 1% of questions correctly, compared to 85% and 60% by students without LD (Mazzocco & Devlin, 2008). Similarly, researchers report fourth and fifth grade elementary students with LD begin their study of fractions with a diminished conceptual understanding compared to their peers (Geary et al., 2008) and show significantly less improvement in their ability to solve problems, estimate, and apply computational procedures with fractions over time (Hecht & Vagi, 2010). An incomplete understanding of improper fractions during the late elementary and middle school years may be the driving force behind why some students view fractions as "really small" or "less than 1" versus other who view them as multiplicative magnitudes (Resnick et al., 2016).

In this study, we present the whole number and fractional reasoning of one student with LD across 14 teaching experiment sessions. We utilize a three phase qualitative analysis to illustrate how this student evidenced his understanding of fractions as quantities through his interactions with varied tasks. Through our analyses of these data, we raise questions about the child's thinking and what his apparent knowing and learning were relying upon. The research questions addressed are (1) How does one child with LD conceive of whole number and fractions as quantities across varying task types? and (2) What persistent ways of reasoning were apparent across the child's activity and how did these contribute towards this child's knowledge of fractions?

Conceptual Framework

We think of students' understanding of fractions as quantities as a result of their propensity to multiplicatively coordinate units(s). Units coordination refers to how students create units and maintain relationships with other units (Norton, Boyce, Ulrich, & Phillips, 2015). It explains transitions children make from additive operations to multiplicative operations. Norton et al. (2015) explain that a student uses one level of unit when she conceives of situations such as five iterations of four by counting on from the first or second set by ones and double-counting the number of fours to reach a stop value (e.g., 4, 8, 12, 13-14-15-16, then 17-18-19-20). A student who uses two levels of units might conceive of five units of four as two units of four plus three units of four (e.g., three 4s is 12; 13-14-15-16; 17-18-19-20). This student breaks apart the composite unit of five into three and two and uses each of those parts to arrive at the solution. This student also sees "20" as both 20 ones and 5 fours all at once, so finding six units of four would not require reconstructing the first five units of four- the student would count-on from 20. Using three levels of units involves three related or coordinated units: (a) one unit of 20 that contains (b) five units of four, each of which contains, for instance, (c) four units of one. Students who anticipate three levels of units demonstrate flexible, strategic reasoning with each of the units.

Fractional units can also be coordinated. Steffe (2002) hypothesized that students would reorganize whole number unit coordinating to develop similar understandings with fractional units. Put differently, students use their whole number units coordination to conceptualize fractional units as a result of equi-partitioning whole units. The size of each fractional unit is one that when iterated n times would result in the size of one (Olive, 1999). To understand a non-unit fraction (m/n) as a number, students must conceptualize m/n as equivalent to m x $1/n$, n of which are the same value as 1. When the number of iterations of $1/n$ exceeds n/n, students must accommodate their part-whole reasoning from thinking of $1/n$ as one out of n total pieces to thinking of $1/n$ as an amount iterated more than n times without changing its multiplicative relationship with the size of 1. Thus, a multiplicative conception of fractions as quantities involves coordinating three levels of nested units: 10/4 as 10 times (1/4) *and* 1 is the same value as 4 times (1/4). Ten-fourths involves both a unit of 1 and a unit of 1/4 coordinated with 1. If students name the size of proper fractions by counting the number of parts of size $1/n$ within the bounds of a whole of n/n, they do not yet iterate $1/n$ (Tzur, 1999). This limits students' propensity to understand unit fractions beyond the size of the whole in a multiplicative manner.

Methods

"Bob"

The data utilized in this study illustrates the case of one fifth grade student who we refer to as "Bob." Eleven years old at the time of the study, Bob was an outgoing child who often imagined creative ways to solve problems and was eager to interact with problematic situations. Inclusion criteria for the study were as follows: (a) individualized education program goals in mathematics, (b) a cognitively-defined label of learning disability (LD) with working memory as the dominant cognitive factor, (c) identification through clinical interview data that the child had constructed at least a parts within the whole concept of unit and non-unit fractions, and (d) identification by the classroom teacher as 'non-responsive' to supplemental, small group intervention from a textbook or supplemental curriculum in advanced fraction concepts.

For Bob, school-based instruction included opportunities to shade pre-partitioned wholes to reflect a designated number of parts. Bob extended this activity to represent various fractional quantities using area, set, and linear models. These experiences were designed to help Bob see the relationship between one of the equal parts and the whole. Area, set, and linear models were also used during school-based instruction to represent equivalent fractions as well as to identify given fraction representations as equivalent. Procedures for fraction operations followed.

Furthermore, although Bob was able to construct unit fractions and identify shaded parts of wholes (e.g., identify one part shared within a partitioned item as one-seventh; determine the share of 4 objects among 3 people as one whole and one third); he could not yet draw parts outside of and relative to the whole. He did not yet conceive of non unit fractions as a summation of unit fractions (¾ = ¼ + ¼ + ¼) or a multiplicative relation with respect to a unit fraction (e.g., ¾ as three iterations of ¼). Instead, ¾ was three of four parts.

Study Design and Data Sources

We report on five sessions conducted as part of a larger individualized teaching experiment of 14 sessions (Steffe & Thompson, 2000) because these sessions provided evidence of how Bob coordinated units with whole numbers and fractions. We also conducted two formative clinical interviews that serve as pre-and post-measures (Ginsburg, 1997). Each interview and instructional session lasted about 30 minutes. The second author was the researcher-teacher. The first and second authors both engaged in the retrospective analysis after data collection concluded. The instruction was conducted in a one-on-one setting in the school library. The classroom was equipped with one circular table, unifix cubes, pens, paper, and chart paper. Sessions took place after school and were in addition to Bob's regular math class time. We collected three sources of data: video recordings, written work, and field notes.

Data Analysis

Data analysis occurred in three phases. The first involved ongoing analysis of video data and written work immediately following each teaching session. The ongoing analysis led to planning the following teaching episode and consistent modification of hypothesis regarding the child's mathematics and goals in activity. The focus was on generating (and documenting) initial hypotheses as to what conceptions could underlie the child's apparent problem-solving strategies during these critical events. These hypotheses led to (a) designing subsequent teaching episode(s) and (b) guiding retrospective analysis.

The second phase of data analysis included a retrospective identification of broad indicators, or stages, of conceptual growth after the sessions concluded (Leech & Onwuegbuzie, 2007). We conducted a line by line examination of the transcribed data, student work, and notes with a side by side of video data to consider Bob's thinking within each session. Analysis of each teaching episode focused on expanding our model of Bob's thinking. We coded segments within the session for indications of Bob's units coordination and operations at the time, using prior research as a framework. Bob's gestures and explanations (e.g., from post-episode field notes) were incorporated into the analysis to provide a thick depiction (Geertz, 1988) of his current operations— served as further triangulation. The third phase involved fine-grained analysis to closely consider how Bob advanced his thinking from one stage to the next and the difficulties he experienced (Tzur, 1999).

Results

"I Just Added Two"

During the first instructional session, Bob was presented with the task of making "double" of several whole numbers of squares. He doubled one and two squares to make two and four squares, yet when asked to double four squares, he made six squares. His explanation for doubling both two and four was, "I just added two."

<u>Session 1: Make double of four squares</u>
Instructor: Could you make double that [points to line of four squares]?

Student: Yeah.
Instructor: Maybe – [student traces one square on each end of line of four squares] What'd you do there?
Student: I just added two.
Instructor: You added two. Hmm, gotcha. So, what's this whole length called? [runs finger along line of six squares]
Student: [tapping pencil on desk] One or one, two, three, four, five, six, six. [pointing at squares, but not counting one to one]

We questioned whether Bob was coordinating whole numbers multiplicatively. Moreover, it was unclear to us whether Bob connected "doubling" with two levels of units (e.g., viewing four as two units of two). This wondering would permeate throughout the teaching sessions.

"One, Two, Three, Four"

The next several sessions continued to provide contradictions in how Bob was coordinating units. For instance, in the transcript below, Bob shares three French fries among four people. At first glance, it seems as if Bob is utilizing two levels of units multiplicatively to consider the resulting quantity. Yet, as the transcript shows, Bob coordinated units with whole numbers and fractional units utilizing additive reasoning.

<u>Session 5: Share three fries among four people</u>
I: Could they each get a whole one? Could they get less than a whole? Remember these are really big fries.
Bob: So one of them you could cut in half [makes a chopping gesture]... two of them could be cut in half.
I: Two of them need to be cut in half, okay.
Bob: And then we need to have one more French fry.
I: What did you do to that one?
Bob: And then now we'll have to split that one up… into… fourths so if I did one [uses finger to mark first line and second line]– that's…
I: Are you showing me the lines?
Bob: So that's 1, 2, 3, 4 [uses fingers to show lines] and there and there [marks lines].
I: Like that? Nice. There you are [draws a smiley face on paper]. How much do you get?
Bob: [draws a smiley face on one of the halves and one of the fourths]
I: So you get this part and this part? [points to pieces labeled with smiley faces] How much is that? Bob: ½ [points to the one-half].
I: What's this part called?
Bob: 1/4. [points to the one-fourth]
I: So would it be fair to say that you get one fourth and one half of a fry?
Bob: [measures ¼ piece and adds it to the end of "his" half] This is how much I will get.

Bob coordinated four sharers across two wholes by partitioning each whole into two parts. At the time, we viewed this as evidence that Bob utilized two levels of units to create four from two twos multiplicatively. However, to coordinate fourths with respect to one whole, Bob seemed to count by ones as opposed to partitioning into halves and then fourths (Confrey, Maloney, Nguyen, & Rupp, 2014). Furthermore, although Bob was able to draw the two fractional pieces together on one strip, he did not yet see the parts as a continuous quantity (i.e., as three-fourths).

Thus, Bob coordinated whole numbers on two levels additively and fractions on one level additively.

“Two Out of Five”

In Session Six, Bob displayed part-whole knowledge of fractions to consider two-fifths as two parts out of five parts. He was able to use his part whole knowledge to create one-fifth using the computer program JavaBars and iterate the one-fifth to make seven-fifths. Yet, his language shows that he views the created quantity as seven as opposed to seven fifths.

<u>Session 6: This bar is two-fifths. Can you make seven-fifths?</u>
Bob: Two-fifths [splits bar into two], so it’s two… it’s two out of five, so maybe if I… That’s two – every one out of five, two out of five…
I: Mm-hmm.
Bob: There’s two now and, well, uh, and… and then that one. [pulls out one fifth]
I: What’s that one? [points to pulled out one-fifth]
Bob: One-fifth.
I: It’s one-fifth.
Bob: And it –
I: We want seven-fifths.
Bob: Seven fifths… one out of five, seven-fifths, so we want… and then that is… [repeats 1/5 four times, pauses to count]. Okay, you just do that. [repeats two more fifths to make seven fifths] One, two, three, four, five, six, mm, six, seventh. But this is how big it is.
I: That’s how big it is?
Bob: Yeah.
I: That’s how long? [student accidently repeats an additional one-fifth] Whoops.
Bob: Uh… one, two, three – eight-fifths. Eight-fifths, whoa.
I: Yeah, a question for you. See this eight-fifths? How many times bigger is that than the two-fifths?
Bob: Mm… three.
I: Three times bigger?
Bob: Because ... these two come together [points to two one-fifth sized parts]. So, these two come together, and these two come together, and these two come together [points to third and fourth, then fifth and sixth, then seventh and eighth one-fifth parts]. And that; two, four, six – and then those two.

In this excerpt, Bob interprets two-fifths as two pieces out of five pieces, with each piece representing one-fifth. This thinking promotes him to pull out one fifth from the two-fifths displayed; he then repeats the one-fifth he removed from two-fifths four times to make five fifths. He pauses, then repeats the part two more times to create seven fifths. We interpreted Bob’s reasoning as additive; he adds one more to achieve seven one fifths. Bob’s justification of the relationship of eight fifths to two fifths was *three more times,* or three extra pairs of two, as opposed to four times as large. Furthermore, we argue that, for Bob, the parts are not fifths, but *ones* that are part of a whole comprised of five units. Evidence for this claim rests in his consistent numbering and counting of the parts as whole numbers and only naming the parts with fractional language when prompted.

“Six Times Six is 12”

Because of his persistent additive reasoning to this point, in Session 11 Bob plays “Please Go and Bring for Me” (Tzur et al., 2013), a game designed to promote multiplicative units coordinating with whole numbers. Below, Bob considers how to coordinate five iterations of a unit of six.

<u>Session 11: Make five towers of six</u>
I: Okay. Five towers of six. Okay. So, um, how many towers did you bring?
Bob: Um, five towers of six. [brings towers back to table (2 purple, 1 green, 2 pink)]
I: Okay, so five towers, and how many in each tower?
Bob: Six.
I: So how many cubes did you bring in all?
Bob: Six [slides over 1 tower], 12 [slides over 1 tower], 24 [slides over 2 towers], 24…, 25, 26, 25, 26, 27, 28, 29, 30 [counts on fingers], 30.
I: Thirty cubes. Can you tell me how you figured that out?
Bob: I just showed – so, six times six is 12, and then 12 plus 12 is 24, and here and I already have a six, which is 30 [moves towers as he talks about them].

Bob conceived of five towers of six as two, two, and one tower with visible cubes. Interestingly, he builds the towers using three different colors of cubes, suggesting that the groups of two created in his towers belong together. This seems to support his counting of the cubes as a “double” (i.e., “Six, 12, 24”). Bob seemed to conceptualize doubling as *adding the same group*, supporting his breaking apart of the composite five into two, two, and one. Thus, he could access a two level structure additively, utilizing his way of doubling for a few iterations. His way of doubling breaks down with larger numbers. Other sessions continued to show sustained use of additive reasoning to solve problems.

Later in this session, the researcher-teacher confirmed understanding of how Bob utilized doubling in both whole number and fractional situations. For this task, Bob again used the computer program JavaBars. Below, Bob considers how to coordinate fractional units beyond a whole by employing his conception of doubling.

<u>Session 11: This ribbon is one-eighth of a yard long. What does twice as much ribbon look like?</u>
I: I want you to pretend this is a piece of ribbon, and you own a store where you sell ribbon in pieces. And the pieces that you sell are one-eighth of a yard long.
Bob: Okay.
I: I'm thinking about two times as much as that.
Bob: [repeats the bar]
I: Okay. What's the name that you give that?
Bob: One-eighth. I mean two-eighths.
I: Two-eighths. How do you know it's two-eighths?
Bob: 'Cause it's two out of eight, and I had just added one, so it's two out of eight.
I: Now, I'm thinking about an, an amount that's two times as much as this [points to Bob’s two-eighths].
Bob: Okay.
I: What would that look like?
Bob: That big. [repeats one-eighth piece twice; adds on to two-eighths]

I: Okay. That big. Um, how much of a whole yard is that?
Bob: Four fourths – I mean, four-eighths.
I: Four fourths, four-eighths, which one?
Bob: I think four-eighths.
I: Four-eighths? How do you know it's four-eighths of a yard?
Bob: Um, 'cause it's four pieces out of eight.
I: Four pieces out of eight?
Bob: Uh-huh.
I: Okay, um, tell me more about that. How do you know it's four pieces out of eight?
Bob: 'Cause there's four, and there's supposed to be eight.
I: How do you know there's supposed to be – ?
Bob: 'Cause that's how big a yard is, and I know, and I'm the manager.

Previous tasks had shown Bob using his reasoning about doubling, but in this task, he explicates his notion of "double" as "add one more group." Furthermore, he displayed his persistent part whole concept of units (e.g., four pieces out of eight; two parts out of eight parts). Bob's activity confirmed our hypothesis that his additive view of whole numbers and fractions was a salient and persistent way of reasoning.

"Then it Would Be a Ninth"

In the post assessment, Bob shows the limitations of his whole number, additive reasoning. He was able to split three-eighths to create a one-eighth but continued to name fractional units as whole number units. The limitations of utilizing the whole number reasoning and equal groups reasoning becomes evident in Bob's conceptualization of one whole. When asked to create one and one-eighth (as opposed to an improper fraction name such as nine-eighths), Bob loses the unit structure.

<u>Post Assessment: This is three-eighths. Make one and one-eighth.</u>
I: This is three-eighths. [gives new piece]
Bob: Three. This is three.
I: That's three-eights.
Bob: Three-eighths. It's three-eighths.
I: What are you doing there?
Bob: Making three parts [folds a strip of paper].
I: You mean three in there? Okay. And then you're gonna use one of them?
Bob: So then, then it's one-eighth now. [has piece folded into thirds] One.
Bob: Two. Three. Four. Five. Six. Seven. Eight [traces eight of the one-eighths in a line].
I: I want you to make one and one-eighth.
Bob: One and one-eighth [traces one more of the one-eighths separately from the line of eight].
I: Oh. So this is one? [runs finger along line of eight] And that's one-eighth? [points to one piece]
Bob: Mm-hmm.
I: Okay. Would it be the same thing if you had made this one-eighth down here? [points to end of line of eight pieces] Would it be the same or different?
Bob: No. Different.
I: That'd be different.

Bob: Then it would be a ninth.
I: Would it be a ninth? How can it be a ninth?
Bob: Because it would at one. [pause] No and the nine it wouldn't. Or it wouldn't work. 'Cause, 'cause this is one entire length [points at line].
I: Can you circle the one whole?
Bob: There [circles one-eighth].
I: Can you circle the one whole?
Bob: This one? [circles the line of eight one-eighths]
I: Where's the one whole that you made? So if I tacked on another eighth ... I couldn't do that? [motions to one-eighth and puts it at end of line again]
Bob: Nope. You'd have to make these smaller.

Discussion

Throughout the sessions, researchers worked to reorganize Bob's whole number unit coordination to support understanding of fractional units. We hypothesized that Bob would use his whole number units coordination to consider fractional units as multiplicative quantities. To that end, we designed various situations to elicit multiplicative reasoning, both in whole number and in fractions. Two key findings emerged from the analysis related to Bob's reasoning.

First, Bob did utilize his whole number reasoning across situations, whether the situations elicited fractions or not. Yet, because his reasoning was largely additive in nature, this placed limitations on how Bob conceived of fractions as numbers. Namely, Bob's pervasive use of a part whole notions of fractions limited his understanding of fractions as quantities. Second, we saw little to no evidence of Bob's cognitive difference (i.e., working memory) apparent across the sessions. For instance, Bob did not seem to have a need to re-run his activity or re-verbalize his thought processes in the midst of learning. For Bob, the single disabling factor in his reasoning seemed to rest in his pervasive part whole notion of fractions and overreliance on additive reasoning.

Implications from the work include the need to provide students with LDs rich experiences to develop multiplicative reasoning in both whole number and fractions, including tasks that utilize a three level structure in early learning experiences. This student with LDs seemed to "need" more experiences developing multiplicative conceptions as opposed directive forms of instruction that emphasized facts and procedures.

Acknowledgments

This work was supported by a grant from the National Science Foundation, DR-K12, grant number 1446250.

Equity Statement

Our research is based in the notion that students with disabilities can and do advance their notions of multiplicative reasoning in whole number and fractions. Addressing conceptual advancement for this underserved population addressed equity because historically these students have been denied access to opportunities to grow their conceptual knowledge of mathematics, limiting school and life outcomes.

This study was conducted to gain understanding about potential influences that learning about quadratic functions has on high school algebra students' action versus process views of linear functions. Pre/post linear functions tests were given to two classrooms of Algebra II students (N=57) immediately before and immediately after they participated in a multi-day unit on quadratic functions. The purpose was to identify ways that their views of linear functions had changed. Results showed that on some measures, students across both classes shifted their views of linear functions similarly. However, on other measures, the results were different across the classes. These findings suggest that learning about quadratic functions can influence students' action or process views of linear. Furthermore, the instructional differences between classes provide insights into how to promote those influences that are productive for students' views.

Keywords: Algebra and Algebraic Thinking, High School Education, Learning Theory

A well-established and widely-held idea in the mathematics education research community is the importance of the relationship between prior ways of reasoning and new learning (e.g., Bransford & Schwartz, 1999; Roschelle, 1995; Vosniadou & Brewer, 1987). However, most of this prior research focuses on the foundational role that prior knowledge plays in new learning. In other words, this research has primarily examined the influence that prior ways of reasoning can have on new learning. This is typically referred to as the *transfer of knowledge* (Lobato, 2008). What has yet to be well examined, especially in the context of mathematics education, is the influence that new learning can have on prior ways of reasoning.

We use the forward and backward direction to distinguish between the two kinds of influences mentioned above. Specifically, we use *forward* to describe influences that go from prior ways of reasoning to new learning and *backward* to describe influences that go from new learning to prior ways of reasoning. While, forward influences (also known as *forward transfer*) have been a well-researched construct in mathematics education, backward influences is a new idea for mathematics education research. Our research addresses this gap by examining backward influences in real algebra classrooms.

We know of only a handful of studies about backward influences in the context of mathematics education, including Hohensee's (2014, 2016) studies on middle school students reasoning about functions, Macgregor and Stacey's (1997) study on secondary students' reasoning about algebra symbols, Young's (2015) study on AP calculus students' reasoning about differentiation and integration, and Moore's (2012) study on undergraduates' reasoning about calculus concepts.

Despite the limited research on this topic, these studies have revealed that backward influences can be unproductive or productive. *Unproductive* backward influences are when students' prior ways of reasoning become muddled or shift to a lower level, because they learn something new (e.g., Macgregor & Stacey, 1997). More theory and research on backward influences are needed to find ways to prevent or at least mitigate unproductive backward influences. *Productive* backward influences are when students' prior ways of reasoning become refined or enhanced because they learn something new (e.g., Hohensee, 2014). More theory and research are needed to uncover ways to promote productive backward influences. The goal for this study was to contribute, as an early step, to developing more understanding about backward influences that occur in high school algebra classrooms, so as to inform ways to inhibit unproductive backward influences and promote productive backward influences.

Theoretical Framework

Our theoretical framework has two parts. The first part involves how we conceptualized backward influences by new learning on prior ways of reasoning. The second part involves the theoretical perspective that guided our study about ways to reason about functions.

Conceptualizing Backward Influences by New Learning on Prior Ways of Reasoning

Backward influences by new learning on prior ways of reasoning in the context of mathematics education have not been well-studied or theorized. However, in other domains, backward influences have been regularly referred to as a form of transfer of learning called *backward transfer*. For example, the effect that learning a second language has on individuals' ability to produce and comprehend their native language has been conceptualized as backward transfer (e.g., Cook, 2003). Therefore, we conceived of backward influences in the context of mathematics education as backward transfer.

Broadening the conceptualization of transfer to include backward influences is a new idea for mathematics education. A theoretical implication from this broad conceptualization is that perhaps one of the well-articulated mathematics education theories of transfer may be a suitable candidate to extend to include backward transfer. Among the theories we considered, Lobato's (2008) *actor-oriented transfer* (AOT) *perspective* is a suitable candidate because of the emphasis in the definition on transfer as an influence. In particular, according to AOT perspective, transfer is "the *influence* of a learner's prior activities on his or her activity in novel situations" (p. 169, emphasis added). An assumption underlying the AOT perspective is that transfer has occurred whenever a learner's prior activities influence their activities in a novel situation (i.e., forward influence), regardless of whether, from an outside-observer's perspective, the new activity involves normative or non-normative performance.

Based on the AOT perspective, we defined backward transfer as the "influence that learning something new has on a learners' prior ways of reasoning about a different or related concept" (Hohensee, 2014, p. 136). Consistent with the AOT perspective, we consider any backward influences by new learning on prior ways of reasoning, regardless of whether they lead to more- or less-normative performance, as cases of backward transfer. A primary reason to study backward transfer in mathematics education contexts is because of the potential that backward transfer unintentionally undermines or weakens learners' prior ways of reasoning (i.e., leads to less-normative performance). Understanding more about backward transfer could enable mathematics educators to develop instructional approaches that minimize unproductive effects.

Note that Young (2015) and Moore (2012), cited previously, adopted the same extension of the AOT perspective to conceptualize backward influences, while Macgregor and Stacey (1997) conceived of backward influences differently (i.e., as interference of learning).

Theoretical Perspective on Ways to Reason about Functions

Within the field of mathematics education research, a number of perspectives on ways of reasoning about functions have been put forth. The perspective we used for this study was the APOS perspective on ways of reasoning about functions (Breidenbach, Dubinsky, Hawks, &

Nichols, 1992). APOS stands for *action, process, object* and *schema*, and represents four ways to view functions (as well as other mathematical concepts). For our study, action- and process-views of functions were most relevant. An action view is described as “any repeatable physical or mental manipulation that transforms objects (e.g., numbers, geometric figures, sets) to obtain objects” (p. 249), and as “a static conception in that the subject will tend to think about it one step at a time (e.g., one evaluation of an expression)” (p. 251). In contrast, a process view is described as “[the] total action can take place entirely in the mind of the subject, or just be imagined as taking place, without necessarily running through all of the specific steps” (p. 249) and as “a dynamic transformation of objects according to some repeatable means…a complete activity beginning with objects of some kind, doing something to these objects, and obtaining new objects as a result of what was done” (p. 251). According to APOS Theory, an action view is a necessary precursor to a process view in the development of conceptions of functions.

One reason the distinction between action- and process-views of functions was important for our study was because, as Breidenbach et al. (1992) point out, “many individuals will be in transition from action to process…the progress is never in a single direction” (p. 251). In other words, an individual can change between action- and process-views of functions. For our study, we wondered if students’ views of linear functions would change because of influences by new learning about quadratic functions. Our research question was the following: *In what ways do algebra students’ prior ways of reasoning about linear functions change, if at all, along the dimension of an action versus process view, after they participate in an instructional unit on quadratic functions?* Next, we describe the methods we used to address this question.

Methods

Participants and Setting

The participants were Algebra II students from two classrooms at two high schools in the Mid-Atlantic region of the US. Both schools were ethnically diverse and drew from an urban population. All students in both classes volunteered to participate in the study (24 in Class 1; 33 in Class 2; N=57). The students reflected the ethnic diversity of their respective schools. The study took place from March to May of the school year. Each class had an experienced teacher: Ms. Henry (Class 1) had 8-years of teaching experience; Mr. Anderson (Class 2) had 17-years of teaching experience.

Procedure

The study procedures followed a pre/post format, in which pre- and post-tests on linear functions bookended an instructional unit on quadratic functions. Before the instructional unit, all students took a 45-minute paper-and-pencil linear functions pre-test. Also, four students from each class participated in one-on-one pre-interviews about their responses on the pre-test.

Students then participated in a multi-day instructional unit on quadratic functions taught by their regular algebra teacher. All lessons were observed and video recorded.

After the instructional unit, all students took a 45-minute paper-and-pencil linear functions post-test. Finally, the same four students from each class who participated in the pre-interviews, participated in one-on-one post-interviews about their responses on the post-test.

Linear Functions Pre- and Post-Tests

We used two versions of the linear functions test. Students were randomly sorted into two equal groups and assigned to either take Version A as the pre-test and Version B as the post-test, or vice versa. Each problem on Version A had a structurally similar problem on Version B. The purpose of having two versions and varying the order was to control for the possibility that students would do better on the post-test if they took the same test pre and post, and for the possibility that items on the versions were not comparable. Each version had one problem based on a graph, one problem based on a table and one problem based on a picture. Results from the picture problem are presented in this report (see Figure 1 for the picture).

Instructional Unit

Each teacher taught their instructional unit on quadratic functions using the Integrated Mathematic II curriculum and were given no direction by the researchers about how to teach the unit. Both teachers typically lectured for part of the class, gave students a seatwork assignment and held a whole-class discussion about the solutions. Ms. Henry's instructional unit was comprised of 16 lessons, and each lesson was 70 min. Mr. Anderson's instructional unit was comprised of 11 lessons, and each lesson was 45-80 min., due to a rotating block schedule. Both teachers seated students in groups. Both teachers were well liked by their students and their lesson were conducted in an orderly manner.

A difference in teaching styles was that Ms. Henry typically used an online platform that students accessed with laptops (i.e., Class Lab), that allowed her to monitor student responses in real time. She would then go over students' responses with the class and provide feedback. In contrast, Mr. Anderson typically had students go the board and write down their solutions to problems. Then, he would go over the responses with the class and provide feedback.

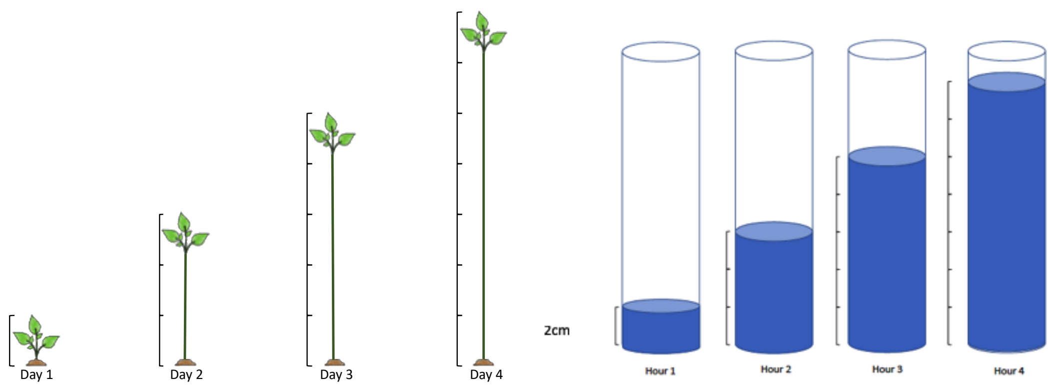

Figure 1: Growing Plant (Version A) and Container Filling with Rain Water (Version B)

A second difference between teachers was the time spent on specific quadratic functions topics. For example, Ms. Henry spent the most lessons on factoring quadratics expressions, real-world problems modelled with quadratic functions and graphing quadratic functions (see Table 1). In contrast, Mr. Anderson spent the most lessons on solving quadratic equations.

Table 1: Breakdown of Lessons Devoted to Each Quadratic Functions Topic

Teacher	Lesson Topic	# of Lessons
Ms. Henry	Lessons on factoring (factoring diamonds, difference of squares, leading coefficient≠1)	4
	Lessons on real-world problems	4
	Lessons on graphing (x/y-intercept, max/min, axis of symmetry)	3
	Lessons on solving by graphing	2

	Lessons on solving by factoring	2
	Lesson on standard, vertex and x-intercept equation forms	1
Mr. Anderson	Lessons on solving (square root both sides, complete the square, quadratic formula)	5
	Lessons on graphing (x/y-intercepts, max/min, axis of symmetry, translations/dilations)	2
	Lesson on solving by factoring	1
	Lesson on factoring	1
	Lesson on real-world problems	1
	Lesson on standard, vertex and x-intercept equation forms	1

Data Set

Our data set was comprised of the pre-/post-tests, video-recorded pre-/post-interviews (4 students per class), video-recorded classroom observations and observation field notes.

Data Analysis

Analysis of the data was conducted in three stages: (a) analysis of the pre-/post-test responses and interviews for students who participated in interviews, (b) analysis of the pre-/post-test responses for remaining students, and (c) analysis of fieldnotes from the classroom observations.

Analysis of pre-/post-test responses and interviews for interviewed students. For stage 1 of the analysis, the first author compared the pre-/post-test responses and the pre-/post-interviews for the 4 students from each class that were interviewed. The unit of analysis was each sub-part of each question. From these comparisons, the first author developed an initial set of codes with *grounded theory* (Strauss & Corbin, 1994). Initial codes and supporting evidence were presented to the second and third authors for feedback on the validity of the codes. Once agreement was reached about the interviewed students, the authors proceeded to the next step in the analysis.

Analysis of pre-/post-test responses for the remaining students. Each author took one-third of the remaining tests and again compared sub-parts on one test for each student to the associated sub-part on the other test, noting whenever a change in reasoning fit one of the existing codes. During this analysis, we blinded ourselves to which tests were pre-tests and which were post-tests. The initial codes were in some cases insufficient to capture changes in students' views of functions. In those cases, the coder either refined an existing code or created a new code. Once, each author had coded their dataset, we met in pairs to discuss changes in reasoning that had been identified, to check for agreement on whether the evidence that a change had occurred was compelling and the right code had been applied. Whenever a pair of coders failed to reach consensus on a response, it was flagged and discussed by all three authors until consensus was reached. As such, we continued to refine our grounded theory with a *constant comparison approach* (Strauss & Corbin, 1994). Once all coded responses had been discussed in pairs or by all three authors, and the codes had stabilized, we recoded all the coded responses to ensure that the refined codes fit the entire data set.

Analysis of classroom observations. Analysis of the classroom observations is ongoing. Thus far, the first author has summarized the field notes on a spreadsheet, and identified differences between the two classes in terms of numbers of lessons devoted to specific quadratic functions topic (see Table 1). In future analyses efforts, the three authors will divide up the recordings of the lessons and identify particular episodes in which potential connections to the changes in reasoning observed in the pre-/post-tests exist. Episodes will be transcribed and analyzed to identify the interactions, visual representations, gestures, etc., that could account for to the observed changes in reasoning identified in the pre-/post-test responses.

Results

Analysis of the pre- and post-tests revealed that, in a number of cases, students' views of functions had changed in terms of an action versus a process view. In some cases, the changes in views were similar across the two classes, whereas in other cases, they differed. Next, we show how students' views of functions changed on each of the three sub-parts for the picture problem.

Reasoning with a Build-up Process or a Repeated Build-up Process

Our first finding was that several students changed the way they reasoned on the first sub-part of the pictorial problem, which asked "*Explain in words how to find the height of the plant on day 17*" (Version A) or "*Explain in words how to find the total amount of rainfall if the storm lasts for 11 hours*" (Version B). One reasoning strategy was to repeatedly add the amount of growth, one day or one hour at a time, while simultaneously keeping track of the days or hours, until the height on the desired day or hour was attained. Kaput and West (1994) called reasoning about linear functions in this way a *build-up process*. The second strategy was to multiply the rate of growth by the number of days or hours. Kaput and West (1994) called this an *abbreviated build-up process*. In other words, the abbreviated build-up process required one step, while the build-up strategy required multiple steps. A third strategy was to add a combination of *given* heights and times to find a desired height, such as finding the height on day 11 by doubling the given height on day 4, and adding the given height on day 3. Since this third strategy also required multiple steps, we included this strategy as a build-up process.

Frequency counts supporting this claim. A change from *build-up* to *abbreviated build-up* process was observed for 6 of Ms. Henry's 24 students and 7 of Mr. Anderson's 33 students (see Table 1). A change in the other direction was less common: only 3 of Ms. Henry's students and 2 of Mr. Anderson's students. The remaining students maintained one strategy on both tests or did not provide sufficient responses for us to determine if their reasoning had changed. Note that the more common change from build-up to abbreviated build-up process was similar across classes.

Table 2: Change Involving Build-up Process and Abbreviated Build-up Process

Teacher	Students per class	From build-up to abbreviated build-up	From abbreviated build-up to build-up	Maintained build-up: Maintained abbreviated build-up
Henry	24	6	3	12:2
Anderson	33	7	2	8:3

Change interpreted in terms of action versus process view of functions. We interpreted a change from reasoning with a build-up process to reasoning with an abbreviated build-up process as a possible shift away from an action view towards a process view of functions, because with a shift to an abbreviated build-up process, students reasoned as if they knew, without calculating each separate change in height, that all the changes in height would be the same and that they could simply multiply by how many changes in height there were. This aligns with Asiala et al. (1997), who described the process view as "it is not necessary to perform the operations, but to only think about them being performed" (p. 8).

Reasoning about Independent and Dependent Variables

Our second finding was that several students changed their way of reasoning on the second sub-part of the pictorial problem, which asked "*Can you find the day* [independent variable] *the plant was measured if you were given the height* [dependent variable]*? If yes, explain how. If no, explain why not*" (Version A), or "*Can you find the hour* [independent variable] *the rain water was measured if given the height* [dependent variable]*? If yes, explain how. If no, explain why not*" (Version B). Students who exhibited this change, either reasoned on the pre-test *it is not possible* to use the dependent variable to find the corresponding value of the independent variable and on the post-test reasoned *it is possible*, or vice versa. Note that *it is possible* is correct because the independent variable in a linear function can be found (i.e., $x = (y - \mathrm{b}) / \mathrm{m}$).

Frequency counts supporting this claim. This change was more common for Ms. Henry's students than for Mr. Anderson's students, by a ratio of 9:2 (see Table 2). Additionally, Ms. Henry's students who exhibited this change were almost evenly split on changing from *it is* to *it is not possible* (4 students) versus changing from *it is not* to *it is possible* (5 students). In contrast, all of Mr. Anderson's students who exhibited this change, went from *it is not* to *it is possible* (2 students). The remaining students maintained the same reasoning on both tests or did not provide sufficient responses for us to determine if their reasoning had changed.

Table 3: Change Involving Finding Independent Variable from Dependent Variable

Teacher	Students per class	From *not possible* to *possible*	From *possible* to *not possible*	Maintained *possible*: Maintained *not possible*
Henry	24	5	4	5:1
Anderson	33	2	0	15:1

Change interpreted in terms of action versus process view of functions. We interpreted a change in reasoning from *it is not* to *it is possible*, as a possible shift toward a process view of functions and a change in the other direction as a possible shift toward an action view of functions. This interpretation is based on Asiala et al.'s (1997) characterization of a process view of functions as when a person can "reverse the steps of the transformation" (p. 7).

Reasoning about Specific or General Intervals of Change

Our third finding was that several students changed their reasoning on the third sub-part of the pictorial problem. Version A asked:

> You have to leave the plant in your office over the weekend. You did not measure the plant for 2.5 days. The plant grows at the same rate the whole time. How much did the plant grow in the 2.5 days you were gone? Show any work that helped you decide.

Version B asked:

> You fall asleep while watching TV. You did not measure the rain water for 3.5 hours. It rained the whole time at the same rate. How much rainwater was collected during the 3.5 hours that you were sleeping? Show any work that helped you decide.

Students either reasoned about *specific* or *general* intervals on this problem. When they reasoned about specific intervals, they either found the height of the plant or rainwater on day 2.5 or at hour 3.5 or the height 2.5 days or 3.5 hours after the last height depicted in the picture. When students reasoned about a general interval, they found the amount the plant would grow or the rainwater would rise over *any* 2.5-day or 3.5-hour interval in general. Notice that reasoning about general intervals is correct because, for each version of the problem, the amount of change in the independent variable is for a general interval, not a specific interval.

Frequency counts supporting this claim. Ms. Henry's and Mr. Anderson's classes showed opposite (and mixed) trends in changes in reasoning (see Table 4). A greater number of Ms. Henry's students went from reasoning about a *specific interval* to reasoning about a *general interval* (7 students), than vice versa (3 students). In contrast, a smaller number of Mr. Anderson's students went from reasoning about a specific interval to reasoning about a general interval (3 students), than vice versa (8 students).

Change interpreted in terms of action versus process view of functions. We interpreted reasoning with *general intervals* as more consistent with a *process view* and reasoning with *specific intervals* as more consistent with an *action view*. Our rationale was that to reason about any general 2.5-day or 3.5-hour interval, an individual would need to think about changes in height across all 2.5-day or 3.5-hour intervals in general, without individually calculating changes in heights for all those intervals. This aligns with Asiala et al.'s (1997) description of the process view as not needing to perform all the operations to think about the results of operations.

Table 4: Change Involving Reasoning about Specific or General Intervals

Teacher	Students per class	From *specific* to *general*	From *general* to *specific*	Maintained *specific*: Maintained *general*
Henry	24	7	3	2:1
Anderson	33	5	8	5:3

Discussion

To summarize our results, we saw one type of change in reasoning on each of the three sub-parts for the pictorial problem. This suggests that backward transfer effects by new learning about quadratic functions on prior ways of reasoning about linear functions may be a fairly frequent occurrence. However, the effects were more varied than we anticipated: they occurred in both classes or in one class only, and in the same direction or in opposite directions. We think these results suggest that backward transfer effects, in real classrooms and with teachers who are not purposefully trying to produce these effects, may be somewhat messy.

Messy results for backward transfer effects are significant because they suggest backward transfer may be difficult for researchers to detect unless deliberately tuned to them. Our messy results may also help explain why teachers may be unaware of backward transfer effects in their students.

To add to the messiness, our findings suggest backward transfer effects can be either productive or unproductive. The evidence of productive backward transfer effects is significant because it suggests there are aspects of learning about quadratic functions instruction that could be emphasized to further enhance *productive* influences on students' views of linear functions. For example, the finding that a number of students changed productively from a build-up strategy to an abbreviated build-up strategy suggests that, with further emphasis, even more students could be supported to change along this dimension (e.g., such as by exploring how students could engage in a kind of abbreviated build-up strategy in a quadratic context).

The findings of unproductive backward transfer effects are also significant because they suggest there are aspects of learning about quadratic functions that could be emphasized to inhibit *unproductive* influences on students' views of linear functions. For example, the finding that a number of Mr. Anderson's students went from reasoning with a general interval to reasoning with a specific interval suggests that researchers and educators should look for ways to emphasize reasoning with general intervals to inhibit or even eliminate this unproductive backward transfer effect. Our future research on the topic of backward transfer in the context of linear functions conceptions and quadratic functions instruction will test some of these ideas.

Opportunities matter when it comes to students' math attitudes and performance. Over two semesters, across treatment sections of college algebra students, we implemented a set of dynamic computer activities linking animations and graphs. Across all sections, we administered a fully online survey of students' attitudes toward math. Using mixed methods, we analyzed students' attitudes toward math and their performance on a course final exam. At the end of each semester, we found statistically significant differences between treatment and comparison students' perceived competence toward math. Furthermore, treatment students outperformed comparison students on the course final exam, with statistically significant differences on an item linked to the dynamic computer activities. When students have opportunities to interact with dynamic computer activities, it can impact their math attitudes and course performance.

Opportunities matter when it comes to students' math attitudes and performance. Ideally, College Algebra courses would be a place where students could gain opportunities to develop their mathematical competence. However, too often students experience College Algebra courses as gatekeepers rather than opportunity makers (e.g., Gordon, 2008; Herriott & Dunbar, 2009). To address this opportunity problem with College Algebra, we investigate the question: How might College Algebra students' opportunities to interact with dynamic computer activities, linking animations and graphs, impact their math attitudes and course performance?

Strategic uses of educational technology, particularly those that involve opportunities for students to interact with others to discuss mathematical ideas, show promise for promoting math learning for underserved students (Kitchen & Berk, 2016). In an exploratory study, researchers implemented dynamic computer activities in a middle school in a high poverty neighborhood, serving primarily students of color (Schorr & Goldin, 2008). During the intervention, researchers found that students demonstrated both sophisticated mathematical reasoning and positive affect toward math, including emotions such as elation (Schorr & Goldin, 2008). We were inspired by this link between the opportunities for reasoning afforded by educational technology and positive affect toward math, and we aimed to investigate such relationships on a larger scale.

We focus on an aspect of students' mathematical affect—their attitudes toward math (Ding, Pepin, & Jones, 2015; Di Martino & Zan, 2010; Pepin, 2011; Zan, Brown, Evans, & Hannula, 2006). Following Di Martino and Zan (2010), we view students' attitudes as multidimensional, encompassing three interrelated dimensions: emotional disposition toward mathematics, perceived competence toward mathematics, and a vision of what mathematics is (p. 44). For example, students may like math because it makes them think (emotional disposition), may consider themselves as capable of doing math when they practice (perceived competence), and they may view math to be difficult, but fun (vision of mathematics).

Researchers have found emotional disposition and perceived competence to be important dimensions when it comes to university students' persistence in mathematics courses (Bressoud, Carlson, Mesa & Rasmussen, 2013; Ellis, Fosdick, & Rasmussen, 2016). In a large study of university Calculus I students, Bressoud and colleagues (2013) found that students' confidence and enjoyment of math *decreased* by the end of Calculus I, despite the fact that the majority of students completing the survey at the end of the course demonstrated success in the course, as measured by a final grade of A, B, or C. Given the findings from students' experiences in Calculus I, we were particularly interested in courses that served as prerequisites for Calculus I, such as College Algebra.

The study we report is part of a larger research project, for which we designed an intervention providing College Algebra students with opportunities to interact with a set of dynamic computer activities (see Johnson, McClintock, Kalir, & Olson, 2018). We designed the activities to promote students' covariational reasoning, a key form of reasoning that can engender students' conceptions of rate and function (Carlson, Jacobs, Coe, Larsen & Hsu, 2002; Thompson & Carlson, 2017). In the larger research project, we have three aims: to measure students' covariational reasoning (see Johnson, Kalir, Olson, Gardner, Smith, & Wang, 2018), to promote students' positive attitudes toward math, and to promote students' outcomes in College Algebra. Here, we focus on the latter two aims. Using mixed methods, we demonstrate that our intervention resulted in differences in students' attitudes toward math and in students' course outcomes, as measured by a final exam.

Theoretical and Conceptual Underpinnings

Designing Dynamic Computer Activities to Promote Students' Covariational Reasoning

We integrated different theoretical perspectives to design dynamic computer activities to promote students' covariational reasoning. Each of the dynamic computer activities linked computer animations with dynamic graphs. In particular, we integrated Thompson's theory of quantitative reasoning (Thompson, 1994; 2002) with Marton's variation theory (Marton, 2015; Kullberg, Kempe, & Marton, 2017). Drawing on Thompson's theory, we problematized students' conceptions of attributes represented in the tasks (e.g., distance, height). We theorized how students might conceive of task attributes as capable of varying and possible to measure. Drawing on Marton's theory, we problematized students' discernment of different aspects of the tasks (e.g., axes of a Cartesian graph). We theorized what students might discern as we designed differences (e.g., Cartesian graphs with the same attributes represented on different axes) against a background of invariance (e.g., a situation involving a toy car moving along a track.)

Our Perspective on Students' Attitudes Toward Math

With our perspective on students' attitudes toward math, we intend to move beyond McLeod's (1992) categories of beliefs, attitudes, and emotions as comprising distinct components of mathematical affect. We ground our perspective on students' attitudes toward math in the work of scholars aiming to explicate the multidimensionality of students' attitudes toward math (Di Martino & Zan, 2010; Zan et al., 2006). From our perspective, students' math attitudes are not distinct from their emotions. Rather, students' attitudes toward math include students' emotions, as well as other dimensions. Accordingly, we adopt Di Martino and Zan's (2010) multidimensional perspective on students' attitudes toward math. That is, students' attitudes toward math comprise three interrelated dimensions: their emotional disposition toward math, their perceived competence toward math, and their vision of what mathematics is.

Method

The research we report is part of a broader research project taking place across all face to face sections of College Algebra at a public university situated in the downtown area of a large city in the midwestern US. The university serves large proportions of students who identify as students of color and are the first generation of their family to attend college. In fall 2017, 59% of incoming freshmen identified as students of color, and 51% of all freshmen were first generation college students.

Intervention: Dynamic Computer Activities

At the university where we conducted this study, College Algebra is divided in to recitation and lecture components. Each section of College Algebra includes both recitation and lecture components, with a recitation occurring before each lecture. Students always have different recitation and lecture instructors. Typically, recitation instructors are graduate students, and the instructors are faculty members. We implemented a set of dynamic computer activities across selected recitations. In spring 2018, we were still developing some of the activities. Hence, in spring 2018 we implemented five dynamic computer activities across two different recitations. In fall 2018, we implemented seven dynamic computer activities across three different recitations.

To increase students' access to the dynamic computer activities, we developed them on a freely available platform—Desmos—in collaboration with Meyer, the chief academic officer of Desmos. As typical with Desmos, each of our dynamic computer activities involves a series of screens that students move through. There are five main components to each activity. First, students watch a video that depicts a moving object, such as a toy car moving along a track, along with a description of attributes on which the activity will focus (e.g., total distance traveled and distance from a stationary object.) Second, students represent variation in each attribute by moving dynamic segments along vertical and horizontal axes of a Cartesian plane. This design choice was an effort to operationalize Thompson's (2002) discussion of students' use of fingers as tools to represent variation. Third, students sketch a single graph representing a relationship between both attributes. In each of the second and third components, students have opportunities to get computer feedback on their work, a hallmark of Desmos activities. Fourth, students repeat the second and third components for a new Cartesian graph with attributes on different axes. This design choice was inspired in part by tasks developed by Moore and colleagues (e.g., Moore, Silverman, Paoletti, & LaForest, 2014). Fifth, students answer a reflection question which asks them to make sense of another student's reasoning.

We designed the Desmos activities to promote students' covariational reasoning, as well as their conceptions of graphs as representing relationships between attributes that are capable of varying and possible to measure. Through the reflection questions, we aimed to promote students' sense making, rather than rushing to judgments (Johnson, Olson, Gardner, & Smith, 2018). We conjectured that opportunities to engage in covariational reasoning could promote students' productive attitudes toward math and successful outcomes in college algebra.

Treatment and Comparison Groups

Spring 2018 was our first semester implementing the dynamic computer activities. In spring 2018, there were nine sections of College Algebra. One section was a treatment section, and the other eight sections were comparison sections. We selected the treatment section, because the lecture instructor is a co-principal investigator on our larger project, and was willing to implement the Desmos activities before we rolled them out to a larger number of sections.

In fall 2018, there were 13 sections of College Algebra. Prior to the beginning of the semester, we invited recitation instructors to participate in a semester long professional development (PD). The PD had three main aims, to provide recitation instructors opportunities to (1) learn who their students are as humans; (2) to engage in covariational reasoning; and (3) to implement the Desmos activities to promote their students' covariational reasoning. We accepted all recitation instructors who volunteered to participate, resulting in six recitation instructors teaching a total of 10 sections. Hence, in fall 2018, 10 sections were treatment sections and three sections were comparison sections.

Attitude Study

To investigate students' attitudes toward math, we adapted methods used by Pepin and colleagues (Ding et al., 2015; Pepin, 2011). We created an online survey shown in Table 1. The first three questions are the same as those from Pepin's (2011) survey. In addition, we added two questions specific to students' attitudes toward graphs, rather than math in general, because graphs were specific to our intervention.

Table 1: The Attitude Survey

Attitude Survey Questions
I like/dislike math because __________
I can/ cannot do math because __________
Mathematics is __________
I like/dislike graphs because __________
I can/ cannot make sense of graphs because __________

During spring 2018 and fall 2018, we administered the attitude survey four times: Once at the beginning of the semester (in week 2 or 3), and once at the end of the semester (in week 13). To ensure that technology was working and to answer any questions, a research team member was present at each administration of the survey.

Two qualitatively code the attitude survey data, a subset of our team built a coding rubric based on preliminary analysis of pilot data collected in fall 2017. We had initially planned to code students' responses into three categories, the same way as did Ding et al. (2015): Like/Can, Dislike/Cannot, and Neutral/Mixed. However, as we discussed responses from the pilot data set, we determined that we needed two additional categories—Ambiguous and Detached—to capture the scope of students' responses. In our view, these mutually exclusive categories do not position themselves along a line, with positive and negative being at opposite ends of the continuum. Rather, the categories begin and end in a more knotted way, as shown in Figure 1.

Figure 1: Coding for Complexity in Students' Attitudes Toward Math

Table 2 includes sample responses from our data set, with two examples for each of the codes. Responses coded as *Positive* included statements of like/can, while responses coded as *Negative* included statements of dislike/cannot. All of the Positive/Negative responses shown in Table 2 include "because" clauses, in which students explain their response. Not all students included these clauses, which we did not require. We did not code differently when students used a clause to qualify their response. Responses coded as *Mixed* included specific statements of both like/dislike or can/cannot. Often these statements included the word "but" or "however" to indicate the juxtaposition of positive and negative attitudes. Responses coded as *Ambiguous* could cross multiple attitudes. For example, students may state that they like or dislike math because it is challenging. Responses coded as *Detached* separated the mathematics from the humans engaging in mathematical activity. Typically, students responding this way described about math or graphs as things that are "out there," rather than products of their activity.

Table 2: Sample Attitude Survey Responses from our Data Set

Attitude Survey Codes	Example 1	Example 2
Positive: Like/Can	I like math because it challenges me to keep trying and learn more.	I can make sense of graphs because of practice.
Negative: Dislike/Cannot	I dislike mathematics because it is too stressful and complicated.	I cannot make sense of graphs because they don't make as much sense as equations do to me.
Mixed	I only like math when I understand it. When I understand it, I enjoy it. But most of the time I feel like I'm lost. So sometimes I dislike math.	I can make sense of graphs because I know how some functions move by heart. I cannot make sense of graphs because I do not know how all functions move by heart.

Ambiguous	It is challenging.	I look at the points and read info given.
Detached	Math is the universal language.	They (graphs) are just a visual representation of inputs and outputs.

To qualitatively code the attitude survey data, two graduate students served as coders. First, they received training with coding rubric by participating in meetings to discuss the Fall 2017 pilot data set. Next, they independently coded responses, identified disagreements, and then calibrated the disagreements via discussion, consulting with an expert coder if disagreements could not be resolved.

To quantitatively analyze the attitude survey data, we conducted chi square analysis using percent responses in each coding category. In each of spring 2018 and fall 2018, we used the following groups: Treatment (Pre) vs. Comparison (Pre); Treatment (Post) vs. Comparison (Post); Treatment (Pre) vs. Treatment (Post). We examined the data for statistically significant results, then we developed explanations to account for those results.

Outcomes Study: Final Exam

We collected data from students' performance on the common final exam, both in terms of letter grade (ABCDF) and raw score. In addition, we collected item level data for a multiple choice covariation item that we included on the final exam. In the covariation item, students selected a graph to represent a situation involving a relationship between variables. Some of the graphs were unconventional, like the graphs in the dynamic computer activities with which the treatment students interacted. We scored the covariation item as correct/incorrect, with correct responses receiving a score of 1 and incorrect responses receiving a score of 0.

To quantitatively analyze the final exam data, we also conducted chi square analysis using percent responses in each coding category. In each of spring 2018 and fall 2018, we used the following groups: Treatment (ABC letter grade) vs. Comparison (ABC letter grade); Treatment (raw score) vs. Comparison (raw score); Treatment (covariation item) vs. Comparison (covariation item). As we did for the attitude survey data, we examined the final exam data for statistically significant results, then developed explanations to account for those results.

Results

We organize the results into sections devoted to the attitude study and the outcomes study. In each section, we report results by semester: Spring 2018 and Fall 2018.

Attitude Study

At the beginning of both semesters, we found statistically significant differences between students' perceived competence in treatment and control groups, with treatment groups entering with more negative perceptions of their competence. By the end of each semester, each group demonstrated more positive perceptions of their competence, and we no longer found statistically significant difference between treatment and control groups. In spring 2018, we found statistically significant results when analyzing students' perceptions of their competence with graphs. In fall 2018, we found statistically significant results when analyzing students' perceptions of their competence with math writ large.

In the next subsections, we include a number of tables to report results of quantitative data analysis. In tables 3-6, the comparison group is shown in the top row, and the treatment group is shown in the bottom row. In table 7, the treatment group is shown in both rows. In tables 3-7, we report results in terms of percentages of student responses coded in each category. In the narrative, we provide specific numbers for the treatment and comparison groups.

Spring 2018: Attitude. In Spring 2018 the comparison and treatment groups demonstrated statistically significant differences in their perceived competence toward graphs. In the first administration of the attitude survey, the treatment group (n=26) demonstrated a more negative perceived competence toward graphs than did the comparison group (n=112). Table 3 shows the percentages of students' responses coded in each category.

Table 3: Spring 2018 Comparison Pre (top) vs. Treatment Pre (bottom)

	Like/Can	Dislike/Cannot	Mixed	Ambiguous	Detached	X^2, p
I can/ cannot make sense of graphs because __________	55.4%	15.2%	8.9%	13.4%	7.1%	13.83* p=0.010
	34.6%	38.5%	3.8%	3.8%	19.2%	

By the end of spring 2018, there were no statistically significant differences in students' perceived competence toward graphs between the treatment group (n=19) and the comparison group (n=77). Both groups saw increases in the number of students who demonstrated more positive perceived competencies toward math. Table 4 shows the percentages of students' responses coded in each category.

Table 4: Spring 2018 Comparison Post (top) vs. Treatment Post (bottom)

	Like/Can	Dislike/Cannot	Mixed	Ambiguous	Detached	X^2
I can/ cannot make sense of graphs because __________	58.4%	10.4%	11.7%	11.7%	7.8%	5.23
	57.9%	26.3%	0.0%	10.5%	5.3%	

Fall 2018: Attitude. In Fall 2018 the comparison and treatment groups demonstrated statistically significant differences in their perceived competence toward math. In the first administration of the attitude survey, the treatment group (n=251) demonstrated a more negative perceived competence toward math than did the comparison group (n=64). Table 5 shows the percentages of students' responses coded in each category.

Table 5: Fall 2018 Comparison Pre (top) vs. Treatment Pre (bottom)

	Like/Can	Dislike/Cannot	Mixed	Ambiguous	Detached	X^2, p
I can/ cannot do mathematics because __________	57.8%	9.4%	17.2%	10.9%	4.7%	13.86** p=0.008
	54.6%	21.1%	19.9%	2.8%	1.6%	

By the end of fall 2018, there were no statistically significant differences in students' perceived competence toward math between the treatment group (n=204) and the comparison group (n=45). As was the case for spring 2018, both groups saw increases in the number of students who demonstrated more positive perceived competencies toward math. Table 6 shows the percentages of students' responses coded in each category.

Table 6: Fall 2018 Comparison Post (top) vs. Treatment Post (bottom)

	Like/Can	Dislike/Cannot	Mixed	Ambiguous	Detached	X^2
I can/ cannot do mathematics because __________	66.7%	11.1%	11.1%	11.1%	0.0%	5.44
	60.3%	24.0%	10.8%	4.9%	0.0%	

Because of the size of the treatment group in fall 2018, we were able to compare differences between the beginning and end of the semester. Within the treatment group, there were statistically significant differences in perceived competence toward math from the beginning of the semester (n=251) to the end of the semester (n=204). Table 7 shows the percentages of students' responses coded in each category.

Table 7: Fall 2018 Treatment Pre (top) vs. Treatment Post (bottom)

	Like/Can	Dislike/Cannot	Mixed	Ambiguous	Detached	X^2, p
I can/ cannot do mathematics because __________	54.6%	21.1%	19.9%	2.8%	1.6%	11.60* p=0.021
	60.3%	24.0%	10.8%	4.9%	0.0%	

Outcomes Study: Final Exam

In spring and fall 2018, there were no statistically significant differences between the number of students who passed the final exam (ABC) in the treatment or comparison groups. In both spring 2018 and fall 2018, the treatment group outperformed the comparison group. In spring 2018, the final exam passing rate for the treatment group was 70.8% and for the comparison group was 65.0%. In fall 2018, the final exam passing rate for the treatment group was 60.8% and for the comparison group was 59.4%.

The analysis of final exam raw scores revealed similar findings to the final exam passing rates. In both spring 2018 and fall 2018, the treatment group outperformed the comparison group. In spring 2018, the treatment students outperformed the comparison students by 8 points (153.8 vs 145.8). In fall 2018, the treatment students also outperformed the comparison students, but only by 2.2 points (143.8 vs 141.5). The score differences were not statistically significant in either semester.

We found statistically significant differences in students' performance on the final exam covariation item that was linked to the dynamic computer activities. In both spring 2018 and fall 2018, the treatment group outperformed the comparison group. The p value in spring 2018 (p=0.000) was stronger than the p value for fall 2018 (p=0.013).

Table 7: Final Exam Item: Comparison vs. Treatment

Semester	Group	Mean Score	Standard Deviation
Spring 2018	Comparison (n=143)	0.31	0.46

Spring 2018	Treatment (n=25)	0.84***	0.37
Fall 2018	Comparison (n=71)	0.28	0.5
Fall 2018	Treatment (n=258)	0.43*	0.5

Discussion

We provided evidence to support our claim that students' interaction with dynamic computer activities impacted their attitudes toward math and their performance on the course final exam. Our intervention impacted a particular dimension of students' attitudes toward math—their perceived mathematical competence, which has been shown to be an important dimension impacting students' persistence in mathematics courses, such as Calculus I (e.g., Bressoud et al., 2013). We implemented this study in conjunction with an earlier, National Science Foundation funded project promoting students' active learning in College Algebra. Hence, we are encouraged that comparison students also reported more positive perceptions of their competence in graphs and math, respectively.

There are differences in the numbers of students responding to the attitude surveys, with numbers declining from the administration at the beginning of the semester (pre) to the administration at the end of each semester (post). Student attrition was a main cause for the differences. The students responding at the beginning of the semester represent all those students who began College Algebra. The students responding at the end of the semester represent those students who continued to persist in the course. Hence, our pre and post groups are not exactly the same student population.

Students have complex attitudes toward math. Langer-Osuna and Nasir (2016) have called for researchers to develop methods that acknowledge the humanity of students' experiences. By coding students' responses to allow for that complexity—to extend beyond a continuum of positive or negative in students' affect, we have responded to the call. Furthermore, our results suggest that Schorr & Goldin's (2008) findings are applicable on a broader scale, to university students as well as middle grades students. That is, opportunities for reasoning afforded by interactions with educational technology can promote students' positive attitudes toward math.

Acknowledgments

This research was supported by a US National Science Foundation Grant (DUE-1709903). Opinions, findings, and conclusions are those of the authors. We are grateful to Dan Meyer for his efforts to support the development of the Techtivities in Desmos.

Teachers' efforts to support students, both academically and socially, can play a role in how high school students productively engage with mathematics in the moment. To examine the connection between teacher support and student engagement, we conducted an exploratory mixed-methods study combining data from 20 high school classroom observations with student self-reports taken during the observed activity. Our findings indicate that when teachers provide academic support to their students during a lesson, they are also likely to provide social support. Higher teacher support of both kinds correlates with higher student self-efficacy, as well as social and cognitive engagement. Investigating relationships between observations of teaching and students' self-reports of engagement in-the-moment is a potentially revealing approach for uncovering engaging instructional strategies in secondary mathematics classrooms.

Keywords: High School Education; Affect, Emotion, Beliefs, and Attitudes; Classroom Discourse

Supporting secondary students' engagement with mathematics is a problem that can be addressed through instructional design. Typically, students' self-efficacy, enjoyment, and sense of the utility of mathematics decreases as they move through middle school and into high school, and the longer students are in high school, the more disengaged they tend to become (e.g., Chouinard & Roy, 2008). In this study, we explore the ways in which teachers' attempts to support students, both academically and socially, can play a role in how high school students productively engage with mathematics in the moment.

Mathematics Engagement

Engagement in school is students' expression of affect, beliefs about themselves, sense of belonging, and observable behaviors in the school setting (Jimerson, Campos, & Greif, 2003). Engagement is thus a complex meta-construct that simultaneously accounts for cognitive, affective, and socio-behavioral dimensions (Fredricks, Blumenfeld, & Paris, 2004). More specifically, mathematics engagement is the interactive relationship between students and the subject matter. It is manifested in the moment through expressions of behavior and experiences of emotion and cognitive activity, and it is constructed through opportunities to do mathematics, as situated in both current and past experiences (c.f., Middleton, Jansen, & Goldin, 2017).

For students to learn mathematics, they must be engaged. For example, in a study of almost 4,000 middle school and high school students in Western Pennsylvania, researchers found that higher levels of cognitive, behavioral, emotional, and social engagement predicted students' course grades in mathematics (Wang, Fredricks, Yea, Hofkens, & Linn, 2016). According to Greene (2015), it is well-established in prior research that motivation constructs such as students' self-efficacy support students' engagement in ways that lead to learning. To understand how instruction can support learning, it is important to understand how instruction supports students' motivation and engagement. To do so, we must account how students experience engagement and how teachers' practice creates a context for students to engage.

Students' engagement is malleable and situated. Engagement is influenced by teachers' instructional practices in the moment and by the classroom climate (Anderson, Hamilton, & Hattie, 2004). Mathematical work, social interactions, and identity enactments differ from classroom to classroom. Understanding how teaching influences engagement requires attending to students' experiences, both collectively and subjectively, as they attend to important social and psychological features of their learning environment (Fraser, 1989).

Potentially Engaging Mathematics Teaching Practices

Mathematics instruction is considered to be stronger when teachers provide students with both *social support* for working together on content and *academic support* for accessing rigorous mathematical content (Shernoff et. al., 2016). Academic and social support can take a variety of forms. Academic support may include opportunities for sense-making and reasoning (Stein, Grover, & Henningsen, 1996), opportunities to make conceptual connections (Hiebert & Lefevre, 1986), pressing students to explain their thinking (Engle & Conant, 2002; Kazemi & Stipek, 2001), providing students with specific and detailed feedback (Stipek, Salmon, Givvin, Kazemi, Saxe, & MacGyvers, 1998), and opportunities to solve mathematics tasks in context (Koedinger & Nathan, 2004), or some combination of these. Social support may include motivational discourse with a focus on learning, positive affect, and encouragement of collaboration with peers (Turner, Midgley, Meyer, Gheen, Anderman, Kang, & Patrick, 2002), positioning students as competent (Cohen & Lotan, 1995; Gresalfi, Martin, Hand, & Greeno, 2009), accountability practices in the classroom (Horn, 2017), or some combination of these.

It is worth investigating whether and how these productive classroom practices support students' engagement at the high school level. Many of these prior studies were conducted in middle grades or upper elementary grades, and not all of these prior analyses of strong mathematics instruction were empirically linked to students' engagement. Thus, the research question that guides this study is: *What ways of providing academic and social support during instruction lead to productive engagement in-the-moment in secondary mathematics classrooms?*

Methods

This exploratory, mixed-methods study was conducted using the first year of data (pilot data) from a three-year NSF-funded study. In Spring 2018, we observed lessons and surveyed students in on-grade level ninth-grade mathematics classes in two states (one in the Southwestern region of the United States and one in the Mid-Atlantic region). We chose these locations because schools in these areas take different curricular approaches: integrated mathematics (Mid-Atlantic) and topics-based courses (Southwest). Mid-Atlantic courses were titled Integrated Math 1 or Integrated Math 2. Southwest courses were Algebra I or Geometry. The three Mid-Atlantic schools implemented a block schedule with approximately 90-minute class periods. In the Southwest, the class periods were approximately 50 minutes long.

We gathered data from six schools – three from each state. In the Mid-Atlantic, the schools' demographics ranged from 12-34% low income, 25-60% white, 27-47% Black, and 6-21% Latinx. In the Southwest, the schools' demographics ranged from 76-94% low income, 1-6% white, 1-16% Black, and 77-96% Latinx.

Teachers were recruited by soliciting nominations of teachers from district curriculum supervisors and the mathematics coaches. We invited nominated teachers to participate in the study. The nine participating teachers averaged 10.6 years of teaching (min = 1 year, max = 26 years). All had completed a Master's degree or were in progress of doing so. One of the teachers in the Mid-Atlantic identified as Black, two Southwest teachers identified as Latinx, and one Southwest teacher identified as Asian. The rest of the participating teachers identified as White.

Teacher-selected, Potentially Engaging Activities

We observed 20 lessons. Lessons were selected by asking teachers to identify a lesson with an activity that they conjectured would be engaging for their students. The teachers provided written rationales for their conjectures about why this activity would engage their students. We video recorded the entire lesson, but we focused our analysis on these teacher-selected episodes. In the Mid-Atlantic, we analyzed 12 lesson episodes (four lessons from each of three teachers) and in the Southwest, we analyzed eight lesson episodes (two lessons from two teachers, one lesson from four other teachers).

These observations were paired with Experience Sampling Method (ESM) surveys (c.f., Shernoff, Ruzek, & Sinha, 2017) for the teacher-selected episode. Administering the ESM immediately after the teacher-selected activity allowed us to capture students' in-the-moment interpretations of their experiences during that activity. Each item was ranged on a Likert Scale from 1 to 5 points.

- *Interest* – 3-items: "I enjoyed the activity I was just working on," The activity I was just working on was personally relevant to me," and "I think the topic covered in the activity I was just working on is interesting" (α=.783).
- *Cognitive Engagement* – 3-items: "How hard were you trying during the activity you were just working on?", "I was on task during the activity I was just working on," and "How hard were you concentrating on the activity you were just working on?" (α = .782).
- *Perceived Instrumentality* – 3-items: "I will use what I learned from the activity I was just working on when I grow up," "I will use what I learned from the activity I was just working on in future courses," "How I performed on the activity I was just working on will affect my future success" (α = .758).
- *Self-Efficacy* – 3-items: "Rate how much you understand the math covered in the activity you were working on," "I felt successful in the activity I was just working on," and "I felt challenged by the activity I was just working on" (reverse-coded) (α =.548).
- *Social Engagement* – 4-items: "I built on others' ideas during the activity I was just working on," "I felt like my contribution was respected during this activity I was just working on," "I felt supported by my teacher in the activity I was just working on," and "I had the opportunity to ask questions during the activity I was just working on" (α = .709).

Data Analysis

Our unit of analysis for coding observations was an episode consisting of a teacher-selected, potentially engaging activity. We analyzed episodes surrounding this activity using rubrics (ranging on a 0 to 3-point scale) developed to document instructional practices which have the potential to support secondary students' engagement, as well as the prevalence and quality of those practices. Seven specific rubrics assessed the *academic support* that teachers provided and seven specific rubrics assessed *social support* that teachers provided:

Academic Support – Seven specific rubrics: (1) Sense-making and reasoning, (2) Connections and coherence, (3) Pressing students to explain, (4) Contexts of tasks, (5) Mathematical correctness, (6) Mathematical language precision, (7) Feedback.
Social Support – Seven specific rubrics: (1) Whole-class discussion, (2) Small group work, (3) Status-raising, (4) Motivational discourse, (5) Enthusiasm about mathematics, (6) Attention to students' lives, (7) Accountability and high expectations.

When coding, we applied the rubrics to 10-minute increments for each episode. At least two coders were assigned to each episode, and coders met to reconcile and resolve all coding disagreements. To assign an overall score for each rubric to an episode, we calculated the resolved rubric means across the 10-minute increments. To determine an overall academic support score for an episode, we took the mean of the mean resolved scores across the seven relevant rubrics across the 10-minute increments. We used this same procedure to create an overall social support score. To examine relationships between teaching practices and students' engagement in the moment, we began by computing Pearson correlations between the overall academic and social support rubric scores and the ESM scale scores across the 20 classes (316 students had complete data). Next, we examined the correlations between the specific observation rubrics, and the mean ESM scale scores for each class . Using these exploratory analyses, we selected a lesson that showed strong support practices, both academic and social, and high student engagement, as indicated by ESM responses. We then conducted an in-depth qualitative analysis of instruction during this lesson to explore what instruction looked like during a lesson when students reported high levels of productive engagement.

Results

Our analyses revealed that teachers who strongly enacted opportunities to provide academic support also strongly enacted opportunities to provide social support (see Table 1 for correlations), and both types of support correlated with student self-efficacy, though less so with other engagement variables. Although one might assume that a secondary teacher might be better at providing either academic support or social support rather than both, we found that most of these teachers tended to be either strong or weak at both. When these teachers provided strong opportunities for students to be supported academically, students reported experiencing higher self-efficacy and more productive social engagement. Similarly, when these teachers provided opportunities for students to be supported socially, students also reported higher self-efficacy.

Among the engagement scales, students' reports of their social engagement correlated with their cognitive engagement, their interest, and self-efficacy in the observed activity. Overall, these results suggest that when teachers supported their students along academic and social dimensions, students felt more confident, which related to their cognitive engagement and social engagement during the lesson.

Table 1: Relationships Between Teaching and Student Engagement (n=20 classes)

	Observation Scores (Teaching)		Experience Sampling Method Survey (Student Self-Reports: In-the-moment Engagement)			
	Academic Support	**Social Support**	**Interest**	**Cognitive Engagement**	**Perceived Instrumentality**	**Social Engagement**
Social Support	.766**	---				
Interest	0.096	0.112	---			
Cognitive Engagement	0.385	0.356	.579**	---		
Perceived Instrumentality	0.028	0.011	.602**	0.184	---	
Social Engagement	.453*	0.44	.620**	.895**	0.199	---
Self-Efficacy	.591**	.559*	0.074	.505*	-0.02	.566**

** Correlation is significant at the 0.01 level (2-tailed).
* Correlation is significant at the 0.05 level (2-tailed).

Relationships Between Specific Observation Rubrics and Student Engagement

Table 2 displays relationships between the specific observation rubrics applied to each lesson and self-reports from students in those class periods on ESM scales. For academic support, efforts to support students' use and understanding of mathematical language significantly correlated with self-efficacy and social engagement, while feedback significantly correlated with self-efficacy. For social support, status raising significantly correlated with self-efficacy. Students appeared to feel more confident when teachers positioned students as competent in specific ways (status raising), helped students understand mathematical language, and gave students more detailed feedback focused on concepts. Students also participated more by sharing their thinking during class (social engagement), often by negotiating meaning, when the teacher developed mathematical terminology (mathematical language).

Table 2: Significant Relationships Between Specific Observation Rubrics and ESM Scales

	Specific Observation Rubrics		
	Academic Support: Mathematical Language	**Academic Support: Feedback**	**Social Support: Status Raising**
Self-Efficacy	0.647**	0.559*	0.784**
Social Engagement	0.495*	0.164	0.376

** Correlation is significant at the 0.01 level (2-tailed).
* Correlation is significant at the 0.05 level (2-tailed).

When these teachers' instruction was observed to have higher mean scores for academic and social support appeared, students appeared to have opportunities to engage productively and feel confident. However, results from the specific observation rubrics (7 academic support rubrics and 7 social support rubrics) did not indicate many significant correlations with students' motivation and engagement on the ESM. These results suggest supporting engagement involves a more complex interaction of observed support variables than a single rubric can detect for a few observations. Academic and social support behaviors may interact in ways that are not easily categorized by our specific rubrics for academic and social support. Moreover, students' reports of their engagement may not be highly related to specific teaching support behaviors, but they may be related to more general patterns (hence the strong correlations of mean academic support and social support to our ESM scales). In other words, our ESM scales may detect general feelings about the class sessions and not make fine distinctions that relate to specific observed support behaviors.

Teaching that Supports Productive Engagement

It is unsurprising that secondary students have better opportunities to engage productively when teachers provide both academic and social support, but it is worth exploring what such support looks like in practice. Correlational analyses indicated that specific forms of academic support productively engaged students: opportunities for students to learn about precise mathematical language and receive specific feedback about concepts. A specific form of social support appeared to productively support engagement: teachers' efforts to explicitly raise students' statuses.

However, it essential to investigate these instructional practices qualitatively to seek insights about enacting them. Our analyses suggest that when these teachers enacted specific academic supports that correlated with engagement (mathematical language and feedback), teachers also supported students' engagement by engaging them in sense-making and reasoning, making connections, and pressing students to explain, as these forms of academic support appeared to also take place when discussing mathematical language and when the teacher gave feedback. Additional social supports that qualitatively appeared to co-occur with status raising were having whole-class discussions that were collaborative and using motivational discourse with students.

We illustrate these features of instruction that appear to support productive engagement among secondary students by describing an episode from the third observation of Kathy's teaching in the Mid-Atlantic region. This episode of teaching was rated as having some of the highest academic and social support scores in the sample (2.07 and 2.00, respectively, out of 3) and Kathy's students reported some of the highest self-efficacy and cognitive engagement scores on the ESM in the sample (4.33 and 4.11, respectively, out of 5).

Kathy selected a card sorting task as a potentially engaging activity. Each card had a type of representation of systems of linear *equations* or systems of linear *inequalities*. The representations were symbolic, graphical, or in story problem form. The activity began with students working in groups for about nine minutes to sort the cards and compare how they were similar and different. They were expected to identify distinguishing features of systems of linear equations and systems of linear inequalities and record these ideas on sticky notes. After working in groups, the teacher led the students in a four-minute whole class discussion about the cards. Below, we share some examples of this first round of whole-class discussion during this activity.

> Kathy: (Rings bell.) Bring in back in 5, 4, 3… Here's where we're going next: You have to make some decisions about which ones [cards] were inequalities and which ones were

equations. Those decisions lead to this question: How are systems of equations and inequalities the same or different? There's something you had to think about and you used that information to make your decisions in your groups. Now before I have you go and summarize that on your post-its, if you haven't done so yet, let's go ahead and make sure that we understand all eight of these correctly.

On a SmartBoard, Kathy wrote an E for equations and an I for inequalities on the projections of the cards as students identified them using "shout it out" (choral class responses). Kathy and her students had interactions that centered around their ideas. For example:

Student 1: Inequations.
Kathy: Did you say inequations? Inequations. It's one or the other. It's supposed to be an inequality. [Student 2] tell us why this is an inequality [symbolic representation].
Student 2: It doesn't have y-equals.
Kathy: Doesn't have that equals, y-equals. Which makes this one what, [Student 2]? [points at a different set of two equations] Equation or inequality?
Student 2: Equations.

This example illustrates that the purpose of the lesson was focused on making sense of mathematical language (inequalities and equations) and concepts (similarities and differences between systems of equations and inequalities). Students were expected to make connections between multiple representations, as they encountered each type of system as symbols, graphs, and story problems. The teacher then gave feedback using revoicing and redirecting. Students were pressed to explain ("tell us why this is an inequality"). This discussion included other similar moments.

Teacher: [reading the problem on the SmartBoard] Two CDs and 4 DVDs cost $40.
Student 3: Equation.
Teacher: Whoa, it's like jeopardy! You didn't let me finish. 3 CDs and 5 DVDs cost $55. Why an equation here?
Student 4: Why a what?
Student 3: Because it's giving $40, right?
Student 4: Because there's no budget.
Student 5: And the other, $55.
Teacher: It's giving an exact amount for a certain number of items. It's not a budget, it's not a limit or restriction. It's exactly equal.

In this interaction, Kathy's feedback revoiced the students ("not a budget") as an example of a constraint that could be a signal for an inequality rather than an equation, which helps position that contribution as valuable. She also gave more detailed conceptual feedback in response to the multiple student contributions about how the representation aligned with being an inequality, in contrast to a shorter evaluative statement or a statement about procedures.

Then, students had another short amount time to work in groups (four minutes) and reflect upon what they identified as important features in systems of linear equations versus linear inequalities. They wrote these reflections on post-its. The teacher brought the students back together as a whole class for two minutes to debrief and highlight the features on the post-its that groups put on a blackboard. Below is an excerpt of how Kathy debriefed the group work.

Kathy: All right stop what you are doing and look at me. You are looking, I appreciate that. [Student 6], open your eyes, pick your head up. These are ideas from your class. I will condense them so there are no repeating ideas. Here are some ideas that your class came up with. Inequalities have the symbols less than or greater than, less than and equal to, greater than and equal to. A system of equations equals something. How many solutions are there to a system of equations? [Student 7] was holding up one finger. If we're talking a linear system with straight lines, how many times can they cross in a graph?

Students: Once

Kathy: Just once. That may change when we talk about things that are not linear, maybe graphs that curve, but for what we're seeing, one solution. This same idea, one has equal signs and the other doesn't. I'll put it in the middle. Oh, here's a new idea! You only shade on the graph when you have an inequality. this one is about shading. An inequality has a feasible region. Does anyone know what a feasible region is? [Student 8], say that again?

Student 8: The shaded part.

Kathy: The shaded part on your graph. It shows all of your solutions.

Motivational discourse was present when the teacher expressed excitement about students' new ideas ("Oh, here's a new idea!") and when she expressed appreciation for students when they paid attention. There was an explicit opportunity to understand mathematical language, at least to some degree, around terms such as "feasible region" and systems of equations and inequalities. There were also attempts to credit students with productive thinking anonymously (reading off what groups wrote on post-its) and by calling attention to students who were calling out productive ideas [students 7 and 8], which could potentially serve to raise students' statuses. Students were also pressed to explain features of systems of inequalities and systems of equations in during the previous classroom discussion and in groups in writing on the post-its. Finally, Kathy gave students feedback on their thinking by reflecting back what she noticed as similarities and differences in groups' responses. (Analysts observed a limitation on mathematical accuracy: linear systems can also have infinite solutions or no solutions.)

This description of a classroom episode illustrates some of the ways that Kathy enacted teaching that aligned with students' self-reports of productive engagement during this activity. Kathy supported students academically through opportunities to make sense of concepts and make connections among representations, and through opportunities for students to negotiate meaning about mathematical language. She pressed students to explain their reasoning and gave them feedback to specifically support understanding of mathematical concepts. Kathy also supported students socially through motivational discourse and status-raising efforts, particularly in terms of how she appreciated students' thinking when they shared ideas and elevated their ideas through revoicing them. Students were asked to explain multiple times throughout the activity, which supported the development of meanings of language and concepts and provided opportunities to position more students' ideas as valuable, to raise their statuses. Thus, for Kathy, both of these two aspects together – the academic and the social support she provided – appear to bolster the mathematical engagement of her students.

Conclusions

Secondary mathematics students in this study reported higher levels of engagement, particularly higher self-efficacy and social engagement, when they had opportunities to negotiate meaning about mathematical language, received specific feedback targeted toward making sense of concepts, and when teachers made the effort to raise students' status. This is an exploratory study; our future analyses will include more observations and ESM measures across an academic year, allowing for more sophisticated statistical analyses. Nevertheless, our preliminary results suggest that investigating the relationships between observations of teaching and students' self-reports of engagement in-the-moment is a potentially revealing approach for uncovering engaging instructional strategies in secondary mathematics classrooms.

RETHINKING MATHEMATICS CLASSROOM PARTICIPATION: STUDENT AND TEACHER PERSPECTIVES

José Manuel Martínez
Texas State University
josemartinez@txstate.edu

Participation in mathematics classrooms has received considerable attention in previous research. Scholars have emphasized researchers' and teachers' perspectives on what it means to participate. I draw on sociocultural theories of learning to explore both students' and a teacher's perspectives on participation. I describe a participatory research study where a Spanish immersion third-grade teacher and I collaborated to elicit students' perspectives on mathematics class participation. Data generation included multi-method focus groups with the students, and an interview with the teacher. Drawing on social semiotics as an analytical framework, findings suggest that there were two connotations of participation in this classroom: While the teacher's connotation characterized participation mainly as quantifiable, observable student talk attributable to individual children, students' connotation characterized participation mainly as qualifiable, amorphous, diverse and focused on the social. I argue that developing mathematics teaching that is inclusive of diverse ways of participating involves learning about students' perspectives on participation.

Keywords: Classroom Discourse, Equity and Diversity

Research on participation in mathematics classrooms has primarily studied the role of the teacher in eliciting student talk. Few studies have focused on how students actually participate, starting with what they have to say about their own participation (Dallimore, Hertenstein, & Platt, 2004). The tendency to overlook students' perspectives in favor of teachers' and researchers' perspectives is particularly marked in studies involving elementary school children (Groundwater-Smith, Dockett, & Bottrell, 2014). This study addresses this issue by considering both students' and a teacher's perspectives. Learning about insiders' (teacher and students) meanings associated with participation was a first step for the teacher to support this class to become receptive of mathematical ideas that emerged in unanticipated ways.

The purpose of this study was to question taken for granted ideas about participation in mathematics classrooms, whose perspectives we acknowledge, and whose we overlook. I report on an exploration of students' and a teacher's participation-related perspectives, in the context of a participatory research study in a third-grade Spanish immersion mathematics classroom. I ask the following research question: What does it mean to participate in a mathematics classroom according to students and to the teacher? I argue that developing mathematics teaching that is inclusive of diverse ways of participating involves learning about students' perspectives on participation. Grounding research and teaching efforts on students' perspectives challenges the imposition of adult-generated visions of what it means to participate, and it helps conceptualizing participation in ways that are consistent with and inclusive of students' classroom experiences.

Literature Review

Participation is nearly equated with student talk in mathematics education research. Many studies use the terms participation and student talk interchangeably (For a few examples see

Brown, 2017; Franke et al., 2015; Jansen, 2006). For example, when studying students' participation in mathematics classrooms Jansen (2006) focused on students "talking about mathematics" (p. 412). Not surprisingly, previous research has characterized the teacher's role regarding participation mainly in terms of eliciting student talk. Specifically, teachers strive to uniformly distribute talk time among students, disrupting the tendency to attend to mathematical ideas uttered by a few dominant students. As Webb et al. (2014) put it, "Teachers can set ground rules and guidelines for desired participation, promoting greater student talk" (p. 81). These norms influence student talk by signaling to students the desirable ways to add to discussions.

Little is known about how teachers become aware of and draw on students' multiple ways of participating in mathematical activity. In this study, I consider the teacher's role not only in eliciting predetermined forms of student talk but also in learning about unanticipated ways of participating. As a first step toward challenging preconceived notions about participation, I focus on students' perspectives on participation and raising the teacher's perspective to awareness.

Theoretical Framework

I draw on sociocultural theory to define participation as an evolving social experience of engaging in meaningful shared activity, that combines doing, talking, thinking, feeling, and belonging (Rogoff et al., 2003; Vygotsky, 1978; Wenger, 1998). Participation is a situated phenomenon in which the individual and the social interact as members of a bounded social community, such as a classroom, coordinate the pursuit of a shared enterprise. It is situated because the context influences both the activities that are considered meaningful and the ways of becoming part of an activity (Thomas, Whybrow, & Scharber, 2012). Participation involves an interaction between the individual and the social because, rather than being a static set of practices, members of a community permanently negotiate what it means to participate (Wenger, 1998). As the community develops over time, the activities in which members engage and how they participate in these activities evolve, too. Different members may introduce novel activities or ways of engaging in activity. When an individual's ways of participating are legitimized and influence how others participate, the member experiences a sense of belonging.

This conceptualization has implications regarding the role of the teacher. What counts as participation varies from classroom to classroom (Anderson, 1998). Even within each classroom, teachers' and students' meanings of what counts as participation may differ (Mafra Goulart & Roth, 2006). Teachers may decide to focus on helping students participate a certain way. Although this approach has the potential of helping students expand the ways in which they participate, it can also exclude children whose preferred ways of participating are overlooked. In contrast, when the classroom allows multiple ways of participating to influence activity, the community expands the ways in which students make sense of ideas and more students experience a sense of belonging in mathematical activity (Dallimore et al., 2004). In this study, I consider the role of the teacher expanding her own conceptualization of participation by learning about students' ways of participating.

Methodology

Participatory Research

Participatory research seeks to challenge power hierarchies, including the positioning of the researcher as an expert that comes to the site to execute a predetermined agenda (Fals-Borda, 1987). Participatory approaches do not regard the researcher as the producer of knowledge and the researched as the object of analysis and the recipient of knowledge. Instead, participatory researchers move from working *on* or *for* participants to working *with* them (Hansen, Ramstead, Richer, Smith, & Stratton, 2001). Accordingly, participatory research is based on the needs of the community and it focuses on the process of working together to gain understandings and initiate transformations of particular situations. In this study, the issue of participation emerged during my prolonged collaboration with the teacher, as we both became aware and were puzzled by students' differential participation. The teacher and I collaborated in making sense of the ideas about participation that coexisted in this classroom.

Sites and Participants

Located in the Midwest of the United States, this school offered a Spanish language immersion program. Instruction was in Spanish all school day (including mathematics class), except for one hour taught in English. There were 21 students in this third-grade classroom: 15 female students (one Latina, one Asian American, two African American, 11 White) and six male students (two Latino, one African American, three White). All students seemed comfortable sustaining conversations, as well as following directions and discussions in Spanish. The teacher, Señora Abad (all names are pseudonyms) was a Spanish-English bilingual Latina, with four years of teaching experience, all in this school.

Consistent with principles of participatory research, I position myself as a research-participant in this study. I am a Latino Spanish native speaker. I was a teacher for 7 years. As part of my involvement with this classroom, I visited the school for three years, collaborating with Señora Abad on my research. I observed this specific third-grade and supported students during small group work throughout the school year.

Data Sources

I conducted multi-methods focus groups with students to discuss participation in general and in math class specifically. I conducted six focus groups with three or four students in each group. Consistent with tenets from participatory research, the structure of these focus groups was flexible: First, I reiterated that participation was voluntary and that students could choose whether to join a focus group or not. I communicated to all students that I would share their responses with the teacher. Second, students chose their own groups, in an attempt to help the children feel comfortable sharing their ideas. Third, students could choose to leave the group at any moment and join another group later. Fourth, students could choose to speak in English or in Spanish at any point. Fifth, students had the option of choosing among multiple methods to share their ideas.

I initially asked students to think about what it means to participate and how they participated in math class. Each student individually decided whether to draw or write about these ideas, or to think and then share during the conversation. Paper and markers were available. Then, each student could decide whether to share the ideas with the rest of the group or not. All students shared their drawings and writings and explained what they represented. I asked follow-up questions to clarify points or to ask for specific examples. In all groups, students frequently addressed each other, adding to what others said or proposing alternative ideas. Each focus group was about 30-minutes long. I audio recorded and transcribed each group and I collected students' sheets.

I also conducted an interview with the teacher. This 45-minute semi-structured interview took place after all the focus groups, and the teacher and I discussed her ideas about participation in her mathematics class. I audio recorded and transcribed the interview.

Analytical Framework

Principles from social semiotics (Halliday, 1978; van Leeuwen, 2005) resonate with this study's focus on a shift away from overvaluing predetermined ways of participating. Social semiotics argues that when individuals communicate, in addition to externalizing personal understandings, they also intend to achieve effects in their community (Morgan, 2006), which is consistent with sociocultural theory's considerations of participation as involving a sense of social involvement. Social semiotics challenges the assumption that pre-given, static meanings reside in specific semiotic resources. Acknowledging the influence of social contexts and interactions in meaning making processes, social semiotics contends that specific practices have different meanings in different contexts, and the culturally situated meanings of those practices can be the focus of social semiotics analyses (van Leeuwen, 2005). In this study, I focus on the meanings and practices associated with participation in this mathematics classroom.

Connotations. I focus on this analytical tool from social semiotics to make sense of the students' and the teacher's responses. Connotations are variations within the culturally shared meanings, values and practices of a social group. The context and the perspectives of different participants influence these variations. When the connotations that different members of a group hold about a practice are sufficiently complementary or similar, the coming together in joint activity is more likely and more inclusive than when these connotations are incompatible. For example, if a teacher's connotation of participation involved students sitting quietly and raising their hands to respond to the teacher's questions and most students shared this connotation, it would seem as if there is cohesion and ease within the group. At the same time, however, the few students whose connotations differed could potentially be ignored. In the presence of this incompatibility, elementary school children tend to conform, and adults' perspectives tend to prevail (van Leeuwen, 2005).

Data Analysis

Consistent with the participatory methodology, the teacher and I collaborated analyzing focus group and interview responses to develop agreed-upon interpretations of the connotations of participation that coexisted in this classroom. I annotated each line of the transcripts, focusing on nuances in characterizations of what it means to participate. I attended to word choice, the use of pronouns, and expressions of emotion or intensity. Analysis of these language cues helped "link micro-analysis of texts to various forms of social analysis of practices" (Fairclough, 2013, p. 7).

I also annotated statements where students agreed, disagreed or built on others' responses to identify convergence and divergence of perspectives on participation among students. I repeated this process, refining annotations. Then, I conducted a thematic analysis to identify emerging themes in the focus groups and in the teacher interview. I shared these tentative themes with the teacher, and we analyzed excerpts of responses from the focus groups that I selected. I selected three excerpts from different focus groups that included references to the main themes that I had identified and that were representative of the entire data set. The teacher confirmed most of my interpretations and she helped me strengthened them by contextualizing some of the responses based on what she knew about the students.

Findings

Analyses suggest that Students characterized participation mainly as qualifiable, amorphous, social and diverse. The teacher, on the other hand, characterized participation mainly as quantifiable, observable, individual student talk.

Students' Connotation

I illustrate the interpretation of students' connotation of participation mainly as qualifiable, amorphous, diverse and focused on the social with a vignette from the second focus group I conducted. Three students were part of this group: Stacey, Rose and Jimmy. Stacey mentioned she participated in gym class watching what the teacher did and then trying to do the same. I followed up asking how they participated in math class.

1	Author	So, I have a question for the group. How do you participate in math class?
2	Stacey	Like, what?
3	Author	You just talked about how you participate in gym, so now I'm wondering how
4		you participate in math class.
5	Stacey	But, like, what? Like in charlas de números [number talks], or when Señora Abad
6		is explaining something, or when we work with our table?
7	Author	Is it different?
8	Jimmy	It's different but it's the same. It's the same because sometimes what we're doing
9		doesn't matter. Like, I love to ask questions all the time.
10	Rose	And it's different at our tables. I like participating because I feel part of the team.
11	Stacey	I like helping others because I can help everyone feel part of the team.
12	Jimmy	And also sometimes you can participate too much because you are not really
13		helping but telling others 'this is the answer.'
14	Rose	Yeah. You have to think, and you have to listen first.
15	Jimmy	And you can say like 'I think we can try this way because I draw it here and I
16		think it works. What do you think?'

Participation as qualifiable. In all focus groups, the idea of qualifying participation emerged. That is the case in the vignette when Jimmy stated: "sometimes you can participate too much because you are not really helping but telling others 'this is the answer'" (lines 12-13), to which Rose agreed. Later in the conversation, Stacey articulated a similar idea. She was referring to a whole class discussion in math class earlier that day when the teacher mentioned it was hard for her to understand because several students were talking at the same time. Stacey stated: "sometimes, like what they were just doing is over-participating cause they shouldn't be talking, and they still were, so that's like kind of participating, but, yeah." In this case, Stacey qualifies a classroom event as involving over-participation.

Amorphous, perceived participation. Although students mentioned observable aspects of participation, they also described a non-observable sense of participating. In the vignette, all three students related ways of participating with something they loved or liked. Jimmy, for example, said: "I *love* asking questions all the time." Similarly, Rose said: "I like participating because I *feel* part of the team" (line 10). Rose related participation with her feeling part of the team. Stacey agreed, adding that she *liked* to "help everyone feel part of the team" (line 11).

Multiple ways. In all focus groups, students mentioned diverse ways of participating. In the vignette, for example, when I asked how students participated in math class, Stacey helped the group consider diversity of participation within math class. Specifically, she focused on diverse ways of participating related to types of activities, including number talks, teacher explanations, and small group work (lines 5-6). Group members added other ways of participating that involved student talk, such as telling the answer to a problem (line 13), and some ways that did not necessarily involve student talk, such as thinking, listening, and drawing (lines 14-15). Additional ways of participating that students mentioned in other focus groups included watching, writing, reading, and using specific materials (e.g. rulers and base ten blocks).

Students' comments did not seem to favor one way of participating over others or to subordinate one way of participating as ancillary to others. For example, students did not mention listening or observing as ways of participating that would ultimately facilitate student talk. Instead, students mentioned these ways of participating as alternative and complementary.

Two ways of participating were salient in all focus groups. One way was helping. In the vignette, Stacey introduced this idea when she mentioned she liked helping others (line 11), and Jimmy and Rose expanded on this by characterizing ways to help and ways that are "not really helping" (line 12). Another salient way of participating that emerged in focus groups was asking questions. Although asking questions involves student talk, it is not a kind of talk where students explain an idea or justify a response. This kind of talk elicits others' ideas and expresses curiosity, confusion, or the need for help. In the vignette, Jimmy offered an example of this way of participating when he said he loved asking questions all the time (line 9) when referring to ways of participating that may occur regardless of the type of mathematical activity.

Relating the individual and the social. Students' connotation of participation tended to consider the interaction between the individual and the social. In the vignette, students mentioned individual preferences related to participation. Students, however, related their individual participation preferences with social interactions. For example, Jimmy mentioned he loved asking questions (line 9) when he was explaining that his awareness of the context of the activity influenced how he participated. Similarly, when Rose mentioned her liking feeling part of the team (line 10), she was simultaneously recognizing the sense of membership to a social group as an aspect of her participation. When Stacey stated she liked helping (line 11), she signaled her involvement with those who she helped as part of this way of participating. Finally, students' characterization of participation as qualifiable implied that what the teacher did or how some students participated influenced others' participation. That is the case when Jimmy said "you can participate too much" by telling others the answer to a problem (line 12).

The Teacher's Connotation

The following vignette illustrates the interpretation of Señora Abad's connotation of participation mainly as quantifiable, observable student talk attributable to individual students. This vignette is part of Señora Abad's response when I asked her what she did to help students participate in math class. Giving an example of the strategies she used, she mentioned the cup where she had popsicle sticks, with the name of one student written on each stick. She mentioned she would randomly draw one stick and call on the student whose name was written on that stick to answer a question or share an idea. Señora Abad shared that besides helping her avoid calling the same student multiple times, this strategy signaled to students everybody needed to be ready.

> I use them [the popsicles] because then they [the students] know anybody can participate. Not only those who always raise their hand. It doesn't always work because they can pass if they don't want to participate, and then I draw another name. But I would like to see everybody participating [in math class]. And there are different forms of participating, it doesn't have to be the same for everyone, but [I'd like to see] everyone participating. Because sometimes some [students] don't participate. I know that sometimes Daniel is going to be doing something else and then he won't be able to say anything when I ask him a question. Or Emi. She doesn't like going to the board and telling us about her strategies. So, it's difficult.

Absence or presence of participation. Señora Abad seemed to characterize participation in terms of a binary: at any given moment, a student either is or is not participating. In this excerpt, this presence or absence of participation refers to whether students shared an idea or answered a question when the teacher called on them. In line 1, she talked about how when she told students she would use the sticks "then they [the students] know anybody can participate." Not everybody would actually participate, but since she randomly selected the name of the student who would participate, all students needed to be prepared. She reinforced the notion of presence or absence of participation when she said that when she called on students, they could pass "if they don't want to participate" (lines 2-3). According to this characterization, students could choose between participation and non-participation. If a student accepted Señora Abad's invitation and contributed an idea, that student chose to participate. In contrast, the student could decline and, therefore, choose to not participate. Señora Abad made this contrast more explicit when she stated: "sometimes some [students] don't participate" (line 6). This comment also suggests that for Señora Abad the status of participating or not participating was not static and changed over time. The use of the sticks strategy relates to the teacher's desire "to see everybody participating" (lines 3-4). This statement further supports the interpretation of Señora Abad's characterization of participation in terms of some students falling into the participating side of the binary and others falling into the non-participating side.

Participation as observable. Señora Abad's connotation focused on observable aspects of participation. That is the case, for example, when she expressed her wish to "*see* everybody participating [in math class]" (lines 3-4). Her characterization referred to "different *forms* of participating" (line 4), suggesting participation that takes a form. Participation seems to be embodied in specific student behaviors accessible to the teacher through direct observation. Specifically, in this vignette Señora Abad referred to participation that takes the form of hand raising and going to the board. The absence or presence of participation relates to its observable nature, in Señora Abad's connotation. According to her comments, whether students were or were not participating was something that she could see. Students' enactment of a specific form of participation would be visible to Señora Abad. Conversely, the absence of such forms would mean that there would be no participation to observe.

Overemphasis on student talk. Señora Abad explicitly acknowledged her perception that different students could participate in different forms when she stated that "there are different forms of participating, it doesn't have to be the same for everyone" (lines 4-5). Señora Abad, however, emphasized student talk during the interview. In several of her comments she suggested that when students talked about mathematical ideas, they participated, and when they did not talk, they did not participate. For example, in the vignette she mentioned that Daniel sometimes got distracted "and then he won't be able to *say* anything" (line 7). Similarly, she talked about Emi not liking "*telling* us about her strategies" (line 8). Talking about mathematical ideas is a form of participation that Señora Abad valued, and students could expect Señora Abad to encourage them to talk. The vignette depicts students who participated as the ones that showed willingness to talk by raising their hands (line 2), and those who did not participate as those who passed when Señora Abad called on them (lines 2-3). The strategies that Señora Abad described communicated to the class that she valued student talk, and they related her idea of absence and presence of participation to absence and presence of talk.

Foregrounding the individual. Señora Abad's connotation of participation tended to foreground the individual over the social. In the vignette, Señora Abad's comments suggest that she attributed participation and non-participation to individual students at any given moment. She provided the example of Daniel (lines 6-7), stating that he tended to not participate when she asked a question. Furthermore, Señora Abad claimed that there was a reason for Daniel not to participate: his getting distracted doing something not related to the class discussion. Similarly, Señora Abad shared that Emi tended to not participate when it required explaining something in front of the class. In the vignette, Señora Abad hinted at Emi's aversion to being put on the spotlight as the reason for her non-participation.

Discussion

In this study, I answered the question: What does it mean to participate in a mathematics classroom according to students and to the teacher? Findings suggest that there were marked differences in the students' and the teacher's perspectives. While students characterized participation mainly as qualifiable, amorphous, social and diverse, the teacher characterized participation mainly as quantifiable, observable, individual student talk. Students' connotation of participation challenges implicit definitions of student talk frequently found in the mathematics education literature. Students' connotation resonates with tenets from sociocultural theory. This suggests the need to examine the theoretical consistencies and inconsistencies in the definitions of participation that researchers implicitly or explicitly use. Methodologically, these findings suggest the need to consider not only adults' but also children's perspectives on participation.

Some aspects of this study's findings reinforce previous research on participation. Specifically, the idea of helping as part of participation that emerged during the focus groups echoes the ideas of students in other contexts (Civil & Planas, 2004; Jansen, 2006). This indicates that some students' ideas about participation may transcend context and be relevant in a variety of classrooms. Simultaneously, findings suggest the need to consider context-specific meanings of participation. For example, unlike other studies, these findings invite a reconsideration of the goal of observing equal participation, understood as the amount of student talk. Students' perspectives, especially when contrasted to the teacher's, suggest that an alternative goal may be to learn about and embrace students' different ways and rates of participation. This way, the class may consider diverse ideas and ways of becoming part of mathematical activity, instead of overemphasizing spoken ideas proposed by talkative students.

Rather than arguing against student talk or against teachers' efforts to support student talk, I argue for teachers and researchers to consider additional ways in which students engage with mathematical activity. Findings from this study suggest that teachers interested in participation may need to consider more than only observable indicators in individual students. Instead, teachers may need to consider a complex network of both social and individual, observable and perceived, quantifiable and qualifiable aspects. In turn, drawing on strategies that help students participate in practices they prefer (such as helping others or asking questions), may foster their exploration of mathematical ideas.

My intention was not to present either connotation of participation as good or bad, but to understand the nuances and contrasts between the two. Moreover, I acknowledge that using focus groups to elicit students' connotation may have favored the emergence of a composite of connotations, but there may be differences within students' connotations. Teachers awareness of their own connotation of participation and learning about their students' is a first step in transforming their practice toward becoming inclusive of diverse ways of participating.

Researchers have investigated how teacher feedback contributes to students' learning, yet there is insufficient research into the connection between teacher feedback and student happiness, which is linked to engagement, socio-emotional well-being, and ultimately academic achievement. We coded lesson transcripts from elementary teachers to determine emergent patterns between types of teacher feedback and average student self-reports of happiness in mathematics. We found teachers to employ specific feedback more than general feedback. In addition, feedback for effort and ability accounted for a small percentage of feedback. Findings suggest that student happiness is linked to specific combinations of feedback dimensions.

Keywords: Affect, Emotion, Beliefs and Attitudes; Instructional activities and practices

The role of teacher feedback in the classroom is both instructional and affective. That is, teacher feedback is multi-dimensional, serving differing purposes. Teachers employ verbal feedback in evaluation of student responses and as a classroom management tool, such as evaluating student behavior (Brophy, 1981; Floress & Beschta, 2018). While learners desire feedback, not all feedback benefits academic performance (Black & Wiliam, 2009; Hattie & Timperley, 2007). In general, researchers agree that for feedback to be considered effective, it must be specific about the learner's performance or behavior (Black & Wiliam, 2009; Burnett & Mandel, 2010; Hattie & Timperley, 2007). However, in Burnett and Mandel (2010), the most prevalent type of feedback documented was general praise, in which the teacher makes a general statement but is not explicit regarding the relationship between a student's action and the awarded praise. Like other studies (e.g., Floress & Beschta, 2018), teachers rarely provide behavior-specific praise. Comparable to our cited literature, a large portion of research on teacher feedback focuses specifically on praise, a subcategory of feedback which goes beyond evaluating for correctness by expressing approval or assigning worth (Brophy, 1981). Interestingly, praise does not correlate with student academic achievement gains (Brophy, 1981). Thus, the types of feedback described as "effective" for supporting student learning in research literature may not be found in classroom interactions.

Classroom feedback and praise not only influences students' learning and behavior, but also influences students' orientation to learning. Mueller and Dweck (1998) found that praising students for ability rather than effort impacted students' orientations towards learning. Students praised for ability focused on the performance of themselves (and others), while students praised for effort adopted a mastery-oriented mindset. Students' orientations towards learning impact their disposition towards learning, especially when encountering failure. In short, praising students for their intelligence communicates that "they can measure how smart they are from how well they do" (Mueller & Dweck, 1998, p. 43). Students' dispositions are also influenced by their preferences for feedback. A preliminary review of the research shows that elementary students prefer effort feedback to ability feedback (Burnett & Mandel, 2010), and prefer private praise to being spotlighted (Burnett, 2001). Thus, feedback type and student feedback preferences impact students' dispositions towards learning.

In this study, we ask: *Controlling for teachers' success at raising test scores, are there associations between the types of verbal feedback provided by teachers and measures of student self-reported engagement and happiness?* To answer this question, we examined lesson transcripts of twelve teachers who were effective at raising test scores but were either in the top or bottom quartile for student self-reported happiness (survey questions shown in Table 1). The twelve teachers were selected from a larger dataset where students were randomly assigned to classroom teachers. Given the teachers' success at improving students' academic performance, it is reasonable to suspect that teacher feedback satisfies the markers of effective feedback. However, the extremes in student-reported happiness that there may be differences in how often and what type(s) of feedback teachers provide.

Table 1: Student Survey Items Measuring Happiness in Class

This math class is a happy place for me to be.
Being in this math class makes me feel sad or angry.
The things we have done in math this year are interesting.
Because of this teacher, I am learning to love math.
I enjoy math class this year.

From Blazar & Kraft (2017)

Our study extends the current research by examining instances of both academic and behavioral feedback, including corrective feedback. Previous studies report that general academic praise is not predictive of a positive classroom environment, but they have not examined the influence of social or behavioral feedback (Burnett & Mandel, 2010). Other studies have examined the use of praise as a classroom management tool, monitoring academic and behavioral praise but not documenting instances of feedback for correction (Floress, Jenkins, Reinke & McKown, 2018). Our research focuses specifically on feedback and praise during mathematics lessons because students' mathematical dispositions are linked to how they engage with the subject (Gresalfi & Cobb, 2006). We posit that students' perceived happiness in class is a component of their disposition towards the content. Thus, our proposed research has the potential to uncover links between feedback, praise, and students' self-reported engagement with and enjoyment of mathematics.

Conceptual Framework

We developed our conceptual framework based on current and seminal research on feedback and praise. Following Hattie and Timperley (2007), we define feedback as "information provided by an agent (e.g., teacher) regarding aspects of one's performance or understanding" (p. 81). As a component of instruction, feedback can be both informative and educative, in that feedback can merely evaluate (denote correctness) or can provide additional information that moves learning forward (Black & Wiliam, 2009). As shown in the table, there are multiple facets, or components, of teacher to student feedback. Our framework posits five dichotomies: behavioral or academic, affirmation or criticism, specific or general, process or product, and ability or effort. As noted earlier, different types of feedback vary in their effectiveness for supporting student learning and disposition (Hattie & Timperley, 2007; Mueller & Dweck, 1998). Academic feedback addresses students' understanding of the content or task, while behavioral feedback includes other non-academic classroom behaviors (Brophy, 1981). For example, "I can tell Student A is ready to learn because she is sitting quietly," is a specific affirmation of Student A's behavior. Whether academic or behavioral, feedback is either affirmative or corrective (evaluative). In our framework, praise is a subcategory of affirmation. Brophy (1981) defines praise as "to commend the worth of or to express approval or admiration" (p. 5). According to Brophy, praise expresses positive teacher affect, providing feedback beyond affirmation or evaluation. Feedback will also be categorized as general or specific. General feedback consists of "any nonspecific verbalization or gesture that expresses a favorable judgment on an activity, product, or attribute of the student" (Floress, Jenkins, Reinke & McKown, 2018, p. 414). By contrast, specific feedback is explicitly linked to "an activity, product, or attribute of the student(s)" (Floress, Jenkins, Reinke & McKown, 2018, p. 414). Thus, "good job" is general feedback, while, "I like the way you are organizing your work on your paper" is specific feedback.

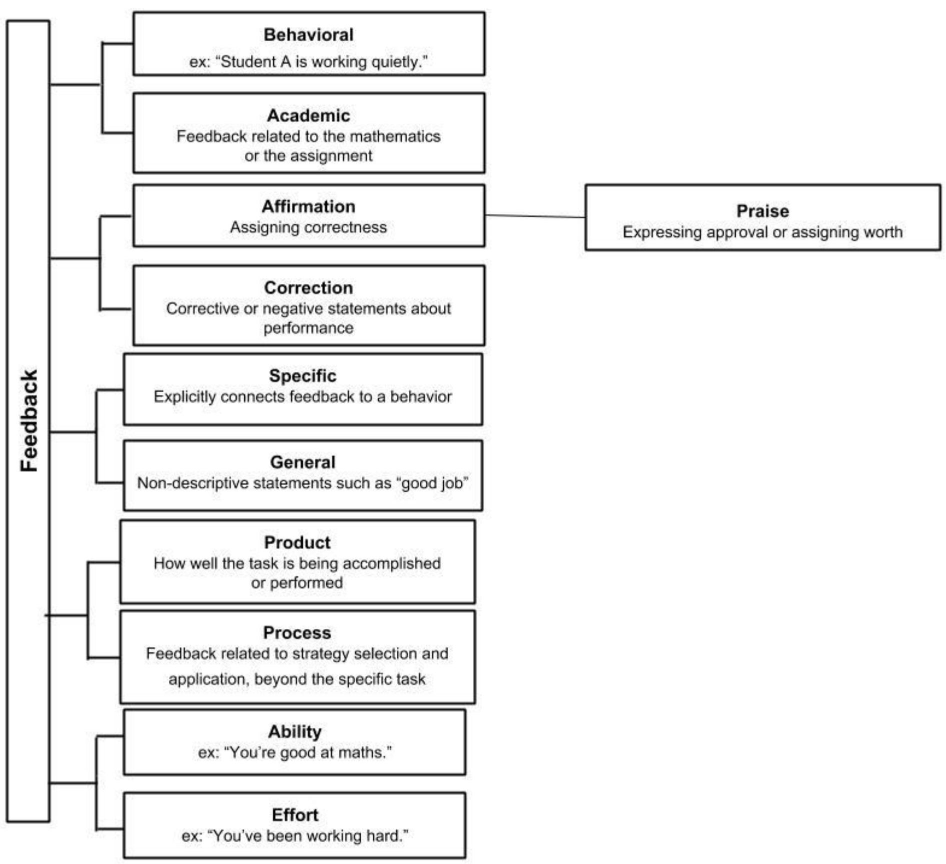

Figure 1: Conceptual Framework: Categories of Teacher-student Feedback

Not all feedback can be assigned to categories on the final two dichotomies: product or process, and ability or effort. Feedback about the product is typically corrective feedback about how well a task is being performed (Hattie & Timperley, 2007). Process feedback addresses the underlying processes of the specific task, potentially linking processes across tasks, or relating to students' error-analysis (Hattie & Timperley, 2007). Consequently, behavioral feedback, such as correcting a student for speaking too loudly, is often not linked to the specific mathematical task, and thus would not be categorized as process or product feedback. Finally, ability feedback is related to intelligence or personal attributes, while effort feedback is characterized by the use of the word "try" or a similar term which emphasizes that the student is putting forth effort (Floress & Beschta, 2018). General feedback, such as telling a student "Good job" for providing a correct response, would not be categorized as effort or ability feedback.

Methods

The primary focus of data analysis is to investigate if teacher feedback (type, frequency, etc.) is associated with student self-reported engagement and happiness.

Data

The transcripts analyzed in this study are from a dataset from the National Center for Teacher Effectiveness (NCTE) (as described in Blazar & Kraft, 2017). The teachers in this study are either 4th or 5th grade comprehensive teachers, who self-selected the lessons to be recorded. The recorded lessons were subsequently transcribed. As part of a larger research study, we first identified teachers who are effective at raising students' test scores. Then, we selected a subset of twelve such teachers who are either particularly effective or ineffective in making their classrooms happy and engaging places for students (as self-reported by students on end-of-year surveys). Six teachers score in the upper quartile of student happiness and engagement ratings while six teachers score in the bottom quartile. For each teacher we have three mathematics lesson transcripts, for a total of 36 lessons. The lessons ranged in length from 33 minutes to 79 minutes with an average length of 52.6 minutes.

Analysis

We coded lesson transcripts in NVivo. Our conceptual framework serves as our coding scheme, with each evidence of teacher feedback coded as behavioral or academic, affirmation or criticism, praise, general or specific, process or product, and ability or effort. For example, the statement "Not seven. Negative seven" was coded as academic, correction, specific, and product. Comparisons across codes, such as instances of affirmation versus criticism, aim to provide evidence for classroom climate and measures of student happiness. The lesson transcripts do not include descriptions, such as non-verbal gestures or how students are configured. Thus, our analysis only examines verbal feedback, which is presumed to be public.

The authors established the codebook, as defined by our conceptual framework, then completed independent coding on their assigned transcripts. Two randomly assigned researchers coded each lesson transcript. During independent coding, the authors regularly met to renorm and examine problematic codes. The authors examined conflicting codes (such as feedback being coded as both academic and behavioral) and were able to reach consensus. Ambiguous feedback where categories of feedback were influenced by potential student interpretation was brought up for review and ultimately excluded from analysis. Examples of ambiguous or interpretable feedback include instances where teachers praise a student, or group of students, in a manner that admonishes the other students ("Student G's group figured it out, so what seems to be the hold-up for this group?").

Limitations. We only have access to lesson transcripts, which do not include video recordings of the lessons, or descriptions of teachers' or students' paralinguistic and nonverbal behaviors. Consequently, we cannot make conclusions about the credibility of teachers' praise or feedback, or how it is received by the students (Brophy, 1981). Another limitation of the data is that measures are collected at the classroom level. Students differ in their preferences for praise and feedback (Brophy, 1981; Burnett, 2001; Burnett & Mandel, 2010), which in turn may influence their self-reported feelings of happiness and engagement. However, we are unable to link specific classroom instances with students' self-reports - we can only examine larger classroom trends.

Findings

We identified a total of 1588 instances of feedback across twelve teachers and thirty-six lessons. Table 2 shows instances and rates of overall feedback and affirmative (positive) feedback per teacher per lesson. Given our strict definition of praise, we are comparing our more inclusive category of affirmative feedback with other authors' reports of teacher praise, which tends to be more encompassing.

Teachers' rate of affirmative feedback (instances per hour) are within the ranges of rate of praise of 4th and 5th grade teachers, as reported by Floress et al (2018). Floress et al (2018) observed an average rate of 22.5 praise statements per hour for 4th grade teachers and an average of 30.9 praise statements per hour for 5th grade teachers. In our data, teachers with high measures of student self-reported happiness and engagement are within these averages, with 24 affirmative statements per hour, while teachers with low measures are about the same rate, with an average of 39.5 statements per hour. Overall rates of feedback are higher for teachers with low measures of happiness and engagement (m = 58.5 statements per hour), compared to those with high measures (m = 43 statements per hour).

Table 2. Amount and Rates of Feedback Per Teacher and Lesson

	High measures of happiness	Low measures of happiness
Total instances of feedback	721	867
Rate of feedback*	43	58.5
Percent of affirmative feedback	56	68.6
Rate of affirmative feedback*	24	39.5

*Calculated in terms of feedback per hour.

Other studies found teachers to provide more general than specific feedback and praise (Burnett & Mandel, 2010; Floress et al, 2018). However, both groups of teachers provided specific feedback more often than general feedback. Specific feedback accounts for 77% of all feedback for teachers with high measures of happiness and engagement and 83.7% of all feedback for teachers with low measures. Feedback for effort and ability accounted for a small percentage of feedback, across all teachers. Together, effort and ability related feedback accounted for only 6% of total feedback for teachers with high measures and 7% for teachers with low measures.

Table 3: Corrective Feedback Counts and Percentages

	Teachers with high measures of student happiness	Teachers with low measures of student happiness
Total corrective feedback	318 (44.1%)	268 (30.9%)
Academic corrective feedback	129 (40.6%)	164 (61.2%)
Behavioral corrective feedback	189 (59.4%)	104 (38.8%)

Number of instances of feedback with percent of total feedback.

Our study extends previous research on teacher-student feedback by examining corrective feedback (Table 3). Nearly half of all feedback provided by teachers with high measures of student happiness is corrective feedback. As shown in Table 3, teachers with high measures of happiness gave more behaviorally-focused corrective feedback while teachers with low measures provided significantly more academically-focused corrective feedback than behaviorally-focused corrective feedback.

Discussion

Our analysis captures the natural rates of feedback for twelve teachers, six of whom scored highly on measures of happiness and engagement and six who scored low, all who are successful at raising students' test scores. Our results show that teachers with low measures of happiness and engagement give more verbal feedback overall. Both groups of teachers have high rates of feedback, tend to give more affirmative than corrective feedback, provide specific feedback, and have low instances of effort and ability feedback.

Burnett (2001) found that 4th and 5th grade students desire teacher praise more than any other group of students under investigation, "indicating that this is a phase of development where students are looking for reassurance and recognition from their teachers" (p. 21). Yet, in our analysis the highest instances of affirmative feedback come from teachers with low measures of student happiness. Thus, the existence of affirmative feedback alone is insufficient to bolster student happiness and engagement in mathematics. Hence, the content of the feedback must be examined more closely. There were observed differences in the types of specific affirmations awarded to students. For example, teachers with low measures of engagement had a total of 278 instances of specific affirmations (including praise), 51 (10.7%) of which addressed students' processes and strategies, compared to teachers with high measures, who had 281 instances of specific affirmations, 53 (19%) of which addressed students' processes and strategies. Furthermore, there are differences in the process and strategies that are affirmed by teachers. For instance, students in low engagement classrooms were praised for helping a peer ("Good. That's what a partner should do."), or for following an algorithm ("I like how you wrote the clusters in there, not the products.”). In contrast, students in high engagement classrooms were affirmed for their higher-order thinking (“I like the connections that are being made. You’re connecting these fractions to division and your multiplication, correct?”). Surface level process feedback (such as successful use of an algorithm) may support student confidence, but feedback related to underlying processes supports students in transferring strategies across tasks (Hattie & Timperley, 2007). Corrective feedback also influences students’ disposition. Teachers with high measures of engagement provided surface level corrections to processes, while teachers with low measures were more likely to reject student ideas related to processes (“I don’t think this is a good idea. Let me show you how I would do it, okay?”). We posit that students may enjoy mathematics more when they are supported in making connections across tasks, and when their thinking is “taken up” by the teacher.

Our proposition is further supported by the differences in effort feedback provided by teachers. Teachers with high measures of happiness and engagement affirmed students for asking questions and for collaborative work, and corrected students for passivity. In contrast, teachers with low measures of happiness and engagement affirmed students for following procedure, being organized, and following along, and corrected students for rushing through tasks and “being messy.” In both sets of classrooms, students are provided feedback about how they are engaging with the content. Students’ interest in or affiliation with mathematics is linked to the ways in which they engage with the content (Gresalfi & Cobb, 2006). The feedback from teachers with high measures of happiness indicates that students are expected and encouraged to be actively engaged with the tasks, ask questions, and work together - all of which we presume to have a positive effect on students’ disposition towards mathematics. Conversely, the feedback provided by teachers with low measures of happiness and engagement reinforces the concept of mathematics as rule-bound and highly structured (Gresalfi & Cobb, 2006).

In addition to the analysis of teacher to student feedback, this study also presents a conceptual framework to investigate a more layered view of teacher feedback. However, our framework did have limitations. Since our definition of feedback was limited to teacher statements that were distinctly evaluative, we did not code instances of teachers revoicing or posing questions in response to a student. While coding transcripts, we did see teachers responding to students in these ways. In fact, there appeared to be an abundance of parroting as revoicing, where the teacher repeats the student response verbatim. Further research should include examining the connections between additional forms of teacher feedback (parroting, revoicing, and responding with a question), and students self-reported happiness and engagement in mathematics.

Conclusion

This study adds to the growing body of literature around teachers’ classroom interactions with students and the influence of those interactions on student engagement and disposition. Our findings provide a new aspect of classroom interactions and feedback by combining student survey results with transcript review. Using this approach, we found that both teachers with high and low measures of student happiness use specific feedback in their classrooms more frequently than general feedback. Contrary to popular discussions about ‘growth mindset’ classroom practices, our analysis did not find evidence that students with teachers who are effective at raising test scores are providing students with high levels for feedback on their effort or ability regardless of the classroom’s designation as either a high or low engagement setting.

BOTTLE FILLING TASK REASONING: A COMPARISON OF MATCHING VERSUS CONSTRUCTED STUDENT RESPONSES

Dominique Banner
Boise State University
dominiquebanner@boisestate.edu

Laurie Overman Cavey
Boise State University
lauriecavey@boisestate.edu

In this paper, we compare the levels of reasoning elicited during the completion of three versions of a bottle filling task: high school level matching; middle school level matching and constructed response. The goal of the tasks was to make visible secondary students covariational reasoning methods. Video of students completing the task while explaining their reasoning during one-on-one interviews were analyzed. Analysis demonstrated a wide range of reasoning when provided a matching version with a greater incidence of accuracy with students who exhibited lower levels of reasoning. Conversely, the constructed response task demonstrated higher levels of reasoning more consistently with decreased accuracy. Implications for assessment are discussed.

Keywords: Algebra and Algebraic Thinking, High School Education, Middle School Education

In this study, video from a larger study in which students completed modified versions of the well-known bottle filling task (Thompson & Carlson, 2017) while explaining their thinking were analyzed (Cavey et al., in press). The solutions and reasoning methods of four groups of students were analyzed for three separate versions of the task: a high school matching, middle school matching, and a constructed response in which the students were asked to draw their own graphs to represent the given situations. None of the versions provided any measures or scales. Across all groups, students were encouraged to verbally explain their reasoning after completing the task.

Assessing student understanding in mathematics from students' written work can be difficult. Students can be successful at completing a task without understanding the targeted learning goal or understand the targeted learning goal but be unsuccessful in the task for an unrelated reason. Although, in mathematics, there is usually one correct answer, it is also important to recognize, and acknowledge, student success in their thought processes. Relatedly, there has been a recent shift in standardized test structures from entirely multiple choice to include some constructed response items (e.g. the addition of "grid-in" questions on the SAT). This shift in testing structure, along with our interest in supporting secondary student's covariational reasoning, motivated us to examine the student reasoning elicited across different types of tasks.

Purpose

In this study, student work on three versions of a bottle filling task, two matching and one constructed response, were compared with the purpose of identifying aspects of the covariational and graphical reasoning students appeared to use and to compare the results between the groups. The questions which guided our analysis are:

- How do the aspects of covariational reasoning exhibited by students compare across the three tasks?
- Do students complete the task more accurately in one format over the other?

In this paper, we describe our methods, results, and analysis of the student work. We also discuss the implications for teaching and student assessment.

Theoretical Framework

This study is informed by research concerning covariational reasoning and assessment of students' mathematical knowledge. The intent of the bottle filling task is to elicit covariational reasoning by asking students to imagine the dynamically changing scenario of a bottle filling with a liquid and think about how the relationship between the height and volume of liquid is represented graphically.

Covariational Reasoning

Covariational reasoning involves coordinating how two quantities vary together and is essential to the understanding of functions (Thompson & Carlson, 2017). Various versions of the bottle filling task have been used in studies designed to assess covariational reasoning. For example, Carlson, Jacobs, Coe, Larsen and Hsu (2002) used a version of the bottle filling task with college undergraduates in which students were asked to create a graph of the height as a function of volume. In addition, Johnson (2012, 2013) used a version in which volume was shown as a function of height and asked high school students to sketch a picture of a bottle which would generate the given graph. The researchers in these studies also developed frameworks for analyzing student covariational reasoning. As the students in our study consist of both middle school and high school level students and we were interested in how the student understanding was translated to a graph, these frameworks informed the creation of our framework, but did not completely align with our purposes.

Assessment

Assessment is an integral component to teaching and learning. Assessment provides teachers and students information regarding a student's level of comprehension. Student work can be assessed: during whole class instruction, small groups, or one-on-one; through verbal or written interaction; and can take the form of formal or summative assessment. Information gathered from assessment can be used to inform instruction, group students, or develop interventions.

Black and Wiliam (2009) discuss the structure of formative assessment in which the teacher presents a task, the learner responds, and the teacher then acts in response to the student. To provide the most appropriate response, it is essential for the teacher to understand the student's reasoning as well as possible. However, as Black and Wiliam (2009) point out, this can be a very difficult task for teachers as it can be impossible to know entirely what a student is thinking.

One method for enhancing teachers' ability to understand a student's reasoning is for the teacher to request the student articulate their thought process, prompting the student to expand the description of their reasoning where necessary and to reflect on their own thinking. Black and Wiliam (2009) cite work by Shayer and Adey (2002) who found that articulating and reflecting on one's own thought is essential to the learning process.

Teachers must determine the types of tasks necessary to elicit student reasoning and questions to create this rich learning environment. Chaoui (2011) cites research regarding the differences in cognitive demand of multiple choice questions compared to constructed response, but also states there can be great difference in the level of cognitive demand required in the way a multiple choice question is constructed. Chaoui (2011) also cites several research studies showing similar performance on multiple choice questions compared to constructed response. This study looks at these types of comparisons specific to the bottle filling task.

Methods

Participants

This study involved the analysis of one-on-one interviews, obtained from a larger study, of secondary students completing one of three versions of a bottle filling task. Thirty-five students completed the task in the first round of interviews (15 high school and 20 middle school) and 16 in the second (9 high school and 7 middle school). It is important to note, high school students in the first round were enrolled in a Calculus class while those in the second round were enrolled in lower level mathematics courses. As we are comparing the reasoning and accuracy levels for each version of the assessment, we do not consider this an issue.

Student Task

During the first round of interviews, students were provided a matching version of a bottle filling task. All versions the bottle filling task used of were adapted from a task created by Swan (1985). The task pictured 3 bottles with different shapes: an evaporating flask, an ink bottle, and a bucket. Two versions of the matching task were developed, one for high school students, which provided 5 graph options, and one for middle school students, which provided 3 graph options. Each version depicted height as a function of volume. Students were also provided the option of creating their own graph.

In the second round of interviews, the bottle filling task was redesigned as a constructed response problem. There were no longer two separate versions, the same three shaped bottles were used, and students were asked to create a graph for each. To assist the students in creating their graph, partial planes were provided with two perpendicular rays representing the first quadrant of a graph. There were no markings on the axes or grid in the plane to indicate any type of scale. The axes were labeled to indicate volume as a function of height. The reason for this change was due to the student's ability to conflate volume with time, and thereby arriving at a correct answer without demonstrating the desired level of covariational reasoning.

Data Analysis

To compare student reasoning and accuracy, videos and transcripts of the interviews were reviewed and coded. Table 1 shows the framework developed for coding student reasoning elicited across all versions of the task:

Table 1: Student Reasoning Coding Framework

Level	Description
1	Recognizes that both quantities increase or provides no explanation related to volume or height (E.g. student graphs a straight line)
2	Makes connections between the shape of the bottle and how one quantity (either volume or height) changes (E.g. Verbally (and with gestures))
3	Coordinates the changes in one quantity with characteristics of a graphical representation (E.g. student explains how one quantity changes over time and translates their ideas to a graph)
4	Makes connections between the shape of the bottle and how volume and height change together (E.g. The student can verbally explain (or show with gestures) how the quantities change together)
5	Coordinates changes in volume and height with characteristics of a graphical representation (E.g. in addition to being able to explain, the student can also translate those ideas to a graph)

While reviewing the student interview videotapes, it was determined that students would occasionally employ differing levels of reasoning for different bottles. Therefore, student work and reasoning for each bottle were coded individually.

For the purpose of coding student accuracy, three different scoring frameworks were implemented, depending on the version of the task. A score of 0 was given for incorrect responses on all versions. For the middle school version of the matching task, students were given a score of 1 for a correct response. The high school version of the matching task was scored as follows: Evaporating Flask, 1 for a correct response; Ink Bottle, 1 for selecting option A and 2 for selecting option D; and Bucket, 1 for selecting option E and 2 for selecting option C. The task was scored in this manner due to the similarities of options A and D (continuous graphs containing 3 sections), as well as options C and E (smooth curves with differing concavity). The constructed response version of the task was scored as follows: 1 for a graph than contained a correct feature (e.g. number of changes in the graph, concavity, etc.) and 2 for a correct graph.

Subsequent to coding student reasoning elicited and the accuracy of their work, a ratio chart was completed cross-referencing the reasoning and accuracy scores. Relative frequencies of each cell were color coded by percentile group (1-9%, 10-19%, etc.) and compared, looking for trends. Trends within individual students were also analyzed.

Results

Through our analysis of the descriptor code ratio charts, it was found students completing both matching versions of the task had a greater incidence of accurately completing the task with lower level reasoning skills. In addition, there was a higher incidence of accurately completing the task for those who exhibited higher levels of reasoning. Students completing the constructed response were more apt to employ higher levels of reasoning: middle school students were much more likely, high school students only slightly more likely (possibly due to the discrepancy between the first round of high school students being enrolled in Calculus). Finally, students completing the constructed response did not show the same level of accuracy as those completing the matching.

During the evaluation of individual students for trends, it was also found, while completing the matching version of the task, students were more likely to employ different levels of reasoning for the variously shaped bottles. Whereas, those students completing the constructed response were more likely to consistently employ the same level of reasoning throughout.

Discussion and Conclusion

Results indicate matching and constructed versions of a mathematical task, such as the bottle filling task, elicit different aspects of student knowledge. Depending on the purpose of the task for the teacher, one version may be more useful over another. For example, a matching version could be more useful as a pre-test to determine prior knowledge on a topic; where constructed response could be more useful to elicit higher levels of reasoning. However, teachers must be mindful of the propensity of a student to perform higher on matching, or lower on constructed response, than their actual ability. To counteract this possibility, teachers may also wish to construct questions aimed at prompting students to articulate their reasoning.

It is important to note the limitations of this study. The groups studied were small and consisted of students who volunteered for a study with a different focus. Although all available videos were included in the study, it was not meant as a representative sample. Therefore, the research conducted here is meant only as an exploratory study.

DOES PARTICIPANT SELECTION SKEW MATHEMATICS EDUCATION RESEARCH FINDINGS? CONSIDERING QUANTITATIVE REASONING RESEARCH

William Zahner
San Diego State University
bzahner@sdsu.edu

Quantitative reasoning (QR) is a set of mathematical reasoning practices rooted in conceptualizing problem situations in terms of quantities and quantitative relationships. QR research building on Thompson's (1993) framework has widely influenced mathematics education research and teaching. In this research report I (a) introduce a rationale for including more diverse research samples as participants in QR research, (b) present a brief systematic review of the literature showing a lack of diversity in research participants in extant QR studies, and (c) discuss potential benefits of broadening the diversity of the participants in QR research.

Keywords: Equity, Research Methods, Algebra and Algebraic Thinking

In a recent commentary, the Research Committee of the National Council of Teachers of Mathematics (NCTM) issued a call for collective action toward equity across the field of mathematics education research (Aguirre et al., 2017). One fundamental mechanism for incorporating an equity stance in mathematics education research is acknowledging the sociocultural diversity of students in school mathematics classrooms and designing studies that are responsive to student diversity. Yet, there is a well-documented lack of diversity, in general, among participants in social science research (Henrich, Heine, & Norenzayan, 2010). Many research-based claims about human cognition are based on research that was conducted mainly with White, educated participants, and Henrich et al. (2010) show that the reasoning of White, educated research participants may be quite unusual when put into global context. Taken together, the NCTM Research Committee's stance and Henrich et al.'s (2010) review prompt reflection on the current state of mathematics education research.

In my recent work, conducted in collaboration with a team of researchers, we[1] have examined the quantitative reasoning (QR) of linguistically diverse groups of middle school students, including many students classified as English learners (Els[2]). To ground our work, we reviewed extant research on QR. Attempting to use insights from QR research has forced us to consider whether and how learning to engage in QR might be different for ELs. In this brief report I present a motivation for investigating QR among students learning the language of teaching and learning. Next, I present a brief review of the peer-reviewed journal articles on QR, focusing on the specific issue of research participant selection. Finally, I close with a discussion of what might be gained by broadening the pool of participants in QR research, and consider implications for other areas of mathematics education research.

QR and Language

Quantitative Reasoning is a form of mathematical reasoning that is rooted in making sense of problem situations. QR as conceptualized by Thompson (1993, 2011) and Thompson and Smith (2008) is a process that involves identifying quantities in a situation and then building and reasoning with quantitative relationships. Thompson and Smith (2008) describe how QR often starts with a student *imagining* a problem situation, identifying initial quantities, and then iteratively developing new quantities. For example, a student may solve a word problem about a race with a head start by imagining herself in the race catching up to another runner. Then she might focus on the rate at which the distance to the runner ahead closes. Smith and Thompson (2008) argue that reasoning quantitatively (rather than applying formulas such as D=RT) can serve as a gateway to algebraic reasoning and that this form of reasoning connects to student experience:

> Quantitative reasoning *draws heavily on everyday experience.* The basic approach… depends on the reasoner projecting herself into the situation…. Quantitatively oriented solutions tend to vary more widely than algebraic solutions to the same problem, primarily because they are *grounded in how students conceive of situations,* and there is *tremendous range in these conceptions* (Smith & Thompson, 2008 p. 105, emphasis added).

Research on students' QR has led to innovations in mathematics education, including the development of learning trajectories (Ellis, Ozgur, Kulow, Dogan, & Amidon, 2016) and technological tools (Roschelle, Kaput, & Stroup, 2000). This research has also influenced curriculum and standards documents. In particular, QR research appears to be one of the primary sources for the second standard for mathematical practice (SMP2) in the Common Core State Standards, "Reason Abstractly and Quantitatively" (National Governors Association Center for Best Practices & Council of Chief State School Officers, 2010). However, it bears noting that Thompson (2011) describes a framework for QR that delves into significantly more detail than the text of SMP2.

What is the Relationship between QR and Language?

The quotation from Thompson and Smith highlights that QR builds from student experience. Typical descriptions of QR start with students interpreting problem situations (usually presented in text), creating abstract models and representations of quantities and quantitative relationships (usually equations, diagrams, tables, or texts), manipulating these models and representations to produce proposed solutions, and then communicating the proposed solution and checking its reasonableness (coordinating texts). Throughout this QR process, students engage in disciplinary literacy practices (Moschkovich 2015). This engagement can be challenging for all students, and it can be especially challenging for ELs when mathematical problems are set in contexts that may be unfamiliar (Martiniello, 2008; Zahner, Milbourne, & Wynn, 2018).

The linguistic complexity of QR, together with researchers' typical focus on students' verbalizations may lead researchers to select participants whose verbal communication is easy for the researchers to understand. For example, Ellis (2007) described criteria for selecting case study participants: "Those who had average-to-high grades and could articulate their thinking were desirable as interview participants because they were likely to have developed powerful generalizations in class that they could subsequently explain and discuss in the interview" (p. 447). Ellis's transparency about these selection criteria helps readers interpret the results of the study. As will be seen below, Ellis (2007) is an exception in the QR literature because Ellis made these participant selection criteria transparent. However, salient to our interest in the reasoning of ELs, this selection process excludes students who are not able to articulate their thinking in a way comprehensible to a researcher but who may provide additional insights into QR.

A Brief Review of Participants in QR Research

To understand this issue better I conducted a brief systematic review of QR research focused on participant selection criteria. The research literature on quantitative reasoning is distributed across journal articles, conference proceedings, book chapters, and monographs. In order to capture a snapshot of the literature, I focused on empirical papers appearing in peer-reviewed journals that have used Thompson's (1993, 2011) framework for QR. I conducted a search of the ERIC Database using the search string "quantitative reason*", restricting the results to peer reviewed studies. The initial search yielded 171 potential articles. I noted that the *Journal of Mathematical Behavior* is not completely indexed in ERIC. Since many QR studies have appeared in *JMB* (e.g., Lobato & Siebert, 2002), I also searched *JMB* individually on the journal website. This yielded 31 additional articles for consideration (with some repeats on the original ERIC list). I and a research assistant then reviewed the titles and abstracts to remove duplicates and identify whether articles were about quantitative reasoning and using the framework from Thompson (1993). (A number of articles were about "quantitative reasoning" courses or tests that had no connection to Thompson's framework). At this stage we also noted there were a number of studies related to newer constructs (e.g. covariational reasoning) or learning trajectories (e.g., a trajectory for exponential functions) that were derived from Thompson's QR work. For the sake of focus we narrowed our attention to studies that primarily relied or developed on the constructs of QR. After applying the exclusion criteria, I narrowed the review to 21 studies. Next, each article was analyzed to identify the study design, number of participants, age of participants, and demographic information provided about participants. Studies were also coded according to primary method used and whether demographic information was provided about the participants. Table 1 contains a summary of the coding.

Table 1: Summary of Methods and Participant Demographics for QR Studies

Method of Study	No Mention of Demographics	International Setting / Comparison	Demographics Described	Explicitly Sampled for Diversity
Interview	7	1	1	
Teaching Experiment	6		3	
Observation			1	
Other		1	1	
Total	13	2	6	0

Thirteen of 21 studies in this review did not describe demographic information about participants. In these 13 studies, case-study students were typically described by grade level, and gendered with a pseudonym, but no additional demographic information was provided. Case selection criteria often highlighted students' salient or interesting forms of reasoning, as well as students' willingness to participate in research. Two studies were conducted in international settings. These studies did not include additional demographic information about participants other than nationality. Of the six studies that included descriptions of participant demographics, all but two described the demographics of the school but not the participants in the study. Details on participant demographics were often vague. For example, Olive and Caglayan (2008) write "The 24 students were between 13 and 14 years old and had been placed in the algebra class based on their success in 7th-grade mathematics. The students were racially, socially, and economically diverse, with an approximately equal distribution of gender" (p. 273). The previously discussed paper by Ellis (2007) was unusual as Ellis included information about participants' racial/ethnic identity and English learner status. Based on the review of QR study methods and participants, I concluded that none of the QR studies in this review explicitly selected culturally or linguistically diverse participants to investigate social, linguistic, or cultural features of QR, with the exception of the one international comparison study (Thompson, Hatfield, Yoon, Joshua, & Byerley, 2017).

Discussion

As described in the introduction, I chose to do this review of QR research in support of an ongoing collaborative project in which we are investigating QR among English learners. One emergent finding in that work is EL groups engaged in significant effort to make sense of the problem context, and they did fewer iterations of QR than non-EL groups in similar conditions. One possible implication of this result is that if educators are designing lessons to promote QR for linguistically diverse students, then they need to consider whether all students have adequate access to the problem context. Current trends in participant selection of case study students for QR research may warp researchers' view of QR and may bias research to recognize only those students whose ideas are typically heard and validated in mathematics classrooms.

The results presented here are not intended to impugn QR research or the people who are doing this work. It is possible, for example, that researchers doing QR research did not include student demographics in case study descriptions to avoid the appearance of stereotyping. Additionally, it is likely that the issues related to participant selection identified in this paper are not unique to QR research, and would be found in reviews of other areas of mathematics education research. Nonetheless, omitting participant demographics is problematic because, paralleling the broader phenomenon of selection bias in social science research (Henrich, Heine, & Norenzayan, 2010), there is a danger that many "research-based" results in mathematics education are based on a small and skewed sample of students--typically White middle-class students whose verbalizations are easy for researchers to interpret.

Moving forward, to respond adequately to the NCTM Research Committee's call (Aguirre et al., 2017), there is an urgent need for mathematics education researchers to develop consistent ways for describing the demographics of research samples, as well as principled rationale for participant selection. This need to report demographics is especially important in domains of research like QR, where there is a preponderance of small *n* in-depth qualitative case studies. Moreover, in the name of both promoting equity and high-quality science, the field of mathematics education must engage in continued dialogue about the overarching issue or research participant selection. Some questions for consideration are, What principles should guide the selection of research participants? How do we ensure that our "research-based" results are, in fact, derived from research that considers the full diversity of students enrolled in our mathematics classrooms? These and more questions must be addressed as we develop a more robust and equitable mathematics education research enterprise.

Endnotes

1 This Research Report was solo authored but reports on work done in a collaborative project. Tracy Noble, Teresa Lara-Meloy, HeeJoon Kim, and Phil Vahey all contributed to the conceptualization of the project. The project was Funded by NSF Grant #1534626. Any opinions, findings, and conclusions or recommendations are those of the authors and do not necessarily reflect the views of the National Science Foundation.

2 The term English learners is limited because it 1) lacks of acknowledgement of students' emerging multilingual status 2) hides the diversity of students under the category ELs, 3) downplays the variation in the criteria used to classify students as ELs, from state to state and even across school districts within a given state (Sireci & Faulkner-Bond, 2015). Nonetheless, the category English Learner (EL) identifies a group of students who have historically not received adequate attention from the research community. For this reason, I will use the category EL for the emerging multilingual students (Hopewell & Escamilla, 2014) described in this paper, while also acknowledging the category's limitations.

"THEN WE GO LIKE… THIS": MATHEMATICAL ACTIVITY AND COLLABORATION IN A TINKERING ENVIRONMENT

Ruben Echevarria
Northwestern University
rubenechevarria2015@u.northwestern.edu

This study aims to push beyond narrow and normative characterizations of mathematics by using Bishop's (1991) definitions of mathematical activity to identify "designing" in the context of a tinkering environment, and to better understand what "designing" accomplished. Tinkering environments focus on interdisciplinary science, technology, engineering, and mathematics (STEM) learning and emphasize creating, inventing, and iterating projects. I analyzed video from a tinkering environment that served nondominant youth and focused on a group of girls who participated in "designing." I identified two different actions of designing, which I call creating "durable" and "ephemeral" representations and found that the group used designing as a way to communicate and coordinate their contributions.

Keywords: Equity and Justice, Using Representations, Communication, Informal Education.

Introduction

Students from nondominant communities have an extensive history with deficit labeling (Medin & Bang, 2014; Valencia, 2012; Yosso, 2002) and their mathematical practices routinely go unnoticed in schools (Appelbaum & Stathopoulou, 2016; Nasir, Rosebery, Warren, & Lee, 2006). Therefore, I argue for using a wider epistemological lens that looks beyond how schools define mathematics as a way to position nondominant communities as resources and producers of knowledge. Although there may still be risks of reproducing a narrow definition of what counts as science, technology, engineering, and mathematics (STEM) and who is considered successful in STEM in ways that exclude nondominant communities, tinkering environments are a possible context where more expansive definitions may be possible because they invite and encourage multiple pathways and solutions. As a result, participants are more likely to create their own systems of value based on what they find useful, such as invented strategies and different mathematical and collaboration practices that are not valued in schools. I understand tinkering as a playful, experimental, and iterative disposition towards design and making, one "often replete with the utterance and practice of *what if, could be, maybe, perhaps, let's try it out*, etc." (Vossoughi, Escudé, Kong, & Hooper, 2013, p. 4). When the kinds of utterances mentioned above are allowed to be pursued, it may support students' learning by creating a context for "reassessing their goals, exploring new paths, and imagining new possibilities" (Resnick & Rosenbaum, 2013, p.164). In theory, tinkering activities are designed to support multiple pathways and solutions (Vossoughi et al., 2013), in part through enabling a "bottom-up" approach where goals and approaches are emergent and negotiated in real-time (Resnick & Rosenbaum, 2013). Of particular interest is the claim that tinkering is "exactly how real science and engineering are done" (Martinez & Stager, 2013, p. 41).

Conceptual Framework and Research Questions

Bishop (1991) argues that mathematics is a product of culture and that all cultures generate mathematics. However, "the face of mathematics is White; the people most credited with 'inventing' or 'discovering' it are the Greeks and others of European descent" (Gutiérrez, 2015, p. 270). There are direct implications of this narrative in mathematics education as reflected in how "girls, Blacks, Latin@s, American Indians, recent immigrants, English learners, and students who come from working class families" are overrepresented in developmental courses, underrepresented in advanced courses, and underperform on standardized tests (Gutiérrez, 2015, p. 272). As a result, the educability of those students is questioned, arising from and often leading to deficit labeling (Valencia, 2012) because mathematics is used as a proxy for intelligence and those that are unsuccessful in school mathematics are seen as less intelligent (Gutiérrez, 2015) or even "disposable" (Pais, 2011, p. 218).

The belief that mathematics is free or absent of culture has also been debunked because culture shapes the form of the mathematics (D'Ambrosio, 1991). In fact, mathematics has been co-constructed through cross-cultural contact between at least Egypt, Greece, Mesopotamia, India, the Arab world, China, the Mayan empire, and Europe (Ascher, 2002; Harris, 1991; Joseph, 2010; Powell & Frankenstein, 1997). Mathematics as "free of culture" or "universal" holds that the rules of mathematics apply everywhere, but does not, for example, question the motivation behind mathematical ideas (Bishop, 1991). In particular, Bishop (1991) claims that there are six universal forms of mathematical practices: counting, locating, measuring, designing, playing, and explaining. However, Bishop warns against interpreting his use of the word "universal" as a claim that everyone, for example, counts the same way. Therefore, using Bishop's wider epistemological lens of mathematical activity, I decided to focus on "designing" because although multiple mathematical practices were enacted in the tinkering environment, the tinkering activity I focused on lends itself to designing which Bishop (1991) defines as

> Creating a shape or a design for an object or for any part of one's spatial environment. It may involve making the object, as a copyable 'template', or drawing it in some conventional way. The object can be designed for technological or spiritual use and 'shape' is a fundamental geometrical concept. (p. 33)

In this study, I draw on Bishop's definition of designing to investigate the following research questions: What does designing look like in the context of a tinkering environment? What did designing accomplish in a tinkering activity?

Methods

This study draws from a larger ethnographic dataset spanning three years of research carried out by Shirin Vossoughi and Meg Escudé at the Tinkering Afterschool Program (TAP), a collaboration with Boys and Girls Club in California that functioned as a drop-in space for youth (K-5). The program predominantly served African American, Latinx and Asian American youth. I drew on interaction analysis (Erickson, 1992; Jordan & Henderson, 1995) to analyze a video clip (1m17s) of two youth, Tania and Stefanie (pseudonyms), who worked on a tinkering activity called Marble Machines. The objective of Marble Machines was to work in pairs, create an obstacle course for a marble, and produce a story about the course from the marble's perspective.

After watching the video, I tagged the stretch of interaction as "designing" as defined by Bishop. Although other mathematical practices were used during the stretch of interaction, I focused on designing for this brief report because Tania and Stefanie engaged in designing as a way to coordinate their collaboration by creating representations to communicate, contest, and invent ideas. I segmented the video for this analysis into four episodes reflecting shifts in activity directions (Matusov, 1998) (Figure 1). In the first episode, Tania and Stefanie worked on deciding the placement of the plastic tube on the pegboard. Then, they worked on deciding the placement of the wooden plank below the plastic tube. Next, they worked on deciding how to block the marble. The final episode is presented as a culmination of all the episodes where Stefanie drew a representation of all their designing from previous episodes. Noting that the youth created varied representations across episodes, I developed grounded codes (Charmaz, 2006) to identify two different actions of designing, which I call creating "ephemeral" and "durable" representations. Creating a durable representation is an action that is physically available for reference or iteration. Creating an ephemeral representation is unlike creating a durable representation in the sense that ephemeral representations as actions disappear from the physical space but can also be remembered and used for reference or iteration.

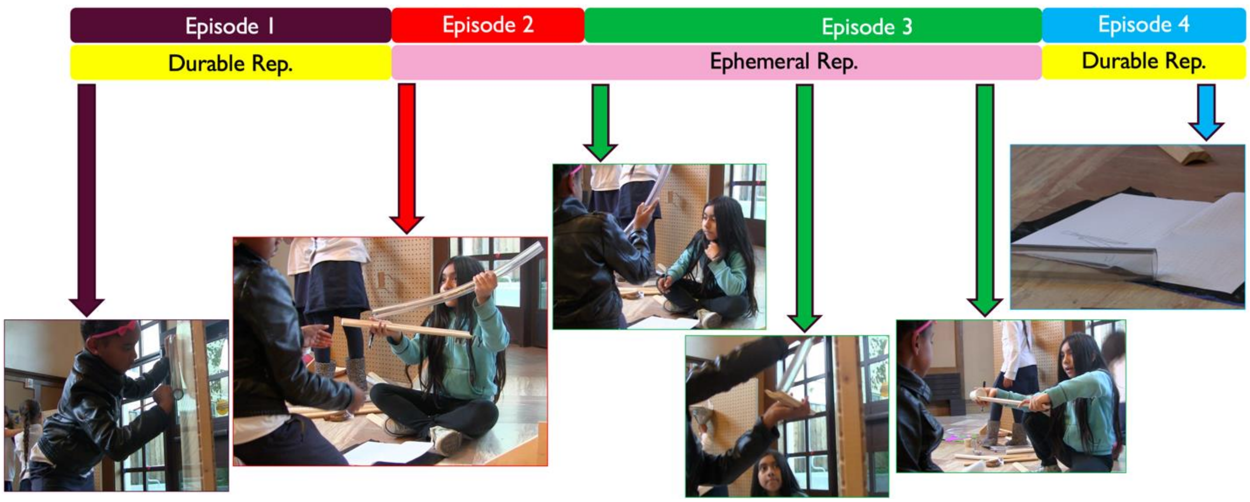

Figure 19: All Four Episodes are Presented Chronologically and Show Actions of Creating Durable and Ephemeral Representations. Tania (left) and Stefanie (right) in Episode Two

For this brief report, I will only elaborate on Episode Two to describe what "designing" looked like and what "designing" accomplished for Tania and Stefanie.

Analysis

To provide a brief overview of the first two episodes, Tania and Stefanie agreed on the placement of the plastic tube in Episode One. Immediately after, they worked on deciding how to add a wooden plank to the design. In Episode Two, Tania and Stefanie decided to put a wooden plank below the plastic tube to catch the marble. When Stefanie sat down, she grabbed a wooden plank and positioned the wooden plank and plastic tube using her hands to show how a marble would drop through the tube and feed into the wooden plank. She created a representation with her hands and the materials and held them in the air to show Tania, and waited for her approval (Figure 1, Episode 2). The episode ends with Tania agreeing and Stefanie handing the materials to Tania.

In Episode Two Stefanie created an ephemeral representation that helped coordinate ideas with Tania. Episode Two began with Stefanie gathering the wooden plank from the floor and the plastic tube from Tania's hand as she said, 'Then, then we go like, then we go like this." It is worth noting that Stefanie could have explained her idea without the materials in her hand, but decided to grab them as she started talking. When Stefanie had the materials in her hands, she started to create the ephemeral representation, and at the same time she said, "Then we go like…

this" to show how to possibly incorporate the wooden plank in the design. Stefanie finished creating her ephemeral representation when she said "this" after pausing briefly to complete her idea and she held her hands still and shook her head up and down more than twice. When Stefanie held her hands still, she created a "copyable template" for her and Tania to think with and remember. I interpret the head nod as an invitation for Tania to give a "yes" or "no" answer, but preferably a "yes" answer. Tania tilted her head and examined the ephemeral representation for nearly two seconds before saying "Yeah." I interpret Tania's pause before saying "Yeah" as an indication that she is contributing to the design and not merely agreeing with the idea for the sake of agreeing with Stefanie. When Tania agreed, Stefanie handed the materials over to Tania in such a way that resulted in Tania holding the materials the same way Stefanie held them, but a mirrored version. This transferring of materials is significant because it extended the life of the ephemeral representation to a new person. Tania then became the author and she used the materials to create an added ephemeral representation to illustrate a concern in Episode Three.

Across all of the episodes (including the other three not discussed here) analysis documented that Tania and Stefanie both created durable and ephemeral representations to coordinate their contributions. Creating durable representations may serve as a way to finalize ideas, such as Tania's drawing in the first episode and Stefanie's drawing in the last episode, and creating ephemeral representations may serve as a way to test ideas. It does appear that ephemeral representations become actors in the interactions in a different way than durable representations because Tania and Stefanie created ephemeral representations to share and contest ideas, but created durable representations less often and only after they reached an agreement. Overall, Tania and Stephanie demonstrated a level of expertise in communication and it is evident in how they collaborated smoothly moving to and from activity directions, even when ideas were contested, and how both of their ideas were represented in the final version of their project.

Significance of the Study

The case study presented is an example of how mathematical practices can be made visible to educators and researchers and raises questions of what other mathematical practices we can see in tinkering environments using Bishop's (1991) definitions of mathematical activity. I was able to make visible the skills that Tania and Stefanie engaged in to communicate, contest, and invent ideas. Without this study, their deep collaboration may have only been attributed to their friendship, erasing the thinking and mathematical activity they both engaged in based on the ubiquity of normative and more narrow ways of recognizing mathematics. One possible implication for educators is to learn how to recognize and acknowledge the mathematical practices that exist in a space and leverage such practices in teaching and designing activities. For example, schools that emphasize the process of working out solutions in their classrooms could benefit from learning to see and value the actions of creating ephemeral representations as well as durable representations. I could imagine a school that would evaluate Tania's and Stefanie's performance based solely on their drawing in Episode Four because it is challenging to grade ephemeral representations as depicted in Episodes Two and Three. Perhaps, as educators, we can find ways to go beyond emphasizing process to our students and learn to see their expertise in different processes. More broadly, my aim is that others will look beyond the stereotypical imagery of mathematics, using my methodology or their own, to learn when, what, and how mathematics emerge in their spaces as a way to see nondominant communities as resources and producers of knowledge. This wider epistemological lens invites new approaches to research on learning and teaching of mathematics, and is a step in repairing the damage caused by researchers that imposed and validated deficit framings on nondominant communities.

EMMA'S COUNTING AND COORDINATION OF UNITS: SUPPORING SENSE MAKING FOR STUDENTS WITH WORKING MEMORY DIFFERENCES

Jessica H. Hunt, Ph.D.
North Carolina State University

Juanita Silva, Ph.D.
Texas State University

We investigated how one elementary child with working memory differences made sense of number as a composite unit and progressed in her reasoning. We analyzed eight teaching experiment sessions using ongoing and retrospective analysis, where we uncovered four shifts in the child's thinking of number over time that suggests an association between the child's participatory knowledge and the extent to which she enacted activity met her goals for solving the problem more than her current "knowing".

Keywords: Learning disability, Working memory, Number knowledge, Constructivism

Number reasoning is one of the most challenging areas in mathematics for children with learning disabilities (LD) (National Center for Educational Statistics, 2009; National Mathematics Advisory Panel, 2008) and a fundamental area to develop (National Mathematics Advisory Panel, 2008). Yet, research on these children's flexible cognitive structures (e.g., Olive, 2001) is rarely if at all utilized as a basis for instructional intervention. We address a gap in relation to what is known in mathematics education concerning how children without LDs develop their number knowledge and how children with LDs advance their knowledge in the same learning environment. We examine the following research question: (a) How does the child's working memory and prior mathematical knowledge interplay with the child's learning of number?

Conceptual Framework: Small Environments

"Small environments" situates learning within children's adaptive activity in place of remediation (see Hunt & Silva, in press). Children advance their cognition by noticing and reflecting upon their actions such that they become coordinated around a central idea (Piaget, 1972; von Glasersfeld, 1995). *Noticing* begins when the child becomes aware of what happens as a result of her actions as she works through pertinent situations. *Reflection* supports the child to begin to anticipate coordinated actions and coordinate them so that she can draw upon them in future situations.

Prior research explains that children with working memory differences experience certain difficulties when constructing new knowledge that is not yet abstracted (Hord, Tzur, Xin, Si, Kenney, & Woodward, 2016). We hypothesize this occurs because the child does not see the need to adapt her reasoning as she is noticing and reflecting on her new actions. The child makes evaluations regarding how new actions help her solve the problem and may discard noticing and reflecting in favor of past compensation aids for learning differences (e.g., automatizing "learned facts" as opposed to forming groups of tens; Piaget, 1972). This is a possible explanation as for why children with working memory differences may not transition toward anticipatory understanding.

Much of the intervention research in special education argues to remove the mathematical activity from the child in instruction once she becomes "stuck" (e.g., Gersten, Chard, Jayanthi, Baker, Morphy, & Flojo, 2009). Yet, we argue that, by necessity, as opposed to delivering knowledge onto the child and measuring her response to teacher, teaching must become responsive to the child's activity and use the child's shifting noticing and reflection as a resource to decision making (Jeltova, Birney, Fredine, Jarvin, Sternberg, & Grigorenko, 2011; Tzur, Johnson, McClintock, & Risley, 2012). Thus, our framework is based on the teacher's instructional decisions to promote the child to remain engaged in noticing and reflecting upon her own reasoning.

Methods

This study utilized a constructivist teaching experiment design (Steffe & Thompson, 2000). Emma, the sole participant, was a 10-year-old child enrolled in an elementary school in the southwest portion of the United States. Inclusion criteria for the study were: (a) having an individualized education program goals in mathematics, (b) a cognitively defined label of learning disability (LD) with working memory as the dominant cognitive factor, (c) identification through clinical interview data that the child used notions of two as a usable unit, and (d) identification by the classroom teacher as not benefiting from supplemental, small group instruction from a textbook or supplemental curriculum over at least a two year period.

We used a trajectory from mathematics education research to plan tasks for Emma (e.g., Olive, 2001). Learning situations were organized into two areas: (a) a linear number board game (Tzur & Lambert, 2011) and (b) a contextualized number game where students converted back and forth between "ones" and "composite units" (Simon, personal communication). We positioned teaching as indirect and a response to student's unique knowing and learning (e.g., Butterworth, Varma, & Laurillard, 2011; Compton, Fuchs, Fuchs, Lambert, & Hamlett, 2012; Mazzocco & Devlin, 2008; Murphy, Mazzocco, Hanich, & Early, 2007; Vukovic, 2012). We define *responsiveness* as the researcher-teacher revisiting *her own behavior* to better align teaching to the child's prior and current knowing. The planned teaching included three primary moves. The first was changing the learning situation in some way (context, constraints, representation, the task itself) to match the child's actions and/or create a need for adaptation.

The second was orienting the child to notice to and discuss how *she* was using representations or strategies. The last was to promote the child' noticing and reflection on why the new activity was more meaningful than how she was, in that moment, operating.

Data were gathered using video cameras to capture student responses when engaging in the tasks throughout the eight sessions. Two teacher researchers formed a research team and met before and after each session to examine the student's understanding, redesign tasks for the next session (conceptual analysis), and afterwards to examine the student's understanding after data were gathered (retrospective analysis). Prior to each meeting, the research team developed weekly field notes, transcripts, and coded these data. Meetings focused on (un)common responses from Emma and the nature of the codes (e.g., open codes, categorized codes).

To depict how meaning became negotiated with the teacher, we considered evidence of bidirectional (child ⟵⟶ teacher) communications (verbal and gesture-based) that seemed to occur and coincide with Emma's conceptual shifts. Specifically, we used in-vivo coding as an initial start to this inquiry (Saldaña, 2015). Next, we applied the codes in a more standard way to the text utilizing three main questions: (a) what is the context of the situation? (b) what are the child and teacher saying and doing? and (c) what might the teacher's actions and statements take for granted about the child's knowing and her reasoning (Charmaz, 2011; also see Corbin & Strauss, 1990). We used these questions to consider how the teaching moves in each instance served to maintain, extend, or, at times, hinder the child's way of reasoning. The analysis yielded emergent evidence (Creswell, 2007) of responsiveness done by the teacher and ways in which the teaching moves enabled the way Emma made sense of the mathematics.

Select Results

During all phases of Emma's learning, evidence of both learning differences as well as past compensations the child made to support her working memory differences constrained her reasoning to some degree. However, Emma could (and did) advance her reasoning. This report shows some examples of Emma's progression with number concepts. Full details of the child's advancements will be shared in session.

Challenges with Finger Patterns and Larger Addends

In one board game problem, Emma quickly responded with "14" when trying to figure out the sum of three and 11. This prompted a suggestion from the researcher-teacher to explain her solution by using her fingers and counting from three. Soon, she began counting from three, raising a finger for each time she counted on, yet miscounted when she crossed the number ten, finally arriving at 15 as an answer as opposed to 14. This miscounting prevented Emma from determining "how many" by coordinating her counting with addends larger than ten; this activity continued across several problems. The next excerpt begins in the first problem in session five, just after the child had rolled a three and a 13. The child quickly said "16". The researcher asks the child to justify her reasoning using her counting. As opposed to coordinating her counting through figurative activity, Emma brought forward her procedural knowledge.

Excerpt 2: 3 + 13 (Session 5)

E: Like 3…4, 5, 6…16. And then the one.

R: You said, 3…4, 5, 6 and the one. What's the one? E: The one is the… [pauses; frowns].

R: Can you show me what you mean? [hands child a paper and pen] E: So it was…13 plus 3 is… [writes 13 + 3 = 16 long form].

R: [points to the one in 13] So this is the one? E: That's the one in the 13.

R: But is that like, ONE [shows one finger]? E: Yeah only one.

R: So, if this is one, how come I can't just count one more…seven? E: Because…three doesn't have a one.

R: Suppose you had started counting from this three [points to the three underneath 13 and references third space on the game board]? How would you do that? [removes paper and game board]

E: [puts up hand] 3…, 4 [raises one finger], 5 [raises 2nd finger], 6 [3rd finger], 7 [4th finger], … 8 [5th finger], 9 [6th finger], 10 [7th finger], 11 [8th finger], 12 [9th finger], 13 [10th finger; stares at ten fingers and pauses for 5 seconds].

R: 13…. How many have you counted so far? E: Ten.

R: How many more do you need to count?

E: I think… [sticks out lower lip; pauses for 3 seconds]. I think…. [frowns, looks down].

R: [grabs a paper and pen] So you started at three [writes three and an empty number line] …and you did 4 [makes hop on number line], 5 [makes hop on number line], 6 [makes hop on number line], 7 [makes hop on number line], 8 [makes hop on number line], 9 [makes hop on number line], 10 [makes hop on number line], 11 [makes hop on number line], 12 [makes hop on number line], 13 [makes hop on number line]. Then you stopped and did this [holds up all ten fingers and wiggles them, covers up the number line].

E: Oh! 13… 14 [raises a finger], 15 [raises a finger], 16 [raises a finger]. I need three more. I needed three more to get 16.
R: How did you know it was three more? E: *Because my answer got me 16.*
R: OK. I wonder if there is a way to figure it out without having to know the answer first. E: [shrugs]

Emma begins this problem by using an algorithm to find the total. She names the one in 13 as "one" as opposed to "10". Yet, when pressed to use her figurative counting, Emma notices thirteen as ten and some more, ceasing her activity. When Emma could not explain the meaning of the "one" in 13, the researcher-teacher realized the child needed a way to relate her algorithmic knowledge to her emerging, coordinated counting. To do so, she introduced a counterargument - "how come I can't just count one more ...seven"- to entice the child to engage in her own misconception about the "one" in 13. Emma said, "Three doesn't have a one in it". In the moment, the response puzzled the researcher-teacher, so she asked Emma to begin counting from the three. This proved to be a fortunate teaching decision, as it restored the child's counting and coordinating activity and also facilitated the child to notice "10" in her figurative counting. Yet, the child struggled to coordinate the "10" on her fingers with the "10" and "three" that comprise the second addend. Realizing this may be due to working memory, the researcher-teacher introduces a second representation—the open number line—to simulate the child's counting. The partial re-showing and supplementation of Emma's previous activity seem to remind her of her counting. Knowing that the answer to the problem was 16, Emma counted up three more.

Emma made a connection, although she was not yet aware of it, between "13", "10" and "three" in her figurative counting. Yet, she did not link this activity to the problem solution. As opposed to decomposing the second addend into 10 and three, reflecting upon and coordinating her figurative counting, and arriving at the solution of 16, the child *counts up to* a known answer that she previously arrived at procedurally. Arguably, Emma used this reasoning to compensate for demands on working memory during the coordination of counting. Yet, we argue that Emma's use of procedures to arrive at a total kept her counting actions *sequential* as opposed to *coordinated*. Over the next several problems, Emma continued to (a) use her fingers to hold a start value for counting, (b) figure out the stop value through an algorithm, and (c) used the known stop value to count up to using her fingers to decompose the second addend and keep track of the count. The activity continued despite our several attempts to ask for alternate ways in which to consider the problem ("I wonder if there is a way to count on without having to know the answer first?"). This use of algorithms to first figure out the answer and then count up to it eclipsed Emma's propensity to notice and reflect upon her figurative activity to coordinate a double count (3... 4 [that's 1], 5 [2], 6 [3] ... 16 [13, or ten and three]). As opposed to an awareness of two number sequences at once, Emma kept the two number sequences separate when considering addends larger than 10 whose result crosses decades.

Yet, later in the sessions, Emma advanced her reasoning in a problem involving the addition of 13 and 14. We include this important shift in the child's reasoning in session.

Conclusion and Significance

The implicit intervention methods used in this study involved explicitness, yet not in ways reported in much of the special education literature and policy (e.g., Gersten et al., 2009). When we first worked with Emma, she evidenced premature counting, suggesting that her learned strategies and procedures replaced noticing, reflection, reasoning and sense making, and (later) abstracting number knowledge. Yet, for Emma, a child who has differences in her working memory, the inclusion of timely tasks, interactions, and questioning were critical in supporting her noticing of and reflecting on her own activity to promote learning.

DISCOURSE AND STUDENT BELIEFS WITHIN A STANDARDS-BASED MIDDLE SCHOOL MATHEMATICS CLASSROOM

Jennifer Ericson
University of Massachusetts Amherst
jericson@umass.edu

Sandra Madden
University of Massachusetts Amherst
smadden@umass.edu

Student participation in high-quality discourse promotes greater opportunities to learn and may lead to higher mathematics achievement. Despite implementation of standards-based mathematics instruction [SBMI], students may not participate in discussions due to their mathematics related beliefs. This study examined students' participation in small-group inquiry in relation to mathematics beliefs. Data consisted of survey responses, classroom observations, and discourse analysis based upon an established discourse taxonomy. Findings revealed consistencies and inconsistencies between observed discourse practices and stated beliefs and point to the need to consider beliefs to support higher-quality discourse.

Keywords: Beliefs, Classroom Discourse, Instructional Practices

Student participation in mathematical discourse—talking, writing, listening, agreeing and/or disagreeing, and gesturing about mathematics—is considered integral to learning mathematics (NCTM, 2014). The degree to which high-quality mathematics discourse occurs in a classroom, including justification of reasoning, predicting, relating to prior knowledge, challenging the thinking or reasoning of others, and generalizing, is a positive predictor of middle-school and high-school students' achievement (Weaver, Dick, & Rigelman, 2005). Despite implementation of pedagogical practices and classroom environments that support high-quality discourse, students may participate in discourse with varying degrees of engagement leading to unequal opportunities to learn mathematics (Esmonde & Langer-Osuna, 2013). Student beliefs about mathematics can impact their discourse engagement. If students believe argumentation or justification is not a part of mathematics or that the teacher is the locus of knowledge, they may not participate in whole class discourse (Hoffman, 2004; Jansen, 2008); nonetheless, there have been few studies on the impact of students' beliefs on small-group discourse (e.g., Esmonde & Langer-Osuna, 2013).

Mathematics-related beliefs [MRB] are the implicit and explicit beliefs one holds true that have an important influence on mathematics learning and problem-solving (De Corte, Op't Eynde, & Verschaffel, 2002). Studies of MRB include beliefs about the nature of mathematics and mathematical learning, the self in the context of mathematics learning and problem solving, mathematics teaching and the social context of mathematics learning and problem solving, and epistemological beliefs (De Corte et al., 2002). These beliefs, often shaped by and situated in classroom practices (De Corte, Verschaffel, & Depaepe, 2008; Greene, Muis, & Pieschl, 2010; Maltese & Tai, 2010; McGregor, 2014; Muis, Franco, & Gieus, 2011; Schoenfeld, 1989), influence how students engage with and conceptualize mathematics as well as continue in their study of mathematics and related sciences (Maltese & Tai, 2010; Moakler & Kim, 2014).

MRB can affect students' academic performance directly and indirectly (Cano, 2005; Trautwein & Ludtke, 2007). Beliefs that result in negative or neutral consequences are considered non-availing and beliefs that result in positive consequences are considered availing (Muis, 2004). When students believe they are capable of learning mathematics through perseverance (an availing belief), they are more likely to employ productive cognitive and behavioral learning strategies (Paulsen & Feldman, 1999; Schommer-Aikins & Duell, 2013) and persist in solving challenging problems (Moakler & Kim, 2014). Students who believe learning is the acquisition of knowledgde imparted by the teacher (a non-availing belief) view public sharing of their thinking as risky for fear of being wrong (Hoffman, 2004).

Research has demonstrated that students' experiences with standards-based mathematics instruction, those practices of learning mathematics that support all learners (NCTM, 2000; 2014), can have a positive impact on students' beliefs about what it means to do mathematics and who can do mathematics (e. g., Boaler, 2006; De Corte et al., 2008; McGregor, 2014; Muis et al., 2011), ultimately having the potential for improving student achievement in and affect towards mathematics (Schoenfeld, 1989; Schommer-Aikins, Duell, & Hutter, 2005). The purpose of this study was to examine the relationship between students' MRB and their small-group discourse within a standards-based mathematics classroom.

Methods

This report draws on a subset of data from a larger mixed methods study that examined students' MRB and their small-group discourse participation during the second quarter of 7th grade. Students were in their second year of this NSF-funded curriculum and it was the teacher's sixth year teaching this curriculum to 7th-graders at this school. The participating class consisted of 22 students (girls = 9; boys = 13) and routinely employed rotating structured roles of reporter, recorder, and project manager to guide small-group inquiry. Classroom norms included ensuring all group members understood the reasoning behind the procedures and equitable airtime. This report focuses on one triad (1 girl, 2 boys) situated within this class.

Data Collection

Students were administered the Conceptions of Mathematics Inventory-Revised (Briley, Thompson, & Iran-Nejad, 2009) survey at the beginning of the study. The 38-item survey was based on a 6-point Likert scale. Focus triads were observed daily over a two-week period beginning with the formation of new groups and the introduction of a new unit within the curriculum. The triads were observed during small-group work and whole-class discussions. Detailed field notes and audio recording of each lesson were created. Each participants' discourse was coded as either low-quality or high-quality (Weaver et al., 2005) and a daily percentage of high-quality discourse for each triad member was calculated. To triangulate findings, each member of the triad participated in a short, semi-structured interview at the end of the project. Student interviews focused on student confirmation of the observer's perceptions of the discourse within the group work as well as student confirmation of survey results.

Results

We examined whether there was a difference in the quality of small-group discourse in relationship to students' mathematics related beliefs. Participants in this setting held availing beliefs across most of the survey questions. The focus triad held similar beliefs to their classmates. The triad's survey results for one of the latent variables of the CMI-R, "Doing, validating, and learning mathematics" [DVLM], and specific indicators within that latent variable as well as their small-group discourse analysis results will be presented.

Survey Results

All three participants held slightly availing to availing beliefs about DVLM, indicating their overall beliefs about the learning and doing of mathematics support learning. Differences within the triad for specific indicators related to the importance of conceptual understanding, sense-making, and the locus of mathematical authority in the classroom were identified.

Sarah. Sarah has the most availing beliefs in her group for the beliefs about DVLM (DVLM = 4.563). She believes her work on mathematics problems needs to make sense and to understand why an answer is correct. She disagrees that it is possible to make good grades in mathematics by following procedures without understanding the steps. However, Sarah holds some non-availing beliefs. She believes that learning computational skills is more important than learning to problem-solve. Sarah also believes that she can only learn mathematics when someone shows her how to work a problem and that she can only find out if her answer is wrong is if it is different from the textbook or the teacher.

Aaron. Aaron holds availing beliefs about DVLM (DVLM = 4.375). Making sense in mathematics of his classmates' answers and his own is important to Aaron. He values conceptual understanding. It is not enough for Aaron to follow an algorithm without understanding why it works. He strongly disagrees that mathematics problems must be solved quickly or not at all. Although Aaron agrees that it is usually possible to solve a mathematics problem and that he and a classmate can work to solve a problem together when they do not initially agree on the answer, he believes the locus of authority and knowledge validation resides with the teacher or textbook.

Marcus. Marcus has slightly availing beliefs about the DVLM (DVLM = 4.063). He indicates he might look to his group or friends to determine if the answer was correct rather than relying on the teacher's validation of his answer. It is important to Marcus to understand why an answer is correct in mathematics and that it makes sense to him. However, he also strongly believes that he can earn good grades in mathematics simply by following the procedures. He also believes he can only learn mathematics when someone shows him how to work a problem.

Small-Group Discourse Analysis

Analysis of the study small-group's discourse revealed about 79% of discourse within the small group was on the low-quality end of the discourse taxonomy, mostly answering a direct question or making a simple statement or assertion. Group members frequently stated their answers, with explanations occurring when there was a request for clarification or a challenge by another group member. A small sample of Day 1 low-quality discourse about which two teams are farthest apart in Jeopardy:

Sarah: "KIA and SB"
Aaron: "Why?"
Sarah: "I don't know…"
Aaron: "-300 plus 150 is -150"
Sarah and Marcus copy the algorithm.
Aaron: "So, RS and SB are 150 points apart"
Marcus: "So RS and KIA are 600 apart?"
Aaron: "No 650"

No further exploration as to why Marcus arrived at an incorrect answer ensued, nor did the group check in with Sarah about her understanding. Group members rarely posed questions to each other to further their understanding or to challenge the thinking of each other.

Generalizations and predications came towards the end of the unit. For example, when Sarah was explaining her understanding of the relationship between adding and subtracting positive and negative integers, she utilized a number line to visualize "When you start with a negative

number and you add a positive number, you go that way (pointing right) towards the positive but when you add a negative number, you go that way (pointing left) towards the more negative." For □ – (-3) = -4, Sarah states, "We know that a negative minus a negative would go up (points to the right on a number line), so the □ has to be smaller than -4".
By the end of the unit, there was more emphasis on understanding. By Day 9, the group now pauses and retraces steps to make sure everyone understands and agrees.

Sarah: "Wait…. why is D1 $^{-}2$?"
Marcus: "Because it ended with 2."
Sarah: "Wait. Go back to D1. 3 negatives plus 5 positives should be $^{+}2$. But you said $^{-}2$?"
Aaron: "No it is $^{+}2$."
Sarah: "Oh ok. Just wanted to be sure we agreed."

Initially, Sarah did not participate much in small group discourse. After believing her answers to be incorrect, she completely withdrew from discussion and put her head down. Over time, Sarah became a more active group member. Marcus began the unit engaged in discourse but focused on the correctness of answers. After presenting incorrect answers to the class and falling behind due to absences, Marcus withdrew from the group and often worked independently. Aaron remained consistent in his participation in group discourse. Regardless of the daily role assigned to him, he often functioned as the project manager and directed the group. Most days he participated in discourse more than either of the other two group members. When Sarah or Marcus had a question, Aaron was usually the one to provide an explanation or justification of the reasoning, relegating to him the role of authority in the group. From the beginning and throughout the entire unit, Aaron made certain that if he had a clarifying question it was heard and addressed by the group.

Summary and Conclusion

A comparison of the study groups' responses to the survey and classroom observations provided for a comparison of the participants' espoused and enacted beliefs. There appeared to be both inconsistencies and consistencies between observed discourse practices and stated MRB.

All students agreed with the importance of explaining work and understanding it conceptually (DVLM), but their discourse was devoid of explanations unless challenged by a groupmate. Providing explanations for how the problem was solved was not a group norm, although it was an established classroom norm. Sarah, with the highest score for the DVLM latent variable, asked for the most explanations and often expressed, verbally and with gestures, her frustration when she did not understand procedures. Marcus, with the lowest DVLM latent variable score, often accepted Aaron's solutions without questioning. He strongly believed it was possible to succeed in mathematics by merely memorizing procedures without conceptually understanding the topic. Individual group members' acceptance or frustration with explanations appear to be in line with their beliefs about DVLM. In particular, their beliefs about needing to understand the concept and not just memorize the information stood out.

All students self-reported that analyzing mistakes is important, yet the observations and interviews suggested that each one of them felt making a mistake was indicative of being less capable than the other group members (Hoffman, 2004). Observed beliefs may be a function of external pressures: grades, parental expectations, teacher expectations, or peer expectations.

Results of this study are subject to limitations yet hold significant signals for future work. The size, scope, and duration of the study limits the generalizability of the findings across settings. Further research is warranted to expand the study across several variables - to multiple small groups, multiple classrooms, and multiple schools in different community contexts, as well as expanding the length of time over which the study is conducted, as different groups and different classroom norms may have different discursive patterns. Better understanding students' beliefs and how those beliefs may impact participation in small-group discourse is necessary to support students' opportunities to learn and potentially promote persistence in STEM pathways.

NARRATIVES OF HYPER-ACCELERATION OF ALGEBRA I: OPPOSITIONS IN PERSPECTIVES ON OPPORTUNITIES TO LEARN

Terrie McLaughlin Galanti
George Mason University
tgalanti@gmu.edu

Hyper-acceleration of Algebra I is an emergent marker of smartness in K-12 mathematics which presumes a greater opportunity to learn (OTL) on advanced mathematics pathways toward STEM careers. This dissertation study elicited the longitudinal perspectives of 12 recent graduates from one International Baccalaureate high school who studied Algebra I in Grade 7. Critical events analysis and temporal resequencing of participant identity claims revealed augmented OTL with a focus on conceptual understanding and diminished OTL with a focus on social positioning. These preliminary findings add to extant literature on acceleration of Algebra I and contribute to critical conversations about what it means to be "good" at mathematics.

Keywords: Algebra and algebraic thinking; Affect, emotion, beliefs, and attitudes

The acceleration of formal algebra instruction to Grade 8 has expanded access to high school calculus with the expected affordance of improving readiness for STEM undergraduate study (Clotfelter, Ladd, & Vigdor, 2015; Rickles, 2013). However, an unintended and controversial trend toward *hyper-acceleration* has emerged in parallel with increased access to formal algebra in middle school. School divisions are now offering high school Algebra I courses in as early as 6th grade to an increasing number of students who seek to distinguish themselves from their peers and to increase their competitiveness for admission to top universities (Loveless, 2013; Domina, Hanselman, Huang, & McEachin, 2016).

Objective of Study

Prior research on acceleration of Algebra I has reported positive outcomes in terms of grades and standardized test scores (Gamoran & Hannigan, 2000; Ma, 2005; Smith, 1996; Spielhagen, 2006). However, these objective measures cannot explicate the subjective beliefs that students construct about smartness and success in mathematics. These beliefs can impact students' development of conceptual understandings in preparation for calculus (Bressoud, Camp, & Teague, 2012), persistence in advanced mathematics, and evolving mathematics identities of competence. The exploration of the lived experiences of hyper-accelerated students can describe a situative opportunity to learn (OTL) beyond quantitative research outcomes. This research can challenge presumptions that further acceleration of secondary courses provides more rigorous and relevant mathematics instruction for high-achieving students.

Narrative inquiry "frames the human experience" (Webster & Mertova, 2007, p. 14) and captures "the range of meanings which shape decisions" (Maynes, Pierce, & Laslett, 2008, p. 25). Through interpretative inquiry, this research retells the stories of 12 recent graduates from one International Baccalaureate (IB) high school who participated in a series of dissertation focus groups. Their collective reflections on their individual mathematical journeys in middle and high school offer new insights on appropriate acceleration in secondary mathematics.

Theoretical Framework

While OTL is often used to reframe the achievement gap discourse and to highlight how marginalized students lack experiences with high expectations and appropriately challenging curricula (e.g. Flores, 2007; Schmidt, Cogan, Hoang, & McKnight, 2011), I argue that it can also be a critical component of characterizing hyper-accelerated Algebra I experiences from a sociocultural perspective. Mathematically promising students who accelerate Algebra I should experience an augmented OTL as productive engagement which transcends the ability to perform or replicate procedures. Yet narrow constructions of mathematics ability and achievement (Louie, 2017) which often characterize students' experiences in secondary courses can compromise opportunities to engage with mathematics in meaningful ways (Boaler, 1997; Gutiérrez, 2012). A situative perspective on OTL (Greeno & Gresalfi, 2008) integrates the content and sociocultural experiences of students within figured mathematical worlds (Boaler & Greeno, 2000; Holland, Lachicotte, Skinner, & Cain, 1998; Horn, 2008). Students, teachers, and parents expect that Grade 7 Algebra I offers an educational advantage (Lucas, 2001). It may instead diminish OTL when success in mathematics becomes social positioning (Hatt, 2012) without an expectation of struggle. I adopt this situative perspective on OTL to answer the following research question: How do recent graduates from one socioeconomically diverse suburban IB high school narrate their quality of learning after hyper-acceleration of Algebra I?

Mode of Inquiry

Using an interpretative phenomenological paradigm (Kim, 2016), I constructed stories of OTL as retrospective narratives of achievement and identity. As a former electrical engineer and a veteran high school mathematics educator at West Valley High School (WVHS), I leveraged my professional knowledge of the IB curriculum and my relationships with the community to construct a rich data set of lived experiences revealing the essence of hyper-acceleration as a privileged educational phenomenon. I sought to build profound understandings of ways in which individuals were socially and culturally positioned within mathematics course trajectories. My subjectivist worldview reimagined OTL as an important intertwining of the pursuit of conceptual understandings and evolving student perspectives as productive doers of advanced mathematics.

Context

I conducted a series of five focus groups with recent graduates of WVHS, a mid-Atlantic public high school with diverse population of over 2500 students and broad Algebra I acceleration policies. IB programs are often placed in mixed-income or disadvantaged neighborhoods with a vision of breaking down barriers to rigorous educational opportunities for traditionally underrepresented students, yet the students in the WVHS IB courses are almost exclusively White and Asian. The IB curriculum is especially appropriate for describing OTL in hyper-accelerated contexts because it emphasizes connected understandings across multiple topics and offers two course pathways to calculus with differing rigor.

Participants

The 12 graduates from WVHS described seven different mathematics high school course trajectories after an honors sequence of Algebra I, Geometry, and Algebra II in Grades 7-9. These trajectories are depicted in Table 1. Shaded cells represent a "deceleration" from the most rigorous two-year IB sequence. With these deceleration choices, students may have studied similar mathematics content for two years, or they may have selected a less rigorous pathway. Blank cells represent the choice not to enroll in a mathematics course during Grade 12.

Data Analysis

An iterative sequence of critical events analysis and thematic analysis offered a rich hermeneutic cycle of moving between transcriptions. These cyclical description of the phenomenon built the reliability of the analysis. In the first stage of analysis, I identified critical, like, and other events (Webster & Mertova, 2007) followed by implicit, explicit, and tacit identity claims (Dennis, 2018) within each of the focus group transcripts. In the second stage of analysis, I sequenced transcript excerpts to create cohesive chronological wholes (Riessman, 2008) spanning elementary school, middle school, high school, and college. In the third phase of analysis, I coded identity claims within each of the reordered transcript excerpts to capture specific experiences which augmented or diminished meaningful OTL. Sampling strategies, peer scrutiny, triangulation of data across focus groups, and researcher reflective commentary promote confidence that the multiple realities of hyper-accelerated mathematics study are historical truths (Polkinghorne, 2007) from the perspectives of the participants.

Table 1: High School Mathematics Course Pathways

Participants	Grade 10	Grade 11	Grade 12
Claire	Precalculus	IB Standard Precalculus	IB Standard Calculus
Ashley	IB Standard Precalculus	IB Higher Precalculus	IB Standard Calculus
Elizabeth	IB Standard Precalculus	IB Standard Calculus

Confirming Identities of Smartness – Selection for Grade 7 Algebra I

Evolving beliefs about smartness in mathematics emerged in the participants' telling of their elementary, secondary, and college mathematical worlds. The selection for Algebra I in Grade 7 was the critical event that confirmed identities of smartness in mathematics which had been established by selection for gifted academics in elementary school. Each of the participants vividly recalled taking the Iowa Algebra Readiness Assessment (IARA) in Grade 6. Failure to qualify for Algebra I in Grade 7 was a threat to their identities of smartness. "That was a whole big thing…if you don't get this then you are looked down upon." (Elizabeth, STEM major).

For many of the participants, this mathematical gate was not perceived as a choice nor as a metric of intrinsic motivation and enjoyment. "I don't remember thinking ever, 'Oh, do I want to?' It was more like I didn't want to be the one person not doing this." (Robert, non-STEM major). The obligation to maintain this identity of smartness was further constructed socially within the Grade 7 Algebra I classroom. Alex, a computer science major, retrospectively questioned the level of competition that he felt in Algebra I. "I think a lot of people were trying to prove how smart they were. They were all crazy stressed about their futures."

In contrast, Jonathan (non-STEM major) described an intrinsic desire to learn more in Grade 7 Algebra I with his anticipation of a more challenging setting to experience mathematics. He remembered scoring one point above the minimum qualifying IARA percentile.

> I'm pretty sure I had to have a conversation with my teacher saying, "Oh, you barely got it. Are you sure you want to do this?" And I was like, "Of course I do," because I felt like math was one of my stronger subjects and it was the most interesting subject for me.

Shifting Identities of Smartness – Intrinsic and Extrinsic Valuations of Mathematics

Identities of smartness were challenged for many of the participants in subsequent mathematics courses. Jonathan "grew a bit disinterested" in Algebra II when he perceived expectations were lowered, while others articulated an augmented OTL with emerging views of struggle as productive and mathematics as relevant. Elizabeth (STEM major) recalled enjoying mathematics when her teachers "derived the formula and explained why it made sense and where it came from". Other saw themselves as creators of mathematics when they could "play with numbers" (Samantha, non-STEM major) and model societal problems (Robert, STEM major).

Evolving identities reflected oppositions in perspectives on OTL that changed with time. "As I got older and mathematics got harder, it was definitely more about understanding the concepts rather than getting A's on tests" (Claire, non-STEM major). Pressures to maintain socially constructed identities of smartness often interfered with "full understanding" (Samantha). Fears of getting a wrong answer or asking stupid questions were extrinsic threats to smartness which diminished OTL. "The whole notion of going afterwards to ask questions and be vulnerable to need to ask for help was always hard for me" (Jessica, non-STEM major). Teacher or peer influences which gave students permission to decelerate mathematics pathways or to take risks in front of one another fostered an intrinsic valuation of mathematics learning.

> I came from feeling like there had to be one right way all the time until maybe halfway through high school. I'd have a mental block when I didn't get that problem right. It made such a big difference for me to finally be like, oh, I can try different things. (Ashley, STEM major)

Contrasting valuations of mathematics also emerged in retrospective consideration of OTL with Grade 7 Algebra I. Nadine's persistence on the most accelerated path reflected an extrinsic valuation of mathematics. "It just seemed logical. I've never taken math in college and I'm never going to. Multivariable calculus gave me the credit and I don't need math." In contrast, Mindy, a mathematics major, regretted that she had not pursued a deeper understanding of concept of function in her early algebra courses. "I think I struggled with that because I just wanted to get the right answer and then I started caring kind of late." She also articulated a diminished OTL in the perceived motivations of her teachers. "They're not preparing people to be mathematicians in high school. They're preparing people to pass tests and to not hate math."

Discussion

With emerging conceptions of the race to high school calculus as "often misguided" (National Council of Teachers of Mathematics [NCTM], 2018, p. 19), there is a need for additional research on the experiences of hyper-accelerated students. Persistence in advanced mathematics has a largely unexplored relationship to quality of learning in accelerated courses. Contextual challenges to identities when students ascribe smartness to correctness and competition may negatively impact students' identity formation as productive doers of mathematics.

The initial categorizations of augmenting and diminishing OTL characterized evolving identities of smartness over the six years of middle school and high school. These themes will be further explored in an additional layer of temporal narrative analysis using individual participants' mathematics trajectories. As a public policy major, Samantha reflected on hyper-acceleration as a "commodity you should be taking" within a mathematics hierarchy. This sociopolitical reality is redefining the ways in which our students build and use mathematics as a resource. Its implications for equitable access to meaningful OTL across the spectrum of demonstrated mathematical readiness should not be ignored.

Declining numbers of undergraduate students, particularly women, graduating in mathematics impact national innovation. In this paper, we report on findings from an Australian study about undergraduate students' conceptions of the supports and challenges that they experience in mathematics departments. Specifically, we discuss findings from our analysis of the visual representations (photographs) provided by the participants and discussed in focus group interviews. We provide insight into students' lived experiences – related to gender issues and peer support in particular – that may contribute to attrition from mathematics.

Keywords: Undergraduate-Level Mathematics; Affect, Emotion, Beliefs, and Attitudes; Research Methods; Gender and Sexuality

In many countries, concerns have been raised regarding the lack of participation of students in university-level STEM education due to a dearth of skilled professionals to meet the needs of a world that is "becoming increasingly technological and significantly more mathematical" (Australian Academy of Science [AAS], 2016, p. 37). In Australia, a very small proportion (0.4%) of students enrol in university degrees in the mathematical sciences (AAS, 2016). Consequently, several organizations (e.g., AAS, 2016; Australian Mathematical Sciences Institute [AMSI], 2017) have stressed the need for increased participation in tertiary mathematical sciences. Women are a minority in these programs, and women's proportion of the enrolments has declined in recent years (AAS, 2016; AMSI, 2017).

There is a paucity of research in Australia on the lack of participation, particularly by women and gender minorities, in undergraduate mathematics degree programs. The ways that students experience mathematics vary due to the gendered constructs placed on mathematical knowledge (e.g., Ernest, 1998). Thus, understanding how students of all genders experience tertiary mathematics is crucial in deconstructing this kind of gendered knowledge.

Here, we report on a study in which we address issues of student experience in mathematics degree programs, via a multimodal methodology, photovoice, combined with individual interviews. We focus on findings from our analysis of the photographs provided by the participants to represent the supportive and challenging aspects of their mathematics departments.

Theoretical Framework

This study is framed by a feminist and social constructivist epistemological stance (e.g., Butler, 1999; Fosnot, 2005). We view knowledge, including that pertaining to mathematics, as a human construction that is gendered and culturally, socially, and historically situated. Regarding this study, we apply this lens to the students' experiences in mathematics degree programs by viewing their learning as “both a process of active individual construction and a process of enculturation into the mathematical practices of the wider society” (Cobb, 1994, p. 13).

We have adopted Piatek-Jimenez’s (2015) socio-cultural perspective, in which participation in mathematics is viewed as a choice. We conceive of our participants as having agency in their educational and vocational pathways. This lens allows us to understand the many factors that contribute to students’ decisions to study mathematics at the university level.

Objectives

The research project is a comparative case study of first- and third-year students in the mathematics departments at two prestigious Australian universities, with a focus on gendered aspects of students’ experiences (Note: Undergraduate mathematics degrees in Australia are typically three years in duration). The aims of this project are: (1) to understand the experiences of undergraduate students enrolled in mathematics degree programs, in order to explore how mathematics departments support or challenge them, and (2) to examine how gender may be playing a role in students’ experiences of studying mathematics at the undergraduate level.

Our project is guided by the following research questions:

1. What are mathematics majors’ experiences of university mathematics departments?
    a. What aspects of the departments do students find supportive?
    b. What aspects of the departments do students find challenging?
    c. How do students’ experiences in the mathematics departments influence their career aspirations?
2. Are there differences in experiences by:
    a. Gender?
    b. Year level?
    c. Institution?

To address these questions, we are using qualitative research methodologies, as outlined next.

Methodology

We first provide an overview of the study’s methodology – comparative case study and photovoice. Then, we discuss the data sources, participants, and analysis methods for the study.

Comparative Case Study

As a case study, our research involves “the study of an issue explored through one or more cases within a bounded system” (Creswell, 2007, p. 73). Our project is an instrumental case study, as we are focusing on a broader issue, of which the case is representative, and a collective case study, also known as multiple case study design (Stake, 1995, 2005). The broader issue is the differential experiences and participation by gender and year level in studying university mathematics, which we explored using a modified version of photovoice (Wang & Burris, 1997).

Photovoice

Photovoice involves participants taking photographs relevant to their lives to “promote critical dialogue and knowledge about important community issues through […] discussion of photographs” (Wang & Burris, 1997, p. 370). The use of photovoice has grown exponentially in the past few years, yet we only know of three such mathematics education studies (Chao, 2012; Harkness & Stallworth, 2013; Tan & Lim, 2010); none were at the post-secondary level.

We began with individual semi-structured interviews about the participants’ educational experiences in mathematics. Then, per the photovoice process (Wang & Burris, 1997), participants took photographs to represent the supportive and challenging aspects of the mathematics department; these photographs were shared in focus group interviews. Supported by the interview facilitator, participants discussed themes that they saw across the photographs.

Participants

Participants were recruited from two comparable, highly ranked Australian universities (herein University X and University Y), both with large mathematics departments. Participants were recruited through classroom presentations, mass emails, posters, and snowball sampling. This resulted in 26 participants: 14 from University X and 12 from University Y. All participants have completed individual interviews, plus three focus groups have been completed.

We focus on findings related to the photographs that the participants provided about supports and challenges that they faced in their mathematics department. Information about the focus group participants and their photographs is provided in Table 1. We view gender as a non-binary social construct, so we asked the participants to identify their genders. However, all participants provided binary genders, so the gender data are separated into “men” and “women” categories.

Table 1: Focus Group Participant and Photograph Information

Name	Focus Group	Institution	Year Level	Gender	“Support” Photos	“Mixed” Photos	“Challenge” Photos
Ang-Yin	1	University X	1st	Woman	3	0	3
Bing	1	University X	1st	Man	0	0	1
Chelsea	1	University X	1st	Woman	3	0	3
Darius	2	University X	3rd	Man	2	0	0
Estelle	2	University X	3rd	Woman	2	0	4
Fiona	2	University X	3rd	Woman	5	0	1
Georgia	3	University Y	3rd	Woman	4	1	4
Hélène	3	University Y	3rd	Woman	0	0	1
Ivan	3	University Y	3rd	Man	1	0	2
Total number of photos					20	1	19

The photographs were evenly split between supports and challenges when considering the dataset as a whole, as well as by year level and gender. However, the women provided far more photographs than did the men (average of 5.7 vs. 2.0 photos per person, respectively).

Analysis

First, using emergent coding methods (Creswell, 2014), we analyzed the photographs in the context of the focus group interviews to retain the participants’ explanations. Second, using content analysis methods (Riffe, Lacy, & Fico, 2014), we further analyzed the photographs to provide detail and description that may not have been evident in the focus group interview videos. In our analyses, we were attentive to differences by gender, year level, and institution.

Results

We discuss two themes that arose from our analysis of the photographs: (1) Gender Issues and (2) Peer Support. Additional themes (e.g., teaching) will be shared at the conference.

Gender Issues

Consistent with the individual interviews, gender issues were only raised in the focus group interviews by the third-year women. While some issues were expected, such as gender imbalances, other, subtler forms of gender discrimination were raised, such as the unsanitary state of the women's bathrooms in the mathematics department building at University Y.

Figure 1: Photograph of a Woman's Bathroom Stall in the Mathematics Department Building at University Y (provided by Georgia)

Georgia and Hélène (3rd year, University Y) discussed how the women's bathrooms were poorly maintained, while Ivan confirmed this was not the case for the men's bathrooms. The women often had to line up to use the bathrooms, and sometimes went to other buildings instead. Such "everyday" microaggressions make mathematics departments uninviting places for women.

Peer Support

Several students discussed the value of peer support, both academically and socially. Many first-year participants, particularly international students, were surprised that their mathematics classes featured group work, with students collaborating to solve problems, as shown in Figure 2.

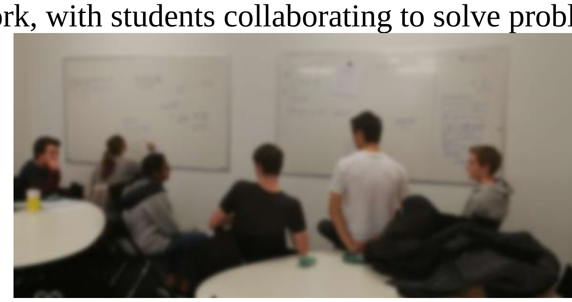

Figure 2: Photograph of Group Work in a First-year Mathematics Class at University X (provided by Bing)

Students at both institutions reported that it was useful to share ideas and learn from each other: "This helped me to […] like the subject better and also just see how other people – be able to, like, combine and collaborate I think to find the solution, which was really fun" (Ang-Yin, 1st year, University X). Students valued student mathematics societies where they had the opportunity to befriend other mathematics students. Hélène (3rd year, University Y) noted, "Subjects where I've got friends, I do better in than subjects when I don't." Third-year students at both institutions expressed a desire for more social spaces to encourage a sense of community.

Discussion and Conclusions

The experiences relayed in the focus group interviews through the participants' photographs highlight issues affecting students enrolled in undergraduate mathematics degree programs, such as those relating to gender issues and learning resources. The participants communicated a desire for a sense of community – socially and academically – within their mathematics departments.

Photovoice is a novel methodology in mathematics education, particularly at the university level. By sharing our experiences with other mathematics education researchers at the

conference, we may assist colleagues in expanding their methodological repertoires.

Our findings will inform practice at the participating universities and hopefully increase retention of mathematics majors. This study contributes to a greater understanding of the mathematics "pipeline" – namely the supports and challenges faced by mathematics students.

TEACHER-STUDENT RELATIONSHIP AND MATHEMATICAL PROBLEM SOLVING IN CHINA: A MEDIATION MODEL

Da Zhou
Beijing Normal University
zhoudadepict@163.com

Xiaofeng Du
Beijing Normal University
dxfice@163.com

Jian Liu
Beijing Normal University
ncctlj@126.com

While previous studies have demonstrated that teacher-student relationship influenced students' school learning, few studies compared the mechanism which teacher-student relationship influenced mathematical problem solving in the urban and rural regions. Structural equation modelling and Multi-group latent variable modelling were used to determine the effect that the teacher-student relationship influences mathematical problem solving by the mediation effects of motivation factors in the urban and rural regions. The results showed that (1) interest and self-efficacy can significantly mediate the link between teacher-student relationship and mathematical problem solving in the urban and rural regions; (2) the mediating effects of interest and self-efficacy are significantly better in the rural region than in the urban region, except for one path.

Keywords: Teacher-student relationship, Mathematical problem solving, Motivation factors, Urban-rural difference

Purposes of the Study

In the early 21st century, China began to implement *the Newest National Mathematics Curriculum Reform* and issued *the Full-time Obligatory Education Mathematics Curriculum Standards (Experimental Version),* which encouraged teachers to change their role from leaders to organizers, guides, and collaborators of mathematics learning. Teaching not only focus on knowledge spreading, but also focus on cultivation of abilities such as problem solving, reasoning and arguments etc. The approaches of developing abilities were also beginning to focus on the motivational factors such as interest and self-efficacy etc. Thus, exploring the relationship between teacher-student relationship and mathematics abilities by the motivational factors is important for teachers and students. In addition, China has been experiencing a huge change since 1978 (the starting point of reform-and-opening policy). However, the huge change also brought some problems. Urban-rural difference has become one of the most important problems (Sicular, Yue, Gustafsson, & Shi, 2007). Therefore, the study will set out to examine whether the effect of teacher-student relationship on mathematical problem solving is mediated by interest and self-efficacy in the urban and rural regions.

Theoretical Framework

Classroom environment contributes to the development of students' motivation, engagement in learning and further student academic performance (Ma, Du, Hau, & Liu, 2018; Wubbels & Brekelmans, 2005). Teacher‑student relationship, as the most important aspect of classroom environment, has been associated with student learning outcome (Wentzel, 2010; Barile, Donohue, Anthony, Baker, Weaver, & Henrich, 2012). Some studies found that supportive teacher-student relationship, based on attachment theory (Bowlby, 1980), had a positive correlation with students' mathematics achievement in Grades 1 through 9 (Hamre & Pianta, 2001; Ang, 2005; Valiente, Lemery-Chalfant, Swanson, & Re, 2008; Roorda, Koomen, Spit, &

Oort, 2011). On the basis of self-determination theory, there were also studies that indicated motivational factors played a crucial role between teacher-student relationship and learning outcome (Deci & Ryan, 2012; Pajares & Miller, 1994; Roorda et al., 2011; Kikas & Mägi, 2017). As motivation factors, self-efficacy and interest generally displayed consistent positive associations with mathematics achievement in most countries through PISA data (Schunk, 1989; Chiu, Zeng, 2008). Meanwhile, some studies have also shown that gender is an important factor affecting mathematical problem solving (Gallagher & De Lisi, 1994; Casey, Nuttall, & Pezaris, 2001), so gender need to be controlled in the study. Based on previous studies, we found that most studies just focus on general academic achievement instead of a specific mathematics ability. Thus, exploring the relationship between teacher-student relationship and mathematical problem solving, the mediation effect of self-efficacy and interest, will expand extant research. In addition, combined with the Chinese social context, further exploring the urban-rural difference in the following mediation model is also very necessary for the development of education. The mediation model as follows:

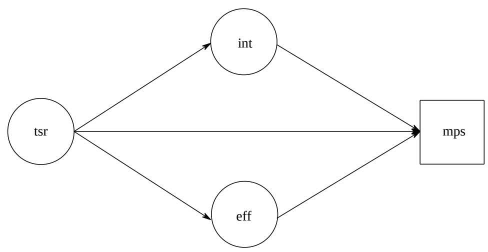

Figure 1: Theoretical Framework of the Present Study

Notes: tsr = teacher-student relationship; int = interest; eff = self-efficacy; mps = mathematics problem solving.

Based on the purposes and the theoretical framework of the present study, three research questions need to be explored. Q1: Does self-efficacy and interest significantly mediate the relation between teacher-student relationship and mathematical problem solving in the urban and rural regions? Q2: Are there differences each path coefficient by the model comparison?

Methods

Participants and Procedures

Participants are 1762 eight graders from 11 lower secondary schools of XX city. We chose participants using Conditional sampling methods for ensuring reasonable sample distribution between male and female, urban region and rural region. Males are 883 (50.1%), and females are 879 (49.9%). The number of students in the urban region is 972 (55.2%), and the number of students in the rural region is 790 (44.8%).

Students were invited to complete a self-report paper questionnaire including teacher-student relationship, interest, and self-efficacy. Except for the questionnaire survey, students were also invited to complete a mathematical problem solving test. The validity and reliability of all instruments are good.

Data Sources and Analysis

The data of this study were drawn from *the Program of Regional Education Assessment* implemented in Chinese XX city, in October, 2017. This study offers two evidence-based models to explore the mediation effects of interest and self-efficacy between teacher-student relationship and mathematical problem solving in the urban and rural regions. Model A and Model B present the mechanism that teacher-student relationship influences mathematical problem solving in the urban and rural regions respectively. According to proposed models, data analyses in this study were performed by three steps. Firstly, confirmatory factor analysis was conducted to provide evidence for psychometric properties of items within each factor construct (they won't be presented in this paper due to the limited words). Secondly, structural equation modelling was generated to assess the effects of independent (exogenous) latent variables on dependent (endogenous) latent variables in the urban and rural regions. Third, multi-group latent variable modelling was used to compare with differences between different models.

Results

Structural Equation Modelling Analysis

Structural Equation modelling was specified and analyzed using Mplus7.11. The standardized path coefficients of the two models are depicted in figure 2, and figure 3 respectively.

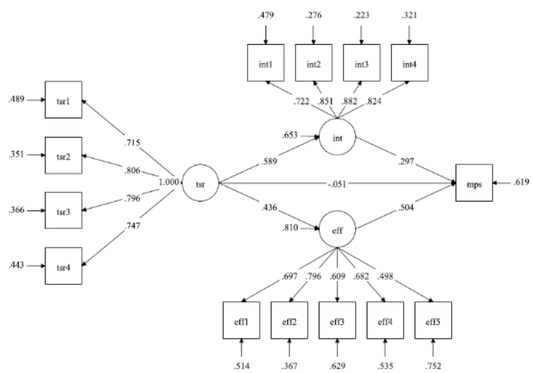

Figure 2: Model A (urban region)

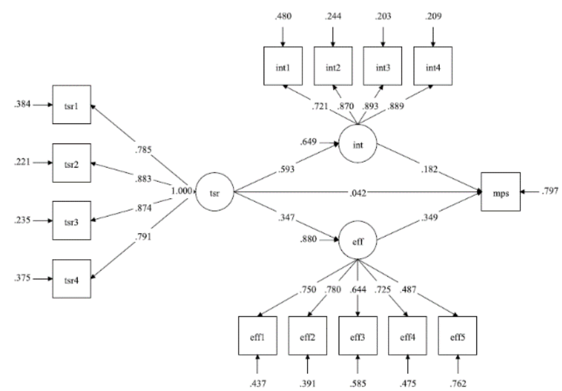

Figure 3: Model B (rural region)

The Model A fitted the data adequately with CFI = .959, TLI = .948, RMSEA = .066, SRMR = .073, $\chi 2$ (73, 1762) = 382.449, p<.001. The Model B also fitted the data adequately with CFI = .956, TLI = .945, RMSEA = .062, SRMR = .071, $\chi 2$ (73, 1762) = 297.014, p<.001. In addition, Model A and Model B shows that teacher-student relationship significantly predicts interest and self-efficacy in the urban and rural regions, and interest and self-efficacy exert significant effect on mathematical problem solving in the urban and rural regions, but teacher-student relationship has no significantly direct effect on mathematical problem solving in the urban and rural regions. In further analysis of mediation effect of interest and self-efficacy, bootstrapping procedures were used to generate a 95% confidence interval (CI 95%) with 1000 samples from the original data (N = 1762). The CI 95% of the indirect effects estimations does not have zero, indicating that the mediation effect will be statistically significant in the urban and rural regions. The results address Q1.

Multiple-group Latent Variable Analysis

Urban-rural difference in each path was examined by means of multi-group latent variable modelling. Table 1 presented the results. Constraining the factor loading corroborated metric invariance (M1 vs M2: p = 0.841), indicated that the measurement models could be equal in the urban and rural regions, and the structural models differed between the urban region and the rural region. For further exploring the difference of structure models in the urban and rural regions, this procedure was conducted from M2 to M7. The results showed that (1) M2 vs M3 ($p < 0.01$) indicated the model A and model B had significant fit-difference; (2) M3 vs M4 ($p= 0.286$) indicated there was not significantly difference, from teacher-student relationship to interest, in the urban and rural regions; (3) M3 vs M5 ($p < 0.01$) indicated M3 fitted significantly worse than M5; (4) M3 vs M6 ($p < 0.01$) indicated M3 fitted significantly worse than M6; (5) M3vs M7 ($p < 0.01$) indicated M3 fitted significantly worse than M7. The results address Q2.

Table 1: Invariance Test Statistics

Model	$\chi2$	df	CFI	RMSEA	$\triangle\chi2$	$\triangle$df
M1: Configural model	679.463	146	0.958	0.064		
M2: Weak invariance model	685.153	156	0.958	0.062	5.69	10
M3: All the Paths in the structure model were set free across region	714.934	161	0.956	0.062	29.781**	5
M4: Path from *tsr* to *int* was set free with constraining the other four ones to be equal across regions	713.794	160	0.956	0.063	1.14	1
M5: Path from *tsr* to *eff* was set free with constraining the other four ones to be equal across regions	706.190	160	0.957	0.062	8.744**	1
M6: Path from *int* to *mps* was set free with constraining the other four ones to be equal across regions	703.200	160	0.957	0.062	11.734**	1
M7: Path from *eff* to *mps* was set free with constraining the other four ones to be equal across regions	700.044	160	0.957	0.062	14.89**	1

*Notes: tsr = teacher-student relationship; int = interest; eff = self-efficacy; mps = mathematics problem solving. *p < .05, **p < .01.*

Discussion

According to the results of structural equation modelling analysis, we can find that interest and self-efficacy are important mediation factors between teacher-student relationship and mathematical problem solving in the urban and rural regions. The result is consistent with the theory of curriculum reform and previous some studies (Jerome, Hamre, & Pianta, 2009; Schunk, 1989; Spark, 2014). Attachment theory and self-determination theory provided theoretical support for model A and model B (Bowlby, 1980; Bandura, 2002). The difference between this study and previous studies is that this study focuses on students from urban and rural regions in the Chinese curriculum reform context. Thus, the results will further extend current research, and provide some implication for teachers on how to improve student mathematical problem solving in China.

Based on the result of multiple-group latent variable analysis, we can find that the mediating effects of interest and self-efficacy are significantly better in the rural region than in the urban region, except for the path from teacher-student relationships to interest. Combined with the Chinese education context, the reason for this phenomenon need to be explained. Parents in the urban region pay more attention to students' mathematics learning, so they usually give students more extra resources for helping students learn mathematics such as online mathematics curriculum, tutorial mathematics class and so on (Liu & Wang, 2018). However, parents in the rural region pay less attention to their children than those in the urban region (Tian & Yuan, 2010). Thus, the influence of schools and teachers on students is particularly important in the rural region. The results make an important contribution to the literature by showing that the difference of each path coefficients in the urban and rural regions, and provide some implications for teachers to develop rural education and urban education together.

STRATEGIES USED BY STUDENTS WITH LEARNING DISABILITIES FOR REASONING ABOUT SLOPE

Anna F. DeJarnette
University of Cincinnati
anna.dejarnette@uc.edu

Casey Hord
University of Cincinnati
casey.hord@uc.edu

Students with learning disabilities (LD), like other learners, show a range of resources and strategies for reasoning about complex concepts in mathematics. This study comes from a project in which a group of five ninth-grade students with LD participated in a once-weekly tutoring program with university pre-service teachers. We asked, what strategies did students use to reason about slope? Students drew upon knowledge of concepts related to constant covariation when given the opportunity. This study suggests that students with LD have rich conceptual knowledge that can be leveraged to improve their success in Algebra.

Keywords: Algebra and algebraic thinking, Classroom discourse, Students with learning disabilities

The concept of slope presents a significant challenge in the teaching and learning of linear functions. On one hand, slope is a complex concept, referring to a single quantity that describes a pattern of constant covariation among two distinct, but related, quantities in a linear relationship (Lamon, 1995). On the other hand, it is possible for students to work somewhat fluently with slope on "rise over run" procedural tasks without attending to the conceptual underpinnings of slope (DeJarnette, Marita, & Hord, 2019; Zahner, 2015). Students with learning disabilities (LD) may be more likely to receive instruction that gives more focus to the correct application of procedures and less focus to underlying concepts (Foegen & Dougherty, 2017). Given the high stakes of passing high school algebra, such efforts seem well-intentioned towards supporting struggling students to be successful. However, there is an opportunity to create more meaningful learning opportunities for all students, and students with LD in particular, by attending to and building upon the conceptual knowledge that they apply to tasks about linear functions.

With this study we posed the question, what strategies do students use to reason about slope across different types of tasks related to linear functions? The purpose of this study is to use knowledge of students' strengths to suggest ways in which future instruction can privilege those strengths. In particular, this study supports the claim that procedural fluency is not a pre-requisite for building upon students' conceptual understanding of slope, and in fact making connections to concepts can support students in completing procedural tasks.

Research Perspectives

Attention to slope as a composite quantity is part of a broader perspective known as a covariational approach to the teaching and learning of functions (Carlson, Jacobs, Coe, Larsen, & Hsu, 2002; Confrey & Smith, 1994; Saldanha & Thompson, 1998). A covariational approach to functions is a contrast to a "correspondence" approach, through which functions are treated as relationships between individual inputs and outputs (Confrey & Smith, 1994). More generally, the covariational approach is part of an effort to develop students' understanding of foundational concepts such as variable, function, and rate of change in ways that can be applied through increasingly advanced levels of mathematics (Thompson & Carlson, 2017).

Many recent efforts to support students' conceptual understanding of slope align with a covariational perspective. Slope as a ratio is a "complex composite unit" (Lamon, 1995), a single quantity representing a multiplicative relationship between two distinct quantities. To work fluently with linear functions, including making interpretations or predictions about what linear relationships represent, students need to act on this ratio as a single quantity (Ellis, 2007). In practice, however, students often treat numerical representations of slope as two distinct quantities representing horizontal and vertical change along a graph (DeJarnette et al., 2019; Lobato, Ellis, & Muñoz, 2003; Zahner, 2015). Such conceptions can be sufficient for solving tasks related to calculating slope given a pair of points or a graph of a line. However, these conceptions tend to leave out foundational ideas, such as how slope describes the steepness or direction of a graph. Knowledge of the concept of slope can serve as a resource for students on a variety of tasks, including correcting errors when procedures are mis-applied.

Methods

This study comes from a broader research effort to train university pre-service teachers to be effective tutors for students with LD taking Algebra 1. Five ninth-grade students from a large suburban high school agreed to participate in the project, after being selected by their math teacher as students who would likely appreciate and benefit from 1-1 tutoring. The students all were identified by their schools as having LD. The students were enrolled in the first year of a two-year Algebra 1 sequence at the school. The tutors were recruited for the project from a mathematics teaching methods course taken by pre-service teachers in the special education program and the middle childhood program at the university. Four of the tutors were pre-service special education teachers; one tutor was a pre-service middle-grades teacher. The tutors were recruited based on high achievement and engagement in their methods course.

Beginning in December 2018, students met with the tutors for 1-1 tutoring one time per week during their usual math class. There were two tutoring sessions from which we drew data for this study. The first was a day on which students had an assignment where they needed to solve systems of linear equations by graphing (Figure 1). The second was a day on which students worked on a task for which they compared slopes of six different lines. We selected these two sessions for analysis because the tasks elicited the use of slope concepts and procedures.

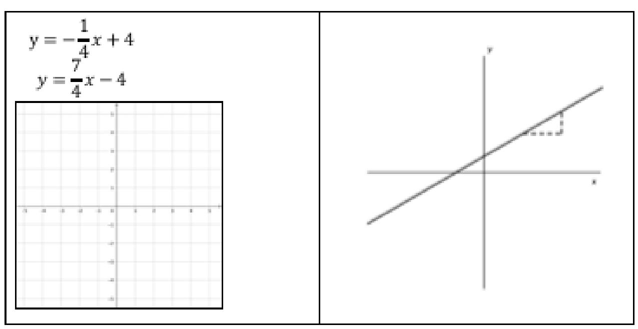

Figure 1: Tasks from the Sessions, Systems of Equations (left) and Comparing Slope (right)

All of the tutoring sessions were recorded with document cameras that captured students' papers as well as the students' and tutors' hands as they worked. We analyzed seven tutoring videos—four videos from the "systems of equations" session and three videos from the "comparing slopes" session. We applied a constant comparison analysis (Strauss & Corbin, 1998), using the video recordings and partial transcripts of the sessions, to look for patterns in the strategies that students used for calculating, graphing, or interpreting slope. The first author viewed each video in its entirety, separating the tutoring sessions into "segments" to highlight key moments in students' and tutors' interactions and constructing transcripts of notable excerpts. After writing a descriptive narrative of each of the relevant segments, the first author used these descriptions to identify emerging themes to characterize students' strategies. The first author shared these emerging themes, as well as the relevant video data, with the second author as well as with a research assistant to refine our interpretation of students' work.

Results

We identified four different types of strategies that students applied to reason about slope.

Strategy 1: Flexible Counting "Rise Over Run"

For graphing lines that had been written in the form $y=mx+b$, students had learned a process of first graphing the y-intercept, followed by one or two more points on the line. One student in particular, Ben, showed a great deal of flexibility in how he applied the "rise over run" technique to identify points on the line. For example, one task on the worksheet required him to plot a line with a slope of 1/2; after plotting the y-intercept of the line Ben audibly counted, "one, one-two; one, one-two" while moving his pencil sequentially up and to the right. With this counting Ben first accounted for the vertical change in the graph and then accounted for horizontal change. The next task required him to graph a line with a slope of two. In this case Ben used the same audible counting pattern, "one, one-two; one, one-two," but this time he accounted for the horizontal change between points first, and then the vertical change. Moreover, although his audible counting was identical to the previous task, Ben moved to the right and down—and, then, to the left and up—on this task to account for the negative slope. Throughout the worksheet, Ben switched back and forth between whether he counted vertical change or horizontal change first, and he did so with few errors.

Ben's flexibility in how he counted "rise over run" is significant because it challenges the assumption that students should apply the same procedure in the same way for every task in order to avoid errors. Our tutors recalled mnemonics that teachers had used (e.g., "place the ladder before you climb it") to reinforce a specific order of graphing procedures. Cases like Ben's illustrate students' flexibility in applying procedures to represent constant covariation.

Strategy 2: Extending Slope Patterns

Another area of strength that students showed in applying linear reasoning was to establish a pattern for the distance between the y-intercept and another point on the graph, and then to extend that pattern to locate other points on the line. For example, Katy needed to graph the line $y=(-1/2)x+3$. After plotting a point at (0, 3), she moved up and to the right to plot a second point at (1,5). She then seemed to interpret the visual relationship between the two points she had plotted, and she transposed that relationship to plot a third point at (-1,-2) to create a line with constant slope. Katy solution here began with an error stemming from apparent confusion about the fraction of -1/2 should be used to determine the slope of the line. However, once she defined a line by plotting two points, Katy applied knowledge of constant rate of change to condense the procedure for locating points on the graph. Although students had spent substantial time developing procedures for counting over and up (or down) between points, examples like this illustrated how students applied broader conceptual knowledge of the shapes of linear graphs.

Strategy 3: Distinguishing Between Positive and Negative Slope

When students worked on the "comparing slopes" tasks (without numerical information), all three of the students from whom we collected data correctly identified which of the six lines had positive slope and which had negative slope. But students often made errors in the directions they needed to move horizontally and vertically to construct a graph with negative slope, even when they had reminders in place. One example of this came from the work of Mia. When working on the "systems of equations" tasks, she consistently wrote each case of a negative slope in two ways on her paper. For example, if given the line $y=(-2/3)x+b$, Mia made a note of $m=-2/3=2/-3$, to remind herself that she could move two places down and three to the right or two places up and three to the left. However, even with this notation and the explanation of why she used it, Mia made several errors in the direction she needed to move along the graph.

Around halfway into the lesson, Mia's tutor had a brief conversation about how lines with positive slope would increase from left to right, and lines with negative slope would decrease from left to right. This concept was familiar to the student, and it seemed to spark her memory that she could use knowledge of the general direction of a graph to construct lines, rather than relying on instructions for what direction to move and when. Several minutes later in the session Mia needed to graph the line $y=(-1/7)x+7$, and her tutor briefly noted the negative slope. Mia reacted with some excitement, noting, "so it's gonna go this way," indicating with her pencil that the graph would move down and to the right, and she made no errors when graphing the line.

Strategy 4: Attending to Relative Horizontal and Vertical Change

When students worked on the "comparing slopes" activity, they attended to the relationship between the horizontal and vertical change without any numbers or scale provided (except to note that the axes were scaled in a 1:1 ratio). When Ben encountered the question of whether the graph include in Figure 1 had slope greater than, less than, or equal to, one, he observed the triangle included with the graph and noted that the horizontal leg of the triangle looked twice as long as the vertical leg. In the next graph he noted that the horizontal and vertical legs of the triangle were equal in length. Ben showed a sophisticated level of reasoning here in attending to the multiplicative relationship between the horizontal and vertical change of the line. This multiplicative reasoning is essential towards conceiving of slope as a composite unit.

Discussion and Conclusion

Prior research has recorded how challenging it is for all students to move beyond procedures for calculating slope towards understanding of slope as a single quantity representing constant covariation (Ellis, 2007; DeJarnette et al., 2019; Lobato et al., 2003; Zahner, 2015). We observed several instances of students with LD applying sophisticated aspects of covariational reasoning—including knowledge of constant covariation and the multiplicative relationship between horizontal and vertical change—in addition to flexible application of procedures. It is illuminating that procedural fluency is not a pre-requisite for the development and application of conceptual understanding, even for students with LD who are struggling in Algebra. Students' knowledge of constant rate of change—and how they interpreted this concept visually—was a resource that they could draw upon to avoid or correct procedural errors. From this preliminary study it is clear that students might sometimes compartmentalize their understanding of concepts away from their use of procedures. But when carefully examining the strategies students draw upon, it becomes clear that students do a better job of bridging concepts with procedures than is immediately apparent. Students may benefit from instruction that makes these connections—and, especially, the strengths of students' reasoning—more explicit.

Acknowledgments

This study was funded by the National Science Foundation's grant to Casey Hord and Anna DeJarnette for the project entitled "Developing Pre-Service Teachers' Capacity to Teach Students with Learning Disabilities in Algebra I," Grant No. 1813903. HIGH SCHOOL MATHEMATICS TEACHERS' POSITIONING WITHIN THE CULTURE OF BLAME: A CASE STUDY

Ashley Garner
Georgia State University
a.marieplummer@gmail.com

Overemphasis on high-stakes testing in mathematics, particularly in schools with economically disadvantaged students, has led to the formation of a culture of blame (Lau, 2009) and inconsistent instructional practices. However, there are teachers who have been successful at ensuring deep mathematics learning takes place in spite of the demands of high-stakes testing instruction (Ladson-Billings, 2009; Leonard & Martin, 2013). The purpose of this qualitative holistic, multiple-case study was to explore how high school mathematics teachers position themselves within the culture of blame that is manifested in the high-stakes testing environment. Positioning theory was employed to examine data. Findings suggest that teachers' instructional decisions are deeply influenced by high-stakes testing and that misalignment of goals among school stakeholders lead to low teacher retention.

Keywords: High School Education, Teacher Belief, Instructional Vision, Instructional Activities and Practices

Introduction

The purpose of this study was to explore how high school mathematics teachers' position themselves within the culture of blame and to understand the instructional decisions that those mathematics teachers make when under pressure to increase student achievement in high-poverty schools. As such, underpinning my research is the culture of blame which manifests itself in the high-stakes testing culture present since the 1980s and the school reform era (Lau, 2009). The culture of blame is the idea that teacher autonomy and instructional decision-making is lost because of their fear of being blamed for students' low high-stakes testing performance. Instead of trusting in their professional pedagogical abilities, teachers are deferring to their administrators and others outside of the classroom to determine the best instructional practices to implement in their classrooms. I chose to focus on one high school mathematics department to provide a deep description of teacher blame within a school across multiple grade levels and mathematics content areas. I used positioning theory as a lens through which to analyze the participants' narratives with the aim to explore teaching practices that counter teacher blame and even defy the common rhetoric of rampant poor teacher quality in schools (National Commission on Excellence in Education, 1983).

Literature Review

Four major issues exist that perpetuate the culture of teacher blame; instability in the mathematics department due to teacher attrition, poor evaluation systems for teachers, an extreme focus on getting students to pass achievement tests, and the lack of focus on gains and students' successes. After retirement, teacher blame was the highest reason for teacher attrition within five years (Curtis. 2012). Owens (2015) found that teacher attrition was linked most prominently with the number and emphasis of mandated tests. High teacher attrition has been shown to negatively impact student achievement, especially in schools with lower achievement, and particularly in mathematics (Hanushek, Rivkin, & Schiman, 2016; Ronfeldt, Loeb, & Wyckoff, 2013). While the Owens (2015) study is specific to the state of Georgia, the Curtis (2012) study included teachers from various states, showing that the problem of low teacher retention persists nationally.

While several studies have been conducted on the deficit view of underserved communities through counternarratives and counterstories (Gutierréz, 2000; Leonard & Martin, 2013; Tan et al., 2012) those success stories are often only given niche status in academic journals and conferences. The niche status of success stories not connected directly to test scores is indicative of the same level of importance these types of successes receive in school buildings and at the district level.

The Culture of Blame and Instructional Practices

According to Lau (2009), control over the accidental has resulted in governments attempting to predict and then neutralize threats before they act, which thereby prevents harm. Lau (2009) further asserts that this constant search for absolute control over the accidental is referred to as *predictability-preventability fetishism*. The notion of predictability-preventability underpins the culture of blame and perpetuates it in culture, resulting in institutions (specifically healthcare and now in education) adopting a blame culture, in which stakeholders avoid risk for fear of being blamed. Dowman and Mills (2008) used participants from primary and secondary education to explore how teachers made sense of teacher blame in the media, but did not emphasize a specific subject area in their study. By exploring stories and discourses and making sense of them, the sensemaker is in turn creating them. Dowman and Mills (2008) found that four distinct repertoires arose from the interviews with teachers; *defensive, empathetic, cynical,* and *collaborative*. The participants' narrative responses within my study mirrored these four repertoires.

Lattimore (2003) discusses the "pedagogy of poverty" or the "pedagogy of mediocrity" that exists in schools, which includes routine instructional practices that are teacher-centered, rather than student-centered. Instruction covers mathematics at a surface level, but student agency is absent. When efforts are made to engage students, "deficient outcomes are countered by reducing expectations to levels of whatever the student seems willing to do" (Lattimore, 2003, p. 124). Instead of preparing students to be able to use and understand mathematics fluently and address misconceptions that led to poor performance, Lattimore found that high-stakes testing forced the teachers into believing that they should teach solely to prepare the test.

However, the scholarship surrounding teachers of successful mathematics students expressed a common theme of effective teachers of mathematics having and promoting strong mathematics identities for their students (Gutiérrez, 2000; Ladson-Billings, 2009). According to Grootenboer and Ballentyne (2010), the participants made quick decisions with minimal consideration, which suggests that the decisions were made from the teachers' identity or sense of self.

Positioning Theory as a Framework

Positioning theory is defined as "the assignment of fluid 'parts' or 'roles' to speakers in the discursive construction of personal stories that make a person's actions intelligible and relatively determinate as social acts" (Harré & van Langenhove, 1998, p. 17). The focus of positioning theory is how phenomena are constructed through discourse. Individuals can position themselves or be positioned by others.

Method

My purpose was to gain insight into how mathematics teachers cope, how they are sustained in their profession, if and how they push back against the blame culture, and how they alter, if at all, their instructional decisions because of the blame culture. As such, my research question was best studied using an exploratory case study; my case being a high school mathematics department consisting of six teachers over the course of one school year. A holistic, multiple-case approach permitted a global analysis of each case. In this research, I examined the experiences of six teachers in one mathematics department. The unit of analysis, which is defined as the entity being studied, is the high school mathematics teacher. While the teachers within this department share the same principal, assistant principals, and even students in some cases, the teachers' experiences with mathematics, their students, and the culture of blame are all unique. Examining participants through a multiple-case study provided the opportunity for a stronger, more in-depth synthesis regarding the culture of blame and its effect on mathematics instruction.

Procedures

High school mathematics teachers' experiences within the culture of blame were explored through multiple sources, including a survey, a group interview session, individual interviews, documents, student work samples, emails, and other artifacts. I facilitated the two-hour group interview by asking a series of open-ended questions based on the survey responses, and then mediated the discussion to ensure that all voices were heard. Of the six mathematics teacher participants, four were able to participate in the group interview. Semi-structured interviews with each individual in the mathematics department, varying from forty to eighty minutes in duration, took place one week after the group interview. Each interview included an opportunity for clarification questions stemming from the previous group interview as a layer of member checking. To provide data triangulation and increase the validity of the study, other forms of data were collected in the form of artifacts. These data included photographs, formal and informal lesson plans, teacher websites, email correspondence between teachers and administrators, student work, newspaper articles, and social media posts for a more complete representation of their experiences.

Data Analysis

To analyze data, I used inductive analysis of the transcripts and other collected data to locate patterns and commonalities that lead to exploring teacher positions with respect to the culture of blame. After the data were organized, I used the whole-part approach to begin thematic analysis (Vagle, 2014). I then used the *three-dimensional space* approach to restory participants' narratives developed by Connelly and Clandinin (2000). The three dimensions Connelly and Clandinin (2000) referred to are interactions (both personal and between other people), continuity (past experiences of the storyteller), and situation (specific places or spaces in the story). I developed a complete and complex view of the teachers' experiences and thus provided a rich description of the phenomenon of teacher blame and the participants' positions within the phenomenon. I also classified the teachers' narratives according to the four repertoires from Dowman and Mills's (2008) research.

Findings

Teachers in the study fell into two categories as a result of the courses they taught; four teachers were responsible for high-stakes tested courses (Algebra 1 and Geometry) and two taught upper-level courses that did not. The teachers in high-stakes courses felt pressure to teach more directly to the curriculum and reported feeling a loss of creativity and flexibility in their classrooms. Although all six teachers discussed students' need for intensive remediation during the school year, only the teachers in upper-level courses were able to deviate from the curriculum to work with students in their deficit areas without the time constraint and pacing pressure placed on them from the district pacing guide and the building administrators.

Students' Perception of Mathematics

Common among individual interviews was what teachers perceived as students' lack of focus on learning mathematics in their classrooms; multiple teachers discussed the culture of passing and the culture of cheating prevalent at DuBois High School. Perseverance came through as a common theme among four of the six teachers. A significant percentage of students at DuBois High School had failed multiple high-stakes tests in the past and brought that defeated attitude to their current classroom. Teachers said that students learn for the immediate benefit of taking a test, rather than the basis for mathematics in future years and beyond in their lives.

High-Stakes Testing

One finding pertaining to testing was that of pass-rate currency from administrators. One teacher who had a higher than average pass rate in Algebra 1 the previous year spoke of having more flexibility in lesson planning from administrators. As a whole, teachers discussed this same flexibility that they felt was favoritism among DuBois High teachers in other tested areas that were traditionally more successful at producing high achievement scores on high-stakes tests. All teachers agreed that they were less stressed when teaching non-tested courses and could focus more on helping students see connections between mathematics and their lives. Teachers also spoke of passing the pressure and anxiety that they felt onto their students, who then pushed back against being measured by testing.

Student Learning Goals and Instructional Decision Making

A common theme among participants was their creating lessons that make connections among topics both across and within content areas. The geometry teachers created connections by repositioning standards within the given curriculum guides to save time and capitalize on students' memories. These connections were eventually accepted by and changed for every teacher in the district. Algebra teachers focused on connecting concepts to real-world situations and problems to access students' funds of knowledge. However, depth of teaching was presented as an issue because of time lost to preparing for the looming high-stakes tests in the form of building-level common assessments and district benchmarks. Differentiation, according to the DuBois High School teachers, was necessary, but difficult because of the overwhelming number of students who needed daily one-on-one instruction and support. Teachers reporting feeling that they catered to lower-performing students to the detriment of students who needed enrichment. In the quest to have students experience success, one participant stated that they lowered their standards and chose assignments requiring a lower depth of knowledge. All teachers discussed how they negotiated their instructional decisions, including how they routinely balanced teaching for the high-stakes test and teaching for a deeper understanding of mathematics.

Conclusion

At the base of this research study is the culture of blame which, according to Dowman and Mills (2008), results from the human need to explain and rationalize the accidental or unexplainable. The culture of blame at DuBois High School encompasses blaming mathematics teachers for high-stakes test scores, dealing with students who cheat leniently, which perpetuates a culture of cheating, and promoting a culture of passing students despite deficient student performance because of the potential effect on the School Performance Index. The culture of blame not only causes teachers to feel undervalued and overwhelmed, but hinders students from getting the highest-quality mathematics education possible and maximizing their growth potential each year. The culture of blame is leading to the dehumanization of students, by assigning their value according to their high-stakes test scores, and the deprofessionalism of teachers. Both of these issues can be rectified through decreasing the importance of high-stakes testing.

Informal STEM learning experiences can provide students with opportunities to apply their knowledge of mathematics. The purpose of this study was to explore middle grades students' perceptions of mathematics after participating in a week long informal STEM learning experience. Using a situated learning lens, we analyzed 254 student interview transcripts collected from informal STEM learning experiences at three different universities in the United States. The informal learning environment (a) positively influenced students' view of mathematics and (b) exposed students to applications of mathematics. Using authentic STEM experiences engaged students in the process of mathematics through real world applications.
Keywords: Equity and Diversity, Informal Education, Middle School Education

Mathematics is often a gatekeeper for more advanced STEM study (Crisp, Nora, & Taggart, 2009; Martin, Gholson, & Leonard, 2015). This begins in elementary school as elementary school mathematics often falls short of preparing students for more advanced coursework (Coxon, Dohrman, & Nadler, 2018). Generally, mathematics instruction often occurs through whole class instruction (Tate, 1995) where students listen to teachers describe the standard algorithm before individually practicing the algorithm at nauseum. In fact, lower quality mathematics instruction is more likely to be the norm for students attending majority minority schools and low-income schools (National Council of Teachers of Mathematics [NCTM], 2014). With underwhelming experiences, many students decide before eighth grade mathematics and more broadly, STEM courses, are not in their futures (Boaler & Greeno, 2000; PCAST, 2010). However, informal STEM learning experiences can provide context for and extend students' learning in formal STEM learning environments (Roberts et al., 2018). For students learning mathematics, concepts are more meaningful when they are situated within real-world problems in a problem-based context that focus on the Standards for Mathematical Practice (SMPs; NGA Center for Best Practices and CCSSO, 2010). Informal learning environments allow for real-world modeling examples (Martin, 2004; Meredith, 2010), help students better understand concepts (Popovic & Lederman, 2015), and encourage students to interact with peers (Barker et al., 2014) and others. Moreover, participation in informal learning environments increases students' interest in STEM (Mohr-Schroeder et al., 2014; Baran et al., 2016). Given the need to spark students' interest in STEM and to address limitations many students experience in formal mathematics, we used a situated learning perspective to answer the following research question: How does participation in an informal STEM learning environment influence middle school students' perceptions of mathematics?

Theoretical Framework

We used situated learning theory to explore how students' participation in an informal STEM learning environment influenced their perceptions of mathematics. Learners have the opportunity to acquire knowledge due to the interactions between them and the environment (Kirshner & Whitson, 1997; Lave & Wenger, 1991), which are mediated by social interactions. By interacting with each other and the environment while participating in authentic activities (Brown et al., 1989), learning is contextualized (Hung, Lee, & Kim, 2012). In a STEM learning environment, learning occurs in a community of practice where "learning is authentic and relevant, therefore representative of … an actual STEM practice" (Kelley & Knowles, 2016, p. 4).

Data Collection & Analysis

Participants in this study were 254 students who attended the STEM summer informal learning experience at the University of Kentucky, Iowa State University, and California State University, Long Beach. The summer learning experience is open to all incoming fifth through eighth grade students, and targets underrepresented populations in STEM fields (i.e., females, Black, Hispanic/Latinx, American Indians or Alaska Natives, and Native Hawaiians or Other Pacific Islands [National Science Foundation, 2017]).

Data were collected from semi-structured interviews designed to explore students "lived experiences" (Van Manen, 1990, p. 9). Students participated in a five-minute, audio recorded interview during the last two days of the summer informal learning experience. The interviewer also took notes to conduct member checks during and at the end of each interview. The majority (78%) of students interviewed were from underrepresented populations in STEM.

We used an inductive approach to analyze the data and managed data through reduction, organization, and connection (Lecompte, 2000). One author used initial coding to develop preliminary codes (Saldaña, 2016), which were then refined and used to code an initial set of interview transcripts. Four authors coded the interviews. Inter rater and intra rater reliability standards were set at 90% agreement (James et al., 1993). All four authors exceeded the 90% threshold on intra- and inter-rater reliability. After initial coding, four of the authors conducted second cycle coding. The team used pattern coding to highlight common themes and divergent cases (Saldaña, 2016; Delamont, 1992). After initial themes were identified, the entire team reviewed themes and supporting data to add content validity.

Findings

Two primary themes emerged from the data. The informal learning environment (a) influenced how students view mathematics and (b) allowed for the exploration of applications of mathematics, particularly in robotics.

View of Mathematics

Students compared their mathematics experiences in the informal STEM learning environment with their mathematics experiences in a formal setting. Jaden explained, "in school they just teach you one way to do it, but here they're teaching me other ways" (Interview, 2016). Laurie noted, "it's showing us different ways to see things other than the way the teacher teaches. Because I have a hard time understanding things and I feel like STEM camp's giving us a way to understand" (Interview, 2016). These "different ways" often focused on active ways of problem solving. For example, Mia explained, "STEM camp is like helping me be a better problem solver and like helping me think outside the box," which helps "in the classroom to develop ideas" (Interview, 2016). Similarly, Rosa said her experience will help her in mathematics class because the interactive STEM learning experiences taught her “new ways how to think, and new ways how to put things together” (Interview, 2017). These new, different ways to approach problems came about because the STEM learning experiences gave the students “different scenarios to work with” which helped them “look at the problem in different ways not just in the same ordinary way” (Interview, 2016). The creativity students associated with problem solving in mathematics contests was markedly different from the “one way to do it” associated with school. As Lexie said, “you get to learn about different like stuff like without actually doing all the equations and stuff. It’s learning different ways how to do like math” (Interview, 2016). Thus, the focus was how to use mathematics and not just solving an equation.

Students also emphasized the importance of problem solving when discussing how the informal STEM learning experience will help them in mathematics classes. For example, Jerel reflected, “I think it prepares me good [sic] because it can help me problem solve and everything because math you kinda have to problem solve and STEM Camp…will help me think through problems, be patient especially” (Interview, 2016). Similarly, Mya noted the importance of “trial and error and what they taught there gives you more patience for math if you can’t figure out the problem you just have to try again” (Interview, 2015). Michael added, “it’s teaching me about the trial and error so that we’re not just gonna get it the first time. We have to try” (Interview, 2016). Without referencing the Standards of Mathematical Practice (SMPs), students consistently voiced the essence of the first SMP, make sense of problems and persevere in solving them. The students’ responses demonstrate how the informal learning environment’s emphasis on the practices over specific content translates to students’ perceptions of STEM. Students’ responses highlight what they perceive to be a different way of doing mathematics than the “one way to do” mathematics in school. This relates to the way students experience mathematics in the informal STEM learning environment and the second theme: applications of mathematics.

Applications of Mathematics

Students identified ways mathematics applied to real world topics. Some students connected their experiences with mathematics to the future or to real life. For example, Alex said “it’s teaching you like real life situations, where like they don’t necessarily teach you math but they teach you like…where you can use this math type of thing” (Interview, 2016). Jared suggested he could use his experiences in college, “We learned a little bit of calculus, which I’m probably gonna learn that in college, but I think it’s preparing me for the real world” (Interview, 2016). One way this was evident was in the use of mathematics in STEM careers. Erin focused specifically on engineering as she explained:

> ...engineering also focuses on um, it focuses on math like how if you measure a plane, if you measure the length or width of a plane, it shows you like the length and width, like base times height, length times width, stuff like that. It helps you with like the width and then you can do the math well. Because in order to build a plane or to do math, so it shows you different ways to do math problems while doing fun things. (Interview, 2015)

Javier had a similar perspective on how mathematics relates to careers. He explained, “It’s going to teach me how to do certain different art like 3D art, so it prepares me for what I want to be when I grow up” (Interview, 2017). For these students, mathematics was relevant for their future. The informal STEM learning experiences helped provide context for when and how mathematics can be used outside of school.

In addition to students mentioning the real world and careers, many students found applications of mathematics in their experiences with robotics. As Janel explained, she learned "other things that could involve math instead of just regular problems like multiplication and things like that like other things you can use math like in robotics and programming" (Interview, 2016). Some students saw the application of specific mathematics content. For example, Darius explained how in programming "you have to use decimals and fractions…you have to coordinate how far you need to go…the multiplication [to] figure all that out" (Interview, 2015). Many students noted how "there's like a lot of measurement involved" (Interview, 2015). Maria elaborated:

> I guess there's a lot of math when you program robots. You have to know the exact number of times your robot's wheels have to rotate so it can go forward. If not, if you miscalculate the whole thing can go bad, as I was experiencing. And you have to know the angle of the turn. (Interview, 2015)

The experiences exemplified real life applications of mathematics through programming.

Students also commented on the importance of precision when programming. Cesar noted, "especially for robotics you have to basically figure out whether it's like 0.6 you have to go forward or 0.65 or like you have to be good at math to be able to do robotics because programming is like precise" (Interview, 2016). Jesse similarly reflected, "The robotics are preparing me for math classes because it's showing me how to be exact, how to build one piece at a time, which is like math" (Interview, 2017). These students voiced another SMP–attend to precision. The mathematical applications in programming required students to be precise to achieve their goals. These students connected the precision required in programming to the precision needed when doing mathematics. As Chris noted, "we've had to work out problems especially in robotics. If something goes too far we need to add something else or try something new…[Just] because we're not actually do[ing] math in that, there's a lot of math required" (Interview, 2016). Thus, the application of mathematics in robotics allowed students to make connections to when they would use mathematics content and processes.

Discussion and Conclusion

The STEM learning environment positively influenced students' views of mathematics and provided access to authentic STEM learning experiences that showcased a variety of real world applications of mathematics. All students do not receive access to this type of engagement with mathematics because constraints and pressures placed on formal settings (e.g., lack of funding, accountability measures, incessant testing) prevents many schools from implementing different curricular options (Meyers et al., 2013; Weis et al., 2015). Students from underrepresented populations tend to feel these negative side effects at a higher rate than others (Coxon, Dohrman, & Nadler, 2018; NCTM, 2014). Thus, one implication from this study is the importance of access to high quality learning environments, such as those provided in the informal STEM learning environment, where students can explore applications of mathematics. The ways in which students engage in mathematics are also important. Students repeatedly voiced the essence of many SMPs, such as persevering in problem solving and attending to precision. By engaging in these practices, students connected mathematics with their projects. They were not doing mathematics problems; instead, they were actually doing the process of mathematics. In the informal learning environment, students engaged in the process of doing mathematics, instead of focusing on thoughtlessly practicing the algorithms of mathematics.

DEVELOPMENT OF PROFESSIONAL VISION IN MATHEMATICS TRANSFER STUDENTS AT A FOUR-YEAR RESEARCH UNIVERSITY

While past research has focused on understanding the overall experiences of transfer students, little work has focused specifically on mathematics majors. This study explores the development of professional vision among mathematics transfer students, drawing from focus groups with 21 participants enrolled in a bundle of three transitional mathematics courses concurrently at a four-year research university. Overall, the experiences of these students in the bundle of courses exposed the importance of community, competence aligned with the structure of mathematics, development as a mathematics student, and resources for understanding future pathways.

Keywords: transfer students, professional vision, college mathematics, HSI

Currently we have very little, if any, research about how to support mathematics majors as they make the transition from two-year institutions to four-year institutions of higher education. While there is more general scholarship about transfer students (e.g., Melguizo, Kienzl, & Alfonso, 2011), there is a need to understand this pipeline for a number of reasons. First, this pipeline includes underrepresented minorities, low income, and first generation college students, who are more often than not underrepresented in the STEM fields. If we understand how to support transfer mathematics students, we likely also support our understanding of those who are traditionally underrepresented, potentially expanding the field and pipeline of mathematics majors and graduates. Second, at this university, and likely at other universities, we have seen a high level of attrition of transfer students from the mathematics major. This leads to a need for research to understand how to retain students in the major and whether the courses suggested in this study support students' retention. There is a clear need to better understand mathematics transfer students, their needs, and those who work to support their success.

Framing

We use Lave and Wenger's (1991) *legitimate peripheral participation* and Goodwin's (1994) *professional vision* as a conceptual framework to consider mathematics transfer students' development along the novice to expert continuum of professional vision. In particular, our research question is: In what ways do community college transfer students develop the professional vision for what it means to be a four-year college mathematics major and to have a career in mathematics?

Legitimate Peripheral Participation

To do this work, we start with Lave and Wenger's (1991) legitimate peripheral participation. Their work draws on apprenticeships and the active participation in a community of knowledge. Legitimate peripheral participation is the "way to speak about relations between newcomers and old-timers, and about activities, identities, artifacts, and communities of knowledge and practice. It concerns the process by which newcomers become a part of a community of practice" (Lave & Wenger, 1991, p. 29). An individual is not just "'receiving' a body of factual knowledge" (Lave & Wenger, 1991, p. 33) in this community; instead, they are actively engaged with it, mutually constituted, and an active agent. Lave and Wenger note that "[t]here is no place in a community of practice designated 'the periphery'" (Lave & Wenger, 1991, p. 36); therefore, peripheral participation is full participation. Legitimate peripheral participation allows for individuals to know what it means to be part of a particular community, such as a four-year mathematics department or the mathematics community more broadly, or what it means to support a student in such a community. We are particularly interested in the interaction between novices and experts. Access to experts provides newcomers with the opportunity to be "apprenticed into the learning of knowledge and skills" (Lave & Wenger, 1991, p. 145).

Professional Vision

Such novice-expert interactions as those previously described are organized for the development of professional vision. Goodwin (1994) notes, "[c]entral to the social and cognitive organization of a profession is its ability to shape events in the domain of its scrutiny into the phenomenal objects around which the discourse of the profession is organized" (p. 626). Goodwin explains that each profession has its own ability to see.

Goodwin (1994) defines professional vision using three characteristics: 1) it is "perspectival, lodged within specific social entities, and unevenly allocated" (p. 626); 2) it is not just a mental process but it is instead "accomplished through the competent deployment of a complex of situated practices in a relevant setting" (p. 626); and 3) "insofar as these practices are lodged within specific communities, they must be learned" (p. 627).

Methods

Twenty-one undergraduate transfer students, nine females and 12 males, from a Hispanic-serving four-year research university in California participated in this study. Eighteen of the students were mathematical science majors and three were applied mathematics majors. In Fall 2018, these students took three mathematics courses as a bundle: 1) special topics in mathematics (an academic and career advising course), 2) group studies in mathematics (a course to develop problem solving and the expectations for upper level mathematics courses), and 3) transition to higher mathematics. This third course was a prerequisite for many mathematics courses that follow, and it was described as an introduction to the elements of propositional logic, techniques of mathematical proof, and fundamental mathematical structures, including sets, functions, relations, and other topics.

We conducted and audio-recorded focus groups with three groups of transfer mathematics students, split evenly between three facilitators. We used these semi-structured focus groups (Yin, 2016) to understand how participants developed professional vision around being a mathematics major and mathematics professional. The interview covered the following: background information, three course bundle, being a transfer student, ways of thinking and doing mathematics, and preparation for a career in mathematics.

We used open coding (Strauss & Corbin, 1990) in our first round of coding, noting themes across the focus groups. We then applied four themes generated from this first round of coding: community, proofs and problem solving, being a student, and future as a mathematician, to code the corpus of data. We then looked within and across each set of coded data and research question, looking for consistencies and inconsistencies.

Findings

We found that the transfer students in the bundle of three mathematics courses in our study were very positive overall about their experiences. The students highlighted four ways that these courses helped them develop professional vision as mathematics students, future mathematics professionals, or both. These courses: 1) cultivated community among the transfer students; 2) created mathematical competence that was different from their prior mathematics learning experiences, particularly around proof and problem solving; 3) developed facility with studying and how to be four-year mathematics student; and 4) provided resources for mapping a future as a future mathematics professional. We will now discuss each of these findings, drawing on insights from the transfer students from these courses (named using pseudonyms below).

These courses helped to create community among the students. In all three focus groups, students mentioned the importance of the presence of community as a result of being in these courses. This community came about from working together on problems, being in all the same classes, and having what students described as a “comfortable” environment (Raul, FG2, 59). Because all the same students were in all three courses, they saw each other regularly, almost forcing community throughout the term. Additionally, because they were all transfers, many of the students lived together in transfer housing, increasing the likelihood that the students would run into each other there, as well. Kacey explained, “It felt like we were going through it together, and we can definitely help each other out” (FG1, 89-90). Sasha reinforced this feeling, “I think having the same people around you definitely was beneficial….Like, it makes you really want to go to class” (FG1, 102-103, 111). This collaboration helped students feel like they were part of the larger mathematics department and part of their smaller cohort of mathematics transfer students. Additionally, Maggie noted importantly, “I feel like a mathematician needs to know how to collaborate with others, too” (FG3, 540). The transfer students were developing professional vision around what it meant to do mathematics, not just singularly and alone, but as a collaborative, comfortable process with their classmates.

The second key finding about how this course bundle supported transfer mathematics students’ development of professional vision was that students felt that the courses created mathematical competence that was different from their previous mathematical experiences, particularly around proofs and problem solving. Two of the three courses in the bundle focused on developing students’ facility with how to approach and write proofs. Multiple students noted that this work with proofs was the most useful coursework throughout the term. Li noted, “I didn’t really know how to write proofs until the bundle of classes” (FG3, 195). Students revealed that these courses made them starkly aware of how different their four-year university mathematics courses were compared to their community college and high school mathematics courses. Antonio explained, “Studying for upper division is a lot different from our community colleges, where we would study formulas and just know where to plug stuff in” (FG2, 276-278). The transfer students repeatedly shared an importance for understanding the mathematics they were learning.

Our third finding is about the transfer students’ study skills and their development as four-year university mathematics students. The transfer students reported that the bundle of courses systematically supported this maturation. Because a mathematics department advisor taught one of the transfer student bundle courses, the students noted that it was helpful to “build a connection” with her (FG3, 233). The advisor also required students to attend five office hours for their courses, instilling in them a practice of what mathematics students should do. Raul explained, “it was a little scary, but after the first time, I kind of got the hang of it…I feel like for the next quarter that’s going to be a lot easier” (FG2, 190-194). The students expanded their understanding of the purpose of office hours over time, as well. Javier shared:

> I realized I don't have to go to office hours with a specific question and can just sit there and hear what people have to ask or just, like, talk to the professors about their research or what I should do with my year here before applying to grad school. (FG2, 201-204)

In their courses, transfer students also learned how to study. All instructors, with one in particular, spent time with the students discussing how to study for exams. Bastian shared that he learned what to study and how to study. The final aspect of becoming a mathematics student was learning about research at a four-year university, as Javier mentioned in his visit to office hours. Because they came to the university later than students who enter as freshman, the transfer students illustrated the challenges associated with getting to know and getting involved with professors' research, which often provides avenues to graduate school. Randy reported, "We don't have as much time as freshman to get involved into research before, like, applying into graduate programs" (FG2, 369-371). Raul shared a similar sentiment, "I wish there was a way to introduce us to, like, faculty professors that are working on research" (FG2, 434-436), because it would make it easier for transfer students to gain access to research opportunities. Several students noted that it felt difficult to gain access to research opportunities, even with the support of the bundle of courses.

The final findings we share are related to the resources transfer students reported for mapping their futures as mathematics professionals. Overall, the transfer students expressed satisfaction with the resources the advisor provided in the course she ran, as well as the multitude of resources she and the department offered outside of class. During class, there were panels with current graduate students and students currently applying to graduate school, as panels on careers in mathematics. Sophia noted, "It seems like the department just really cares and wants us to go to grad school or wants us to get a job right out of school" (FG1, 502-503). Even with this support, similar to comments about visiting their professors about research opportunities, the transfer students noted that they felt behind in the process. Keith shared, "it's still early on, so it's hard to know what we are interested in, because there are some math concepts we haven't learned" (FG1, 569-570). Additionally, students felt crunched for time. Michael explained, "we only have two more years…you kind of start thinking about your future now since we only have, like, one summer for an internship" (FG1, 554-557), and it was hard to know whether to go to graduate school, get a job, or do research with a professor. Multiple students mentioned this short timeline of having to make a decision about their futures and having limited time to make connections with professors to do research and/or have opportunities to do internships in the field. They described being behind before they got to the university.

Discussion & Conclusions

Transfer students in this bundle of courses developed several aspects of professional vision. The first aspect was a community to work with, which could help not only with their mathematics professional vision but also provide comfort at a new university, hopefully keeping them in the mathematics major and at the university. These transfer students also saw themselves differently *as* mathematics students and saw what mathematics students *do* differently. The clear role of problem solving and proof in upper-level mathematics work and their increased facility with this work was evident. To cross the threshold into a professional career, the courses provided some clear supports and requirements to build professional vision, like forced office hours attendance and career panels. But students still felt uncertain because of their late admittance, especially with research and internships. It may be that community college and four-year partnerships are needed earlier to ensure that students feel that they are not behind in these processes.

INTENSIFYING FLUENCY INTERVENTIONS FOR MIDDLE SCHOOL STUDENTS WITH MATHEMATICS LEARNING DISABILITIES

Nicole B. Tucker-Whitaker
The Ohio State University
tucker.289@osu.edu

Students with executive function (EF) disorders, including ADD, ADHD, and dyslexia, are prevalent in our nation's public schools. Too often, students with learning differences have had a lack of exposure to complex academic language considered to be a critical component for the conceptualization and learning of mathematics. Additionally, there is a gap in research and understanding of how academic language might mediate building mathematical understanding for students who have EF disorders. This project is a small part of a larger ethnographic study and seeks to investigate what role modeling academic language might play in differentiating the fluency component of a curriculum that is being adopted nationally. Teacher modeling in the form of think-aloud protocols, feedback and reinforcement, and Detect, Practice, Repair (DPR) strategies are investigated as initial intensifications for the intervention.

Keywords: Middle School Education, Modeling, Number Concepts and Operations, Special Education

Introduction

Rationale and Purpose

A primary goal for students according to the Principles and Standards for School Mathematics is the ability to fluently and naturally speak using mathematical language as a "powerful tool...to foster the learning of mathematics" (NCTM, 2000, p.128). These process standards call for an increased role of language in the development of mathematical conceptual learning. "Communicating is a broad goal in mathematics learning that provides means to develop and share understanding" (Rubenstein, 2007, p.206). Thus the study of language as one of many learning tools enacted in the classroom, "of the ways in which it is employed in the classroom, and of the classroom as a social system, has been given considerable and increasing attention" (Austin & Howson, 1979, p. 174). An examination of how the development of academic language can be used and integrated into remediation techniques may be an initial step in aiding students with mathematics deficits to achieve mathematics procedural proficiency. This teacher-researcher teaching experiment seeks to understand the possibilities for academic language mediating the development of student procedural understanding and enculturating students into the community of mathematicians.

Perspectives

Numerous studies indicate that not all practice opportunities are equally effective in fluency building (Codding, Burn & Lukito, 2011). Research has found that "adding demonstration to standard drill and practice procedures resulted in better outcomes for students with learning disabilities, and … that students with low fluency benefited more from a treatment including modeling than one without." (Codding, et al., 2011, pp.43-44). However, feedback and reinforcement may be particularly important when fluency-building activities are in the form of timed activities (Duhon, House, Hastings, Poncy & Solomon, 2015). In addition to learning difficulties, many special education students have also been exposed to years of deficit model teaching, often languishing under the judgment and ridicule of both teachers and students alike. Therefore it is not just feedback that must be provided to the student about their academic performance, but more specifically, positive and academic self-confidence building feedback that incorporates the language of mathematics which may act as an external motivator for students to persevere. Duhon, et al. defines performance feedback as “a set of procedures in which students are given detailed information about some aspect of their academic performance such as accuracy or fluency.” (2015, p. 77). When such performance feedback is couched in the language of mathematics, it may then also serve the purpose of aiding students to move toward a position of “legitimate peripheral participation” on their way toward becoming a full participant in the community of practice of mathematicians (Lave & Wenger, 1991). Thus, academic language used by the teacher may serve numerous purposes simultaneously. For this research, modeling is defined as “an expert’s performing a task so that the students can observe and build a conceptual model of the processes that are required to accomplish it” (Collins, Brown & Holum, 1991, p. 13). Modeling, in the form of teacher think aloud, specifically using the complex academic language of mathematics, makes the invisible visible. Collins, Brown & Holum term this “cognitive apprenticeship… a model of instruction that works to make thinking visible” (1991, p. 1). Because “concurrent reasoning takes place in verbal form in working memory” (Cowan, 2017, p. 3), making the invisible thought processes visible through language may be a significant scaffold for students with executive function disorders to begin to develop structures to organize and retrieve the large quantities of verbally encoded procedural knowledge that may be required for success in mathematics.

Method

Participants

The research was conducted at a small, midwestern, independent school for students with learning differences. The larger study began in December 2017 when the teacher-researcher was made aware that she would be “looping” a cohort of students. From the original group of 2017-2018 seventh graders (n = 16), eight students continued on to eighth grade. Of the eight students having the teacher-researcher as both their seventh- and eighth-grade mathematics teacher, two are adopted (25%), eight have been diagnosed with ADHD (100%), two have been diagnosed with an anxiety disorder (25%), one has been diagnosed with a math learning disability (12.5%), one has been diagnosed with expressive-receptive language disorder (12.5%), four have been diagnosed with dyslexia (50%), one has been diagnosed with dyscalculia (12.5%), one has been diagnosed with a conversion disorder (12.5%), one has been diagnosed with auditory processing disorder (12.5%), and two have been diagnosed with dysgraphia (25%); many students have multiple diagnoses. The entire class participated in the intervention and intensification of intervention. The student featured in this brief report is a reasonably intuitive mathematics learner who experienced anxiety that often prevented meaningful engagement with learning throughout much of fifth- and sixth-grade, and like many students, has multiple diagnosis including dyslexia and ADHD.

Materials

The focus of this investigation is one aspect of the Eureka Math curriculum: Fluency Support for the development of procedural automaticity. All fluency materials come directly from the Eureka Math curriculum.

Task Identification

Eureka Math fluency support speed drills were matched to learners needs in order to provide intervention at an appropriate level. Determining where procedural supports are required is of primary importance to appropriately match the intervention with the skill to be remediated (Burns, M., 2011). Prior to the beginning of the intervention intensification, fluency support drills from Eureka grades three through six were administered to determine proficiency. These trials were all administered using the prescribed Eureka Math protocol.

Procedures

To capture both the intervention intensification as well as gauge success of the intervention intensification, all class periods where fluency sprints were administered were video-recorded. Since intensifying an intervention often begins with the adding the least intensive, least intrusive treatment component first, followed by additional components until an effective program is developed (Duhon, et al., 2015; Codding et al., 2011), the first layer was a combined intensification of teacher-researcher think aloud modeling and explicit feedback and reinforcement both utilizing academic language. The fluency drills were administered as follows: Trial A, two minutes, completed independently and individually. Upon completion the teacher-researcher modeled, using think-aloud protocol with academic language, how she thought about the fluency trial working to make the invisible thought processes visible through language. Students were encouraged to self-correct and ask questions during the think aloud before Trial B. Following the two minute Trial B, answers for the fluency drill were put up and students were asked to correct their work looking for progress between Trials A and B. The teacher-researcher circulated the room, viewing each student's work, giving specific feedback on progress and cues for improvement using academic language.

The second layer of intervention intensification, DPR, was implemented over three weeks for a total of seven sessions, consecutive to the first layer of intensification. Following a partial Trial A think aloud with initial feedback, students were asked to detect errors in the remainder of their work and make corrections. After two to five minutes of silent work, the teacher-researcher put the answers for the sprint not covered in the think aloud on the board. Students then checked their work one more time to ensure that they detected and repaired all problems. While students were working, the teacher-researcher circulated the room, answering questions and providing additional support to specific students as necessary. Once the process was complete, students completed Trial B as above, looking for progress and receiving feedback and reinforcement.

Data Analysis

The first step in analyzing the data was to view and code video recordings. The identification of a pattern of student behavior, which occurred repeatedly, with more frequency, and by more students as the intervention continued, determined specific sections of video to be transcribed. Specifically, students began asking to lead the think-aloud modeling portion of the procedure. As students were allowed to lead the think-aloud, being required to do so using specific and detailed academic language as had been modeled by the teacher-researcher, the rate of student requests to lead the think-aloud increased as did the number of students requesting to lead the think-alouds. Each of the student-led think-alouds were transcribed for further analysis.

Data analysis is informed by Nagy & Townsend who posit that it is not merely the imitation of academic vocabulary that is a significant indicator of developing conceptual understanding in mathematics but rather it is the ability to generate discourse within the mathematical register for the purposes of clearly communicating mathematical ideas (2012; Corson, 1997; O'Halloran, 1998). Changes in the uptake and use of academic language may also indicate the degree to which students are becoming enculturated into the community of mathematicians, along with growth in academic confidence, and may be indicated by increased willingness to share academic thinking aloud (Bloome, Puro, & Theodorou, 1989).

Results

Preliminary Findings

This study is still in data collection and analysis stages, however, a pattern of student behavior of interest has been identified. As students became familiar with the fluency practice protocol and teacher modeling, they began to request to lead the think aloud portion of the intervention. Following is a brief excerpt from just one of the many student demonstrations:

Student (S): Can I do the think aloud?
Teacher/Researcher (T/R): Let me start and you can take over
T/R (begins the process): We should recognize that these are operations with integers
S: Okay, so, with this it's like adding positives but they are negatives
S: It's getting more negative

When the student-led think aloud stalls, other students chime in to encourage the process and get the presenting student to give more detail about what is "going on in his head." This pattern of student interaction serves to demonstrate one way in which language may be mediating a mathematics procedural fluency intervention while simultaneously mediating student movement toward a position of "legitimate peripheral participation" (Lave & Wenger, 1991).

Discussion

From a sociolinguistic ethnographic perspective, attention must be given to the way in which students are "establishing a public system of cultural meanings and significance" (Bloome, Puro, & Theodorou, 1989, p. 269) for the engaging with, and doing of, mathematics within the classroom, with a focus on "how classrooms function to promote the enculturation of new members" (Bloome, Puro, & Theodorou, 1989, p. 270). Thus, modeling the language of mathematics to support fluency sprints through think-alouds allowed the teacher-researcher to verbalize the thought processes, and thus make visible the invisible, that a mathematician may engage in when completing the types of problems on the sprint. If we view the think-aloud process from the sociocultural perspective, "the development of a social language is a process of being socialized or acculturated into a specific community of practice, such as 'academic' social practice in school mathematics" (Huang & Normandia, 2007, p. 296; Gee, 2001, p.13). Student requests to begin to participate in the community of mathematicians being modeled by the teacher-researcher may then be viewed as a request to engage in the construction of knowledge through social interaction in the classroom. In this way, using the language and logic structures of mathematics to do the work of engaging students in the culture of mathematics and academic thinking, a third space was opened for students to engage in the practice of verbalizing their academic thinking helping them to move from apprenticeship toward a position of "legitimate peripheral participation" on their way toward becoming a full participant in the community of practice of mathematicians (Lave & Wenger, 1991). Such opportunities are critical to create a cognitive connection between vernacular language, mathematics vocabulary, and symbols used to describe mathematical concepts that are represented in the computations and procedures that may be performed in fluency sprints (Miller, 1993).

WHAT MATTERS FOR INVESTIGATING IDENTITY IN MATHEMATICAL LEARNING SETTINGS: POSITIONS, FUNCTIONS AND INDIVIDUALIZED REPERTOIRES

Fady El Chidiac
University of California, Berkeley
fchidiac@berkeley.edu

In the last two decades, research on identity has been multiplying and building on various theories and methodologies from different disciplines. The task of providing a comprehensive framework of identity for mathematics learning has been arduous. Based on a broad literature review, I highlight three indispensable components for a robust mathematical identity research: positions framed culturally and discursively, functions/goals set by participants, and individualized semiotic/behavioral repertoires. I leverage this framework to shed light on a puzzling comparative case of two undergraduate women learning number theory through small-group work.

Keywords: Identity, Research Methods, Gender, and Post-Secondary Education.

Since the end of the twentieth century, a multitude of studies have been employing the construct of identity to shed light on the learning and teaching of mathematics (for reviews of this scholarship see Darragh, 2016; Hand & Gresalfi, 2015; Langer-Osuna & Esmonde, 2017; Radovic, Black, Williams, & Salas, 2018). These studies have been building on various theoretical approaches within and across many disciplines, such as psychology, sociology, anthropology, psychoanalysis and linguistics. They investigated various units of analyses pertaining to individuals, societies, discourses and learning environments. Consequently, the increasing complexity of the construct of identity in mathematics educational research is hindering the advancement of the field and communication across researchers.

In this paper, I lay out three indispensable components, namely positions, functions, and individualized repertoires (see Table 1), to which any research on learners' identities must attend to claim robustness. The three components were distilled from a broad literature review encompassing multiple theoretical approaches (Interested readers may consult El Chidiac (2018) for more details). After outlining the three components of learning identities next, I will illustrate their indispensability through a comparative case study of two women learning number theory by working with four other men in small groups over a semester. The learning identities of the two focal women, Bettie and Melissa, developed drastically in two different ways, which could not be explained without attending to the three aforementioned components.

Table 1: Three Components that Matter for Investigating Mathematics-learners' Identities

	Positions framed culturally or discursively	**Functions/goals**	**Individualized semiotic/behavioral repertoires**
Time relevance	Current behaviors/acts	Near and far future	Past experiences
Theoretical approaches	Social, cultural, discourse and pragmatics	Social and cognitive	Psychoanalytic, psychology and socio-historical

Positions

Positions are *behaviors and acts framed culturally or discursively in a learning activity,* such as a solitary study, small-group work, whole-class discussion, and outside of school project. They can be behaviors performed by students, such as searching the internet for an answer to a mathematical problem. They can also be acts done to participants, such as assigning a grade to a student's work. The component of position is concerned with students' behaviors in the *hic et nunc* of a learning activity. The meanings of behaviors and acts are mediated by cultural and discursive frames, commonly called storylines (Davis & Harre, 1990), figured worlds (Holland, Lachicotte, Skinner, & Cain, 1998), community of practice (Wenger, 1998), big 'D' discourses (Gee, 1999), and meta-rules (Sfard, 2007).

Functions/Goals

I define a *function as a goal set to be achieved or a state unintentionally achieved by enacting a position in a cultural activity*. Functions are concerned about the effect that a position can have beyond the *hic et nunc* of its animation. They may pertain to different timescales; they can be or aim at being achieved immediately, shortly or in a while. For example, the function of explaining mathematical ideas to peers can be immediate, as in improving the shared understanding of group members, short-term, as in preparing for the exam by testing one's own mathematical understanding with peers, or long-term, as in rehearsing being a teacher for a future career. The relationship between functions and learners' identities have been established in the work of Martin (2000), Nasir (2002), and Sfard & Prusak (2005). What we thrive to become in the near or far futures are part of who we are now.

Individualized Semiotic/Behavioral Repertoires

The component of individualized repertoires attends to students' histories that bear on their animation of positions and functions. It covers the *frames of mind and entrenched habits that students have individualized through their life experiences*. People construct and negotiate their understandings of self, others and the world through the mediation of semiotic repertoires, such as metaphors (Lakoff & Johnson, 1980) and *l'imaginaire* (Lacan, 2006), which they have made their own over their life experiences. People also individualize embodied habits of dealing with and negotiating different ecologies (Bourdieu, 1990). Individualization is the process by which *what we saw, heard, knew, and did in the social realms of our past become who we are now* (Copjec, 2015; de Certeau, 2011; Erickson, 2004; Martin, 2000). What count for this component are the repertoires, not as set socially, linguistically, and culturally, but rather as idiosyncratically processed by participants.

Methods

Activity and Focal Participants

Data reported was collected from a semester-long number theory class at a Northern California University. The class met for one hour ten minutes twice a week. Professor Hoffmann, the instructor, used group work as the predominant form of teaching in class. He gave students worksheets of theorems and problems to solve in class with their groups. A weekly homework, consisting of selected problems from the worksheets, was assigned to be submitted individually. It was assessed and returned to students. Students took a midterm and final exams. For the purpose of illustrating the centrality of the aforementioned three components of identity (see Table 1), I report a comparative case study (Yin, 2013) of two focal students: Melissa and Bettie. Both of them participated with four men in classroom groupwork and reported low self-efficacy at the start of the class. Melissa was majoring in Mathematics for teaching and Bettie in

Mathematics for liberal arts.

Data Sources

Starting from the second week of class, all group sessions of participating groups were *videotaped*. Participants submitted *individual memos* after every group session and took three types of interviews. First, they participated in *early individual interviews*, where they were asked about their motivations for majoring in mathematics, feelings about the mathematics discipline, history with mathematics classes in high school and college, experience with group work in classes, and first impressions about current group members. They also participated in *SCNI interviews* (Stimulated Construction of Narratives about Interactions; see El Chidiac, 2017). In the SCNI interviews, participants watched a video of their recent group session and commented on their social interactions. The SCNI interviews were conducted individually and within twenty four hours of the end of class. Lastly, they participated in *individual interviews by the end of the semester*, where they were asked about their understanding of number theory, confidence in the material, the changes throughout the semester in their learning methods and behavior in group work, and the roles their groupmates tended to play.

Data Analysis

I tracked the enactment of ten active and passive positions for each participating student through the videotaped group sessions (for details see El Chidiac, 2018, pp.34–35). Then I documented all functions and individualized repertoires pertaining to these positions as reported by participants in their interviews.

Illustrative Comparative Case

Melissa's and Bettie's Positions

Melissa and Bettie lacked confidence in their abilities to construct and understand mathematical proofs, a pre-requisite skill for the course. In classroom, they worked with peers whom they considered "smarter" than them. However, their modes of participation in group work differed, mainly with respect to two positions (see Figure 1). While Bettie sustained the same participation pattern throughout the course, Melissa enacted active participation in the second and thrid months of the course. Surprisingly, the participation patterns in classroom groupwork did not explain Bettie's and Melissa's learning gain. Despite her active participation in groupwork, Melissa's scores were low (45%) on the midterm and continued to drop (20%) on the final exam. Contrary to Melissa, Bettie improved her scores from the midterm (53%) to the final (61%) exams. Additionally, Bettie invested in her learning by regularly joining a study group outside classroom, which Melissa joined only once.

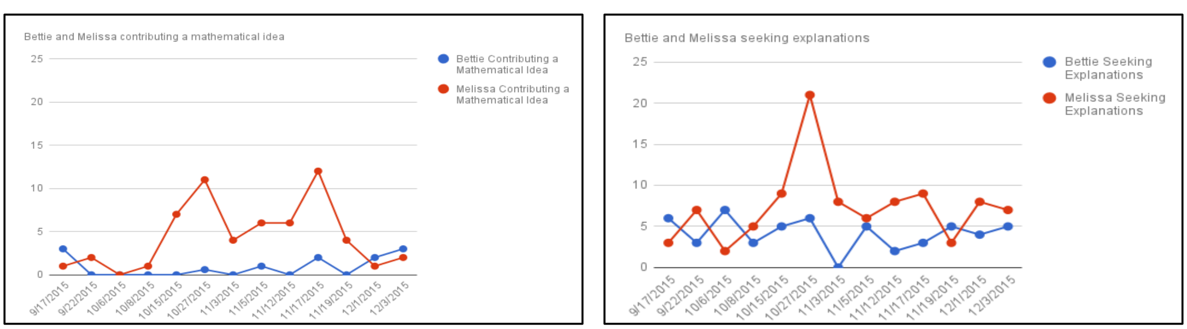

Figure 1: The number of instances when Bettie (Blue) and Melissa (Red) contributed mathematical ideas to group (left graph) and sought mathematical explanations from

groupmates (right graph) in the group sessions of classes attended by both of them.

Melissa's and Bettie's Functions/Goals

Melissa and Bettie set two opposite functions of their participations in classroom group work. Melissa animated her positions in groupwork to stimulate her groupmates' brains instead of hers, whereas Bettie intended to enhance her mathematical understanding. The following reported evidence was typical.

Melissa remained a passive learner despite her active participation in classroom group work. During her early interview (on 9/17), Melissa described her participation in classroom groupwork as follows.

> Melissa: more than trying to figure out what's going on I'm trying to help my friends who know better . like give them my ideas of what I might be thinking to help them put put it together because once they put it together then they can explain to me what's going on. […] And so they [Tom, Robert and Emil] are kind of like the three main brains […] if they stop talking I just kind of like ask a question to get their brains going again because I mean they know way more than I do.

On the contrary, Bettie primarily intended to foster her mathematical knowledge through her participation in classroom. During the SCNI interview on 10/15, Bettie commented on her participation in classroom groupwork as follows.

> Bettie: when I hear people [groupmates] talking and I don't understand I just zone them out because it confuses me more […] I just keep looking on my own. […] That's basically all I do when I'm in class. I just listen to what [my groupmates] are saying and look at the book . cause if I don't understand it then . when they're like talking […] I just zone people out . until I look at it myself because . otherwise it just confuses me more.

Melissa's and Bettie's Individualized Repertoires

Melissa invested in classroom groupwork (see Figure 1), while Bettie joined a study group outside classroom. Functions alone could not explain Bettie's and Melissa's differential investment. However, their individualized repertoires could.

Melissa was passionate about dancing yet decided to become a middle-school mathematics teacher. For Melissa, teaching was a long-term reliable career to provide for a living, whereas a dancing career would last only as long as her body is agile. In the exit interview on 12/02, she confessed that the multiple dance rehearsals did not leave her time to study number theory outside classroom. She thus focused on classroom to learn it.

On the contrary, based on her schooling experience, Bettie considered herself "really good at math [arithmetic] and sucks at everything else" (Early interview on 9/22). Sustaining a positive self-concept in mathematics was existential for her. After month through the course, Bettie realized that her learning in classroom was not sufficient to improve her scores on the homework. Wanting to replicate a past tutoring experience that helped her succeed the modern algebra course, Bettie asked a groupmate, Ted, to tutor her. Instead of providing one-on-one tutoring, Ted invited all groupmates to study together in the library. In the study group, Bettie had the opportunity to go over the classroom materials a second time with her group after reviewing them at home between the class and study group sessions.

Conclusion

The comparative case study of Melissa and Bettie, two undergraduate women majoring in mathematics, highlighted the insufficiency of attending solely to their positions in order to understand their learning trajectories. The analyses of the functions they set for their participation in groupwork and the individualized repertoires they actuated were necessary to explain their discrepant learning trajectories.

MATHEMATICAL IDENTITIES AND GENDERED INTERACTIONS IN AN 8TH GRADE CLASSROOM

Bailey Braaten
The Ohio State University
braaten.7@osu.edu

This research project examines how gendered interactions in an 8th grade mathematics classroom can influence students' mathematical identity formation. Microethnographic methods were used to collect and interpret the data within this study. Preliminary results of this study indicate that gendered interactions have an influence on female students' mathematical identity formation, particularly for those who have weak mathematical identities. This study has implications for understanding the social and cultural influence of gender on mathematical identity formation for female students.

Keywords: Classroom Discourse, Gender and Sexuality, Middle School Education

Introduction

As the science, technology, engineering, and mathematics (STEM) job market continues to grow at a rapid pace, especially jobs related computer science and mathematics, there is still a major divide between male and female participation in these jobs (U.S. Department of Labor, 2017; Fayer, Lacey, & Watson, 2017). A foundational aspect of students who pursue STEM majors is their experiences in middle and high school mathematics (Shapiro & Sax, 2011). Mathematics courses have been viewed as a critical filter for participation in STEM fields (Damarin, 2008), and a foundational time in deciding to continue mathematics studies occurs for students in 8th and 9th grade (Erchick, 2001). An essential component to how students relate to mathematics is based on students' mathematics experiences and mathematical identity (Bishop, 2012). If we are to better understand the rationale for the lack of female participation in STEM careers, particularly computer science and mathematics, it is crucial to understand female students' experience in mathematics in 8th and 9th grade, how their mathematical identities are constructed with in the classroom space, and how gendered interactions influence mathematical identity construction. This study proposes to examine how students' mathematical identities are constructed through gendered interactions in an 8th grade mathematics classroom.

Background

For the purposes of this study, *identity* is operationalized as a personal characteristic that is socially constructed through relationships and interactions that are bound by specific contexts and also informed by an individual's personal narratives (Anderson, 2007; Boaler, 2002; Bucholtz & Hall, 2005; Davies & Harre, 1990; Duff, 2002; Mendick, 2005; Nasir & de Royston, 2013; Solomon, Lawson & Croft, 2011). Following this definition of *identity*, *mathematical identity* is defined as a personal characteristic that is socially constructed through students' interactions and relationships that are bound by a mathematics context and informed by their own personal mathematical narratives (Anderson, 2007; Bishop, 2012; Boaler, 2002; Cobb, Gresalfi, & Hodge, 2009).

In this study, *gender* is operationalized as a socially constructed characteristic associated with individuals that is broader than male and female, and is also of consequence in mathematical identity construction (Damarin & Erchick, 2010). Particularly, gender can be examined using the theory of hegemonic masculinity, in which the culturally dominant form of masculinity devalues all other expressions of gender (Connell, 1997). According to Burton (2008), the epistemology of mathematics is masculine, white, and classed. Both the masculine epistemology of mathematics (Burton, 2008) and hegemonic masculinity (Connell, 1997) create an environment in many mathematics spaces that influence how students are able to construct their mathematical identities. Gender is examined through the social construction of the participant students within this study, who in most cases operationalize gender within a binary male-female structure.

While not all mathematics contexts are constrained to a classroom environment, the cases examined within this study are bound in particular to an 8^{th} grade mathematics classroom. Thus, this study attends to mathematical identities that students construct within the bounds of their 8^{th} grade mathematics classroom, and how gendered interactions play a mediating role in mathematical identity construction.

Research Design and Methods

This study examines a set of interactions from within the course of a two-year ethnographic study of students' mathematical identities over the course of 8^{th} and 9^{th} grade mathematics classes. In this study, gendered interactions during the 8^{th} grade year of mathematics six focal students were examined. Focal students were selected based on student interactions and participation during classroom observation, teacher perception of student mathematical achievement, and student mathematical narrative given within interviews. The six focal students were selected to represent a range of experiences within each of these criteria. In conducting this research, a microethnographic perspective was taken to analyze these interactions, and how they influence students' mathematical identities.

The location for this research project is an 8^{th} grade mathematic classroom in a large suburban school district in the Mid-Western United States. The data collected for this study were 50 classroom observations throughout the school year with field notes and video recordings of each classroom observation. In addition to the classroom observations, each focal student was interviewed twice during the school year, once during the fall semester and once during the spring semester, about their mathematical identities.

The collected data was analyzed using a coding scheme to identify when gender was a salient part of classroom interactions for the students, and when students were actively constructing their mathematical identities around these gendered interactions. Transcripts were generated for the selected interactions, and these transcripts were then analyzed further using Wortham and Reyes' (2015) narrative analysis framework.

Findings

Within the observations, several instances where gendered interactions intersected with students' mathematical identity construction were identified. During these interactions the female student responses were of particular interest, often times challenging gender norms or gendered expectations. The following excerpt exemplifies these types of gendered interactions. The students in this class were working on a project creating a poster that illustrates a linear relationship.

Richie: This is easy. (Pointing to the assignment instructions.)
Cayla: I can't draw.
Richie: You literally just have to do that (Pointing to the assignment instructions.) Just write little flowers and show growth.
Cayla: Just because I'm a girl doesn't mean I'm feminine and have to draw flowers on my paper.
Richie: Yeah, it does.
Kyle: No, it doesn't.
Cayla: No, I don't even like flowers.
Richie: Then draw a bicycle.
Cayla: What do bicycles have to do with slope and y-intercept?

In this interaction, Cayla interprets Richie's suggestion that she draws flowers as an implication of how a traditionally feminine person could represent their linear relationship. Cayla actively rejects this assertion from Richie, and is supported by a male classmate in this rejection of traditional femininity. In addition to this, she continues to assert her own mathematical identity in re-focusing the conversation on how Richie's next suggestion of using a bicycle is related to linear functions. In this example, Cayla has a strong mathematical identity that she is able to assert, as well as the confidence to disrupt gendered expectations.

Another example occurred when students were arranged in small groups for instruction. The teacher was working on small group instruction with Cayla, Pete, Ayman, James, Kyle, and Paris. In this classroom event, the group was reviewing how to simplify expressions using the properties of exponents. The teacher had several mathematical exercises projected onto the white board, at which point James and Pete immediately went to the board to begin writing their solutions to two of the problems, and were quickly joined by Ayman and Kyle. Cayla had been absent the previous day, but asked the teacher if she could go to the board and attempt a problem by saying "Can I go up there too? Or is this just for the boys?" Cayla is disrupting hegemonic masculinity by asserting her own place at the board with the boys. This particular event continued with Pete telling Paris that she needed to go to the board to solve a problem. Paris was instead solving the same problems on her own on her worksheet. When called out by Pete, Paris refuses to go to the board. Pete is wielding his hegemonic masculinity to police Paris' behavior of not going to the board. Paris' refusal is a disruption of the masculine epistemology of mathematics through rejecting the notion that participating in public displays of mathematical knowing is essential to mathematics.

The interactions examined illustrate how two female students demonstrate their own mathematical identities in different ways that work to disrupt hegemonic masculinity and the masculine epistemology of mathematics. The focus of this study is to examine instances such as these where female students disrupt hegemonic masculinity and the masculine epistemology of mathematics in asserting their own mathematical identities. These instances provide insight into the powerful work that female students engage in when disrupting social constructs, even in seemingly small moments of classroom interactions.

Conclusion

The implications of this study relate to a better understanding of female experiences in STEM majors and careers in which they have underrepresented (U.S. Department of Labor, Bureau of Labor Statistics, 2017). The experiences of young women developing their mathematical identities in environments where hegemonic masculinity and masculine epistemology are dominant cultural forces are important to examine. The moment to moment classroom interactions in which young women disrupt or attempt to disrupt these forces are critical to their mathematical identity development. Examining these moments allow for insight into how mathematical identity development may shape these female students' future choices to pursue majors and careers within STEM.

READING AND MATH GO SIDE-BY-SIDE: STUDENTS EXPLORE THE COMPLEXITIES BETWEEN TWO CORE DISCIPLINES

Gregory Beaudine
Michigan State University
gbb@msu.edu

Mathematics and reading have shared a long history in schooling, where both have regularly served as a core discipline. Despite the strong correlation researchers have observed between mathematics and reading, schooling has separated the disciplines into sterile spaces where mathematics is largely absent in reading spaces, and vice-versa. The text below explores the responses of middle school mathematics students as they are asked about their feelings toward mathematics, toward reading, and how reading and mathematics relate. The responses identify the importance of both disciplines, though reading was deemed more leisurely. Additionally, these students expressed a relationship between reading and mathematics that focuses on word problems, directions, and definitions.

Keywords: Middle School Education, Classroom Discourse, Instructional Activities and Practice, Affect, Emotion, Beliefs, and Attitudes

Against suggests either opposition or adjacent items. This project takes up the latter definition, to recognize the ways reading and mathematics relate to each other with regard to student learning and achievement (Grimm, 2008). Past research has demonstrated a strong correlation between reading and mathematics in early elementary school, and the achievement of students (e.g., Duncan et al., 2007; Grimm, 2008). Additionally, mathematics and reading are the two most tested subjects in public schooling (U.S. Congress, 2002, 2015), and both reading and mathematics are heavily utilized in other subject areas. The two disciplines could be viewed as sitting “against” one another, touching, related. It is in this sense that I view reading’s influence, or lack thereof, on mathematics to be a “new horizon,” worthy of exploration.

If it is accepted that “literacy involves the integration of listening, speaking, reading, writing, and critical thinking and includes the cultural knowledge that enables a speaker, writer, or reader to recognize and use language appropriate to different social situations” (Gibbons, 2009, p. 7), then mathematical literacy involves an individual’s focus on the same five components, through the lens of mathematics. In other words, learning to become mathematically literate includes learning to listen, speak, read, write, and think like a mathematician. The study, described below, explores a single question: What do middle school students believe about the relationship between mathematics and reading?

Literature

While much of the work around mathematical literacy tends to focus on discourse and writing (e.g., Herbel-Eisenmann et al., 2015; Sigley & Wilkinson, 2015; Moschkovich & Zahner, 2018), a subset of this work attends to reading in mathematics. This study sits as a single component of a larger line of research that aims to improve upon the ways students read text in mathematics spaces. Reading in mathematics, as identified by Adams (2003), pertained mathematical text that utilized numerals, words, and other symbols to communicate mathematical ideas. A decade of research expanded this idea to include graphical representations within the mathematics texts that readers must also interpret (Hillman, 2014). While it appears that mathematicians read a variety of styles of written text, “American students do little reading of published mathematics texts, either in or out of class” (Adams, Pegg, & Case, 2015, p. 499).

Recent years have brought several studies that relate to mathematical reading (e.g., Doerr & Temple, 2016; Shepherd & van de Sande, 2014). These studies tend to focus on the expert in the room, whether it be a professor of mathematical or a K-12 classroom teacher, and rarely attend to the reading done by students of mathematics. While Shepherd and van de Sande did explore the ways graduate and undergraduate students read mathematics, “the perspective of [elementary and secondary] students are recognized as valuable, but not often queried or considered” (Zheng, Arada, Niiya, & Warschauer, 2014, p. 279), and yet we know little about the ways K-12 students read mathematical texts, or the relationship students see between reading and mathematics.

Method

Ten middle school students were kind enough to sit through a “deliberately nonstandardized” (Ginsberg, 1997) clinical-style interview, designed to explore how these participants view reading, mathematics, and reading in mathematics. The semi-structured nature of the interview allowed the researcher flexibility to shift the line of discussion when the opportunity arose. The students were each asked three questions: How do you feel about mathematics? How do you feel about reading? What role do you see reading play within mathematics?

The ten students who participated in this study range from 6th grade to 8th grade, and were all enrolled in either 8th Grade Mathematics or Algebra 1 (Table 1). These students shared a range of opinions about mathematics and reading, which will be explored below. All ten students attend the same suburban middle school, and they were selected from four separate classes – two 8th Grade Mathematics and two Algebra 1 classrooms.

Table 1: Study Participants

Mark	M	6
Sammy	F	8
Caroline	F	8
Ophelia	F	8
Zeta	F	8
Zahera	F	8

The one-on-one interviews were video recorded and averaged 27 minutes. Each interview was completed in two segments. The first consisted of a read- and work-aloud, where participants engaged with standardized test questions. The second section explored the participants’ feelings toward reading, mathematics, and reading in mathematics. The interview transcripts and videos were paired and examined through a discourse analysis lens, an appropriate lens for one interested in the “examination of speech, writing, and other signs” (Wortham & Reyes, 2015, p. 01). In this process, the top three words most often spoken within each question (Table 2) were revisited and themes were established from the ways the participants used these words.

Table 2: Top 3 Words

	First	Second	Third
How do you feel about mathematics?	math (15) mathematics (4)	like (16) liked (1)	understand (9) understanding (2)
How do you feel about reading?	reading (17) read (8)	like (18) unlike (1)	really (11)
What role do you see reading play within mathematics?	reading (16) read (10)	math (16) mathematics (2)	like (18)

Results

The words above are not surprising, considering the participants were asked about reading and mathematics, and each showed up over 35 times across all ten interviews. The intrigue stems from the ways words were used, and by whom. The remainder of this paper will focus on three root-words – like, really, and understand – and the phrases in which they were used.

Like

After *reading* and *math*, *like* was the most commonly used root with over 50 usages across all three interviews. Five students said "I like math" or "I really like math." Zeta repeated this phrase three times in four sentences, then proceeded to explain "I don't like doing problems … [but] I like math, I like discussing about it." When asked about reading, Zeta stated "I like it very much and it's awesome." Awesome, an adjective not used by any student about mathematics. Participants also stated they "enjoy" or "love" reading, without a qualifying statement, whereas the highest praise offered about mathematics was "I really like math" (Eric) or "I enjoy it. It's okay" (Melanie).

When discussing reading in mathematics, *like* was most commonly used to direct attention to something. Caroline, for example, suggested "If you don't know how to read, then you can't really do math because math is about problem solving and questions like these [word problems]." This is an interesting comment when compared to Zeta, who suggested "I like story problems but I feel like story problems are way different from math." In one interview, word problems qualify as reading mathematics, in another, they do not.

Really

In 19 moments, *really* was used by these participants to accentuate their beliefs. Two of the 19 came in the mathematics discussion, where Eric "really likes mathematics" and Ophelia must "really try" understand her mathematics work. When discussing reading, the participants collectively used *really* 11 times. In most cases, these participants did so to describe the kind of text they enjoy reading (e.g., "I really like graphic novels." or "I really like fantasy."). Mark described struggles with reading math problems, stating that they get "confusing if it gives you things you really don't need." Zahera "really loves reading" and Sammy likes reading because "it's really easy and really fast."

When discussing the relationship between reading and mathematics, these participants used *really* four times, to make two completely different claims. Melanie believes "reading is a really big part of Math," a perspective echoed by Caroline who said reading is important, because without reading "you can't really solve the problem and you can't understand what the problem means." Junhai and Mark both recognize minor roles for reading in mathematics, but when asked about a relationship between reading and mathematics, they both close with "not really."

Understand

Understand or *understanding* was used a total of 19 times across the three questions, with 11 coming when participants were talking about their feelings of mathematics. In this mathematics conversation, Ophelia used nine of them. She suggested that mathematics is good and "fun when you understand … [math is] not something that I can just look at and just understand … [but] it's something that I can understand if I really try or want to." Saed reported that reading helps him understand the mathematics, a perspective shared by other participants. Junhai, for example, suggested "if I was better at reading, I might understand the problem better." Across all discussion, the idea of understanding was only applied to mathematics. None of the participants discussed a need to understand reading.

Discussion

The project and results described above sit as a small part of a larger line of inquiry. The pursuit outlined above was to gather information about how students view the relationship between reading and mathematics. Specifically, these students spoke of reading and mathematics quite differently. Reading was identified to be more leisurely and enjoyable for the participants. Mathematics, conversely, seemed to be more about a search for understanding – a goal helped by better reading abilities.

When exploring the perceived relationship between reading and mathematics, the responses were really mixed. The participants in this study have differing views as to what extent reading plays a role in mathematics, if at all. Broadly speaking, researchers have discussed the variety of forms used by mathematical texts (e.g., Adams, 2003; Hillman, 2014). These ten students, when asked about the role of reading in mathematics, largely focused on written prose (e.g., word problems, definitions, and directions) as opposed to the symbolic and graphical representations found in equations, graphs, and diagrams.

The qualitative data used for this study stems from three questions within a 30-minute interview exploring the mathematical reading of middle school students. The student responses came toward the end of their session, just before they went to, or returned to, class. Even with the limited time, their responses suggest a promising line of study, relating to the way students view reading in mathematics. With a better understanding of what students view as reading and an added exploration on how reading is instructed within mathematics spaces, we might find more effective strategies for teaching middle school mathematics.

THE USE OF PARADOXES FOR UNDERSTANDING AND REVEALING STUDENTS' MISCONCEPTIONS IN PROBABILITY AND STATISTICS

Vladislav Kokushkin
Virginia Tech
vladkok@vt.edu

Jesse L.M. Wilkins
Virginia Tech
wilkins@vt.edu

Keywords: Probability, Undergraduate-Level Mathematics.

There is a substantial body of research confirming that students often have misconceptions about probability (Anway & Bennett, 2004; Kahneman, Slovic & Tversky, 1982; Konold, 1991). These misconceptions impede students' ability to judge in situations of uncertainty and master fundamental concepts related to probability. Paradoxes may play an important role in the teaching and learning of probability and statistics (Shaughnessy, 1997; Movshovitz-Hadar & Hadaas, 1990; Wilensky, 1995; Sowey, 2001; Leviatan, 2002; Klymchuk & Kachapova, 2012). The purpose of this study is to provide evidence that carefully selected paradoxes can help to understand and reveal undergraduate students' probabilistic and statistical misconceptions. More specifically, we address the following research question: *How can classical probabilistic paradoxes be used for revealing and understanding undergraduate students' misconceptions in probability and statistics?*

Tversky and Kahneman (1982) described different heuristics that are employed to assess students' thinking under uncertainty. The basic assumption underlying this discussion is that a great deal of human judgement involving probability is based on heuristics. In this study, we focus on the representativeness heuristic, referring to students' tendency to erroneously think that samples which resemble the population distribution are more probable than samples which do not. This approach to the judgement of probability leads to numerous misconceptions, such as "insensitivity to prior probability of outcomes," "insensitivity to sample size," "misconceptions of chance," "insensitivity to predictability," "illusion of validity," and "misconceptions of regression" (1982, 4-9).

The study involved four undergraduate students of different majors and ages. Three of the students were first-year females and one a senior male. The rationale for involving undergraduate students is that they are familiar enough with the concept of probability and have some knowledge of making judgments under uncertainty, but often have numerous misconceptions in probability and statistics. The participants were involved in a semi-structured clinical interview, lasting approximately 60 minutes. Participants were presented with four probability tasks and asked to solve them. The four probability tasks each involved a different classical paradox: Galton's paradox, Simpson's paradox, the Monty Hall paradox, and the St. Petersburg paradox (for discussion of the paradoxes see Grimmett & Stirzaker [2004] and Székely [1986]).

The findings of this study support the hypothesis that classical paradoxes can play an important role in revealing and understanding students' different misconceptions in probability and statistics. By engaging with the four paradoxes, the students demonstrated the effect of three misconceptions associated with their judgement under uncertainty. More specifically, the Galton's and the Monty Hall paradoxes revealed an "insensitivity to prior probability of outcomes"; Simpson's paradox turned out to be useful for understanding students' "insensitivity to sample size"; and the St. Petersburg paradox revealed the gambler's fallacy in students' reasoning (which is an indication of a "misconception of chance"). Future research could examine other classical paradoxes that may reveal additional misconceptions within different heuristics and how these too could be useful for instruction of probabilistic thinking.

Keywords: Attitudes toward mathematics, Undergraduate-Level Mathematics, Mathematical competencies

Low academic performance and negative attitudes toward mathematics are persistent problems among students in the first undergraduate semesters, and this leads to a deficient understanding of problems in their areas of study and inadequate application of solution strategies. In this investigation we evaluated the impact of adaptive learning strategy through an Adaptive Hypermedia System (AHS) in the development of three mathematical competencies: use of Symbolic Language, to model mathematical problems and to solve problems through mathematical reasoning. In addition, we measured the impact on attitudes toward mathematics and toward computer-taught mathematics of the first semester students on a private university in Mexico. Through a quasi-experimental design with two groups, we tried to answer the questions: What is the impact of an AHS in the mathematical competencies' development, what is the impact in the attitudes toward mathematics and what is the impact in attitudes toward computer-taught mathematics? To measure mathematical competencies, a pretest-posttest were applied in both control and experimental groups (158 students). For measuring attitudes, a modified version of the Ursini, Sánchez, & Orendain, (2004) scale was used. For the statistical analysis, we used the U-Mann-Whitney test.

The analysis of the pretest-posttest showed that the experimental group exposed to the use of AHD during the course achieved significantly higher performance than the control group in the competence *modeling situations through the appropriate use of mathematical expressions*. However, the levels reached in the competencies *to solve problems through mathematical reasoning* and *use of symbolic language* were statistically equivalent in both groups. About changes in attitudes toward mathematics, results showed that although both groups initially had similarity in attitudes toward mathematics, at the end of treatment, the experimental group showed a positive difference with respect to the control group.

Among the most important findings, it was observed that using AHS had a positive impact on the development of mathematical competencies as well as attitudes toward mathematics. However, the impact on attitudes towards mathematics taught by computer was slightly negative. It is necessary to continue investigating the effect of the AHS in the teaching-learning of mathematics in order to reinforce these findings.

AFFORDANCES OF CONNECTING MATHEMATICAL REPRESENTATIONS IN COMPUTATIONAL SETTINGS

Sylvia Valdés-Fernández
Oregon State University
valdesfs@oregonstate.edu

José Fernández
Oregon State University
fernanj2@oregonstate.edu

Elise Lockwood
Oregon State University
elise.lockwood@oregonstate.edu

Constructing, interpreting, and connecting various mathematical representations is an important mathematical practice, as it can help students develop mathematical conceptions. We present findings from a study in which a pair of students solved combinatorics problems in a computational setting using Python programming. We present a case of the students' use of representations in this setting, highlighting ways in which the computational setting offered unique opportunities for connections among multiple representations.

Keywords: Using Representations; Undergraduate-level Mathematics, Technology

Introduction and Motivation

The notion of computational thinking (CT), a way of thinking that one uses to formulate a problem in such a way that a computer could effectively carry it out (Wing, 2014), has gained prominence among computer scientists and STEM educators. We present results from a study in which students solved "counting" problems using Python programming to explore such problems. We focus on ways in which students engaged in computational thinking to develop and make connections among mathematical representations. Students often have partial understandings of concepts, so connecting multiple representations allows them to develop more complete mathematical conceptions (Greeno & Hall, 1997). Thus connecting representations is highly valued as a means for students to deepen their understanding (eg. Pape & Tchoshanov, 2001; Stein, Engle, Smith, & Hughes, 2008). We address the following research question: *In what ways can representations that students develop and use in a computational setting help them deepen their understanding of combinatorial concepts?*

Methods

Students worked at a computer together and coded in the the PyCharm environment on tasks that covered a variety of counting problems. We asked the students to explain their work and predict the output of their code. We qualitatively coded the data for several types of mathematical representations, and analyzed the data for observable student behaviors, such as verbal explanation, gazing, pointing and gesturing as evidence of a connection.

Results

We identified five representations: computer codes, outputs, lists, tree diagrams, and expressions. For example, one pair answered the question "*Write a program to list all possible outcomes of flipping a coin 7 times."* They related code output (Fig. 1) and a tree diagram (Fig. 2), saying, "this [tree diagram] is what we talked about with the third column [of output] like it's splitting into four." We explore how CT afforded such connections.

OPPORTUNITY TO LEARN: DIFFERENT TYPES OF TASKS AND MATHEMATICAL LITERACY

Jihyun Hwang
University of Iowa
jihyun-hwang@uiowa.edu

Yeajin Ham
University of Iowa
yeajin-ham@uiowa.edu

Keywords: Opportunity to learn, Mathematics tasks, Mathematical literacy, PISA 2012

The purpose of this exploratory research is to model the relationships among students' perceived opportunities to learn (OTLs; Carroll, 1963) with different types of tasks, students' perceived control, and students' mathematical literacy. Specifically, we examined how the OTLs facilitated with different mathematics tasks are related with mathematical literacy, and the role of perceived control in the relation between different task types and mathematical literacy.

We collected the PISA 2012 data of 1,649 Korean students. The structural equation modeling (SEM) approach was applied to the database using the R package *lavaan.survey* (Oberski, 2016). In the hypothesized model for the SEM analysis, latent variables representing four different types of tasks were considered: algebraic word problem, procedural tasks, pure mathematics reasoning, and applied mathematics reasoning (see OECD, n.d., pp. 37–41). OTLs with each type of tasks were measured through students' responses to the survey questions – how often they have encountered each type of tasks in their mathematics lessons and in the tests. We considered other two latent variables in the model: Internal perceived control (e.g. 'whether or not I do well in mathematics is completely up to me') and external perceived control (e.g. 'if I had different teachers, I would try harder in mathematics'). Using all these 6 latent variables, we investigated the relationships among OTLs with different tasks, perceived control, and mathematical literacy.

The results showed that the four types of tasks had different relationships with mathematical literacy. Specifically, for the three task types (algebraic word problems, procedural tasks, and pure mathematics reasoning tasks), the more frequent engagement with those tasks were linked with higher mathematical literacy score (β's are approximately 0.1, $p<0.05$). Contrarily, in the case the applied mathematical reasoning tasks, the more frequent engagement was linked with students' mathematical literacy scores ($\beta = 0.16$, $p < 0.01$). This implies not only that all of the four different types had varying relationships with mathematical literacy, but also that applied and pure mathematics reasoning tasks have different relations with mathematics literacy, even though the both are categorized as higher-order thinking. This could be because of differences between cognitive processes required to solve pure and applied mathematics reasonings tasks.

The results also showed that OTLs with the procedural tasks were likely to increase mathematical literacy indirectly through internal perceived control ($\beta = 0.103$, $p<0.001$). Engaging in the applied reasoning tasks is positively related to external perceived control ($\beta = 0.08$, $p<0.1$), but no relationship was observed between mathematical literacy and external perceived control. Considering cognitive demands of tasks, we speculate that students are likely to have repeated succeeds to solve procedural tasks, which may contribute to shaping internal perceived control.

LATINX LEARNERS AND TRANSLANGUAGING IN A MATHEMATICS CLUB

Craig Willey
Indiana Univ.-Purdue Univ. Indianapolis
cjwilley@iupui.edu

Hector Morales, Jr.
Northeastern Illinois University
hmorale3@neiu.edu

Keywords: Latinx Bilinguals, Translanguaging, After-school, Activity Systems

This paper reports on a study designed to showcase Latinx bilingual children's linguistic and cultural resources for learning mathematics in an after-school mathematics club. Specifically, we examine the design of the activity system (Engstrom, 1999) and social interactions therein through a translanguaging perspective in which students leverage their language and culture to engage in mathematical learning. Our primary objective is to highlight some of the triumphs and struggles of bilingual children as they expand communicative practices and mathematical resources via interactions with facilitators and communication with a math wizard, *El Maga*.

Theoretical Underpinning and Context of Study

Our research was conducted in an after-school club in a large, urban context with a school population was 99.4% Latinx and 68% English learners. Sociocultural theory guided the design of the club, which was adapted after *The Fifth Dimension* (Cole, 2006) and *La Clase Mágic*a (Vásquez, 2003), and aimed to provide Latinx students experiences doing nonremedial math in an environment that challenged traditional classroom experiences through bi-literacy. We draw on translanguaging to reconceptualize bilingualism as a set of liberating and empowering communicative practices, capable of transforming learning, that goes beyond students' transition to the dominate school language (Cenoz, 2017; García, 2017; MacSwan, 2017).

Thirteen students, five undergraduate Latinx facilitators, four graduate student facilitators, and five parents participated. Ethnographic methods were employed to capture the meaning participants made of engaging in mathematical activity through a translanguaging approach. Twenty sessions were video-recorded. Facilitators' descriptive and reflective fieldnotes captured participants' interactions as well as student work and correspondence with *El Maga*.

Findings and Conclusions

First, language resources (e.g., L1) were observed to be used automatically. A pedagogy intentionally designed to build L1 to support L2 was needed. Second, asking students who were already used to the exclusion of their home language in school, to reappropriate features of their home language in an after-school setting proved challenging and took time. In addition, bilingual facilitators often expressed discomfort with doing math in Spanish. Persistence and explicit support from project leaders were key to maximizing opportunities for children to use Spanish. We also found that when activities in the after-school involved parents and community, L1 was more readily used by students and reclaimed for academic purposes.

The combination of foregrounding Spanish and incorporating families had a direct impact on how mathematical norms are socially (re)constructed, and ultimately how bilingual Latinxs see themselves as competent math learners. Furthermore, a consistent effort to redefine the role of Spanish in mathematical activity is critical to easing the discomfort, or unnaturalness, that has been built up historically and serves to cast math as something to be done in English only.

ADDRESSING THE MATH ANXIETY OF A STUDENT WITH A LEARNING DISABILITY DOING ALGEBRA

Casey Hord
University of Cincinnati
casey.hord@uc.edu

Anna F. DeJarnette
University of Cincinnati
anna.dejarnette@uc.edu

Keywords: Learning Disabilities, Math Anxiety, Algebra, Gestures, Strategic Questioning

To access many post-secondary educational and occupational opportunities, students with learning disabilities (LD) have to succeed in gatekeeper mathematics courses such as Algebra I (Achieve, 2015; Ysseldyke et al., 2004). While students with LD are often quite capable with academics at this level, these students often experience difficulties with memory and processing (e.g., working memory) that can contribute to difficulties with higher level mathematics (Marita & Hord, 2017; Swanson-Beebe Frankenberger, 2004). Math anxiety (i.e., a detrimental, emotional response to mathematics which can have a negative effect on mathematical performance) is a common challenge facing many students with LD and can exacerbate these students' issues with working memory (i.e., the processing, storing, and integration of multiple pieces of information) (Ashcraft & Krause, 2007; Baddeley, 2003; Nelson & Harwood, 2011).

Researchers have implemented interventions involving strategic use of visual representations—often in the form of gestures or diagrams—to support students' working memory as they engaged in mathematics that was likely to present challenges related to working memory (e.g., Hord et al., 2016; van Garderen, 2007). The use of these visuals can help students with LD to offload information from short-term memory (e.g., storing information in visuals), allowing students to focus attentional resources on critical thinking (Risko & Dunn, 2010; Xin, Jitendra, & Deatline-Buchman, 2005). In an exploratory study, Hord and colleagues (2018) described how a teacher addressed the needs of a student with LD and a high level of math anxiety; the teacher provided a combination of visual representations and emotional support at key moments of challenge while still pushing the student toward higher levels of understanding.

To further explore this topic, the researchers in this study conducted a qualitative case study of ten sessions of a tutor working on Algebra I content in a one-on-one setting with a student with a LD with high levels of math anxiety. His math anxiety was described in his school records (e.g., concerns of his father about his son's anxiety limiting his academic performance) and demonstrated by the student during tutoring sessions (e.g., frequent comments about his worries about finishing his work on time and avoidance behaviors such as changing the conversation to topics unrelated to the task at hand when he started to struggle with math). The tutor worked with the student on Algebra I topics such as systems of equations and comparing the slopes of two lines. To gauge the level of challenge she could present to the student, the tutor carefully considered the level of rapport and trust she had built with the student while monitoring the student's signs of fluctuating levels of math anxiety, current mathematical knowledge, and potential difficulties with working memory (Hackenberg, 2010; Hord et al., 2018). This poster will summarize our analysis of the interactions between the tutor's perceptions of the student's anxiety, the tutor's decisions about how to support the student, and the student's progress towards communicating his understanding verbally and in writing.

PRESERVICE TEACHER ANXIETY: A CROSS-CULTURAL STUDY

Heidi B. Hansen
Bemidji State University
hhansen@bemidjistate.edu

Keywords: Teacher Education-Preservice; Affect, Emotion, Beliefs and Attitudes

The Study: Examining Anxiety Differences Across University Type

Mathematics anxiety has been studied in a wide variety of settings (Dowker, Sarkar, & Looi, 2016), but not necessarily across cultural boundaries in preservice teachers. To answer the question about whether differences exist in preservice teacher anxiety levels among different types of universities in the US and abroad, this small-scale exploratory study examined students at three universities: one US public, one US private, and one Scandinavian.

The Research Questions

The questions the author was attempting to answer with colleagues at the three universities were as follows:

- To what extent do preservice teachers at public, private, and foreign universities differ with respect to their levels of math anxiety?
- To what extent does preservice teachers' math anxiety correlate with their skill levels in mathematics, and is there a difference among the university types?
- To what extent are the variables, age, gender, past mathematics experience, and grade level teaching preference related to math anxiety in the different universities?

The Tools and Subjects

The author selected three instruments: 1) a demographic survey to identify possible factors related to the students' anxiety level, such as age, gender, math background, desired grade level for teaching, and year in college; 2) the 9 question Abbreviated Math Anxiety Scale (AMAS) designed and validated by Hopko and colleagues (Hopko, Mahadevan, Bare, & Hunt, 2003); and 3) a 15 question math quiz designed to assess math skill level (Johnson & Kuennen, 2006).

Students from three small universities (one public, one private and one foreign) were studied. An $n = 97$ was obtained from the preservice teaching courses. Students had no significant pedagogy background. Some had taken a liberal education or problem-solving course. The participants numbered 21 males and 76 females.

The Results

Results as tested by ANOVA indicated no difference among the three university populations in math anxiety levels as measured by the AMAS. Math skill levels were found to be higher at the private university. There was a significant negative correlation between math anxiety and quiz scores, controlling for math background and grade level preference ($r = -0.329$, $p < 0.05$). Without controlling for any variable, quiz score correlated negatively with anxiety score (Spearman's Rho = -0.315, $p = 0.02$). Grade level preference was related to anxiety (Spearman's Rho = -0.259, $p = 0.010$): the higher the grade level preference, the lower the anxiety score. In a surprising finding, math background correlated negatively with grade level preference: the more math courses the students had taken in high school and college, the lower the grade level they preferred to teach. Gender and age were not significantly related to anxiety or skill level in this study.

Keywords: Affect, Emotion, Beliefs and Attitudes; High School Education; Instructional Activities and Practices

The purpose of this study is to investigate how ninth-grade students define what it means to be engaged with mathematics and the classroom factors they report as impacting their engagement. Student engagement has a strong influence on student achievement (Finn, 1993). Specifically, self-regulation of effort has shown to improve achievement with mathematics among high school students (León, J., Núñez, J. L., & Liew, 2015). Thus, it is important to understand the many different, and specific ways in which students come to be engaged in a classroom setting. However, teachers' or adults' perspectives on engagement likely different from students' perspectives. It is important to understand what mathematical engagement means to *students*. A premise underlying this work is that awareness of students' definitions of engagement can inform teaching practice in ways that can lead to higher engagement with mathematics among students. Two research questions guide this study: (1) How do high school students define being engaged with mathematics? (2) What classroom features to high school students report as impacting their engagement with mathematics?

Ninth-grade students (N = 39) were interviewed for this study. Interviewees were selected from surveys (N = 256) in which reported their typical levels of self-efficacy, interest, and other aspects of their engagement with mathematics. Interviewees represented various profiles in the sample, as determined by cluster analysis. Interviewers were one-on-one interviews or in focus groups of two to four students. Open coding was used to develop themes to categorize student conceptions of engagement and the factors students reported that impacted their engagement.

Five themes were found for student definitions of engagement: understanding (cognitive), fun/interesting (affective), focused/attentive (cognitive), willpower & effort (behavioral), and relevancy (utility & relevance). Seven themes or features of the learning environment were found to have impacted student engagement in both positive and negative respects. These themes are: teaching style, understanding (cognitive), peer support (social), math topic, type of activity, sleep/rest and attentiveness, and competition (performance goals).

This study will help teachers gain an understanding of how students view what it means to be engaged in mathematics and the features of the mathematics classroom that impact their engagement. These findings provide insight to help teachers develop and facilitate classrooms in which there is higher student engagement.

STUDENTS' PERCEPTIONS OF FEEDBACK IN UNDERGRADUATE MATHEMATICS

Evan Czysz
Univ. of Northern Colorado
evan.czysz@unco.edu

Jenna Krieschel
Univ. of Northern Colorado
jenna.krieschel@unco.edu

Adam Ruff
Univ. of Northern Colorado
adam.ruff@unco.edu

Keywords: Affect, Emotion, Beliefs, and Attitudes; Undergraduate-Level Mathematics

To be beneficial to students, feedback should be accessible, robust, unbiased, unambiguous, encouraging, timely, iterative, and unique (Cardella, Diefes-Dux, Oliver & Verleger, 2009) or should answer the questions: "Where am I going?", "How am I going?", and "Where to next?" (Hattie & Timperley, 2007). However, there are a lot of unknowns about student use of feedback. Some feedback may come too late to help (To, 2016) or students may lack the knowledge of how to use the feedback on their own (Jonsson, 2012; Diefes-Dux, et al., 2012; Van der Kleij, Adie & Cumming, 2017). Which form of feedback is best and under what circumstances is relatively unknown (Jonsson, 2012).

Traditional feedback in a mathematics classroom is written feedback given by the instructor which is often ineffective and not beneficial for students (e.g. Attali, 2015; Harks, Rakoczy, Hattie, Besser, & Klieme, 2014; Hattie & Timperley, 2007). Students frequently find the feedback they receive to be unsatisfying (e.g. Nicol, 2010; Ferguson, 2009; Poulos & Mahony 2008; Landers & Reinholz, 2015) and instructors often give feedback that cannot be acted upon or vague and general comments, both of which are received poorly by students (Rodgers, Horvath, Jung, Fry & Diefes-Dux, 2015; Jonsson, 2012). Prior studies have focused on what feedback instructors should give. However, even if instructors give the kind of feedback that can help students bridge the learning gap, this feedback is useless if students are not motivated to use the feedback they are given.

We conducted hour-long semi-structured interviews with undergraduate students enrolled in Calculus I or Mathematics for Elementary Teachers. Interviews focused on students' perceptions of the feedback they received and their motivations for using or not using the feedback. Despite the diversity in student backgrounds and goals, the interviewees had very similar views on the aspects of feedback they preferred yet diverged on their motivations for making use of that feedback.

Using open coding and thematic analysis we found types of feedback that students are motivated to use. The students in our study clearly indicated a preference for feedback targeted at specific mistake points, positive feedback directed at specific components of the work, and feedback that provided hints as opposed to providing correct solutions. Together these findings indicate that these students are interested in feedback that helps them to correct their work and perform better on future assignments.

Even if students receive the type of feedback they prefer, they may not be motivated to use that feedback. For the students in this study grades and time were significant factors in students' choices around using feedback. Considerations about future use of the knowledge also seemed to play a role, especially for the two students planning careers in education. Our study considered only a small number of students. More research is needed in this area to better understand the mix of factors that determine if a student uses feedback that is provided.

INVESTIGATING PARTICIPATION AND MATHEMATICS IDENTITIES OF DEVELOPMENTAL MATHEMATICS STUDENTS

Francis Nzuki
Stockton University
francis.nzuki@stockton.edu

Keywords: Developmental Math, Mathematics Identity, Equity

One of the significant challenges facing higher education is narrowing the educational attainment gap between students who are academically prepared and those who are not. Although the intention of developmental education is to help support underprepared students in achieving academic success, there have been disagreements among researchers on the effectiveness of achieving this goal (Goudas & Boylan, 2012). On one hand, developmental mathematics has the capability of providing the impetus that can propel students to their overall academic success. On the other hand, the long road the students have to go through in completing mathematics requirements causes many to give up before they can finish the sequence of courses (Rosin, 2012).

This study examines how developmental students' general and mathematical experiences help to shape mathematical identities they develop and how these identities in turn hinder or enhance their successful participation in mathematics. Also examined are the factors that influence students' mathematics identities after taking a developmental mathematics course. To this end, the following research questions guided this study of first year students taking a developmental mathematics course at a mid-sized, urban public university:

1. What mathematics identities are held by students taking developmental mathematics?
2. What factors shape students' mathematical identities after taking a developmental mathematics course?

Data was collected using pre-post surveys and semi-structured interviews. The analysis reported here is based on the data from the survey instrument. The statements in the survey were grouped into five aspects of mathematics identity; self-concept, self-efficacy, motivation, and anxiety, and value of mathematics. Qualitative data from the open-ended items of the instrument was systematically analyzed using grounded theory to uncover patterns and trends in participants' responses while descriptive statistics was calculated for the quantifiable portions of the surveys. Items were compared both within surveys and across surveys to identify correlations and trends, as well as to support qualitative themes.

Analysis revealed that differences of the overall mean scores of all five aspects of mathematics identity between females and males were not statistically significant. Further, students scored the lowest on self-concept while the highest score was on their perception of the value or importance of math in their lives. As Klinger (2004) pointed out there are many students who do not particularly enjoy mathematics and report a disliking for the subject (negative affect), even though they still respect the utility and importance of math in their future lives and careers. Also, the study revealed that students' self-efficacy and self-concept increased significantly over time.

THE STORIES OF AFRICAN AMERICAN MALES LEARNING MATHEMATICS USING SOCIAL JUSTICE

Audrea Bankston
Georgia State University, Graduate Student
abanskton4@student.gsu.edu

Keywords: Teaching for Social Justice, Critical Race Theory, Stories, African American Males

Current discourse surrounding African American males in K-12 mathematics is often shown in a deficit manner (Martin, 2012). African American males are often placed in lower level mathematics courses or do not have access to rigorous courses such as Pre-Calculus (Thompson & Lewis, 2005). Since the discourse surrounding African American males is predominately negative, more research is needed to document mathematical success surrounding African American males (Jett, 2011).

Researchers such as Malloy (2009), Mathew (2009) and Tate (1995) suggest relating instruction to the lives of students. Teaching for social justice is one type of critical pedagogy that is related to students' lives and their communities (Gutstein & Peterson, 2013). Teaching mathematics for social justice allows African American students to engage in inquiry learning, work with peers and to discuss mathematics, which are characteristics that contribute to the success of learning mathematics (Malloy, 2009; Ladson Billings, 1995).

Modeling Gutstein's (2003) implementation of teaching for social justice with a Latino population, this proposed study will capture the experiences through stories of African American males engaged in learning mathematics for social justice situated in an informal setting. This proposed study intends to capture the stories using open-ended interviews as well as surveys recording their mathematical experiences before, during, and after the instruction.

A critical race theoretical perspective will guide this proposed study. This proposed study will focus on storytelling, which is one of the major tenets of critical race theory (Ladson-Billings & Tate, 1995). Stories from marginalized groups can give different perspectives from the stories of the oppressors (Tate, 1997; Delgado & Stefancic, 2012; Dixson & Rousseau, 2006). In this proposed study, allowing African American male students to share their stories will possibly provide insight into their 'realities' of learning mathematics using social justice.

Data from this proposed study will provide a viewpoint about the mathematical experiences of African American males using their own stories. In conducting this proposed study, academia and the public would have information documenting their experiences, which could encourage implementing a critical pedagogy such as teaching for social justice to teach mathematics to students of color.

GIRLS, LEADER, FOUNDER: INFLUENCES OF AN AFTERSCHOOL STEM PROGRAM FOR GIRLS

Sue Ellen Richardson
Purdue University
richa114@purdue.edu

Lili Zhou
Purdue University
zhou756@purdue.edu

Girls begin to lose interest and confidence in STEM fields in middle and high school, even though they perform as well as boys (Hill, Corbett & Rose, 2010). Research suggests that informal learning programs can provide female role models, hands-on activities, collaborative learning, and single-sex environments can help girls build identities and confidence in STEM fields. Many previous studies used quantitative instruments to measure girls' interest, engagement, and confidence in STEM fields; fewer studies utilize participants' voices to understand these attributes. Extant research has focused on girls' interest or identity during STEM programs or post-course or career selection, but less often on how the informal STEM learning shapes their life experiences in the long term. Even though the number of girls who study STEM in K-12 schools is increasing, the number of women who become scientists and engineers is not increasing at the expected rate. Many women who earned STEM degrees either did not pursue a career in STEM fields or left STEM fields early in their career. Therefore, understanding retention issues is critical for women's participation in STEM fields.

The mission of the *Girls Excelling in Math and Science* (*GEMS*) program is to increase girls' interest in STEM by providing integrated activities that engage girls in the fun and wonder of these fields. In this study, participants' narrative descriptions of their experiences in *GEMS* were used to understand the long-term impact of this informal learning programs. Through understanding participants' (i.e., founder, leader and girls) stories, we expected to learn more about how the earlier STEM experiences impact females later career and life choice. The research questions include:

1. How do *GEMS* participants remember and describe their experiences? In what ways did participation in *GEMS* shape their personal and professional experiences?
2. What are the perceptions of the *GEMS* founder and a leader about their experiences in developing and implementing the program?

Because the purpose of this study is to understand participants' experiences, our framework includes Dewey's (1938, 1998) *experience* construct, particularly *continuity*, which indicates that a current experience is influenced by past experiences and will influence future experiences. We also used Lave and Wenger's (1991) Community of Practice framework to understand participants' experiences from a community perspective.

We used narrative inquiry as both phenomena under study and method of study to understand the general construct of continuity in our participants' lives and personal experiences (Clandinin & Connelly, 2000). Original *GEMS* participants, a leader, and the founder completed questionnaires about their experiences with *GEMS* clubs. Some participants, the leader, and founder also completed semi-structured interviews. Initial narrative analysis of the founder's interviews, indicate that, although the founder's original motivation for starting *GEMS* was from a mom perspective, her story indicated that after twenty years of running *GEMS*, her role has grown far beyond a mom: she has integrated roles as a teacher, an educator, a STEM leader, and

most importantly to her, an advocate for girls' learning and empowerment. The findings will be utilized to comprehensively improve the strength of *GEMS* and expand learning approaches in an effort to scale-up STEM learning participation for girls.

Examining the Trajectories of Black Mathematics Teachers: Learning From the Past, Drawing on the Present, and Defining Goals for the Future is a three year-long research study funded by the National Science Foundation. Our study was designed to reflect on the dearth of Black mathematics teachers, including problems with recruiting and retaining Black mathematics teachers. The research study mitigates some of the oversights in the history of mathematics education. The first phase of the study was a large-scale survey of more than 500 currently practicing Black mathematics teachers. Simultaneously, the research team began conducting oral histories of retired Black mathematics teachers. In the second phase of the project, there will be focus group with currently practicing Black mathematics teachers. Ultimately, the objective of the research is to leverage the epistemological wealth of Black teachers, particularly through an historical lens, to guide contemporaneous teacher education policy and practice. This paper focuses on preliminary findings from the oral histories part of this multifaceted research study.

Objectives

Examining the Trajectories of Black Mathematics Teachers: Learning From the Past, Drawing on the Present, and Defining Goals for the Future is a three year-long research study funded by the National Science Foundation. Our study was designed to reflect on the dearth of Black mathematics teachers, including problems with recruiting and retaining Black mathematics teachers. The research study mitigates some of the oversights in the history of mathematics education. The first phase of the study was a large-scale survey of more than 500 currently practicing Black mathematics teachers. This paper focuses on preliminary findings from the oral histories part of this multifaceted research study.

Education theorist Popkewitz (1987) noted that what is *not included* in the history of education is just as telling as what gets to be told. Toward the centering of race, Milner (2006) offers the charge that educators and researchers should look to "Black teachers' experiences and success both pre- and post-desegregation for insights about how all teachers can deepen and broaden their knowledge and understanding to better meet the needs and situations of students at present, particularly among Black students" (p. 90).

Henry (2006) highlighted the powerful nature of oral history in collecting the stories of marginalized groups, as this methodology honors the generative power of spoken word, which has been noted as central to Black peoples' collective way of knowing. We argue that our mixed methods research study contributes to the Critical Race Theory (CRT) literature through its linkage of the historical counternarratives of retired Black mathematics teachers with current

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

educational policies for racially diversifying STEM instruction (National Math and Science Initiative, 2016; U.S. Department of Education, 2016). These counternarratives in the form of oral histories help fill the gap left by many texts that claim to be comprehensive. One such text, published by the National Council for Teachers of Mathematics and commonly used by professors of education, is *A History of School Mathematics* (Stanic & Kilpatrick, 2003). Our oral histories intend to offer a meaningful historical foundation for understanding the contemporary racialized experiences and practice of Black mathematics educators.

Two components of Critical Race Theory (CRT) shape our research – racial realism and counternarratives. Racial realism is an integral component of critical race theory (Bell, 2005). It accepts that we live in a society in which racism has been internalized and institutionalized to the point of being an essential and inherently functioning component, in this case an intransigent, intractable component of educational institutions, including the ways that whiteness appears in mathematics education (Battey & Levya, 2016).

In response to the racial realism that dominates educational practice and outcomes, we look to history for counternarratives (Solorzano & Yosso, 2002), or evidence of equity-centered pedagogies that focused on teaching excellence for well-rounded student achievement, particularly for Black children and particularly in the discipline of mathematics. These pedagogies include but are not limited to culturally relevant teaching (Irvine, 1989; Ladson-Billings, 2009) and African American pedagogical excellence (Acosta, Foster, & Houchen, 2018; Siddle-Walker, 2001).

We were curious about the extent to which retired Black mathematics teachers – facing the intractability of racism in a discipline that falsely purports to be race-neutral and objective – challenged and overcame systemic barriers during the historical period of formally racially segregated schools, well into the mid-1970s. We wondered whether they manifested African American Pedagogical Excellence (Acosta et al., 2018). In short, we wondered whether these teachers demonstrated the characteristics described in Ladson-Billings' seminal work *The Dreamkeepers: Successful Teachers of African American Children* (2009). Just as there is evidence of enduring institutional racism in schools – a legacy of the history of segregated schooling -we queried whether there was there evidence of enduring teaching ideologies and common behaviors that historically helped students achieve academic success overall and mathematics success specifically while maintaining a positive identity as African Americans (Ladson-Billings, 2009). Our research team explores how the past and the present communicate with one another to shape educational policies.

Participants

Collecting histories of retired Black math teachers is time-sensitive, as these educators who have experiences spanning decades, are aging. To date, our team has conducted 13 oral histories. A total of 20 fulfills the deliverables for our NSF grant. The oral history participants taught mathematics in Atlanta, Washington, DC, and Maryland schools between the 1950s and the 2000s. Their ages ranged from mid-60s to late-80's. The average teaching experience was 40 years, meaning a cumulative total of over 400 years of teaching mathematics to Black children. And all participants were women.

Methods and Data Sources

In qualitative research, generating findings to explore research questions typically involves making direct field observations, conducting in-depth interviews, and collecting artifacts such as written documents (Patton, 2002). Oral history is one method of qualitative research methodology that gathers thick description from information-rich participants, contextualized within specific historical moments across space and time (Llewellyn & Ng-A-Fook, 2017; Patton, 2002). In-depth interviews, digital video recording, as well as both document and artifact analysis were the primary forms of data collection for our research study.

Due to the age and stamina of our participants we conducted one pre-interview by telephone and one follow-up interview. The first interview encouraged participants to recollect and arrange their teaching experiences. The second interview explored their experience in detail and the context in which it happened, as well as an exploration of the meaning that their experience holds for the participant. This second interview happened in person and was professionally video recorded. During this second interview, many of the participants shared artifacts.

Qualitative data analysis is an iterative process that begins at the design of the research study. As a team, we made amendments to the protocols as we conducted pre-interviews by phone and face-to-face professional videos. At the same time, we began the process of crafting initial codes and using the codes to create categories and sub-categories for understanding the first interview and shaping the second interview. We housed these codes in Excel. By using Rev.com, our research team was able to analyze transcripts while watching the video recording. The next step in our data analysis was archiving clips of videos with time stamps related to the codes that were initially created.

Following this process was a close examination of the written transcripts. All transcripts were both printed and became digitized copies when added to a Qualitative Data Analysis Software. These digitized transcripts afforded the research team a way to analyze the same documents individually and together during team meetings. We continued to add additional codes or modify existing codes for each individual participant. It was during this time that our analysis incorporated participants' artifacts such as yearbooks and curricula unit plans. This allowed the team to get a more holistic view of the participants.

The team worked as a cohesive unit to discuss difference and similarities among codes and categories to develop consensus and address potential validity threats in our analysis. As we continue the iterative process of coding, we are beginning to construct a narrative of each participant. While constructing narratives for each participant, we repeat the process of coding and categorizing *across* participants to gain a collective narrative of the experiences of retired Black mathematics teachers. In order to deepen our understanding of the participants' life experiences, we also began analyzing historical artifacts such as school board records, mathematics curricula, and records from the Miner Teachers' College. This process will continue with the additional interviews.

Our analysis of these transcripts and digital video oral histories of retired Black mathematics teachers empowers us to "address historical harms" (Llewellyn & Ng-A-Fook, 2017, p. 5) or the absences demonstrated in the history of mathematics education textbooks, as well as to offer "intergenerational dialogues" (p. 7) to transform "masculinist approaches for socially constructing knowledge in STEM…to (re)orient ways of knowing away from disembodied, objective truths and toward an embrace of positionality, inquiry, and social context." (p. 8).

Results

We knew from the start of our study that finding retired Black mathematics teachers would be a challenge. Our participants were recruited from our personal and professional networks as well as using snowball sampling. Even as such, our research team become keenly aware that all retired mathematics teachers that we interviewed were female. As such, we began to develop theories to understand this phenomenon. We will continue to search for male retired mathematics teachers and anticipate that doing so will bring a different dimension to our research study.

To date, the experiences of retired Black teachers of mathematics suggest alignment with the ideology, beliefs, and instructional practices expressed by African American Pedagogical Excellence (Acosta et al., 2018), as adapted to the context of each teacher. as well as alignment with Ladson-Billings' (2009) descriptions of successful and culturally relevant classroom interactions, which we have labeled "Dreamkeeper" codes. She describes instructional methods for eliciting *student competence* (p. 134), building student confidence through *instructional scaffolding* (p. 135), creating a collective classroom *focus on instruction* (p. 135), an approach to education that extends and contextualizes *student knowledges* (p. 136), and teachers having *deep knowledge* of both the students and the subject matter (p. 140). These transcripts also suggest codes for *institutional racism* (such as *teacher tracking*), *interpersonal microaggressions* (such as *parental vetting* and *peer disdain*), *racialized teacher professional development* and *mentoring*.

For example, one teacher expressed *oppositional consciousness* in a late 1960s setting with Black administrative leadership by insisting that James Brown's song, *Say it Loud - I'm Black and I'm Proud* was a governing ideology for her classroom presence and, by extension, her mathematics instructional practices.

An example of interpersonal microaggressions included a teacher stating: One [colleague] even told me several times, he said, 'you just don't have the experience to teach math'...He was a [white] navy man, been in the navy for years and retired. I don't know what he meant by that, but he kept telling me that [*peer disdain*]…and the white parents would pick their teachers for their students…and didn't want their kids in my class [*parental vetting*]. In response, she persisted with an *ethic of care* and *high student intellectual expectations* that eventually earned the respect of colleagues and parents.

Several teachers who taught in multiracial school settings recalled *teacher tracking* where they were initially assigned to teach "consumer math," or "the Black kids' math," and introductory algebra, rather than Algebra 1, Algebra 2, Geometry, or "intensive math" that was offered to white students. To counteract these professional slights, these retired Black math teachers described the ways they used planning time, departmental meetings, after school clubs, grant-seeking and professional conferences to both design instruction to improve student content knowledge and to provide one another opportunities to advance their professional skills. Forming *interdependent learning communities* with an eye on *collective success,* these teachers offered one another the *mentoring* and *racialized teacher professional development* that was lacking in their schools and districts.

Despite the barriers of racism, the teachers described student-teacher relationships and classroom environments that speak to several of the Dreamkeeper and AAPE codes. One extended quote is an example:

> I kind of enjoyed working with [the really tough kids] because I enjoyed the results that I was getting, enjoyed the kids coming to me and saying, ' I want be in Mrs. L's class because she *teaches*!'…I think [they meant] that I presented lessons in a way that they understood it, they could comprehend it…I had this thing always that I would tell them that my classroom is not a quiet room…we don't have holy quietness in this room. We're going to talk, we are going to talk about the work. We are going to learn the language of mathematics.

This quote has been coded as follows: "I kind of enjoyed working with [the really tough kids] because I enjoyed the results that I was getting [*student knowledges]*, enjoyed the kids coming to me and saying, 'I wanna be in Mrs. L's class because she *teaches*!' [*student competence*; *focus on instruction*]…I think [they meant] that I presented lessons in a way that they understood it, they could comprehend it [*student knowledges; scaffolding*]… I had this thing always that I would tell them that my classroom is not a quiet room…we don't have holy quietness in this room. We're going to talk, we are going to talk about the work. We are going to learn the language of mathematics [*deep knowledge; student knowledges*]."

The individual and collective narratives that emerge from the coded transcripts illuminate their own stories about their K-12 and undergraduate learning, and their experiences of teaching mathematics in schools pre- and post-desegregation. Ultimately, these narratives will be compared with data from other quantitative and qualitative components of our research study that focus on the experiences of contemporary Black teachers of mathematics. The "dialogue" between past and present will help shape an understanding of both change and continuity over time.

The research is ongoing and we expect to have the concluded all of the oral history interviews by September 2019.

Scholarly and Policy Significance

Ladson-Billings (1998) stated that, "adopting and adapting CRT as a framework for educational equity means that we will have to expose racism in education *and* propose radical solutions for addressing it" (p. 22). Teacher education for pre-service teachers and teacher professional development for in-service teachers, particularly in mathematics education, stand to benefit from the insights gained from the oral histories of retired Black mathematics teachers. The stories shed light on the origins and persistence of what Ladson-Billings refers to as the "education debt" (2006) as a direct counter to the language of the "achievement gap" in mathematics acquisition and numeracy. While the oral histories to date suggest that not all 20th century Black children, particularly in rural areas, had access to formal instruction in higher mathematics, their experience of numeracy stands in stark contrast with the lower level, rote mathematics that is typical in most 21st century majority-Black classrooms (Clark, Badertscher, & Napp, 2013; Gillen, 2014; Neil, 2015).

Teacher education placement offices may attempt to mitigate the intractability of the hiring discrimination that D'Amico, Pawlewicz, Earley, & McGeehan (2017) document and which finds its origin in some of the histories of retired Black mathematics teachers. The wisdom of seasoned Black mathematics teachers, made available on the project website in digital form, can lead to greater reflexivity for in-service teachers and to metaphorical cross-generational "conversations" with novice teachers in teacher education programs. Without this knowledge, teacher education and professional development programs will continue to lack sufficient data for reforming their curricula and pedagogy to recruit and retain high-quality Black math teachers who have the resilience and readiness to meet 21st century needs (Battey et al., 2018). Teacher education programs that talk about "equity" and "diversity" while explicitly ignoring how the history of race and racism impact the praxis of former and current Black mathematics teachers serve no one (Cook, 2015).

EXAMINING THE TENSIONS BETWEEN HIGH QUALITY DISCOURSE AND SHARING MATHEMATICAL AUTHORITY WITH STUDENTS

Patrick Sullivan
Missouri State University
patricksullivan@missouristate.edu

Current reform efforts challenge teachers to create more student-centered classrooms focused on high quality classroom discourse (NCTM, 2014). There are difficulties, however, teachers face in bringing this vision to fruition. Over the past three years, we have worked with a group of 7-12 teachers supporting their efforts to implement high quality classroom discourse. Although their espoused beliefs aligned with our vision of high-quality discourse, their enacted practices did not align with those espoused beliefs. Further analysis suggested that many of these challenges are related to sharing mathematical authority with their students. We intend to share a set of "Look Fors" to build awareness of features of sharing mathematical authority that might be inhibiting the quality of teachers' classroom discourse. A set of questions will also be shared to help teachers decide upon a plan of action to overcome those challenges.

Keywords: Classroom Discourse, Teacher Education-Inservice/Professional Development, Mathematical Knowledge for Teaching

Purpose of the Study

Over the past three years practicing middle and secondary mathematics teachers (n = 16) from small, rural school districts (75% from high school needs school districts) participated in a grant project to improve the quality of classroom discourse in their classroom. During the project, teachers engaged in over 300 hours of professional development focused on Effective Mathematics Teaching Practices (NCTM, 2014) that supported high quality classroom discourse. Emphasized practices included: 1) implementing tasks that promote reasoning and problem solving, 2) facilitating meaningful mathematical discourse, and 3) posing purposeful questions. In spite of our best efforts to support their growth in these areas, teachers faced challenges in improving the quality of their classroom discourse. The quote from one teacher captures the emotional toll of these challenges:

> "I am really trying to change the way I teach, I really am, but I am so frustrated! I turn my students loose with a task, but our classroom discussions seem to get bogged down! The students are frustrated, I am frustrated! So, I end up going back to my old way of teaching: telling them how to do everything!"

We sought to better understand the nature of these challenges. Analyzing teaching episodes, we explored four questions: 1) Did teachers' espoused beliefs align with their practices, 2) Were there elements of their specific elements of their classroom discourse that reflected growth, 3) What role did sharing mathematical authority play in teachers' ability to implement high quality classroom discourse, 4) As facilitators of professional development, what are the additional tools that we need to provide teachers with so that they can navigate the challenges of implementing high quality classroom discourse?

Perspective

Teacher Beliefs

Guskey (2002) suggests a sequential model of teacher change moving from the professional development experiences to the teachers' classroom practices, to changes in student learning outcomes, and lastly, to changes in teachers' beliefs and attitudes (p. 383). Using Guskey's model, it was our view that if we were able to quantify changes in teachers' beliefs aligned with our desired instructional practices then we would expect to see those beliefs enacted in their instructional practices. The REU (Research Experience for Undergraduates) Beliefs Instrument (O'Hanlon et al., 2015) seemed to be an appropriate instrument to measure these changes because it assessed the three domains of beliefs (teaching, student learning, and personal learning) that we believed were central to teachers' decision-making about their instructional practices.

High Quality Discourse

The Instructional Quality Assessment (IQA) Classroom Observation Tool (Boston, 2012) was used as a tool to quantitatively measure elements of what we viewed as high quality classroom discourse. It also served as a shared lens for teachers to reflect upon the nature of their classroom discourse. The IQA consists of two components, academic rigor and accountable talk. Each component has five aspects each of which has an accompanying rubric. These elements include 1) implementing cognitively demanding tasks (AR1 and AR2); 2) holding students accountable for their thinking (AR3, AT4, AT5); 3) asking academically relevant questions (AR-Q); 4) linking mathematical contributions (AT2, AT3); and 5) whole-class engagement (AT1).

Table 1: Instructional Quality Assessment Rubrics

Academic Rigor	Accountable Talk
AR1: Potential of the Task	AT1: Participation
AR2: Implementation of the Task	AT2: Teacher's Linking
AR3: Student Discussion After Task	AT3: Students' Linking
AR-Q: Questioning	AT4: Asking (Teacher Press)
AR-X: Mathematical Residue	AT5: Providing (Student Response)

Mathematical Authority

It was our hypothesis that a necessary condition of high-quality classroom discourse, as described by the elements of the IQA, was teachers' capacity to share mathematical authority with their students. Sharing mathematical authority requires teachers to listen to students' thinking, process and act upon potentially unplanned, and sometimes unfamiliar, mathematical statements. It also requires teachers to press students for explanations, and ask questions, in the moment, to move students' thinking forward. Sharing mathematical authority is not about who is in charge of the classroom but about who gets to decide which tools to use to solve a problem and who determines the correctness of mathematical contributions (Gresalfi, Martin, Hand, & Greeno, 2009; Hiebert et al, 1997). It is also about the nature in which students' mathematical reasoning and sense-making is valued and affirmed by the teacher during classroom discourse. Sharing mathematical authority is about the opportunities teachers give students to share ideas, evaluate others' ideas (Harel & Sowder, 2007) , and provide justification for their reasoning and sense-making (Hufford-Ackles, Fuson, & Sherin, 2004).

Methods and Analysis

A mixed-method design was used to capture both quantitative and qualitative aspects of teachers' classroom discourse. At the beginning of the professional development experience, teachers were asked to complete the REU (Research Experience for Undergraduates) Beliefs Instrument (O'Hanlon et al., 2015). During the first year, teachers engaged in a series of professional development experiences (over 100 hours) to understand the Cognitive Demand Framework (Stein, Smith, Henningsen & Silver, 2000) and the rubrics of the Instructional Quality Assessment. During the first year, several teachers agreed to have teaching episodes video-recorded. With the support of our coaching and using the IQA, the teaching episodes were evaluated by their peers and feedback was provided. This process supported two goals: 1) to create a professional learning culture in which participants were comfortable sharing episodes of their teaching with peers and willing to receive constructive feedback from their peers, 2) to use these episodes to develop consistency in rubric ratings.

Each of the IQA rubrics are scaled from 0 to 4 with 0 being the lowest rating and 4 being the highest rating. The rubrics of the IQA focus on two dimensions of high-quality classroom discourse: academic rigor and accountable talk. For example, one of the rubrics of the IQA related to academic rigor *is Potential of the Task.* At the highest ratings, students are engaged in a task that involves complex non-algorithmic thinking or applying a broad general procedure that is closely connected to mathematical concepts. In order to be considered a 4-rating the task must explicitly prompt for evidence of student thinking. At the lower ratings students are either engaging in no mathematical activity or memorizing rules, formulae or definitions. The *Potential of the Task* is strictly about what the teacher puts in front of students to do. Likewise, one of the rubrics related to student accountability during classroom discourse is *Asking (Teachers' Press)*. The higher ratings of the rubric correspond with the teacher consistently asking students to provide evidence of their contributions (i.e. press for conceptual explanations) or to explain their reasoning. At the lower ratings there is no discussion or efforts to ask students to provide evidence for their contributions (Boston, 2012). It is important to note that during the first year, each teacher was visited at least once by a researcher, and their teaching episode was scored using the IQA.

During Year 2 and Year 3, each teacher was provided with a SWIVL robot and iPad to record lessons. Teachers were given the autonomy to record and share lessons that they believed best represented their growth in classroom discourse. These lessons were shared with researchers via the cloud and scored using the IQA rubrics. Each teacher who agreed to share lesson recordings was scored at least once. These episodes were rated by two or more facilitators who were trained in scoring the IQA. Due to scheduling conflicts, the facilitators were unable to develop inter-rater reliability. As a result, the ratings for the cohort (n = 16) on each rubric for the last two years were averaged. Each teacher was also provided with scoring on each rubric for the episodes that were shared. Written constructive feedback corresponding to each rating was also provided.

Teachers continued to participate in professional development experience (over 100 hours each year). These experiences involved deepening the content knowledge (i.e., geometry and data analysis) and continuing to improve the quality of classroom discourse. These experiences also involved small groups analyzing teaching episodes using the IQA and providing constructive feedback to their peers. Teacher were assigned a "teacher buddy" to share additional teaching episodes and to provide feedback aligned with the rubrics of the IQA.

At the end of the third-year professional development experiences, the REU (Research Experience for Undergraduates) Beliefs Instrument was given to teachers again. Teacher responses were averaged and Cohen-D effect sizes were computed to measure the significance of changes in teachers' beliefs from the beginning to the end of the professional development experiences.

In the post analysis of our data, after analyzing changes in teachers' beliefs and the IQA rubric ratings of teaching episodes, we took a Grounded Theory approach (Corbin & Strauss, 1996) to understand the role of mathematical authority. Teachers had strong initial beliefs related to elements of sharing mathematical authority with students, and the strengths of those beliefs over the three years of professional were either sustained (see table 2, questions 19 and 21) or advanced (see table 2, question 6 and 14). We wanted to understand whether those beliefs were present in teachers' practices and, if so, what were the challenges teachers faced in sharing mathematical authority with students?

In our fine-grained analysis of a few teaching episodes, IQA ratings (3 or higher) in the rubrics related to task potential (AR1) and questioning (AR-Q), we noticed that sharing mathematical authority was not as prevalent in the actual teaching episodes as teacher beliefs would suggest. Also, we noticed that, in the instances in which teachers did attempt to share mathematical authority with students, there were different challenges that they faced in continuing to share the mathematical authority with students. These instances were analyzed to categorize the nature the classroom activities that either had the potential to or resulted in the sharing of mathematical authority with students. Themes that emerged were: 1) a teacher pressed a student to further explain their reasoning, 2) a teacher asked a question to advance students' reasoning (Bill & Smith, 2008), 3) a student generated a conjecture, 4) a student asked a question, or 5) the validity of mathematical contribution by a student needed to be established.

Results

Teacher Beliefs

Items from the REU (Research Experience for Undergraduates) Beliefs Instrument (O'Hanlon et al., 2015) related to elements of classroom discourse are shared. Bolded item numbers are reverse scored and those with large effect sizes (Cohen's D > 0.60) are starred.

Table 2: Pre and Post Significant Changes in Beliefs (|ES| > 0.60)

#	Question	Pre	Post	Effect Size
6	During class discussions, students should analyze and critique another students' work.	$\bar{x} = 3.80$ $s = 1.23$	$\bar{x} = 4.40$ $s = 0.60$	0.68*
11	The teacher should demonstrate how to solve mathematical problems before the students are allowed to solve problems.	$\bar{x} = 3.00$ $s = 0.82$	$\bar{x} = 4.05$ $s = 0.51$	1.84*
14	During class discussions, the teacher should be the authority in terms of whether a student's mathematical conjecture or justification is correct.	$\bar{x} = 2.60$ $s = 1.07$	$\bar{x} = 3.50$ $s = 0.89$	0.91*

19	Teachers should provide opportunities for students to critique mathematical arguments, and discuss their own conjectures.	$\bar{x} = \mathbf{4.50}$ $s = \mathbf{0.52}$	$\bar{x} = \mathbf{4.50}$ $s = \mathbf{0.53}$	0.00
21	During class discussions, students should play a role in determining whether mathematical justifications are valid.	$\bar{x} = \mathbf{4.50}$ $s = \mathbf{0.52}$	$\bar{x} = \mathbf{4.50}$ $s = \mathbf{0.52}$	0.00
31	Struggling with mathematical concepts is detrimental to understanding.	$\bar{x} = \mathbf{2.80}$ $s = \mathbf{1.55}$	$\bar{x} = \mathbf{3.94}$ $s = \mathbf{1.12}$	0.84*
32	Group discussions often lead to tangents, or incorrect mathematics, and should be limited in their use.	$\bar{x} = \mathbf{3.70}$ $s = 0.82$	$\bar{x} = \mathbf{4.25}$ $s = 0.45$	0.83*
49	The teacher should provide verification for mathematical arguments, rather than expecting students to do so.	$\bar{x} = \mathbf{3.50}$ $s = \mathbf{0.97}$	$\bar{x} = \mathbf{3.81}$ $s = \mathbf{0.75}$	0.36

Quality of Classroom Discourse

These results suggest that the cohort's beliefs about classroom discourse either moved, or were already consistent, in the direction we espoused. The average ratings for Years 2 and 3 are shown below. A two-sample unequal variances t-test was conducted to determine whether there was a statistically significant change in average cohort ratings (n = 16) on the rubrics of the IQA.

Table 3: Comparing Year 2 and Year 3 IQA Cohort Ratings

	Year 2	**Year 3**	**P-Value**
Academic Rigor			
R1: Task Potential	2.63	2.97	0.25
R2: Task Implementation	1.91	2.22	0.32
R3: Student Discussion	1.69	1.91	0.45
AR-Q: Questioning	1.84	1.78	0.84
AR-X: Mathematical Residue	1.85	2.07	0.46
Accountable Talk			
AT1: Participation	2.02	2.56	0.049*
AT2: Teachers' Linking	1.68	1.94	0.32
AT3: Students' Linking	1.63	1.27	0.19
AT4: Asking (Teacher Press)	1.82	1.94	0.68
AT5: Providing (Student Response)	1.66	1.81	0.61

These results indicate that the only statistically significant ($\alpha < 0.05$) change in the ratings occurred in Participation (AT1) rubric, the percentage of students participating in teacher-facilitated discussion. It is important to note that the numerical rating indicate an average of between 50% and 75% of students participating in class discussions.

Mathematical Authority

Although teachers expressed strong beliefs about sharing mathematical authority with students (see table 2), we identified very few teaching episodes in which teachers shared mathematical authority with their students. Analyzing the specific instances in which teachers did share mathematical authority with students, we attempted to categorize teacher actions that supported those efforts, or hypothesized about the nature of the challenges they faced in as they shared mathematical authority with their students. From this analysis, a set of guiding questions were generated to enable us to further reflect upon teacher actions that supported the sharing of mathematical authority with students.

1. Are students given an opportunity to choose the tools, or understandings, they want to use to make sense of the problem or task?
2. Are students deciding the mathematical correctness of an answer or a students' contribution to the discussion?
3. Are students given an opportunity to share their reasoning and sense-making with the class?
    a. If so, in what forum? (e.g. group discussions, whole class, etc.)
    b. Are these contributions valued by other members of the class? By the teacher?
4. Is the teacher asking pressing/assessing questions to better understand their students' reasoning and sense-making?
5. Is the teacher asking questions to advance students' understanding of their ideas?
6. Is the teacher giving their students opportunities to explore their own conjectures?
    a. If so, do my students have access to the necessary tools to do so?
    b. If so, does the teacher value these experiences? How is the teacher making this evident to students?
    c. If so, what demands is this placing on the teachers' knowledge (e.g. mathematical, pedagogical content knowledge, etc.) to meaningfully orchestrate this experience?

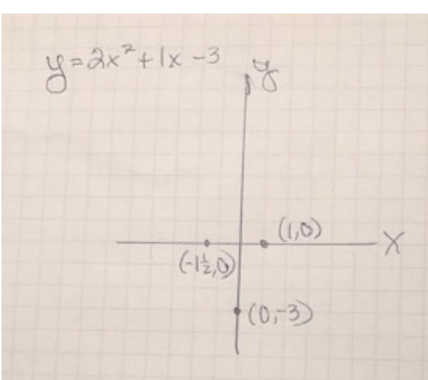
Discussion

It seems important to share a few, brief teaching episodes that exemplify the role of sharing mathematical authority with students in high-quality discourse. The episodes also illuminate a few of the demands sharing mathematical authority with students places on teachers.

Mrs. Barnes Classroom

Mrs. Barnes (pseudo-name) gave the following task to her 10th grade students, "Graph $y = 2x^2 + 1x - 3$." Working in groups, students were provided graph paper, no technology, and no guidance. Most groups were able to locate the zeros and y-intercept, but most struggled to find the location of the vertex.

After a few minutes, one of the groups *shared a mathematical contribution* about the relationship between the zeros of the function and the location of the axis of symmetry (see fig. 1, lines 50-53). The exchange between Mrs. Barnes and the group is shown in Figure 1.



S1: Okay so we found the zeros, but we really don't know where to go from there. I mean we kind of guessed on the vertex but we don't really know.
T: You guessed the vertex…
S2: The axis of symmetry is right here.
T: Axis of symmetry is at the y-axis. Do you think it is right there at x equals zero? Why?
S1: No, because it is uneven. You have one at one and one at negative one and a half.
T: Could you find the middle between those two points?
S1: Yeah
T: Could you find the middle between those two points.
S1: We did, it's negative one-fourth. That is where we tried to put our point. We just don't really know what we are doing.
S2: Okay, so we used the negative three and went down three and then did that negative one-fourth, we think.
T: Okay, so do you think the negative one-fourth should be higher or lower than that negative three?

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* St Louis, MO: University of Missouri.

Figure 1: Small Group Discussion of the Location of the Axis of Symmetry

During the small group discussion there are multiple ways in which Mrs. Barnes shared the mathematical authority with her students. She asked the group to *clarify a statement*, "we kind of guessed on the vertex" to better understand the meaning of <u>their</u> words (see fig. 1, lines 46-48). She also asked students to *provide a justification for a conjecture* she inferred from the location of their finger on the graph, "Axis of symmetry is at the y-axis. Do you think it is right there at *x* equals zero? Why?" (lines 50-51). Also, instead of giving the students the answer, she *asked a question to advance students' understanding of their ideas* related to the possible location of the vertex (lines 60-61), "So do you think the negative one-fourth should be higher or lower than the negative three? "[referring to the location of the vertex].

However, during the whole class discussion Mrs. Barnes struggled to continuing sharing the mathematical authority with her students (see fig. 2).

T: What if I can't immediately look at that and know it? Is there a way for me to find the axis of symmetry just by doing some math?
S1: Can't you just add both of them and divide by two?
T: You mean your intercepts? Yeah, we could average them. We could average the intercepts. We could also take negative b over 2a. Do you remember we did the quadratic formula and we started with negative b plus or minus you got that big long square root and then it was 2a. Did you know that the number on the outside of the radical, not the discriminant, the number to the outside, actually procedures the axis of symmetry?

Figure 2: Excerpt of Mrs. Barnes Whole Class Discussion

In reflecting upon the teaching episode, Mrs. Barnes expressed frustration that she was unable to do more with the conjecture shared by students, "the axis of symmetry of symmetry is halfway between the two x-intercepts" (see fig. 1, lines 50-53). She indicated that the conjecture was unanticipated, and that it challenged her because she did not know, in the moment, what to do to further advance students' reasoning and sense-making." She recognized that she dismissed the group's contribution by stating "Is there a way for me to find the axis of symmetry just by doing some math?" (see fig. 2, lines 242-243). She also stated that this group was actually "doing mathematics" based on their engagement in multiple Standards of Mathematical Practice (CCSSI, 2010). It is interesting to note that even in the midst of Mrs. Barnes explanation, the student, desiring to retake the mathematical authority exclaimed, "Can't you just add both of them and divide by two?" (line 244).

Mr. Pho's Classroom

Unlike Mrs. Barnes' classroom episode, in which there were productive moments of sharing the mathematical authority with students, Mr. Pho's classroom episode did not have those same moments. Mr. Pho (a pseudo-name) gave students the following task, *A virus is doubling every 30 minutes, if the initial number of virus present is 2000, how long will it take before there are 3 million virus? 10 million virus? Write an equation to model the situation.* After a lack of meaningful small group discourse, Mr. Pho started a class discussion in which the following dialogue occurred.

Otten, S., Candela, A. G., de Ara ... gs of the forty-first annual
*meeting of the North Americ ... ology of Mathematics
Education.* St Louis, MO: U

T: What unit are we on?
S1: Exponents
T: So you know it has something to do with exponents.
S2: B squared…B squared. I don't know.
T: We are looking at exponential functions. [T goes to back of class and grabs a student-made poster that involves characteristics of exponential functions.]
T: We are looking at exponential functions.
S3: Okay, prime factors.
T: Exponential functions
S4 Hey, can I see that again!
S5: a times b, whatever that is supposed to mean.
T: Yes
S6: Didn't you explain this one once like it was time times growth?
T: I am giving you a hint. [Holding poster in front of the student.]
S3: It is how many times it duplicates.
S7: Multiply it.
T: Exponential functions
S3: Two-thousand
S4: What's the multiplier
S2: Three

Figure 3: Excerpt of Mr. Pho's Whole-Class Discussion

In reflecting upon the teaching episode with Mr. Pho, we hypothesized as to the nature of the challenges he faced in sharing the mathematical authority with students, and potential strategies to overcome those challenges. Mr. Pho recognized that he lowered the cognitive demand of the task, and reclaimed mathematical authority when he stated, "what unit are we on? (Line 46)". He stated, however, that, in the moment, he could not think of a question to advance students' reasoning and sense-making without imposing his mathematical authority. It was our hypothesis that students did not seem to be able to access the necessary tools to reason and make sense of the task. By *asking an advancing question*, such as "Could you make a table to make sense of the situation?" or "How could you find the number of virus after 30 minutes, 1 hour, etc.?" , Mr. Pho may have been able to continue to share the mathematical authority with students. Thus, letting students' reasoning and sense-making drive the discussion instead of Mr. Pho's mathematical topic hint. We also hypothesized that, asking students, as part of the initial prompt, to "write an equation", instead of giving students an opportunity to make sense of the task may have hindered their ability to assume the mathematical authority. Giving students an opportunity to read the stem of the initial prompt and ask him clarifying questions, such as "What does it mean to double every 30 minutes?", might have been enough for students to feel that they had the permission, and necessary reasoning tools, to assume the mathematical authority.

Conclusion

As the teaching episodes of Mrs. Barnes and Mr. Pho illustrate, teachers' capacity to implement high quality discourse is closely connected to their ability to share mathematical authority with their students. While teachers may have strong beliefs that support sharing mathematical authority with students, there are significant demands placed on teachers in enacting instructional practices that support those beliefs. Sharing mathematical authority with students requires the teacher to not only listen and make sense of student contributions, but to, in the moment, act upon what was heard and understood. Effectively acting upon student contributions requires teachers to determine the nature and validity of student reasoning, and ask questions to advance their current understanding. In other instances, sharing mathematical authority with students challenges teachers to identify instructional barriers (e.g., unfamiliarity with the task, lack of reasoning tools) that are hindering students ability to assume the mathematical authority. Future teacher training sessions that involve improving the quality of classroom discourse needs to include: 1) opportunities to develop an awareness of the nature of the challenges associated with sharing mathematical authority with students, and 2) sharing of specific strategies that support teachers efforts to share the mathematical authority with students.

USING A DISCURSIVE FRAMEWORK TO ANALYZE GEOMETRIC LEARNING AND INSTRUCTION

Peter Wiles
Eastern Illinois University
pswiles@eiu.edu

Rick Anderson
Eastern Illinois University
rdanderson@eiu.edu

In this study we applied a discursive perspective of learning (Sfard, 2008) to a sequence of 21 geometry mini-lessons taught in a fourth grade classroom. From this perspective, learning is defined as changes in mathematical discourse. We first characterize and then compare discourse from the beginning and the end of the mini-lesson sequence. We identify shifts in the discourse that occurred during the sequence. We then discuss how the characteristics of the students' geometric discourse informed task design and instruction. This perspective provided a useful means for linking instruction to student learning in an operationalized manner.

Keywords: Classroom Discourse, Geometry and Geometrical and Spatial Thinking, Instructional Activities and Practices, Learning Theories

While geometry is an important branch of mathematics, U.S. students' geometry achievement lags behind achievement in other areas of mathematics (Mullis, et al., 2016). At the same time, scholars have observed that the geometry instruction students receive is often lacking (Sarama & Clements, 2009). Much of the early research on geometry learning (e.g., Burger & Shaughnessy, 1986; van Hiele, 1959) has stemmed from a cognitive perspective, while more recent research has shifted to a participationist perspective (Lave & Wenger, 1991; Sfard, 1998; Wenger, 1998), specifically, a discursive perspective (Sfard, 2007, 2008; Sfard & Lavie, 2005). This shift results in advantages, both analytic and practical (Sinclair, Cirillo, & De Villiers, 2017). From an analytic perspective, a discursive theory operationalizes learning and does not require researchers to make inferences about unseen cognitive processes. From a practical point of view, the theoretical framework can provide suggestions for task design and implementation to inform instruction.

This project aimed to analyze the discourse about geometric shapes and properties that developed in a fourth grade classroom across a series of 21 geometry mini-lessons. We use a discursive framework (Sfard, 2008) to (1) characterize learning and (2) identify ways instructional changes were made in response to students' discourse. We focus on the following questions:

- What is the impact of geometry mini-lessons on students' geometric learning?
- How does a discursive theory of learning inform instruction?

Discursive Theory of Learning

According to Sfard (2007), "the different types of communication that bring some people together while excluding some others are called discourses" (p. 571). *Communication* is the patterned activity where the action of one individual is followed by the action of another individual and "*thinking* is an individualized version of (interpersonal) communicating" (Sfard, 2008, p. 81). Used in this way, the notion of discourse embodies more than the communicative features of talk, but positions one in a larger community of practice. Sfard (2008) identifies two important types of discourses: colloquial and literate. Colloquial discourses are those that arise in one's everyday experience, while literate mathematical discourses are those that make use of standard mathematical terminology and symbolism recognized by the broader mathematical community. Sfard notes that *commognitive conflic*t "arises when communication occurs across incommensurable discourses" (p. 296). Much of schooling involves this intersection of discourses, with students moving from the colloquial discourse to the literate discourse. From this perspective, *learning* is defined as a lasting change in discourse.

In Sfard's framework, four features distinguish mathematical discourse: word use, visual mediators, narratives, and routines. *Word use* consists of the various terms and words that are unique to mathematical discourse. The meaning that is conveyed by these words, however, may differ depending on the discourse community that one is acting in. *Visual mediators* represent the symbolic and visual artifacts that are used as the basis for mathematical communication. As with words, the way that we attend to these visual mediators depend on the discourse. *Narratives* embody the ways that we describe, engage with, and identify relationships between mathematical objects. Narratives can be endorsed or rejected within the discourse. For instance, a possible narrative may be that all squares are rectangles. This narrative may be rejected by students in a discourse community based on the notion that a rectangle should have two long sides and two short sides. Finally, *routines* represent the patterns of activity found in a discourse. For instance, a routine for identifying a shape in one discourse community might involve matching the shape to a set of canonical shapes. In another, it might involve measuring side lengths and angles. Similarly a routine for comparing shapes in one discourse community could focus on their size and orientation, while in another, the routine might focus on their geometric properties.

Much of the research that has applied a discursive framework to geometry learning has focused on narrow instructional segments or small populations. Some of these studies have included students. For example, Sinclair and Moss (2012) analyzed one 30-minute lesson on creating and transforming triangles with a group of 11 kindergarten students. A pair of bilingual high school calculus students exploring in a dynamic geometry environment were the participants in a study by Ng (2015). Other studies have teacher participants. Pre- and post-tests were administered to 63 prospective elementary and middle school teachers in a study by Wang and Kinzel (2014). They report on two participants' geometric discourse but do not link to instruction. Sinclair and Yurita (2008) analyze the discourse of a high school geometry teacher, comparing static and dynamic environments. A goal of our project was to expand beyond the scope of these studies and explore the shifts in geometric discourse for a whole classroom over instructional episodes spanning several weeks. Further, we wanted to investigate how the discursive framework could also inform instruction.

Methodology

A teaching experiment methodology (Steffe & Thompson, 2000) was adopted for this study. As teacher-researchers in the project, we developed and implemented 21 geometry mini-lessons over the course of 11 weeks in a fourth grade classroom in a small, midwestern town. Approximately 22 students were in each class session. The mini-lessons occurred before students received geometry instruction in the regular fourth-grade math class. For each mini-lesson, one researcher acted as the instructor, while the other was an observer.

The geometry mini-lessons followed a format similar to that of *number talks* (e.g., Humphreys & Parker, 2015). Like number talks, these geometry mini-lessons were 15-20 minutes long and focused on geometric shapes and relationships (as opposed to number and computation). The teacher solicited ideas from several students and facilitated the subsequent discussion connecting these ideas. The mini-lesson tasks were designed to allow for multiple entry points and a range of student responses. We discuss three types of tasks:

- Quick Image (Wheatley, 2007). Students were shown a figure for 2-3 seconds and asked to draw it. Students described how they saw the figure and how they knew what to draw. This was repeated with three other related figures. The task concluded with a discussion of the similarities and differences of the figures.
- Which One is not Like the Others? (Danielson, 2016). Students were presented with four shapes and asked: Which one is not like the others? Any of the four shapes could be chosen as not like the others. Students discussed their reasons for their choice.
- Guess My Shape. The class was presented with a collection of shapes, one of which had been secretly selected by the teacher. The students asked yes/no questions that the teacher answered. The teacher led a discussion of the consequences of a yes or no answer to the questions before answering. The instructor strategically selected questions to answer based on the goals for the mini-lesson.

The data sources for this report come from video recordings, copies of students' written work, and field notes of each mini-lesson, along with notes from teacher-researcher post-lesson debriefing. Two video cameras captured the lesson from different angles in the classroom. When viewing video of the sessions in ATLAS.ti, each student utterance was identified and coded in two ways. First, codes were created to identify the geometric properties and shapes under consideration in the utterance. Then the utterance was coded for features of discourse, namely word use, routines, narratives, and visual mediators (Sfard, 2008). Any words related to the geometric properties and shapes, whether colloquial or literate, were coded. Instances where students compared or identified shapes were coded with the specific routines they used. Following Sfard, we coded students' descriptions of shapes as narratives.

We then looked at all the lessons and identified the main geometric topics addressed, e.g. angles, parallel lines, congruence. We examined each task and identified the potential geometric topics to be discussed by students. We looked for the emergence of these topics in the classroom discourse and linked together sessions that addressed the same topic. This gave us a mapping of the geometric topics that were addressed during the 21 mini-lessons.

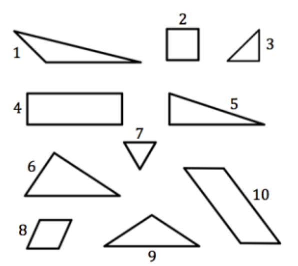
Changes in Discourse over Time

To identify learning that occurred during the sequence of mini-lessons, we characterize the discourse of two lessons, one occurring near the beginning (mini-lesson 4) and one near the end (mini-lesson 18) of the 21-lesson sequence. Sfard (2007) noted that, "because mathematical discourse learned in school is a modification of children's everyday discourses, learning mathematics may be seen as transforming these spontaneously learned colloquial discourses rather than building new ones from scratch" (p 573). As such, we focused on the characteristics of the students' use of words, visual mediators, narratives, and routines in both mini-lessons, and examined how these shifted. Both mini-lessons used the Guess My Shape task structure, so the nature of the mathematical activity was similar.

Early Discourse

The fourth mini-lesson in the instructional sequence featured a collection of triangles and quadrilaterals (Fig. 1a). Notably, the shapes included right, acute, and obtuse triangles, as well as several shapes with different configurations of congruent sides. The students used these shapes as visual mediators to establish routines for categorizing or differentiating between shapes. The routines could be identified primarily through the questions that they suggested, as well as the accompanying discussion surrounding those questions. Figure 1b shows the questions generated by the students during the lesson.

Many of these questions demonstrated that students' routines for distinguishing between two shapes were tied primarily to the shapes' visual characteristics such as size and orientation. Only two questions focused on using geometric properties as a basis for distinguishing shapes, namely side congruence or number of sides. Even the use of the terms "rectangular" and "triangular" rather than "a rectangle" or "a triangle" highlight a focus on visual characteristics rather than identifying the shape as part of a class of shapes.



(a)

1. Is it slanted or up?
2. Is it upside down?
3. Is it long?
4. Is it short?
5. Is it on its side or flat?
6. Does it have four sides?
7. Is it rectangular?
8. Is it triangular?
9. Are the sides equal?

(b)

Figure 1: Early Discourse Guess My Shape Task and Student-generated Questions

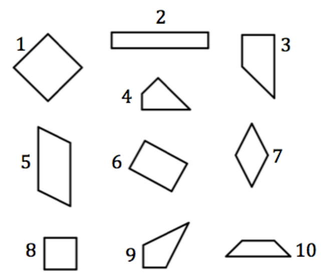
The questions and the discussion surrounding them heavily featured colloquial word use such as *slanted*, *up*, *flat*, *upright*, *upside down*, *laying*, and *corner*, words that are not well defined in the literate geometric discourse. Some words, which do have specific meaning in the literate discourse, were used in alternative ways. For example, a student referred to a shape being "straight" as a way to differentiate it from shapes she considered to be "slanted." Similarly, the sides were considered "equal" rather than "congruent." A rhombus (Fig. 1, shape 8) was referenced as a "little square" and a parallelogram (shape 10) was referred to as "rectangular."

Several competing narratives regarding the characteristics of the shapes under consideration emerged during the discussion. In the end, the students were left considering shapes 1, 5, and 6. The students were considering the question, "is it up"? When asked to show with their fingers how many of the shapes were "up," the responses were roughly equally distributed between 1, 2, 3, and 5. Some students only considered the isosceles triangle (shape 9) as being "up." Others included shapes that had vertical sides (e.g., shapes 1 and 5). Generally, the students did not clearly communicate their descriptions (narratives) of shapes that were "up" in a manner where it could be subjected to endorsement and agreement by the group. After the questions with geometric properties (e.g., number of sides and congruence) were answered, there was no clear resolution of the task due to the differences in the discourse. The words and narratives students were using made it difficult for them to determine which shapes to eliminate. In the end, the teacher had to reveal to the students which shape was selected.

Later Discourse

The eighteenth mini-lesson occurred approximately six weeks after the aforementioned mini-lesson. The quadrilaterals in the Guess My Shape task (Fig. 2a) were purposefully selected and oriented to serve as visual mediators for the students' geometric discourse. As with the previous mini-lesson, the shapes we selected gave students an opportunity to focus on both visual characteristics, such as size and orientation, as well as geometric properties, such as presence of right angles, parallel sides, and congruent sides.

The discursive routines students used to distinguish between shapes is evident in the questions they posed (Fig. 2b). Except for the final two, each question featured a distinguishing geometric property. The question, "Is the shape congruent?" was later clarified by the student to mean, "Does the shape have congruent sides?" The final two questions came at the end of the mini-lesson after all the shapes had been eliminated except for the two squares (shapes 1 & 8). Since both squares shared all salient geometric properties, the students' routines naturally reverted to using orientation and size, both visual characteristics.



(a)

1. Does it have two sets of parallel sides?
2. Does it have a right angle?
3. Is the shape congruent?
4. Does the shape have congruent sides?
5. Is it a rectangle?
6. Does it have obtuse angles?
7. Are all four sides congruent?
8. Is it big?
9. Is it tilted?

(b)

Figure 2: Later Discourse Guess My Shape Task and Student-generated Questions

The narratives generated in this mini-lesson emphasized geometric properties, and were communicated in ways that could be endorsed by other students and the broader mathematical community. Late in the lesson, the instructor answered yes to the question, "Is it a rectangle?" When asked to consider which shapes should be eliminated from consideration, a few competing narratives surfaced. One student indicated a rectangle needed to have "even" sides, while another indicated that a rectangle needed to have four right angles. The latter narrative was endorsed when the instructor asked whether shape 9 (kite) should be eliminated from consideration. Several students agreed, with one stating that even though it had a right angle, it should be eliminated, "since it [didn't] have four [right angles]." This discussion came to a head when students were asked if shape 1 (square) should be eliminated. After checking that the shape did, indeed, have four right angles, the students were reminded that the question answered was "Is it a rectangle?" At this point, some students proclaimed that the shape was a square, not a rectangle. Others, however, argued that it should remain since a rectangle has four right angles. In the end, the class was asked to raise their hands to indicate if they felt the shape should still be considered, and all but one student agreed. It is important to note that there is little evidence to suggest that this constitutes endorsing the narrative *all squares are rectangles*. In fact, some students' hesitation based on naming the shape "square" rather than "rectangle" suggests that they have not. This episode does suggest that the students were comfortable endorsing the narrative *rectangles have four right angles*.

Comparing the Discourse

We see a stark contrast in the discourse between the two mini-lessons. This change is learning (Sfard, 2008). To begin, there is a difference in the questions the students asked to identify the shapes (Fig. 1b & 2b). Although the shapes were similar in each mini-lesson, students focused on orientation and visual appearance in the early mini-lesson; whereas, they were mostly attuned to properties of the shapes in the later mini-lesson. This suggests their routines for comparing shapes changed, i.e., students learned to focus on the properties of the shapes rather than the appearance of the shapes.

Word use also changed markedly from the early to the later mini-lesson. The early discourse was filled with colloquial and sometimes ambiguous words when referring to the shapes. The only words students used from the literate geometric discourse were the names of specific shapes (e.g., rectangle, rhombus, square) and these were not always used in conventional ways. For example, one student referred to a rhombus as a "slanted square." A hallmark of the students' later discourse was the frequent use of geometric words recognized by the mathematical community. Only a few utterances featured colloquial word use. The discussion was replete with geometric terms such as *parallel*, *congruent*, *obtuse angle*, and *right angle*.

We can also see changes in the apparent student narratives for the geometric shapes. In the early discourse, for example, students described a rectangle as have 4 sides, two of them longer than the other. In the later discourse, students had come to describe rectangles as having 4 right angles. This change of narrative set the stage for future consideration of the narrative: *A square is a rectangle*. Class inclusion is the prevailing narrative in the broader mathematical community although it proves challenging for students (De Villiers, 1994).

Sfard's discursive framework proved useful in identifying students' geometric learning across the span of several mini-lessons. As students had opportunities to discuss geometric shapes, the words they used to describe shapes, the routines they used to compare shapes, and the descriptions (narratives) about shapes all changed. In sum, the students' everyday discourse was transformed to be closer to that of the literate discourse of geometric shapes. This did not happen in isolation, however, but was influenced by the instruction they received. As teacher-researchers, we were uniquely positioned having one foot in the students' discourse and the other in the discourse of the mathematics community.

Initiating Changes in Discourse through Instruction

We now turn our focus to show how the discursive framework allowed us to analyze the existing discourse and how it informed the instructional decisions for the subsequent mini-lesson. We consistently monitored the discourse in each mini-lesson and designed the subsequent mini-lesson to modify the students' discourse in specific ways to shift it closer to the discourse of the mathematics community.

The content goals for grade 4 geometry (CCSSI, 2010) include, among other things, identifying parallel lines in two-dimensional figures and classifying two-dimensional figures based on the presence or absence of parallel lines. After the first six mini-lessons, students had not yet noticed or discussed, either informally or formally, parallel lines.

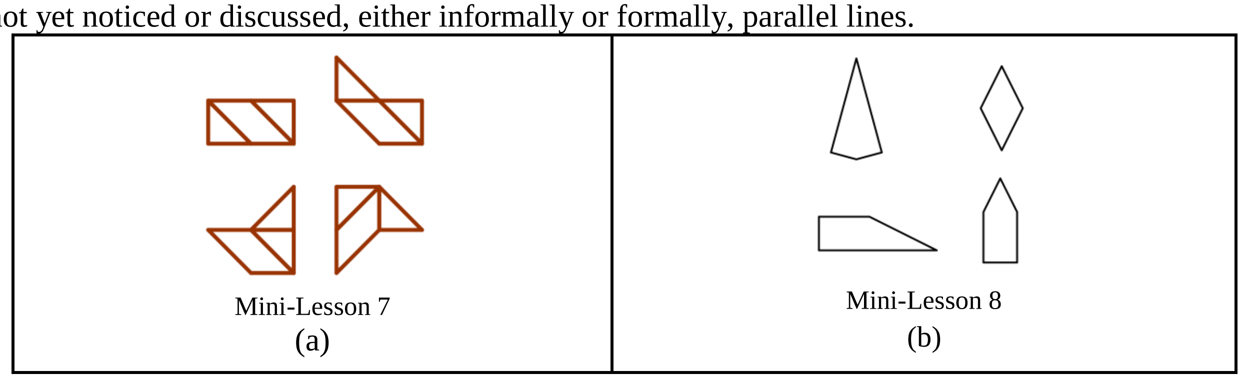


Figure 3: Four Tasks Used in Mini-Lessons

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

The task for the mini-lesson 7 provided opportunities for students to talk about parallel lines due to the figures chosen for the task. The Quick Image task (Fig. 3a) featured four different arrangements and orientations of parallelograms and right triangles. The teacher projected the first image (upper left) for the students to draw. Then, the teacher asked the students to describe what they drew. Students described the figure as having a sideways slanted square, a rectangle, a slanted rectangle, and a square. Some students commented on the diagonal lines but after reviewing their work, we noticed many students had drawn two diagonal lines while some had drawn three.

As we progressed sequentially through the images, a student noticed a parallelogram in each figure. The teacher asked the class what made that shape a parallelogram. The only verbal response was that it had four sides, although one student gestured the shape, indicating a routine of identifying a shape by matching it to a visual prototype. The teacher continued by mentioning "parallel" was part of the word *parallelogram*. "What does parallel mean?" the teacher asked. Students responses included, "the two shorter sides and the two longer sides are the same," "same size," and "side by side."

By the end of the discussion, it was clear that students did not share a narrative for parallel lines. Moreover, the students did not spontaneously use the word parallel, as this exchange was initiated by the teacher. The student-used words (side by side, same size) are not part of the literate mathematical discourse for parallel. Also, students' routines for classifying the parallelogram focused on congruence rather than parallel sides. This, then, informed their narratives about the meaning of parallel, conflating it with that of congruence.

In an attempt to change the students' discourse (i.e., learning) about parallel lines, we used the discursive framework to design and implement mini-lesson 8. We used a task where students would decide Which One is not Like the Others? We selected shapes that had the potential to encourage students to identify and discuss parallel lines. In particular, we selected three shapes that had parallel sides and one that did not (Fig. 3b). Other properties that we included were symmetry, right angles, and number of sides. Furthermore, we wanted to introduce a narrative: *parallel lines go in the same direction*. To this end, we had two long, thin wood dowels to position over the sides of the projected shapes to further illustrate that the sides go in the same direction. We specifically chose to focus on direction rather than the alternative narrative that *parallel lines do not intersect*. We wanted to avoid the possibility of introducing a narrative that conflated segments with lines. Two segments that do not intersect are not necessarily parallel. For example the left and right sides of the right trapezoid do not intersect and they are not parallel.

When we implemented this task in the classroom, students described ways in which the right trapezoid ("The only one pointing to the side."), the pentagon ("The only one with 5 sides."), and the rhombus ("It has two spikes [acute angles].") were different from the other shapes. At this point in the mini-lesson, the students have not provided any reasons for why the kite was different from the other shapes. The teacher had students recall the parallelogram in the previous mini-lesson. He introduced the dowels as a way to focus on the direction the sides were going and introduced the description of parallel lines as going in the same direction. Together the class revisited each shape and checked to see if any had parallel sides. Since the dowels extended the sides, it was clear that parallel sides did not intersect, but, more important, they had the same slope (go in the same direction). After checking the shapes, the mini-lesson ended with a student noting that the kite was the "different one because all of the other ones have parallel sides," to which no one disagreed.

Although new words, visual mediators (dowels), narratives, and routines for determining parallel lines were introduced by the teacher, they became part of the students' discourse. As we saw in the discussion of the later mini-lesson, the students' routine for comparing shapes included noticing the presence or absence of parallel lines.

Discussion

As we have shown, Sfard's discursive framework was useful for analyzing the impact of the mini-lesson sequence on students' geometric learning, defined here as a change in discourse. By operationalizing learning in this way, we can see "the expansion of the existing discourse, attained through extending a vocabulary, constructing new routines, and producing new endorsed narratives" (Sfard, 2007, p. 573). Taken together, these characteristics are pieces of a larger puzzle. Using the words rectangle and parallelogram was not always indicative that students could identify distinguishing properties (e.g., right or acute angles) when comparing them. Likewise, students were not necessarily willing to call a square a rectangle even though they acknowledge they both had four right angles.

Just as learning is a change in discourse, instruction can be viewed as catalyzing changes in the discourse. Sfard (2008) argued, "proactive participation of the expert interlocutors is critical to the success of learning" (p. 605). One of the most important roles of the teacher is to serve as the source of commognitive conflict where the encounter between the teacher's and the students' discourses necessitates a change in discourse. Commognitive conflict arises in the interaction between two discourses that do not operate under the same discursive rules. We can observe this commognitive conflict taking shape in the above episodes surrounding the norms that govern how shapes are described or differentiated. In the instructor's discourse, the means for discussing shapes was through identifying the geometric properties of the shapes, while the students allowed for the use of visual characterizations such as size and orientation. It was not enough to just introduce the properties into the students' discourse, the goal was for the students to similarly focus on geometric properties when examining shapes. In order for this shift in discourse to occur, it is important that the students agree that this shift is both necessary and advantageous.

The tasks outlined above were chosen because they had specific objectives (e.g., guess the mystery shape, find the shape that does not belong) that were more effectively resolved through the use of geometric properties than visual characteristics. As we saw in mini-lessons 4 and 8, the students' existing discursive routines acted as a hindrance to accomplishing this objective. In lesson four, the teacher had to eventually tell the students the mystery shape since their questions could not adequately distinguish the shapes. Similarly, the students could not tell why the kite did not belong without attending to parallel sides. The introduction of the word parallel, the routine of checking the direction of the sides with the dowels, and the narrative of parallel lines going in the same direction served as important tools to successfully resolve the task.

As teacher-researchers investigating elementary school students' geometry learning, we found great utility for Sfard's discursive theory in both unpacking the nature of the learning that took place, as well as being explicit about the instructional actions to support learning. By viewing learning as changing discourse, and attending to the characteristics of the students' discourse, we believe that teachers could be supported to become more explicit about their instructional goals.

In response to the call for research on integrating best general practices in teaching with those that promote equity and access, we present a two-part study focused on instructional strategies that may remove learning barriers for English Language Learners[1]*. We theoretical developed and empirically explored supplemental components for traditional quality of instruction measures (MQI, Hill, 2014, Math Habits Tool, Melhuish & Thanheiser, 2017). We share results from a quantitative study empirically verifying the effect of suggested ELL-focused instructional strategies (Chval & Chávez, 2011) on ELL learning via the creation of an additional MQI dimension. Based on these results, we then provide theoretical operationalizations of these strategies to integrate into the student-and-teacher interaction tool: the Math Habits Tool (Melhuish & Thanheiser, 2017) as means to concretize these strategies for researchers and practitioners.*

Keywords: Classroom Discourse, Instructional Activities and Practices, Inclusive Education

In general, the mathematics education field has endorsed certain images of classrooms that are student-driven and supported by instructional practices that serve to focus on student thinking and support students in engagement in productive discussion (e.g., Jacobs & Spangler, 2017). Recent work, however, has revealed that simply engaging in such practices without attention to issues of equity and access can produce classrooms where not all students have opportunity to learn (e.g., Johnson, Andrews-Larsen, Keene, Melhuish, Keller, & Fortune, in press). As a result, researchers have called for attention to equitable teaching that can support the engagement of all students in mathematical practices (Bartell, Wager, Edwards, Battey, Foote, & Spencer, 2017).

Our work addresses this call in the context of English Language Learners (ELLs.) This growing population (National Academies of Sciences, Engineering, and Medicine, 2018) frequently incur barriers to fully engage in learning opportunities in the classroom. While there is literature about teaching practices that may support this population (Barwell, Moschkovich, & Setati Phakeng, 2017), little work has been done at-scale to empirically explore what instructional strategies may support these students. We share results from a quantitative study identifying the effect of suggested instructional strategies on the mathematical achievement gains of middle grades ELLs. We pair this work with a theoretical, qualitative analysis serving to operationalize these results in a way that is congruent with other best practices for instruction

(Melhuish & Thanheiser, 2017), and can serve as grounds for teachers to concretely work on their practice.

Literature Background

There is general consensus in the mathematics education literature that high quality mathematics classrooms contain certain attributes. These classrooms are ones in which student voices are heard and orchestrated, and student thinking is leveraged as the means to move instruction forward (e.g., Ball, 1993; Jacobs & Spangler, 2017; Nasir, & Cobb, 2006; Schoenfeld, 2011; Turner, Dominguez, Maldonado, & Empson, 2013). However, teachers hold an essential role in orchestrating opportunities that encourage and support such forms of student participation to promote active student learning and engagement (Franke, Kazemi, & Battey, 2007; Gresalfi, 2009; Jacobs & Spangler, 2017). Students are not just passive receivers of mathematics, but active participants in sense-making including through the use of justifying and generalizing mathematics (e.g., Boaler & Staples, 2008). Such qualities have influenced a number of quality of instruction tools including the summative Mathematical Quality of Instruction (MQI) instrument (Hill, 2014) and the formative Math Habits Tool (Melhuish & Thanheiser, 2017).

In alignment with this research, standards reform movements have also increasingly called on students to use language in a variety of ways to increase their mathematical understandings, e.g., explaining their thinking or discussing connections between multiple representations (National Governor's Association Center for Best Practices & Council of Chief School Officers, 2010). However, merely providing tasks and discussion support focused on mathematical practices may conceal the complexities of students in the classroom (Bartell et al., 2017). In particular, students such as ELLs, may encounter barriers to full participation and engagement if they are not able to access the mathematical discourse and content in the classroom (Moschkovich, 2002, 2007).

Scholars have explored pedagogical strategies to bypass such barriers, including: (1) exposing students to mathematical content and instruction in multiple modalities, e.g., gestures, mathematical representations, and manipulatives, and (2) exploring the meanings and multiple meanings of words used in the mathematical register (Bartell et al., 2017; Barwell et al., 2017; Campbell et al., 2007; Moschkovich, 2002, 2007; Shein, 2012; Turner et al., 2013). These strategies are designed to develop students' understanding of mathematical content while simultaneously acquiring higher levels of language proficiency (de Araujo et al., 2018; Bartell et al., 2017; Barwell, et al., 2017; Campbell et al., 2007; Moschkovich, 2002, 2007; Turner et al., 2013). In order to provide students with opportunity to learn, instructors need to attend to both general best practices in instruction, but also to the particular needs of their students.

Theoretical Orientation

In our work, we take the viewpoint that mathematically productive classrooms are ones in which each and every student has access to high quality mathematics. High quality mathematics is mathematics in which students regularly have opportunities to make sense of big mathematical ideas via opportunity to justify, generalize, and leverage mathematical structure (e.g., Boaler & Staples, 2008). Further, these classrooms leverage high cognitive demands tasks (e.g., Stein & Smith, 1996), and support students in productively engaging in mathematical discourse (e.g. Jacobs & Spangler, 2017), in order to develop mathematical habits of mind (Cuoco, Goldenberg, Mark, 1996). Such classrooms reflect a micro-community where teachers and students interact in

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

tandem to develop norms around mathematical activity (Takeuchi, 2016; Staples, 2007; Yackel & Cobb, 1996).

In order to operationalize these interactions, we identify core classroom components in the Mathematically Productive Classroom Framework: *mathematically productive teaching routines* that are extended routines enacted by teachers (such as selecting and sequencing student ideas), *catalytic teaching habits* are in-the-moment teaching moves to support students in mathematical reasoning (such as prompting a student to justify), and *mathematical habits of mind* and *interactions* which are ways that students engage with mathematics and each other around mathematics (habits such as justifying, using representations, or engaging in critique and debate) (Melhuish & Thanheiser, 2017). Through this lens, mathematically productive classrooms can be analyzed through a series of connections across these interaction types. However, we acknowledge that the foci of such analysis may obscure the complexities of attending to mathematical access where different members of a classroom community bring individual lenses, backgrounds, and knowledge to engage with mathematics.

As such, we have aimed to complement traditional quality of instruction frameworks with nuanced attention to the qualities of instruction that can promote mathematical learning and engagement for students from linguistically diverse backgrounds. In particular, we focus on the discursive moves that provide students, and specifically ELLs, with *opportunity to learn* (Gresalfi, 2009; Jackson et al., 2013; Takeuchi, 2016). As noted in the recent commentary by Cai, Morris, Hohensee, Hwang, Robison, and Hiebert (2017), one of the most robust results from the research literature is that students learn best when provided opportunity to learn. Identifying moves that can support learning opportunities is imperative. As an initial grounds of analysis, we leverage the elements of Chval and Chávez's (2011) research-based instructional strategies to support ELLs. Our adaptions of these strategies can be found in Table 1.

Table 1: Instructional Strategies for Linguistically Diverse Classrooms (ISLD)

Instructional Strategy	Description
Connections of mathematics with students' life experiences	Teachers reference the mathematics found in daily life by students.
Connections of mathematics with language	Teachers reinforce a mathematical representation with its meaning.
Meaning and multiple meanings of words	Teachers and students explore the meaning of mathematical words and objects through speech and other forms of expression.
Use of visual aids or support	Teacher supplements instruction with powerful visual media that enhance comprehension of mathematical concepts.
Record of written essential ideas and concepts on board	Teacher makes careful and conscientious use of the board or any visual display media, and students have access to pertinent information throughout instruction.
Discussion of students' mathematical writing	Teachers use student work as an instructional tool and point of discussion.

See Sorto and Bower (2017)

Methods

We leverage several video-banks of lessons from grades K-8 to explore the integration of access to learning opportunities in partnership with instruments such as MQI and the MHT. In this report, we share results from two phases of our research: (1) empirically establishing the impact of the instructional strategies for linguistically diverse classrooms through adjoining a qualities of linguistically diverse classroom dimension to the standard MQI instrument and (2) theoretically developing teaching routines, catalytic teaching habits, and student habits of mind/interactions to operationalize what this looks like in the classroom.

To address the research aim in phase 1, we share the results of coding 99 mathematic lessons from a sample of 34 sixth-eighth mathematic teachers and their 4,522 students representing all of the 11 middle schools in a large district in the southwest United States. The majority of the teachers (75%) taught in classrooms with at least half of students classified by the school district as ELLs. Lessons were coded using the MQI and the augmented new dimension, ISLD, with each 7.5-minute segment assigned a code of Not Present, Low, Medium, and High (0 – 3). All videos were coded by two coders independently (average alpha=0.824) with disagreements settled via discussion.

To measure the effect of the set of strategies, as a whole, on teachers' student learning gains and in particular on their ELL students, a multivariate statistical analysis was conducted. We hypothesized that the presence and quality of implementation of the routines, teachers' knowledge, and general quality of instruction, might impact student achievement differently depending on students' language status. We developed the following Hierarchical Linear Model (HLM) in which the outcome variable of student achievement, Y, for the ith student of teacher n in school j was seen as a function of a vector of students' background variables, $\boldsymbol{X}$, and individual teacher quality measures, T:

$$Y_{inj} = \beta_X' \boldsymbol{X}_i + \beta_T T_n + (u_n, u_j) + \varepsilon_i$$

The model includes fixed effects at the school level, u_j, and random effects at the teacher level, u_n. Student achievement was measured as a standardized gain score by using the difference between their state test result at the end of the study year and the previous year's result. The data were pooled across all three middle school grades, and the control variables for students included measures for current grade, grade repetition status, economic status ("disadvantaged" is the label adopted by the state to designate students who qualify for free and reduced-price meals), and their baseline (prior year) mathematics test score. Because of potential collinearity the modes were estimated separately (one by one) for each individual teacher quality measure.

To address the research aim in phase 2, we leverage the empirical results to both identify existing components of the Mathematically Productive Classroom Framework and develop new components to best account for the types of teacher and student interactions that may provide access to mathematical learning opportunities. This process involved theoretically analyzing the existing framework, operationalizing new habits and routines, then testing and refining these habits and routines through qualitative analysis of videos. The goal of this theoretical contribution is to provide a testable theory of in-the-moment interactions, and provide a means to traverse the holistic research results in order to concretize the work in an actionable way.

Results

In this section, we share first the empirical evidence around instructional strategies to support ELLs. We then put these results in communication with the Mathematical Productive Classroom Framework to concretize the teaching work involved.

Phase 1: Empirical Evidence of Effectiveness for ELLs

Table 2 presents the results of a side-by-side comparison of the variables in separate regression models restricted to ELL and Non-ELL.[2] Table 3 provides a breakdown of the individual elements (measured on a 0-3 scale). The augmented MQI dimension, *Instructional Strategies for Linguistically Diverse Classrooms*, was only a significant variable in the ELL student model validating the hypothesized instructional strategies support ELL students above and beyond *Mathematical Quality of Instruction*. We unpack these results further below.

Table 2: Teacher Knowledge and Quality of Instruction Effect Sizes (Standard Deviations of Gains in Mathematics' Achievement Scores) by ELL/non-ELL Students

Independent Variable	ELL	Non-ELL
Mathematical Knowledge for Teaching	0.03 (0.60)	0.30* (2.40)
Instructional Strategies for Linguistically Diverse Classrooms	0.10* (2.36)	0.16 (1.43)
Mathematical Quality of Instruction	0.07† (1.87)	0.25**(2.74)

† $p < .10$; * $p < .05$; ** $p < .01$

Note: t-statistics in parentheses

Table 3: Mean and Standard Deviation of Teaching Strategies for Linguistically Diverse Classrooms

	Mean (0-3)	Standard Deviation
Connections of mathematics with students' life experiences	0.28	0.27
Connections of mathematics with language	1.32	0.41
Meaning and multiple meanings of words	1.16	0.40
Use of visual aids or support	0.70	0.65
Record of written essential ideas/concepts on the board	2.32	0.39
Discussion of students' mathematical writing	0.97	0.51

As expected, the variable of MQI is positive and significant for both samples, but effects were much larger in the non-ELL sample. If we take the MQI measure as a proxy for 'good teaching', this result may imply that the common phrase 'good teaching benefits *all* students' is supported by this data, with the caveat that 'it more greatly benefits the non-ELL'. It further suggests that the gap of learning opportunities still remains and that teachers' pedagogical actions and moves may not reach students in an equitable manner. Additionally, the measure of MKT was only significant for non-ELL, and with a strong effect size. On the contrary, the only variable that was positive and statistically significant for ELLs, but not for non-ELL, was the overall measure of the instructional strategies for linguistically diverse classrooms (see Table 1 for the list of strategies). An increase of 1 point on the 0-3 point scale corresponds to an estimated gain of 0.1 standard deviation in achievement score. This result may be interpreted as a necessary aspect of instruction (going 'beyond good teaching') to help close the learning opportunity gap. These results imply that effective teachers of ELLs need to provide quality mathematics instruction in general, and that they also need to incorporate teaching routines that attend to providing access to learning opportunities, in particular reinforcing the connections between mathematics representations and their meaning, exploring the meanings of mathematical words and objects through speech and other forms of expression, and making conscientious use of the board or any visual display media so that students have access to pertinent information throughout instruction.

Furthermore, we also verified that the overall score for the augmented dimension of the MQI, *Instructional Strategies for Linguistically Diverse Classrooms* was significantly and positively associated with the overall score of MQI (r = 0.592; p = 0.0002) and with the Mathematical Knowledge for Teaching (MKT) survey (r = 0.311; p = 0.0776). These results reflect that anticipated relationships with outside variables hold, providing validity evidence for the measure.

Phase 2: Theoretically Deconstructing Instructional Strategies into Teacher and Student Interactions

In this section, we share examples of how we have adapted and augmented the Mathematically Productive Classroom Framework to operationalize the above aspects of classrooms. We focus on teaching routines that promote learning opportunities through engagement with mathematical tasks and contexts (*Providing access to mathematical tasks and terminology*), and through engagement with one another's mathematical ideas (*Working with public records of students' mathematical thinking*). The first routine aligns with the instructional strategy *Discussion of Students' Mathematical Writing* from the prior section. The second routine incorporates components of the instructional strategy *Meaning and Multiple Meanings of Words*. The following two excerpts provide brief exchanges to illustrate the interconnected nature of teacher and student interactions, and how specific interactions can facilitate potential learning opportunities. In particular, we focus on key triangles of an extended routines into (*Access to Learning Opportunity* (ALO) routines), embedded with a catalytic teaching habit to support students in a particular habit of mind or interaction (see Figure 1).

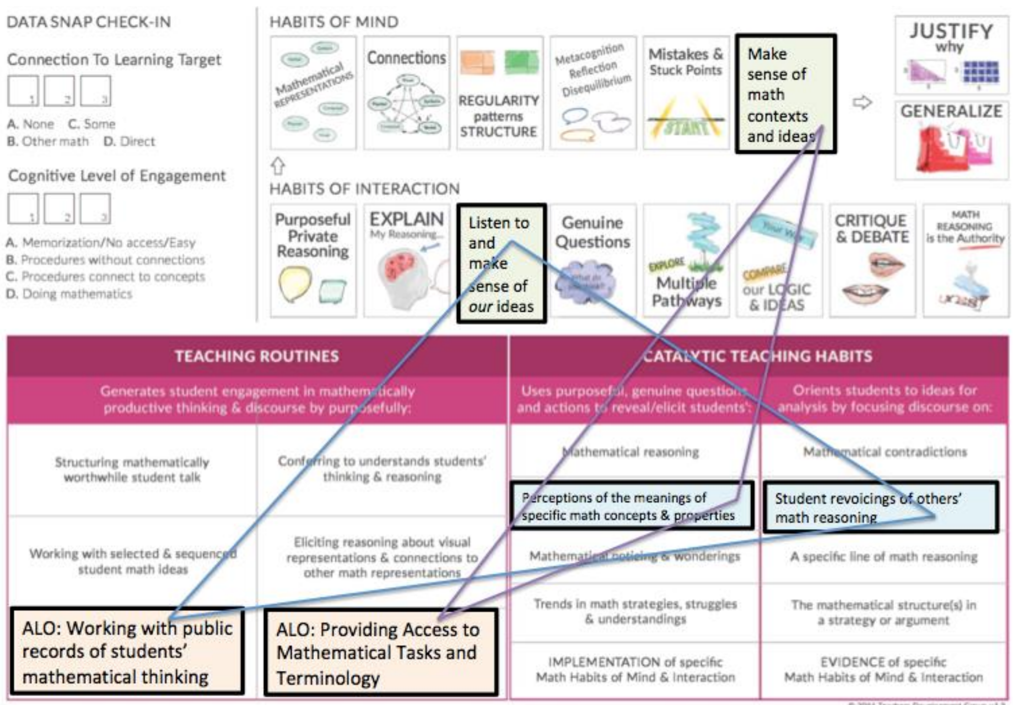

Figure 1: Mathematically Productive Classroom Framework -Connection Between Teaching Routines, Catalytic Teaching Habits, and Student Habits of Mind and Interactions

In this first clip, a pair of 7th grade students from a middle school located in the US southern border is engaged in a task related to the circumference of a circle. However, one of the partners' (identified as ELL by the district) is becoming familiar with words that describe the task.

T: (to S1) Can you explain to her what is circumference? S1: Umm Sure. …	Routine: Access to Learning Opportunities: Providing Access to Mathematical Tasks	CTH: Uses purposeful genuine questions and actions to reveal/elicit students' perceptions of the meanings of specific math concepts & properties.
S1: Well *(Spanish) Circumference is like the area of a circle.* T: *(Spanish) The distance.* S1: *(Spanish) The distance.* T: [inaudible] good. *(Spanish) Did you understand?*		Math Habit: Make sense of mathematical contexts and ideas
S2: *(Spanish) Yes.* T: (to S2) *(Spanish) Show me the circumference of the circle? What did she do?*		CTH: Orients students to ideas for analysis by focusing discourse on student revoicing of others' math reasoning
S2: *(Spanish) [inaudible]* (tracing the circle)		Math Habits: Make sense of mathematical contexts and ideas, Reason with mathematical representations

Figure 2: Student Teacher Interaction on Circumference Analyzed with the Mathematically Productive Classroom Framework

This excerpt (Figure 2) illustrates explicit attention to the mathematical meaning of terms where the teacher spends extended attention (that goes beyond the scope of the brief excerpt above) having students engage with the mathematical context. Within this routine, the teacher prompts for the perception of the meaning of a specific mathematical idea (circumference) (CTH), a student makes sense of this idea (habit of mind), the teacher prompts for revoicing (CTH), and the second student makes sense and reasons with a representation (habit of mind) to illustrate circumference.

P: …yeah- it's greater than- cause it's above the half of 42.	Routine: Access to Learning Opportunities: Working with public records of students' mathematical thinking Terminology	Math Habit: Explain my reasoning
T: So, that was a little bit- that was a lot of information for us. I'm going to ask N to revoice, but before N revoices I'm going to ask one other person to revoice. I want a total of two students to revoice P's thinking. So if what P did made sense to you, you can talk about it... Let's have J revoice, and then N, I'm going to ask you to revoice after J. So J, if you need to stand up here, go on. I actually do want you to, so we can hear you better.		CTH: Orients students to ideas for analysis by focusing discourse on student revoicing of others' math reasoning
J: She said she divided 42 divided by two and she got 21. And since 24 is greater than 21, than it's over- the half. It's greater than half.		Math Habit: Listen to and make sense of our ideas

Figure 3: Student Teacher Interaction on Fraction Comparison Analyzed with the Mathematically Productive Classroom Framework

The second excerpt (Figure 3) comes from a fourth-grade classroom where the teacher has students share their strategies publicly for comparing 24/42 to ½, providing a written record of their ideas. We see Student P's conclusion in the excerpt (preceded by a long explanation). The teacher then leverages a revoicing prompt to engage students in analyzing and making sense of the idea proposed by student P. J then makes sense of P's thinking, through revoicing. As in the prior exchange, teachers and students engaged in interactions within the larger routine, this time the routine was working with public records of students' mathematical thinking' By prompting for revoicing, the teacher engaged in a CTH that catalyzed students in listening and making sense of mathematical ideas (Math Habit of Interaction.)

Due to page limit constraints, we provided shortened excerpts to highlight the primary routines supporting ALO including the pre-existing public records routine, and the newly developed task-focused routine. High quality mathematics classrooms do more than just provide contexts for students to engage in valued mathematical activity (such as justifying and generalizing), but also attend to establishing common ground (e.g., Staples, 2007) where students have opportunities to access the mathematics embedded in tasks and in one another's ideas. We can make sense of classroom interactions through attention to the ways in which routines, catalytic teaching habits, and math habits of mind and interaction co-occur.

Discussion

The work presented above stems from a major effort to bring knowledge of teaching to support ELLs in communication with standard mechanisms of best practices in mathematics teaching. As such, we presented dual prongs of work focused first on empirically establishing that literature-suggested supports do in fact support ELLs in their mathematical learning, and second on putting such work in communication with a framework designed to support researchers in parsing student-teacher interactions and support teachers formatively as they grow in their practice.

We posit that research focused on equitable teaching practices must be both empirically grounded, and operationalized in a way to bridge the research practice divide. Through cycles of empirical exploration, theoretical operationalization, and refinement, we have worked to develop actionable teacher routines and catalytic teaching habits that may remove barriers providing access for ELLs' learning opportunities. We acknowledge that our work is limited to the particular lenses we have adopted and certainly cannot attend to all aspects of mathematical productive classrooms, nor are we exhaustive in the teaching practices to support ELLs. Rather, we focus our work in the context of mathematical reasoning first and what types of instructional routines may engage students deeply in mathematics regardless of language background. We see our work as having implications for research (in the creation of operationalized in-the-moment interaction patterns that can be explored in relation to important outcome variables) and for practice (in the creation of actionable routines and catalytic teaching habits that can be incorporated into practice.)

Endnotes

[1]We use this terminology to align with majority of literature; however, we acknowledge this terminology privileges the English language and has potential deficit connotations.

[2]We choose to only report on selected variables, for effect size on other variables related to teacher preparation and education see Sorto, Wilson, & White (2018).

In this study we document how a mathematical idea, shared by a student, changes the development of the class discussion. Our work characterizes the flexible and open dynamics in mathematics instruction that a teacher adopts to give her students control of their own mathematical ideas. Our work argues that this flexibility is necessary for teachers to engage in instructional practices that respond to students' mathematical thinking. To demonstrate the teacher's flexibility we use the analogy of soccer, relying on the literature of Game Sense coaching approach, which suggests that the coach (the teacher in our context) is positioned to manipulate the practice environment with the purpose of facilitating learning.

Keywords: Elementary Education, Equity & Justice, Standards, Teacher Knowledge

Our article describes a typical day in Ms. Amaris' bilingual second-grade classroom in a southern U.S. public school. We intend to present the characteristics of a fluid and productive mathematics class discussion. Our analysis focuses on how one idea can change the trajectory of an entire class' discussion and the ways that teachers take up new ideas that students propose. We identify the origins of mathematical ideas within a collective discussion and show an idea continuing to develop during an exploratory, one-on-one conversation between Ms. Amaris and a student. Eventually, this conversation becomes the key to expanding the mathematical ideas that the whole class discussed. In order to better explain how one student's mathematical idea can spread throughout a classroom, we have decided to use an analogy that connects to our Latinx culture: soccer. We view the teacher as a coach, with a general plan for the class' discussion—in this case the match. But, as any true soccer fan knows, a soccer match is rich in possibilities and the potential for surprise. In this case we will see how students begin to toss around a more complex idea, passing the ball back and forth. Gabriel, the focal student in our analysis, launches the ball — his mathematical idea— and Ms. Amaris, seeing where her students have taken the game, decides to follow their ideas, allowing the students to control the direction of their class' discussion. This case allows us to see how a mathematics class can support the natural development of mathematical ideas by positioning students as the stars on the field.

In this class, 21 students learned mathematics without any restrictions on their language practices. In other words, students were asked to share ideas in either English or Spanish, based on their preference. Additionally, the students' culture was an important component in daily instruction. In previous investigations in Ms. Amaris' classroom we have argued that allowing students to express their mathematical ideas, even when they were incomplete or could be interpreted as incorrect, allowed for the creation of a space where mathematical ideas could flow and where a teacher could help develop ever stronger mathematical understandings (Maldonado, Krause & Adams, 2018; Carpenter; Fennema; Franke; Levi & Empson, 2015). We have also argued that, for a teacher to support students as they develop stronger conceptual understandings, both the teacher and the students need to understand one another clearly. For this reason, the use of language plays a central role in the practice of teaching and learning mathematics (Maldonado et al., 2018). Based on our prior work, along with the analogy of a soccer match, we will present how Ms. Amaris' students were able to promote a mathematical idea, encouraged by their teacher, making visible how mathematical ideas can be formed collectively through rapid interchanges that could be difficult to trace in the moment. In this class, while discussions began with a set plan, the coach was always ready for a change of tack in order to better meet the game's dynamics. Ms. Amaris was not only focused on the individual passes from player to player, she also had a view of the entire field of play. In this way, through her questioning, she was able to guide students and their emerging ideas until they were finalized as a deep mathematical idea or a rich connection (and, following our analogy, until they ended in a winning goal!). The experience of seeing ideas pop up helped us identify the role the teacher plays in helping her class to solidify their mathematical ideas. Specifically, our analysis presents an answer to the questions: *What does mathematics instruction look like when students' emergent ideas are the central focus? How can teachers support students to develop these ideas?*

Our article contributes to the literature by demonstrating how mathematical ideas develop in a bilingual classroom in the U.S. This article focuses on describing how a teacher observes and participates in order to facilitate productive classroom discussions, where students' mathematical ideas serve to build the class' ever deeper mathematical understanding. We argue that ideas are produced collectively, where individual cognition is embedded within a collective cognition in which all the members of a classroom community participate. This can be seen when one idea, as it is passed to Gabriel, develops in ways that could support the entire class' growing mathematical understandings.

Theoretical Framework

A mathematics class where students have the opportunity to share, justify, connect and extend ideas has been the center of educational reforms in the US in recent years (NCTM, 2014). As a response to this focus, many researchers have conducted studies on how mathematical discussions positively impact students (Moschkovich, 2018). These same studies have shown that including students' mathematical ideas in classroom discussions is a complex task. At the same time, other studies have indicated that students are not benefited equally by discussions. For example, Moschkovich (2018) found that discussions can serve to strengthen certain students' positioning as experts, allowing and even naturalizing, their domination of the class' discussions because those students who are identified as using more advanced strategies tend to share more often. This ensures that students labeled English Language Learners are further disadvantaged due to their minimal participation in class discussions (Adler, 1997; Secada & De La Cruz, 1996).

There are studies that have demonstrated the contributions of bilingual students and the significant role they can play in supporting an entire class' learning (e.g. Turner & Celedón-Pattichis, 2011; Turner, Dominguez, Maldonado & Empson, 2013). Regardless, given the complexity of managing a culturally and linguistically diverse classroom, questions remain around what teachers must do in order to orchestrate productive discussions around rich mathematical content, particularly as bilingual and multicultural contexts become increasingly common across the U.S. Our work is an effort to contribute to an understanding of what needs to take place in bilingual mathematics classroom through an example of how this can be done.

We intend to establish a clear methodology by delineating what Ms. Amaris' practice looked like. In order to do so, we have decided to employ a theoretical framework common in the literature on sports known as the Game Sense coaching approach (GSA). In GSA, the coach uses the game, or the format of the game, as the starting point and continuing focus during training sessions. With GSA, the coach supports players' development of stronger decision-making techniques on the field by encouraging players to understand the game and acquire tactical knowledge and techniques through authentic play (Australian Sports Commission, 1996). GSA argues that the use of games in practice provides players greater opportunities to test out ideas and propose strategies that can be developed through team discussions (Evans & Light, 2008; Light & Evans, 2010). The literature on GSA suggests that the coach should be positioned as a facilitator (Light & Evans, 2010). As a facilitator, the coach guides players to make decisions and solve problems as they arise during games. This "athlete-centered" stance gives players more options and a greater sense of control in the game. The "coach as educator" (Jones, 2006) can adjust the context and conditions during practice in order to facilitate greater learning (Light, 2013). Some work in education has also suggested that the practices of coaches can support teachers (Duncan-Andrade, 2010). Duncan-Andrade (2010) argues that coaches often employ motivation tactics and relationship building in ways that can also benefit the work of teachers.

If we think of lesson planning as a form of preparation for the game, in which there is more than one way to approach the goal, then we would want to avoid linear progressions, instead focusing on the complexity of the field of play—the classroom—and the abundance of possibilities at any given time. It is precisely this abundance that makes it impossible for a teacher to determine all the possible directions that a discussion might take. At the same time, it also would be counter-productive to focus only on what interests the teacher and ignoring the desires of students. For this reason, the role that the teacher assumes is so important—she can read and react to what occurs instantaneously, changing plans to fit the dynamic she encounters (Duncan-Andrade, 2010). We know that mathematics learning is complex and cannot be limited to one sole pathway or trajectory (Empson, 2011). It requires teachers to accept that they are not in control of where the game is headed. Just like in a soccer match, the coach and the players must react to and follow the game in the moment.

Methods

Data

We have worked closely with Ms. Amaris and her students during two consecutive years and have collected extensive data demonstrating her work in the classroom. The data presented in this article is focused on one conversation between Ms. Amaris and Gabriel, one of her 2nd graders. This conversation was video-recorded and transcribed for analysis.

Problem Solving and Number Talks

The episodes from the class that we present in our analysis come from a discussion that generated in response to the problem in Figure 1 and the two equations in Figure 2.

Ms. Amaris typically begins math lessons with a Number Talk (Parrish, 2014; Bray & Maldonado, 2018). This lesson she began with a problem that connected to the class' study of the crisis affecting the water supply in Flint, Michigan (Figure 1). The problem used the context of the class' fundraiser, organized by the students, and asked them to think of how they could get from $38 to $60. After following a lesson sequence common in CGI classrooms (Carpenter, et al., 2015), the class moved to a Number Talk. Ms. Amaris' class had done Number Talks since the beginning of the school year. The students were familiar with this routine, and knew that these discussions focused on their thinking when solving equations and the strategies they used. Ms. Amaris' original plan to see how students used place value knowledge to subtract (Carpenter, et al., 2015).

Analysis

Our analysis involved not only the consideration of what Ms. Amaris and Gabriel said and did, but also of the situation and context within which they were situated. This meant that we included what other students said and did. We identified specific points in the conversation to determine our unit of analysis (Jacobs & Morita, 2002). At times, this unit consisted of an individual comment or question from Ms. Amaris. At other times it included a sequence of comments. Our analysis began with the initial problem (Figure 1). There we identified the mathematical ideas that emerged as well as the linguistic practices of all those involved in the discussion.

Last week we had 38 dollars in the jar of money for Flint. If at the end of this week we have 60 dollars, how much money would we have raised during the week?

Figure 1: Problem to Start Class

62 – 38 = □	65 – 38 = □

Figure 2: Number Talk

Results and Discussion

The Number Talk began with a discussion of the equation *60 - 38 =* □ which emerged from the problem in Figure 1. The purpose of posing this equation was to continue engaging students in using their knowledge of Base-10 and place value in order to compose and decompose numbers and find ways to 'take 8 from 0.' Ms. Amaris starts off asking Emilio for his idea on how to solve the equation and he states that the answer is *22*. Ms. Amaris writes the answer and insists on an explanation for why that was the answer, asking: "¿Cómo sabían que la respuesta era 22?" Many students shared different explanations. As an example:

> Diana: *60 minus 30 equals 30. 8 plus 10 equals, wait, 8 plus 2 equals 10. So then, 8 minus, I mean, 30 minus 8 equals 22.*
> MA: *Okay, so 60 menos, 30 es 30. Luego al 30 le quitas 8 y te quedan 22* [Ms. Amaris scribed on chart paper while repeating in Spanish what Diana shared in English]

After sharing strategies that resulted in *22*, Ms. Amaris continues the Number Talk by writing the following equation: *62 – 38 =* □ (Figura 2). This equation also prompted various strategies. For example:

> Juan Luis: *It's 22, just that you take more, 2 more, 20.*
> MA: *Okay, some people are saying that. Let's see if there's some other ideas, too.*
> Diana: *24.*
> MA: *Ah, I hear two ideas now.*
> Diana: *'Cuz last time we added 71 and the answer was 20, it was, the answer was 22, wait, 24.*
> MA: *I'm gonna put up the two answers that I've heard. I heard Juan Luis say 20. I heard Diana say 24. If you have another idea, go ahead and call it out.*

Ms. Amaris continued the discussion asking for explanations of why they thought the answer might be 20.

MA: *Okay, so háblame de como sacaron 20.*
Kellys: *La respuesta no más de 60 – 38, fue 22 yo no más le quité los 2 del 22 y después el cero.* (The answer from 60 – 38 was 22 and I just took 2 from 22 and then the zero.)
MA: *Okay, voy a escribir lo que me explicaste. 60 – 38 son 22* (OK, I'll write what you explained to me, 60 – 38 was 22) [Ms. Amaris writes 60 - 38 = 22] *le quitaste 2 más. ¿Por qué le quitaste 2 más?* (You took away 2 more, why did you take away 2 more?)
Diana: *It's 20. I thought of it in my head.*
MA: *Why? ¿Por qué le quitas otros 2?* (Why did you take away another 2)
Kellys: *Le quité el 2 y después puse el 60, le quité el 60 el cero del 60* (I took the 2 and then I put the 60, I took the 60 the zero from the 60)
Hugo: *It's gone past.*
MA: *Gone past what?*
Gina: *The 22. If you take away the 2 from the 22.*
MA: *Why?*
Diana: *El sesenta también se puede quitar.* (You can also take away the 60)
SA: *Okay, Carlos is jumping out of his seat. What are you thinking?*
Carlos: *24, because if the 60 minus 38 equals 22, and then you, on that 60- And then, you added 2 more, 'cuz 62.*

The conversation starts with the search for making sense of why the answer is *20*, but the explanations end up justifying why the answer is *24* or *20*. In this case, many students are starting to divert the direction of the game, from place value strategies to pre-algebraic thinking, but they still don't manage to fully shift the course of the discussion Ms. Amaris continues by asking "why one or the other?" Finally, she proposes: "Should we try and prove it?" and the whole class sets to work. Ms. Amaris suggests that they might think of using tens and ones, which they had used the day before. In this moment, students shared many ideas about how to represent *60* using groups of *10* and how to represent the ones, then taking away until finding the answer *24*. After modeling, they decide to prove their answer by adding *38* and *24* to see if it gave them *62*.

Now Ms. Amaris turns to the last equation: *65 – 38* = □. During the discussion of this equation, the game takes the unplanned turn in the direction first suggested by Juan Luis.

Gabriel: *It's just like 62 minus 38, but you add 3 more.*
MA: *3 more where?*
Gabriel: *To the 62.*
MA: *Okay. Gabriel, go ahead and tell us what you're thinking.*
Gabriel: *It's 30-something. It's just like 62 minus 38, but you add 3 more to the 62 and then you should have 65.*
MA: *Okay, so to this one I added 3 and I got the 65. I'm still taking away 38. What do I do to the 24?* [Sra. Amaris escribe la idea de Gabriel (Figure 3)]
Kellys: *24 take away 4?*

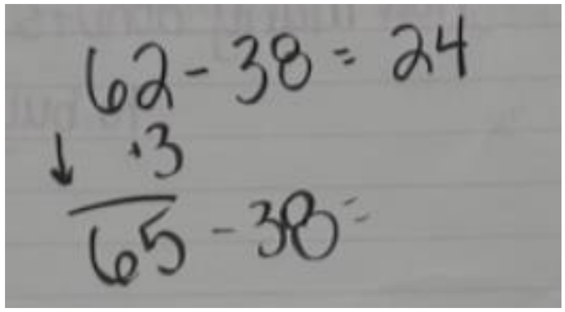

Figure 3: Gabriel's Strategy as Represented by Ms. Amaris

Ms. Amaris' notation (Figure 3) and her questions show she had every intention of getting students to notice how what is done to one side of an equation must also be done to the other. But, the conversation again took another turn and the idea was sidetracked momentarily (think of a ball kicked off course). So, Ms. Amaris decided to give students more time and the freedom to work at their desks in order to find the answer. Meanwhile, Ms. Amaris made her way to Gabriel hoping to better understand his thinking

Gabriel: *If it's 65 minus 38, 'cuz you're taking away 38 and there's only 5 in the 65, and then… And if you're taking away 38 and then you, um, take away the 8 from the 30, then you take away 5, there's gonna be 2 more in the 8.*
MA: *So, ¿lo que te está como atorando es la idea de quitarle 8 cuando solo hay 5 en las unidades?* (So, what's bothering you is the idea of taking away 8 when you only have 5 ones?)
Gabriel: *Hm…*
MA: *Oh, okay. Pues ¿cómo lo haríamos?¿Hay algún otro lugar donde le podríamos quitar?* (Well, how could we do it? Is there somewhere else where we could take from?)
Gabriel: [Nodded, pointing at a stack of ten cubes]
MA: *Ah! Okay, vamos a quitarle este 8.* (Oh! Ok, let's take away that 8, then)
Gabriel: *two, four, six, eight.*
MA: *Okay, ¿qué nos quedó?* (Ok, so what do we have left?)
Gabriel: *10, 20, 30, 40, 50. 50. 50, 55, 56, 57. 57.*
MA: *Okay, diez, veinte, treinta, cuarenta, cincuenta, cincuenta y uno, cincuenta y dos, cincuenta y tres, cincuenta y cuatro, cincuenta y cinco, cincuenta y seis, cincuenta y siete. So, lo que nosotros encontramos es que, para quitarle el ocho, tuvimos que entrarnos a uno de los dieces. ¿Qué te faltó quitar? Porque sólo le quitaste 8.* (Okay, ten, twenty, thirty, forty, fifty, fifty-one, fifty-two, fifty-three, fifty-four, fifty-five, fifty-six, fift-seven. So, what we found was that to take way the 8 we had to get inside one of the tens.What's left to take away? Because you've only taken away 8 so far.)
Gabriel: *30 ...*
MA: *¿Ves una manera mas fácil de quitar 30?* (Do you see an easy way to take away 30?)
Gabriel: *Should I just take away these?* [Pointing to 3 groups of 10 cubes]
MA: *That sounds easier, right?*
Gabriel: *Yeah.*
MA: *How many did you take away?*
Gabriel: *30. The answer is twenty-seven.*

The mathematical details in Gabriel’s strategy are important. He takes *8* from a *10* and then takes *30* more from the *5* tens that were left. This flexibility, in both his thinking and his sense of number (eg. seeing *65* as a group of *6* groups of ten and *5* ones) allowed him to see how he could take *8* from *10* instead of *5*, which had at first struck him as being difficult. Once this difficulty was noted and tackled with Ms. Amaris’ support, she kept talking with Gabriel. At this point, she suggests that they go and look at the equation that the class had been trying to solve (Figure 3).

> SA: *¿Hay alguna relación entre 24 y 27? So, tú me habías dicho: 62 más 3 es 65. ¿Qué es 24, si le sumamos otros 3?* (Is there some relationship between 24 and 27? So, you had said: 62 plus 3 is 65. What’s 24, if we add another 3?)
> Gabriel: *27*
> SA: *27. So, si hubiéramos ido con tu idea de hacer como una balanza entre lo que teníamos y lo que acabamos de hacer… Tu dijiste, aquí le sumamos 3, pues aquí también le podemos sumar 3. Y eso te dio la respuesta que sacaste, ¿no?* (So, if we had kept going with your idea of making like a balance between what we had before and what we just did…You said, here we added 3. Well, here we can also add 2. And that gave you the same answer that you just found, right?)

Ms. Amaris was able to identify an opportunity to return to the initial idea that Gabriel had shared. At first, he thought of $62 - 38 = \square$ and how, if you added *3* to *62* you would get *65*, but then he got stuck and was not able to continue. Ms. Amaris saw the opportunity to broaden the scope of his thinking by returning to his initial idea after he had solved the problem. In Figure 3, we see how Ms. Amaris uses the idea of a scale to find an equilibrium between both sides of the equation that Gabriel had attempted to solve. Ms. Amaris tried to support Gabriel in recognizing that the problem the class had, $62 – 38=\square$, was very nearly the problem they were attempting now, $65 – 38=\square$. In keeping with the techniques of GSA, the coach uses the game itself during training sessions in order to develop the technical understanding necessary to better control the game’s dynamics. In this case, Ms. Amaris saw that Gabriel could take the discussion further than where she had planned for it to go, but it didn’t quite get there. So, once she had sent students back to their desks, Ms. Amaris improvised a strategy, where her focus was to develop Gabriel’s idea giving him the opportunity to prepare to share with the class in future discussions.

These moments from a portion of a class session are just one example of how Ms. Amaris used an open and fluid dynamic to cede control of the discussion to her students, allowing them to determine the ideas that would be shared and how they might grow. In this example, we see how the idea of the balance starts with Juan Luis, Kellys and Gina, is picked up by Carlos and, eventually, is passed along to Gabriel. The idea never belonged to only one student, nor were Juan Luis or Kellys’ initial attempts a failure. As the idea was generated collectively, it continued to grow as more students participated. By stopping to focus on Gabriel, Ms. Amaris responded to the ideas that emerged from the group, shifting from her initial focus on base-10 concepts to fundamental concepts of pre-algebra.

Conclusions

Throughout this article we show Ms. Amaris’ flexibility in determining the content of her class discussions, an example that we feel justifies an argument for curricula, including grade level standards, to be similarly flexible. For example, Ms. Amaris’ initial goal was basically regrouping, using base-10 concepts and place value. However, Juan Luis, Kellys, Carlos and Gabriel's idea took the class to a new discussion on "balancing" an equation. In allowing the students to guide the direction of the discussion, letting them determine which plays to follow, we can see how Ms. Amaris' class not only met the initial objective of solving the equation, but also went further than what their teacher had planned. The idea of "balancing" the equation goes far beyond the curricular standards established as content to cover in second grade. According to Principles and Standards for School Mathematics (NCTM, 2000) this idea only begins to develop in third grade. Additionally, in classrooms with linguistically diverse students, who are traditionally silenced during mathematical discussions (Adler, 1997; Secada & De La Cruz, 1996), it is of utmost importance that teachers recognize that the control they impose on students' mathematical ideas and on the language in which ideas can be shared also impose mathematical silence. In other words, the more control we place on what is welcome in our discussions, the more ideas may be left out.

To conclude, based on our work this far, we pose the following questions for our field to consider in future investigations: Who decides what is taught each day in any given mathematics classroom? If we truly wish to promote the centering of students' mathematical ideas in mathematics instruction, what role do those ideas play in deciding what should be taught each day? And, if we are working to see our Latinx students positioned as true knowers of mathematics, how can we ensure that their classrooms are really theirs to direct and inspire? Perhaps, to start, we can play a little soccer, as a model of a collective dynamic that inspires through cooperation.

En este estudio documentamos cómo una idea matemática, compartida por un estudiante, cambia el desarrollo de la discusión de la clase. Nuestro trabajo caracteriza la dinámica flexible y abierta en la instrucción de matemáticas que una maestra adopta para dar a sus estudiantes control de sus propias ideas matemáticas. Nuestro trabajo argumenta que esta flexibilidad es necesaria para que los maestros se involucren en prácticas de instrucción que responden al pensamiento matemático de los estudiantes. Para demostrar la flexibilidad de la maestra usamos la analogía del fútbol, apoyándonos en la literatura de Enfoque Comprensivo del Sentido de Juego, la cual sugiere que el entrenador (el maestro en nuestro contexto) se posicione como un facilitador para manipular el entorno de práctica con el propósito de facilitar el aprendizaje.

Keywords: Educación Primaria, Equidad y Justicia, Estándares, Conocimiento del Profesor

Nuestro artículo describe una investigación desarrollada en un salón de segundo grado bilingüe en una escuela pública en el sur de los Estados Unidos. El objetivo de nuestro trabajo es delinear las características de una discusión productiva y elocuente durante la instrucción de matemáticas. Principalmente nos enfocamos en el análisis de cómo una idea puede cambiar el desarrollo de una discusión, y cómo los maestros pueden seguir las ideas nuevas que proponen sus estudiantes. Nuestro artículo identifica el origen de las ideas matemáticas durante una discusión colectiva, y cómo las ideas continúan desarrollándose en una pequeña conversación entre la maestra y un estudiante. Eventualmente esta conversación se convierte en la clave para expandir las ideas matemáticas discutidas por la clase. Para intentar explicar cómo la idea de un solo estudiante se propaga por todo el salón, hemos decidido usar una analogía muy propia a nuestra cultura Latina, el fútbol. Así la maestra, como una entrenadora técnica, tiene un plan general para la discusión — en este caso, el partido — pero, como los aficionados bien conocen, en un partido de fútbol lo que sobra son posibilidades. En este caso, veremos como los estudiantes proponen una idea más compleja, pasando la idea como la pelota. Gabriel, el estudiante en nuestro análisis, tira la pelota — su idea matemática — y Sra. Amaris, la maestra en nuestro análisis, viendo adónde sus estudiantes han llevado el partido, decide seguir esta idea, dándoles libertad a los estudiantes de tener control del partido. En este caso, lo que pudimos ver es cómo una clase de matemáticas apoya el desarrollo natural de las ideas matemáticas posicionando a los mismos estudiantes como las estrellas del campo.

En esta clase 21 estudiantes aprenden matemáticas sin restricciones de lenguaje. La cultura de los estudiantes es un componente importante en su aprendizaje diario. En investigaciones anteriores, basados en el aula de la Sra. Amaris, hemos argumentado que el permitir que los estudiantes expresen sus ideas matemáticas, incluso cuando aún no están completas o son temporalmente incorrectas, permite que se abra un espacio para que las ideas matemáticas fluyan y también se abra un espacio para que la maestra pueda ayudar a construir un conocimiento aún más sólido de las matemáticas (Maldonado, Krause & Adams, 2018; Carpenter; Fennema; Franke; Levi & Empson, 2015). Hemos argumentado también que esta construcción de conocimiento se hace posible cuando la comunicación entre la maestra y los estudiantes es clara (para los dos). Por lo tanto, el uso del lenguaje juega un papel central en el aprendizaje y la enseñanza de las matemáticas (Maldonado et al., 2018). Usando como base nuestro trabajo anterior, y usando la analogía del fútbol, presentamos aquí como los estudiantes de la Sra. Amaris son capaces de poner en marcha una idea matemática que la Sra. Amaris apoya con ánimo, fomentando y haciendo visible cómo las ideas matemáticas se forman de manera colectiva a través de intercambios rápidos y a veces difíciles de trazar. En esta clase, aunque las discusiones inician con un plan trazado previamente, la directora técnica está lista para cambiar su estrategia en cualquier instante siguiendo la corriente del partido. La Sra. Amaris no solamente se enfoca en los pasos de jugador a jugador, sino tiene la vista en la cancha entera. De esta manera, por medio de sus preguntas, guía a los estudiantes con sus ideas matemáticas emergentes hasta que finalizan en una idea o conexión matemática profunda (y tal vez, siguiendo nuestra analogía, podríamos decir, ¡hasta que terminan en un victorioso gol!). La experiencia de ver surgir las ideas nos ayuda a identificar el papel que juega la maestra en ayudar a la clase a solidificar la idea matemática. Específicamente nuestro análisis presenta una respuesta a las preguntas: *¿Cómo se ve la instrucción de matemáticas donde las ideas emergentes de los estudiantes determinan el enfoque de la clase? ¿Cómo pueden los maestros apoyar la evolución de estas ideas?*

Nuestro artículo aporta a la literatura demostrando cómo se desarrollan las ideas matemáticas en un salón bilingüe, específicamente en el contexto educativo de los Estados Unidos. Nuestro artículo se enfoca en describir cómo una maestra observa y participa para facilitar discusiones productivas, en dónde las ideas matemáticas de los estudiantes se usan para construir una idea matemática más avanzada. En argumentar que estas ideas se producen de manera colectiva, argumentamos que la cognición individual es parte de una cognición colectiva en que participan y comparten todos los miembros del salón. Esto se puede ver cuando una idea, pasada a Gabriel, se convierte en la idea que servirá para apoyar a la clase entera.

Marco Teórico

El intercambio de ideas durante la clase de matemáticas dónde los estudiantes tienen oportunidades de compartir, justificar, conectar y extender ideas ha sido el centro de reformas educativas en los últimos años en los Estados Unidos (NCTM, 2014). Siguiendo este enfoque varios investigadores han realizado estudios sobre discusiones matemáticas demostrando un impacto positivo en el aprendizaje de los estudiantes (Moschkovich, 2018). Estos mismos estudios han demostrado que incluir las ideas matemáticas de los estudiantes a través de la discusión en clase de matemáticas no es una práctica fácil. Al mismo tiempo otros estudios han indicado que no todos los estudiantes se benefician de igual manera durante las discusiones en la clase de matemáticas. Por ejemplo, Moschkovich (2018) encontró que muchas veces estas discusiones sólo consiguen afianzar la posición de expertos con la que algunos estudiantes se identifican y usan a diario para dominar las discusiones. También aquellos estudiantes que se identifican por usar estrategias avanzadas tienden a compartir sus estrategias más frecuentemente. Estas desventajas son aún más marcadas en aquellos estudiantes cuya primera lengua no es inglés porque tienden a participar de una manera mínima en estas discusiones (Adler, 1997; Secada & De La Cruz, 1996).

Muy pocos estudios se han enfocado en demostrar las contribuciones de estudiantes bilingües y sus aportes significativos al aprendizaje de toda la clase (por ejemplo Turner & Celedón-Pattichis, 2011; Turner, Dominguez, Maldonado & Empson, 2013). Sin embargo, dada la complejidad de manejar un salón de clase con una amplia diversidad cultural y lingüística, todavía existen preguntas sobre cómo, y qué se requiere de las maestras para, orquestar una discusión productiva y rica en contenido matemático, especialmente en el contexto bilingüe y multicultural característico de los Estados Unidos. Nuestro trabajo es un esfuerzo para contribuir a entender qué se necesita y para dar un ejemplo de cómo se puede hacer.

En un intento por establecer una metodología clara que delinee cómo se ve la práctica de la Sra. Amaris, hemos decido usar un marco teórico común en la literatura deportiva conocida como Enfoque Comprensivo del Sentido de Juego (Game Sense coaching approach). En GSA (por su sigla en inglés) el entrenador usa el juego o la forma de juego como el punto de partida y el enfoque continuo en la sesión de entrenamiento. Además, a través de GSA el entrenador anima a los jugadores a comprender el juego y a adquirir conciencia táctica y técnica dentro del contexto del juego para ayudar a desarrollar una mejor toma de decisiones cuando juegan (Australian Sports Commission, 1996). GSA argumenta que el uso de esta práctica permite que los jugadores tengan más oportunidades de probar ideas y proponer estrategias que se desarrollan mediante la discusión entre ellos y el entrenador (Evans & Light, 2008; Light & Evans, 2010). La literatura de GSA sugiere que el entrenador se posicione como un facilitador (Light & Evans, 2010). Como facilitador, el entrenador guía al jugador en la toma de decisiones para resolver los problemas del juego. Esta postura educativa "centrada en el atleta" hace que los jugadores tengan más opciones y control sobre el juego. El entrenador como educador (Jones, 2006) puede manipular el entorno de práctica para estructurar y facilitar el aprendizaje (Light, 2013). La literatura en educación también tiene precedente en ver a la maestra como una entrenadora (Duncan-Andrade, 2010). Duncan-Andrade (2010) argumenta que la enseñanza requiere tácticas de motivación que deben ser parte de la formación de cualquier entrenador técnico.

Si vemos la planeación de lecciones como una preparación para el juego, en donde no hay una sola manera de llegar al arco, en lugar de enfocarnos en un progreso lineal, podremos ver la complejidad del campo — el salón de clase — y la abundancia de posibilidades. Por esta abundancia, precisamente, no es posible para una maestra determinar todos los caminos que una discusión puede tomar. Al mismo tiempo no sería muy productivo enfocarse sólo en lo que le interesa a la maestra. Por esta razón el papel de la maestra es fundamental. Ella puede leer y reaccionar a lo que sucede instantáneamente, cambiando de plan de acuerdo con la dinámica que encuentra (Duncan-Andrade, 2010). El aprendizaje matemático es complejo, y no se puede limitar a un solo camino o trayectoria (Empson, 2011). Requiere que la maestra acepte el no controlar la dirección del juego. Igual con un partido de fútbol, el entrenador y los jugadores deben reaccionar y seguir el juego en el momento.

Métodos

Datos

Durante dos años consecutivos hemos trabajado muy de cerca con la Sra. Amaris y sus alumnos y hemos recolectado datos extensos de su trabajo en el aula. El trabajo que presentamos en este artículo se centra en un pasaje de una conversación entre la Sra. Amaris y Gabriel, uno de sus estudiantes del 2do grado. El pasaje fue grabado en video y transcrito para su análisis.

Problemas y Conversaciones Numéricas

Los episodios de la clase que presentaremos en nuestro análisis vienen de la discusión que generaron el problema en la Figura 1 y las dos ecuaciones en la Figura 2.

La Sra. Amaris suele comenzar sus lecciones de matemáticas con una conversación numérica (Number Talks en inglés) (Parrish, 2014; Bray & Maldonado, 2018). En esta lección comenzó la clase con un problema basado en la crisis de contaminación de agua en Flint, Michigan (Figura 1). El problema usó el contexto de un recaudo de fondos que los niños organizaron y pidió que los niños pensaran en cómo llegar de $38 a $60. Después de seguir una secuencia de lección común en clases de CGI (Carpenter, et al., 2015), pasaron a una conversación numérica.

La semana pasada recolectamos 38 dólares en la jarra para mandar dinero a Flint. Si después de una semana tenemos 60 dólares almacenados, ¿cuánto dinero recolectamos durante la semana?

Figura 1: Problema para iniciar clase

62 – 38 = □	65 – 38 = □

Figura 2: Conversaciones Numéricas discutidas después del problema inicial

La conversación numérica es una práctica pedagógica que la Sra. Amaris ha usado desde el principio del año escolar. Los estudiantes ya familiarizados con esta rutina sabían que estas discusiones se centraban en la manera de pensar acerca de ecuaciones y las estrategias utilizadas para resolverlas. Estas ecuaciones se seleccionaron con el propósito inicial de la Sra. Amaris de ver como los niños usan valor posicional (Carpenter, et al., 2015).

Análisis

Nuestro análisis involucró no sólo una consideración de lo que Sra. Amaris y Gabriel dijeron e hicieron, sino también la situación y el contexto, incluyendo lo que todos los otros niños dijeron e hicieron. Identificamos puntos específicos en la conversación para determinar nuestra unidad de análisis (Jacobs & Morita, 2002). A veces la unidad consistía en el comentario o pregunta individual de la Sra. Amaris, y otras veces incluía una secuencia de comentarios y preguntas. Nuestro análisis comenzó con el problema inicial (Figura 1). Ahí identificamos las ideas matemáticas que surgieron y las prácticas lingüísticas de todos los involucrados en la discusión.

Resultados y Discusión

La conversación numérica empieza con la discusión de la ecuación *60 - 38 =* □ del problema en la Figura 1. El propósito de la ecuación era continuar trabajando en la instrucción de Base-10 y valor posicional, de tal manera que los estudiantes pudieran componer y descomponer los números para "quitar 8 al 0". La Sra. Amaris comenzó preguntándole a Emilio sus ideas para resolver la ecuación y él dijo que la respuesta era *22*. La Sra. Amaris escribe la respuesta e insiste en una explicación acerca de por qué esa respuesta: "¿Cómo sabían que la respuesta era 22?" Varios estudiantes compartieron explicaciones diferentes. Por ejemplo:

> Diana: *60 minus 30 equals 30. 8 plus 10 equals, wait, 8 plus 2 equals 10. So then, 8 minus, I mean, 30 minus 8 equals 22.*
> SA: *Okay, so 60 menos, 30 es 30. Luego al 30 le quitas 8 y te quedan 22* [La Sra. Amaris escribió todo en el tablero a medida que repitió en español lo que Diana dijo en inglés]

Después de compartir las estrategias que resultan en *22*, la Sra. Amaris pasó a escribir una ecuación, *62 – 38 =* □ (Figura 2), para continuar con las conversaciones numéricas. De la misma manera esta ecuación provocó varias ideas. Por ejemplo:

> Juan Luis: *It's 22, just that you take more, 2 more, 20.*
> SA: *Okay, some people are saying that. Let's see if there's some other ideas, too.*
> Diana: *24.*
> SA: *Ah, I hear two ideas now.*
> Diana: *'Cuz last time we added 71 and the answer was 20, it was, the answer was 22, wait, 24.*
> SA: *I'm gonna put up the two answers that I've heard. I heard Juan Luis say 20. I heard Diana say 24. If you have another idea, go ahead and call it out.*

La Sra. Amaris continua la discusión pidiendo explicaciones sobre ¿Por qué *20*?

> SA: *Okay, so háblame de como sacaron 20.*
> Kellys: *La respuesta no más de 60 – 38, fue 22 yo no más le quité los 2 del 22 y después el cero.*
> SA: *Okay, voy a escribir lo que me explicaste. 60 – 38 son 22* [La Sra. Amaris escribe 60 - 38 = 22] *le quitaste 2 más. ¿Por qué le quitaste 2 más?*
> Diana: *It's 20. I thought of it in my head.*
> SA: *Why? ¿Por qué le quitas otros 2?*
> Kellys: *Le quité el 2 y después puse el 60, le quité el 60 el cero del 60*
> Hugo: *It's gone past.*
> SA: *Gone past what?*
> Gina: *The 22. If you take away the 2 from the 22.*
> SA: *Why?*
> Diana: *El sesenta también se puede quitar.*
> SA: *Okay, Carlos is jumping out of his seat. What are you thinking?*
> Carlos: *24, because if the 60 minus 38 equals 22, and then you, on that 60- And then, you added 2 more, 'cuz 62.*

La conversación inicia con la búsqueda de ¿por qué es *20*? y las explicaciones terminan justificando porque la respuesta es *24* ó *20*. En este caso, Carlos y Kellys están empezando a dirigir el partido en una dirección inesperada, pero todavía no logran cambiar la discusión. La Sra. Amaris continúa preguntando ¿por qué la una o la otra? Luego termina por proponer: "Should we try and prove it?" Y la clase entera se embarca en la tarea. La Sra. Amaris propone que usen las decenas y unidades de las que habían hablado el día anterior. En ese momento los estudiantes comparten varias ideas sobre cómo representar *60* usando grupos de *10* y cómo representar las unidades y quitando hasta encontrar la respuesta 24. Después de modelarlo lo deciden comprobar con una suma de *38* y *24* para ver si les salía el *62*.

Finalmente La Sra. Amaris propone la última ecuación *65 – 38* = □. Durante la discusión de esta ecuación el partido toma un giro fuera de lo planeado, va en la dirección inicialmente sugerida por Juan Luis.

Gabriel: *It's just like 62 minus 38, but you add 3 more.*
SA: *3 more where?*
Gabriel: *To the 62.*
SA: *Okay. Gabriel, go ahead and tell us what you're thinking.*
Gabriel: *It's 30-something. It's just like 62 minus 38, but you add 3 more to the 62 and then you should have 65.*
SA: *Okay, so to this one I added 3 and I got the 65. I'm still taking away 38. What do I do to the 24?* [Sra. Amaris escribe la idea de Gabriel (Figure 3)]
Kellys: *24 take away 4?*

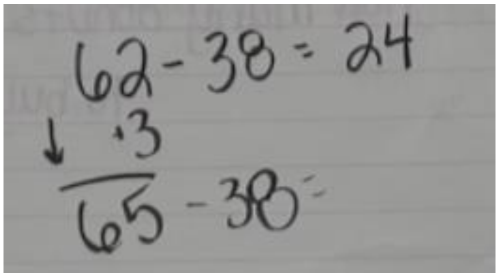

Figura 3: Idea de Gabriel representada por la Sra. Amaris

La notación de la Sra. Amaris (Figura 3) y sus preguntas tenían toda la intención de hacer que los estudiantes pudieran ver que lo mismo que se hace a un lado de la ecuación se debe hacer al otro lado. Pero la conversación tomó un giro diferente, la pelota se desvió. La Sra. Amaris decidió darles más tiempo y la libertad de trabajar en sus escritorios para encontrar la respuesta. Mientras eso pasaba, la Sra. Amaris se acerca a Gabriel tratando de entender un poco más su manera de pensar.

Gabriel: *If it's 65 minus 38, 'cuz you're taking away 38 and there's only 5 in the 65, and then… And if you're taking away 38 and then you, um, take away the 8 from the 30, then you take away 5, there's gonna be 2 more in the 8.*
SA: *So, ¿lo que te está como atorando es la idea de quitarle 8 cuando solo hay 5 en las unidades?*
Gabriel: *Hm…*

SA: *Oh, okay. Pues ¿cómo lo haríamos?¿Hay algún otro lugar donde le podríamos quitar?*
Gabriel: [Asintió, apuntando a un grupo de 10 cubos]
SA: *Ah! Okay, vamos a quitarle este 8.*
Gabriel: *two, four, six, eight.*
SA: *Okay, ¿qué nos quedó?*
Gabriel: *10, 20, 30, 40, 50. 50. 50, 55, 56, 57. 57.*
SA: *Okay, diez, veinte, treinta, cuarenta, cincuenta, cincuenta y uno, cincuenta y dos, cincuenta y tres, cincuenta y cuatro, cincuenta y cinco, cincuenta y seis, cincuenta y siete. So, lo que nosotros encontramos es que, para quitarle el ocho, tuvimos que entrarnos a uno de los dieces. ¿Qué te faltó quitar? Porque sólo le quitaste 8.*
Gabriel: *30 ...*
SA: *¿Ves una manera mas fácil de quitar 30?*
Gabriel: *Should I just take away these?* [Apuntando a 3 grupos de 10 cubos]
SA: *That sounds easier, right?*
Gabriel: *Yeah.*
SA: *How many did you take away?*
Gabriel: *30. The answer is twenty-seven.*

Los detalles matemáticos en la estrategia de Gabriel son importantes. Quita *8* de un *10*, y luego quita *30* más de las *5* decenas que quedaron. La flexibilidad en su forma de pensar y su sentido numérico (es decir, ver a *65* cómo un grupo de *6* decenas y *5* unidades) le permite ver cómo quitar *8* de *10* en lugar de *5*, lo que él había calificado como difícil. Una vez que esta dificultad fue notada y abordada por Sra. Amaris, ella continuó hablando con Gabriel. Esta vez ella propone ir y ver la ecuación que estaban resolviendo antes como clase (Figura 3).

SA:*¿Hay alguna relación entre 24 y 27? So, tú me habías dicho: 62 más 3 es 65. ¿Qué es 24, si le sumamos otros 3?*
Gabriel: *27*
SA: *27. So, si hubiéramos ido con tu idea de hacer como una balanza entre lo que teníamos y lo que acabamos de hacer… Tu dijiste, aquí le sumamos 3, pues aquí también le podemos sumar 3. Y eso te dio la respuesta que sacaste, ¿no?*

La Sra. Amaris pudo identificar una oportunidad para volver a las ideas iniciales compartidas por Gabriel. Al principio pensó en $62 - 38 = \square$ y que si sumaba *3* a *62* obtendría *65*, pero luego se atoró y no pudo continuar. La Sra. Amaris vio la oportunidad de ampliar su pensamiento volviendo a su idea inicial después de haber resuelto el problema. En la Figura 3 vemos como la Sra. Amaris usa la idea de una escala para equilibrar ambos lados de la ecuación en la que Gabriel estaba pensando. La Sra. Amaris trataba de ayudar a Gabriel a darse cuenta de que el problema que él realmente resolvió, $62 – 38=\square$, era casi el problema que quería resolver, $65 – 38=\square$. Como en las técnicas de GSA, el entrenador usa el juego durante entrenamientos para desarrollar la conciencia táctica necesaria para controlar mejor la dinámica del juego. En este caso la Sra. Amaris vio que Gabriel podría llevar a la discusión de la clase una idea más allá de lo que ella había planeado, pero no se logró. Pero al enviar a los niños a trabajar en sus mesas, la Sra. Amaris improvisó una estrategia, en dónde su enfoque era desarrollar la idea de Gabriel y darle la oportunidad de prepararse para compartirla con la clase en futuras discusiones.

Este fragmento de la clase es un ejemplo de como la Sra. Amaris usa una dinámica flexible y abierta para ir pasándoles el control a sus estudiantes, a que ellos determinen y controlen las ideas que logran fluir y ser compartidas. En este ejemplo podemos ver la idea del balance empezando con Juan Luis, Kellys y Gina y luego pasando a Gabriel. Esta idea no le pertenece a un solo estudiante, es una idea generada en grupo que continúa creciendo. Al parar y enfocarse en Gabriel, la Sra. Amaris respondió a las ideas que surgían (como grupo), cambiando el enfoque inicial, base-10, para discutir conceptos básicos de pre-algebra.

Conclusiones

A través de nuestro artículo hemos demostrado como la flexibilidad de la Sra. Amaris para determinar el contenido de la clase justifica el argumento de que el currículo debe ser flexible de la misma manera. Por ejemplo, el punto inicial de la Sra. Amaris era básicamente reagrupar, usando conceptos de Base-10 y valor posicional. Sin embargo las ideas de Juan Luis, Kellys, Carlos y Gabriel los llevó también a hablar sobre "balancear" una ecuación. En permitir que los estudiantes guiaran la conversación, dejándolos determinar las jugadas a seguir, pudimos ver que la clase de matemáticas de la Sra. Amaris no sólo cumplió con el objetivo inicial de solucionar la ecuación, pero también llevó la discusión aún más allá de lo que la Sra. Amaris había planeado. La idea de "balancear" la ecuación va mucho más allá de lo que los estándares curriculares establecen como contenido que se debe cubrir en segundo grado. De acuerdo con Principles and Standards for School Mathemtics (NCTM, 2000) esta idea empieza a desarrollarse en el tercer grado.

Adicionalmente, en salones de clase con estudiantes lingüísticamente diversos, quienes tradicionalmente se ven silenciados en discusiones matemáticas (Adler, 1997; Secada & De La Cruz, 1996), es de mayor importancia que las maestras reconozcan que el control que imponen a las ideas matemáticas de los estudiantes, y que el idioma en que las ideas son compartidas impone igualmente un silencio matemático.

Para finalizar, basado en el trabajo que hemos expuesto hasta este punto, queremos dejar algunas preguntas al campo de investigación de educación de matemáticas como punto de partida para futuras investigaciones: ¿Quién determina qué se debe enseñar cada día en el aula de clase? Si en realidad estamos proponiendo usar las ideas matemáticas de los estudiantes durante la instrucción de matemáticas, ¿qué papel juegan las ideas matemáticas de los estudiantes en lo que se debe enseñar diariamente? Si estamos trabajando verdaderamente para ver a nuestros estudiantes Latinx posicionándose como verdaderos conocedores matemáticos, ¿cómo podemos asegurar que los salones de clase sean suyos para dirigir e inspirar? A lo mejor, para empezar, podemos jugar al fútbol, pero cómo un modelo de dinámica colectivo que promueva cooperación e inspiración.

CO-CONSTRUCTING "QUIET" THROUGH PEER INTERACTIONS: UNDERSTANDING "QUIET" PARTICIPATION IN A SMALL-GROUP MATH TASK

Heather Fink
University of California, Berkeley
hfink@berkeley.edu

To disrupt patterns of marginalization that play out through interactions in math classrooms, teachers need to identify and address inequities in student participation, both in terms of participation outcomes and processes. In this study, I take an expansive view of participation and examine how the "quiet" participation of one 9th grade student is co-constructed through small-group interactions during an Algebra task. Analysis reveals three features of the group's interactions that fostered the co-construction of Becca's "quiet" participation: 1. Becca was positioned as a non-contributing silent beneficiary of learning, 2. Becca's contributions received less support than her peers', 3. Disagreement with Becca was softer than with John. Findings suggest that the perceived issue of low verbal production did not reside within Becca, but rather was the result of inequitable participation processes that played out through peer interactions.

Keywords: Classroom Discourse, Equity and Diversity

Educational inequities come in all shapes and sizes and are enacted through classroom interactions in many different ways. Institutional level inequities connected to race, gender, and socioeconomics undoubtedly shape students' mathematical experiences (Esmonde & Langer-Osuna, 2013; Herbel-Eisenmann, Choppin, Wagner & Pimm, 2011). While teachers alone cannot fix these historical injustices, they *can* disrupt patterns of marginalization by supporting more equitable interactions among students (Boaler & Staples, 2008). In this paper, I focus on equity as it relates to student participation in a math task. I examine how the participation of one student, labeled as "quiet" by her math teacher, is co-constructed through group interactions.

Labeling students based on behavioral patterns is common and done often with good intentions. However, labeling can be harmful if behavioral tendencies are seen as inherent characteristics of students (Gutierrez & Rogoff, 2003). By accepting that some student voices will inevitably take up more space than others, we run the risk of endorsing different participation expectations for different students, leading to inequitable learning opportunities (Hand, 2012). In addition, labels can position certain students as being deficient or inferior, since the labels themselves are typically not neutral (McDermott, 2010). Being "quiet" in a math class is often associated with less-than-desirable traits, such as being timid, less confident, and less knowledgeable. Instead, if we acknowledge that "quiet" tendencies are a byproduct of human interactions within learning environments (Cole, 1998; Lave, 1996), we can then address participation disparities through interactional interventions. The goal is not to *fix* individual students, but rather to support more equitable interactions among students. To do this, we need a better understanding of how students labeled as "quiet" participate through interaction, and we must be careful not to assume all "quiet" students share the same backgrounds or have the same strengths or needs (Gutierrez & Rogoff, 2003).

This study explores the interactions of four 9th grade students during a small-group math task. I pay particular attention to Becca, a student described as "quiet" by her math teacher. Research questions are: 1) *What did participation look like for a "quiet" student working on a small-group math task?* 2) *How was "quiet" participation co-constructed through peer interactions?*

Theoretical Framework

My work draws on sociocultural and situated theories that claim learning happens through participation in cultural activities (Lave & Wenger, 1991; Rogoff, 1990; Vygotsky, 1978; Wenger, 1998), considering language and discursive practices as central to developmental processes (Lerman, 2001). In this study, my perspectives on equity, learning, and participation are based on those described by Esmonde (2009). Esmonde asserts that "in the context of cooperative group work and participation in mathematical practices, equity can be defined as a fair distribution of opportunities to learn or opportunities to participate" (p. 1010). She views mathematical learning as referencing both the development of content-related understandings *and* the development of productive positional identities. Esmonde takes a broad view of participation, noting that "Although talk is a valued form of participation in many mathematics classrooms, there may be other valuable forms of participation that are less visible" (p. 1033).

One key part of combatting participation inequities is understanding how opportunities for participation are constructed and taken up (or not) through classroom interactions, since equity is both a *goal* and a *process* (Martin, 2003). If opportunities for participation are unfair, then it is reasonable to assume participation (the process through which students learn) will be inequitable as well, since a person's participation in learning activities is a function of the opportunities that person is given to participate (Gresalfi, Martin, Hand, & Greeno, 2009). And those opportunities for participation are shaped by the roles and responsibilities that a student is assigned through acts of positioning (van Langenhove & Harré, 1999). Equitable learning processes require that each and every student be positioned as a competent learner and doer of mathematics who has ideas worth sharing and from whom her peers can learn. Students positioned with competence and authority have more opportunities to participate in consequential and influential ways during student interactions, and therefore, have better access to opportunities for rich mathematical learning in terms of content and identity development (Cohen & Lotan, 1995; Engle, Langer-Osuna, & McKinney de Royston, 2014; Gresalfi et al., 2009; Langer-Osuna, 2011).

Methods

Data Collection

Participants. The group consisted of two girls (Becca & Paloma) and two boys (John & Kyle) from an Algebra 1 class in an urban, public high school. Names were changed. Becca was identified as a focal student based on her being described by her math teacher as "really quiet." The students' math teacher taught the lesson and shared post-lesson reflections. This class used CPM curriculum (cpm.org) and worked in groups on a daily basis.

Task. I designed the task and lesson plan for this lesson with the goal of eliciting productive mathematical participation from all group members. The math task, Searching for Sequences, addressed content related to linear growth patterns. Task materials include 16 pattern cards and a playing board, shown in Figure 1. The image below shows the focal group's final task solution.

Figure 1: Searching for Sequences Task - Pattern Cards and Playing Board

At the start of the task, four pattern cards were dealt to each student and kept hidden. Students then took turns placing one card at a time on the board, trying to create 3-card pattern sequences. Students were instructed to justify card placements by explaining patterns they saw. Cards were designed to allow for multiple correct solutions.

Video. Using an external microphone, video recorded participants' speech, gestures, body movements, and eye gaze. The video was 15 minutes long, the time it took to complete the task.

Data Analysis

Video was transcribed for speech, card placements, and salient gestures then divided into talk turns. A *talk turn* was uninterrupted speech by one person. If two people spoke simultaneously, each person was assigned a separate talk turn with overlapping timestamps. Drawing on previous research (e.g., Reinholz and Shah, 2018), I coded two forms of verbal participation: explanations and questions. I also coded one task-specific form of non-verbal participation: card placements. Details of the coding scheme are organized by form of participation and described below.

Questioning. I started by identifying every question that was asked based on speaker's word choice and intonation. I then coded who the question was *asked by* and *answered by*. *Answered by* included any verbal response to the question asked, even if the response was "I don't know." If more than one person responded to a question, multiple people were coded as *answered by*. If no one responded verbally to a question, the *answered by* was coded as "no one". I then tracked to whom questions were directed. The content of the question, students' body positions and eye gaze, and the sequence of talk and action were used to determine *directed to*. If a question was asked without a clear target (e.g., the asker was looking at the board and the content of the question did not indicate who was expected to respond), *directed to* was coded as "everyone."

Sense-making. Initially, I coded sense-making participation based only on explanations of pattern growth. *Explaining growth* was when a student talked about how a pattern was growing / shrinking or described how another figure in the pattern sequence might look. Growth explanations were then attributed to particular sequences to determine who explained which sequences. I then flagged non-verbal indicators (i.e. suggesting the 2^{nd} or 3^{rd} card in a sequence) and non-explanatory verbal indicators (i.e. exclamations) for each sequence. *Suggesting 2^{nd} / 3^{rd} card* was assigned if a student made a verbal suggestion for or placed the 2^{nd} or 3^{rd} card in a mathematically correct pattern sequence. *Sense-making exclaiming* was assigned if a student gave verbal indication that she agreed with a 2^{nd} or 3^{rd} card placement or understood a completed sequence (e.g., "Yeah, that makes sense" or "Oh!" after a 3^{rd} card was placed). These additional indicators assume sense-making happened internally even though the details were not shared verbally. *Explaining growth* is the clearest indicator of sense-making since we had access to how students were thinking about patterns. *Suggesting 2^{nd}/3^{rd} card* is a moderate indicator, since a mathematically correct placement was made, but we did not have access to exactly how students were thinking about patterns. *Sense-making exclaiming* is the most speculative indicator, since nothing is known about how or what students were making sense of with regard to the patterns.

Card placement. For each card placement, I captured the card image, the starting and ending card locations, and the person placing the card. A *card placement* was when a pattern card was placed on the board from someone's hand, a card was moved from one location on the board to another, or a card was removed from the board. For each person, I totaled the number of placements made and the number of unique cards placed. A *unique card* was a pattern card that had not yet been placed by that student. For example, if a student placed a card then on her next turn moved that same card to a new location, that process would count as two placements and one unique card. I then determined if someone other than the student placing the card had suggested where to place it. If so, I coded it as a *placement suggestion*. I also coded how each student responded to the placements made by her peers. *Positive response* was coded with clear approval of placement, either verbal (e.g., "Yeah, that makes sense") or non-verbal (e.g., head nod). *Negative response* was coded with clear disapproval, either verbal (e.g., "No, I don't think that goes there" or non-verbal (e.g., head shake no). *Neutral response* was coded if no clear approval or disapproval was given but the student seemed to know the placement had been made based on eye gaze, body position, or subsequent talk. *Unaware response* was coded with no clear evidence the student knew the placement had been made.

Findings

Findings are divided into two sections and organized by research question: 1) *What did participation look like for a "quiet" student working on a small-group math task?* 2) *How was "quiet" participation co-constructed through peer interactions?*

Becca's "Quiet" Participation

Table 1 summarizes key participation metrics for each of the four students and the teacher. Students worked for 15 minutes on the task. The teacher joined for 90 seconds of that time.

Table 1: Participation Metrics by Person

	Talk Turns		Words Spoken		Words	# of Questions		# of Growth	# of Card Placements	
	#	%	#	%	per Turn	Asked by	Answered by	Explanations	Total	Unique Cards
Becca	**32**	**11%**	**98**	**5%**	**3.1**	**7**	**14**	**0**	**11**	**5**
John	111	37%	806	45%	7.3	20	32	2	20	12
Kyle	49	16%	240	13%	4.9	10	14	5	8	5
Paloma	100	33%	504	28%	5.0	21	17	5	8	5
Teacher	8	3%	141	8%	17.6	5	0	0	3	2
TOTAL	300	100%	1789	100%	6.0	63	77	12	50	n/a

Note. Some questions received multiple responses, hence the number *answered by* exceeds the number *asked by*.

Becca spoke the least out of the four students in the focal group. She took the fewest talk turns (11%, 32 turns), spoke the fewest words (5%, 98 words), and had the shortest talk turns (avg. 3.1 words/turn). John and Paloma led the group with roughly the same number of talk turns (111 and 100 turns respectively), although John spoke the most words (45%, 806 words) and had the longest talk turns (avg. 7.3 words/turn). Becca also asked the fewest questions (7 questions) but answered the same number of questions as Kyle (14 questions) and just three fewer than Paloma (17 questions). John dominated the answering of questions by responding to twice as many questions as everyone else (32 questions). Becca made 11 card placements but did not offer any verbal explanations of growth patterns she saw. John made about twice as many placements as everyone else (20 placements) and offered two explanations. Kyle and Paloma made the fewest card placements (8 placements each) but gave the most explanations (5 explanations each). We also see that Becca, Kyle, and Paloma each made placements with 5 unique cards, meaning they each touched the four cards originally dealt to them plus one additional card. In contrast, John made placements involving 12 unique cards, meaning he touched his four original cards plus eight more, accounting for 75% of all pattern cards.

After considering these metrics, much is still unknown about Becca's mathematical sense-making, a key part of her learning trajectory. We do not yet know if Becca's 11 placements were based on her own mathematical reasoning, someone else's, or no mathematical reasoning at all. If we use student explanations as an indicator of learning (e.g., Hatano, 1993), we see no evidence of sense-making by Becca. However, if we broaden our view of sense-making to include contextual non-verbal indicators (i.e., suggesting 2nd/3rd card in a sequence) and non-explanatory verbal indicators (i.e., sense-making exclaiming), there is evidence of Becca's sense-making for five out of the group's six sequences. Even though the final task solution included only four sequences, the group completed six mathematically correct sequences in the process of reaching their solution. Students formed two sequences that were later dismantled in favor of using the cards for other sequences. Table 2 shows the six pattern sequences the group formed in chronological order. The shaded blocks on the right represent the clearest sense-making indicator by person by sequence. The darker the shading, the clearer the indicator. For example, Kyle and Paloma's dark boxes in the top row of the table indicate they both explained growth for this first sequence. John's lightly shaded box indicates he made a sense-making exclamation, and Becca's unshaded box indicates no evidence of sense-making by Becca for this first sequence.

Table 2: Students' Mathematical Sense-Making by Sequence

				Mathematical Sense-Making							
		Time of Pattern…		Indicated by…				Enacting by…			
Order	Pattern Sequence	Completion	Dismantling	Explaining Growth	Suggesting 2nd Card	Suggesting 3rd Card	Sense-making Exclaiming	Becca	John	Kyle	Paloma
1		4:59	13:56	Kyle & Paloma	Kyle	Kyle	John & Paloma				
2		7:18	n/a FINAL FOUR	John	Kyle	John	Becca & Paloma				
3		7:33	20:10	No one	Becca	John	John & Paloma				
4		11:41	n/a FINAL FOUR	Kyle & John	John	John	Becca, Kyle, & Paloma				
5		13:46	n/a FINAL FOUR	Kyle & Paloma	Kyle	Becca, Kyle, Paloma	Becca & Paloma				
6		14:41	n/a FINAL FOUR	Paloma	John & Paloma	John & Paloma	Becca, John, Paloma				

Even though Becca did not explain any growth patterns, her 2nd and 3rd card suggestions for two different sequences, indicate she was indeed making some sense of those growth patterns. Becca made sense-making exclamations for three additional sequences. For example, Becca said, "Yeah, that makes sense," just after John placed the 3rd card in the fourth sequence and Kyle explained the pattern he saw. Considering all sense-making indicators together, we see evidence

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

that Becca made sense of at least five out of the six sequences, the same number as John and one more than Kyle. Paloma was the only student who indicated sense-making for all six sequences.

Participation metrics indicate that Becca was indeed the "quietest" student in the group, with Kyle coming in a close second. Becca spoke least often, said the fewest words, asked the fewest questions, and offered no verbal explanations of the patterns she saw. However, her card placement data were comparable to those of Kyle and Paloma, and a broader view of mathematical sense-making participation indicated Becca made sense of five out the six sequences the group created, the same number as John and one more than Kyle.

Co-Constructing "Quiet" Through Interactions

Three features of the group's interactions fostered co-construction of Becca's "quiet" participation: 1. Becca was positioned as a non-contributing, silent beneficiary of learning 2. Becca's contributions received less support than her peers', 3. Disagreement with Becca was *softer* than with John.

Becca was positioned as a non-contributing, silent beneficiary of learning. This task challenged all four students; they looked to each other for help and guidance. Well, they looked first to John for help, and then to Kyle and Paloma, but never to Becca. Out of 63 questions asked in this group, 26 were directed to everyone in the group and 37 questions were directed to a particular person. Out of the 37, only two were directed specifically to Becca. When students were deciding who should take the first turn based on birthdays, John asked Becca, "What day of December are you?" Later when they were determining whose turn was next, Paloma asked Becca, "You don't have any more cards?" Both questions elicited specific information from Becca related to task facilitation not to mathematics. Neither question required more than a one-word response. No one asked Becca for help, ideas, or approval, which therefore positioned Becca as a beneficiary of the group's learning as opposed to a contributor to it.

Throughout the process of task completion, Becca did much more listening than talking. By listening to her peers' explanations and not offering justifications for the placements she made or explaining patterns she saw, Becca reinforced her role as a non-contributing beneficiary. However, Becca answered 9 of the questions directed to everyone in the group, the same number as Paloma, three more than Kyle, and just four fewer than John. Becca also had the highest ratio of questions *answered by* compared to questions *directed to* (14:2), meaning she answered seven times as many questions as were directed to her. Becca's peers answered 1.5 to 2.5 times as many. Overall, interactions between Becca and her peers positioned Becca as a non-contributing, "quiet," beneficiary of the group's learning, though her willingness to answer questions directed to everyone or to people other than herself contradicted this positioning in subtle ways.

Becca's contributions received less support than her peers'. As an active member of the group, Becca's contributions included question asking, question answering, and card placements. However, many of these contributions received less support from her group than those made by her peers, as revealed by the responses Becca received to her card placements (Table 3).

Table 3: Card Placement Responses from Peers

	Total Placements	Responses from Peers	Positive		Negative		Neutral		Unaware	
			#	%	#	%	#	%	#	%
Becca	11	33	5	15%	3	9%	7	21%	18	55%
John	20	60	26	43%	1	2%	32	53%	1	2%
Kyle	8	24	11	46%	0	0%	12	50%	1	4%
Paloma	8	24	10	42%	0	0%	14	58%	0	0%

Note. **Responses** from **Peers = 3 *** Total Placements

John, Kyle, and Paloma had similar distributions of responses across categories, all very different from Becca. Over half the time, Becca's peers seemed unaware of her placements. Six out of Becca's 11 card placements, occurred while her teammates were talking with one another and making other card placements, resulting in the 18 unaware responses. Looking closer at Becca's placements that *were* noticed, we find that all five positive responses were in response to two placements that were made by Becca but suggested by John. For one placement, John pointed to a location on the board and described how the next pattern card should look, asking, "We don't have one that has three slots, or do we?" Becca responded, "Yeah," as she placed the card described by John in the location suggested by John. Becca's other positive placement occurred after John shared an idea for a new 3-card pattern sequence that required dismantling one of the previously created sequences. Becca helped enact John's suggested sequence by placing a specific card in the location John had suggested. John and Paloma responded positively to both of these placements made by Becca; Kyle gave a neutral response to the first and positive response to the second, accounting for the five positive responses. Becca received no positive responses for placement decisions she made on her own. In addition, she was the only student to make a placement that received negative response from everyone, described in the next section. Interactions within the group allowed many of Becca's contributions to be invisible and others unvalidated, perpetuating Becca's "quiet" participation.

Becca's silent, often subtle movements were not enough to attract the attention of or elicit validation from her peers. She made 10 out of her 11 card placements without saying a single word. The one time she spoke was to ask John, "This one here?" to clarify the placement he had suggested she make. Despite lack of support, Becca continued to engage with her peers' ideas throughout the task. She even made several verbal attempts to propel the group's learning forward. At one point, Becca said, "Let's try it," in response to a suggestion by John, and another time she said, "Show us what you mean," prompting Paloma to describe a pattern in more detail. Becca contributed to her group's collective work, though much of her work went unrecognized.

Disagreement with Becca was *softer* than with John. Two card placements during the 15 minutes of work time received negative responses from peers. One was made by Becca and the other by John. The interactions surrounding these two placements were quite different and led to different outcomes. The challenge to Becca's placement was relatively *soft*, and her card remained in the location she had chosen. The challenge to John's placement was *firm*, and his card was removed from the location he had initially chosen.

The interaction around Becca's placement began when John pointed to her and said, "Now it's your turn." Becca looked down at her cards. Paloma and John pointed to the same card on the board as Paloma suggested, "Maybe that goes there," pointing for a moment to another location. At the same time, John said, "Move this one, move this one, move this one to where you think it goes." Becca looked up to see them pointing. Becca put her finger on the card John was still pointing to. John responded, "Yeah, that one." Becca slid the card to a new location on the board, a different location from the one suggested by Paloma. Surprised by the move, Paloma and John turned to each other and smiled. Becca watched. Paloma said, "I think it goes-" and stopped. Still smiling, John turned back to the board and said, "Alright." Becca put her hand to her mouth, smiling slightly, and looked at the board. Kyle then said, "Ah, probably this one goes there," pointing to the location Paloma had suggested. Paloma responded, "Yeah." Becca whispered the words, "I don't know," audible only after close examination of the video. Paloma softened her response by saying, “Maybe. I mean, you never know.” This interaction was *soft* in that Becca’s peers did not push too hard; their actions and words were gentle. They made their opinions known but did not put Becca on the spot by asking her about her placement decision. It was as if they all believed she was wrong, but did not want to make her feel bad, so they just let it go.

The interaction around John’s negative response placement occurred immediately after Becca’s. Five seconds after Paloma’s “you never know” comment, John said, “I think this one goes over there,” as he slid a different card from one location on the board to another. John pulled his hand away from the card, looked down at the two cards left in his hand and continued, “Cuz I have a card here.” Kyle then rejected John’s placement by saying, “No, I have a card that goes here.” As Kyle said this, he slid John’s card back to its previous location. For a moment, John put his fingers back on the card, saying “Nnnnno.” Kyle said again, “I have a card that goes here,” pointing to the now empty location where John’s card used to be. John took his hand away and looking directly at Kyle’s eyes asked, “Are you sure?” Kyle looked back at John and said confidently, “Yeah.” John then continued his turn by placing an unrelated card. This interaction was *firm* in that Kyle challenged John’s placement confidently and directly. Kyle moved John’s card back to its previous location without waiting for approval and despite John’s initial attempt to stop him. Ultimately, John accepted Kyle’s rejection of his placement and moved on.

Becca’s peers did not challenge her in the way that Kyle challenged John. They treated Becca as if she was fragile, sensitive, and less knowledgeable than they. These traits often go hand-in-hand with the label of “quiet” student. In response, Becca did not offer any defense of her placement even though it was mathematically sensible. She appeared timid and unsure of her decision, fulfilling the students’ expectations of her. However, she could have moved her card to the location suggested by her peers, but she did not. Instead, she rejected the suggestion and left the card where it was. Becca stood her ground and exercised some agency, albeit silently.

Discussion

Teachers and researchers agree that in discourse-heavy classrooms student talk is important for student success (e.g. Barron, 2003; Engle & Conant, 2002; Langer-Osuna, 2011), but I argue there is more for us to learn if we expand our participation lens to include non-verbal indicators and underlying interactional mechanisms, as opposed to just isolated participation metrics. An expansive view of participation allowed me to look beyond Becca’s lack of talk to understand more about a) Becca’s mathematical participation b) the co-construction of “quiet” participation through interactions c) how inequitable opportunities for participation unfolded, and d) what might be done to support more equitable participation in the future. In addition, I argue that caution needs to be taken when labeling students based on easily observable participation metrics, because this non-neutral, often gendered and racialized process can be detrimental to students’ learning experiences. In the case of Becca, her “quiet” label encompassed more than simply an expectation for limited verbal production. Becca and Kyle’s “talk” participation in the task was similar in that they both spoke very little compared to John and Paloma. However, the *opportunities* they had for various types of participation were considerably different due to how they were positioned by their peers. Becca was positioned as an insecure, less knowledgeable, non-contributor to the collective learning; Kyle was positioned as a confident, knowledgeable contributor. Coincidentally (or not), Becca and Kyle were described differently by their teacher. Becca was described as a student who is “really quiet,” “very shy,” and “uncomfortable being in a group.” Kyle was described as a student who is “independent” and “does not like working in groups." Although both descriptions set low expectations for verbal participation, the underlying assumptions about students' self-beliefs and competences are quite different.

Students perceived to be "quiet" are an understudied group of young people who have strengths that are going unrecognized and potential that is going unrealized. I fear "quiet" students' contributions are going unnoticed and their participation is misunderstood. While I cannot claim this is true for *all* "quiet" students, I can claim this was true for Becca, a non-white, female student. I fear that these oversights and misunderstandings are happening in racialized and gendered ways that are perpetuating the status quo, allowing marginalized students to be further marginalized in our math classrooms. Our quest for more equitable educational outcomes through more equitable means, requires more in-depth study into the learning experiences of students who are perceived as "quiet" by their teachers, parents, peers, and/or themselves.

USING INTERPERSONAL DISCOURSE IN SMALL GROUP DEVELOPMENT OF MATHEMATICAL ARGUMENTS

Shande King
The University of Tennessee
nking5@vols.utk.edu

Tye Campbell
The University of Alabama
tgcampbell1@crimson.ua.edu

The development of proofs and argumentation is one of the major standards for mathematical practices in K-12 education that researchers and practitioners alike are continuing to improve. Further, the use of discourse is considered essential in the learning of mathematical concepts at these levels. However, K-12 educators continue to confound how best to utilize student interpersonal discourse to advance the development of mathematical arguments. This qualitative study examines the nature of student discourse in small-group interactions as students create collective arguments based on mathematical evidence. In examining the patterns of discourse in small groups, the study concludes the effectiveness of various types of discourse in peer-to-peer interaction as students develop more analytical thoughts through the support of their discourse with one another in creating proofs and arguments.

Keywords: Argumentation, Reasoning and Proof, Classroom Discourse

The ability for students to develop their own mathematical arguments at the K-12 level remains a priority in mathematics education. Scholars agree that developing mathematical arguments ensures true understanding when one can convince oneself and others of one’s mathematical explanation (Ellis, 2007, p. 195; Cáceres, Nussbaum, Marroquín, Gleisner, & Marquínez, 2017, p. 356, Stylianou, 2013, p. 23). Additionally, the eight mathematical practice standards in which students should consistently engage include the development of mathematical arguments and the critique of others’ arguments (National Governors Association Center for Best Practices & Council of Chief State School Officers, 2010). A major factor in creating the space for students to develop and critique mathematical arguments with one another is the dynamic of social interaction in the mathematics classroom. Student participation in a mathematical learning community in a classroom is dependent on the culture. Civil and Hunter (2015) found it was necessary to have an open atmosphere that allows social talk and humor, so that students feel comfortable to share, make mistake, and engage in dialogue about the mathematical learning. To further the mathematical learning, Rojas-Drummond and Zapata (2004) state that this opened the door for students to engage in exploratory talk, where they felt free to examine their own opinions, observations, and explanations of the mathematics. This interpersonal discourse allowed students to engage in healthy and open dialogue focused on the mathematics.

Purpose of the Study

The connection between student interpersonal dialogue and mathematical understanding remains the area that researchers have yet to fully explore. The mathematics education community seems to agree upon and have substantial research on the importance of mathematical argument development at the K-12 level (Brown, 2017; Byrne, 2013; Yee, Boyle, Ko, & Bleiler-Baxter, 2017). However, a dearth of research about the interpersonal dialogue and its relationship to the development of mathematical arguments at the K-12 level persists. This study analyzes student discourse and the mathematical arguments developed. Further, the project will not only discover research-based facts for the elements of and the reasoning for social discourse in student interactions with the mathematics, but also the pedagogical approaches that K-12 mathematics teachers can take towards implementation in regular practices in their classrooms. Finally, as a result of collaborative discourse, students will begin to grow in their autonomous thoughts about the mathematics and thus develop their own valid mathematical arguments.

Theoretical Framework

The situated learning lens is used in this study to understand how students learn. Using this perspective, we seek to understand learning in the context in which it happens. Particularly, this research study emphasizes social participation of students in the small group discussions, so they consider social norms and the culture of the classroom as they participate in their argument development. All of these factors impact their learning in the K-12 setting (Anderson, Greeno, Reder, & Simon, 2000). Learning mathematics in the context of the standards of mathematical practice is a collaborative process, and it should be studied within the contexts in which it is occurring, particularly for K-12 education. This project study of small group discourse in collective argumentation requires participation in the mathematical learning community. The community can influence the discourse that supports student learning.

Further, with the emphasis on discourse of the students, this research takes on a discursive framework, narrowing in on the elements of discussion that students use with one another in their collaborative small groups as they discuss, argue, and critique mathematical concepts with their own ideas of mathematical facts and evidence.

Finally, both the situated learning and discursive framework fall within a greater idea of social constructivism, in which student learning is formed through the interactions that students have with the content in the classroom settings. The foundational learning theory of constructivism provides the necessary lens to look at a deeper, more refined look of learning in this research in the overlapping ideas of the situated learning lens and discursive learning framework.

Review of the Literature

Student creation of mathematical arguments has been established as a primary focus in K-12 mathematics classrooms by national organizations and the recent creation of national standards for mathematical practices. The National Council of Teachers of Mathematics (1989) recommended that reasoning and proof should regularly be incorporated in K-12 classrooms, which was emphasized again in 2010 by the Common Core State Standards (CCSS) publication of eight mathematical practice standards in which students should consistently engage (National Governors Association Center for Best Practices & Council of Chief State School Officers, 2010). Although argumentation has been established as a recommendation for K-12 mathematics, classroom teachers still lack in fostering student development of valid mathematical arguments in a way that satisfies these standards.

Argumentation in the Development of Student Learning

Though argumentation has consistently been a recommended practice of K-12 mathematics, students are generally unable to produce valid arguments (Stylianou, Blanton, & Knuth, 2010), and current methods of teaching proofs and arguments are largely inaccessible to K-12 students (e.g. Karunakaran, Freeburn, Konuk, & Arbaugh, 2014). In several K-12 mathematics classrooms, students learn to create arguments simply by watching the teacher's approach and attempting to recreate the same process. This type of instruction leads students to believe that the teacher is the supreme authority of an argument in terms of what is acceptable and what is not. Thus, students develop an authoritarian proof scheme (Harel & Sowder, 1998), wherein the process of developing a proof becomes a computational exercise to find the specific solution for which the teacher is searching.

In contrast to the traditional teaching approach to teaching mathematical arguments, encouraging collaboration and allowing students to engage in the process of proving can improve students' proof development (e.g. Brown, 2017; Byrne, 2013; Yee, Boyle, Ko, & Bleiler-Baxter, 2017). Collective argumentation, as one example, allows students to engage in a process where they collaborate to create arguments and come to agreement on the arguments that can be accepted within a community. Students create arguments within a group and present their work to the class, helping students gain authority (Stein, Engle, Smith, & Hughes, 2008) in their work and participate in authentic mathematical community.

The Role of Collaboration in the Mathematics Classroom

Research has shown that mathematical communication within a classroom community is crucial for the development of students' reasoning and mathematical understanding (Alrø & Skovsmose, 2003; Forman, 2003). Lampert and Cobb (2003) argue that by providing students the opportunity to discuss their ideas with others can develop their mathematic reasoning more readily. According to Howe and her colleagues, the most successful instances of collaboration occur when students propose and defend their ideas and when they explain their reasoning to each other (Howe et al, 2007). Further, Howe et al. (2007) discovered that collaboration was most productive when the teacher offered little intervention and allowed students to exercise their own authority in solving the mathematical tasks proposed to them.

Teacher Use of Mathematical Arguments

To discover more about the role of the teacher in fostering a community that encourage collaboration to develop student learning via mathematical arguments, Mercer (2008) builds upon the research of Howe et al. to explain that the teacher's role should be one where he or she guides the students in creating mathematical arguments. In this capacity, the teacher assists the students as they learn to collaborate effectively and utilize "exploratory talk" as a cultural and psychological tool to contribute to their development of reasoning (Mercer, 2008; Mercer, Daws, Wegerif, & Sams, 2004). Exploratory talk is the idea where partners engage critically but constructively with each other's ideas. Their statements and suggestions are considered jointly, as they challenge and counter-challenge, requiring justification and alternative hypotheses (Mercer, Daws, Wegerif, & Sams, 2004). Exploratory talk holds students accountable to reasoning.

To create an atmosphere where exploratory talk is commonplace in the mathematics classroom, Brown (2017) encourages teacher participation in a way that guides and pushes student thinking, as they listen and observe the activities of students in their small groups, as in the aforementioned collective argumentation model. The observation of activities can then inspire students by then challenging them to engage in different types of representations, explanations, and justifications (Brown, 2017) than what they had previously created. Brown (2017) continues that the teacher can do this by asking questions about representations, adding to the representations, or even by providing his or her own personal representation. The active role of the teacher can create an environment where students are not only accountable to developing viable mathematical arguments, but they also are inspired to actively engage in them as they are challenged to create new representations of the mathematics.

Discourse in Collaboration of Mathematical Arguments in a Mathematical Learning Community

Discourse in the classroom is dependent upon the social setting of the classroom and can have multiple meanings, involving more than language (Gee, 1996; Moschkovich, 2007). Moschkovic (2007) contends that discourse also involves representations and behaviors, which involves collaboration about arguments and proofs in the context of mathematics classrooms. The discourse of a mathematics classroom is important to note, then, because the language, representations, and behaviors in a class because the teacher and the students may have different interpretations to meanings and focus of attention.

During the act of collaboration in a mathematics class, collective mathematical understanding may take place when students work together on one mathematical task (Martin, Towers, & Pirie, 2006). This collective understanding requires the social context of the learning environment, and it cannot be described by looking at the actions of the individual learners. Through the process of working jointly on a problem, problem-solving leads students to share ideas and their ways of solving, so individual understanding becomes shared. Teachers should establish a classroom environment that encourages this type of discourse where students will jointly partake in a discourse that transforms individual student thinking about mathematics due to the collective understanding that takes place via student language, patterns, behavior, and interactions with the mathematics as well as each other. This study pursues the nature of the small group discussions and the class-wide, whole-group consensus in collective argumentation, hoping to clarify the elements of these discussions that most encourage student learning through the development of mathematical arguments.

Modes of Inquiry

Research Design

The research is qualitative by nature, as audio recorded conversations of the individual small groups for each day of the instructional sequence were transcribed verbatim to allow for coding to occur. We use open and a priori coding to discover patterns concerning student discourse, particularly the types of discourse used that led to mathematical breakthroughs or insights into developing their mathematical arguments. By gaining insight into the patterns of discourse, we see the necessity of interpersonal discourse of the mathematics so that students can be able to defend and justify their critical thinking as others critique their reasoning, as encouraged by the third standard for mathematical practices. Because of the theoretical grounding in a situated learning lens via social constructivism, a qualitative study of the discourse in the small groups will open doors to understanding different factors influencing valid argument development. The findings will lead to discovery of what elements of the discussion best support autonomous student formation of mathematically sounds arguments, as well the practices that teachers can use to best support this environment in a K-12 mathematics classroom.

Methods

Our study took place during the 2018-2019 school year at a private middle school in the Southeast. The participants included 44 eighth-grade students enrolled in one of four different Pre-Algebra classes. The students were all taught by the same teacher, and they were accustomed to collaborating with one another while working on mathematical tasks. For the purposes of our study, we co-taught each of the four class periods for three days of instruction (55-minute class periods), which made up the entire teaching series. On each day of instruction, students worked on one task (see Figure 1) where they were to create a collective mathematical argument. Each class discussed the criteria to create a valid mathematical argument, and the criteria was written on a whiteboard to ensure that it was visible to each member of the class.

Within each class, students were placed into groups of three or four (14 groups in total), and we used Brown's (2017) key-word format to organize our time. Students first spent four minutes creating an argument on their own, then they spent twenty minutes creating a collective argument within their groups. After creating collective arguments, groups shared their arguments with the class to be validated based on the criteria from the beginning of the teaching series.

Task 1

The sum of any three consecutive integers is divisible by three. Is this conjecture true? Write an argument for why or why not.

Task 2

Conjecture: *The sum of two odd numbers is even.* Is this conjecture true? Write an argument for why or why not.

Task 3

How many triplet primes of the form *p, p+2, p+4* are there? Write an argument for how you know.

Figure 1: Tasks

Data Collection

Three types of data were collected: student written work (both in class as collective argumentation groups and homework assignments), audio recordings of the group discussions, and field notes written. Individual written arguments (during the four minutes of individual think time) were not collected, as they were not included in the analysis of the data. The arguments created by each group on each task are the primary source of data collection. Groups were tracked to allow comparisons to be made between each task. Observational field notes were taken during the instructional sequence to record any relevant remarks made by students in both small group and whole group discussions.

Data Analysis

To determine how students' arguments developed as a result of the discourse in collective argumentation, a coding system was developed. Students' collective arguments as evidenced by the audio recordings and written work were coded according to Stylianides and Stylianides (2009) framework. Their framework consists of five hierarchical levels for judging the sophistication of a mathematical argument. Students create *non-genuine arguments* (Level 1) when they commit little effort. *Empirical arguments* (Level 2) are arguments that rely on examples as warrants for a mathematical claim. An *unsuccessful attempt at a valid general argument* (Level 3) is an argument that uses general warrants but contains flaws. A *valid general argument but not a proof* (Level 4) is an argument that uses a deductive chain to argue a claim but uses warrants that are not accepted by the mathematical community. A *proof* (Level 5) is a deductive argument that uses warrants accepted by the mathematical community.

Beyond the arguments themselves, we transcribed and studied the small group discussions to account for different types of discourse that impacted student thinking, particularly as they moved to more advanced levels of arguments. We discovered which patterns of explanation, interjection, questioning and defense, for example, best led students to understanding mathematics and advancement of mathematical arguments. Further, we begin to understand what the classroom environment requires for this collective argumentation and collaborative discussion to foster advanced mathematical proofs and arguments. This will develop findings in pedagogy to inspire further research and practitioner models to encourage small group discourse

Data Sample

When split into groups of 3 students (or less depending on number of students in the class), students were audio-recorded by group. One specific group developed a mathematical induction proof orally in explaining his reasoning to his group:

> So, you start with 0,1,2 as your base one. And then, what you do to bring it up to 1,2,3, is you add one to each of the integers. So, when you're adding one to each of the integers, you're really just adding three. So, that's why it's divisible by three. And then, that's why it's divisible by three every single time.

This oral argument aligns with a proof by mathematical induction. The speaker explains that the base case (0+1+2) is divisible by three. Then, he explains adding one to each integer will gives the next case (e.g. 1+2+3). He explains why this new case is divisibly by three by stating "you're really just adding three" appealing to the property that adding three to a number already divisible by three creates a new number that is also divisible by three. His group asked for further clarification, to which the speaker further explained his reasoning.

- Speaker 2: But I do feel like in some instances it won't be right.
- Speaker 1: No, it will be right every time because you're just adding three every time.
- Speaker 2: But, why? We need facts and evidence.
- Speaker 1: Because if you have three consecutive numbers, if you go up one for each of them, you just add three. And if the base one does—is divisible by three that means all the other ones will be divisible by three. And in this instance the base one is divisible by three.

In being able to provide a rationale to a problem, particularly in response to a question about the validity of the response, the speaker thoughtfully engages in personal discourse to promote a valid argument and its reasoning.

Results

Table 1 shows the frequency of the types of arguments that were created by each group across the three tasks. The data suggest an overall increase in the level of argument created by the groups over the three tasks. There was a steady decrease in the use of empirical arguments; however, students had less success in creating a proof on task 3 than on task 2. This is likely due to the difficulty of task 3 in comparison to task 2, and the expectation of creating a conjecture before attempting to write an argument. Even so, the data suggests that by task 3, students understood that an argument that uses examples (empirical argument) was not viable in their mathematical setting.

To understand how each group progressed across the tasks, we tracked their level of argument from task 1 to task 3. Table 2 shows the level of argument for each of the fourteen groups (listed A-N) on task 1 and task 3 and the difference in level of argument. Most groups increased in their level of argument while few groups decreased or remained the same. To determine whether there was a statistically significant difference in level of argument from task 1 to task 3, a Wilcoxon-signed rank test was used. There was no statistically significant difference in the level of argument the groups created from task 1 to task 3 (T=47.5, p=0.178). The sample size, lack of variability in the levels of argument, and ceiling effects of not including baseline data likely contributed to the non-significant test statistic. Still, the descriptives illustrate that groups generally made progress in the sophistication of their collective arguments from task 1 to task 3.

Table 1: Level of Argument by Task

Task	**Level 1: Non-genuine Argument**	**Level 2: Empirical Argument**	**Level 3: Unsuccessful Attempt at Valid General Argument**	**Level 4: Valid General Argument but Not a Proof**	**Level 5: Proof**
Task 1	2	8	2	0	2
Task 2	1	5	2	2	4
Task 3	3	1	5	4	1

Table 2: Difference in Level of Argument from Task 1 to Task 3

	Groups													
Tasks	*A*	*B*	*C*	*D*	*E*	F	G	H	I	J	K	L	M	N

Difference	0	-1	2	1	0	-1	1	-2	-1	-1	-1	0	-3	-1

Discussion

Preliminary quantitative results of this study suggest that the eighth-grade students benefited from engaging in interpersonal discourse via collective argumentation. Communication among peers provided access to the standards for a viable mathematical argument, thus making it more likely that they will have success in creating their own arguments. Further, engaging in collective argumentation gives students opportunities to critique and validate others' work which places them in a position to learn directly from their peers, as supported by the review of the literature. Our study was unique in its application of the aforementioned supports for middle grade students, and it agrees with findings from previous research that students benefit from interpersonal discourse in creating mathematical arguments (Rojas-Drummond & Zapata, 2004). However, more research should be devoted to how students use interpersonal discourse to create increasingly sophisticated arguments. Furthermore, scholars should test the supports mentioned in this paper in other settings such as primary and secondary schools. The preliminary results of this paper is promising in providing further promotion of and support for K-12 mathematical argument development.

MAINTAINING THE MATHEMATICAL FOCUS OF WHOLE-CLASS DISCUSSIONS: DILEMMAS AND INSTRUCTIONAL DECISIONS

Nicholas J. Gilbertson
Winona State University
ngilbertson@winona.edu

As teachers shift their practice from traditional student-to-teacher interaction patterns to collaborative discussions around rich mathematics, they often encounter instructional challenges. One such challenge is deciding when to pursue interesting and productive ideas that run contrary to the particular mathematical goal of the lesson. In this research summary, I report results from a study involving one experienced teacher's instructional decisions and how she maintained attention to the lesson-specific content goal given possible alternative pathways.

Keywords: Classroom Discourse, Instructional Activities and Practices

Over the past several decades professional mathematics teaching organizations and mathematics education research has described the potential benefits of classroom discourse for supporting students in meaningfully understanding mathematics. This attention to student thinking and discussions have important implications for students' opportunities to access mathematical ideas and their views of what it means to be mathematically competent. As such, many sets of instructional techniques have developed to support teachers in facilitating rich mathematics discussions. These foci have varied from identifying cognitively demanding tasks (e.g. Stein & Smith, 1998), developing instructional practice (Smith & Stein, 2011), the use of various talk moves (Chapin, O'Connor & Anderson, 2009), and attention to equity (Khisty & Chval, 2012), to name a few. Many of these approaches share the common goal of creating opportunities for equitable access to meaningful mathematics.

At the same time, it has been well documented that many U.S. teachers still use direct instruction approaches by asking simple-fact based questions, receiving responses from students, and then providing feedback or evaluation (Cazden, 1988; Chapin, O'Connor & Anderson, 2009; Franke, Kazemi & Battey, 2007; Sahin & Kulm, 2008; Stigler & Hiebert, 1999). Perhaps one reason for this more traditional approach is that by limiting student talk, there is a clearer pathway forward in a lesson, providing less opportunity for a student question or insight to potentially deviate the trajectory of the lesson. Additionally, researchers have contended that facilitating classroom discussions where students are collaboratively engaged around rigorous mathematical content is quite challenging (e.g. Franke, Kazemi, & Battey, 2007; Lampert & Cobb, 2003; Lampert et al., 2013; Tyminski, Zambak, Drake & Land, 2013), especially when teachers have multiple goals they are attempting to satisfy (Sleep, 2012). Lampert and colleagues (2010) for example, argued that, "Maintaining a coherent mathematical learning agenda while encouraging student talk about mathematics is perhaps the most challenging aspect of ambitious teaching" (p. 131).

As such, facilitating discussions has the potential to create instructional dilemmas as teachers grapple with advancing the mathematical agenda of the lesson while balancing possibly competing instructional goals such as developing student engagement in mathematical practice, supporting long-term content goals (e.g. understanding linear relationships), and establishing a mathematical community within the classroom. Because facilitating discussions around rich mathematical tasks requires a different set of skills, this raises the question, as to what barriers still persist in supporting teachers with facilitating these types of mathematics discussions and how one might go about mitigating these barriers.

One approach to studying this phenomenon would be to study teachers who typically use direct instruction but are open to the idea of facilitating discussions. This could provide insight as to the reasons why these teachers have not yet taken the first step towards a shift in their instruction. In the study described in this article, I take a different approach, focusing on teachers who are well beyond their first step in facilitating discussions. The middle school teacher described in this research summary is an experienced teacher (having taught at other grade levels), is philosophically aligned with the value of student talk, and she used the *Connected Mathematics* (Lappan et al., 2005; Lappan et al., 2014) middle grades curriculum – a textbook series designed to engage students in thinking through student discourse.

The results described in this summary attend to instructional decisions during whole-class discussions where the decisions took place at a potential crossroads in the lesson, where the teacher could have chosen to pursue alternate goal-types but was able to maintain her attention to the lesson-specific content goals through her instructional choices. The results described in this research summary focus on this teacher's decisions when she was presented with situations which could have deviated her instruction from lesson-specific content goals as she instead chose to attend to broad content goals, mathematical practice goals, or goals for establishing a mathematical community.

Purpose

Broadly, the purpose of this study was to better understand the potential barriers and inherent complexity in teachers' decision-making while facilitating classroom discussions. More specifically, the results given in this proposal describe pivotal moments in lessons, where teachers chose to maintain the lesson-specific content goal instead of deviating and focusing on a different type of instructional goal. The hope is that by better understanding how experienced teachers navigated the complexity of attending to the lesson-specific content goal(s), that this might better inform the field as to the potential deviations that teachers are likely to encounter while facilitating whole-class discussions. In some ways, these potential deviations might be viewed negatively as they move the focus away from the mathematical goal within the lesson; however, the reason these posed actual dilemmas for teachers is because they are important aspects of the long-term development of students as thinkers, reasoners, and doers of mathematics. Thus, it is through understanding how experienced teachers supported these other goals while still maintaining focus on the lesson-specific content goal, that we might better understand how to support novice teaching practice in facilitating discussions.

Theoretical Framework

The guiding theoretical perspective for this study was *situated cognition* (Greeno, 1989). The situated perspective places strong emphasis on the interaction between individuals and their environment. As Greeno (1989) stated, "Cognition, including thinking, knowing, and learning, can be considered as a relation involving an agent in a situation, rather than as an activity in an individual's mind" (p. 134). In this study, teacher's activity and decisions were understood in the context of their activity in their classrooms. I attended to teachers' interactions with their students over multiple lessons, observing behavior, hypothesizing about their decisions, and later interviewing them about possible decisions. This approach differs from simply interviewing teachers about a simulated classroom or asking teachers to state what decisions they would make in a theoretical situation in their own classroom. The approach I used in this study aimed to provide a more authentic view of teachers' decision-making as a cognitive activity necessarily embedded in their environment.

Additionally, I investigated the nature of teachers' decisions, by using the theoretical construct of *professional obligations* (Herbst & Chazan, 2011) which states that teachers' decisions are a function of their obligation to (a) students as individuals, (b) in developing students interpersonally in the classroom, (c) in representing the school as an institution and (d) in representing the discipline of mathematics. This construct helped in better understanding the nature of instructional decisions when teachers encountered instructional dilemmas, defined as a conflict between one of four instructional goal types (lesson-specific content goals, broad content goals, mathematical practice goals, and goals for establishing a mathematical community). A teacher's professional obligations differ from their goals in that goal(s) are about accomplishing a task (e.g., supporting students in effectively communicating their thinking with the class), whereas the teacher's professional obligation(s) describe who or what they feel obliged to satisfy (e.g., the individual student, the school, etc.) during the discussion.

Methods

To better understand the nature of teachers' instructional goals and identify the moments where potential conflicts occurred I analyzed data from a variety of sources, including an initial interview with each of the three grade-seven teachers, a baseline lesson observation, lesson plans for three rounds of at least three consecutive lessons per round, post-lesson interviews, and video-stimulated interviews at the conclusion of each round. To identify points at which goals may have been potentially in conflict with one another, I first conducted a preliminary analysis to identify teachers' instructional goals and determined moments when any consistent patterns of instruction deviated from what was observed. Across the three teachers in the study, I identified goals in all sources of the data. The instructional goal is defined as what the teacher hopes to accomplish as a result of enacting a whole-class discussion. Most goal statements occurred during interviews, where teachers were asked directly about their goals such as, "…were there like a few big things you really wanted to come out of [this lesson]?" or "Were there other goals, or other things you wanted…"

During the initial round of data analysis, I identified goal statements where the teacher either explicitly stated their goal or described their intended learning outcome. For example, during Ms. Mitchell's post-lesson interview (Round 2, Observation 2) she stated "…my goal as I told you was for them to get a better sense of what a sample space is." This is an example when the teacher explicitly identified her instructional goal. As a second example, Mr. Sandberg stated his goal in the form of an expected learning outcome, "…they need to be able to understand y-intercept, what that looks like on a table, graph, and equation" (post-lesson interview, Round 1, Observation 2).

After identifying goal statements, I coded goals as to whether the goal was primarily focused on (a) lesson-specific mathematical content, (b) mathematical content that was beyond the scope of an individual lesson: (long-term or unit-level), (c) mathematical practice goals (including goals attending to communication and dispositions) or (d) goals focused on being a member of a mathematical community. All teachers had cases of all four types of goals.

This first category, *lesson-specific content goals*, focused on mathematical content to be learned in a particular lesson. The second category *broad content goals*, included unit-level content goals such as understanding linear relationships, a topic taught over several lessons. This category also included long-term content goals dealt with goals that went beyond the unit, such as learning goals that connected to the high school curriculum. This type of goal is strongly related to Ball's (1993) notion of teaching towards the "mathematical horizon".

Mathematical practice goals are consistent with NCTM's (2000) Process Standards and the Common Core's Standards of Mathematical Practice (NGA-CCSSO, 2010). This goal type is related to the first two goal types in that they focus on mathematics, but they differ in that they focus not on content, but on types of mathematical practices, such as justification and critiquing other students' arguments. The fourth category, *goals for establishing a mathematical community* included statements about developing a classroom that would support shared exploration and expectations of having students to learn in a social environment.

It is worth noting, that I do not make the claim that teachers are always aware of their goals or, if they are aware of them, that they are able to articulate them clearly. In many cases, teachers may have instructional goals that are somewhat unknown to them (e.g., a novice teacher knowing what they should be teaching a particular activity without a clear reason why they ought to be doing it). A teacher may be acting consistent with a goal, without knowing what their goal is. Some teachers, for example, might simply have a goal to make sure the class runs smoothly, and maintaining order is the most important aspect of their instruction with very few mathematical goals. I take as an assumption that the nature of teaching falls in the category of "goal-oriented activity," but I am cautious in not assuming that any discussion necessarily includes all of the four types of goals.

Results

In this section, I describe the results specifically pertaining to instances where Ms. Mitchell's goals actively competed with lesson-specific content goals. To illustrate these instances, I describe one instance of each of the three types of conflict between lesson-specific content goals and the other three goal types. While all three teachers had at least one conflict between the lesson-specific content goal and each of the other three goal-types, I provide data only on Ms. Mitchell as she had the most collective instances of conflicts between lesson-specific content goals and the other three types.

As an overview of her instructional approach, Ms. Mitchell could be best characterized as a teacher who thinks deeply about her teaching practice, as she often reflected on her instructional decisions in relation to developing content, practice, and dispositional goals for her students. More than once, she described the importance of social inequities and her role in teaching mathematics as a way to provide opportunities for students to grow both personally and academically. As such, she often found herself in various instructional dilemmas where lesson-specific-content goals potentially conflicted with other goal types.

In one of Ms. Mitchell's lessons, a student was describing the y-intercept as the "starting point" on the graph, and during the post-lesson interview she described how uncomfortable that made her feel. "When I first saw that [the y-intercept] I was like, oh, I don't like that one bit, 'cuz in high school I had to fight that for three years. It's not a starting point." Ms. Mitchell allowed the student to talk about the y-intercept as a starting point as they were just beginning to understand this important point across representations. This exchange highlighted Ms. Mitchell's attention to long-term content goals (broad-content), specifically related to her experience as a high school teacher.

Ms. Mitchell also frequently mentioned Common Core standards (NGA-CCSSO, 2010) at the beginning of class – both content and practice – and her use of CCSSM practice standards was a theme throughout her instruction both in describing her decisions and in making these standards explicit to students during class time. In one interview she mentioned wanting students to engage in repeated reasoning and thinking about structure. Other practices she mentioned included having students provide evidence to support a claim and persevering when trying to solve a problem. These statements reflected mathematical practice goals.

Ms. Mitchell also talked about the importance of protecting students' think time, and what students can learn from each other in groups (establishing a mathematical community). She wanted her students to be able to interact with each other directly in the discussion and for her role to be minimized in the discussion. In Ms. Mitchell's classroom this involved one lesson where she explicitly changed the typical norms of interaction taking a less prominent role in the classroom discussion allowing for greater student-to-student interaction.

Case 1: Lesson-Specific Content Goals vs. Broad Mathematical Goals

In this first lesson, students were analyzing their previous day's work from a problem involving the fundraising graphs for a walkathon by three fictitious students (Figure 1). The problem in the textbook (Moving Straight Ahead, p. 8, *CMP2*) gave the fundraising as follows: Leanne \$10 regardless of distance; Gilberto \$2 per km; Alana \$5 plus \$0.50 per km. The lesson-specific content goal of this lesson was for students to make and recognize linear tables, equations and graphs from contexts.

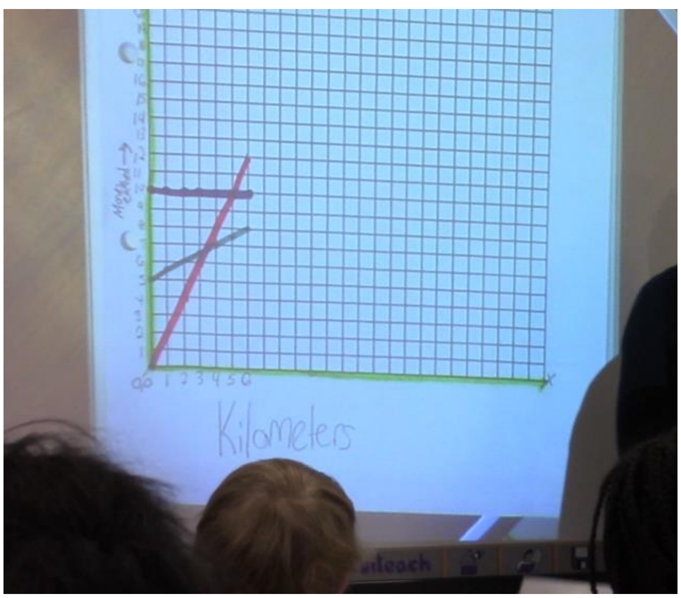

Figure 1: Ms. Mitchell Displays Walkathon Results

During the class discussion, Ms. Mitchell pressed a student to explain why the graphs were linear, after the student noticed the consistent shape in the three graphs. To contrast linear and non-linear graphs, Ms. Mitchell asked the student to draw a graph of a non-linear relationship on the board. Whereas the student may have simply drawn a non-linear function (e.g., a quadratic or exponential relationship), the student instead drew a graph that was not even a function (Figure 2). Given this strange graph, a different student asked, "Could a graph actually go backwards like that? Like could it go like this way and then eventually go back that way again?" This question focused on an important relationship in understanding a mathematical function. At this point, Ms. Mitchell was faced with a decision of whether to (a) pursue this important mathematical insight, which was beyond the scope of the lesson, but was potentially productive in supporting students' thinking about functional relationships, or (b) refocus attention to the lesson-specific content goal.

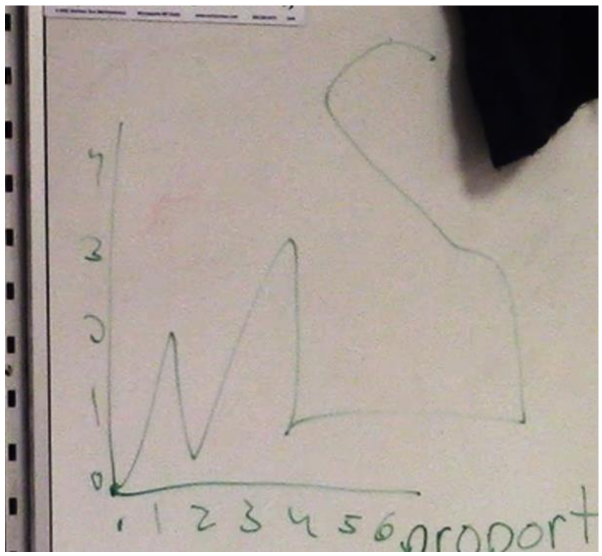

Figure 2: A Student Draws a Graph of a Non-linear Function

Ms. Mitchell could have moved on from this student's thought, minimizing the opportunity for disruption. Her decision was to write a note on the side of the board and to validate the importance of the student's insight. "I'm going to write that right here Charlie because that's outside what we want to talk about today. But that's an extremely important question; could a graph actually go backwards? And we need to talk about that."

During the video-stimulated interview after the first round of observations, Ms. Mitchell commented on this clip:

> Charlie's question was so awesome as it usually is. That is an example where I don't want to shut down the conversation or, well I do want to shut down the conversation because the level of thinking it would take based on what they had had by one-two would be too great…I do want to push a little bit…Now that thing about going back on itself I still have that written down and we will come [back] to that.

Although Ms. Mitchell's decision was to move on from the student's question, she did this only after valorizing the student's question. Ms. Mitchell could have chosen to pursue the student's idea directly, essentially moving away from her lesson goals for the discussion. Instead, she refocused the discussion in line with the lesson goals. By supporting the student's thinking and publicly acknowledging its importance, she continued to make explicit the importance of thinking and questioning in her classroom.

Case 2: Lesson-Specific Content Goals vs. Goals for Establishing a Mathematical Community

This second case occurred as students explored a problem on compound probability. In this lesson, students rolled two six-sided dice and found the product of the two values. They did several trials. One student won if the product was even; the other student won if the product was odd. This game would not be considered a “fair game”, because the likelihood of getting an even product is greater than an odd product. The lesson-specific content goal for this lesson was to develop an initial understanding of whether a game is fair or not.

During the discussion, Ms. Mitchell asked the class if they thought the game was fair. One student, Jonathon, said the game was fair because there are 3 odd outcomes and 3 even outcomes per die. This is incorrect since the outcome is based on the products of the two values, not just the individual values appearing. Ms. Mitchell was faced with how to appropriately respond to the student given that this particular student often has difficulties in the class. On the one hand, Ms. Mitchell needed to advance lesson-specific content goals, helping students see the inherent unfairness to this game. On the other hand, if her response was to be consistent with trying to establish a mathematical community, she would need to be careful about how she responded to a student who typically has difficulties in the class.

One choice would have been to press students to see why the claim was incorrect. She also could have simply stated that Jonathon was incorrect, or called on a different student in the class to explain why he was incorrect. Instead, Ms. Mitchell supported Jonathon’s thinking, and acknowledged how he was reasonable (in some way) in thinking that the game could be fair. The decision Ms. Mitchell made when faced with an incorrect student solution was to attend to the lesson-specific content goals and goals for establishing a mathematical community. During the discussion she had a student (Josh) sitting close to Jonathon talk to him about the odd number times odd number case, and later asked for other students’ thinking about the problem. She described this scenario during the post-lesson interview, describing her thought process during this moment in the lesson.

> Jonathon, you know, he flat out fails; he doesn't have a whole lot of perseverance intellectually. He thinks of things sometimes really in strange ways, but I was happy that he was participating, and is in fact that half the numbers are even and half the numbers are odd. So I wanted to, you know, honor that he said, and then, but also try to build on that and then I felt like Josh kind of jumped ahead and wasn't real clear about odd times odd. So rather than just go there, and have him or someone explain how he knew that, I felt like the whole group would kind of get lost, so I just stated it very simply after he said it so people could think about it. Seemed to me there was still a question about the odd times odd. And they were all just kind of letting it go… (Ms. Mitchell, video-stimulated interview, May 11, 2015)

Case 3: Lesson-Specific Content Goals vs. Mathematical Practice Goals

A common dilemma for Ms. Mitchell was the need to meaningfully engage students in mathematical practice while also attending to lesson-specific content goals. This dilemma occurred across several lessons. Primarily, Ms. Mitchell worried about whether her students were developing their abilities in independent problem solving. During one lesson, students were learning how variability affects the mean and median of a data set, in relation to large clusters (the lesson-specific content goal). Throughout the lesson, there were several opportunities for Ms. Mitchell to focus on mathematical practice goals, but she continued to focus on the lesson-specific content goals due to the pressure of a standardized department final at the end of the month. She felt frustrated about having to choose one over the other given the content coverage expectations.

> Well there's a dilemma, because on the one hand I would love to have all the ideas for them to have access to; on the other hand there's the bigger idea of the mathematical practices, like what do I do when I don't know what to do?...And, so I've got this treadmill keeping us moving toward the end at the same time as I'm trying to incorporate as much of the thinking stuff that I can. (Ms. Mitchell, post-lesson interview, May 19, 2015)

She later referred directly to how this dilemma impacted that day's lesson and the previous day's lesson, wondering if students saw the mathematical purpose of what they were doing. She also worried about the long-term impact of her instructional decisions to focus on the lesson-specific content goals in order to satisfy a common department final at the sacrifice of developing students' self-efficacy in problem solving. In contrast to the two previous cases, where Ms. Mitchell was able to navigate the potential conflict between lesson-specific content goals and other instructional goals, this case highlights that not all potential conflicts end in a productive resolution even for an experienced teacher. The institutional constraints of expectations for content coverage, standardized assessments, and time constraints was sufficiently pervasive to cause challenges for Ms. Mitchell.

Conclusion

During whole-class discussions, teachers are faced with decisions related to the types of questions they ask students, which student ideas they choose to highlight, and how deeply to pursue a student response. As teachers facilitate discussions, the dilemmas they encounter and the decisions they make send messages (explicitly or implicitly) to students about what is valued as thinkers and doers of mathematics. These messages are important because as Jansen (2006, 2008) pointed out, students participate in discussions for various reasons, yet student participation is a necessary component of teaching using whole-class discussions.

As was seen in the three cases provided in this research summary, Ms. Mitchell's experience in facilitating discussions and her orientation to balancing several competing instructional goals allowed her to make decisions that maintained the focus on the lesson-specific content goals. Much like other approaches to supporting teachers in facilitating discussions which include sets of instructional practices (e.g. Smith & Stein, 2011) and talk moves (e.g., Chapin, O'Connor, & Anderson, 2009) this study highlights that there are particular sets of technical skills needed to make in-the-moment decisions which likely impacted the immediate and long-term experiences and opportunities for students to learn mathematics via classroom discussions. In the findings reported in this summary, Ms. Mitchell showed particular techniques for how to navigate potential situations as they appeared in the course of an open dialogue with her students. These particular techniques might not all be obvious or clear to teachers who are shifting their practice from more traditional interaction approaches to a more open discussion format.

This study has the potential to further complexify existing sets of instructional techniques as well as to develop its own set of categories of situations a teacher may potentially encounter while facilitating discussions, such as, responding to an incorrect answer, responding to a question that moves beyond the scope of the lesson, or responding to an answer that other students do not understand.

As one such example, one of Smith and Stein's (2011) *Five Practices* is anticipating student thinking. In the findings in this study, one might consider particular likely scenarios, such as the Case 1 situation, where a student raised an interesting mathematical question that is relevant to the lesson but would likely move the focus of the discussion elsewhere. The teacher could anticipate this particular situation and consider how they would generally approach a similar scenario. The teacher could consider under what conditions it would be appropriate to deviate from the lesson goal, or alternatively, how one refocuses the class on the more immediate lesson goal while still attending to the productiveness of the question and the student's engagement. By identifying and naming these types of situations, teachers that are shifting their practice towards increasing the quality of student talk in their classrooms may be better positioned to make in-the-moment decisions that allow them to maintain their lesson-specific content goal while also addressing other valuable instructional goals.

AGAINST THE EPISTEMIC HORIZON TOWARD POWERFUL DISCOURSE

Sunghwan Byun
Michigan State University
byunsun3@msu.edu

In mathematics classrooms, teachers are often the authority as a knower of mathematics. To support students to develop their identity as doers of mathematics, teachers need to decenter the authority and to place students in a more powerful position as autonomous thinkers. Building on the work of Herbel-Eisenmann and colleagues (2013), this paper aims to expand the notion of powerful discourse from a conversation analytic approach. By examining the fine-grain epistemic characteristics of interactional sequences, I argue for the significance of the interactional knowledge domain, in which positioning of students as more or less knowledgeable takes place. Further, I discuss the need for examining the discursive dimension of knowledge and discursive practices that can redistribute the epistemic authority in mathematics classrooms.

Keywords: Classroom Discourse, Positioning, Conversation Analysis

The social turn in mathematics education (Lerman, 2000) widened the view on mathematics teaching. Beyond transmitting mathematical knowledge to students, teachers need to attend to the development of student identity as doers of mathematics. Through social interactions, students' identities are constructed and reconstructed over time (Hand & Gresalfi, 2015); hence, the attention to interpersonal aspects of social interactions became crucial. One way to attend to the interpersonal aspect of classroom interactions is through the lens of powerful discourse (Herbel-Eisenmann, Steele, & Cirillo, 2013), which entails purposeful positioning of students during mathematical discussions to support their identity development. The goal of this paper is to offer a concrete way to examine powerful discourse through a fine-grain analysis of social interaction. Drawing on conversation analysis (CA), I identify important aspects of interactions related to the nature of knowledge and teacher authority. I begin with a discussion on powerful discourse.

Powerful Discourse in Mathematics Classrooms

As a framework for mathematics teachers and researchers to examine discursive practices in a mathematics classroom, Herbel-Eisenmann and colleagues (2013) offered two theoretical lenses: productive discourse and powerful discourse. Productive discourse is for widening students' access to mathematical language and ideas, whereas powerful discourse attends to the social and interpersonal functions of language in discourse. Although these two lenses may overlap and interact each other, this paper mainly focuses on powerful discourse since it is closely related to the social interactions and relationships among students and teachers—a significant part of the social turn.

Drawing on positioning theory (Harré & van Langenhove, 1999), Herbel-Eisenmann and colleagues (2013) highlighted the significance of the linguistic functions that position a person or a thing (e.g., student, textbook, mathematics) to a particular position (e.g., a "smart" student). Note that "positioning" is an active doing of language, in contrast to the static meaning of "a position." For discourse to be powerful for student learning, both people (e.g., teachers and peers) and social and material environments (e.g., textbook, and policy) can position a student as a doer of mathematics, a legitimate participant in mathematical activity. Wagner and Herbel-

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

Eisenmann (2013) argued for purposeful positioning of students, teachers, and textbooks during instructions to reorganize the authority structure (i.e., who or what decides what is true or good) within a mathematics classroom. This deliberate form of positioning can be a tool for teachers to support identity development of students, especially those with marginalized social markers (e.g., students with disabilities, students of color, girls, emergent bilingual learners). Through this mode of positioning, teachers can promote a more equitable learning environment.

This idea of supporting a student's identity development by disrupting the visible social asymmetry within a classroom is an interest of many equity-oriented researchers in mathematics education. For instance, one of the major discussions in complex instruction is "assigning competence" (Featherstone et al., 2011, Ch. 6). In a small group setting, by deliberately drawing "public attention to a given student's intellectual contribution to a group's problem-solving efforts" (p. 90), a teacher can encourage the student and other peers to see the given student as a valuable and intelligent member of the group. Thus, assigning competence is one of the many ways a deliberate positioning by a teacher can take place in the mathematics classroom. Through the lens of powerful discourse, we can see many ways, sometimes subtle and difficult-to-notice ways, that positioning could happen in a classroom. One of the strengths of the positioning theory is its conceptual flexibility, which allows an analyst to apply the theory in a broad range of interactional contexts with a variety of analytic tools (Herbel-Eisenmann, Wagner, Johnson, Suh, & Figueras, 2015).

Building on the work of Herbel-Eisenmann and colleagues (2013), this paper expands the notion of powerful discourse from a conversation analytic approach. Positioning can happen at multiple levels within the range of "scales" (Herbel-Eisenmann et al., 2015, p. 193). The conversation analysis presented in this paper allows for the finest-grain analysis (i.e., "utterance" level with a typical duration of 10^0–10^1 seconds). This paper highlights that this type of fine-grain analysis is necessary to understand powerful discourse in the context of moment-by-moment interaction in which a teacher and students are engaged in sequences of acting and reacting. Furthermore, Herbel-Eisenmann and colleagues (2015) stated that mathematics education researchers often make claims about positioning without much attention to communication acts. This paper illustrates how the application of CA can address the common pitfall by grounding the discussion of positioning on the temporal progression of the sequence of actions. The following section discusses CA and its key constructs related to powerful discourse in more depth.

Epistemic Dimensions in Conversation Analysis

The primary focus of CA is to understand normative practices of conducting social interactions, in particular, talk-in-interaction. As the term "talk-in-interaction" refers, CA attends to forms of talk (e.g., lexical, syntactic, speech features) and other visible social cues (e.g., gaze) in interactional contexts. The context includes not only when, where, and by whom the utterance was made but more importantly the temporal sequence of talk-in-interaction. As Heritage (1984b) articulated, "any speaker's communicative action is doubly contextual in being both *context-shaped* and *context-renewing*" (p. 242, emphasis original). In other words, an utterance is examined based on the context shaped by the prior interactions—notably, the immediately preceding action. The same utterance also reshapes the context for the following action. Both before- and after-utterances are, therefore, considered to infer action-performing aspects of a given utterance.

Influenced by ethnomethodology (see, for more information, Ingram, 2018), CA lays its epistemological grounding on what *participants* orient to (i.e., treat something as relevant to the conversation at hand) and on how both speaker and recipient treat the target utterance, which offers a window into participants' view on conducting moment-by-moment interaction. CA scholars argue that mainstream social science researchers too often impose a presupposed social model to explain a system of social interaction (Schegloff, 1997; Speer, 2004). On the contrary, the focus of *ethno*-methodology is on revealing participants' (i.e., ethno-) methods to design an utterance as a social action (e.g., advising, offering) and to recognize the utterance as such by the recipient. The social norms, from the view of CA, are not seen as theoretical rules that govern interactions among participants. Normative practices of social conduct are rather accomplished by the participants through routinized, seen—but unnoticed—procedures, which is the main interest of CA.

Epistemic Dimensions in Conversation and Epistemic Engine

This paper focuses on a particular topic in CA called *epistemic dimensions*—the "dimensions of knowledge that interactants treat as salient in and for conversation, particularly with respect to asymmetries" (Stivers, Mondada, & Steensig, 2011, p. 9). Epistemic dimensions include but not limited to: epistemic status (relative status as more or less knowledgeable based on social relationships); epistemic stance (moment-by-moment expression of being more or less knowledgeable); epistemic access (relative access to knowledge); and epistemic authority (relative authority of knowledge). Initiated by Goodwin (1979) and Heritage (1984a), CA scholars have been discussing the significance of participants' relative statuses as more or less knowledgeable in a particular knowledge domain. For instance, Heritage (2012b) coined the term, "epistemic engine," which is a normative social force for participants to engage in a sequence of interaction when information imbalance between participants is acknowledged. The sequence closes when the participants acknowledge that the imbalance is equalized for a practical purpose. Notably, CA does not concern what participants actually know in their minds. The focus is on how participants display themselves and treat the other participants as relatively more or less knowledgeable and on how such visible actions function as an epistemic engine, which shapes the normative patterns in interaction.

According to Heritage (1984a), the epistemic dimensions are an important concern for participants *in situ* because participants' epistemic positioning, called "epistemic status" (Heritage, 2012a), is a crucial part of the interactional context for participants as they design and interpret each other's actions in everyday conversations. Heritage (2012a) illustrated the differing action-performing nature of particular morphosyntax and intonation depending on the epistemic status of participants. For instance, the declarative syntax with falling intonation is often aligned with a speaker in a knowing position (K+) *conveying* new information to a recipient in an unknowing position (K–). A speaker in a K– position, however, can use the same morphosyntax and intonation to *request* information from a recipient. In an interview setting, for instance, when an interviewer (K–) says, "You have a child," despite the declarative syntax and falling intonation, the interviewee (K+) would respond as a request for information (e.g., "Yes, I have a son.") rather than an assertion from the interviewer. In other words, participants rely on their relative epistemic statuses to determine what the utterance performs and to project ways they can respond.

Heritage's (1984a; 2012a) argument above brings up an important issue when teachers and researchers examine the action-performing nature of discourses in a mathematics classroom. Solely focusing on textual and speech features of talk-in-interaction may overlook the epistemic dimensions of the conversational exchange, an important source for participants to interpret and respond to social actions *in situ*. To attend to the epistemic dimensions, analysts need to consider the knowledge domain in which the sequence of interaction is situated. The epistemic status is not static—the same participants may occupy different epistemic statuses depending on the knowledge domain in which participants are engaged. In a classroom setting, for instance, the teacher is often a sole K+ individual during a mathematical discussion (Ball 1993, Lampert 1990). However, when students share out what they did over the last weekend, students can be positioned as K+ in such a knowledge domain. This "epistemic asymmetry" (Heritage & Sefi, 1992) between the teacher and students is shaped by the institutional context of the mathematics classroom, in which a teacher with required educational credentials teaches and students learn school mathematics. This normative institutional setup thus creates an inherent epistemic asymmetry with K+ teachers and K– students.

Epistemic Dimensions in Mathematics Classroom Interactions

To illustrate the significance of knowledge domains and epistemic stance during moment-by-moment interactions, I first compare two cases from the study by Ingram (2012) in a secondary classroom setting in the U.K. I place a particular focus on teacher-initiated question-response sequences to discuss the contrasting epistemic characteristics of the sequences. Second, I turn my attention to two extracts from an article by Ball (1993), which is widely read and known for "Sean's number" in mathematics education. I apply the epistemic lens to offer an insight into the important discursive characteristics embedded in the discussions in Ball's (1993) study.

Epistemic Dimensions in Question-Response Sequences

The following two extracts share a common characteristic—they both consist of teacher-initiated question-response sequences, what Mehan (1979) called Initiation-Response-Evaluation sequence (IRE). In Extract 1 below, Simon is the teacher, and other speakers are students.

Extract 1 (Ingram, 2012, p. 110)

```
Simon:   … what was the highest number of days absence.
A:       eight
Simon:   it was eight. And what was the lowest number of
         days absent.
B:       zero or one I don't know
Simon:   you don't know. ok someone else then, what's the
         lowest number of days pe- someone was absent.
         George.
         2.5)
Alex:    zero?
         (0.9)
George:  zero.
Simon:   that was Alex talking I want to hear it from you.
         look at the table, what was the lowest number of
         days that someone had absent.
George:  zero.
Simon:   it is zero, because ↑twenty people had no days off.
```

Figure 1: Extract 1

The epistemic stances, which Simon and the students display, align with the epistemic statuses of K+ teacher and K– students. For instance, in the third turn position (i.e., the turn after the question and response turns) of the question-response sequence (line 330), Simon repeats the answer and confirms that the answer is correct. The action performed by the third turn is twofold. First, it closes the question-response sequence as a "sequence closing third" (Schegloff, 2007), which indicates that Simon has received a preferred response from a student. Second, Simon reasserts his K+ position. In this IRE sequence, the teacher holds a K+ position with K– students, and the third turn publicly displays that Simon already knew the answer to the question he posed, reaffirming his K+ position.

Simon's epistemic authority is also evident based on how the students treat the question-response sequence. Students orient to his epistemic authority with their downgrading epistemic stance. Note, for instance, that Alex offered his answer "zero?" (line 337) with rising intonation (noted by "?") thus downgrading the certainty of his answer. Moreover, students offer only short answers (e.g., "eight," "zero") without offering any account for their answers. This lack of accountability (i.e., the social norm that requires the speaker to offer an account for their response) can be explained by the epistemic statuses among the K+ teacher and K– students. The epistemic engine, the normative social force, works so that information flows from K+ position to K– position. When students are positioned in a K– position, students offering additional account works against such normative social force. To further argue for this point, I illustrate a contrasting case in the following extract, in which Richard is the teacher.

Extract 2 (Ingram, 2012, p. 115)

```
561   Richard: what do you understand by the idea of (.) proof.
562            mathematical proof. p r double o f.
563            (0.9)
564            what do you understand by that (.) concept, that
565            idea. Maybe say one thing about it (.) then let
566            somebody else say something else. Um:: hands going
567            up. Alex.
568   Alex:    you can't prove anything apart from maths because
569            it's all point of view.
570   Richard: oh I see
571            (0.7)
572            um: can you give an example or something
573   Alex:    um (there's different kinds of things) everybody's
574            eyes might be slightly different, you can't tell
575            (.) because it's like, (.) you see different
576            shades ((inaudible)) the eye could be different.
577   Richard: oh so when you look at your red thing there,
578            somebody might (.) see it differently.
579   Alex:    yeah
580   Richard: I see, whereas mathematically? What are you saying
581            about maths that's different?
582   Alex:    it's because the maths deals with absolute
583            (substances) like numbers, you can't be
584            ((inaudible)) can you.
585   Richard: ah: ok that's very interesting. very good. …
```

Figure 2: Extract 2

Similar to the case of Simon, we see Richard also practices his process-authority (Oyler, 1996). He selects who speaks next (e.g., line 567), and he controls the topic of the discussion by initiating a series of question-response sequences. The epistemic statuses are, however, shaped differently compared to the earlier case of Simon.

In the first question-response sequence, after Richard selects Alex as a next speaker (line 567), Alex offers his response with an account—note the use of "because" in line 568. Richard responds to Alex with "oh," a "change-of-state token" (Heritage, 1984a), which indicates that Richard's epistemic position changed from K– to K+. In other words, Richard displays that he now knows Alex's understanding of proof, which he did not know before the conversational exchange. The following "I see" also reaffirms that his question is a "genuine question," not what Searle (1969) called a "test question." This third turn closes the sequence, and Richard initiates another sequence (line 572) by requesting an example. This second question can be categorized as "probing a student's thinking" (Herbel-Eisenmann et al., 2013), but also there are important yet subtle epistemic stances that Richard and Alex display. Alex offers his response with an account—note "because" (line 575) once again and then Richards responds with his "oh" (line 577) with a subsequent statement. Despite its declarative syntax, we see Alex orients to Richard's statement as not an *assertion* but a *request for confirmation*, to which Alex responds with his approval of "yeah" (line 579).

The teacher and student, in this case, are positioned in contrasting epistemic statuses compared to the case of Simon. Richard is in K– position, wanting to know how his students understand the concept of proof, and Alex is in K+ position with his exclusive epistemic access to his own understanding of proof. In this epistemic terrain, the epistemic engine naturally works for the flow of information from K+ student to K– teacher. In other words, as a knower of his own understanding of proof, Alex is under the normative social force for explaining his knowledge to Richard and other students, which is evidenced by Alex's use of "because" and additional accounts that he provides after his responses. Thus, the question-response sequences above position Alex in a more powerful position with his epistemic authority.

Richard's case also shows how teachers' epistemic authority is tied to the notion of mathematics. In line 580, Richard focuses his question on the *mathematical* meaning of the proof by invoking "mathematically" and "maths." Alex shifts his epistemic stance by downgrading his certainty about his answer with a tag question, "… can you." (line 584). Alex's downgraded epistemic stance shows that, for his idea to be "mathematical," it requires approval from an external authority like a teacher. This particular sequence serves as an example of a teacher' identity as a legitimate bearer of "official knowledge" (Apple, 1993).

Examining the epistemic dimensions in the above extracts shows that epistemic statuses are shaped differently *relative to the knowledge domain* that teacher and students dwell during the question-response sequence. On one hand, when the question is targeted at the mathematical understanding that students hold in their mind, the students are positioned in K+ position. On the other hand, when the question is targeted at the mathematics defined by the institution, the teacher occupies K+ position.

Epistemic Dimensions in Reform-based Teaching

I now turn to two extracts from Ball's (1993) study to situate the current discussion on knowledge domains and positioning in the broader discussion of reform-based teaching. CA can reveal the routinized, seen—but unnoticed—procedures. In the case of Ball's study, by applying the lens of epistemic dimensions to her data, it may explain what Ball (1993) described as an abstract goal of reform-based teaching as more tangible discursive practices. In her paper, Ball (1993) discussed her dilemma as a teacher between hearing what students know now and supporting them as they transcend their present understanding. Her paper in part illustrates how she *hears* students' understanding, and I examine her actions through the lens of epistemic dimensions and positioning. In Extract 3 below, Mei offers her understanding of Sean's number, which can be both even and odd.

Extract 3 (Ball, 1993, p. 386)

Mei: I think I know what he is saying ... is that it's, see.
I think what he's saying is that you have three groups
of two. And three is an odd number and an even number.
T: Is that what you are saying, Sean?
Sean: Yeah.

Figure 3: Extract 3

After Mei explains her understanding of what Sean is trying to convey, the teacher asks Sean to confirm if that is what he is saying (line 304). Sean also orients to the teacher's question as seeking confirmation, and he gives his approval of "Yeah." Asking Sean to confirm is a discursive move that positions him as a K+ individual, but there is more to show in this scene. In this sequence of seeking and offering confirmation, the participants are engaged within the knowledge domain of *Sean's* understanding. That is, the goal of the exchange is not to know how school mathematics defines even and odd numbers, but rather, the participants' concern in the interaction is how Sean understands even and odd numbers. In this knowledge domain, Sean holds the primary right and authority as a knower of his own thinking, which positions Sean as K+ individual. This epistemic terrain aligns with Mei's downgrading epistemic stance indicated by her use of "I think …" (lines 301-302) and the teacher's confirmation-seeking. I discuss another example in the following extract of how epistemic status can be reshaped in interactions.

Extract 4 (Ball, 1993, p. 390)

Mei: So when we put two in each group in order to make
one because it's below zero.
T: I don't understand this part— put two in each group
in order to make 1.
Mei: If we take six and add six to it, we get twelve above
zero, but it's below zero, so— and three plus three is
six, so we add three more to the six above zero.

Figure 4: Extract 4

Starting from line 401, Mei explains her way of understanding 6 + (–6), and then the teacher indicated that she does not understand a part of her explanation. As a response, Mei expands her explanation. Here, we see the visible working of the epistemic engine. The teacher did not ask a question, but she only indicated her K– position of unknowing what Mei explained earlier. The publicly displayed epistemic status was enough for Mei to expand her explanation. This move is similar to what Herbel-Eisenmann (2000) observed from one teacher, named Karla, who often voiced her own confusion (e.g., "You lost me ….”). Through the epistemic lens, Karla publicly displayed her K– position and pushed her student to offer further explanation. As Drew (2005) suggested, we can see the state of confusion as an interactional resource generated *for* an interaction. Thus, teachers downgrading their epistemic status in a particular knowledge domain, to which students have primary access, is a powerful pedagogical move. This way, teachers can unleash the power of the epistemic engine and allow information flow from a K+ student.

Discussions and Implications

Through the lens of epistemic dimensions, I have discussed how positioning can happen in a sequence of interaction based on the knowledge domain in which participants engage and epistemic stances that participants display. In this section, I make connections between the epistemic dimensions in conversations and important discussions on knowledge and authority in the mathematics classroom.

The examination of discursive practices related to epistemic dimensions expands the notion of knowledge in the mathematics classroom. Often in mathematics education, the discussion of knowledge is limited to what individuals have in their mind. As Barwell (2013) critiqued, this individualistic approach overlooks the discursive dimension of mathematics knowledge embedded in social interactions. Barwell (2013), for instance, noticed that displays of teacher knowledge are "often inter-related with constructions of students as *not* knowing" (p. 605, emphasis original). His observation aligns with the relative nature of epistemic status that I discussed above, and I argued that powerful teaching is sometimes teachers displaying themselves as not knowing (i.e., downgrading epistemic status). That is to say, expanding the discussion from what knowledge a teacher *has* to how a teacher *performs* knowledge can further our understanding of the nature of knowledge situated in the interpersonal context.

The epistemic dimensions in conversation offer a framework to understand the interactions between the discursive dimension of knowledge and teacher authority in a more nuanced way. For instance, in her discussion on teacher authority, Herbel-Eisenmann (2000) illustrated how the tag questions (e.g., … isn't it?) used by one teacher made his corrective course of actions appear more polite and less authoritative. Through the epistemic lens, Herbel-Eisenmann's (2000) insight shows the graded nature of epistemic asymmetry. The teacher's use of tag questions downgraded his epistemic stance; yet, staying in the same knowledge domain, the teacher continued to maintain a K+ position. This case shows that teachers' deliberate effort to downgrade their epistemic status—without moving the discussion to another knowledge domain—has limited effect on reshaping epistemic status.

The significance of the knowledge domain to reshape the epistemic asymmetry between a teacher and students points to the need for moving across multiple knowledge domains during a mathematical discussion. Such as the case of Sean's number, focusing the discussion on how students understand a mathematical idea is one way to distribute epistemic authority to students based on their exclusive epistemic access to their minds. As Greeno (1991) stated, valuing students' thinking and reasoning encourages "positive epistemological beliefs and attitudes that are favorable to participation" (p. 211). The epistemic dimensions of interaction offer a lens to see what "valuing" students' thinking and reasoning looks and sounds like *in practice* and its fine-grain interactional characteristics. Based on the significance of the knowledge domain, the "valuing" requires moving the target of the conversational inquiry from official mathematics to the mathematics in students' mind. Furthermore, there are other knowledge domains to which students have relative epistemic access. For instance, students' cultural knowledge (Ladson-Billings, 1995) and community knowledge (Civil, 2006) can serve the same purpose, especially when the teacher's cultural and communal backgrounds do not overlap with those of students. These knowledge domains are great interactional resources to position students in a K+ position with epistemic authority.

Lastly, the distinction that I presented between teachers' content-authority and process-authority (Oyler, 1996) requires further discussions. This paper does not argue for an anti-authority stance. Rather, it argues for a more nuanced, multi-dimensional understanding of teacher authority and better use of authority during discussions for student learning. For instance, to reshape the epistemic terrain during the discussion, teachers need to be in authority to control the topic of discussion so that the teacher can intentionally steer the discussion toward different knowledge domains. Moreover, to accomplish more equitable participation among students, teachers may need to intentionally distribute the speakership among students with a particular social marker (e.g., race, gender) or prior history of participation. Without teachers' enactment of process-authority, the participation patterns in classroom discussions would likely continue to marginalize a particular group of students and remain dominated by a small number of students. Epistemic authority, a content dimension of authority, however, needs to be displaced from the teacher to allow students to engage in a mathematical activity as legitimate doers of mathematics rather than mere receivers of knowledge. The powerful discourse that I addressed in this paper concerns this epistemic authority.

Acknowledgments

The study reported in this paper was supported by the University Distinguished Fellowship funded by the MSU Graduate School. The author also likes to thank Beth Herbel-Eisenmann for her guidance in the process of developing this paper.

Mathematical modeling is a high-leverage topic, critical STEM education and civic engagement. This study investigates culturally responsive, school and community-based approaches that support mathematical modeling with elementary students. Specifically, we analyzed two modeling lessons in one fifth grade classroom, with a focus on how students drew upon their experiences and funds of knowledge as they engaged in the mathematical modeling process. Our findings illustrate different ways that students' experiences and situational knowledge informed and guided their modeling activity, including the quantities that they deemed relevant, and how they interpreted and refined their solutions. We also attend to the teacher's role in supporting such connections. Implications for mathematics teacher educators and research are included.

Keywords: Elementary School Education, Equity and justice, Modeling, Instructional activities and practices

Mathematical modeling is a high-leverage topic, critical for participation in STEM education and civic engagement (Aguirre, Anhalt, Cortez, Turner & Simic Muller, in press). Unlike typical textbook word problems that often require students to disregard realistic considerations (Greer, 1997; Verschaffel, De Corte & Borghart, 1997), modeling tasks invite students to consider real-world contexts, as well as real-world solutions. Students engage in a cyclical process of: (a) analyzing situations; (b) constructing models that represent the situation, based on information and assumptions; (c) using models to perform operations and reason about results; (d) validating or revising models; and (e) reporting conclusions (CCSSM, 2010; Lesh & Doerr, 2003).

Although mathematical modeling has a well-established research base in secondary and undergraduate education (Doerr & Tripp, 1999; Gainsburg, 2006), it has been underemphasized and under-supported at the elementary level, with a few notable exceptions (e.g., Carlson, Wickstrom, Burroughs & Fulton, 2018; English, 2006; Suh, Matson, Seshaiyar, 2017). This may be due to limited attention to modeling in elementary teacher preparation, and an absence of mathematical modeling tasks in elementary curricula (Burkhardt, 2006). However, research conducted with elementary grade students and teachers demonstrates that mathematical modeling *is accessible* to children in elementary grades (GAIME, 2016), including students with limited prior experience with modeling (Chan, 2009; English, 2006), and students from a diverse range of mathematical and cultural backgrounds (Turner et al., 2009).

Mathematical Modeling with Cultural and Community Contexts

Research suggests that culturally responsive, community-based approaches to teaching mathematics have added benefits, particularly for students from underrepresented groups

(Aguirre & Zavala, 2013; Civil, 2007; Ladson-Billings, 2009; Lipka et al., 2005; Turner et al., 2008). Grounding mathematics in meaningful contexts that connect to students' experiences can enhance student engagement and learning, and encourage students to draw upon situational knowledge and real-world considerations, instead of "cutting bonds with reality" (Bahmaei, 2011). Moreover, these connections help students understand how mathematics matters in personal and socially meaningful contexts (Anhalt, Cortez & Smith, 2017).

We build on this prior research to investigate culturally responsive, school and community-based approaches that support mathematical modeling with elementary students. Specifically, we collaborated with elementary teachers to develop modeling lessons that build on students' mathematical thinking (Carpenter et al., 1998) *and* their community-based knowledge and experiences (Civil, 2007). As teachers enact tasks in classrooms, a focus of our research has been on how students' contextual knowledge and experiences inform and support their modeling activity. Specifically, we focused on these research questions: How do students draw upon their experiences and funds of knowledge as they engage in the *mathematical modeling process*? How do teachers support these connections, and how do they shape students' modeling activity? We explored these foci via an analysis of modeling lessons in one fifth grade classroom (Mr. H).

The Mathematical Modeling Process

Figure 1 depicts the mathematical modeling process we have used with teachers and students. This model is informed by prior research (Anhalt, Cortez, & Bennett, 2018), and the modeling cycle included in the CCSSM's (2010) standard. The arrows represent what we have found to be frequent pathways through the modeling process, but others are possible.

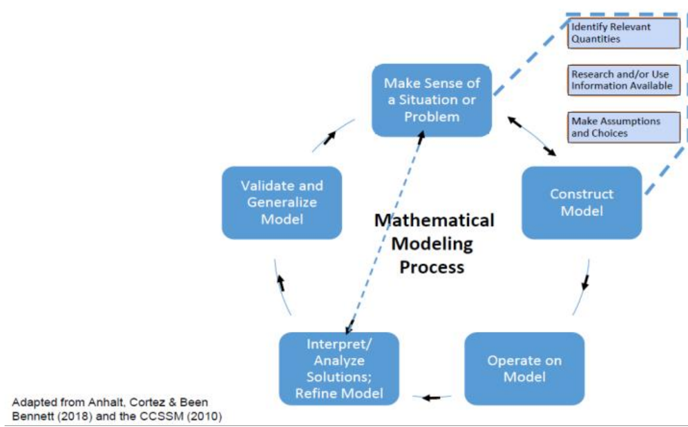

Figure 1: Mathematical Modeling Process for Elementary Students and Teachers

Phase 1, Make Sense of a Situation or Problem

Students begin the mathematical modeling process by making sense of a situation or problem. They consider questions such as: What do I know about this situation? What experiences have I had related to the situation? What additional information do I need?

Phase 2, Construct a Model

Next, students consider what quantities are relevant and important, and how those quantities relate to one another. They also consider what information is provided, what might need to be collected, and what they will need to assume or decide. These considerations are connected to the context, so as students construct a model, they continue to make sense of the situation.

Phase 3, Operate on Model

Next, students create a solution for the problem, perform computations, and check for precision both in their results and in their labels and/or explanation of their work.

Phase 4, Interpret/Analyze Solutions and Refine Model

Students then interpret their solutions in relation to the original situation. They ask whether their solution makes sense based on their experiences and knowledge about the context, draw conclusions about what the solution(s) imply, and refine and revise their model (if needed).

Phase 5, Validate and Generalize Model

This final phase in the mathematical modeling process involves validating and generalizing the model so that it is reusable and allows for applications to similar scenarios.

Study Context and Participants

As part of the broader project, approximately 30 teachers from two districts participated in 30-hour summer institutes focused on *teaching mathematical modeling in grades 3-5.* During the institutes, teachers engaged in modeling tasks developed by the research team, explored key phases of mathematical modeling, and discussed critical features of meaningful, relevant tasks.

During the academic year, teachers met on a monthly basis to plan, discuss, and reflect on modeling tasks enacted in their classrooms. Twice per year, researchers presented tasks and related lesson materials (photos, handouts, lesson launch slides) designed by members of the research team. These tasks addressed content-standards reflected in district quarterly curriculum maps, and connected to relevant contexts in schools and communities. All teachers were invited to enact these tasks, to facilitate analysis of a common lesson across different contexts.

Focal Teacher: Mr. H

We selected Mr. H's class because Mr. H enacted multiple mathematical modeling tasks across the school year, including tasks that connected to different school and family contexts. Mr. H is a White 5th grade teacher with 13 years of teaching experience. In his class of 27 students, 6 students were new learners of English. The racial/ethnic demographics mirrored the school with 30% Latinx, 19% White, 15% African American, 14% 2 or more races, 9% Asian, 3% Native Hawaiian/Pacific Islander, 1% American Indian/Alaskan Native. His classroom included a typical range of student backgrounds in mathematics.

Focal Modeling Lessons

We analyzed two mathematical modeling lessons in Mr. H's classroom, *Abuelo's Birthday* from the beginning of the year, and *Upcycling Jump Ropes* from the end of the year.

Abuelo's birthday. This task adapted from Aguirre and Zavala (2013) presented a realistic scenario about four grandchildren who want to share the cost of a birthday gift for their grandfather. Using information about each grandchild, students generate a "fair" plan for sharing the costs, and explain how their plan could be used in similar situations.

It is Sr. Aguirre's 70th Birthday. Four of his grandchildren want to buy him a gift. They found a photo printer on sale for $119.99. They want to buy him the printer to print family photos.

- Alex, a 9th grader, earns between $15 and $20 each week from babysitting jobs.
- Sam, a 6th grader, earns $10 each week taking care of a neighbor's pets.
- Elena, a 4th grader, earns about $5 each week doing odd jobs for an aunt.
- Jaden, a 1st grader, has no weekly job but has saved $8 in her piggy bank

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

One of the grandchildren says that they should split the cost of the printer among them and each pay the same amount. Another grandchild says that it is not fair and they should each pay different amounts. Help the children make a plan to share costs in a fair way to buy the gift.

- Your plan should work in other situations where family members want to share costs fairly.

Figure 2: Abuelo's Birthday Task

Upcycling jump ropes. This task focused on upcycling plastic bags to make jump ropes. This task was inspired by students' interest in environmental issues, including recycling and upcycling to reduce waste. Students designed a set of jump ropes for their school, calculated the number of plastic bags needed to make the jump ropes in the set, and then explained how their model could be used in other situations. The task materials included a video that showed how to braid plastic bags to make ropes, and the number of bags needed per foot of rope (3 bags/foot).

We selected these two modeling lessons because they were designed to facilitate different kinds of connections to students' experiences (i.e., to family practices in the Abuelo's birthday task, and to environmental concerns and school-based play practices in the Jump Rope task).

We want to make a jump rope set to be used in gym class. A set contains jump ropes of different lengths. How many plastic bags will be needed? Your plan for making the jump rope set must show:

- How you know that you will have enough jump ropes for gym class, without a lot of extra
- How many plastic bags you will need
- How others could use your plan to make jump rope sets for their school

Figure 3: Upcycling Jump Ropes task

Methods

Case Study Design

Using a qualitative case study design (Creswell, 2013; Stake, 1995; Yin, 2013), we considered lesson as a case, and the students who participated in the lesson as the primary focus of study. Case study research lends itself to "how and why questions" regarding social phenomena, especially questions that require "extensive and in-depth description" (Yin, 2013, p. 4). Correspondingly, we examined patterns within and across the two lessons (Stake, 2006).

Data Sources

Data sources included video-recorded observations of mathematics lessons, post-observation teacher interviews, teacher reflections on lesson enactments during a subsequent teach study group, student work, and other lesson artifacts (e.g., images of board work). The two lessons analyzed in this study ranged in length from 1.5 to 2 hours. When video-recording, we followed the teacher to capture instructional decisions and moves. All interviews were audio-recorded and transcribed. Videos were selectively transcribed with a focus on pivotal teacher questions and prompts, and examples of students' thinking and experiences that they brought to the task.

Data Analysis and Analytical Framework

Through multiple and iterative cycles of analysis, we developed preliminary categories based on themes identified in the literature related to modeling and connecting to students' experiences and funds of knowledge, and emerging themes evidenced in our data. These included: teacher moves to elicit and/or connect to students' experiences; ways students' experiences/knowledge connected with each phase of the modeling cycle; ways that connections to students' experiences supported sense-making. We engaged in iterative cycles of sorting data under these categories and writing analytic memos to identify and refine themes (Miles, Huberman, & Saldaña, 2013). To achieve *interpretive convergence*, multiple researchers developed and reviewed the memos. While viewing the data through the lens of the phases of the modeling cycle, we generated a *narrative compilation* (Creswell, 2013) of preliminary findings across the two lessons.

Findings

We structure our findings by the first four phases of the mathematical modeling process. (We address Phase 5 in the discussion.) In each section, we draw on examples from lessons analyzed.

Phase 1: Making Sense of the Situation or Problem

In both lessons, students drew upon understandings and experiences, from family and community, and school activities, to make sense of the task context. Mr. H also shared his own stories relevant to the context, as way to mirror the kinds of connections students might make.

Connections to family practices sharing costs in Abuelo's birthday task. During the launch of the Abuelo's birthday task, Mr. H began by narrating a personal story about eating out at a restaurant with a friend, and determining a fair way to split the cost.

> Mr. H: This happened to me last night actually. I went out to dinner with a friend, and then we ordered all this food, and we had to think about how we were going to pay. … Is it fair that one person pays for all it? I make more than my friend, so should I pay for all of it, because I make more?
> Students: No!
> Mr. H: She ordered more, so she should pay for all the things that she got, and I pay for my things? [Students call out both Yes! And No!]
> Mr. H: So I want you guys to think, what situations with your family, friends or siblings, have you been involved in where you had to share costs for something? … Can you talk about that for a minute?

Students then contributed their own family stories related to sharing costs such as splitting the cost of a new video game system evenly among siblings, with one sibling contributing the extra funds to cover the tax, or collaborating with cousins and an uncle to pool the money needed to purchase a family television set, with everyone contributing as much as they could.

Connections to play activities in the Jump Rope task. Mr. H also used personal stories to invite students to share experiences in the Upcycling Jump Ropes task. For example, he described his own attempts at specific jump rope styles.

> Mr. H: Yesterday I tried to use this [pointing to a jump rope] in some ways I was successful and some ways I was not as successful. ... Maybe it's [the jump rope] not a good fit for me. … If I had the longer one I would have been able to do the cross over thing [gesturing by crossing his hands in front of him to cross the rope] and that would have been kind of cool.

This prompted students to discuss different jump rope activities (i.e., "double dutch" versus "normal jumping"), and their ideas about height and rope length, noting that jump ropes need to be "different lengths, because … there are people of different sizes [in our class]."

Across the two lessons we found that Mr. H used his own stories, coupled with targeted probes to elicit students' experiences related to the task context, and to connect those experiences to key features of the task, such as quantities that would be important in building a model.

Phases 2 and 3: Constructing a Model and Operating on a Model

As students continued to make sense of the situations, they identified relevant quantities, and discussed information that was known, or that they needed to decide or assume. While we found similar patterns in both lessons, we focus here on *Abuelo's Birthday*, highlighting students' reasoning about quantities and relationships that were central to their model-building. Given that students' often iterated between constructing and relating quantities (Phase 2) and operating on those quantities (Phase 3), we describe both phases in this section.

Reasoning about the role of tax. As students in Mr. H's class discussed how the cost of the printer should be shared among the grandchildren, they considered the role of sales tax in the total price. Several groups assumed that tax would be approximately 5 dollars, because, as one student explained, "usually if you buy something from the grocery store, it's [tax] usually underneath $5." Other students drew on experiences shopping at dollar stores to reason about the tax. In the excerpt below Students 1 and 3 suggest that Jaden (the youngest sibling) pay the tax using his savings, because tax "is never over 5 dollars." Student 2 disagrees, drawing on experiences at the dollar store to explain that tax is charged at a rate of 10 cents per dollar.

Student 1: The littlest one [Jaden] can just pay tax.
Student 2: Eight dollars wouldn't be enough for tax [Jaden has $8 saved.]
Student 3: The tax is never gonna be like over 5 dollars.
Student 2: Tax is always over 5 dollars! Tax is ten cents, ten cents on a dollar. That means it would be 10 dollars [estimating the tax on the printer].
Student 1: But if you are [only] buying one thing-
Student 2: Listen. 1 dollar is 1 dollar and 10 cents, 2 dollars is 2 dollars and 20 cents.
Tax is 10 cents [per dollar]! Do you guys ever like go to the dollar store? You buy [one] thing and have to give them one dollar and 10 cents. …
Student 1: Tax is usually like under 5 dollars. Like at the grocery store. …
Student 4: We can add the tax after we do everything else. That's what people usually do.

Ultimately, this group decided to follow Student 4's suggestion to focus first on how the four grandchildren should split the cost of the printer (without tax) and "add the tax after." Yet their conversation evidences that they leveraged their experiences with tax charged at different stores to reason and make decisions about key quantities in their model.

Deciding how to share costs "fairly". Most students decided that the youngest sibling should only pay the tax; yet they made different decisions about "fair" plans for the other siblings. Some assumed that each sibling should pay the same amount, "that wouldn't be fair if 1 kid paid more." Others reasoned that the older siblings should pay different amounts, proportional to their earnings. Figure 4 displays one group's solution - the older three siblings each contribute their weekly earnings for four weeks, which added to Jaden's savings ($8), gives $148 total.

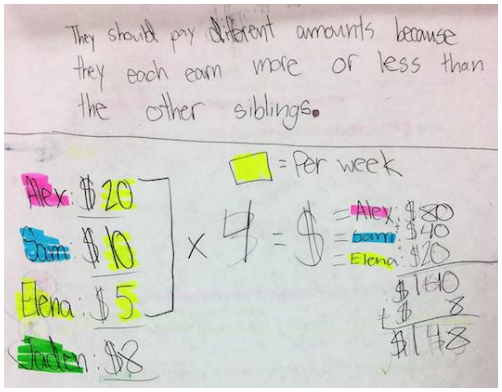

Figure 4: Equal Time Model for Sharing Costs. Each Sibling Contributes Earnings for 4 Weeks

In the discussion that follows, students explain both the quantities they deemed important (in this case, each sibling's weekly earnings) and the way that they related and operated on those quantities in their model (multiplying each weekly earnings by a set number of weeks).

> Student 1: we got what they all made in a week, except for Jaden. And we multiplied it by 4 weeks. And we got these [total earned per sibling in 4 weeks] and we added them …
> Mr. H: Why did you pick 4 weeks to multiply by?) Do you remember?
> Student 2: Because when we did 3 weeks we had less than what we needed, so then we added another week. … Alex paid $80, Sam paid $40, and Elena paid $20 and Jaden paid $8.
> Mr. H: Why did you think that was fair? What was your thinking? … Was there a reason, though, that you let them pay different amounts?
> Student 3: Well because each person, well, Alex made the most. So he would pay like most of it. Well, like Elena, and Sam would pay some of it too. ..
> Student 4: A question I have is … since the printer was $120, but when I look at your paper, it said they paid $148 if you add everything together.
> Student 3: We will just have extra.
> Student 5: They could use the extra money they had to pay tax.

Students drew on shopping experiences, including understandings about tax, as well as perspectives on "fair" ways to share costs to relate and operate on quantities in their models. While some students proposed models based on equally dividing the cost among the three older siblings, other students drew on sensibilities about fairness and sharing in families to reason that fair does not always mean equal. Yet all models were based on the assumption that all four siblings should contribute to the gift, something that students reasoned was important.

Phases 4: Interpret/Analyze Solution, and Refine Model

After students operated on their models to determine the amount paid by each sibling (in Abuelo's Birthday) or the number of bags needed to make the jump ropes in their set (in Jump Ropes), they analyzed their solutions, and in some instances, refinements were needed. While we found similar patterns in both lessons, we focus here on *Upcycling Jump Ropes*, with attention to how students' experiences informed this phase of their modeling activity.

In some instances, students' analysis of their emerging models led to revisions in how they defined an appropriate set of jump ropes for their target audience. For example, several groups of students proposed models based on grouping students by height, and then providing each group of students with a set of appropriate length ropes. As one student explained, “We came up with the idea that we could split people into different categories based on their height because some people are different sizes.” Often students also included one or more long jump ropes in the set, to allow for group jumping activities. Figure 5 below display such a solution.

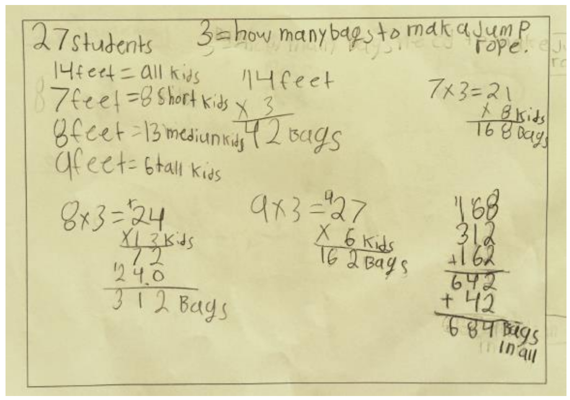

Figure 5: Mr. H’s Students Operate on a Model Based on Grouping Students by Height

As this group explained their model to the class, they highlighted the ropes of different lengths, and how they operated on those quantities to find the total number of bags needed (i.e., “we thought if one foot is 3 bags, we did 3 times 7 is 21 [bags for one 7-foot rope], 21 times 8 is 168 bags [for eight 7-foot ropes], etc.” Yet because they included only one 14-foot rope in their set, a classmate (Student 1) asked them to consider whether that configuration would allow for double-dutch style jumping (which requires two 14 foot jump ropes).

Student 1: For double-dutch you have to have two [jump ropes].
Mr. H: Oh, for double-dutch you have to have two? (to group of students who shared their model) Did you mean actual double-dutch or big jumping?
Student 2: [We meant] double dutch.
Student 3: I just want to jump rope.
Mr. H: If actual double-dutch was a requirement of our class, would that change our outcome? What would we need [to change]? … So if you are doing double-dutch what do we have to do for the bags for the 14 foot [rope] if we are doing double-dutch?
Student 2: We have to double it [double the number of bags]
Mr. H: We could double it to get a double dutch rope [to have enough for two ropes].

This exchange highlights how students’ prior experience and understandings related to jumping rope informed their analysis and interpretation of their own solutions (and those of peers), as well as the teacher’s roles in prompting students to consider refinements. We found that as students analyzed, interpreted and refined quantities (e.g., the number of jump ropes of a given length in a set), they often refined ideas generated in *Phase 2*, and these refinements were informed by the knowledge and experiences students brought to the task.

Discussion

Across the two lessons, we found that students' (and in some instances the teacher's) experiences and understandings were pivotal to their engagement in each phase of mathematical modeling. Students leveraged their experiences to identify important quantities and relationships, to make assumptions, to analyze and interpret the reasonableness of their solutions, and to revise their models when needed. Students' reliance on their own experiences and sense making highlights the potential of relevant mathematical modeling lessons to support students' empowerment as mathematical learners, as well as their real-world reasoning (Bahmaei, 2011). Perhaps the salience of student experience was a reflection of the relevance of the tasks. A well-chosen context supports students in developing "informal, highly context-specific models and solving strategies," (Doorman & Gravemeijer, 2009). Yet we also suspect that Mr. H's frequent invitations for students to share their experiences played a key role. Consistent with other research that has noted the positive impact of honoring students' ideas (Ladson-Billings, 2009), we found that students responded to teachers' invitations with interest, and that these discussions provided opportunities for students to consider and respond to the perspectives of others.

The most challenging phase of the modeling process was generalizing. This is in part due to time constraints; after an extended period of work students were left with minimal time to explore how their models could be used by others. Though not taken up, we see Mr. H's invitation for students to consider how their models could work in other similar situations as an initial step. Future research should investigate how to support generalization in elementary mathematical modeling, both through task development and lesson implementation.

Implications and Conclusion

Our findings have important implications for mathematics modeling instruction and research. Given the salience of children's funds of knowledge across all phases of the modelling process, teachers should explicitly elicit students' experiences and perspectives, and position these experiences as resources to support meaningful engagement in mathematical modeling. A detailed analysis of how specific teacher moves support connections to students' experiences during modeling lessons would be a productive focus for future research.

FLIPPED INSTRUCTION IN ALGEBRA 1: IS IT AN OLD IDEA IN NEW CLOTHES?

Wenmin Zhao

What are the substantive differences between flipped and non-flipped instruction? This study examined the instruction of two teachers who have worked together within the same school using the same Algebra 1 curriculum for years. One teacher flipped his instruction (creating lecture videos assigned as homework), while the other teacher continued with non-flipped instruction. Data from classroom observations were analyzed qualitatively using the Flipped Mathematics Instruction Framework. Results show that although there were clear differences in the format of flipped and non-flipped lessons, there were also substantial similarities with regard to features of instruction (e.g., procedural mathematical development, teacher authority, and tasks with low cognitive demand). Our analysis indicates that flipped instruction is not necessarily an innovative model when compared with non-flipped.

Keywords: Flipped instruction, Instructional activities and practices, Algebra, Technology

Introduction

In the past decade, mathematics teachers have increasingly adopted or at least tried flipped instruction in their classrooms (Smith, 2014). *Flipped instruction* is an instructional model in which a teacher assigns videos or other types of multimedia to be viewed as homework, which frees up in-class time for other purposes such as practice problems or collaboration (Bergmann & Sams, 2012). With the increased availability of electronic devices accessible to students, flipped instruction holds promise in terms of allowing students access to lectures at their own pace (and also retroactive access), as well as allowing the teacher to use more of the classroom time for activities that are more collaborative than lecture-based.

Flipped instruction is often regarded as innovative due to the use of video technology or the fact that it appears on the surface to be different than the traditional lecture model of mathematics teaching. Some advocates of flipped instruction (e.g., Bergmann & Sams, 2012) believe that its innovative nature may lead to more favorable student outcomes. However, it is still unknown whether flipped instruction as implemented by secondary mathematics teachers is substantively different than non-flipped instruction. Therefore, in this study, we examined the similarities and differences between the instruction of two teachers, one employing flipped instruction and the other not, who are from the same mathematics team within the same school using the same curriculum for lessons on Exponential Rules. More specifically, in this paper we use the Flipped Mathematics Instruction Framework (Otten, de Araujo, & Sherman, 2018) to answer the following research question:

In what ways are these flipped and non-flipped lesson implementations similar and different with regard to activity formats, duration, instructional quality characteristics, and interactivity characteristics?

Literature Review

Many studies of flipped instruction have focused on its impact on various learning outcomes, presuming that flipped instruction is different in an important way from non-flipped instruction. Some of the studies revealed that secondary students in a flipped section have higher learning gains on their pre- and post-tests than those in a traditional section (e.g., Bhagat, Chang, & Chang, 2016; Charles-Ogan & Williams, 2015), whereas others have shown no differences in learning gains between the flipped and non-flipped sections (e.g., Clark, 2015; DeSantis, Van Curen, Putsch, & Metzger, 2015). In either case, there was insufficient detail with regard to what was happening in the classroom. The authors did not report on the substantive differences between flipped and non-flipped instruction, nor did they draw inferences about which features of the instruction contributed to learning outcomes.

Some studies (e.g., Maciejewski, 2018; Rudd et al., 2017) included classroom observations of the in-class activities but did so generally. For example, Maciejewski (2018) evaluated the effectiveness of a flipped undergraduate calculus course. Students in the non-flipped sections spent more time listening to the instructor, while students in the flipped sections spent more time on individual or group work. In another study, Rudd and colleagues (2017) reported that elementary students in a flipped mathematics section had many opportunities in class to explain what they had learned at home and to solve real-life problems. However, these studies only recorded the types of activities and teacher actions without considering more detailed quality indicators such as conceptual development and interactivity.

In the present study, we look more closely at the lesson implementation in flipped and non-flipped instruction and we add to the growing research base of flipped instruction in secondary mathematics by focusing on Algebra 1. This mathematical setting is important because Algebra predicts the future success of students (Williams, 2011) and mathematical concepts introduced in Algebra are critical for mathematics learning in future mathematics courses (Carraher & Schiemann, 2007).

Theoretical Framework

The framework (Figure 1) of this study draws upon existing frameworks (e.g., Remillard & Heck, 2014; Stein, Grover, & Henningsen, 1996), observation instruments (e.g., MQI, M-Scan), and advice from experts in different fields (e.g., educational technology, mathematics education). Our framework, which is built for a lesson-level scope, allows us to distinguish the different roles that students participate either when viewing the video/multimedia at home or when taking part in in-class activities (Otten et al., 2018). The *in-class* phase captures what occurs during class time, including the *whole-class* and *non-whole-class* activity formats. The *at-home* phase captures the expected activities of students outside the classroom and includes any videos, multimedia, or traditional homework problem sets assigned to students. Within each phase, we focused on certain aspects of the quality of implementation.

We used our framework to develop a classroom observation protocol (Zhao, Han, Kamuru, de Araujo, & Otten, 2018) to capture the general lesson characteristics in terms of focus (what is to be learned), rationale (why is it to be learned), and flow between activities (how the learning activities link together or not). We further distinguished two main in-class components of a lesson, *whole-class* and *non-whole-class* discourse. The *whole-class* discourse is when everyone in the class is expected to be attending to the public discourse regardless of whether it is the teacher (e.g., lecture) or another student (e.g., classroom discussion or student presentation) who is speaking. Within the *whole-class* discourse, we noted the quality of instruction regarding the mathematical development of ideas, integration of mathematical representations, absence of unmitigated errors, and connections to past/future mathematics content. We also focused on the interactivity during the *whole-class* discourse, namely, the exhibited mathematical authority, student public involvement, the sharing/collaborative nature of discourse (Staples & Colonis, 2007), and video/media involvement.

The *non-whole-class* discourse component of our protocol captured time spent when students were expected to work either in groups or independently. We further specified the extent of peer talk, students' use of video/multimedia (e.g., if students watched an instructional video while they were working in class), teacher circulation, and cognitive demand of the tasks. In addition, our framework allowed us to analyze the level of behavioral engagement during the *whole-class* and *non-whole-class* discourse.

For the *at-home* phase, the key video characteristics were examined along three aspects: instructional quality, multimedia design, and interactivity. Instructional quality was the same as described above. The multimedia design was analyzed according to Clark and Mayers' (2008) six digital material design principles: multimedia, modality, contiguity, redundancy, coherence, and personalization. Another aspect, interactivity, documented the interactive elements of the video, such as embedded questions, discussion boards, or virtual manipulatives. More details can be found from Otten, Zhao, de Araujo, and Sherman (in press). Due to the space restriction, the findings of the *flow* and *multimedia design* in this study will not be reported in this paper.

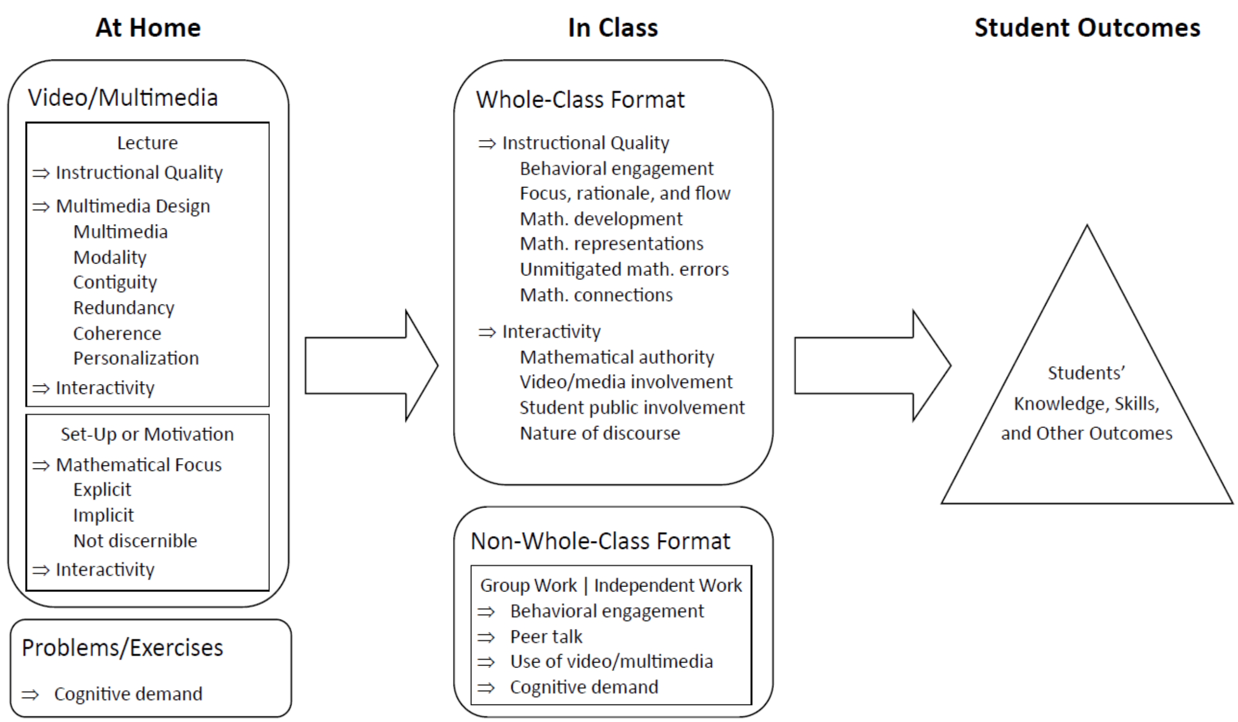

Figure 1: Framework for Flipped Mathematics Instruction (Otten et al., 2018)

Mode of Inquiry

Sample and Setting

The two teacher participants, Mike and Kristen, were both Algebra 1 teachers working at the same public high school in a rural area of Missouri. They worked on the same mathematics team and shared the same curriculum. Mike has a Bachelor of Science in Mathematics. He had eight years of teaching experience and had been using flipped instruction in Algebra 1 for two years. Mike flipped more than 75% of his lessons but still incorporated non-flipped homework (e.g., problem sets) or sometimes no homework. Mike's class had 22 students who knew the class was flipped when they enrolled, though that may not have been the primary motivation in choosing his class. The other teacher, Kristen, had a Bachelor of Science in Secondary Mathematics Education and nine years of mathematics teaching experience. She had 23 students in her class and was *not* flipping her instruction.

Data Collection and Analysis

The primary data sources for this study were classroom observations and lesson artifacts (e.g., video homework and in-class worksheets). Two researchers observed the classroom instruction three times during a semester using our observation protocol. In this study, we focused on the data from the first classroom observation and examined both teachers' lessons on the rules for operating with expressions that involve exponents (Missouri Learning Standards–A1.NQ.A.1) which is an important topic in Algebra 1. The length of Kristen's lesson was 47 minutes, and the length of Mike's lesson was 47 minutes with an additional seven minutes and three seconds of lecture video assigned to be watched before class. Mike produced the video using a digital pen and a tablet, with an audio voice-over from himself (Figure 2).

Based on the observation protocol, we analyzed the field notes from the classroom observation and coded the interactive features as well as the quality of classroom instruction and the instructional video. A third rater reconciled disagreements between the two raters.

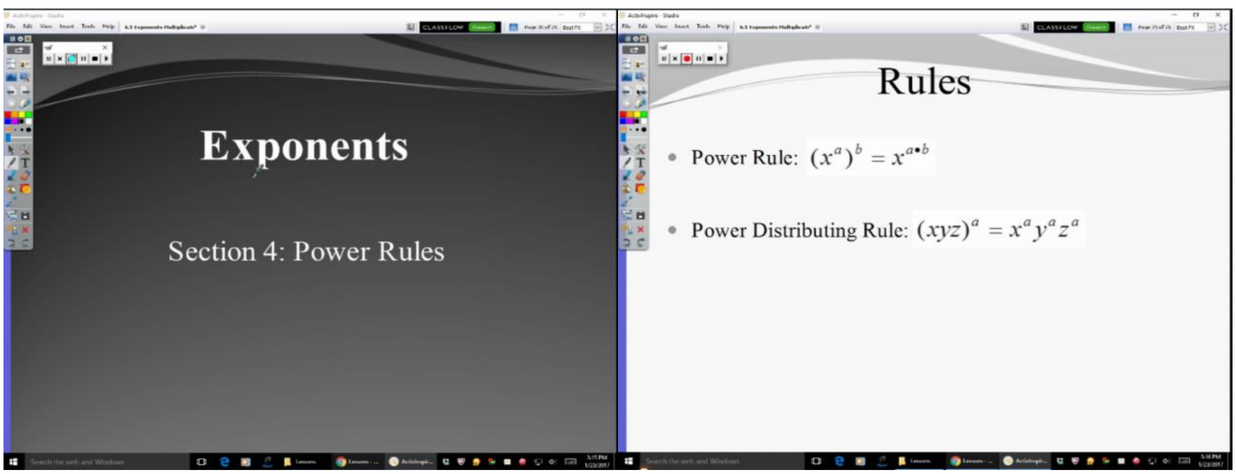

Figure 2: The Lesson Focus on Mike's Lecture Video

Findings

In this section, in our comparison of the two teachers' lessons, we share the research results focusing on the differences and similarities in the (1) lecture video and whole-class discourse, and the (2) non-whole-class discourse phases of the flipped and non-flipped lessons with regard to the instructional quality, interactivity, cognitive demand of the tasks, and student engagement.

Video and Whole-Class-Discourse Phases of the Lessons

Both lessons started with a lecture. Mike's lecture took the form of a video assigned as homework before class, with a brief follow-up in class (i.e., Mike used a whole-class discourse format to go over a few key ideas from the video). Kristen's lecture began when students entered her classroom. Beyond the obvious distinction in the modalities of the lessons (i.e., at-home video vs. in-class lecture), we captured the differences and similarities in terms of the time allocation of in-class activities, lesson focus, rationale, mathematical development, mathematical errors, mathematical connections, use of multiple representations, and nature of discourse.

Differences. As previously mentioned, both lessons began in different physical locations and modalities of interaction. The lecture portion of Mike's lesson started with his seven-minute video. He then spent another eight minutes of class in a whole-class discourse format, for a total of 15 minutes as the first portion of the lesson. A unique piece of Mike's lesson was that his initial whole-class discourse involved several verbal references back to the video, to which students still had access. In contrast, Kristen's lecture was live and started in-person in the classroom. She spent 24 minutes (rather than 15) addressing the class on the content of the lesson and, unlike Mike, she wove this whole-class discourse with brief instances of independent work time (i.e., students tried an example after a worked example).

Similarities. Although there were differences in time allotment, modalities, and spaces of instruction, the teachers had many similarities in their lesson enactments. First, both teachers started their lessons with **content delivery**, which included **an explicit lesson focus** but did not include a **rationale** for why it should be learned. For example, in Mike's lecture video, he started the lesson with the **explicit focus**, "Power Rules," on the screen (Figure 2). Mike mentioned that the lesson would involve learning how to multiply exponents and how to apply power rules and power distributing rules. When the lesson continued into the in-class time, Mike was also clear about the **lesson focus**; he explicitly mentioned that students would continue to learn the properties of exponents. However, in neither the at-home nor in-class phases did Mike give students **a rationale for learning** the rules. Similarly, near the beginning of Kristen's lesson, she displayed a PowerPoint slide that explicitly introduced the **focus of the lesson** and displayed the definition of "Quotient of Powers." Like Mike, however, she too gave **no additional rationale**, such as a real-world application or an expanded understanding of mathematical operations, for why students should learn the lesson.

In terms of the mathematical instructional quality, the lectures were also similar. Both had a **procedural emphasis** with regard to mathematical development. For example, in the video, Mike began by showing the power-to-a-power rule and "power distributing" rule. He then applied the rules to solve problems in which he explicitly directed students to "distribute" the "four" or the "two" as an exponent onto all of the interior terms (Figure 3). Mike did not give reasons for why the rule works. Similarly, Kristen showed the students $\frac{a^m}{a^p} = a^{m-p}$ on the board and worked through three examples. She offered no further explanation other than the procedure that she presented. At no time during the observed lesson did Kristen offer the students a conceptual model to understand the procedures in the lesson.

For both lectures, neither Mike nor Kristen committed any **mathematical errors**. Both teachers referred briefly to the previous lesson, yet neither gave substantial emphasis to the **mathematical connections** between the lessons. For example, Mike mentioned that the new lesson was connected to the previous lesson which only included multiplication of exponents with same bases. However, he did not explicitly explain how the new lesson developed from the previous one. In comparison, Kristen gave her students procedural problems which were a review of the previous lesson as a warm-up before class began. She went over those problems and reminded students of the power rules that they had already covered (e.g., multiplication rule). Then she started her new lesson without any conceptual connection between the previous lesson and the new lesson. In both lessons, the teachers only solved the problems symbolically without attending to other types of **representations** (e.g., tables and graphs) to help students understand the Exponential Rules.

The nature of discourse of both lectures was "sharing" (Staples & Colonis, 2007) because ideas were generally conveyed from the teacher as a source of mathematical authority to the students as receivers. Students were not oriented to each other's thinking or encouraged to connect, extend or critique ideas. Most students only answered in one-word answers or small phrases. For instance, Kristen wrote an equation on the board, $\frac{1c^4d^4f^3}{2c^2d^4f^2}$, then she asked, "What can you tell me about the *d*'s?" The students chorally responded, "Cancel out." We found that leading questions with fixed answers dominated most of both Kristen's and Mike's classroom discourse. The teachers were the **authority** over the mathematics knowledge in both lessons. Kristen and Mike, rather than the classroom community or students, determined the validity of a student's strategy. Overall, **students' public involvement** in both classes was low. Few students asked questions related to the procedures that the teachers worked on the board or responded to the teachers' prompts.

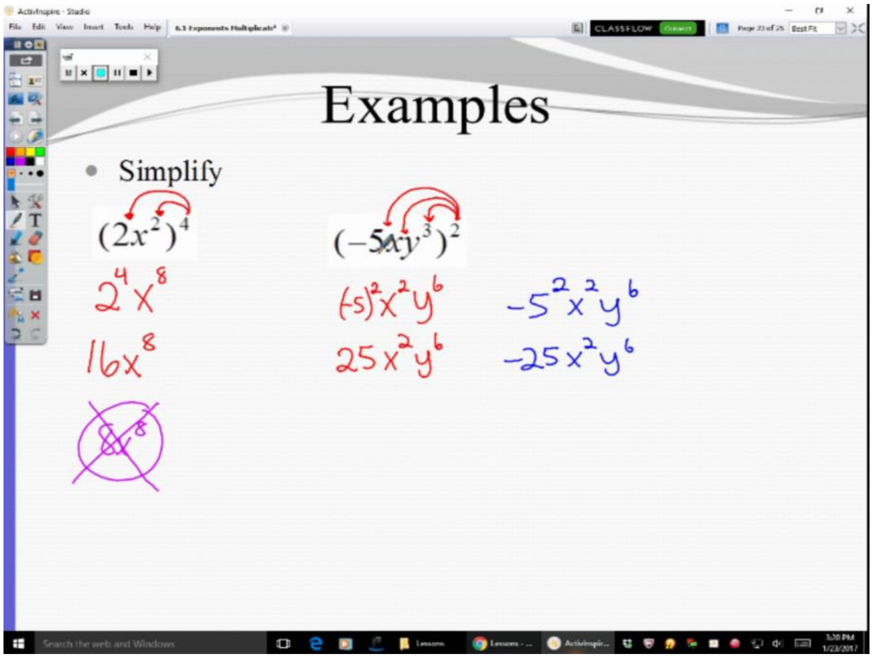

Figure 3: Two Examples in Mike's Lecture Video

Non-Whole-Class-Discourse Phases of the Lessons

For both Mike and Kristen, the lecture or content delivery portions of the lessons were followed by a substantial amount of non-whole-class-discourse (i.e., independent) work time. During the independent time, the teachers were available for questions or even purposely attended to certain students, however, the expectation was for students to work on their own. During this portion of both flipped and non-flipped lessons, we examined three lesson characteristics: the length of the independent work time, cognitive demand of the practice problems, and student engagement.

Differences. The two lessons differed in the amount of time that each teacher allotted for independent work. Because Mike's flipped lesson moved seven minutes of content delivery to the homework assignment, he gave substantially more in-class time for students to work on the practice problems (36 minutes out of 54, or 66.7%). Kristen's lesson, on the other hand, 20 minutes out of 47, or 42.6% was independent work comprising practice after the lecture was completed. Some of Kristen's students finished all the problems during that time, but others were left to finish additional problems at home.

Similarities. It is worth noting that both lessons were similar in the fact that they followed the content delivery portion by then providing students with independent work time for practice problems. The lessons were also similar in that the **cognitive demand** of the practice problems was low. In both Mike and Kristen's classes, they passed out a worksheet with the prompt "Simplify. Your answer should contain only positive exponents." Problems such as $(2m^3)^3$and $(-4n^4)^{-1}$were included in Mike's worksheet. Problems such as $\left(-\frac{vu^4}{2u}\right)^3$and $\frac{(-2x^3y^4)^4}{-2x^4}$were included in Kristen's worksheet. We considered these problems as *procedures without connections* since the main intent of the problems was to produce the correct answer without conceptual connections to the procedure beyond what their teachers had already demonstrated. There was also no explanation or justification required.

The levels of **student engagement** were similar in both lessons. During the students' independent work time, the behavioral engagement was mixed (i.e., many students on task for a majority of the time but also many students off task for at least a substantial portion of the time). In both classes, there were periods where the vast majority of students were working on the practice problems, but in Kristen's class, some were slow to get started and talked to their peers about non-mathematics related topics. In Mike's class, and to a lesser extent in Kristen's class, as some students completed their worksheet, they started to chat with their classmates about non-mathematics related content.

Figure 4 depicts a summary of the two lessons examined in this article.

Conclusion and Implications

The major objective of this study was to compare and contrast the instructional implementations of a flipped and a non-flipped lesson by teachers from the same school using the same curriculum. Many people continue to uphold flipped instruction as an innovative instructional method, which allows teachers to make better use of their in-class time to create more collaborative activities leading to a deeper conceptual understanding of the content. However, as is evident from our analysis, this is not necessarily the case.

Although the modalities of delivery (i.e., in person vs. via video) and the time allocation between the two lessons were different, we found similarities in the instructional quality, interactivity, cognitive demand of the practice problems, and student engagement of both lessons. The flipped instruction, as we examined in this paper, did not move beyond the "video lecture at home and homework in the classroom" model of instruction and in this way remained similar to the non-flipped instruction. Thus, in this case, it seems that merely flipping the spaces and modalities through which content is delivered does not necessarily change the nature of instruction. We invite researchers to be more cautious in crediting flipped instruction as an innovative model of mathematics teaching. Our framework allows us to gain insights into the nuances of similar lessons taught in both flipped and non-flipped classrooms. In reporting future findings of flipped classrooms, we encourage researchers to consider the importance of reporting the details of actual classroom instruction.

asacrist@cinvestav.mx

La selección de recursos para la enseñanza es una actividad desafiante en el trabajo de los profesores. Determinar qué recursos usar requiere de conocimientos profesionales específicos que orientan la acción del profesor. En este sentido, presentamos algunos resultados de un estudio que utiliza la Aproximación Documental de la Didáctica para analizar el trabajo documental de un grupo de profesores de primaria al seleccionar recursos digitales para la enseñanza de la geometría en quinto grado. Para inferir los esquemas que orientaron su selección de recursos, se llevó a cabo una investigación reflexiva, utilizando también una técnica de introspección. El análisis obtenido permitió inferir invariantes operatorias en el proceso de selección de los maestros, las cuales categorizamos como "criterios de selección". Ejemplificamos todo esto a través del análisis de datos de dos profesores.

Palabras claves: Actividades y Prácticas de Enseñanza, Tecnología

Introducción

La selección de recursos es una parte fundamental del trabajo documental del profesor (Gueudet & Trouche, 2009), la cual involucra conocimientos profesionales mediante los cuales los profesores identifican recursos y los usan en clase. En este artículo presentamos resultados de un proyecto que buscaba analizar la selección de recursos digitales para la enseñanza de la geometría por profesores de primaria en Colombia. Dicho proyecto tomaba, como marco teórico y metodológico, la Aproximación Documental de la Didáctica propuesta por Gueudet y Trouche (2009, 2012).

En el proyecto se estudió el trabajo de cinco profesores de primaria para sus clases de geometría. En Santacruz y Sacristán (2016) ya habíamos reportado datos de una primera fase de investigación donde se infirieron las rutas de selección y orquestación de recursos digitales que siguieron dos de los profesores participantes. Ahora presentamos datos de una segunda fase del estudio, analizando los casos de dos profesores de quinto grado para inferir y categorizar sus conocimientos profesionales que orientaron sus procesos de selección de recursos en "criterios de selección" (considerados invariantes operatorias en el sentido de Vergnaud, 1998).

Marco teórico

La Aproximación Documental de la Didáctica o ADD (Gueudet &Trouche, 2009, 2012), consiste en un enfoque teórico y metodológico que se ocupa del estudio del trabajo documental de los profesores. El trabajo documental es el conjunto de actividades que realiza el profesor en interacción con recursos; incluye actividades como la selección, diseño, adaptación, y uso de recursos, así como el trabajo colaborativo del profesor con colegas y sus reflexiones sobre su trabajo.

Una de las ideas centrales de la ADD es el concepto de recurso y sus usos. Adler (2000) considera que un recurso es todo aquello que da sentido al trabajo del profesor; y contempla que los recursos pueden ser: materiales, humanos y culturales. Otro concepto clave en la ADD, es el de documento (por ende se habla de trabajo documental), el cual no es algo que se le proporciona al profesor, sino que éste lo construye por medio de procesos de génesis documental; es decir, un documento se construye a partir de los recursos disponibles mediante un proceso extenso y continuo a lo largo del tiempo. Gueudet y Trouche (2009) consideran que un documento está constituido por uno o varios recursos junto con sus respectivos esquemas de utilización.

Los esquemas de utilización de los recursos corresponden a estructuras cognitivas del profesor que orientan el uso que él hace de ellos (Gueudet & Trouche, 2009). Vergnaud (1998, citado por Gueudet & Trouche, 2009) señala que los esquemas dependen de la situación, de la intención y competencia del sujeto, por tanto, no son algo predefinido. Los componentes de los esquemas son: metas y sub-metas; anticipaciones; reglas de acción, invariantes operatorias (que corresponden a los conocimientos contenidos en el esquema y son de dos tipos: concepto-en-acto y teorema-en-acto) y posibilidades de inferencia (Vergnaud, 1998). En nuestro estudio inferimos los aspectos arriba señalados mediante una técnica de introspección descrita más abajo.

Metodología

Como se dijo, en nuestro estudio analizamos la selección de recursos de cinco profesores de primaria en Colombia. Para su participación, se tomó en cuenta: su participación voluntaria, su interés en la enseñanza de la geometría y el uso, en su práctica docente, de recursos digitales.

El desarrollo de nuestro estudio se fundamentó en la investigación reflexiva de Gueudet y Trouche (2012), mediante la cual se fomenta, en entrevistas, que los profesores lleven a cabo una mirada retrospectiva de su práctica, para estudiar su trabajo documental. En el estudio empezamos observando y analizando la planeación de clases de los profesores participantes, su bitácora (registro) de clase, y, sus clases (*in situ*). Posteriormente, en entrevistas con cada profesor, se aplicó una “técnica de introspección” (ver abajo), para promover su reflexión y la elaboración de representaciones de su ruta de selección de los recursos para sus clases. Los datos recabados se analizaron para inferir los componentes de los esquemas (en términos de Vergnaud, 1998) que orientaron la selección de recursos por cada profesor, principalmente sus invariantes operatorias o criterios de selección.

La técnica de introspección

Esta técnica integra aspectos de la investigación reflexiva (Gueudet & Trouche, 2012) y de la investigación introspectiva (Vollstedt, 2015). Consiste en estimular la introspección para evocar conocimientos profesionales de los profesores a través de “recuerdos estimulados” (Calderhead, 1981). Dicha técnica la diseñamos para que el profesor evoque (*a posteriori*) sus pensamientos y acciones en un momento o actividad específica; la usamos para indagar sobre lo que llamamos la “ruta-recorrida” por el profesor en su selección de recursos. La técnica se aplicó durante entrevistas donde se presentaba a cada profesor información de su práctica (extractos de videos, de fotos, de las planeaciones de clase, etc. –generalmente una semana después), y se le pedía que representara sus procesos de selección de recursos mediante mapas o diagramas, junto con explicaciones verbales. Los datos que obtuvimos a través de nuestra técnica de introspección fueron transcritos, segmentados, codificados y categorizados para inferir los esquemas, particularmente las invariantes operatorias (los criterios de selección) de estos esquemas.

Estudios de caso de dos profesores: Sonia y Pedro

Sonia y su selección de recursos, basada en las necesidades de sus estudiantes

Aquí, analizamos el tipo de recursos que Sonia seleccionó para su clase y propuso a sus estudiantes respecto a un tema específico: la estimación y medición de longitudes. Sonia es una profesora normalista, licenciada en enseñanza de las matemáticas, con once años de experiencia como maestra de primaria; trabaja en una escuela pública que atiende población vulnerable.

Identificamos que Sonia ha ido reuniendo una colección de recursos para la enseñanza que incluye: recursos curriculares, textos escolares con sus correspondientes guías del profesor, hojas de trabajo para estudiantes (que ella misma diseña o adapta), y presentaciones de diapositivas (que incluyen imágenes, hipervínculos a sitios web o a videos).

Sonia, en la primera clase que observamos, propuso a sus estudiantes algunas actividades de estimación de longitudes mediante comparaciones de líneas con igual longitud (aunque de distinta forma); posteriormente, introdujo el uso de uso de la cinta métrica pidiendo a los niños que agregaran marcas en una tira de papel. En la siguiente clase, Sonia decidió introducir algunas ideas del sistema métrico decimal, para lo cual decidió usar un recurso digital –un *applet* en GeoGebra (https://www.geogebra.org/m/qYHjHDAf)– para que los estudiantes observaran la medición de longitudes usando una regla graduada virtual. En una de las sesiones de planeación de Sonia de sus clases, observamos cómo esta maestra realizó una búsqueda extensa en un repositorio de recursos de GeoGebra, encontrando finalmente ese *applet*. Para profundizar en la manera en que Sonia seleccionó ese recurso, utilizamos nuestra técnica de introspección.

Para la elaboración de su "ruta-recorrida", le propusimos a Sonia representar su proceso de selección de ese *applet*. Le proporcionamos a Sonia el video de la sesión en la cual ella buscó el recurso por Internet, lo seleccionó y lo adaptó para su clase.

En su mapa de su ruta-recorrida es notorio el interés de Sonia por organizar sus acciones en bloques de actividades consecutivas, tomando en cuenta: las orientaciones curriculares, qué ha hecho en clases pasadas (registrado en su bitácora de clases, que ella llama "parcelador"), y los libros de texto. Para Sonia es importante ubicar su selección dando seguimiento a sus clases previas y tomando en cuenta hacia dónde quiere avanzar con sus estudiantes. Más aún, ella considera que el uso de recursos digitales puede servir para atender las dificultades de estudiantes con bajo desempeño escolar.

La situación de selección de Sonia se caracterizó por su búsqueda de un recurso digital que complementara un trabajo que ya venía realizando en clase y que se articulara con la hoja de trabajo para los estudiantes, ya prevista. De allí que sus anticipaciones se relacionaran con el repositorio en el cual buscó el recurso, en términos de la calidad ergonómica (el diseño del recurso) y didáctica (la situación que el recurso le propone a los estudiantes).

Las invariantes operatorias) que inferimos como parte del esquema de Sonia para seleccionar recursos digitales para su clase, se centran en el papel de la estimación, de la equivalencia, el concepto de unidad de medida, y el uso de geometría dinámica. Dichas invariantes muestran su interés por focalizar su enseñanza en aspectos que ella considera centrales y que van más allá de aprender fórmulas. Por ejemplo, Sonia tomaba en cuenta criterios de orden didáctico-matemático cuando señalaba: *"De nada sirve que los niños se aprendan las tablas de equivalencia del sistema métrico si eso no tiene sentido para ellos. […] Usando el* applet*, los niños pueden estimar, medir, mover, hacer cosas diferentes, pero en una actividad controlada que no sea mover 'por mover puntos', sino que sea guiada y que les quede claro que están estudiando."*

Pedro y su proceso de selección de recursos para diseñar en la clase de geometría

Pedro es normalista, licenciado en matemáticas con énfasis en computación, y experiencia docente de 9 años (en primaria y secundaria); los últimos 4 años ha trabajado como profesor de matemáticas (en la escuela participante en el estudio) en grados cuarto y quinto. A este profesor le hicimos seguimiento durante 2-3 meses cada año, en dos años escolares.

Para que sus estudiantes de quinto grado aprendieran sobre las magnitudes, su medida y medición, Pedro propuso a los niños un proyecto donde diseñaran y construyeran una casa; de esa manera, tenían que realizar mediciones y trabajar en colaboración. El proyecto involucró trabajo con papel, lápiz, reglas y compás y el uso de un recurso digital: Sweet Home 3D (http://www.sweethome3d.com/) el cual incluye herramientas diversas para el diseño de una casa (e.g., herramientas para hacer bocetos, para medir, para modificar lo construido, etc.).

En una de las clases observadas, la tarea era que los alumnos reprodujeran y modificaran la escala de un plano de una casa que habían trazado previamente en sus cuadernos, y construyeran un primer boceto de su diseño usando el recurso digital. Las principales ideas matemáticas involucradas en esta actividad eran el cambio de escala y la medición de longitudes (de las paredes y otras partes de la casa).

El mapa de la ruta-recorrida por Pedro para seleccionar su recurso digital, tuvo varias versiones a lo largo del tiempo. En la última versión de su mapa hay varios elementos a tener en cuenta y que Pedro enfatizó al explicar su ruta: Pedro resalta, en primer lugar, la necesidad de contar con criterios didácticos y matemáticos claros a la hora de escoger un recurso para la clase. Consideramos a esos criterios de selección como invariantes operatorias del esquema de Pedro. Pedro escoge el recurso dependiendo de si puede adaptarse a sus objetivos: en este caso considerando la disponibilidad de herramientas para el diseño y la medición, y luego definiendo otros criterios (e.g. de orden ergonómico: de libre acceso, "agradable", "motivante"). También pone su énfasis en el trabajo colaborativo. Por ejemplo, Pedro tomó en cuenta criterios de orden didáctico-matemático y ergonómico cuando señaló: "*Busco una herramienta que sea útil para muchas cosas, porque estamos trabajando en un proyecto de varias semanas. […] La idea es que, al trabajar con Sweet Home, los niños pueden ver qué cosas se pueden medir y qué cosas no se pueden explorar, y que prueben diferentes [herramientas].*"

Los criterios de selección de Sonia y Pedro

Sonia se ubica en una situación de selección "local", dado que escoge recursos específicos para una clase particular; mientras que la situación de selección de Pedro es "global", en el sentido de que escoge un recurso para promover un proyecto que involucra muchas sesiones de clase. Los principales criterios de selección de recursos de Sonia, fueron de orden didáctico-cognitivo: la visualización, la aplicación de las equivalencias y la interacción estudiantes-recursos. Sus criterios de selección fueron bastante específicos respecto a la demanda cognitiva del recurso y del currículo. En el caso de Pedro, sus criterios se centran en diseñar varios tipos de tareas para sus estudiantes, tener muchas posibilidades para tareas matemáticas y exploraciones, y permitir el trabajo colaborativo de sus estudiantes; de hecho, poder utilizar el recurso de múltiples maneras, era uno de los principales criterios de selección de Pedro para el recurso.

Conclusiones

Así pues, en este trabajo buscamos inferir los conocimientos y esquemas de los profesores participantes, específicamente sus criterios, que orientan su trabajo documental y su proceso de selección de recursos. Para esto, el uso de nuestra técnica de introspección permitió recabar datos del trabajo documental de cada profesor y analizarlos de acuerdo el contexto de cada profesor. En particular, nuestro intento por inferir y categorizar los conocimientos profesionales de los profesores nos permitió reconocer la variedad de conocimientos involucrados, en particular las invariantes operatorias de los esquemas de cada profesor, identificadas como criterios de selección. Los criterios de selección de los dos profesores presentados aquí, fueron categorizados en tres tipos: (i) Criterios de orden didáctico-matemático (los cuales corresponden al uso didáctico del recurso y el tipo de tareas matemáticas que se pueden desarrollar a través de él). (ii) Criterios de orden cognitivo-curricular (los cuales se refieren a la demanda cognitiva del recurso y las orientaciones curriculares que el profesor tiene en cuenta para su selección). (iii) Criterios de orden ergonómico: los cuales contemplan aspectos técnicos y de funcionamiento del recurso.

CRITERIA OF DIGITAL RESOURCE SELECTION FOR THE TEACHING OF GEOMETRY IN PRIMARY SCHOOL

Marisol Santacruz-Rodríguez

Ana Isabel Sacristán
Cinvestav
asacrist@cinvestav.mx

The selection of resources for teaching is often a challenging task in teacher's practice. Determining what resources to use, requires professional knowledge that guides the teacher's action. It is in that sense that we present here some results from a study based on the Documentational Approach to Didactics, which focuses on analyzing primary-school teachers' documentation work when selecting digital resources for their teaching of geometry in fifth-grade. In order to infer the schemes that guided their selection of resources, we carried out a reflective investigation and used, as well, an introspective technique. Through the analysis of the data, we were able to identify certain operational invariants in each teacher's resource selection process, which we classified in "selection criteria". We illustrate the above, through the analysis of data from two teachers.

Keywords: Instructional Activities and Practices, Technology.

Introduction

The selection of resources is a fundamental part of a teacher's documentation work (Gueudet & Trouche, 2009), involving professional knowledge through which teachers identify resources and use them in class. In this paper, we present results derived from a project that sought to analyze the selection of digital resources for the teaching of geometry by primary-school teachers in Colombia. That project used, as a theoretical and methodological framework, the Documentational Approach to Didactics proposed by Gueudet and Trouche (2009, 2012).

We studied, in that project, the work of five primary-school teachers in their geometry classes. In Santacruz and Sacristán (2016) we had already reported data from a first research phase, presenting the selection paths and orchestration of digital resources that two of the participating teachers followed. We now present data from a second phase of the study, analyzing the cases of two fifth-grade teachers, and infer and categorize their professional knowledge that guided their resource selection processes into "selection criteria" (considered as operational invariants in Vergnaud's, 1998, terms).

Theoretical Framework

The Documentational Approach to Didactics or DAD (Gueudet & Trouche, 2009, 2012), consists of a theoretical and methodological approach that deals with the study of the documentation work of teachers. The documentation work is the set of activities that the teacher performs in interaction with resources; it includes activities such as the selection, design, adaptation, and use of resources, as well as the collaborative work of the teacher with colleagues, and his/her reflections on his/her work.

One of the central ideas of ADD is the concept of resource and its uses. Adler (2000) explains that a resource is everything that gives meaning to the teacher's work; she considers that the resources can be: material, human and cultural. Another key concept in ADD is that of a document (which is why we talk of documentation work), which is not something that is provided to the teacher, but that the teacher constructs through a process of documentational genesis; that is, a document is constructed over time from available resources through an extensive and continuous process. Gueudet and Trouche (2009) consider that a document is constituted by one or more resources, together with their respective usage schemes.

The schemes of resource use correspond to cognitive structures of the teacher that guide the use he makes of them (Gueudet & Trouche, 2009). Vergnaud (1998, cited by Gueudet & Trouche, 2009) points out that the schemes depend on the situation, the intention and mathematical competences of the subject and, therefore, are not predefined. The components of the schemes are: goals and sub-goals; anticipations; rules of action, operational invariants (that correspond to the knowledge contained in the scheme and are of two types: concept-in-act and theorem-in-act) and possibilities of inference (Vergnaud, 1998). In our study, we inferred the above components through the use of an introspective technique described below.

Methodology

As mentioned above, in our study we analyzed the selection of resources of five elementary teachers in Colombia. For their participation in our study, we took into account: their voluntary participation, their interest in the teaching of geometry and their use, in their teaching practice, of digital resources.

Our study was based on the reflective investigation proposed by Gueudet and Trouche (2012), through which, in order to study teachers' documentation work, they are encouraged, in interviews, to carry out a retrospective reflection of their practice. In our study we began by observing and analyzing, the participating teachers' class planning, their class logs, and their classes (*in situ*). Subsequently, in interviews with each teacher, an "introspective technique" was applied (see below), to promote their reflection and the elaboration of representations of their paths of selection of resources for their classes. The data collected was analyzed to infer the components of the schemes (in Vergnaud's terms, 1998) that guided the selection of resources by each teacher, mainly the operational invariants or selection criteria.

The Introspective Technique

This technique integrates aspects of Gueudet and Trouche's (2012) reflective investigation and of Vollstedt's (2015) introspective research. It consists of a "stimulated recall" (Calderhead, 1981) in order to evoke teachers' professional knowledge. This technique is designed for the teacher to evoke (*a posteriori*) his/her thoughts and actions at a specific time or in a specific activity; we use it to investigate the route or path followed by the teacher in his selection of resources. The technique was applied during interviews where each teacher was presented with information from their practice (extracts of videos, photos, class planning, etc. –usually a week later), and asked to represent his/her resources selection processes, through maps or diagrams, along with verbal explanations. The data we obtained through the use of that introspective technique, was transcribed, segmented, coded and categorized, in order to infer the schemes particularly the operational invariants (the selection criteria).

Case Studies of Two Teachers: Sonia and Pedro

Sonia and Her Selection of Resources, Based on the Needs of Her Students

We analyze here the types of resources that Sonia selected and that she proposed to her students for her class on a specific topic: the estimation and measurement of lengths. Sonia is a primary-school teacher, with a bachelor's degree in mathematics teaching, with eleven years of experience; she works in a public school with a low-income student population.

We identified that Sonia has been gathering a collection of resources for teaching that includes: curricular resources, textbooks with corresponding teacher's guides, worksheets for students (which she designs or adapts), and slide presentations (including images, and hyperlinks to websites or videos).

In the first class that we observed, Sonia proposed length estimation activities to her students for comparing lines of equal length (but of different shapes); subsequently, she introduced the use of the measuring tape, asking her students to add marks on a strip of paper. In the next class, Sonia introduced some concepts related to the metric system, for which she opted to use a digital resource –a GeoGebra applet (https://www.geogebra.org/m/qYHjHDAf)– for the students to observe the measurement of lengths using a virtual graduated ruler. In one of Sonia's planning sessions of her classes, we observed how this teacher carried out an extensive search in a GeoGebra repository, finally finding that applet. To deepen our understanding of the way in which Sonia selected this resource, we used our introspective technique.

For determining the selection path followed by Sonia, we proposed to her that she write or draw a representation (a map) of her selection process for that applet. For that, we provided her with a video of her planning session in which she searched for the resource online, selected it and adapted it for her class.

In her selection process map, we observed Sonia's interest in organizing her actions in blocks of consecutive activities, taking into account: the curricular guidelines, what she has done in past classes (registered in her class log), and textbooks. For Sonia it is important to follow up on her previous classes and to take into account where she wants to go with her students, in order to make her resource selection. Furthermore, she considers that the use of digital resources can help students with low school performance.

Sonia's selection situation was characterized by her search for a digital resource that would complement a work she had already done in class and that was articulated with the worksheet for students, already planned. Hence, his anticipations were related to the repository in which he sought the resource, in terms of ergonomic quality (the design of the resource) and didactic (the situation that the resource offers to students).

The operational invariants that we infer in Sonia's scheme for selecting digital resources for her class, center on the role of estimation, of equivalence, the concept of a measuring unit, and the use of dynamic geometry. These invariants show her interest in focusing her teaching on aspects that she considers central and that go beyond the simple learning of formulas. For example, Sonia considered didactical-mathematical criteria, when she said: "*It is useless for children to learn the equivalence tables of the metric system if that does not make sense to them. [...] Using the applet, children can estimate, measure, move [objects], do different things, but in a controlled activity that is not just the moving of 'moving points', but is guided and it is clear to them what they are studying."*

Pedro and His Process of Selection of Resources to Design in the Geometry Class

Pedro has a bachelor's degree in mathematics with an emphasis in computer science, and a nine-year teaching experience (in elementary and high school); for the past four years he has worked as an elementary mathematics teacher (at the school participating in the study) in grades four and five. We followed this teacher for 2-3 months each year, in two school years.

In order for his fifth grade students to learn about magnitudes and their measurement, Pedro proposed to the children a project where they would design and build a house; in that way, students had to take measurements and work collaboratively. The project involved work with paper-and-pencil, rulers and compass and the use of a digital resource: Sweet Home 3D (http://www.sweethome3d.com/), which includes diverse tools for the design of a house (e.g., tools for sketching, for measuring, for modifying what was already built, etc.).

In one of the observed classes, the task was for the students to reproduce and modify the scale of a house's blueprint that they had previously drawn in their notebooks, and to create a first draft of their design, using the digital resource. The main mathematical ideas involved in this activity were the change of scale and the measurement of lengths (of the walls and of other parts of the house).

The map of the selection path followed by Pedro of his digital resource, had several versions throughout the time. In the latest version of his map, there are several elements to consider and that Peter emphasized when explaining his selection path: Pedro highlights, first of all, the need to have clear didactic and mathematical criteria when choosing a resource for the class. We consider these selection criteria as operational invariants of Pedro's scheme. Pedro chooses the resource depending on whether he can adapt the resource to his class-goals: in this case, he considered the resource's affordances for designing and measuring, and then defined other criteria (e.g., ergonomic criteria: a resource that is freely available, "pleasant", "motivating", etc.). He also placed emphasis on collaborative work. For example, Pedro took into account didactical-mathematical and ergonomic criteria when he said: "*I am looking for a tool that is useful for many things, because we are working on a project that lasts several weeks. [...] The idea is that, by working with Sweet Home, children can see what things can be measured and what things cannot be explored, and that they try different [Sweet Home tools]. "*

The Selection Criteria of Sonia and Pedro

We consider that Sonia’s selection was “local”, because she chose a specific resource for a particular class; while Pedro's selection was "global", in the sense that he chose a resource to promote a project that involved many class sessions. The main selection criteria of Sonia's resource were didactic-cognitive: the visualization, the application of equivalences and the student-resource interaction. These selection criteria were quite specific regarding the cognitive demand of the resource and of the curriculum. In the case of Pedro, his criteria are centered on designing various types of tasks for his students, having many possibilities for mathematical explorations, and for his students to work collaboratively; in fact, being able to use the resource in multiple ways was one of Pedro's main selection criteria for the resource.

Conclusions

In our work we sought to infer the knowledge and schemes of the participating teachers, specifically the criteria that guided their documentation work and their process of selection of resources. For this, the use of our introspective technique allowed us to collect data from the documentation work of each teacher and analyze it according to the context of each teacher. In particular, in our attempt to infer and categorize the teachers’ professional knowledge we were able to recognize the different knowledge involved, in particular the operational invariants of each teacher's schemes, identified as selection criteria. We categorized the selection criteria of the two teachers discussed in this paper, into three types: (i) Didactic-mathematical criteria (which correspond to the didactic use of the resource and the type of mathematical tasks that can be developed using it). (ii) Cognitive-curricular criteria (which refer to the cognitive demand of the resource and the curricular guidelines that the teacher takes into account for the selection). (iii) Ergonomic criteria (which includes the technical and operational affordances of the resource).

LANGUAGE AND MATHEMATICS: QUESTIONING STRATEGIES IN A DUAL LANGUAGE BILINGUAL EDUCATION CLASSROOM

Gladys Krause
William & Mary
ghkrause@wm.edu

Katherine Barko-Alva
William & Mary
kbarkoalva@wm.edu

This study presents an emerging framework of teaching moves for teaching mathematics in a DLBE classroom. Our preliminary findings indicate how the teacher in our study uses language during mathematics instruction to a) support the development of conceptual understanding, b) create opportunities for cross-linguistic connections, and c) create opportunities to support bilingual students' linguistic and mathematical understanding.

Keywords: Curriculum, Elementary School Education, Classroom Discourse, Equity and Diversity

Introduction

In this research report, we present an emerging framework of teaching moves for teaching mathematics in a DLBE classroom. We use examples from the linguistic interactions enacted by a 4th-grade teacher, Ms. Lucía, with her students during mathematics instruction. We identify salient elements throughout her mathematics instruction that provide insight into how Ms. Lucía approaches questioning strategies: 1) to elicit bilingual learners' responses during class discussion, and 2) to explore how she uses Spanish while formulating questions during mathematics instruction.

Our present work is guided by two theoretical frameworks. First, we use Moschkovich's (2015) framework of academic literacy in mathematics that suggests language learning goes beyond simply learning new vocabulary. Second, we build on Bunch's (2013) definition of pedagogical language knowledge (PLK). This particular viewpoint provides insight into how teachers should negotiate language within the context of a particular academic discipline. Supported by these frameworks, our study is guided by the following research question: how does a dual language teacher use Spanish to implement questioning strategies designed to teach problem solving strategies to (Spanish-English) bilingual learners?

We approach this question by documenting the use of Spanish and English during instruction that centers on teaching mathematics based on students' mathematical thinking. In addition, we attempt to explore the balance between language and content instruction in a DLBE classroom. Documenting the elements of this interaction is a key step in promoting the development of teaching expertise in dual language classrooms. We seek to maintain rigorous mathematics content by ensuring the development of bilingualism among students.

A Word on Terminology

The following terms will be used throughout this research report: *bilingual* students, classrooms, and teachers. By using the term *bilingual,* we refer to those teachers and students who speak English and Spanish and those who are actively engaged in learning English or Spanish as a second language (i.e., both simultaneous and sequential bilinguals). In the present work we adopt the term Dual Language Bilingual Education (DLBE) as noted in Menken's

(2017) work. We will refer to DLBE classrooms as those intentionally serving students who are learning academic content in two languages: in this particular case, Spanish and English.

Conceptual Framework

For decades, research in mathematics education has documented best practices for learning mathematics; understanding children's mathematical thinking; focusing on the process of learning mathematics, of problem solving in mathematics, and of discussing mathematical ideas as revealed through children's strategies (Carpenter, Fennema, Peterson & Carey, 1988; Boaler & Staples, 2008; Carpenter; Fennema; Franke; Levi & Empson, 2015). The exchange of ideas about problems, solution strategies, and mathematical connections closely aligns with the mathematics education reform view of what it means to do and learn mathematics (NCTM, 2014). Despite growing evidence that discussions during mathematics instruction can support students' learning, counterbalancing literature suggests that all students may not benefit in the same way from discussion-oriented instruction (Turner, Dominguez, Empson, Maldonado, 2013). Studies by Civil & Planas (2011) have shown that students who are less familiar with the language of instruction, culture, and classroom norms are often marginalized or invisible during classroom discussions. Our work presents a window into a mathematical discussion in a DLBE classroom.

Our purpose is to identify the potential benefits of discussion for linguistically and culturally diverse students. In addition, we attempt to analyze instructional moves tailored to provide ample opportunities to capitalize on students' thinking and linguistic repertoires. Recent work by mathematics educators across the country adds to the perspective of our work by incorporating culture, language, and social differences into mathematics instruction (see Aguirre, Mayfield-Ingram, & Martin, 2013; Turner & Celedón-Pattichis, 2011; Turner, Dominguez, Maldonado, & Empson, 2013; Maldonado & Krause, 2017; Maldonado, Krause, & Adams, 2018). These perspectives impact lesson development, mitigating the overemphasis on learning English (Gándara, et al., 2010), and the narrow focus within the teaching and learning of mathematics in bilingual contexts which tends to underline, for the most part, supporting bilingual students as they solve word problems and tackle standardized tests, without fully recognizing the linguistic complexity of such endeavors (see de Oliveira, 2012; Martiniello & Wolf, 2012). Our work contributes to the literature by offering an understanding of the language practices a bilingual teacher enacts in the context of teaching and learning mathematics.

Methods

This case study (Guba & Lincoln, 1981) facilitates a deep exploration and a robust description of the teacher's and students' academic language negotiation in a DLBE classroom within the context of mathematics. We conducted classroom observations during mathematics instruction in Spanish, debriefed after each observation with Ms. Lucía, and collected students' artifacts. We then analyzed Ms. Lucía's teaching practices to explore how she approached her instructional decisions.

Data and Participants

Our 4th grade DLBE classroom is located in the Tidewater region of Virginia. Libertad Elementary School (pseudonym) is currently a PK-4 elementary Title I and Title III school with approximately 300 students. Ms. Lucía's DLBE classroom has 14 students. Eight students are native English speakers, six native Spanish speakers. Both groups of students intermingle throughout the day, receiving academic instruction in all content areas 50% of the time in English and 50% in Spanish.

Analysis

Using Charmaz's (2006) Constructivist Grounded Theory we began by transcribing each debriefing session and classroom observation. We read the transcripts to gain insight into the data, and we identified words and phrases that resonated while reading the data. We then wrote memos to examine our thoughts and identified patterns in the data. We conducted an initial coding phase which involved identifying segments of the data with short phrases that represented what was happening in the segment. After discussing and deciding on more simplified codes for the segments, we moved to a focused, selective coding phase to separate, sort, and synthesize our segments. Finally, we synthesized all of this information to develop profiles that reflected teaching moves. We double-coded the data, with discussion and resolution of discrepancies

Tasks

Ms. Lucía started the class with a discussion about interpreting decimal numbers using a 10-by-10 grid (see Figure 1). The task consisted of writing the decimal represented in the figure. After the class discussion, they worked on the second problem (see Figure 2). Ms. Lucía translated the problem into Spanish from a problem found in the pacing guides for 4th grade.

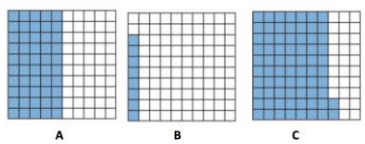

Figure 1: 10-by-10 Grids

En el primer día de clases, el profesor puso 1 centavo en un frasco. En el segundo día de clases el profesor puso 2 centavos en el frasco. En el tercer día el profesor puso 4 centavos en el frasco. Todos los días el professor puso el doble de monedas en el frasco del día anterior ¿Cuántos centavos habría en el frasco en el quinto día de clases? [On the first day of class a teacher placed 1 penny in a jar. On the second day the teacher placed 2 pennies in the jar. On the third day the teacher placed 4 pennies in the jar. Every day the teacher placed twice the number of pennies in the jar than the day before. How many pennies would be in the jar on the fifth day of classes?]

Figure 2: Word Problem Used in Problem Solving Lesson

Findings and Discussion

Through a systematic analysis of Ms. Lucía's instructional practices, and the language she used during her questioning strategies in Spanish, three themes emerged.

Incorporating Language to Increase Mathematical Conceptual Understanding

While attempting to tease out the definition of *doble* [double] when unpacking the word problem (Figure 2), Ms. Lucía utters the following question: "¿Qué es *el doble*?" [what is *double*?]. One student was quick to provide the corresponding English: 'double'. Ms. Lucía then asked the following question: "¿Me pueden dar un ejemplo?" [can you give me an example?]. Some students provided examples such as: "dos más dos" [two plus two] or "ocho es el doble de cuatro" [eight is twice four]. Ms. Lucía acknowledged students' responses and continued to unpack the problem. Ms. Lucía was asking students to provide the conceptual definition of the word 'double'. While it is clear students understand the concept of double, a specific definition was not procured.

In a DLBE classroom, teachers are tasked with teaching to increase students' access to the language and content. This teaching skill seems to be particularly developed as teachers become more comfortable discovering the nuances of language, and how it is used in academic contexts (de jong & Barko-Alva, 2015). We argue that a purposeful shift in how questions are posed in math classrooms could foster the integration of language and content instruction. For instance, Ms. Lucía could have asked, "¿Quién me puede dar el significado de la palabra *doble*?" [who can provide the meaning of the word 'double'?]. Thus, by incorporating *meaning* into the question, the teacher is creating opportunities to further explore verbs such as: to 'define', to 'identify', and to 'describe', which will likely reinforce students' skills in defining specific academic concepts.

Incorporating Language to Create Opportunities for Cross-linguistic Connections

The word "frasco" [jar] was featured in the word problem. She asked, "¿Qué es frasco?" [what is 'jar'?]. Students proceeded to provide the common English equivalent "jar." In this particular interaction, the question could have been reframed to signal number and gender. For instance, "¿Qué significa frasco?" [what does 'jar' mean?] could have created a teaching opportunity to briefly discuss that the noun "el frasco" [jar] marking its gender and number (i.e., singular and masculine). Ms. Lucía could have then identified connections between the similarities and differences in how Spanish and English signal the use number and gender.

Incorporating Language to Create Interdisciplinary Connections

As Ms. Lucía continued to unpack the problem, she asked, "¿Qué sabes?" [what do you know?]. Had she reframed this question as "¿Qué información nos da el problema?" Or "¿Qué evidencia nos da el problema?" [what information is the problem providing/what evidence is the problem giving us?], Ms. Lucía could have strategically used words such as 'information' and 'evidence' to highlight cross-disciplinary connections as well as increase student access to cognates. While working on interpreting the decimals represented in the 10-by-10 grids (Figure 1), Ms. Lucía addressed students by asking them the following question, "¿Qué es A?" [what is A?]. This question is quite open-ended (a possible answer would be 'Una letra.' [a letter (of the alphabet)]). Ms. Lucía could have followed up by specifying the intended sense of the question with more refined phrasing: A is the label of a grid, and it represents a specific decimal number. Thus, shifting the question to, "¿Cuál es el decimal representado en el diagrama A?" [what is the decimal represented in grid A?] introduces students to the verb "representar" [to represent] and to the noun "grid" [el diagrama], which are found across different academic disciplines (e.g., math, science, social studies, and language arts), thus not only increasing students' access to common academic collocations, but arguably more importantly, also modeling the importance of refining one's use of language to more closely fit the thoughts expressed. We conjecture that these categories of teaching moves can vary depending on the part of the lesson the teacher is working on. For instance, in the unpacking part of the lesson, the teacher is focusing more on making sure students understand the context of the problem, and for this reason a focus on vocabulary might be more prominent than during the part of the lesson where the teacher is sharing specific strategies for solving a problem.

Conclusions

The emergent themes highlighted in this work provide concrete examples of how Ms. Lucía could shift her language practices to promote math instruction. As illustrated here, these questioning strategies could be strategically crafted and formulated to further support dynamic language practices designed to increase students' linguistic repertoires while learning Spanish within the academic context of mathematics (Bunch, 2013). We argue that limiting the complexity of the language teachers use while asking questions during mathematics instruction does not necessarily foster an active bilingual learning environment. We encourage DLBE teachers to plan their lessons including multiple opportunities to integrate language and content instruction as bilingual learners actively negotiate mathematical and linguistic concepts.

INTRODUCING AN "OPPORTUNITIES TO IDENTIFY" FRAMEWORK

Emma C. Gargroetzi
Stanford University
egroetzi@stanford.edu

Just as the learning of mathematics requires that students have opportunities to learn, it also requires that children have opportunities to see themselves and be seen by others as mathematical doers and knowers. This paper proposes a framework for identifying teacher-introduced opportunities to identify through the examination of 1) instructional tasks, 2) participation structures and 3) storylines. The framework was developed and is illuminated through a year-long ethnographic case study of Ms. Wong's classroom, a place where students had opportunities to identify (a) as people with dignity and competence, (b) who have mathematical ideas worthy of consideration, (c) and mathematical lives worthy of exploration, and (d) whose participation is vital to their communities.

Keywords: Equity and diversity, Instructional activities and practices, Identity

Just as the learning of mathematics requires the availability of opportunities to learn (Walkowiak, Pinter, & Berry, 2017), it also requires that children have opportunities to see themselves and be seen by others as mathematical doers and knowers. Attention to mathematics identity has been named a core component of any approach to mathematics education that centers equity (Gutiérrez, 2013; Martin, 2012), of particular importance for students from minoritized groups whose recognition as mathematical knowers and creators has been historically and systematically denied (Tate, 1994; Delpit 2012). While a handful of "opportunities to learn" frameworks have begun to incorporate the importance of attending to student identities (see Gresalfi & Cobb, 2006), this work has yet to be centered in its own right as a way of examining classroom practice. This paper offers a framework for considering a construct that I name *opportunities to identify*. I propose a framework that includes examination of 1) instructional tasks, 2) participation structures and 3) storylines, as they are explicitly introduced by the classroom teacher. The paper takes a positional approach to identity, making use of an ethnographic case study of one high school classroom to illustrate how the teacher introduced student opportunities to identify as (a) people with dignity and competence, (b) who have mathematical ideas worthy of consideration and (c) mathematical lives worthy of exploration and, (d) whose participation is of value to their communities.

Identity as Positioning

The paper approaches identity as positional (Davies & Harre, 1990; Holland, 2001). Positioning theory conceptualizes identity as a process of negotiation, enactment and inhabitance of available social positions that are made available through existing structures and storylines. A positional approach to identity affords for analytical distinction between *positional resources* – the material, relational, and ideational resources which make certain identities available (Nasir & Cooks, 2009), and *acts of positioning* – the moment-to-moment interaction through which an individual's position within an existing *storyline* becomes salient (Davies & Harre, 1990). These storylines are recognized bundles of associated rights, duties, and obligations that can be invoked implicitly or explicitly through language, actions or structures. The "Opportunities to Identify" framework offered here focuses solely on positional resources introduced by the classroom teacher: instructional tasks, participation structures and explicit storylines.

From Opportunities to Learn to Opportunities to Identify

Opportunities to learn (OTL) frameworks developed over the last fifty years (McDonnell, 1995) as a way to shift measures of student learning from a narrow focus on assessment-based outcomes to a more holistic focus on classroom practice. In mathematics education, Walkowiak, Pinter and Berry (2017) offer an OTL framework focused on four classroom features: 1) the teacher's mathematical knowledge for teaching, 2) time, 3) tasks, and 4) talk. In another OTL framework that builds on Ladson-Billings's (1994) tenets of culturally relevant teaching, Gresalfi and Cobb (2006) name four crucial behaviors of teaching math for equity: 1) holding high regard for students, 2) believing that all students can succeed, 3) encouraging students to make connections between their multiple communities and identities, and 4) using instructional practices that validate and draw on students' mathematical meaning making.

Building off these two OTL frameworks, I propose a related framework for illuminating teacher-introduced *opportunities to identify* – the opportunities that students are offered for coming to see themselves as doers and knowers of mathematics, in the context of a larger community of other such doers and knowers. I propose that opportunities to identify introduced by the teacher can be traced through three classroom features: 1) instructional tasks, 2) participation structures, and 3) the storylines a teacher explicitly introduces or interrupts. While all classroom communities are co-constructed through the interaction of students and teachers, this paper focuses only on the opportunities to identify that are introduced by the teacher.

Methods: The Case of Ms. Wong's Classroom

The case of Ms. Wong's Integrated Math 1 (IM1) class comes from a year-long ethnographic study of the mathematics identity pathways available to, and negotiated by, students at one predominantly Latinx-serving California high school. Ms. Wong was selected as a focal teacher because her teaching practice was recognized as largely fulfilling the tenets of both OTL frameworks mentioned above.

Development of the "Opportunities to Identify" framework emerged from coding of field notes, lesson plans and other classroom artifacts from over 80 days (~130 hours) of classroom observation, and was elaborated and refined through analytic memos focused on the classroom practices and available student identities in Ms. Wong's classroom. The classroom was hypothesized to be a space where students were consistently offered opportunities to identify as (a) *people with dignity and competence, (b) who have mathematical ideas worthy of consideration and (c) mathematical lives worthy of exploration, and (d) whose participation is vital to their communities*.

The "Opportunities to Identify" framework was developed in conversation with existing literature in order to facilitate ongoing analysis of student uptake, notably not included here. Presented here are only a small set of illuminating examples from a much larger data set of Ms. Wong's teaching practice.

The Opportunities to Identify Introduced by Ms. Wong

Ms. Wong's practice offers an illustration of one model for how teachers introduce opportunities to identify in their classrooms. Through the instructional tasks, participation structures and storylines that she introduces, Ms. Wong offers students opportunities to identify as (a) people with dignity and competence, (b) who have mathematical ideas worthy of consideration, and (c) mathematical lives worthy of exploration, and (d) whose participation is vital to their communities. Table 1 summarizes the ways in which this occurred.

Table 1: Positional Resources and "Opportunities to Identify"

Resources	"Opportunities to Identify"
Instructional Tasks	Tasks have multiple solutions and/or solution pathways Tasks examine student contexts and experiences
Participation Structures	Students move between individual, pair, group, and whole class structures Students have time to prepare, revise and refine ideas Multiple strategies and solutions are considered publicly Students evaluate the mathematical reasonableness of shared ideas
Storylines	Participation is vital to one's own learning and the learning of others Everyone has something to teach and something to learn Smartness is not restricted to a limited few: everyone has competence

Instructional Tasks

Curriculum and pedagogical materials are common features examined through OTL frameworks (e.g. Walkowiak, Pinter, & Berry, 2017). Research suggests that open-ended tasks with multiple potential solutions or solution pathways offer more opportunities for students to construct mathematical meaning and make connections between concepts (Smith & Stein, 1989). In Ms. Wong's classroom, tasks often have multiple solution pathways and all pathways are treated as worthy of consideration, whether it be through a directive to share individual thinking with a partner, or through the solicitation of multiple representations for whole class consideration. The introduction of tasks with multiple entry points and multiple solution pathways provides all students an opportunity to identify people with mathematical ideas. Literature also suggests that opportunities to learn are supported when students can make authentic connections between classroom academic content and their lived experiences (Gresalfi & Cobb, 2006; Ladson-Billings, 1994). Ms. Wong introduced tasks that drew on student lives at various levels. In a unit on systems of equations, students predicted when the Latinx population in California will surpass the non-Latinx population of the state (Fieldnotes 5.08.18). In a statistics unit, students examined responses to two class surveys that they took on participation, one from November, the other from February, and identified trends in participation from their own classroom (Fieldnotes 2.06.19). These tasks and others offered students opportunities to identify as part of a mathematical world with lives that are worthy of mathematical exploration.

Participation Structures

Different participation structures allow for the demonstration of different forms of competence (Philips, 1972). In Ms. Wong's class, participation structures shift frequently between individual, pair, group, and whole class interaction. Students seated in groups of four were consistently given time to consider ideas individually before being asked to share those ideas with a partner or their group. Pairs and groups were then given time to share, revise and make sense of those ideas collaboratively. Groups were frequently asked to share their ideas with the class. Ms. Wong elicited multiple solutions and strategies, soliciting participation from multiple groups, and often times verbally reminded students that all contributions were valuable for mathematical consideration and refining. Students were then asked to consider the differences and connections between the responses, increasingly working toward a more robust and connected understanding of the mathematical concept.

These participation structures communicate that mathematical sense making takes time and requires multiple modes of engagement including both individual and with peers. By providing all students multiple opportunities to prepare and revise their thinking before calling on students to share, Ms. Wong communicates the expectation that everyone has something to share given sufficient time to think and prepare. While individual work provides students opportunities to identify as independent mathematical thinkers, group work and whole class conversations, both of which entail prior preparation, provide students opportunities to identify as people with mathematical ideas worthy of the consideration of others, and vital to the community.

Storylines

The storylines introduced by a teacher include the explicit messages that they provide about who is in the classroom and their rights and obligations within that space. In Ms. Wong's classroom one of the dominant storylines she introduced repeatedly was about participation. She repeatedly emphasized the importance of participation of all students as vital to the whole class's learning including through instruction such as the task described above. On one occasion, the day before a national election, she made a connection between the importance of student in-class participation and the importance of people sharing their voices in order for a democracy to function (Fieldnotes 11.05.18). Ms. Wong's storyline around the importance of the participation of all students offered students the opportunity to identify as people whose participation matters to not only their own learning but also to the learning and wellbeing of others in the community. Storylines about the exceptionality of "smartness" in mathematics are widespread and known to be damaging to all students, but especially to students from social identity groups historically excluded from mathematics (Storage, Horne, Cimpian, & Leslie, 2016). Comments about some students being "smart" came up in Ms. Wong's classroom, like in most American classrooms. Ms. Wong interrupted this storyline when it came up. On one occasion, when one referred to another student as "really smart" Ms. Wong responded firmly, asserting that everyone in the class was both learning and a person others could learn from, and that everyone is equally smart in this class (Fieldnotes 10.03.18). She also offered alternative storylines of dignity and competence. In an activity that Ms. Wong called "Math Identity Rainbows," students were asked to consider and rank their own mathematical competencies and then share how their strengths could support their group (Fieldnotes 1.07.19). Through her explicit rejection of the idea that only some people are smart, and through activities like the Math Identity Rainbows activity, Ms. Wong introduced alternative storylines around competence that offered students opportunities to identify as people with dignity and mathematical competence based on a wide variety of forms of mathematical thinking and engagement.

Discussion and Future Directions

Essential to providing students opportunities to learn mathematics are the opportunities students are provided to identify as doers and knowers of mathematics, and to be recognized by others as such. While some OTL frameworks (Gresalfi & Cobb, 2006; Walkowiak et al, 2017) have this construct buried within them, equitable approaches to mathematics must center the role identity plays in learning. The "Opportunities to Identify" framework provides a way to do so.

Ongoing analysis attends to the teacher-student co-construction of opportunities to identify, including student uptake and creative re-purposing of opportunities introduced by the teacher.

COGNITIVE INTERVIEWS TO LEARN ABOUT STUDENT STRENGTHS AND PREFERENCES RELATED TO LANGUAGE IN MATHEMATICS TASKS

Analysis of data from cognitive interviews with 43 sixth grade students who are English Learners (ELs) identified students' strengths with making meaning of mathematics tasks, specific challenges with oral language, and complexity of students' language preferences. We discuss our use of cognitive interviews, and the findings and implications for supporting teacher learning and designing mathematics instruction for ELs.

Keywords: Classroom discourse, equity and diversity, and instructional activities and practices.

Research suggests that teachers need deep understanding of the language strengths and needs of students who are English learners (ELs) *in content courses* (Bunch, 2013). Teachers, however, may be unprepared or unfamiliar with how to support ELs in their mathematics courses (Reeves, 2006; Walqui et al., 2010). Addressing students' language needs in mathematics as well as identifying the language resources that students are bringing to the classroom are critically important given the increasing language and literacy expectations across the mathematics curriculum and the attention to mathematical practices and communication (Bunch, 2012). Deepening teacher understanding of language issues relates to deepening teacher understandings of students who are ELs. Not only is it critical that teachers know their students, they must understand that how they see themselves *in relation to* their students who are ELs impacts students' positioning in class and students opportunities for equitable participation (Yoon, 2008). Teachers' understanding of ELs' cultural and social needs and their active responses to them has been shown to positively influence ELs' classroom participation and positioning (Yoon, 2008). Supporting mathematics teachers to learn more about ELs and to identify students' strengths and needs in the context of mathematics may lead to more learning opportunities for ELs.

Purposes of the Study

Our project is developing and testing an innovative instructional unit designed to support students who are ELs and focused on division of fractions, a key topic in Grade 6 that is foundational to ratio and proportional reasoning and fraction problem solving. Research shows that fraction knowledge gained and consolidated in the middle grades is predictive of high school mathematics achievement (Siegler et al., 2012). Our intervention is hypothesized to support fraction content understanding and problem-solving and communication for students who are ELs. This unit is being developed through an iterative design and research process and it will be tested to understand outcomes for students. The purpose of the cognitive interview sub-study is to investigate: How do students engage with the language in mathematical tasks and what are implications for mathematics teachers and mathematics lessons related to students who are ELs?

Theoretical Framework

Cognitive interviews provide an opportunity for students to think aloud as they work on a task and retrospectively report on what they are thinking after task completion (Branch, 2000)

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

and they have been found to be particularly helpful for learning about ELs' interactions with a task (Johnstone, Bottsford-Miller, & Thompson, 2006). Cognitive interviews are also an approach that can take into account language variation among ELs, which is "critical to ensuring appropriate inclusion of these students" during materials development (Solano-Flores & Prosser, 2010, p. 13). As part of our iterative design process, we conducted cognitive interviews to learn about the language strengths and needs of students who are ELs. These cognitive interviews respond to calls for research using cognitive interviews with ELs (Prosser & Solano-Flores, 2010) and support us to understand the experience of students who are ELs in the math classroom and to refine our materials to minimize any unnecessary linguistic complexity.

Methods and Modes of Inquiry

Cognitive interviews were conducted with 43 sixth grade students designated as ELs by their school—note that we use the phrase "students who are English learners," abbreviated as ELs, to align with ways in which schools label their students, while recognizing that this term can be problematic because it privileges the learning of English rather than language (and other) resources that students bring to the classroom. We interviewed students from six school districts across a New England state. The average percentage of students designated as ELs was 15.7% across participating schools, but all participating students were designated as ELs, and teachers provided available data on students' overall English proficiency and proficiency levels in reading, writing, speaking, and listening.

A researcher worked with each student individually or in a pair (depending on the scheduling of interviews and available researchers), with each interview lasting thirty to sixty minutes. The researcher presented the student with a fraction division task and asked the student to read it aloud. An example task is: "The teacher has 4 cups of ice cream. He would like to give each student a $\frac{1}{2}$ cup serving of ice cream. How many $\frac{1}{2}$ cup servings can the teacher give?" Next, the researcher asked: "Are there any words that you, or other students, may not understand?" Asking about words that other students might not understand allowed students to identify words that are confusing even if they do not want to admit to being confused. The researcher clarified the meaning of any unfamiliar words or phrases, then students worked on solving the task. While the student was working, the researcher asked questions, probing for student understanding of the task and seeking to learn more about a student's problem-solving approach. The interview concluded with questions about the student's language and educational background and preferences such as: "What language(s) do you speak at home?" and "Do you feel more comfortable speaking [that language] than English, a little more comfortable speaking [that language], or almost the same speaking [that language] and English?"

We first analyzed the interview data, including researcher notes and student work, by task. Analyzing all student responses for a particular task, we identified students' struggles and successes with specific words or phrases in that task. Next, we looked across all tasks to see how there were similar or different critical events, such as struggles or successes on tasks or specific challenging words, present across students' work as tasks varied (e.g., Powell, Francisco, & Maher, 2003). In this cycle of analysis, we noted questions and made hypotheses about possible explanations (Corbin & Strauss, 2007). In our analysis of students' responses to the language background and preferences questions, we made note of key ideas, such as language preferences related to context, within a student's response, and then proceeded to look across student responses for themes related to language background and preferences.

Results

Three themes emerged from qualitative analysis of the cognitive interview data.

Making Meaning of Math Tasks Despite Unfamiliar Contextual Words

Analysis of cognitive interview data suggests that students with varying levels of English proficiency could sometimes identify key information in math tasks and make sense of the tasks despite encountering unfamiliar English words related to the context. For example, four students identified "servings" (in the task about servings of ice cream) as a word that someone else may not understand, but these students did not evidence struggling with the word in the context of working on the task and they were able to get started on the task and in some cases accurately solve it. In another example, where the task included the name Maureen, some students could not pronounce the name and mentioned it as unfamiliar, but did not struggle to complete the task.

Oral Language When Reading a Task

The cognitive interview data also indicate that some students mispronounced some words, such as "syrup," when asked to read a task aloud. Many students also struggled to read the fractions in a task aloud correctly; for example, students said, "two over three" instead of "two thirds." By having students read tasks aloud, we were able to identify these oral language challenges that may limit student understanding or participation.

Language Preferences

We found that students have a complex set of language preferences depending on the context and content. Across the 43 participating students, 13 home languages were represented, and Spanish was the most reported home language. Students also ranged in the number of years spent in US public schools, English language proficiency, and home countries. Seventeen of 43 students said they feel more comfortable speaking their home language, while fourteen said they feel equally comfortable speaking their home language and English, and that they speak English at home some of the time. Only a few (n=5) said they prefer to speak English at home although their home language was not English. Yet students acknowledged that their language use is influenced by the people they interact with and the setting (e.g., home, school, etc.). Some said that while they generally feel more comfortable speaking their home language, in school settings they prefer to speak English, and they indicated three main reasons: (1) English is the language of instruction and the only language the teacher speaks; (2) they do not have the vocabulary in their home language to discuss new material; and (3) they want to improve their English.

Discussion

Our interviews were designed to identify student language challenges and support task revisions to support access for all students. The interview findings have practical implications for lessons and for teachers, and also add knowledge about the experience of students who are ELs.

Sociocultural Perspective of Language

Findings about students' fluency with making meaning of unfamiliar words is consistent with other research using a sociocultural perspective of language, where language learning in mathematics is about participation (e.g., Moschkovich, 2002). As students identified words that were names or other proper nouns, they evidenced that they had a process to identify which words were not essential to the problem-solving. Similarly, students were successful in navigating a mathematics task when words, such as "servings," were embedded in full sentences and contexts. Our analysis suggests that while some everyday words were identified as challenging, students were able to get started on the task when these words were embedded in a task structure. This is consistent with Moschkovich (2002), who encourages mathematics teaching and learning to embrace a perspective that is considerate of the variety of resources that students bring to communicate mathematically, rather than focusing more narrowly on the difference between the everyday register and the mathematical register.

Importance of Specific Language Supports

Given our findings, it is important to consider instructional approaches that support students in understanding the language and mathematics in context. Analysis of the cognitive interview data points to the need in this unit (and in other lessons) for modeling language and reading aloud to support student understanding of mathematics concepts and everyday language. Reviewing pronunciation of mathematics terms and everyday language can develop students' skills as readers, listeners, and producers of language. We added teacher instructions to our unit for supporting all students to read fractions, as this may be an area where ELs, as well as students who are low literacy, struggle. We also removed some context words—for example, changing a task about "ribbon" to be about "string"—in response to analysis of student struggles. We did not remove all potentially challenging words because students demonstrated an ability to get started even when faced with unfamiliar words. Instead, we integrated language supports for all students to access each task. We sought to draw on the language resources that students bring to the classroom by providing instructional strategies for students and teachers that provide access to the language context (e.g., around serving ice cream) while supporting students to think through the words that they need and the ones they do not. A focus on the task context and on the overarching content (in this case, fraction division), rather than the specific vocabulary, supports students in building upon the mathematical skills they already possess and in developing their mathematical understanding while they gain English proficiency.

Diversity of Students' Language, Cultural, and Educational Experiences

Our interviews highlighted the diversity of language, cultural, and educational experiences that exist within the EL student subgroup. Students had different levels of comfort speaking in English and different levels of English use at home. Some students who have a home language other than English noted that they may prefer mathematical instruction in English because they are not familiar with mathematical terms or concepts in their home language. It is critical that classroom teachers work to uncover and then to understand this diversity within the EL student subgroup in their own classrooms. Interviews to learn about student language and cultural backgrounds, two critical aspects of a student's background, may support teacher understanding and learning and will inform their assumptions about connections between language and culture. Students' language use may be both context- and content-specific.

Conclusion

The opportunity to interview students while doing a task provided rich insights into students' language use and understanding. Our methods and analysis have identified specific learnings about language use and preferences for ELs and offer insight into how teachers may continue learning about their students. Knowing about ELs' home language, language preferences, and educational background may support teachers in understanding their students and themselves, in designing their instruction, and in positioning themselves in ways that support ELs' equitable participation. Student interviews within teacher education coursework or professional development may provide opportunities to include attention to ELs' strengths, needs, and language preferences and support teacher learning.

FOSTERING STUDENT AGENCY AND DISTRIBUTED MATHEMATICAL AUTHORITY: SURFACING TEACHER LEARNING AND TEACHER CHANGE

Kathleen Pitvorec
University of Illinois at Chicago
kapitvor@uic.edu

Christopher Fry
University of Illinois at Chicago
cfry3@uic.edu

Few studies provide insights into how teaching practices shift over time as teachers become adept at engaging students in mathematical discourse. This report presents the early stages of a study that through the analysis of field notes, observations, teacher interviews, and teachers' reflections on videotapes of their lessons, looks to understand what shifts teachers make in their practices and how these shifts relate to mathematical discourse in the classroom. Our coding system for analyzing discourse captures the extent to which student ideas function at the center of the mathematical activity (student agency) and the extent to which teachers foster space for students to explore their own understanding of mathematical ideas versus ideas presented by the teacher or text (the distribution of mathematical authority). We believe this study has important implications for understanding teacher learning and teacher change.

Keywords: classroom discourse, teacher professional development, teacher learning

Since the 1980s, national reforms in mathematics teaching have called for increasingly engaging students in mathematical processes and practices (Common Core State Standards Initiative, 2010; Kilpatrick, Swafford, & Findell, 2001; NCTM, 1989, 2000). Assuming a strong link between social interaction and the construction of knowledge (Bruner, 1997) and drawing on a sociocultural framework (Cobb & Yackel, 1996), this movement towards processes and practices has been accompanied by research focused on discourse in elementary school mathematics classrooms. For example, Cobb et al. (1992) explored qualitative differences in the practices of explanation and justification. Wood, Williams, and McNeal (2006) described different interaction patterns they found in classrooms. Hufferd-Ackles, Fuson and Sherin (2004) described developmental trajectories of math talk across classroom communities. More recently, Correnti et al. (2015) went further than simply "documenting and describing" teachers' classroom discourse practices by developing an instrument that they propose might be used to help teachers improve their practices in the context of "orchestrating productive classroom discussions." Beyond cataloguing and describing types or different levels of classroom discourse, few, if any studies provide insights into how teaching practices might shift over time as teachers become more adept at and successful with engaging students in mathematical discourse. This paper presents the early stages of a study designed to investigate shifts in teaching practices and how those shifts correlate to changes in classroom discourse.

The study described here is situated in a larger study focused on providing professional development (PD) around learning trajectories (LT) and formative assessment (FA) with the goal of improving middle school algebra teaching and learning. The study included workshops for deepening content through explorations of a curriculum-based LT (Maloney, Confrey, & Nguyen, 2014). Later, teachers engaged with researchers in reflecting on videotape of their own teaching. The video sessions focused on the development of FA practices. Wiliam and Leahy (2015) recommend FA practices that promote student agency and increased attention to making student thinking visible providing teachers with opportunities to better understand what students

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

know and how they know it. The PD supported enhanced classroom discourse such that, student thinking would be surfaced, and students' ideas would become the objects of reflective discourse and collective reflection (Cobb, Boufi, McClain, & Whitenack, 1997). Specifically, this study aims to unpack how teaching practices evolve towards surfacing student thinking and making student thinking central to the mathematical activity, thus enhancing FA opportunities.

Conceptual Framework

This study follows sociocultural theorists who emphasize interactions and the social world as the location for the process of learning (Cobb, 1994; Cobb et al., 1997; Confrey, 1991; Sfard, 1998). A key premise of a sociocultural theory of learning is that interaction is a primary mediating factor for development (Vygotsky, 1978; Wertsch & Stone, 1985). Interactions among people act to develop and move understandings forward. Since dialogue or communication is at the heart of interaction, discourse and communication become key factors for making sense of development (Bakhtin, 1981).

This emphasis on social interactions intersects with recommended FA practices to activate students as resources for each other and as owners of their own learning (Wiliam & Leahy, 2015). Teachers simultaneously support students' engagement in discussions and students becoming owners of their own learning—that is, teachers foster student agency. In an effort to maximize student agency, teachers promote students' mathematical ideas to prominence in discussion as objects of collective reflection (Cobb et al., 1997). For decades, National Council of Teachers of Mathematics documents have called for distributing mathematical authority from its traditional location in textbooks to include and privilege student reasoning (Herbel-Eisenmann, 2007; NCTM, 1991).

Methods

Three sixth-grade mathematics teachers are at the center of the study in this report. One teacher had two years of experience at the beginning of the project. The other two had respectively twelve and fifteen years of experience. All three teachers worked in diverse high-needs schools in suburbs just outside of a large Midwestern city. Class sizes ranged from 18 to 32 over the two years of data collection. Forty-one lessons were videotaped. At least one project researcher observed each of these lessons and took field notes.

In addition to welcoming researchers to observe lessons, each of the three teachers participated in videotaped reflections before and after lessons as well as at least two retrospective video reflections—that is, they watched video of themselves teaching lessons reflecting and commenting on differences they noticed. Based on teachers' reflections as well as researchers notes, we generated a narrative for each teacher about the kinds of instructional changes that took place over the course of two years.

Because whole-class discussions were more consistently accessible in the video than small-group discussions, we selected ten whole-class discussions to analyze. We segmented the selected five- to twenty-minute discussions into turns. We took a grounded theory approach (Strauss & Corbin, 1990) to developing codes aimed at capturing who was doing the intellectual work as well as who was talking to whom (that is, was the student talking to the teacher or to other students). A significant foundation for our early process involved surveying existing mathematics discourse coding systems (e.g., Alexander, 2017; Chi & Wylie, 2014; Correnti et al., 2015; Hennessy et al., 2016; Elizabeth A van Es, Tunney, Goldsmith, & Seago, 2014; Wei, Murphy, & Firetto, 2018; Wood et al., 2006). When possible, we drew on language others used to describe turns. Twenty-two student codes and thirty-three teacher codes emerged from the iterative process of coding. We realized that the discourse nuances captured by our 55 codes were overwhelming for trying to discern patterns in the discourse.

After coding the ten whole-class discussions, we aggregated the codes with respect to where there might be shifts in the discourse activity. We ultimately arrived at a set of six course-grained codes for students and six course-grained codes for teachers. Within the teacher codes we identified shifts from (T1, T2) teachers doing all of the intellectual heavy lifting to (T3, T4) teachers supporting students in limited engagement with the mathematics, and ultimately to (T5, T6) teachers becoming facilitators with student thinking as central to the mathematical activity. On the student side, we identified shifts from (S1, S2) students simply listening to the teacher and responding to the teacher's prompts to (S3, S4) students listening to and responding to each other's mathematical ideas, and finally to (S5, S6) students thinking and problem solving together in the context of a discussion. We conceptualize these course-grained codes as falling on continua. The continuum on the teacher side (see Table 1) captures the degree to which mathematical authority is distributed during discussions—that is, the extent to which teachers make space for students to explore their own understanding of mathematical ideas versus exploring the way the teacher or the textbook present content. The continuum on the student side captures student agency during discussions (see Table 2)—that is, the extent to which student ideas are at the center of the mathematical activity.

Table 1: Continuum of Distribution of Mathematical Authority

Code	Mathematical Reasoning	Interaction Diagram	Examples of Features of interactions
T1	T does intellectual work	T→S	T provides instructions. No S engagement.
T2	T does intellectual work	T→S	Invites S to respond to T prompts.
T3	T does intellectual work	T→S	Setting the stage for S-to-S engagement.
T4	T and S do the mathematical reasoning	T→S	T invites and engages with S contributions
T5	T and S do the mathematical reasoning	T→S↔S	T facilitates in-the-moment S interactions around listening and dialogue.
T6	Ss do the mathematical reasoning (T facilitate S-to-S engagement)	T↓ S⇔S	T facilitates Ss reasoning about and solving problems together.

Table 2: Continuum of Student Agency as Related to Reasoning about Mathematics

Code	Mathematical Reasoning	Interaction Diagram	Examples of Features of Interaction
S1	Reasoning not relevant	S→T	Student is speaking to teacher
S2	Individual reasoning	S→T	Student is speaking to teacher
S3	Individual reasoning	S→(T) S	Share own individual ideas/ explanations with classmates.
S4	Individuals reason and respond to others.	S↔(T) S	Active listening & responding to classmates' ideas
S5	Individuals reason and connect with others.	S↔S	Students engage others in conversations about mathematical ideas.

S6	Students reason together.	S⇔S	Students construct/generate new ideas/ knowledge together.

The interaction diagrams in the tables indicate the directionality of the interaction as well as the speaker (left) and intended audience (right). The diagrammatic configuration in T5 indicates that the teacher presence serves to facilitate student-to-student talk. In T6, the teacher's presence serves to facilitate a productive level of mathematical reasoning in student-to-student talk already in progress. The configuration in S3 indicates that a teacher may facilitate one student talking to another. Although the teacher may be involved in S4, students are talking to each other. Wider arrows in T6 and S6 indicate that students are engaged in knowledge building.

Results

We are still at the first stages of correlating shifts in instructional practices with discourse patterns. We have noted, for example, that there is little to no student-to-student discourse in early videos for any of the three teachers' whole class discussions. Both teacher and student codes are low on our continua. Prompted by professional development experiences, teachers begin to engage in new instructional practices aimed at making student thinking more central and to distribute the mathematical authority. For example, all three teachers institute the five practices for orchestrating discussions (Stein, Engle, Smith, & Hughes, 2008). In their reflections, the teachers comment that the new instructional practices do not seem to result in increased agency. Students are still responding mostly to teacher prompts and not to each other. The discourse analysis aligns with this assessment in that the discourse is almost entirely constituted of lower codes for both teachers and students.

By Year 3 of the study, the researchers and teachers reflected on teachers' own videotaped lessons to unpack possible reasons why implementing new instructional techniques such as the five practices did not seem to provide improved conditions for student-to-student talk. In these early reflective sessions, teachers noticed that during small group exploration time, they (the teachers) were "supporting" students in successfully completing assignments. This support took the form of teachers "stepping in" to small groups to, for example, ask students funneling questions intended to lead students towards solving problems, question students about their strategies, or simply validate student answers. In response to noticing this, teachers intentionally started "stepping out" of small groups and aiming to turn the intellectual work over to the students. New discourse patterns during whole-group discussions accompanied the emergence of the teacher's intentional "stepping out" of small-group discussions. We see the teacher codes build up and the student codes follow. When the teaching codes are low in this context, they are often in service of supporting higher agency for students (for example, interjecting a content question to get them back on track or to remind them of norms for engagement). In addition, teachers exit and enter the discourse as needed. There are places where teacher codes disappear entirely as student thinking becomes the object for further mathematical activity and as student agency increases.

Discussion

Although this is a small case study of three teachers, we believe that it may have significant implications for teacher learning and teacher change. As others have reported, videotape of teaching can be a powerful tool for professional growth (Borko, Jacobs, Eiteljorg, & Pittman, 2008; Geiger, Muir, & Lamb, 2016; Jacobs & Philipp, 2004; Sherin, 2000; Sherin & Han, 2004;

Sherin & Van Es, 2009; Elizabeth A. van Es & Sherin, 2002), but there is scant research involving teachers reflecting on their own classroom video with a focus on how shifts in instructional practices might correlate with changing discourse patterns. We believe the two-part discourse coding system we have developed (for teachers and students) informs our understanding as we study how shifts in practice aimed at distributing mathematical authority and increasing student agency work in concert to provide students with opportunities to own their own learning and to engage with their own and each other's ideas.

STUDENT-TO-STUDENT RESPONSIVENESS IN MIDDLE-GRADES CLASSROOMS

Hamilton L. Hardison

NCTM's Principles to Actions called for teachers to develop environments that support students' engagement with each other and teachers. In this report, we consider how often students discursively engaged with the mathematical thinking of their peers (i.e., student-to-student responsiveness) in whole-class settings across 11 middle-grades classrooms. We consider the prevalence and variability of two types of student-to-student responsiveness: responses requested by the teacher and responses offered spontaneously. Although student-to-student responsiveness was not uncommon, we noted considerable variability in prevalence across classrooms.

Keywords: Classroom Discourse, Responsiveness

Responsiveness to students' mathematical thinking is the extent to which students' mathematical ideas are present, attended to, and used to drive mathematics instruction (Bishop, Hardison, & Przybyla-Kuchek, 2016; in press). Extant literature focusing on how student ideas are taken-up and used in mathematics classrooms has primarily emphasized how *teachers* might respond to student thinking. For example, Leatham, Peterson, Stockero, and Van Zoest (2015) explicated criteria teachers might use to determine when to pursue a particular student idea. Other researchers have outlined various kinds of talk moves teachers can enact to publicize, support, or extend student thinking (e.g., Chapin, O'Connor, & Anderson, 2013; Jacobs & Empson, 2016). We agree teachers' intentions, choices, and actions are important components of characterizing responsiveness to students' mathematical thinking; however, we also recognize that students can (and do) respond to peers' mathematical ideas in classroom discussions. Moreover, NCTM (2014) has recommended for teachers to develop "environments in which students feel secure and confident in *engaging with one another* and with teachers" (p. 115, emphasis added). Yet, there is little empirical research characterizing how students respond to one another in whole-class discussions (see Hufferd-Ackles, Fuson, & Sherin, 2014 for an exception). In this report, we shift our focus from teacher-to-student responsiveness to consider the prevalence of student-to-student responsiveness—instances in which students respond to the mathematical thinking of their peers—in whole-class discussions. The research questions guiding this study were: (a) how prevalent is student-to-student responsiveness during whole-class mathematics discussions in middle-grades classrooms? (b) how often is student-to-student responsiveness spontaneously enacted by students versus prompted by classroom teachers? and (c) how does student-to-student responsiveness vary across classrooms?

Methods

We report on data from a larger study investigating characteristics of mathematics classroom discourse in grades 5–7. Participants included teachers and students in 11 classrooms across 4 U.S. states. Participating teachers were recruited due to reputations for using discussion in their mathematics lessons. All teachers had at least 6 years of teaching experience. In each classroom, we videorecorded and transcribed four lessons from the first curricular unit on fractions (44 total lessons); we chose fractions because it is a foundational middle grades topic. Lesson transcripts and videorecordings were partitioned into segments, which we define as a series of turns of talk with a common focus (e.g., activity or strategy) and a consistent form of participation format (e.g., whole class, small group). In this report, we present an analysis of only those segments that were in whole-class participation format and also contained mathematical talk; we prioritized whole-class format since all individuals were potential discursive participants. These segments were analyzed using the Mathematically Responsive Interactions Framework described below.

Conceptual Framework

Previously (Bishop, Przybyla-Kuchek, & Hardison, 2017; 2019), we developed a framework for characterizing mathematically responsive interactions (Figure 1). The core of the framework comprises two components that holistically describe in-the-moment interactions between teachers and students: (a) students' mathematical contributions and (b) the moves teachers enact in response to these contributions. Additionally, we developed adjunct components to capture the presence of student-to-student responsiveness, as well as beyond-the-moment responsiveness—instances when student ideas originally expressed in previous lessons or segments are revisited. In this report, we limit our focus to instances in which a student mathematical idea was expressed and attended to by a peer within the same segment (i.e., in-the-moment student-to-student responsiveness; see bolded components in Figure 1).

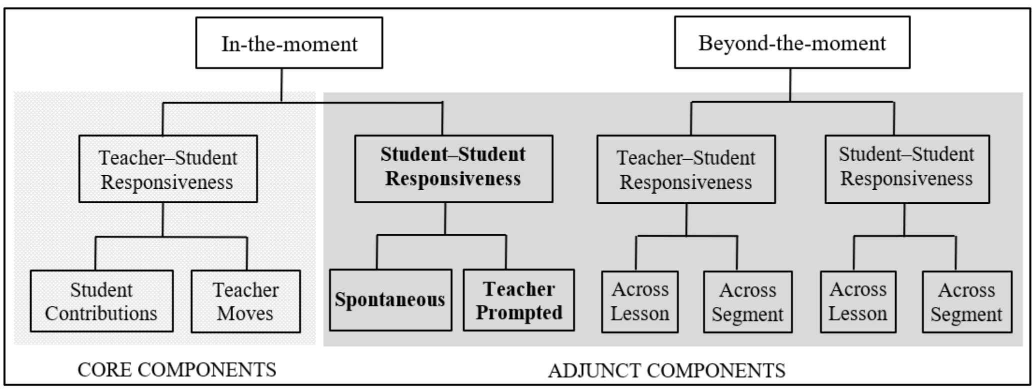

Figure 1: The Mathematically Responsive Interactions Framework

Two kinds of student-to-student responsiveness. To illustrate a distinction in ways students might respond in-the-moment to one another whole-class discussion, consider a portion of a segment from Teacher EK's 5th grade classroom. Prior to the excerpt, Teacher EK asked students to consider whether the equation $3 \div 4 = \frac{3}{4}$ is true or false and to provide a justification. After students considered the equation independently, Teacher EK asked several students to share their reasoning in whole-class discussion including Adam, who had developed two different strategies: one symbolic (represented by equations and discussed below) and one pictorial (partitioning 4 circles into fourths and shading one portion in each circle). In the transcript below, Adam begins by explaining his symbolic strategy. While reading the transcript, consider the ways in which students respond to one another's ideas.

Tchr EK: All right, tell us what you got.

Adam: Um, I think it's true because…I just divided three up into ones and so that I had three ones. And then, I divided each one by, then I divided it by four, one by four equals one

fourth. And then I timesed it by three again. So I pretty much three divided by three then equals one, divided by four, one fourth times three, and then that equals three fourths.
Tchr EK: Very nice, very nice. Can anyone kind of, uh, restate what Adam did in your own words? What did he do? Anyone want to take a chance and kind of tell us what Adam did up there? Rylan?
Rylan: Um, he made it kind of like easier by divided the three into its own, like own little fractions, and he thought it would be easier so he, he drew it first, then he showed how he got the answer.
Adam: Actually, that's actually another way I did it. I did, so I divided each, uh, I wrote down one circle, then I divided each circle into fourths, and then I got three fourths from that too.
Tchr EK: All right. Let's give Adam a round of applause, nice job. Thank you, Adam.

In this excerpt, we noticed two clear instances of student-to-student responsiveness, namely Rylan's and Adam's last turns of talk. Adam's initial explanation of his symbolic strategy in the excerpt above can be summarized as $3 \div 4 = (1 + 1 + 1) \div 4 = 3 \times (1 \div 4) = 3 \times \frac{1}{4} = \frac{3}{4}$. After his explanation, teacher EK invites other students to restate Adam's strategy, and Rylan responds by interpreting Adam's pictorial strategy, which was also visible. Because Rylan's interpretation of Adam's ideas was preceded by Teacher EK's invitation, we characterize Rylan's response to Adam's thinking as an instance of *teacher prompted student-to-student responsiveness*. Without prompting from Teacher EK, Adam responds to Rylan, "Actually, that's actually another way I did it," implicitly rejecting her interpretation of his thinking. Because Adam responded to Rylan's contribution without an invitation from Teacher EK, we characterize this as an instance of *spontaneous student-to-student responsiveness*.

Segment Coding

Across all 11 classrooms, we analyzed 615 whole-class mathematical segments. We coded for the presence of each type (i.e., spontaneous or teacher prompted) of student-to-student responsiveness at the segment level. For example, the segment from Teacher EK's classroom above was coded as containing both teacher prompted and spontaneous student-to-student responsiveness. The presence of a teacher's request for students to engage with a peer's mathematical contribution was necessary but not sufficient to code a segment as containing teacher prompted student-to-student responsiveness; in addition, one or more students actually had to respond to a peer's mathematical contribution to receive the teacher prompted code. Finally, we emphasize that our coding for each type of student-to-student responsiveness was binary at the segment level; therefore, we did not count instances of student-to-student responsiveness within the same segment. Because the number of whole-class mathematical segments per classroom varied, we report the percent of segments per classroom containing different types of student-to-student responsiveness in our results to compare across classrooms.

Results

Looking across all 615 whole-class mathematical segments, we found 35.6% (219 segments) contained some form of in-the-moment student-to-student responsiveness (see last row of Table 1). At large, teacher prompted student-to-student responsiveness was more prevalent than spontaneous student-to-student responsiveness, with these codes occurring in 30.9% and 16.4% of segments, respectively. The co-occurrence of teacher prompted and spontaneous student-to-student responsiveness within the same segment (e.g., Excerpt 1) was common; of the 101 segments containing spontaneous student-to-student responsiveness, 72 also contained teacher prompted student-to-student responsiveness.

Each classroom contained segments in which students responded to peers' mathematical ideas. Across classrooms, the percentage of segments containing student-to-student responsiveness per classroom ranged from 8.9% to 75.4% (Table 1). All classrooms contained instances of teacher prompted student-to-student responsiveness, which ranged from 6.1% to 59.6%. In all but one classroom (SY), the percent of teacher prompted student-to-student responsiveness exceeded the spontaneous counterpart, and, in general, higher percentages of teacher prompted student-to-student responsiveness were associated with higher levels of the spontaneous counterpart ($r^2 = .68$). In 7 of the 11 classrooms, spontaneous student-to-student responsiveness was found in less than 10% of segments. The remaining four classrooms (SY, LE, MA, and AE) accounted for 83% of all 101 segments containing instances of spontaneous student-to-student responsiveness with percentages ranging from 16.1% to 63.2%.

Table 1: Percentage (Frequency) of Segments with S2S Responsiveness by Classroom

Classroom	# of Segments	Either S2S	T Prompt	Spontaneous
SY	57	75.4% (43)	59.6% (34)	63.2% (36)
LE	44	65.9% (29)	59.1% (26)	38.6% (17)
MA	56	50.0% (28)	44.6% (25)	16.1% (9)
AE	75	49.3% (37)	41.3% (31)	29.3% (22)
KM	71	33.8% (24)	31.0% (22)	9.9% (7)
TA	38	39.5% (15)	39.5% (15)	2.6% (1)
EK	44	20.5% (9)	20.5% (9)	4.5% (2)
NY	63	20.6% (13)	19.0% (12)	3.2% (2)
EY	73	16.4% (12)	12.3% (9)	4.1% (3)
SN	49	10.2% (5)	6.1% (3)	4.1% (2)
AY	45	8.9% (4)	8.9% (4)	0.0% (0)
All Classrooms	**615**	**35.6% (219)**	**30.9% (190)**	**16.4% (101)**

Discussion

The results presented in the previous section indicate that it is not uncommon for students to respond to the mathematical ideas of their peers and, in many instances, classroom teachers successfully support them to do so. We were also struck by the variation across classrooms in our study: in some classrooms, student-to-student responsiveness was relatively rare and in other classrooms it occurred in over 50% of the segments. And finally, we note that the presence of spontaneous student-to-student responsiveness may be a particularly powerful indicator of the overall responsiveness in a classroom. Further studies are needed to coordinate how other factors (e.g., classroom norms, authority, etc.) might account for variation in the prevalence of student-to-student responsiveness across classrooms and what practices best support students to spontaneously engage with the reasoning of their peers. Finer-grained analyses are needed to characterize distinctions in the nature of students' responses to their peers' mathematical thinking, as well as to account for the within-segment density of student-to-student responsiveness. Additionally, subsequent analyses are required to examine how student-to-student responsiveness relates to other factors of our framework (e.g., core components). In closing, we note that we analyzed whole-class mathematics discussions in four fractions lessons from each classroom; the prevalence of student-to-student responsiveness may have been different in these classrooms if we had examined other content areas or participation formats.

CALCULUS TUTOR INTERACTIONS AND DECISION MAKING

Carolyn Johns
The Ohio State University
Johns.125@osu.edu

While most universities offer undergraduate mathematics tutoring, currently is it unknown what occurs during these tutoring sessions or why tutors choose to enact certain practices. Relying on analysis of tutoring sessions and stimulated-recall interviews, we considered what one tutor did during tutoring sessions and factors that influence her decisions regarding how to navigate the interactions. Results indicate the tutor was inclined to ask questions but concern for students' affect may have taken precedence to attempts to further probe student thinking.

Keywords: Post-Secondary Education, Instructional Activities and Practice, Informal Education

In 2010, the Mathematical Association of America performed a survey of calculus students, instructors, and programs, as a step toward understanding the current state of college calculus (Bressoud, Mesa, & Rasmussen, 2015). Undergraduate mathematics tutoring or the presence of a learning center was cited as one of the primary features of institutions with successful calculus programs. In addition, 97% of institutions surveyed in the study offer some form of calculus tutoring with the overwhelming majority offering tutoring by undergraduate tutors. Further, attending tutoring has been shown to positively impact calculus performance as measured by final course grades (Rickard & Mills, 2018). This indicates tutoring plays an important role in undergraduate mathematics education, yet little is known about what occurs in this type of tutoring or the work that these tutors do.

What research exists on tutoring is often content independent, examining the general pedagogical practices of tutors, such as tutor questioning practices (Graesser & Person, 1994). In addition, these studies often examine the practices of 'expert' tutors, most of whom have had formal education training (Lepper & Woolverton, 2002) or teaching experience (Arcavi & Schoenfeld, 1992; Schoenfeld et al., 1992). In addition, studies on tutoring often explore tutor moves in the context of working with a student on a pre-determined topic for a fixed amount of time and number of sessions. Research has not attended to the specific context of undergraduate tutors working in a drop-in tutoring site, the most common form of calculus tutoring (Bressoud et al., 2015).

This report is a part of a larger study in which we attempt to compile and analyze descriptive case studies on tutoring practices in the specific context of drop-in undergraduate Calculus tutoring. In particular, in the larger study we seek to answer the questions: 1) What do tutors do in the course of their interactions with students? and 2) What factors influence the tutors' decisions regarding how to navigate the interactions? This current report offers an analysis of one tutor along the two research questions.

Literature Review

This work is grounded in two conceptual principles: 1) in response to others, humans make decisions based on what they assume is important, drawing from what they notice in the course of interactions (Herbst & Chazan, 2003) and 2) responses humans make in the course of interactions draw on current understandings of the event, such as its circumstances and content, and resources they have at their disposal (Schoenfeld, 2008). Schoenfeld argues teachers' in-the-moment decisions are the result of their resources, goals, and orientations. Resources include knowledge, materials, and interpersonal skills. Goals occur on multiple levels and may be academic or non-academic in nature. Finally, orientations include preferences, values, and beliefs. The data was analyzed with this framework in mind to examine the tutor's references to these factors which influence decisions. We assume tutors make rational decisions as they interact with students and organize the type of experiences they provide for those seeking help. We elaborate in detail in the following section how these points shaped the analysis of data in this study.

We also draw on literature regarding teaching practices that support student learning. In order to create a learning environment that supports students' conceptual understanding, certain social and socio-mathematical norms are accepted as critical to be negotiated by the instructor and student (Cobb, et al. 1992; Cobb & Yackel, 1996; Yackel & Cobb, 1996). Further, scholars have argued that in order to encourage the student to be an active participant and build on students' thinking, instructors need to develop eliciting skills to engage the student in the interaction and draw out the students' thinking. While the student is talking, the instructor needs to listen to the student in order to build an understanding of what the student is thinking (Teuscher, Moore, & Carlson, 2016). Instructors should not be listening for specific answer but instead engage in listening in order to negotiate meaning with the student they are working with (Davis, 1997). Tesucher et al. describe the instructor's cognitive process in listening to the student, "de-centering". In de-centering stance, the instructor builds a model, or way of explaining the student's understanding based on what the student communicates. The instructor then uses this mental model to make in-the-moment instructional decisions on how to proceed.

Methods

The larger study is being conducted using a case study approach with each case being a Calculus I tutor in their first year of tutoring. This report will focus on one these cases, Betty.

Betty is a sophomore working in the Calculus I room in a drop-in tutoring center. Betty is a mathematics major in the education track. Her intended career is as a high school teacher. She previous tutored students in high school but did not feel it impacted her current tutoring practices. When asked how her education courses have influenced her tutoring, she indicated her adolescent development class made her think about how she can be there to guide students but in the end, they need to be able to do it on their own in the future.

Students come to the tutoring room either with questions in mind or to work on their homework and ask questions as they arise. Typically, students ask for help on a specific homework task rather than for help understanding a general concept. Tutors generally help students with their particular task and then move on to the next student. A typical tutoring session may last 5-15 minutes. While tutors may have worked with a particular student in the past, it is more likely they have not worked together before.

As part of her training requirements, Betty recorded three tutoring sessions at four points during her first year of tutoring. A session was defined as an interaction with an individual student, typically on one task. At each of the four points in time, Betty had approximately two weeks to audio record her three sessions and submit the recordings and photographs of the task and written work. Betty collected one set of recordings during her first weeks as a tutor (beginning of September), one set halfway through her first semester (mid-October), at the end of her first semester (late November), and at the beginning of the subsequent semester (late

January). It was left to Betty to select the sessions she recorded and submitted. These recordings and photographs constituted the tutor session data for the study.

In addition, Betty met with the researcher twice to discuss her recorded tutoring sessions. Each meeting was conducted as a stimulated recall interview, having Betty listen to each of her tutoring sessions. At key points while listening to the session, the interviewer stopped the recording to ask Betty to explain what she thought was going on, why she did what she did, or what she was trying to do or get at. This allowed the researcher to better understand Betty's decision making and thought processes rather than making assumptions. In addition, during the interviews, the researcher asked the Betty questions regarding her beliefs about tutoring and learning.

Data Analysis

Analysis of the data occurred in waves. First, Betty's tutoring sessions from September and October were transcribed and indexed to describe the actions of each talking turn. Then these transcripts were open coded to look for patterns of behavior to begin to formulate hypotheses regarding these behaviors and possible rationales. Betty's session transcripts were then marked for passages where these behavior patterns emerged. It was at these marked points in the tutoring sessions that during the stimulated recall interviews, Betty was asked questions regarding her thoughts and behaviors. In addition, the hypotheses for factors influence Betty's behaviors were also addressed through additional interview questions.

After conducting the first interview, the interview transcript was analyzed using a grounded theory approach as we looked for themes which emerged from the data. This phase of the analysis drew on several bodies of literature. Because this was an exploratory study seeking to find baseline data on tutoring, the exact frameworks which may be useful in examining tutoring sessions were not known. Employing grounded theory techniques allowed the researcher to look for aspects of the data which come out as key features of tutoring. However, of particular note was the literature on social norms (Cobb, et al. 1992), decentering (Teuscher, Moore, & Carlson, 2016), and teacher decision making (Schoenfeld, 2011).

During analysis, social and socio-mathematical norms were inferred based on the patterns of interactions. Tutoring sessions were examined for negotiation of social norms such as justifying answers, the student writing, or pushing against the idea of the tutor as the authority on mathematics (Cobb, et al., 1992). In addition, they were examined for negation of socio-mathematical norms such as justifying with reasons why steps work rather than just procedural steps, or drawing of representations to help solve tasks (Yackel and Cobb, 1996). Further, Betty's rationale for their behaviors attempting to negotiate these norms were analyzed. To analyze the data for decentering, Bas Ader and Carlson's (2018) levels of decentering framework was employed. Bas Ader and Carlson's levels of decentering framework provides observable instructor behaviors as indicators they are working at a particular level of decentering.

In light of the analysis of the first interview, an initial model accounting for Betty's thinking and factors influencing her work was constructed. Betty's tutor sessions from November and January were then analyzed and again marked for stimulated recall interview questions. In particular, these sessions and the second interview were examined for data which confirmed or contradicted the existing theory.

Results and Discussion

Betty's first round of recordings from September dealt with analytical limit tasks, and in particular, with each of the three students, at least one task involved an absolute value expression. Overall, Betty's interactions with the students in these sessions can be characterized setting up a solution path she wanted the student to follow. She frequently asked questions to elicit specific information and listened for what she wanted to hear (Davis, 1997). Throughout these sessions, Betty was often at a decentering (Bas Ader and Carlson, 2018) level one or two as she was asking questions to elicit the student thinking but did not attempt to further understand what the students shared or build on their thinking. When the student did not give Betty the answer she desired, she often attempted to redirect them to her planned path. She frequently referred to wanting to "establish" information, assuring that she and the student were on the same page. She assessed the success of the interaction based upon whether the student followed her set path. In addition, Betty rarely asked students to justify her answers or explain why certain procedures worked. What was unique about Betty was her attention to student affect and the ways in which it both constrained and enhanced her tutoring. Although at times she attributed differences in the way she worked with students to the student, she also attributed differences to herself, such as wording her question poorly. When discussing her beliefs surrounding tutoring, learning, and her role as a tutor, one does see alignment between her behaviors and beliefs. For example, Betty understood students need to be able to do the mathematics on their own and discussed her role as being a guide. However, she also talked about her goal being to show them what they can do on their own. This seemed to indicate Betty thought of her role as showing students and guiding them on the current problem, so that it transfers to when they do problems on their own.

Betty's second round of recordings from October showed similar tendencies. However, there were some subtle differences. On the whole, with these related rates task sessions, Betty still looked for the students to take her solution path and have her ways of thinking, however, Betty used more questions in attempt to uncover the students' thinking than in her prior sessions, decentering level two (Bas Ader and Carlson, 2018). In addition, Betty asked the students more regarding if the student understood why procedures worked, rather than immediately explaining why herself. Furthermore, in these sessions, Betty seemed to be implicitly modeling problem solving techniques. In her prior sessions, Betty often referred back to the goal of the task. However, in these related rates tasks, she also organized information by drawing pictures, labeling, and focusing on what information is given in the problem, and what it is asking. Betty described this role of helping students organize information as important for problems such as related rates and optimization.

Data from Betty's 3rd and 4th rounds of recordings, as well as data from her second interview confirmed findings from her earlier data. She continued to press her students to participate and ask for them to carry out steps. She also continued to ask primarily information gathering questions (Boaler & Brodie, 2004) but occasionally asked students if they knew why something was true. Based on these sessions, the amount of time Betty spent explaining and leading the student down her path versus allowing the student to work more independently appeared to be based on her initial impression of the student's understanding.

Results indicate Betty desired for her tutors to be active participants in her sessions. However, her goal of not wanting to harm their confidence appeared to be a primary reason why she did not inquire further into student's incorrect thinking, thus she does not address the student's unique thinking. This indicates that tutor training programs may need to address reconciling concern for student's affect when responding to incorrect responses in pedagogically sophisticated ways. Further, once tutors are asking questions of their students, additional training may be needed to encourage them to ask questions beyond information gathering questions (Boaler & Brodie, 2004). Tutors need to be trained to ask 'why' questions and follow up questions to further understand their student's thinking.

Examples play a critical role in mathematical practice. Indeed, the underlying hypothesis guiding this study is that students who are able to strategically think about and productively use examples as they engage in proving-related activities (e.g., developing conjectures, exploring conjectures) will not only gain a deeper understanding of the mathematical content, but also learn to successfully develop proofs. Yet, students typically receive very little, if any, explicit instruction on how to become more deliberate and strategic in their use of examples to support their efforts in proving and learning to prove. The study reported here explores fifty-four middle school mathematics teachers' beliefs about the role examples play in proving-related activities and the instructional practices (or lack thereof) they implement to foster the development of students' productive example use.

Keywords: Instructional Activities and Practices; Reasoning and Proof; Teacher Beliefs

Despite more than two decades of calls to elevate the status and role of proof in school mathematics, students of all ages continue to struggle learning to prove (e.g., Stylianides, Stylianides, & Weber, 2016), and teachers as well struggle to facilitate the development of students' learning to prove (e.g., Bieda, 2010; Bieda, Drwencke, & Picard, 2014; Stylianides, Stylianides, & Shilling-Traina, 2013). Researchers have suggested that students' treatment of examples and, in particular, their overreliance on examples as a means of justification, is a primary source of their difficulties in learning to prove (e.g., Zaslavsky, Nickerson, Stylianides, Kidron, & Winicki, 2012). Yet, examples-based reasoning plays both a foundational and essential role in the development, exploration, and understanding of conjectures, as well as in subsequent attempts to develop proofs of those conjectures. Moreover, we posit that instructional activities designed to help students learn to strategically think about and productively use examples in proving-related activities will facilitate the development of their learning to prove.

The Role of Examples in Proving-related Activities

Examples play a critical role in proving-related activities (e.g., Lakatos, 1976; Polya, 1954). Indeed, the time spent thinking about and analyzing examples can provide not only a deeper understanding of a conjecture, but also insight into the development of a proof. Not surprisingly, Epstein and Levy (1995) contend that "Most mathematicians spend a lot of time thinking about and analyzing particular examples," and they go on to note that "It is probably the case that most significant advances in mathematics have arisen from experimentation with examples" (p. 6). To that end, mathematics education scholars have noted a number of roles and uses of examples related to various aspects of proving (e.g., Alcock & Inglis, 2008; Buchbinder, & Zaslavsky, 2018; Ellis et al., 2012; Iannone et al., 2011; Sandefur, Mason, Stylianides, & Watson, 2013). In our recent work (see Knuth, Zaslavsky, & Ellis, 2017), we extended prior research and developed a comprehensive analytic framework for characterizing and making sense of the roles and uses of examples in the proving-related activities of middle and high school students, undergraduate students, and mathematicians. Although going into detail about the framework is beyond the scope of this paper, the framework illustrates the complexity of example use in proving-related activities and serves as the analytic lens for the study presented here.

Table 1: Example Use Framework

Category	***Sub-categories***		
Purpose of Example (to…)	*Understand what (the conjecture is saying)*	*Understand why (the conjecture is true or false)*	*Explore the truth domain of the conjecture*
	Test the truth of the conjecture	*Refute the conjecture*	*Confirm a belief*
	Convey the claim that the conjecture is true/false	*Develop a new conjecture*	*Convey a general argument*
	Illustrate a representation	*Make sense of a representation*	*Placate the interviewer*
Category	***Sub-categories***		
Criterion for choosing a particular example	*Easy (to work with)*	*First thought of*	*Different from other(s)*
	Minimal case	*Familiar or known example*	*Unusual*
	"Random"	*Boundary case*	*Typical*
Category	***Sub-categories***		
Affordances from example use activity	*Gain insight*	*Produce a justification*	*Lead to new/revised conjecture*
	Generalize	*Learn the limitations of examples*	*Discover an error*
Category	***Sub-categories***		
Strategies employed during example use activity	*Diversity of examples*	*Searching for counterexamples*	*Random feature/pattern search*
	Systematic variation of examples	*Jumping to formality*	*Trying to see the examples through a structural lens*
	Choosing a set of examples with specific properties	*Building formality from examples*	*Informal induction*

We characterize productive example use during proving-related activities as use that helps a learner make progress toward the development of a proof. In particular, we view productive example use as activity that leads to a deeper understanding of a conjecture and the underlying mathematics; leads to insight with regard to the development of a proof; leads to a an awareness of a generalization or structure by using a *generic example* (i.e., a specific example through which one can see the general case); leads to the generation of a counterexample; leads to the development of a new or revised conjecture; or leads to an appreciation for the need for proof. As might be expected, the extent that example use is productive in the proving-related activities of sophisticated learners (i.e., mathematicians) often stands in contrast to the extent that example use is productive in the proving-related activities of less sophisticated learners (i.e., students). Although some secondary students did use examples productively in their proving-related activities (Aricha-Metzer & Zaslavsky, 2017; Ozgur et al, 2017), it was a minority of students; in fact, we posit that students' lack of instructional guidance and experience with using examples productively during proving-related activities is the overarching reason that many students fail to learn from examples.

Research Objective and Questions

The objective of the study was to examine middle school mathematics teachers' views about the role of examples in proving-related activities, and the nature of their instructional practices with regard to example use during proving-related activities. The study was guided by the following research questions: (1) What is the nature of middle school teachers' thinking about and instructional practices related to example-use in proving-related activities? and (2) To what extent do middle school teachers support students with instructional guidance and experience with using examples productively during proving-related activities?

Methods

Participants

Fifty-four Texas middle school mathematics teachers participated in the study; 25 Grade 6 teachers, 22 Grade 7 teachers, and 20 Grade 8 teachers (note that some teachers taught multiple grade levels). Teaching experience was categorized into three levels: 1-3 years of experience (n = 13), 4-10 years of experience (n = 21), and 10+ years of experience (n = 20). Curricula used by the teachers was guided by the Texas Essential Knowledge and Skills (TEKS), and included a variety of curricular programs (e.g., McGraw Hill, Carnegie Learning, Go Math).

Data Collection

Teachers responded to a 26 question Qualtrics on-line survey. The survey included four background questions (e.g., years of teaching experience) and 22 questions related to their views about the role of examples in learning to prove. In particular, question focus ranged from their own instructional practice related to example use during proving-related activities to their views related to expectations for students' example use during proving-related activities. Questions included forced choice responses and open-ended responses; see Table 2 for sample questions.

Table 2: Sample Survey Questions

When developing, exploring, or justifying conjectures, students often use examples. a) To what extent are students strategic in thinking about their use of examples when developing, exploring, or justifying conjectures? *Not very strategic* *Somewhat strategic* *Very strategic* b) What purpose(s) do you think their use of examples serves? c) To what extent do you think students' use o examples when developing and exploring examples helps them learn to develop mathematical proofs? *Very little help* *Somewhat helps* *Significantly helps*
In your own instruction, how often do you explicitly talk with students about how to use or think about examples when developing, exploring, or justifying conjectures? *Rarely* *Occasionally* *Frequently* Please given examples of what you might say to students.
Given the following conjecture: If you add any number of consecutive whole numbers together, will the sum always be a multiple of however many numbers you added up?

a) How likely is it that your students would use examples when exploring this conjecture?
Unlikely *Somewhat likely* *Very likely*
b) Describe a typical student approach to exploring and justifying the conjecture.
c) Assuming your students would use examples, the choices below reflect potential criteria for why middle school students might select examples when exploring and justifying the conjecture. For each choice, select how often you think students use that criterion. [Each choice had the following options: Rarely, Occasionally, & Frequently]
   - to help them understand what the conjecture states or means
   - to check whether the conjecture is true
   - to test a variety of cases in order to see when the conjecture is true (or false)
   - to prove that the conjecture is true (e.g., examples are sufficient as proof)
   - to disprove the conjecture
   - to gain insight about why the conjecture is true
   - to help explain (to someone else) why the conjecture is true
   - to help develop a general argument that the conjecture is true

Data Analysis

Data were analyzed using the examples use framework (Table 1) and the research literature related to proving and example use. Analysis focused primarily on teachers' views about the role examples play in proving-related activities, about students' thinking about and use of examples, about curricular opportunities for engaging students in example use, and about instructional practices related to proving and example use. The analysis resulted in the identification of categories and relationships related to the aforementioned foci as well as the identification of clusters of categories and relationships about example use during proving-related activities.

Results and Discussion

We found that many teachers have limited views of what it means to use examples strategically during proving-related activities; in particular, the teachers did not tend to think students are very strategic in their example use, they tended not to provide explicit instruction designed to help students learn to strategically think about and productively use examples in proving-related activities, and when students do use examples, they thought students primarily use examples to confirm or verify the truth of conjectures. We also found that teachers demonstrated low expectations regarding generic examples, a particularly accessible form of general argument for middle school students (Leron & Zaslavsky, 2013; Zaslavsky, 2018). Specifically, teachers did not expect students to generate generic examples, to understand them, or to be convinced by them (in fact, teachers thought that students would be more convinced by several confirming examples). Excerpts and further details to be provided at the presentation.

Conclusions

Proving is a mathematical practice that is not only critically important to knowing and doing mathematics, but also notoriously difficult for teachers to teach and for students to learn. The perspective underlying this study represents a re-conceptualization of research concerning students' examples-based reasoning, moving from a view of such reasoning as a stumbling block to quickly overcome toward a view of such reasoning as a necessary and critical foundation in learning to prove. Yet, the findings suggest that middle school teachers may have a lack of (or at least limited) awareness and experience with respect to strategic and productive uses of examples during proving-related instructional activities. The findings further suggest the need for both professional development and curricular resources to support teacher efforts to help their students learn to strategically think about and productively use examples.

AUTHORITY DURING ELEMENTARY MATHEMATICS DISCUSSIONS

Keywords: Classroom Discourse, Elementary School Education, Reasoning and Proof

We analyzed interactions in a third grade classroom with the intent to study the ways that different members of the class positioned as math experts during group discussions. Learners took on the role of expert status to explain their reasoning and validate each other. In contrast, the teacher used her position as expert during discussions to challenge and stretch students' mathematical thinking.

The ways in which students justify their thinking, both verbally and in writing, are assumed to be central to effective mathematics learning (Ball & Friel, 1991). The need to engage students in reasoning and justifying ideas appear in both the Common Core State Standards for Mathematical Practice (National Governor's Association Center for Best Practices & Council of Chief State School Officers, 2010) as well as NCTM's Principles and Standards for School Mathematics (National Council of Teachers of Mathematics, 2000). There is agreement that by justifying results and reasoning about ideas students gain a deeper understanding of mathematics as they reflect on both their own contributions and those of their peers. Constructing arguments and explaining them are not individual activities; they must happen in the context of interactions with others to be meaningful (Cobb, Wood, Yackel, & McNeal, 1992). There is also agreement that the teacher plays a critical part in establishing sociomathematical norms that stress reasoning and student autonomy (Cobb & Yackel, 1996; McClain & Cobb, 2001). Of particular interest is gaining a better understanding of interactions that provide a shared space for teachers and learners to actively participate in the construction of knowledge (Wood, Williams, & McNeal, 2006). Observations of a third grade classroom were used to consider this issue. Examining the conversational patterns of the students and the teacher, we considered the locus of authority during the discussion and whether class members used their authority in different ways.

Theoretical Framework

Clarifying and justifying ideas are key components of discourse in mathematics classrooms (Manouchehri & Enderson, 1999). During discussions, the teacher plays a central role in both eliciting student responses and asking for justification. As the most experienced mathematician in the room, the teacher has the responsibility to ask questions and use various interventions to guide the discussion towards specified lesson outcomes (Manouchehri & St. John, 2006). However, it is important that the teacher not be seen as the only expert within the classroom. For meaningful learning to occur, "the intellectual authority in the classroom belongs with the students" (Bennett, 2014, p. 25). Thus, an effective mathematical discussion involves a balance between achieving the teacher's objectives and allowing for student input and discovery.

The term expert references Vygotsky's (1987) concept of the more knowledgeable other; someone who has more knowledge or expertise than the learner. The expert is traditionally an adult, but could also be a peer. In a community of practice approach to learning, members take on various roles and participate in different ways throughout a lesson (Gutiérrez & Rogoff, 2003). Using this framework, “expert” is not a static role in a classroom setting. It allows for both students and teachers to have authority depending on the situation. In addition, classroom authority is influenced by a student’s ability to justify their reasoning. Lampert (1990) observed students take on the role of “more experienced knowers in relation to one another” when involved in whole class discussions that required students to justify their reasoning (p. 42). In these discussions, students were also required to critique the reasoning of others.

Methods

The setting for this study was a third grade classroom at an elementary school in a Midwestern state. The class consisted of a teacher, Ms. Jones, along with 22 students and two support staff (all names are pseudonyms). Data collection and analysis, relying on a naturalistic inquiry method (Armstrong, 2012), focused on how members of the classroom are positioned as experts. Data consisted of field notes and transcripts of classroom interactions. Observations took place during mathematics instruction at least once a week over a six-week period, for a total of 14 hours of observation.

This analysis focused on isolating instances of discourse episodes during which different members of the community acted or were perceived by others as experts. Occasions where students were asked to justify their thinking were noted and tallied. These interactions were analyzed to identify who was seen as an expert and how they used their expert status.

Mehan (1985) emphasizes that turn taking looks different in educational settings than outside of them. Classrooms frequently include patterns where the teacher has both the primary right to speak and the ability to choose who else participates in the discussion (Erickson, 2004). Because of this, moments where students were in control of the discussion were also highlighted as potentially significant in terms of classroom authority.

Findings

Analysis of classroom discussion episodes revealed significant differences in the ways that the teacher used authority as compared to her students. While the students took on the role of resident experts as they expressed, explained or defended ideas, Ms. Jones exercised authority by requesting that students listen to one another, justify results, and/or challenge shared ideas.

Conversational Patterns and Authority

The following vignette from one class discussion illustrates how different members of the classroom community used their authority. Two students, Ashley and Sophie, had just presented their work on a problem involving boxes of doughnuts and are were receiving feedback from their peers. This vignette highlights the differences between a section of discourse involving student control versus one primarily guided by the teacher.

Sophie: James?
James: I like how you organized your boxes.
Sophie: Thanks.
Sophie: Maggie?
Maggie: I like how you put a little mystery box there so it doesn’t tell you what the answer is so people can figure it out on their own.
Ashley: Sarah?
Sarah: I like how your equation was 6+6+6+6
Ms. Jones: Can I ask a follow up question?

Ashley: Yeah
Ms. Jones: Where did you get those 6s and how did you know that there were 4 of them?
Sophie: Boxes of doughnuts
Ms. Jones: The boxes of doughnuts so *(circles one box on whiteboard)* this is like one 6? And this box would be a 6 *(circles another).* Is that true?
Ashley: Yeah
Ms. Jones: And this one is a 6. Hmmm. Why did we need to use 4 6s?

The turn taking in this interaction features several important elements. First, it is noteworthy that the discussion was entirely student-led for the first part of the excerpt. Ashley and Sophie were given charge of the discussion as they solicited feedback from their peers. The structure of this interaction gave Ashley and Sophie a position of authority because the class was discussing their work. In addition, when getting feedback Ashley and Sophie were given the authority to determine who speaks next, a rare occurrence in classroom interactions (Mehan, 1985).

The vignette described above was a common pattern for discussions in the classroom. When students were explaining their work, Ms. Jones stepped to the side and at times even redirected students when they looked to her to take charge. In this mode, Ms. Jones positioned the students as experts during discussions. However, the fact that students still sought assurance from her implies that they saw her as an authority figure even when someone else was leading.

The different ways that Ms. Jones and the students used their opportunities to speak are also significant. Student leadership did not necessarily shape the discussion in mathematically meaningful ways. Note that in the vignette above James, Maggie, and Sarah all gave positive critiques of Ashley's and Sophie's work and explanation. The student-led discourse was characterized by a cycle of compliments which do not appear to be moving the discussion forward mathematically. Most students in the class had gotten the correct answer, so perhaps there was not much to discuss from the students' perspective.

The complimentary dialogue most likely would have continued without Ms. Jones' deliberate intervention. She first asked permission to pose a follow up question. This reinforces the idea the Ashley and Sophie are in charge of the discussion. It is noteworthy that Ms. Jones did not provide an evaluation of whether the students' work was correct; she used her questions to get them to explain their thinking. During this section it appears that Ms. Jones' authority supersedes that of her students; she easily took control using a more traditional initiation-response pattern (Mehan, 1985) to move in a direction which aligned with her lesson goals.

While the previous interaction contained only positive peer feedback, when students had differing answers they were willing to ask questions or challenge them. An example of this is depicted in the vignette below. The discussion concerned how many loaves of banana bread would be needed for the whole class if each loaf has 6 slices.

Paige: I disagree that it is 4 loaves because if there were four loaves then it wouldn't give exactly 21 slices.
Maggie: We were thinking that it would be better to have some extra slices than not enough for everyone.
Paige: I guess I sort of agree, but the problem didn't say anything about having extra.
Ms. Jones: I'm really interested to hear more about what Maggie meant by not having enough – can you say more about that?

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

In this instance, both students saw themselves as experts with something to contribute; Paige was willing to dispute an answer which has been presented, and Maggie stood up for her solution after Paige's critique. In addition, it is interesting that, as in the previous example, Ms. Jones' entrance into the conversation was not to evaluate either student as correct, but to push students to think more about the mathematics in the problem.

Importance of Justification

An emphasis on justifying responses and explaining reasoning was a staple of Ms. Jones' practice. The culture reinforced in class was the notion that it is not just a correct solution that is required for a response; one must also be able to explain reasoning. This specific practice defined expert status in the learning community and was one which students exhibited repeatedly as evidenced in the vignette presented earlier in this paper. Regular references to "I agree" or "I disagree" during debates were typical. Students' behaviors were shaped by Ms. Jones' frequent use of phrases that encouraged students to explain their thinking, explain their ideas, rely on "neighbor's" suggestions, and listen carefully to one another. In doing so she emphasized the importance of justification and reasoning in mathematics- endorsing them autonomy in determining legitimacy of ideas shared and at the same time legitimizing their own thinking.

Discussion

Recent standards in mathematics have emphasized the important role of constructing and justifying arguments. In the context of this classroom, justification is prerequisite to mathematical authority during class discussions. However, it appears that expert status is used in different ways by the students and teacher. Analysis suggests that effective discussions where students construct and critique arguments do not happen automatically or easily; they require careful teacher moderation and practice. Because of the preliminary nature of this study, more research is needed to determine if these observations are typical of other educational spaces.

EXAMINING FEATURES OF ALGEBRA INSTRUCTION IN CLASSROOMS USING A REFORM-ORIENTED CURRICULUM

Erica Litke
University of Delaware
litke@udel.edu

Julien Corven
University of Delaware
jcorven@udel.edu

Drawing on video observations of algebra lessons in classrooms using a curriculum aligned with supporting ambitious instruction, we investigate additional instructional practices that support students' learning opportunities in algebra. We examine instruction on algebraic procedures and the types of connections teachers make within and across algebra content. We find that while identified practices are prevalent across lessons, they are not always enacted in depth. We also find differences in which practices varied more across lessons and which varied across teachers.

Keywords: Instructional Activities and Practices, Algebra and Algebraic Thinking

Contemporary visions of improving mathematics instruction in the U.S. focus on developing teachers' enactment of ambitious instructional practices, positioning students as sense makers, and centering conceptual understanding (National Council for Teachers of Mathematics, 2000; National Governors Association Center for Best Practices, Council of Chief State School Officers, 2010). These goals require teachers to provide students opportunities to reason about mathematics, engage in mathematical discussions, solve authentic problems, and engage in productive struggle (e.g., Hiebert & Grouws, 2007). This vision has been supported by the development of curriculum materials that feature meaningful tasks and questions requiring students to engage in mathematical reasoning and justification (Kieran, 2007).

In the domain of algebra, curricula aligned to reform-oriented ideas aim to support teachers in evolving instruction along the lines described above. There are also finer-grained instructional practices that support students' learning opportunities in algebra specifically, and the extent to which these practices feature in more reform-oriented classrooms remains an open question. For example, supporting students' flexibility in algebraic procedures or making connections across algebraic representations supports conceptual understanding in algebra (e.g., Chazan & Yerulshlamy, 2003; Star & Rittle-Johnson, 2009). While curriculum materials may be designed to include these practices, the enacted curriculum often differs from the intended one (Remillard & Heck, 2014). In this study, we explore the extent to which algebra-focused practices are present in classrooms using a reform-focused curriculum. We ask: *To what extent and in what ways do instructional practices that support students' learning opportunities in algebra feature in lessons focused on conceptual understanding? To what extent do particular instructional practices vary between lessons within teachers or across teachers?*

Background and Framing

We take as a framework that not only is the mathematical work in classrooms distinct from general classroom strategies, but that the work of teaching algebra is tied to the specific content taught (Litke, 2019). Any lens brought to observing instruction must select a particular focus—we examine instructional features that offer the potential to support students' learning opportunities of algebra content specifically, regardless of whether they are typically considered elements of ambitious instruction.

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

Success in algebra likely demands student fluency in both symbolic representation and manipulation in addition to conceptual understanding (Kieran, 2007). Researchers acknowledge that while conceptual knowledge can lead to the development of procedural fluency, procedural fluency can also aid in the development of conceptual understanding (e.g., Rittle-Johnson, Siegler, & Alibali, 2001). Procedures involving symbolic manipulation feature prominently in algebra (Kieran, 2013). Deep procedural knowledge may in fact be highly beneficial to student understanding of algebraic ideas (Star, 2005). Teachers can support the development of procedural knowledge by connecting procedures to their underlying concepts (Kieran, 2013) or support procedural flexibility through practices such as comparing multiple solution methods or exploring multiple pathways through a procedure (Star et al., 2015).

Connections between and across algebraic ideas may also support students' learning opportunities in algebra. For example, situating the content of an algebra lesson by relating it to other topics in the curriculum may mitigate difficulties students face transitioning between topics (Hiebert & Grouws, 2007). Developing connections between algebraic representations (e.g., graph, table, equation, and context) may help to support understanding of important algebraic relationships (e.g., Chazan & Yerulshlamy, 2003). Finally, connecting abstract algebraic ideas to their concrete or numerical analogs can support students' understanding of algebraic abstraction and promote learning and transfer (Booth, 1988; Booth et al., 2007; Kieran, 2007).

Methods

Data for this study comes from classroom video recorded as part of a project examining the enacted curriculum across teachers implementing a reform-oriented algebra text (Dietiker, Miller, Brakoniecki, & Riling, 2018). The sample includes 29 video recordings of algebra lessons taught by six teachers across two years (3–6 lessons per teacher), each teaching the same three lessons from CPM's *Core Connections: Algebra* textbook. We coded videos using an algebra-focused observational tool—the Quality of Instructional Practice in Algebra (QIPA)—reflecting instructional practices shown in prior research to support students' learning opportunities in algebra (Litke, 2019).

The QIPA is organized into two broad categories. The first captures aspects of instruction that occur during instruction on algebraic procedures and includes *Making Sense of Procedures*, *Supporting Procedural Flexibility*, and *Organization in the Presentation of Procedures*. The second captures the ways in which teachers make connections between and within mathematical ideas and representations and includes *Connecting Across Representations*, *Situating the Mathematics*, and *Connecting Between Numeric and Abstract Algebraic Ideas* (for more information about the QIPA, see Litke, 2015; 2019).

Both authors used the QIPA to independently score all sample lessons, breaking each lesson into 7.5-minute segments and pausing after each segment to record scores on each of the codes listed above. We first scored each segment on whether or not procedures were taught and excluded segments in which no procedures were taught from analyses around the teaching of procedures. Using a rubric, raters independently assigned each segment a score of *not present* (1) to *high* (5) on each element, indicating the extent to which that element characterized the segment and the depth with which it was enacted. We met weekly to reconcile scores. To address the extent to which specific instructional practices feature in this sample, we calculated segment-level frequencies for each code, generating lesson-level scores by averaging scores across segments. To address the extent to which specific practices vary between lessons within teachers and across teachers, we analyzed scores using a cross-classified hierarchical linear model.

Results

Out of 207 segments total, procedures were taught in 98 of them (47%), appearing in 19 of the 29 lessons. Notably, when procedures were taught, they were reasonably well organized with only 12% of segments scoring low, indicating some lack of clarity or mathematical issues. Less attention was given to other important aspects of teaching algebraic procedures. For example, over one third of segments in which procedures were taught scored not present on *Supporting Procedural Flexibility* and another third scored low on this code, indicating only brief attention to elements of flexibility (e.g., noting multiple pathways through a procedure, attending to key decision points in a procedure, or comparing multiple solution methods). In some segments, the attention to flexibility was more sustained, with 27% of segments scoring mid or higher. There was somewhat more attention to giving meaning to algebraic procedures—just over 30% of segments in which procedures were taught scored low on *Making Sense of Procedures* and 34% of segments scored mid. In these segments, teachers connected procedures to underlying concepts or made meaning of solutions generated by procedures, though this happened in passing or relatively briefly. No segments scored high on this code and in only 14% of segments did this feature occur in any depth.

While this distribution seems to indicate that some practices that support students' learning opportunities are only moderately present, scores at the lesson level show these features to be spread out across sample lessons. In Table 1, we show the percent of the 19 lessons in which procedures were taught that had at least one segment scoring at each level. Encouragingly, nearly all lessons included at least one segment in which teachers and students worked to give meaning to algebraic procedures, and almost half of lessons had at least one segment scoring mid/high or high on this code. Over half of lessons also included at least one segment that scored mid or higher on *Supporting Procedural Flexibility*. We note that teaching is a complex endeavor and there may be good reasons *not* to engage in a specific practice at any given moment in a lesson.

Table 1: Percentage of Lessons with at Least One Segment Scoring at Each Score Point

	Low or Above (≥ 2)	Mid or Above (≥ 3)	Mid/High or High (4–5)
Making Sense of Procedures	95	79	47
Supporting Procedural Flexibility	89	53	21
Organization of Procedures	100	100	58
Connecting Across Representations	97	83	21
Situating the Mathematics	86	38	14
Connecting Numeric and Abstract Ideas	90	83	34

Examining the connections codes, we found these practices to be instantiated less frequently and in less depth. For example, 40% of all segments included no work connecting across representations (e.g., graph to equation). When this practice did occur, it happened only briefly or in passing; only 5% of segments scored above mid on this code. However, this practice was spread across more lessons than the segment level distribution may indicate (see Table 1). Across all 29 lessons, the vast majority (83%) had at least one segment that scored mid or higher. Half of segments included no instances of *Connecting Numeric and Abstract Algebraic Ideas*. When these connections occurred, they were largely at the low (17%) or mid (24%) level. In these lessons, teachers made only brief connections between abstract ideas in algebra and their numeric or concrete underpinnings. However, at the lesson level, the majority of lessons had at least one segment that scored at least a mid on this code, and about one third of the lessons included at least one segment that scored at the higher levels. In contrast, situating the mathematics of the lesson within other algebra topics or the broader domain of algebra rarely occurred—71% of segments included no instances of this type of connection and an additional 20% of segments had this practice occur only in passing. Looking across lessons, fewer than half included at least one segment that scored at least mid on this code. Taken together, these scores indicate that, while these types of connections are prevalent across lessons, they are not always instantiated in depth, despite a curricular emphasis on opportunities to engage in connections.

We used intraclass correlations to examine the extent to which variance in segment scores was more attributable to differences between teachers or between lessons. In Table 2, we show the Intra-Teacher Correlation (ITC), reflecting the percent of variance between teachers, and the Intra-Lesson Correlation (ILC), reflecting the percent of variance between the three textbook lessons within teachers. We find differences in which practices seem to be more lesson- than teacher-dependent. For example, the variation in this sample around *Connecting Across Representations* may reflect differences in the lesson content, tasks, or instructions. Indeed, one lesson focused explicitly on multiple representations of quadratic functions, though other lessons also provided opportunities to for connecting representations that were not always taken up. In contrast, in segments in which procedures were taught (n=98), practices appeared more teacher- than lesson-dependent. For example, twice as much of the variance in *Supporting Procedural Flexibility* was attributable to teachers rather than lessons, indicating that, in this sample, the extent to which procedural flexibility is supported varies quite a bit from teacher to teacher.

Table 2: Percent of Variance Attributable to Teachers (ITC) and to Lessons (ILC) by Code

Code	ITC	ILC
Making Sense of Procedures	8.38	0.01
Supporting Procedural Flexibility	22.91	10.15
Organization of Procedures	4.77	0.00
Connecting Across Representations	0.00	12.02
Situating the Mathematics	1.19	0.02
Connecting Numeric and Abstract Ideas	0.01	12.44

Discussion and Conclusion

Results from this study indicate that teachers relying on reform-oriented curricula like the one used here might consider ways to deepen aspects of their instruction that support students' learning of algebra content. While instructional practices that support developing students' procedural knowledge occurred in these lessons, they were not always enacted in depth. In addition, the limited focus on making connections in this sample was particularly surprising given the focus on such connections in the materials themselves. We also find differences in which practices seem to vary among teachers and which seem to be more strongly linked to a particular lesson. It may be that lesson topic or curriculum materials influence the frequency and degree to which some instructional practices are enacted, although we caution generalizing from a small sample of teachers and lessons. A larger-scale study and more detailed qualitative analysis could help us better understand these differences. Findings indicate that these lessons feature instructional practices that support students' learning of algebra content, but the depth of enactment and the differences between enactments on the same lesson demonstrate that additional support may be needed to develop teachers' instruction along these lines.

ANALYSIS OF MATHEMATICAL REPRESENTATIONS IN A SYNCHRONOUS ONLINE MATHEMATICS CONTENT COURSE

Theresa Wills
George Mason University
twills@gmu.edu

This study investigates the student-created representations in a synchronous online mathematics course. Over a 15-week semester, a select group of mathematics specialists candidates took the course, MATH 613 - Algebra for K-8 Math Specialists using a 100% synchronous online format. Data collection included interactive slides and reflection paper assignments. The findings indicate that the mathematical representations included abstract, pictorial, concrete and dynamic-pictorial. Dynamic-pictorial is defined in this research as pictorial models that use the advantages of technology to move representations on the screen in a way that could not be reasonably replicated using hand held manipulatives. Implications for this research include supporting instructors of math content courses with planning and delivery of online coursework with the expectation of student-created dynamic-pictorial representations. Further research could address the variety of dynamic-pictorial representations to analyze the complexity of these representations.

Significance of Problem on a Personal Level

I am a Professor of Mathematics Education and teach mathematics through conceptual understanding using rich tasks and multiple representations. I struggled with the geographical barrier that restricted access to my courses and wanted to reach out to new communities. I have taught asynchronous online classes, and did not find that they supported my students in areas of engagement, community, mathematical representations and rich mathematical debate. I resorted to creating representations ahead of time and included them in the slides, but these representations lacked engagement because they were not student-created. My goal was to incorporate my knowledge of representations to create a synchronous online course that is modeled as closely as possible to a traditional face-to-face course. In order to do this with as much fidelity as possible, I taught two sections of the same course back to back on the same evening. The 100% synchronous online course was taught on Mondays from 4:30 - 7:10, and the face-to-face course was taught Mondays from 7:20 - 10:00. I attempted to keep my presentation slides as similar as possible, and only changed the wording from “create a slide” to “create a poster” or something similar. This allowed me to maintain similar class experiences.

Broader Educational Significance of the Problem

Universities are implementing more online courses (Yamagata-Lynch, 2014). NCTM (2000) recommends that mathematics courses are taught using contextual examples with a variety of student-created representations in order to enhance their conceptual understanding of the big mathematical idea. Universities need to evaluate their online courses for these representations and the student engagement in these representations. The pedagogical strategies that are identified could be used in all mathematics content courses such that distance learning can be just as engaging as face-to-face learning.

Statement of Research Problem and Question

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

Research Problem

Universities are implementing more online courses (Yamagata-Lynch, 2014) and these courses need to be evaluated for effectiveness (Herrington et al.,2001). In earlier studies, Herrington et al. (2001) found that online courses lack critical learning experiences that are found in face-to-face classes. However, Polly (2016) found that mathematics teacher leaders in online courses were able to attain similar course outcomes. NCTM (2000) recommends that mathematics content courses use a variety of representations, but this can be difficult to experience in an online course.

Research Question

How do mathematics specialist candidates engage in creating multiple mathematical representations in a synchronous online mathematics content course?

Review of the Literature

Higher education has an increasing need to evaluate the process of designing and delivering online learning (Herrington et al., 2001). Education has been slow to pick up on online courses (Polly, 2016). Online courses have an added challenge of engaging students in a virtual environment that has many differences from the traditional face-to-face learning environment. This online environment must be structured to actively engage students in meaningful tasks for effective learning to occur (Simon, 2002). In order to evaluate online courses, Herrington et al. (2001) developed a framework for evaluating online learning settings which focused on incorporating authentic tasks, opportunities for collaboration, learner-centered environments, engagement, and meaningful assessments. This framework can be used across content areas, and will be used to address mathematics, specifically mathematical representations.

It is vital that students have the tools needed to produce, analyse, understand and recognize representations in their world (Lesh & Doerr, 1998). "Having representational fluency, being able to translate a mathematical idea among these representations, strengthens one's strategic competence and conceptual understanding" (Suh & Seshaiyer, 2007, p. 8). Further, NCTM (2000) states that "when students gain access to mathematical representations and the ideas they express and when they can create representations to capture mathematical concepts or relationships, they acquire a set of tools that significantly expand their capacity to model and interpret physical, social, and mathematical phenomena" (NCTM, 2000, p. 4).

In 1991, Kaput stated that researchers are interested in discovering new types of multiplelinked representations (such as how tables link to graphs). Synchronous online course delivery provides an opportunity to research these representations that, without technology, were previously inconceivable (Puentedura, 2006). While these findings show a potential benefit of online courses, further research is needed on various types of courses with a focus on attributes of the course that support student engagement (Dyment, Downing, & Budd, 2013; Polly, 2015). "There is a need for subsequent studies to further examine the influence of specific characteristics of online courses on learning outcomes and learners' perceptions and experiences" (Polly, 2016, p.14).

Method Context

Description of Participants

There were 16 mathematics specialist candidates in the first synchronous online cohort at George Mason University, including female (87%) and male (13%); a combination of White (69%), African American (19%), and Indian American (6%) educators. All of the candidates were employed in K-12 schools, with the majority (81%) in elementary schools (K-5) and 19% who taught at the secondary level (6-12). The candidates represented varied educational settings, including 81% who resided in districts in Virginia, which does not use Common Core State Standards; others were outside of Virginia in Common Core states (13%) or in international schools (6%). Prior to the beginning of the cohort, 25% of the candidates were already working in mathematics specialist positions without formal preparation coursework. The course met weekly on Mondays from 4:30 - 7:10 EST.

Description of the Online Setting

Math specialists candidates were selected for this program knowing that all courses are delivered using a 100% synchronous online delivery method, however there were no technology skill prerequisites. The math specialist program is a 6-semester program that is completed in two and a half years (3 fall, 2 spring, and 1 summer semester). All classes were based in an online classroom environment using Blackboard Collaborate Ultra. This online classroom allowed participants to access audio and video as well as a shared whiteboard, however video was rarely used. Participants continuously talked together as a whole class or in small breakout rooms that limited audio to the small group. Participants were all also engaged simultaneously in Google Slides which was used as a collaborative whiteboard. At any moment, all group members were adding photos of their handwritten work to the slide, adjusting text boxes, and adding screenshots of a virtual manipulative. The slides were frequently overcrowded, but this allowed candidates to see similarities and differences in their representations. Specialists candidates and the instructor held joint ownership over the slides, and participants could add additional slides as needed. Participants easily navigated multiple websites simultaneously.

Data Collection

Google Slides. Since traditional poster paper cannot be used in an online class, the candidates created their "posters" using Google Slides. This online collaborative tool allowed an entire class or small group of candidates to add text boxes, shapes, drawings, pictures, clipart, tables, and many other virtual representations to a shared slide. All candidates and instructors had ownership of all slides, and any participant could add to, or delete materials to the slides.

Reflections assignments. As part of an assignment, all specialists candidates were required to reflect on four of the rich tasks that were completed in class. The rubric for the reflections required that specialist candidates discuss the representations that were created and presented in class and explain their understanding of the representation in detail.

Data Analysis

It has long been established that three common mathematical representations are abstract, representational/pictorial, and concrete (Robold 1978). While these representations are widely referenced, there were some representations in the synchronous online course that didn't fit into either category. Therefore, slides and reflections were analyzed qualitatively using grounded theory. Codes and properties were explored during open coding, and relationships between the codes were identified. Finally, specific properties were selected for codes and all slides and reflections were coded again under these selective codes.

Findings Identification of Representations

Mathematics Specialist Candidates created a plethora of representations. These include hand drawn, virtually sketched, program tools, and virtual manipulatives. The codes identified in this study are the three established categories, abstract, concrete, and pictorial (Robold 1978) and a new category called dynamic-pictorial.

Description of Dynamic-Pictorial

This type of representations was observed in every class, therefore it was common enough to be described and characterized. Dynamic-pictorial refers to a pictorial representation that moved during the discussion.

Using dynamic-pictorial for a large quantity. In one representation, the candidate was able to use the technology to copy and paste the single square into a row of ten squares, and then into an array of over 200 squares. Then, they modeled the distributive property by separating 54 squares away from another quantity. It would be unrealistic to model this problem in a classroom with over 200 square tile manipulatives, and it would be time consuming to model this task in a similar way in a face-to-face classroom environment. If this representation were to be drawn on a traditional poster, there would be no way to move the model. Instead, the presenter might explain the movement or draw a before and after pictorial representation on their poster.

Using dynamic-pictorial for visually connecting. Smith and Stein (2011) discuss the importance of making mathematical connections to various student invented strategies. The synchronous online class showed a unique way of using the technology to connect candidate's strategies. For example, a candidate created a 5x5 array and explained that they could determine the number of tiles on the border of the array by adding the top and bottom row (5 + 5) and the side rows (3+3) to get a total of 15. Another candidate struggled to explain the connection to their strategy and therefore they decided to copy and paste the same 5x5 array such that they were positioned side by side. Then they changed the colors of the top, bottom and side to match their representation. Other candidates continued to copy and paste this array to show a variety of visual strategies. This is fundamentally different from what can be done using a poster in a classroom. While different pictorial representations can be shown side by side, the technology offers a quick color change option that can change rapidly. This simple use of the technology animates the pictorial representation and creates a whole new representation.

The nature of these representations can be described as a mixture of concrete and pictorial. These representations rely on the advantages of technology, and are unique to the synchronous online class setting.

Discussion and Implications Impact on Participants

Classroom teachers are often required to use a combination of virtual and physical or concrete manipulatives (Moyer-Packenham, Salkind, & Bolyard, 2008). Further, Simon (2002) states that students must actively engage in meaningful tasks for effective learning to occur. With the implementation of Google Slides, candidates were able to actively engage in the creation of a variety of mathematical representations. In fact, the candidates demonstrated a variety of ways that they were able to use the virtual manipulative as a dynamic-pictorial model and therefore used the manipulative in a more meaningful and engaging way.

Impact on Education Field

With the increased demand for online teacher education courses in higher education (Yamagata-Lynch, 2014), universities are implementing synchronous online delivery methods. This research can support instructors with suggestions on how to use student-centered representations. Additional research should be done to analyze dynamic-pictorial representations.

EXPERIENCING EQUIVALENCE WITH GRASPABLE MATH: RESULTS FROM A MIDDLE-SCHOOL STUDY

Understanding equivalence is fundamental to STEM disciplines, but many students struggle with the concept. We present a novel method for students to explore ideas of equivalence where students dynamically transform expressions from initial states to goal states in the web-based app Graspable Math. The structure of the goal state activities implies that any initial and goal state pair represent the same quantity (or varying quantity). We propose that for students, the physical experience of moving algebraic objects and observing how the initial state transforms into the goal state helps generalize notation mechanics. In fall of 2019, we will test this supposition in a randomized control trial of 1500 students in which student performance in pre- and post-tests will be compared to an online problem set control.

Keywords: Algebra and Algebraic Thinking, Technology, Instructional Activities and Practices, Middle School Education

Student misunderstandings or misconceptions about the equivalence and the equals sign have been noted as inhibiting success in upper-level mathematics and other STEM disciplines (Kieran, 2007; Knuth, Stephens, McNeil, & Alibali, 2006; Stephens, Knuth, Blanton, Isler, Gardiner, & Marum, 2013). For example, a common misconception is when students view the equals sign as marking or calling for a computation, such as interpreting "4+1=5" as "four and one makes five." This type of operational understanding of the equals sign has been found to be stable in middle school students (Alibali, Knuth, Hattikudur, McNeil, & Stephens, 2007) and is associated with difficulty in equation solving, even when controlled for grade level and standardized mathematics test scores (Knuth, et al., 2006). A robust perspective, in contrast, is what Stephens and colleagues (2013) describe as a *relational-structural* view of the equals sign - understanding that the equals sign expresses an equivalence relation between the two expressions on either side.

Much of the research on students' understanding of equivalence is embedded in work on students' understanding of the equals sign (Blanton, Stephens, Knuth, Gardiner, Isler, 2015; Kieran, 1981, 1992, 2007; Knuth, et al., 2006; Leavy, Hourigan, & McMahon, 2013; Rittle-Johnson, Matthews, Taylor, & McEldoon, 2011). As a case in point, Rittle-Johnson and colleagues (2011) talk about the distinction between numerical equivalence - the ability to match sets of objects on the basis of quantity, and mathematical equivalence - "understanding that the values on either side of the equal[s] sign are the same," (Rittle-Johnson et al., 2011, p. 86). Kieran describes this formally as "the symmetric and transitive character of equality," and informally as "the 'left-right equivalence' of the equal[s] sign," (1992, p. 398).

Our work takes a different tactic by having students work through what we call *goal state* activities using the dynamic notation tool, Graspable Math (GM). In GM, algebraic objects (terms, expressions, and equations) operate according to the mechanics of symbolic notation. For example, permissible moves (such as adding $2x$ and $4x$) transform an expression or equation, while impermissible moves (such as adding $2x$ and $4y$) do not. From a perceptual learning perspective, students' experience of moving algebraic objects on the screen, reinforced by the visual feedback of transformed expressions, helps students to generalize notation mechanics and attend to relevant details. In goal state activities, students are presented with two equivalent states: an initial state and an equivalent goal state (See Figure 1). The students' task is to transform the initial expression into the goal state. These transformations can only happen through algebraically permissible actions. Thus, students are finding the road map of equivalence between the initial state and the goal state.

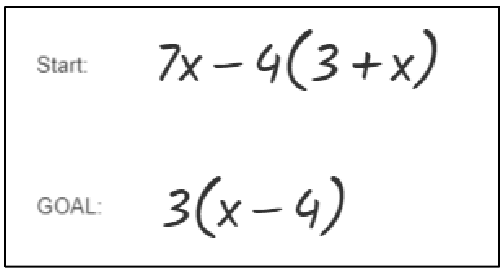

Figure 1: An Example of a Goal State Activity in Graspable Math

In fall of 2019, we will run a randomized control trial of 1500 students in 2 intervention conditions: a GM goal state condition and an online problem set control. Student performance in pre- and post-tests will be compared to explore how GM goal state work might be associated with students' performance on equivalence-related tasks to address the research question, "How does experience with a transformation-based intervention affect student performance on equivalence items compared to a control of traditional online problem set?"

Theoretical Framework

The operational-relational dichotomy in students' perspectives of the equals sign is well-documented in the literature (Blanton et al., 2015; Carpenter, Franke, & Levi, 2003; Kieran, 1992; Knuth et al., 2006; Leavy, Hourigan, & McMahon, 2013; McNeil, Grandau, Knuth, Alibali, Stephens, Krill, 2006). Stephens, et al. (2013) adds nuance to that discussion by differentiating between a *relational-computational* view, where students understand that two sides of the equals sign calculate to the same value, and a *relational-structural* view, where students understand that the equals sign expresses an equivalence relation between the two expressions on either side of the equals sign. This subtle difference is tied to a structural understanding of algebra (Kieran, 2007), where "[students] can see complicated things, such as some algebraic expressions, as single objects or as being composed of several objects" (CCSS.Math.Practice.MP7 http://www.corestandards.org/Math/Practice/).

Landy, Allen, and Zednik (2014) proposed that sense making of symbolic notation happens through perceptual and sensorimotor systems. If the capacity for symbolic reasoning is in part the ability to "perceptually group, detect symmetry in, and otherwise perceptually organize symbolic notations," (Landy, Allen, & Zednik, 2014, p. 1), part of the algebraic objectification described above could be perceptual. In other words, since "what students notice mathematically has consequences for their subsequent reasoning" (Lobato, Hohensee, & Rhodehamel, 2013, p. 809), perception of notation is part and parcel of symbolic reasoning (Goldstone, Marghetis, Weitnauer, Ottmar & Landy, 2017). Mathematical fluency, therefore, derives not only from understanding the content, but also a heightened focus on relevant perceptual details. Perceptual learning theory suggests that training one's perceptual and sensorimotor systems in symbolic notation may result in more effective reasoning about the relationships represented by the symbols (Kellman, Massey, & Son, 2010).

Grounded in this theory, GM creates a learning environment where algebraic objects behave according to the mechanics of symbol manipulation in a virtual environment. By making moves on expressions or equations and observing the system response, generalized mathematical properties such as commutativity, distribution, and order of operations, and simplifying expressions or solving equations becomes experiential for students.

For example, imagine a situation where a student is working with the expression "3 + 8 + 4x" (Figure 2). In the first row, the student moves the "8" to the right and drops it past the "4x," experiencing the commutative property by seeing the resulting "3 + 4x + 8." In the second row, the student moves the "8" to the left and drops it on top of the "3." The terms combine, resulting in the expression "11 + 4x." Thus, the student experiences addition. In third row, the student drops the "8" on top of "4x," not a permissible operation since "8 + 4x" is already in simplest form, and the "8" snaps back to its initial location. In each case, the program responds to student actions, and the student has immediate feedback on the impact of their actions. Other gestures beyond selecting and moving allow users to enact most forms of symbolic manipulation including each of the four basic operations, decomposition, distribution, and factoring.

Possible actions on "3+8+4*x*"	Final State in GM	Mathematical Description
move "8" to the right	$3 + 4x + 8$	Commute 8 and 4*x*
move "8" on top of "3"	$11 + 4x$	Add 3 and 8
move "8" on top of "4*x*"	$3 + 8 + 4x$	Not a permissible move ("8+4*x*" shakes)

Figure 2: GM Actions and Response on the Expression "3+8+4*x*"

Research Methods

For the purposes of the 2019 PME North American conference, we will be presenting data from a classroom study to be run in fall of 2019. This study involves a student-level randomized trial of 2 conditions, using the ASSISTments platform (Heffernan & Heffernan, 2014) to maintain condition assignments for each student to either self-paced GM goal state problems or online problem set. The study itself is 3 hours of content over 6 weekly sessions covering the four operations, fractions, and order of operations. Students in the GM tutorials will solve goal state items, while the problem set control will work through similar content items compiled from three open-source mathematics curricula: Engage NY (2014), Utah Math Project (2016), and Illustrative Math (2017). A sample of questions from the control condition is in Figure 3.

Student participants in the pilot will include approximately 1500 middle school students from 50 to 100 classrooms across a large, urban district in the southwestern United States. Participant schools have student populations comprised of 20% to 50% English Language Learners and over

75% identified high needs students, including but not limited to such characteristics of low income, limited English proficiency, and identified learning disabilities. Mathematical performance assessment items are drawn from the Rittle-Johnson, Matthews, Taylor, and McEldoon (2011) and Rittle-Johnson, Star, & Durkin, (2016) assessments of mathematical achievement.

1. Fill in the blank. ____ + $\boldsymbol{g} - \boldsymbol{g} = \boldsymbol{k}$ (adapted from Engage New York)
2. Select **all** the expressions that are equivalent to 4b. a) b+b+b+b b) b+4 c) 2b+2b d) b*b*b*b e) b÷4 (adapted from Illustrative Math)
3. Without solving completely, determine the number of solutions of the equation $3(m-3) = 3m-9$ a) No solution b) one solution c) infinitely many solutions (adapted from Utah Middle School Math Project)

Figure 3: Sample Items from Online Problem Set Control

Approach to Analysis

In line with research question, "How does experience with transformation-based intervention affect student performance on equivalence items compared to a control of traditional online problem set?" we will compare post-performance on mathematical equivalence items from the two conditions. We hypothesize that the immediate, experiential feedback provided in GM heightens student awareness of the mechanics of algebraic notation and is an aide to students' generalizing those mechanics. The primary analysis testing GM for improving math achievement will use linear regressions to estimate mean posttest equivalence scores between students in the GM and the control condition, controlling for pretest scores. We will examine whether GM is more effective for students with lower prior knowledge by testing the condition × pretest interaction. We expect that GM will improve students' knowledge of equivalency more than the control condition, and the effects of condition will emerge in procedural fluency, conceptual understanding, and mathematical flexibility items. This effect is hypothesized to be larger for lower performing students.

Conclusion

Despite major efforts in research, curricula development, and policy, students still struggle with understanding equivalence and the equals sign. Our session presents a novel student experience with equivalence: transforming expressions and equations dynamically and explicitly within a notation environment. Positive results from prior work using a similar arrangement of multiple sessions using a gamified version of GM has shown that it may be effective for decreasing notation errors and improving mathematical understanding (Daigle, Harrison, Braith, Ottmar, Hulse, & Manzo, 2019; Ottmar & Landy, 2017; Ottmar, Landy, Goldstone, Weitnauer, 2015). What will be unique in the analyses is the focus on mathematical equivalence and comparison against a control condition.

Productive small-group work begins with the selection and implementation of higher-demand tasks focused on procedures with connections or doing mathematics. Previous research has established factors that result in maintenance and decline of task demands. In developing an instrument for documenting evolution of demands in small groups, we identified two limitations of the Mathematics Task Framework: higher-demand tasks also involve lower-demand elements, and students engage in both higher- and lower-level cognitive work when engaging with higher-demand tasks, without the overall demand necessarily declining. We share a promising instrument for documenting evolution of students' engagement with various task demands.

Keywords: Cognition, Instructional Activities & Practices, Research Methods

Small-group learning environments promote opportunities for conceptual learning and powerful mathematical work (e.g., Mercer, 2005; Veenman, Denessen, vanden Akker, & van der Rijt, 2005). The Peers Engaged as Resources for Learning project studies small-group learning environments in secondary mathematics classrooms, addressing the research question: How is the functioning of small-group learning environments characterized by aspects of mathematics tasks, peer cultures, and mathematics discourse?

Focus of the Study

This report focuses on development of an instrument for analyzing students' cognitive engagement while enacting mathematical tasks in small groups. We share initial findings about the nature of students' engagement as they enact high- and low-level cognitive demand tasks.

Theoretical Framework

We conceptualize the small-group learning environment as comprising three major elements: the mathematics task (Stein, Grover, & Henningsen, 1996), the social peer dynamics among the group members (Hamm & Hoffman, 2016), and the discourse related to the mathematics content (Sztajn, Heck, & Malzahn, 2013). We are broadly interested in what Ryve (2011) distinguishes as Discourse (the culture), viewing the small-group learning environment as a micro-culture in the classroom. It is shaped by and, in turn, shapes these three elements to constitute the opportunities students have to learn mathematics by engaging with content and with one another.

Regarding the implementation of tasks, we ground our work in the literature on cognitive demand of mathematics tasks. Selecting a "group-worthy" task that engages students in high-level mathematics cognition is necessary for productive group work (e.g., Lotan, 2003). However, researchers have found that cognitive demand evolves during classroom enactment from the selected, written task to the teachers' set-up of the task for students, through the students' enactment of the task (e.g., Stein, Grover, & Henningsen, 1996; Warshauer, 2015), and continuing with teachers' conclusion of the task (Otten, 2010). Assessing the cognitive demand of an enacted task therefore requires measurement at multiple points to capture this evolution.

Mathematics Task Analysis Guide

The structure and expectations of written tasks denote a set of demands for what students are intended to do, which may include providing an answer, showing work, justifying a solution method, and/or representing and making meaning of the method and answer. We use Stein and colleagues' Task Analysis Guide (Stein, Smith, Henningsen, & Silver, 2000) to characterize the cognitive demand of a task as written (see Figure 1). The Task Analysis Guide also provided the basis for our characterization of the task as enacted by students in small groups.

Lower-Level Demands	Higher-Level Demands
Memorization	*Procedures with Connections*
• Involves either producing previously learned facts, rules, formulae, or definitions OR committing facts, rules, formulae, or definitions to memory. • …	• Focus students' attention on the use of procedures for the purpose of developing deeper levels of understanding of mathematical concepts and ideas. …
Procedures without Connections	*Doing Mathematics*
• Are algorithmic. Use of the procedure is either specifically called for or its use is evident based on prior instruction, experience, placement of task. • …	• Requires complex and non-algorithmic thinking (i.e., there is not a predictable, well - rehearsed approach or pathway explicitly suggested by the task, task instructions, or a worked-out example). • …
Adapted from Stein, Smith, Henningsen & Silver, 2000	

Figure 1: The Task Analysis Guide (excerpt)

Study of Small Groups in Mathematics Classrooms

Data collection for our broader study of small-group learning environments took place in two waves. In the first wave, we observed lessons that involved small-group work in a naturalistic environment, with no intervention or expectation other than the inclusion of small-group work. In the second wave, teachers consulted with project researchers prior to implementing their lessons. Researchers shared suggestions for making the lesson more "group-worthy," drawing on the three-part framework for the study. Teachers and researchers refined tasks and integrated supports for peer interaction and mathematics discourse. The teachers worked in two different school districts, one municipal and the other rural, in four different middle schools and one high school. Participating classrooms spanned grades 6–9. We observed 50 lessons involving small-group work in classrooms of 11 teachers during the first wave and 8 teachers during the second wave. Seven teachers participated in both waves. Two researchers observed each 90-minute block or 45-minute period, keeping field notes as data. During the lessons, we also audio-recorded the work of small groups of students ranging from pairs to groups of four, with five to fourteen student groups per lesson. A sample of five student group recordings was selected for this instrument development study. To analyze student group recordings, each recording was parsed into 1-minute intervals and researchers applied codes to each interval.

Instrument 1: Factors Associated with Maintenance and Decline of High-Level Demand

Our instrument development began with Stein and Smith's factors associated with the maintenance and decline of high-level cognitive demands (1998, p. 274). We conducted coding trials using two small-group recordings: Group 1 and Group 2. The groups had different teachers and enacted different tasks, which we informally identified as higher- and lower-demand using the Task Analysis Guide. Group 1 experienced a whole class review of formulas for various polygons; afterward, in their small groups, students calculated areas and perimeters of a series of shapes—a lower-level cognitive demand task because the review made evident which procedures students should use. For Group 2, the teacher implemented a high-level cognitive demand task in which students were to minimize the surface area of a box made to contain six identical cylindrical packages, with no arrangement of the cylinders prescribed.

For our study, maintenance and decline of cognitive demand coding did not adequately capture differences in students' experiences enacting these two tasks. Students in Group 1 engaged in lower-level procedures without connections and recall of previously learned information. Students in Group 2 cycled among higher-level non-algorithmic thinking and lower-level procedures without connections and recall of previously learned information. Our coding indicated the original tasks' cognitive demand was maintained in both groups because students enacted the tasks as they were designed. Yet this instrument failed to capture variations and flow in students' engagement with higher- and lower-level demands throughout task enactment.

Instrument 2: Student Engagement in Higher-Level and Lower-Level Cognition

For the second stage of our instrument development, we drafted a rubric based on the Task Analysis Guide to document whether students engaged in higher-level cognition and lower-level cognition during each minute (see Figure 2).

Description	Specific Indicators
Students engage in higher-level mathematical cognition	Students engage in one or more the following: • Complex, non-algorithmic thinking where a procedure is not prescribed or apparent • Seeking and making conceptual connections • Explaining their thinking and reasoning, beyond describing an algorithmic procedure that was used • Pressing one another for justifications, explanations, and meaning, beyond descriptions of an algorithmic procedure • Developing mathematical conjectures or posing new mathematical questions
Students engage in lower-level mathematical cognition	Students engage in one or more of the following: • Applying or explaining algorithmic procedures that are specifically called for or evident based on prior instruction, experience, or placement of the task • Recalling previously learned facts, rules, formulas, or definitions • Routinizing a problematic aspect of the task (e.g., student press the teacher to reduce the complexity of the task by specifying exact procedures or steps to perform)

Figure 2: Student Cognitive Engagement Rubric

Four researchers applied the new rubric to our existing sample and to Group 3, which had enacted a higher-level demand task that was different from Group 2's task. As intended, the new instrument documented differences in the cognitive demand that students experienced throughout the lessons. In addition, for Group 1we generally agreed on the ratings for each minute—students did or did not engage in lower-level mathematical cognition and consistently did not engage in higher-level cognition—and cited the same evidence for applying those ratings. For Groups 2 and 3, which enacted the higher-demand tasks, we found that for some minutes researchers disagreed on the ratings for higher-level or lower-level cognition even though we identified the same evidence to support those ratings. That is, our ratings differed due to researchers' interpretations of what constituted higher-level and lower-level cognition in the context of the higher-level demand task, rather than disagreement about what students were doing.

Instrument 3: Student Cognitive Engagement With Task-Specific Indicators

To develop the third instrument, we documented elements of the task that required higher-level, lower-level, or non-mathematical cognition. To address inconsistencies in our ratings on Instrument 2, we used these task-level elements for decisions about students' cognition. We first conducted a more thorough analysis of the cognitive demands of tasks. We identified likely strategies for tasks and steps students would complete if they used each strategy. We classified each step as memorization, procedures without connections, procedures with connections, or doing mathematics, according to the Task Analysis Guide. Using these task-specific indicators, we rated additional recordings using our Student Cognitive Engagement Rubric.

Results

The Student Cognitive Engagement Rubric has now been applied to a small sample of higher-demand tasks with two important results. The first is that each of the high-demand tasks we have coded includes both higher-demand and lower-demand elements. A second result is that student groups engaged in both higher- and lower-level cognition when enacting these tasks. For example, Group 2 students engaged in higher-level cognition as they figured out how to approach the task and came up with potential arrangements of the cylinders. For each arrangement, students engaged in higher-level cognition as they determined the dimensions of a box to contain the cylinders. They calculated areas using those dimensions, engaging in lower-level cognition by recalling previously learned information and completing procedures without making conceptual connections. Completing, checking, and correcting these calculations sometimes took several minutes, during which there was often no higher-level cognition even though students were actively engaged in work to complete a higher-level demand task. Once the calculations were completed, the students briefly engaged again in higher-level cognition as they considered how to apply their calculations to determine the full surface area of the box. This flow of higher-level to lower-level to higher-level cognitive engagement was characteristic of several strategies identified for addressing higher-demand tasks. In this group, the students engaged in lower-level cognition for several minutes without an overall decline of task demand because the lower-level cognition served the higher-level demands of the task. Consequently, we found that the Student Cognitive Engagement Rubric addressed the limitations of our earlier efforts which failed to capture this evolution of demands in students' task enactment.

Discussion and Conclusion

Our results to date support the importance of selecting and implementing a high cognitive demand task for small-group work, but suggest that teachers and researchers should expect periods of lower-level cognitive engagement during the enactment of such tasks. Groups that enacted lower-demand tasks had few, if any, minutes that included higher-level cognitive engagement, although such tasks allow the possibility for students to do so. Groups that enacted higher-demand tasks tended to have periods of both higher-level and lower-level engagement. The findings suggest that periods of lower-level engagement may occur even when the overall cognitive demand of the task is maintained over the course of a lesson.

Our instrument development work for investigating the evolution of cognitive demand as tasks are enacted by student groups highlights the utility of fully documenting the various cognitive demands of a task in order to support analysis of task enactment.

Keywords: Classroom Discourse, Teacher Education-Inservice/Professional Development

We have conceptualized the whole-class teaching practice of building (Van Zoest, Peterson, Leatham, & Stockero, 2016) as a productive way to take advantage of particularly high-leverage student contributions, which we call Mathematically Significant Pedagogical Opportunities to build on Student Thinking (MOSTs; Leatham, Peterson, Stockero, & Van Zoest, 2015). Building is defined as making student thinking an object of consideration by the class in order to engage the class in making sense of that thinking to better understand an important mathematical idea. The practice is composed of four subpractices: Make Precise, Grapple Toss, Orchestrate, and Make Explicit. From studying teachers’ enactments of the building practice, important aspects of these subpractices and how they are related to one another have emerged. Our poster elaborates on these aspects and relationships.

For example, each subpractice lays the foundation for the subsequent practices. Clarifying the MOST by creating a public record of the student thinking during the Make Precise subpractice facilitates a clear, focused Grapple Toss, and provides a ready scaffold to draw on during the Orchestrate and Make Explicit subpractices. During the Grapple Toss, tossing the MOST to the “right” sized group significantly impacts the ability of the teacher to Orchestrate meaningful, sense-making discussion. Finally, working to keep the MOST in the air and the students’ sense-making focused on the MOST during the Orchestrate subpractice seem to naturally lead to a return to the MOST, supporting a smooth transition from the Orchestrate subpractice into the Make Explicit subpractice.

By elaborating on these subpractices and their coordination, we hope to provide further insights into the complex practice of productively using student mathematical thinking that emerges in whole-class interactions, and thus contribute to efforts (e.g., Grossman et al., 2009; Sleep, 2012) to understand and aid teachers in productively using student mathematical thinking.

La enseñanza de las matemáticas tiene problemáticas y afronta retos específicos en dos modalidades de la educación básica en México: multigrado y telesecundaria. En este estudio se analizan las estrategias para adaptar el currículo y organizar la enseñanza de las matemáticas en una primaria unitaria y en una telesecundaria, en contextos rurales. A través de dos casos, se muestran elementos de la práctica docente que determinan la actividad matemática de los alumnos. En la docente de primaria unitaria, el diseño de tareas matemáticas generales y de tareas diversificadas por edad, para abordar conceptos matemáticos. En el docente de telesecundaria, el diseño de una situación de naturaleza interdisciplinaria para construir significados en matemáticas y física.

Palabras clave: Actividades y prácticas de enseñanza, currículo, educación primaria, educación secundaria

Introducción

La primaria multigrado y la telesecundaria son dos modalidades de la educación básica en México que se crearon para atender problemas de analfabetismo y cobertura educativa, en población ubicadas en zonas rurales con altos índices de migración y pobreza. Existen dos formas de organización en las primarias multigrado –6 a 12 años–: escuelas unitarias, en donde un profesor atiende a los grupos de primero a sexto grado en un mismo espacio y escuelas con secciones multigrado. Para la educación secundaria –12 a 15 años–, la organización multigrado se ubica en la modalidad de telesecundaria (unitaria y bidocente), cuya característica es que un profesor imparte todas las asignaturas a uno o varios grados escolares. Actualmente 43.2% de las primarias en México son multigrado y 47.7 % de las secundarias son telesecundarias, de las cuales, 20.6% son multigrado (INEE, 2018).

Aunque los datos destacan la presencia importante de estas modalidades en educación básica, el currículo nacional es estandarizado, basado en una concepción homogénea y graduada de los grupos escolares, adecuado para contextos urbanos. Aunado a esto, la especialización que requieren los docentes para la enseñanza multigrado no es prioridad en los programas de actualización o de formación inicial (Galván y Espinosa, 2017).

La enseñanza de las matemáticas en las modalidades de multigrado y telesecundaria presentan problemáticas específicas. Por una parte, atienden a población en zonas rurales, casi siempre en zonas con presencia de población indígena y con altos grados de marginación, por lo que su infraestructura es inadecuada (Juárez, 2017). Las escuelas en muchas ocasiones no cuentan con recursos y materiales básicos como agua, luz, internet y personal de intendencia (Juárez, 2017; Juárez, Vargas y Vera, 2015). Los docentes de ambas modalidades desempeñan funciones adicionales a las de docencia, funciones administrativas y de gestión escolar. Si bien generan estrategias propias de atención para los grupos diversos, no cuentan con una propuesta curricular acorde a sus necesidades y es limitado el uso de materiales educativos. No se cuenta con libros para escuelas unitarias, o para grupos multigrado, tampoco se cuenta con planes de estudio que agrupen los contenidos a aprender si se tienen varios grados en un mismo grupo. Además, la formación inicial de los docentes no se enfoca en los grupos con características multigrado. De este modo, se advierte a nivel curricular y de política educativa, que se invisibiliza en la práctica a la modalidad multigrado.

Pese a este panorama, hay estudios que muestran aportes pedagógicos en estas modalidades. En primaria, Juárez (2017) señala como potencialidades de los docentes, trabajar en un aula diversa y tener autonomía para desarrollar sus actividades, así como mantener contacto estrecho con la comunidad. En telesecundaria, García (2016) evidencia indicadores contextuales que construyen un sentido de pertenencia del docente a la modalidad, generando una autonomía para la toma de decisiones. Como lo advierte Arteaga (2011), existe una invisibilidad de la escuela multigrado en el ámbito de la investigación educativa, pues los estudios sobre el tema son relativamente recientes, sin embargo, algunas investigaciones comienzan a mostrar estudios en esta dirección (Rebolledo y Torres, 2019; Cano e Ibarra, 2018).

En el análisis de las estrategias utilizadas por docentes para la enseñanza de las matemáticas, se muestran las condiciones en que realizan adecuaciones curriculares, para adaptar el trabajo a estas modalidades (Block, Ramírez y Reséndiz, 2015; Block, Carrillo y Reséndiz, 2017). Se observan en estas estrategias, que las actividades al interior del aula están diseñadas por el conocimiento que el profesor pone en uso sobre los alumnos, el currículo, el conocimiento matemático, entre otros. Es decir, las decisiones que toman los docentes se sitúan en sus contextos propios de actuación.

El objetivo de este estudio es caracterizar la enseñanza en primaria multigrado a través de un estudio de caso en una primaria unitaria, sobre las decisiones docentes relacionadas con la enseñanza de las matemáticas. En telesencundaria, se analiza a través de otro estudio de caso, los saberes matemáticos y extra matemáticos que se construyen mediante un diseño de naturaleza interdisciplinaria, como estrategia curricular para la enseñanza de las matemáticas.

Marco teórico

Este estudio se inscribe en una perspectiva sociocultural de la educación matemática. Nos posicionamos con respecto al proceso de enseñanza y aprendizaje de las matemáticas, como un aquel en que intervienen factores sociales y culturales en contextos escolares y extraescolares en diversos ambientes económicos, políticos y multiculturales (Blanco, 2011).

Toma de decisiones docentes en aula multigrado

Arteaga (2011) hace referencia a que el trabajo del docente dentro del aula está regido por saberes que regulan su actividad, los cuales se basan en un tipo particular de conocimiento que frecuentemente, no está sistematizado. Esto implica la solución de problemas que las condiciones de trabajo presentan, además de una reflexión sobre el trabajo diario. Estos saberes y experiencias nutren la práctica docente y con ello las relaciones que existen entre diversas propuestas curriculares. Se reconoce como un referente teórico a la etnográfica, para sustentar el estudio de la complejidad de las prácticas docentes, en las cuales están inmersas también variables institucionales, sociales y personales (Rockwell y Mercado, 2003). Consideramos que estos saberes determinan la toma de decisiones docentes. Algunos autores (Schoenfeld, 2008; Thames y Ball, 2013, citados en Garzón, 2017) han centrado la atención en la toma de decisiones del profesor en los “momentos de enseñanza”, aquellas situaciones de una clase en que emergen oportunidades pedagógicas que posibilitan la transformación del pensamiento matemático del alumno. Stockero y Van Zoest (2013) reconocen que los momentos de enseñanza y la toma de decisiones pueden ser evaluadas a fin de establecer su influencia en el aprendizaje de los alumnos. Las decisiones se caracterizan en los diferentes recursos que usa el docente para lograr su tarea y pueden variar de acuerdo a la organización que use dentro del aula, la forma en que los alumnos se involucren, las estrategias de gestión e intervención, o la manera en que se promueva el trabajo individual y colectivo.

La interdisciplina para la enseñanza de las matemáticas

García (2016) reportó una estrategia utilizada en la práctica de los docentes de telesecundaria, la cual consiste en el uso de situaciones transversales. Las actividades de esta estaretgia pretenden construir significados de varias asignaturas, destacando la manera en que se vinculan. Con este significado que los docentes le otorgan a la transversalidad se corre el riesgo de que los saberes –matemáticos y no matemáticos– se perciban triviales. Velásquez (2009) define a la transversalidad como una estrategia curricular mediante la cual algunos ejes o temas considerados prioritarios impactan todo el currículo; es decir, están presentes en todos los proyectos y actividades que producen los estudiantes, como el medio ambiente, el tiempo, la lengua maternal. Magendzo (1998) considera una concepción reconstruccionista de la transversalidad, la cual está ligada a temas que hacen referencia a los problemas y conflictos de gran trascendencia que se producen en la época actual. Se tratan de atender problemáticas sociales como la corrupción, el abuso infantil, la polución y se entienden como temas trasversales la educación para la paz, la educación moral, la educación vial, la educación del consumidor, la educación sexual, entre otros.

Otra aproximación sobre la vinculación de contenidos se realiza desde la interdisiciplinaridad. De acuerdo Klafki (1998) la enseñanza y el aprendizaje interdisciplinarios en la escuela no es una nueva reforma pedagógica y mostró ventajas en la comprensión de contenidos a través de muchos experimentos de enseñanza interdisciplinarios. Sin embargo, algunas limitantes para definir con precisión las características de una enseñanza que promueva la interdisciplina es la falta de claridad y consenso sobre los conceptos de disciplina, la forma de describir las intervenciones y programas interdisciplinarios, así como la falta de consistencia para identificar y medir los resultados de aprendizaje que (Williams et al., 2016).

En esta investigación se propone documentar los saberes matemáticos y no matemáticos construidos utilizando una estrategia de enseñanza en telesecundaria que vincule contenidos, por lo que nos posicionamos desde la interdisciplina, como una forma de construir significados sobre al menos dos disciplinas, a través de una situación de modelación matemática. La modelación matemática se ha estudiado ampliamente, reconociéndose como un paradigma de enseñanza el uso de los modelos para el aprendizaje de distintos conceptos (Vorhölter, Kaiser y Borromeo, 2014), con el fin de establecer una relación entre las matemáticas y el resto del mundo.

Metodología

Se documenta un estudio de caso en una primaria multigrado unitaria en el municipio de Pinal de Amoles, Querétaro, México. La comunidad tiene alto índice de marginación y los problemas sociales emergentes son altos índices de alcoholismo, drogadicción, vandalismo y migración nacional y a Estados Unidos. La escuela es rural unitaria y se compone de 20 niños: 5 en segundo grado, 6 en tercero, 3 en cuarto, 4 en quinto, 2 en sexto. En cuanto a infraestructura, se cuenta solo con dos aulas, una que se utiliza como biblioteca y sala de medios y la otra, como aula de clase. Se realiza trabajo etnográfico al interior del aula, con la finalidad de llevar registro en audio y video de varias sesiones de clase. Adicionalmente, se realizan entrevistas a la maestra para conocer sus planeaciones, adecuaciones curriculares y materiales utilizados.

La telesecundaria se ubica en un contexto rural en la comunidad de La Laborcilla, en Querétaro, México. En la escuela sólo hay un grupo para cada grado escolar y el grupo de estudio está conformado por 18 estudiantes de tercer grado, sus edades oscilan entre los 14 y 15 años. En esta investigación nos interesa analizar la implementación de una estrategia que nos permita contextualizar contenidos matemáticos y propiciar un tratamiento interdisciplinario. El diseño de la situación interdisciplinaria se fundamenta en el problema de la Separación Ciega de Fuentes (Blind Source Separation-BSS) (Vázquez, Romo, Romo-Vázquez, y Trigueros, 2016). Se realizará un diseño situacional y secuencial, en el que se pongan en juego hipótesis de construcción de conocimiento de cómo tendría que darse el proceso entre las disciplinas: matemáticas y física. Se implementará el diseño y reportarán los resultados del aprendizaje generado sobre saberes matemáticos y saberes no matemáticos.

Discusión y Conclusiones

La docente de la primaria unitaria está a cargo de la escuela, atiende a los alumnos, realiza actividades de dirección, organiza la limpieza de las instalaciones y están en contacto con los padres de familia. Proviene de una institución formadora de maestros y lleva dos años enseñando en multigrado. Atiende de manera simultánea a sus alumnos, organiza y planifica las tareas matemáticas de tal manera que pueda entretejer los contenidos de las asignaturas y grados, evitando planear y dividir los temas por grados. Sus decisiones están centradas en la planeación previa a su intervención en el aula. Consideramos importante visibilizar y sistematizar los saberes que subyacen a las decisiones de la maestra, así como impulsar estudios desde la educación matemática que contribuya a caracterizar los procesos de enseñanza y aprendizaje que ocurren en estas modalidades.

La estrategia curricular de situaciones integradoras transversales vistas desde la perspectiva de la interdisciplina, puede reconceptualizar la práctica de los docentes de telesecundaria, pues para hacer un diseño con estas características, se requiere romper con un paradigma de una vinculación muchas veces limitada de contenidos, hacia un estudio de situaciones de modelación matemática, para dotar de significados a los objetos matemáticos a través de nuevos contextos, en los cuales los discursos de otras disciplinas se mezclan para producir conocimiento.

Se ha destacado la problemática del aprendizaje de las matemáticas en escenarios socioculturales diversos en cuanto a formas de organización escolar. Para muchos niños y jóvenes, la primaria multigrado y la telesecundaria son las únicas opciones de acceso a la educación en esos niveles. Si el currículo nacional es estandarizado, basado en una concepción homogénea y graduada de los grupos escolares y adecuado para ciertos contextos urbanos, no se está promoviendo un acceso equitativo a la educación. El estudio presentando pretende ser un aporte sobre las diferentes estrategias que emplean los docentes de estas modalidades para potenciarlas y seguir proponiendo formas de abordar la construcción de significados de los objetos matemáticos en el aula.

TEACHING MATHEMATICS IN MULTIGRADE SCHOOLS AND TELESECUNDARY SYSTEM

Mathematics teaching faces specific problems and challenges in two modalities of basic Mexican education: multigrade schools and telesecundary systems. This study analyses the strategies used to adapt and organize the teaching of mathematics in a one-group elementary school and in a telesecundary system in rural contexts. Elements of teaching-practice and the effects on students' mathematics activities are presented in two scenarios. On one hand, the one-group teacher designing general mathematic activities and diversified-age task to teach mathematical concepts. On the other, a telesecundary system teacher designing interdisciplinary situations to construct meanings for mathematics and physics.

Recent shifts in curriculum standards have led to a greater emphasis on students' conceptual understanding of mathematical topics (National Council of Teachers of Mathematics, 2000; National Governors Association, 2010). The discussion in mathematics education about the benefits and limitations of both teaching for conceptual understanding and teaching for procedural understanding is not a new one (Brownell, 1947; National Research Council & Mathematics Learning Study Committee, 2001; Skemp, 1976). Using lesson study as a tool to study the implementation of reform-oriented instruction (R Huang, Kimmins, Winters, Douglas, & Tessema, 2017; Rongjin Huang, Barlow, & Prince, 2016; Rongjin Huang, Zhang, Chang, & Kimmins, 2018), the researchers have identified a unique perspective to enrich this discussion by Comparing and contrasting two research lessons from two lesson study groups.

Using data collected from each separate lesson study group (one in China and one in the United States), key differences in pedagogical choices between the two research lessons are salient -. The data for this comparison consisted of lesson plans and verbatim transcripts of instruction. As the Chinese lesson was taught in Chinese, it was transcribed verbatim in Chinese, and then translated to English for analysis.

The Chinese lesson introduced the topic additive comparison, using a game to develop a best strategy for comparing sets. The students then worked several variations of practice problems to emphasize the mathematical structure of additive comparison. The lesson was intended to guide students to understand the underlying invariant structure within various contexts and representations. Instead, it led to an emphasis on rote student procedures relating to the comparison of sets.

The United States lesson introduced the topic by developing an illustrative definition of additive comparison. The students engaged with different representations of comparison using familiar objects before working independent practice problems. This afforded students the opportunity to find strategies to solve problems and explain their reasoning to the class. While the students produced many strategies for attaining solutions, many were not representative of the additive comparison model.

These lessons offer a distinct perspective on instructional balance (Sfard, 2003). The Chinese lesson offers an emphasis on the use of structure; however, students are given few opportunities to make sense of the structure. The United States lesson offers students a chance to reason about a problem solving method; however, it fails to provide connection to the mathematical structure. Baroody, Fiel, and Johnson (2007) proposed that conceptual and procedural knowledge develop mutually. However, both lessons presented material from a procedural aspect, leaving conceptual development minimally attended within the lessons. Structure and strategy must both be present to attain the goal of conceptual understanding.

TEACHERS' STORIED PERCEPTIONS OF STUDENTS AS LEARNERS OF MATH

Mari Altshuler
Northwestern University, School of Education and Social Policy
marialtshuler@u.northwestern.edu

Keywords: Affect, Emotion, Beliefs, and Attitudes; Teacher Knowledge

Math is a highly polarizing subject, and there are great inequities in the field within and outside of schools (Boaler & Greeno, 2000). In order to expand access to positive mathematical trajectories for young students, we need to understand how students view themselves and how others view them both as people at large and in relationship to mathematics specifically (Aguirre, Mayfield-Ingram, & Martin, 2013). Students' math identities emerge through experiences and through stories that students, peers, parents, and teachers tell about who students are as math learners, and those identities impact students' interest in, commitment to, and success in mathematics (Langer-Osuna & Esmonde, 2016). In particular, teachers' perceptions of students and their responses to students in math class play critical roles in how students begin to identify themselves in relation to math (Erickson, 2011; Russ, 2018; Horn, 2007; Bertrand & Marsh, 2015). This study explores teachers' perceptions of their students by gathering teachers' stories. The study asks: How do K-3 teachers describe their students as learners of math?

Data for this study consisted of 11 semi-structured, one-on-one interviews with K-3 classroom teachers in a diverse, public, midwestern school district. During the 45 min–1hr interviews, teachers moved through their rosters in an order of their choosing, describing each student in relation to math. Teachers described between 8 and 15 students each, and approximately half of the teachers referred to student work samples during the interviews. I used in vivo coding (Miles, Huberman, & Saldaña, 2014) of the interview transcripts to identity themes across stories about students and highlight characteristics that emerged as salient to teachers. Clustering descriptors and comparing students who were described similarly revealed emergent patterns in the ways teachers understand their students as math learners.

Analysis revealed that when K-3 teachers described their students as math learners, they included distinct judgements about students' performance in math class and their aptitude for math in addition to descriptions of students' personalities, effort and engagement, emotional and behavioral development, and family context. Teachers described these characteristics in repeated combinations, suggesting that there are archetypal ways in which teachers categorize math students. These archetypes are predominantly not described by teachers in wholly positive or negative lights, but rather paint nuanced pictures of students' engagement with math class and the discipline of mathematics.

What that nuance means for the complex relationship between how teachers understand their young students as math learners and their instructional decisions and interactions with students remains an open question. Continuing to unpack these relationships is critical for understanding how young children begin to develop mathematical identities and for supporting students on their mathematical journeys through and beyond their time in school.

USING PROFESSIONAL DEVELOPMENT TO CREATE A COLLABORATIVE KNOWLEDGE BASE FOR LAUNCHING

Rob Wieman
Rowan University
gomathman@yahoo.com

Kim Johnson
West Chester University
kjohnson2@wcupa.edu

Keywords: Instructional Activities and Practices, Teacher Knowledge, Research Methods

Background: The Problem

The work described by this poster lies at the intersection of two problems in mathematics education, the need to develop a knowledge base for teaching that bridges the gap between research and practice and the need to develop a shared set of methods for effective launching.

There is widespread agreement that how teachers launch demanding tasks determines the learning opportunities that students may have (Jackson, Garrison, Wilson, Gibbons & Shahan, 2013). Experts agree that students need support in making sense of problems, accessing prior knowledge, and identifying important mathematical relationships, but too much support can lower the task's demand. The field lacks research that describes, in detail, the purpose of a launch, typical challenges in launching, and effective moves for launches (Wieman, et al., 2018).

There is a profound gap between educational research and practice, contributing to the lack of a widely shared knowledge base for teaching. In response, researchers have called for collaboration with teachers to identify important research questions and share, disseminate, and preserve shared professional knowledge for teaching (Hiebert, Gallimore, & Stigler, 2002).

Types of Launches: Types of Problems

In 2018 the PME-NA working group on launching engaged participants in sorting tasks according to how they might launch them (Wieman et al., 2018), leading participants to discuss which types of problems might go with certain types of launches. In this poster, we describe professional development involving participants using similar activities to answer two questions:

- What types of launches do teachers say they use, and with what types of tasks?
- How does this activity help us build a collaborative knowledge base for teaching?

Connection to Conference Theme

Educational research can disempower teachers, and poorly launched contextual can create barriers for students. This work is an effort to move beyond the present horizon, accessing teacher knowledge to inform research and open up learning opportunities for all students.

THE BALANCING ACT: MEETING THE SOCIAL-EMOTIONAL NEEDS OF STUDENTS AND ACCOMPLISHING LEARNING GOALS

Sara Gartland
University of Delaware
sgart@udel.edu

Keywords: Equity and Diversity, Culturally Relevant Teaching, Instructional Activities and Practices

As Rochelle Gutierrez notes "giving voice to the contextual factors that enable or constrain learning in a given situation is equally important" as identifying best practices and effective interventions (2012, p. 18). Kozol's (2005) indictment of the conditions under which urban elementary schools must operate highlights an important and understudied contextual factor in mathematics education – that "the issues are big; children are small" (p. 285).

Specifically, the stress associated with living in poverty may manifest in emotional outbursts that can derail classroom activities (Brantlinger, 2018). However, it has been shown that a sense of belonging can influence students' connection to school, academic motivation, and wellbeing (Maestas, Vequera, & Zehr, 2007; Tyler, Uqdah, Dillihunt, Beatty-Hazelbaker, Conner, Gadson, Henchy, Hughes, Mulder, Owens, Roan-Belle, Smith & Stevens, 2008). Furthermore, a sense of belonging fostered by teachers described as "warm demanders" (Delpit, 2012) helps students productively engage with mathematics (Allexsaht-Snider & Hart, 2001). Thus, I hypothesize that addressing students' social-emotional needs by attending to their feelings of belongingness may lead to better learning outcomes for students.

To begin exploring this hypothesis, I observed a third-grade mathematics teacher at a high-needs public elementary school located in a mid-size US city. The school serves approximately 450 students enrolled in Grades 3-5 who identify as: 76% African American, 18% Hispanic/Latinx, 2% Multi-Racial, 2% White, 1% Asian, and 1% American Indian. To best serve the needs of a low-income population, the school employs two sets of curricula: The Common Core State Standards and a social-emotional learning curriculum. Additionally, teachers have participated in training on trauma-informed teaching.

The research question for this study is: in what ways does a third-grade teacher address the social-emotional needs of students and work to meet mathematics learning objectives? Observation data were analyzed using a grounded theory approach (Strauss & Corbin, 1994) and coded using an open coding process (Hatch, 2002). Conversations with the teacher throughout the analysis stage occurred to refine codes and verify interpretations.

Analysis revealed three salient findings. First, the coupling of the teacher's high expectations for behavior and learning with her use of repetition as a support strategy addressed students' social-emotional and mathematical needs. Second, incorporation of student voice to drive the lesson content and structure emerged as a way in which the teacher fostered belongingness. Third, the teacher consistently used student names to personalize the learning process and give students ownership of the ideas they generated.

These findings are unique in the field, providing both actionable best practices and a foundation for continued exploration of the topic. They answer a question not frequently asked specifically within a mathematics context. Also, they serve as an initial step in unpacking what it means to address student's social-emotional needs *and* mathematical needs. Moving forward, this study will inform the framework and methodology for an expanded and more in-depth study.

Keywords: Classroom Discourse, Instructional Activities and Practices, Communication

Engaging in productive mathematical discourse supports students to improve their mathematics learning (NCTM, 2014). The authority structure within a class can determine the efficacy of this discourse. Authority has been examined from a variety of lenses. Wilson & Lloyd (2000) distinguish between *pedagogical* and *mathematical* authority, which focus on orchestrating classroom activity versus making mathematical contributions. Herbel-Eisenmann & Wagner (2010) explored authority in mathematics classrooms by relating stance bundles to interpersonal positioning. This proposal investigates how authority distribution might be operationalized within a classroom.

Inspired by Amit & Fried (2005), we define *authority* as a dynamic and negotiated relationship between people where one party defers to another within a mathematical situation. Drawing from Goffman (1981), we consider three key activities to operationalize authority for our framework: (1) Authorship, (2) Animation, and (3) Assessment of the mathematical ideas. We used our framework (referred to as the AAA Framework hereafter) to analyze authority relations during whole-class (WC) discussions in 1 lesson from 4 middle-grade classrooms. Every lesson was broken into *segments*, each a series of turns of talk with a common focus and a consistent form of participation, that were then coded using our framework. From this, we were able to determine (1) whose idea the segment was grounded upon, (2) which individuals were contributing to the conversation and by which mode, speaking and/or scribing, and (3) who was evaluating mathematical aspects of the conversation. (See Table 1 for a coded segment.)

Table 1: Example of AAA Framework

5th-graders discuss strategies and symbolic notation for sharing 3 sandwiches amongst 4 kids
Teacher: Okay. Tell us about person two’s strategy. *Lexi*: I think that person was giving a ½ to 2 people [at board gesturing], like 2 of the 4 kids, and then she had 2 [sandwiches] left. So she did it again. And then she realized that right here [gestures to student work on board] she only had, uh, 1 [sandwich] left. So she couldn't do a ½, because then it wouldn't be equal to everyone. So she did a ¼ 4 times to get that last whole. And then her answer was a h-- not a ½. Was ¾. [Lexi writes ½ + ¼ and sits down.]
Author – Student, **Animate Speak** - Student, **Animate Scribe** – Student, **Assessment** – None

We found that although all students participated in Speaking in whole-class discussion, there was large variation in students’ opportunities to Author mathematical ideas (i.e. students as sole or shared authors ranged from 15 to 100% of WC discussions). Additionally, half of the teachers maintained control of the board; whereas the other half allowed students sole authority to Scribe at the board in over half of the WC discussion. Further analysis will be presented on the poster.

UNDERMINING A DISCOURSE

Christopher Leatherwood
Northwestern University
chrisleatherwood@gmail.com

Keywords: Classroom Discourse, Instructional Activities and Practices, Communication

Discourse is central to understanding many classroom interactions, and in regard to math classrooms this importance has been seen in shifts within the curriculum standards (Common Core, 2010; NCTM, 1991; 2000), researcher community (Knuth & Peressini, 2001; and for extensive review see Walshaw & Anthony, 2008), as well as preservice instruction and professional development focused on implementing and/or improving discourse in the classroom (McDonald et al., 2013; Kazemi et al., 2016; Borko et al., 2008;). However, discourse is not monolithic; different contexts or forms invite different opportunities for participation and learning. The context of this research was error episodes in middle school math classrooms. Error episodes were defined as bounded events (Bloome et al., 2004) that included the introduction of an error, the interaction that error produced, and the completion of the interaction in which the error was the focus. I focused on these moments because even though there has been a shift away from an identify and eliminate model (in regard to errors) in both researcher and practitioner communities (Kramarski, B., & Zoldan, S. 2008; Lannin et al., 2007; Common Core, 2010), this model continues to influence day to day classroom interactions (Bray, 2013; Cohen, 1990; Santagata, 2004). This study seeks to understand how discourse is shaped within these moments and how participants come to understand and interact within this discourse.

Data for this study consisted of video recordings of one 8th grade classroom at School Insight International Charter School. School Insight is a K-8 charter school located in a Midwestern city. 98% of the student body identified as African-American, and the school is self-described as African-centered. Using conversation analysis notation (Sacks, Schegloff and Jefferson, 1978), I present one portion of an extended error episode. This interaction was chosen because it was one of the longest error interactions in the data corpus.

Analysis revealed that there was a recognizable discourse around errors with particular rules for entry and rules governing the interaction itself. These rules involved not confronting the error itself but giving the correct procedure to solve the problem at hand. The student in the interaction first adhered to these rules by presenting her misunderstanding as a computational issue. She then attempted to reframe this discourse before outright rejecting it by stating that her misunderstanding was not housed within the problem itself, but that her misunderstanding was in how she conceptualized parentheses in general.

There are implications to teaching and learning with this error discourse. For students who understood that their misconceptions couldn't be addressed with the correct procedure, they had to navigate this discourse to force it to resolve their mistakes by reframing or rejecting the discourse. Students who simply followed this discourse without challenge rarely had their underlying misconceptions addressed at all. Moving forward it is necessary to see if this type of discourse is specific to mathematics, or if it also exists in error episodes in other fields. Also, because students internalized this error episode discourse, it is imperative that we analyze how this interpretation impacts individual student identities and participation around errors.

BENEFITS AND CHALLENGES TO MATHEAMTICS TEACHER EDUCATORS' INSTRUCTION USING ELECTRONIC JOURNALS WITH PRESERVICE TEACHERS

Heather Gallivan
University of Northern Iowa
heather.gallivan@uni.edu

Chepina Rumsey
University of Northern Iowa
chepina.rumsey@uni.edu

Keywords: Technology; Instructional Activities and Practices

The benefits of utilizing technology in the mathematics classroom are numerous and include improved students' learning of mathematical content (Lim, Son, Gregson, & Kim, 2018) and supporting teachers' learning (e.g., Seago, Koellner, & Jacobs, 2018). However, few studies have looked at how technology can be used by mathematics teacher educators (MTEs) to support their planning, instruction, and formative assessment practices. Studying MTEs' practices over time can provide the field with insights into MTE development (Tzur, 2001) as well as practical knowledge for the field (Arbaugh & Taylor, 2008). New electronic journal technology has the potential to support MTEs with their planning, instruction, and formative assessment practices while teaching mathematics content courses with preservice teachers (PSTs). The electronic journals function like a paper journal, but utilize cloud technology such that PSTs' written work can be uploaded to a Google Drive folder as a PDF. As with any new technologies, it can be beneficial to document both the benefits and the challenges faced by MTEs when using them.

Purpose and Methods

The goal of this narrative study is to determine the impact of using electronic journals with elementary PSTs on two MTEs' abilities to manage the challenges of using these journals and to adjust their instruction to meet the needs of their students. The two MTEs were the instructors of a mathematical problem solving course for elementary PSTs across two consecutive semesters where they utilized the electronic journals. Narrative inquiry methodology was employed for this study to document the experiences of the MTEs across two semesters as they used the journals for the first time and made adjustments for the second semester in their planning, instruction, and formative assessment practices in response to challenges they faced. Both MTEs kept a journal to document their experiences using the electronic journals. Additionally, the electronic journals the PSTs' kept throughout the semester were downloaded and they were asked to respond to an open-ended survey regarding their use of the journals. Data from these sources will be used to provide support to the narratives of the MTEs.

Results and Discussion

There were several benefits to using the electronic journals for both MTEs. Because the MTEs had daily access to PST writing, (1) they were able to use the PSTs' writing to plan for future lessons and (2) the MTEs had more flexibility when providing formative feedback because there was no need to collect and carry the physical journals around. However, both instructors experienced similar challenges. For instance, both MTEs struggled with how to hold PSTs accountable for writing during class as well as for reading and responding to feedback. Thus, for the second semester, the MTE's made adjustments to their formative assessment practices to address these issues. With the advent of electronic journal technology, there are going to be challenges to overcome in implementation so that MTEs can use them effectively.

The narratives from both MTEs can provide practical knowledge for the field and the process MTEs go through to learn to implement new technologies.

Keywords: Mathematical Modeling, Classroom Discourse, Instructional Activities and Practices

Mathematical modeling has become increasingly pertinent to mathematics education due to its benefits on student learning and engagement (e.g., Blum & Niss, 1991; Lesh, Hoover, Hole, Kelly, & Post, 2000; Zbiek & Conner, 2006). One integral aspect of mathematical modeling is mathematical discourse (Lesh et al., 2000), which activates and builds students' background knowledge (Henningsen & Stein, 1997). Productive mathematical discourse promotes the sharing of ideas, expands upon student thinking, clarifies understandings, and fosters credible argumentation (Smith, Steele, & Raith, 2017). While research has been sufficiently conducted on classroom discourse (Boaler & Brodie, 2004; Chapin & O'Connor, 2007; Chapin, O'Connor, & Anderson, 2003; Reinhart, 2000), little is known about discourse and teacher discussion strategies unique to mathematical modeling. This study aims to answer the question, "What discussion strategies specific to mathematical modeling promote students' diverse thinking and facilitate productive mathematical discourse associated with mathematical modeling problems?"

The study examined the implementations of three mathematical modeling activities with 21 middle-grade students. We analyzed the video transcripts of classroom interactions and students' written work using analytical-inductive methods, which included a-priori codes from literature on discourse (e.g., Chapin & O'Connor, 2007; Chapin et al., 2003; National Council of Teachers of Mathematics, 2014) and new codes for mathematical discourse developed using the constant comparative method (Glaser, 1965).

Preliminary Findings

Analyses and coding of the lesson transcripts demonstrated a toolkit of discussion strategies which harnessed the unique aspects of mathematical modeling. Teachers facilitated discourse by relevantly recontextualizing the problem, probing students' responses for assumptions, encouraging multiple perspectives, stimulating students' decision-making, emphasizing students' reasoning, promoting common language, and prompting revision of students' thinking. Students presented diverse thought processes within the mathematical discourse, as well. Specifically, analysis of students' written solutions and the transcript showed diversity in students' mathematical approaches, which resulted in manifold, valid solutions. Further, the use of these strategies generated productive mathematical discourse; that is, students shared their ideas, expanded on each other's thinking, formed convincing arguments, and clarified understandings. In our session, we will present how productive discourse can be used in conjunction with authentic, open-ended tasks and report the positive student outcomes associated with discussion strategies specific to mathematical modeling.

HOW DO TEACHERS' ARTICULATED VIEWS RELATE TO THEIR IMPLEMENTATION OF EQUITABLE TEACHING PRACTICES?

Jonee Wilson
North Carolina State University
jwilson9@ncsu.edu

Keywords: Inclusive Education; Culturally Relevant Teaching; Instructional Activities and Practices; Classroom Discourse

Mathematical *Standards* (NCTM, 2014; CCSSM, 2010) lay out rigorous goals for "all" students' learning (Franke et al., 2007). However, *Standards*-based mathematics instruction remains uncommon and opportunities for students to develop the understandings outlined in the *Standards* are not equally distributed. In fact, it has been well documented that the quality of mathematics instruction and learning opportunities in US schools, particularly in classrooms serving majority students of color and students for whom English is not their first language, is typically of inadequate quality and at best supports the development of procedural competence (e.g. Boston & Wilhelm, 2017; Hill & Lubienski, 2007; Nasir & Cobb, 2002).

One proposed reason for this phenomenon is that most teachers do not view _all_ students as capable of participating in *Standards*-based mathematics activity and many teachers attribute the sources of students' mathematics difficulty to inherent traits of the students. In fact, research offers evidence of a relationship between teachers' views and the *quality of the activities in which students have an opportunity* to participate (Jackson et al., 2017; Wilhelm et al., 2017). However, research connecting teachers' views of students to the extent to which the *practices implemented by the teachers are equitable* is absent from the literature (i.e. research already connects teachers' views to *what* the students have a chance to experience, but not *who* is participating or *how* students are being supported).

My analysis addresses this gap by examining data (surveys, interviews, and video-recorded lessons) collected from 16 in-service teachers at multiple points in their first-year of teaching. Munter (2014) provides a framework for classifying teachers' articulated visions of high-quality mathematics instruction and Jackson et al. (2017) provide a framework for classifying teachers' views of students' mathematics capability. I used these frameworks to guide my analysis and coding of the interview and survey data. Boston (2012) provides a framework for classifying the quality of instruction and Shah and Reinholz (Reinholz & Shah, 2018; Shah et al., 2016) provide an approach for conceptualizing equity in terms of participation patterns, which I used to analyze and code the video-recorded lessons. I also used a set of rubrics (the Equity and Access Rubrics for Mathematics Instruction, EAR-MI) developed to capture practices aimed to support marginalized students in gaining access and more equitably participating in rigorous mathematics activity (Wilson et al., Accepted) to analyze and code the extent to which the practices implemented by the teachers were equitable. I report on differences and patterns seen across these different codes within the group of 16 teachers and share qualitative findings from "deep dive" comparative case studies based on scores from the rubrics.

Preliminary findings indicate that despite articulating strong commitments to equity and productive views of students' capability, the practices implemented by some teachers still reify inequalities found in many mathematics classrooms. Findings also suggest that in order to support teachers in developing more equitable practices, it is not only important to support shifts in their views, it is also important to support a reconceptualization of their roles as math teachers.

THE INSTRUCTIONAL PRACTICES OF SECOND-YEAR ELEMENTARY TEACHERS: DOES THE TEACHER PREPARATION PROGRAM MATTER?

Temple A. Walkowiak
NC State University
tawalkow@ncsu.edu

Heather M. West
NC State University
hmwest@ncsu.edu

Elizabeth L. Adams
Southern Methodist University
eladams@smu.edu

Keywords: Elementary education, Instructional practices, Teacher education-preservice

Teacher education has been subject to much scrutiny in recent years about whether preparation programs matter (e.g., Peck et al., 2014) with calls to conduct investigations after graduates enter their career (Cochran-Smith & Zeichner, 2005). Although this type of work is resource-intensive, there are examples of researchers investigating impact of teacher preparation (e.g., Henry et al., 2014). However, there are very few examples of researchers systematically following graduates (e.g., Morris & Hiebert, 2017), particularly in the area of elementary mathematics. The current study is unique in its aim to understand if a mathematics-intensive elementary teacher preparation program (TPP) matters for the instructional practices adopted by teachers early in their careers. Using a quasi-experimental design, the overarching research question was: Are there differences between the *frequency* and *quality* of learning opportunities provided by teachers from the focal TPP and comparison TPPs?

This study took place in the context of a STEM-focused elementary teacher preparation program where the candidates take more mathematics-related courses than is typical. Specifically, they take 12 credits (4 courses) of mathematics content (two of which were specifically designed for them), 2 mathematics methods courses that anchor pedagogy around K-5 number/operations mathematical content, and 1 instructional design seminar focused on developing, implementing, and analyzing a series of mathematical tasks.

The participants in this study were recruited purposefully using propensity score matching. We matched graduates of the focal TPP (n=49) to graduates of other elementary TPPs (n=96) in the same state using pre-program covariates (e.g., high school GPA, SAT score). During their second year of teaching, the teachers completed a teaching log (Walkowiak et al., 2018) for 45 days at three 15-day time points. The log includes questions about the *frequency* of opportunities for students to engage in particular behaviors (e.g., using pictorial representations). Also, three video-recorded mathematics lessons were coded using a quantitative observational protocol that attends to the *quality* of the students' learning opportunities (Walkowiak et al., 2014).

We fit a series of doubly-robust hierarchical linear models with inverse propensity weights to test the effect of the focal TPP on second-year teachers' use of instructional practices. Results indicated that graduates of the TPP reported using math talk more frequently, as measured by the log. Also, graduates of the focal TPP: facilitated higher quality discourse in their classrooms; utilized and translated between representations in more meaningful ways; and facilitated lessons that were more coherent in structure. These results suggest that mathematics-intensive preparation matters for elementary teachers, but more research should investigate why there were no effects in relation to the mathematical tasks the teachers implemented.

MEANINGFUL MATHEMATICS: NETWORKING THEORIES ON MULTIPLE REPRESENTATIONS AND QUANTITATIVE REASONING

Nicole L. Fonger
Syracuse University
nfonger@syr.edu

Nigar Altindis
Syracuse University
naltindi@syr.edu

This paper articulates a stance on the study of students' meaningful mathematics understanding with multiple representations. We integrate Thompson's theory of quantitative reasoning and Dreyfus' theory of multiple representations in our approach to frame and conduct empirical investigations of the study of meaningful understanding of function. We provide empirical data to support our approach to examining representational fluency and functional thinking from this networked stance. Our research articulates how the coordination of theories can be productive in informing the design, conduct, and analysis of contexts aimed to understand students' meaningful math learning with a focus on functional thinking.

Keywords: Functional thinking, Representational Fluency, meaning, Quantitative Reasoning, Multiple representations, Networking theories

Motivation and Aim

The complexity of studying and bolstering students' conceptual understanding of mathematical ideas remains a key challenge in mathematics education (Drijvers, 2019). In studying such a complex phenomena, Sfard (1998) articulates a tension of relying on one metaphor or theory of learning to the detriment of another. Consistent with this view on a need for multiple theories, in this work we aim to coordinate two theoretical orientations on understanding the mathematical idea of function—multiple representations and quantitative reasoning. Networking theories is one approach to theory development to advance knowledge in the field of mathematics education that may help to address such key challenges (BiknerAshbahs & Prediger, 2010; Cobb, 2007; Johnson & McClintock, 2018; Johnson, McClintock, Gardner, 2019). As such, this theoretical report is driven by an aim to coordinate theories for the purpose of developing new theory (cf. Cobb, 2007), not to supplant or replace existing theories.

We aim to network theories to better articulate a local theory for the purpose of addressing an enduring challenge of characterizing meaningful learning of mathematics with multiple representations. This theoretical report seeks to extend prior studies by offering both (a) a step toward the articulation of theory development focused on meaningful learning vis-à-vis the networking of theories, and (b) additional empirical investigation of the relationship between students' conceptions of functions and representational fluency. This aim emerged from both a review of empirical studies in the domain of scholarship on functions, a functions approach to mathematics, and functional thinking (e.g., Cai et al., 2010; Stephens et al., 2017a; Stephens et al., 2017b), and a discernment for the utility of networking of theories to expand possibilities for framing problems and understandings (e.g., Cobb, 2007).

In this report we also enact some of the recommendations and lessons learned from participating in a recent international conference working group focused on theoretical perspectives, networking theories, and methodological implications (Bikner-Ashbahs, Bakker, Johnson, Chan, 2019). We focus on the following recommendations of the working group as a structure for this report: (a) elaborate how the networking of theories helps to address a research problem, (b) take care in elaborating not only theoretical constructs being coordinated but background theories and underlying assumptions, and (c) communicate how the networking of theories and methodologies are in symbiotic exchange in all phases of research. We draw on empirical findings to bring these issues to life.

Theoretical Orientation on Meaningful Learning

Meaning is a creative act. Our current framing of meaningful understanding involves a critical focus on students conceptual or relational understanding (Skemp, 1976). We follow Lobato's (2013) articulation of concept to include meanings to include: (a) "*meanings*, which refer to one's interpretation of situations, conversations, symbols, and operations (Thompson & Saldanha, 2003; Voigt, 1994); and (b) *connections*, which include the specific links or ways of integrating representations, ideas, objects, and/or situations (Hiebert & Carpenter, 1992; Hiebert & Lefevre, 1986)" (emphasis in original, p. 2-3). From this stance, a person (e.g., student) is viewed as active in their meaning-making processes through the activities of creating and interpreting invariant features among representations.

Multiple Representations

We conceptualize representations as different "faces" of the same mathematical object; looking at an object through only one representation cannot reveal all features of the object (Kutzler, 2010). Representational fluency (RF) is "the ability to create, interpret, translate between, and connect multiple representations" in doing and communicating about mathematics (Fonger, 2019, p. 1). The notion that "using multiple representations" supports students' conceptual understanding of mathematics is prevalent in mathematics education research, practice, and policy in the United States (e.g., NGO & CCSSO, 2010; NCTM, 2000, 2014). Some argue that creating and interpreting representations are "important cognitive processes that lead students to develop robust mathematical understandings" (Huntley, Marcus, Kahan, & Miller, 2007, p. 117). This work draws predominantly on a theory of multiple representations (e.g., Dreyfus, 1991; Lesh, Post, Behr, 1987).

From this theoretical stance, scholarship contributes to an understanding of how the practices of representing and the processes of learning are complexly intertwined and emerge over time in symbiotic relation (Fonger, 2019; Selling, 2016). However, a lens on characterizing sophistication in representational fluency alone is often insufficient for garnering evidence of the nature of students' meanings of mathematical objects. Thus, to attend to the goal of studying meaningful learning with multiple representations, a coordination of lenses is needed (as we have argued in earlier work Fonger, 2019; Fonger, Ellis, Dogan, 2016). In our work, we aim to grow our theoretical orientation on meaningful learning to include not only students' representational activity in creating and connecting representations, but also hypotheses of the *meanings* students hold of the mathematical objects being represented.

Quantitative Reasoning and Functional Thinking

We narrow our focus in this report on the domain of scholarship on supporting and characterizing students' understanding of students' functional thinking (FT)—the ability to generalize and represent functional relationships (Stephens et al., 2017a; Kaput, Blanton, & Moreno, 2008). There is a growing body of work in this domain that draws on Thompson's theory of quantitative reasoning (Thompson, 1994, 2011). Much of this work is grounded in constructivism a background theory of learning (Glasersfeld, 1995; Piaget, 2001). From this perspective, an individual constructs knowledge through processes of assimilation and accommodation, creating mental models that are viable according to their interactions. A researcher then aims to build models of the mathematics of students (Steffe & Olive, 2010).

From a quantitative reasoning orientation, attention to students' conceptions of attributes as measurable and that vary are key (cf. Johnson, McClintock, & Gardiner, 2019). We see an overlap in literature that focuses on characterizations of students' functional thinking, and students' quantitative reasoning, that tends to fall along three types of reasoning: covariation, correspondence, and recursive.

As Johnson et al. (2019) have reported, investigations of students' covariational reasoning are intertwined with students' creation and interpretations of representations such as Cartesian graphs. Along a related line of investigation, Moore et al. (2013) found that pre-service secondary math teachers' meanings of graphs and functions were in some cases constrained by their attachment to canonical forms (e.g., horizontal axis is x, vertical axis is y), limiting their ability to draw meaning about a graphical representation of x as a function of y. In another study, Fonger, Ellis, & Dogan (2016) found students engaged in covariational and correspondence reasoning to support their sense-making of symbolic function rules as generalizations of relationships among quantities. Consistent with this study, students' reasoning about relationships among quantities can support students' meaningful use of multiple representations (Moore, 2014). Moreover, the meanings students hold of representations and representational conventions may constrain their meanings of mathematical ideas such as angles or linear functions (Moore, 2012; Moore et al., 2013). In the domain of research on functional thinking, we see a need to more explicitly integrate attention to how students are creating and connecting representations to shed light on the creative aspects of doing mathematics with representations as important tools that may support or constrain students' activity and meanings of and for mathematics (cf. Brownell, 1947).

Methodology

In this section we focus on how the networking of theories and methodologies are in symbiotic exchange in all phases of research.

Data Sources and Mode of Inquiry

We employed a case study methodology (Stake, 1995) in our focus on meaningful understanding of quadratic function. The participant of this case study was a secondary preservice teacher in her second semester of a two-semester methods sequence. The authors conducted a 60-minute audio-recorded semi-structured task-based interview with the PT. We prompted the PTs to think aloud and clarify the meanings of her thoughts, such as: Can you tell me what connections do you see?; and Did you see the acceleration in your table/graph? In this task, we intended to observe the PT's functional thinking and representational fluency while they interpreted a diagram and table to make sense of a quadratic relationship. We created enhanced transcripts be embedding participant's written artifacts into verbatim transcripts. This method improved our ability to code students' activity.

Task. Consider the following series of diagrams illustrating how a rectangle grows in several iterations.  In general, what is the relationship between height, h, and area, A, in the growing rectangle context? Why?	**Structured Interview Probes**. • How did the diagram help you to notice the pattern you observed? • Can you describe any connections across the methods you used? Does it make sense? • What is the connection between the symbolic generalizations you wrote? What about the rules and the diagram, or tables? • How would you sequence representations to teach this task? Why?

Figure 1: Task Design (adapted from Ellis, 2011) and Structured Interview Probes

Data Analysis Techniques

We used cyclic methods of coding (Miles, Huberman, & Saldana, 2013). In the first cycle of coding, we analyzed participants' representational fluency and functional thinking. In the second cycle of coding we employed axial coding (Strauss, 1987) by analyzing instances of coding-cooccurrences (i.e., where in a code for FT and RF was applied in the same data segment). In this round of coding we aimed to identify relationships between participants' functional thinking and representational fluency. The cycles of coding were an iterative process of questioning and reflecting. We compared and contrasted the data related to PTs' functional thinking with preexisting data and situated it in existing literature (Baxter, & Jack, 2008).

Coding for Representational Fluency

In this study, we employed Dreyfus' (1991) theory of learning with multiple representations, to inform decisions about students' creation, interpretation, and connection of representations. We also employed a variant of Lesh, Behr, and Post's "rule of five" or "web" of representation types to inform distinctions of when the participant was drawing on one or more of symbolic, numeric, graphic, or diagram representations. From this conceptualization or theoretical stance on the use and connection of one or more representations, we employed Fonger's (2019) analytic framework for representational fluency (Table 1) to characterize the nature of the PTs discursive activity in creating, interpreting, and connecting *across* multiple representations in solving a task. The framework developed by Fonger (2019) builds on a structure of observed learning outcome taxonomy (Biggs & Collis, 1982) and employs an actor-oriented approach (Lobato, 2012) to problem solving. Each method or approach to a problem was analyzed as a unit of analysis to discern meaningfulness in representational fluency according to eleven levels (8 are below).

Table 1: An Excerpt of Fonger's (2019) Analytic Framework for Representational Fluency

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

Lesser Meaningfulness	*Greater Meaningfulness*
Student expresses a canonically inappropriate or incomplete creation, interpretation, or connection.	*Student expresses canonically appropriate and complete creations, interpretations, and connections.*
Move Between. Moves between more than one representation type, does not correctly create *and* interpret the meaning of the representations to solve the problem.	*Uni-Directional Translation*. Perform a translation from one representation type to another representation type. *Bi-Directional Translation*. Perform translation and complementary translation processes. *Multi-Directional Translation*. More than two representation types are related by translation processes.
Multi-Representationally Grounded. Moves between more than one representation type, giving an incorrect creation *or* interpretation of their meaning.	*Uni-Directional Connection*. Create and give a correct interpretation of an invariant feature across multiple representations or types. *Bi-Directional Connection*. Create and interpret a source representation with respect to a target representation and vise-versa, and recognize invariant features across the two representation types. *Multi-Directional Connection*. More than two representation types are related by translation processes and involve a correct interpretation of an invariant feature.

Lower levels include: *Pre-structural* students create and interpret a representation with incomplete understanding and *Multi-structural* students interpret, create, or connect more than one representation type without making sense of a mathematical object. Higher levels include: *Unistructural* students create and interpret a representation without making a connection to more than one representation, and *Relational* students create, interpret, and connect multiple representations with sophisticated understanding of a mathematical object.

Coding for Functional Thinking

We employed Thompson's (2011) theory of quantitative reasoning to inform our conceptualization of participants' engagement with one or more quantities and relationships between them. From this orientation toward students' quantitative reasoning and ways of thinking about function, we employed an analytic framework on functional thinking as articulated in the literature (e.g., Confrey & Smith, 1991; Stephens et al., 2017a; Thompson & Carlson, 2017; Fonger, Ellis, Dogan, 2016) as an a priori lens. We attended to three types of functional thinking: recursive, correspondence, and coordinated change.

Table 2: A Quantitative Lens on Modes of Functional Thinking

Functional Thinking	includes students' abilities to generalize and represent functional relationships
Coordinated change	students' reason with change in more than one quantity together by comparing or linking change across these different quantities (e.g., change in *x* and change in *y*) with explicit quantification of the magnitude of both changes (e.g., change of 1 in *x* and 3 in *y*) (Fonger, Ellis, Dogan, 2016).
Correspondence	students determine output values (range) related to input values (domain) as a direct mapping or dependency relation
Recursive	"Recursive patterns describe variation in a single sequence of values, indicating how to obtain a number in a sequence given the previous number or numbers" (Stephens et al., 2017, p. 145)

Coding Co-occurrences

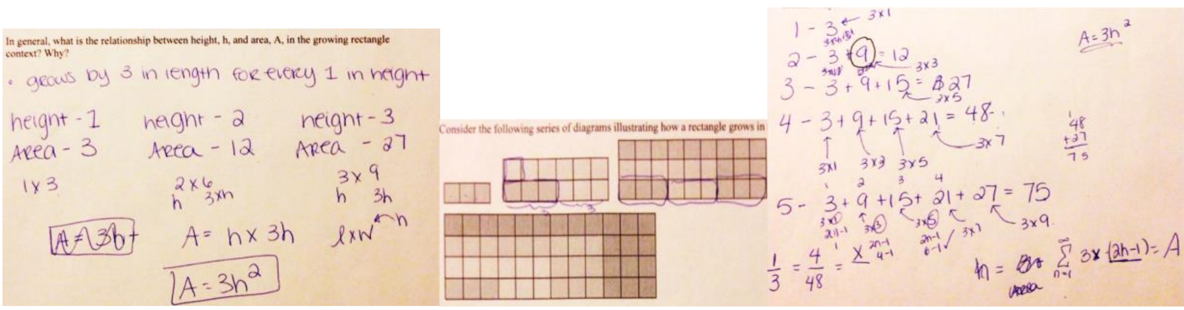
In the second round of analysis we re-analyzed instances of code co-occurrences for themes. This allowed us to identify relationships between the PTs' representational activity and their ways of thinking about function. In essence, this thematic analysis was concerned with answering the question of "what counts" as meaningful understanding when a coordination of analytic lenses it taken together?

Characterizing Meaningful Understanding in Problem Solving

In this section we highlight Vignettes to elaborate how the coordination of lenses enriches researcher sensitivity to characterizing meaning in students' problem solving activity.

Meaning May Emerge from Representational Disfluencies

In Vignette 1 (Figure 2a, b, lines 1-5) we show how meaning may emerge in problem solving.



(a) **(b)** **(c)**

Figure 2: Emy's Problem Solving Activity in Words, Numbers, Symbols, Diagrams

1 Emy: The question is like what is the relationship between height and area and the growing rectangle? So the relationship between the height and length is that it grows a 1 box in height for every 3 boxes in length, which makes it grow. So if the height is 1, the area is 3, if the height is 2 to the area is 12, then 1, 2, 3; 1, 2, 3; 4, 5, 6 times. Height is 3, an area is 27. So it's relation between height and area and the growing rectangle context. So it's 3, 3 times 1. Yeah, 2 times 6, 3 times 9, 3 times 9. So, I would say that the area equals 3, 3 times. Yeah. Three times the height (see left side of Figure 2a)

2 Nicole: How did you get a equals three h [A=3h]?

3 Emy: how we got the area, which would be the height was type 1 times 3 and then I looked in the box and it was 2 for the second one. … No, hold on. … This may be wrong. Yeah. Area equals the height times 3 times of height. So, this is what we are equals 3 height squared because if you look at the height in each one of these … So each of these is just starting out and then this is the high times 3, height times 3 times 3.

4 Nicole: So what was this, like 3h, like how did you get, how did you know to change your rule?

5 Emy: Well, because if you try to apply this to this one, it doesn't work. So area equals 3h would work for a 3 times 1, but it doesn't work for the height of two because 2 times 3 to 6. … if you try to look at that pattern and the next one, … you'll have to get 3h squared.

In interpreting this vignette from our networked lenses, we notice that Emy initially attended to coordinated change in height and length of the growing rectangle diagram by stating "the relationship between the height and length is that it grows a 1 box in height for every 3 boxes in length." Emy created a table of values and interpreted a correspondence between height and area stating "So if the height is 1, the area is 3, if the height is 2 to the area is 12" and concluding "So I would say that the area equals … 3 times the height", yet came to an incorrect generalization of A=3h (lines 1-2, *multi-representationally grounded*, *coordinated change*, *correspondence*).

Prompted to elaborate (line 2), Emy initially expressed uncertainty about her generalization A=3h, "No, hold on. … This may be wrong" drawing on a correspondence perspective of this function rule, Emy articulated independent and dependent quantities that did and did not match her rule, leading her to express a correct generalization and symbolic rule "Area equals the height times three times of height" (lines 3, *bidirectional translation*, *correspondence*). Asked to explain (line 4), Emy interpreted the symbolic rules A=3h and $A=3h^2$, and discerned that the rules give the same (height, area) only when h=1, while $A=3h^2$ accurately generalizes heights 1, 2, and 3 (line 5, *unidirectional connection*, *correspondence*).

From this vignette we learn that Emy's representational fluency changed from lesser to greater sophistication in her problem solving approach (*multistructural* to *relational*), and her engagement in functional thinking (*coordinated change* and *correspondence* reasoning) may have supported that shift as she interpreted the diagram, and created and interpreted a table of values to lead to her generalization in words and symbols. In this case, evidence of Emy's expressions of functional thinking give insight into her meaningful understanding of the growing rectangle situation as represented in diagrams, values, and a symbolic rule.

Flexibility in Meanings of Functions Engenders Representational Fluency

In Vignette 2 (see Figure 2c above, and lines 6-8 below), Emy was asked to solve the same problem in a different solution approach. Emy engaged in recursive thinking with greater sophistication in representational fluency across a diagram, table, and symbols.

6 Emy: Because you're adding a 3 on the bottom to the original 3 and then 2, 3 is on the top. So you're always going to be adding an odd number of 3s … to the original one from the past. … It's the length that's being added. So, you can group them by 3s is what I'm trying to make sense of … So you're adding 3 times. One, 2, 3 times 3 instead of 3 times 2. Um, and then you're adding 3 times 5, but we're skipping 3 times 4 and you're adding 3 times 7 but no 3 times 6 if that's like a pattern. But, um, I saw something like that. I don't know how to write that.

7 Nicole: Does it make sense why that's occurring?

8 Emy: Yes. Because you're adding a 3 on the bottom to the original 3 and then 2, 3 is on the top. So you're always going to be adding an odd number of 3s because I'm here. You're adding two 3s to bottom and then an even number 1, 2, 3, 4, 5, 6, 7, 8. This is an odd number 3 is from before and the third one? … You're adding an odd number of 3s to the original one from the past. … It's a sequence of adding groups of 3s. I don't know how to write the odd groups of 3s. I guess this could be like 3 times 2 N minus 1. Would that work?... This would be the formula [$A=\sum 3*(2h-1)$] for the area and I guess n would actually be h, it would be the height that would be a formula that relates height to area.

From a networking of lenses, we learn about Emy's meaningful understanding of this quadratic growth situation from a recursive perspective. Emy engaged in recursive reasoning, moving fluently between the diagram and the table she created to explain her generalization of adding an odd number of groups of three to the previous area in both the diagram and the table (line 6, *bidirectional connection*, *recursive*). Prompted for sense-making (line 7), Emy elaborated her recursive thinking as a "sequence of adding groups of 3s," as strongly connected to her interpretation of the diagram, again concluding with a correct symbolization of a generalization (*multidirectional translation*, *recursive*).

In this vignette we learn that in her solution approach Emy demonstrated greater sophistication in representational fluency at a *relational* level, and in moving among representations her ability to generalize the functional relationship was interpreted as meaningful from a recursive perspective. Taken together with the first vignette, we see evidence of Emy's representational fluency as going hand in hand with her functional thinking. For instance, if we illustrate Emy's activity from a "web" diagram perspective, with each node taken as a representation type, and Emy's creation, interpretation, and connection across representations as a form of functional thinking, we observe important connections. For instance, Emy began with coordinated change on a diagram (Figure 3), and side bar chart (Figure 2c). Then she built correspondence reasoning on coordinated change by shifting into the summation formula. Emy used a correspondence approach to check if the summation formula she created is meaningful for her by plugging in values of height and area for each step through correspondence reasoning.

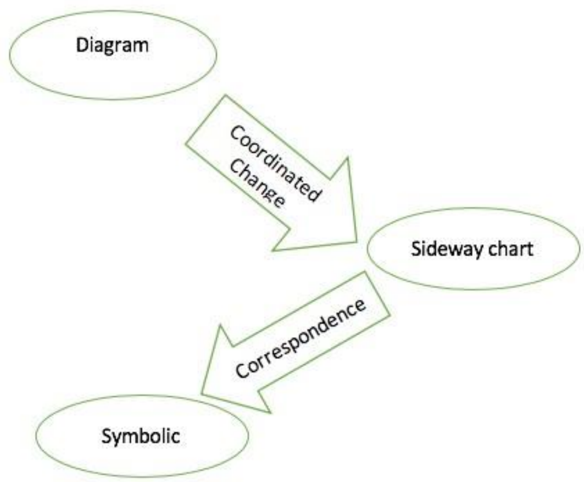


Figure 3: Emy's Solution Web with Representations and Functional Thinking

Discussion and Conclusion Characterize Meaningful Understanding

The networking of theories in this study was borne out of a need to address an enduring challenge in the field of mathematics education: characterizing students' meaningful mathematics learning. In this paper we elaborated how a networking of theories of multiple representations and quantitative reasoning is one productive approach for characterizing meaningful learning of mathematics. The theoretical groundings and assumptions guiding this study span constructivist and semiotic lenses on cognition. In particular, we drew on theories of learning that posit that students learn by creating, interpreting, and connecting multiple representations in doing and communicating about mathematics (Dreyfus, 1991), with covariation, correspondence, and recursive reasoning about relationships among linked quantities as supports for students' meaningful understandings of functions (e.g., Confrey & Smith,1994, 1995; Ellis, 2011).

From this networked stance, we examined how students' representational fluency and quantitative reasoning about relationships between varying and dependent quantities seemed to support and constrain one another. Results of this study highlight (a) how lesser meaningfulness in representational fluency may serve as a productive starting point for more sophisticated thinking and mathematical meaning to follow, and (b) how flexibility in thinking across multiple meanings of function (i.e., correspondence, covariation, and recursive modes) go hand in hand with representational fluency. We see these results as contributing evidence for the productiveness of networking theories to advance tools for characterizing meaningful learning.

Lessons Learned on Networking Theories

We have also learned that the activity of networking theories has contributed to our sensitivities as researchers to the importance of communicating explicit assumptions in background theories, theoretical constructs, and analytic tools. As we reflect on how we've learned new nuances in characterizing meaningful learning, we are left asking how other theoretical backgrounds and assumptions about learning might be brought to bear to paint a different picture of students' meaningful learning. For example, tracing the bodies of work that researchers draw on in defining "meaning" and "meaningful learning" brings us to other theories such as Voigt's (1994) articulation that personal meanings are negotiated through social interaction. Such social interaction and proactive role of the teacher-researcher (e.g., lines 2, 4, and 7) needs to be accounted for in analyses of situations, even interviews that would otherwise be thought of as "purely" psychological in orientation (see also Cobb & Yackel, 1996).

Next Steps

Next steps of this research program are to further investigate how the networking of theories can inform not only our ability to characterize more nuanced models of students' meaningful learning, but also to elaborate design principles as the basis for instructional supports aimed at engendering meaning-making. Future studies can build on this networking across the design, enactment, analysis, and communication of research.

We found the recommendations of the international working group (Bikner et al., 2019) to be a helpful grounding for continuing the work of theory development vis-à-vis networking theories in mathematics education. We encourage others to engage with and extend these recommendations for theory networking to advance theory building in mathematics education toward aims of addressing enduring challenges related to understanding and supporting students' meaningful mathematics learning.

En este artículo se presentan y discuten algunos elementos teóricos y metodológicos de una investigación más amplia que analiza la práctica de dos profesores -novato y experto- desde una aproximación teórica de orientación semiótica. Se presenta un encuadre teórico que nos permite atender las dimensiones epistemológica y didáctica de la práctica docente. Se resaltan tres conceptos: signo, artefacto y mediación. Asimismo, se propone, a través de la red de teorías (Kidron & Bikner-Ahsbahs, 2015), el modelo de enseñanza del profesor como constructo teórico-metodológico para analizar la práctica docente. Se reporta el modelo de enseñanza para el fenómeno de la caída libre de objetos; en donde se considera, a su vez, la estrecha relación entre matemáticas y física. Se presentan algunos resultados sobre la aplicación del modelo de enseñanza para el análisis de un profesor novato.

Keywords: Modelos, Artefactos, Recursos, Teoría de la Actividad

El presente trabajo se ubica tanto en el marco de investigaciones enfocadas en analizar la práctica del profesor (e.g., Adler, 2000; Pepin, Xu, Trouche, & Wang, 2017; Sfard, 2005; Stockero et al., 2018), así como en el interés de situar la enseñanza de las matemáticas y de las ciencias como una actividad mediada (e.g., Dobber & van Oers, 2015; Mariotti, 2009). Moreno-Armella y Sriraman (2010) consideran que el acceso a los objetos [matemáticos] ocurre a través de los mediadores (como el lenguaje). De manera que la relación objeto-sujeto no tiene lugar de manera directa.

Dos elementos [*mediadores*] que permiten al sujeto interactuar con los objetos matemáticos tanto en su carácter histórico como en su contexto cultural son el *signo* -en el sentido de Vygotsky (2009)- como instrumento psicológico; y los *artefactos* -en el sentido de Wartofsky (1979)- como representaciones de los modos de la *actividad*. Ambos elementos aparecen, a su vez, como *mediadores* entre el hombre y su entorno. Los *signos* se caracterizan no por su naturaleza representacional sino por su papel funcional: como medios de regulación externa o material de autocontrol. Son utilizados [los *signos*] por los individuos para controlar su propia actividad e influir en la de los demás (Kozulin, 2000). Por lo tanto, al colocarse entre el sujeto y el entorno, el lenguaje y otros medios culturales de significación [*signos*] hacen que el entorno sea percibido por el sujeto ya no en su estado ‘puro’ sino como un entorno transformado por la acción que ejercen inevitablemente los lentes que ofrece la cultura. La noción de *artefactos* se desarrolla en la siguiente sección.

Es así como se resalta el aspecto de la *mediación* como elemento fundamental para el análisis de los procesos de enseñanza-aprendizaje. Es importante señalar que en la presente investigación se considera que la noción de la *mediación* no es suficiente para llevar a cabo el análisis de las prácticas de enseñanza. Para situar la *mediación* en el plano pedagógico se incorpora una aproximación que resalta el *uso* de *recursos* en la práctica docente: la *Aproximación Documental de lo Didáctico* (ADD) (Gueudet & Trouche, 2009; 2012). Con el objetivo de analizar la manera en que los profesores estructuran y representan sus conocimientos en el salón de clases, en este trabajo se aborda el fenómeno de la caída libre de objetos y sus representaciones a través de gráficas cartesianas. En su investigación, Salinas-Hernández y Miranda (2018) analizan cómo las gráficas cartesianas están incluidas en una forma cultural sobre el entendimiento [de formas de hacer y de pensar] del movimiento de objetos. Se plantea así la siguiente pregunta de investigación: ¿cuáles son las características del *modelo* de enseñanza de un profesor novato en torno a la enseñanza de la caída libre de objetos?

Marco conceptual

El marco conceptual de la investigación considera elementos de la *Teoría de la Actividad* (TA) en el trabajo de Engeström (2001), el uso de *artefactos* y la noción de *modelos* (Wartofsky, 1979) y el *uso* de *recursos* (Gueudet & Trouche, 2009; 2012). Estas aproximaciones teóricas se integran alrededor de un objetivo común: interpretar la práctica docente como una *actividad* concreta orientada a objetos (motivos), a través de la *mediación* de *signos*, *herramientas/artefactos* y *recursos*. A su vez, este marco proporciona un encuadre teórico que permite dar atención a las dimensiones epistemológica y didáctica de la pregunta de investigación. La dimensión epistemológica se asocia, por un lado, con el análisis sociocultural del concepto de *sistema de referencia* –dentro de los procesos de producción de significados que ocurren en el salón de clases– para el análisis del fenómeno de caída libre; y por el otro lado, también se asocia al análisis del conocimiento de los profesores sobre el mismo concepto. A este respecto, se sigue una perspectiva que sitúa al conocimiento bajo prácticas sociales que se constituyen social y culturalmente. La dimensión didáctica de la pregunta de investigación está relacionada con los criterios y la manera (a partir de las experiencias docentes y conocimientos propios) que tiene el profesor novato para representar ante sus alumnos el concepto de *sistema de referencia*.

La Teoría de la Actividad a través del trabajo de Engeström

Lo que distingue a las diferentes aproximaciones de la TA, entre sí, es: qué constituye la esencia de la *actividad*. Lo más importante es que los tres elementos: el porqué un individuo [maestro o estudiante, en el contexto educativo] participa en la *actividad* de “hacer matemáticas”, con quién realiza la *actividad* y con qué *herramientas*; estos tres elementos no pueden ser separados y analizados en sí mismos, sino de manera integral. En particular, Engeström (2001) extiende el planteamiento de Vygotsky sobre la *mediación* a través de los *signos* y *herramientas* y el de Leont’ev sobre la labor, a múltiples formas de *mediación* en lo que denominó: *sistema de actividad*. Ahora la unidad de análisis es, al menos, dos sistemas de actividad interactuando entre sí (Figura 1).

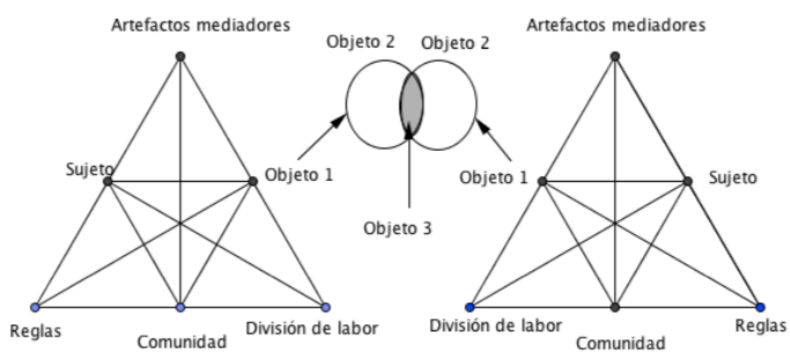

Figura 1: Representación de Engeström sobre los *sistemas de actividad*, basado en la mediación y en el trabajo de Leont’ev

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

Una aproximación sobre el uso de artefactos: la noción de modelos

Para Wartofsky (1979) la característica fundamental de la práctica cognitiva humana es la habilidad para crear representaciones. Señala que, a diferencia de los animales no humanos, los seres humanos crean los medios de su propia cognición: los *artefactos*. Además de considerar al lenguaje, Wartofsky (1979) introduce las formas de organización e interacción social, las técnicas de producción, y la adquisición de habilidades, como *artefactos* . De manera que, al producir *artefactos* [medios cognitivos] para su uso, se producen *representaciones*. Porque los *artefactos*, además de su uso, representan el modo de actividad en el que se usan, o el modo de su propia producción [modos de representación]. Es decir, el *artefacto* es tanto un *medio cognitivo* como un *modo de representación*. Por lo tanto, al producir *artefactos* se producen *representaciones*, a través de las cuales el ser humano logra el conocimiento. En el ámbito científico, la producción de *artefactos* [cognitivos] produce a su vez *modelos*. Wartofsky (1979) define los *modelos* como *representaciones* para nosotros mismos de lo que hacemos, de lo que queremos y de lo que esperamos. Son modos de acción adquiridos. En palabras de Wartofsky (1979):

> El modelo se considera una construcción en la cual organizamos símbolos de nuestra experiencia o de nuestro pensamiento, de tal manera que realizamos una representación sistemática de esta experiencia o pensamiento, como medio de entenderlo o de explicarlo a los demás. (p. xv; traducción libre)

De manera que: (1) no hay conocimiento sin *representación* y (2) las *representaciones* y *artefactos* son los elementos que evidencian el conocimiento humano (en nuestra investigación, el conocimiento del profesor).

Aproximación documental de lo didáctico

Gueudet y Trouche (2009; 2012) proponen un enfoque teórico cercano, en la conceptualización de *recursos*, de la propuesta de Adler (2000). Pero ampliando la noción de *recursos* a todos aquellos que intervienen en la comprensión y resolución de problemas, no restringiéndose a los provenientes de objetos materiales. Estructuran su propuesta teórica bajo el nombre de *Aproximación Documental de lo Didáctico* (ADD). En esta propuesta, el *trabajo documental* (TD) es el núcleo de la *actividad* de los profesores y de su desarrollo profesional. Comprende todas las interacciones de los profesores con los *recursos*: su selección y el trabajo con ellos.

Los autores hacen la diferencia entre *recursos* y *documentos*. Así, los *documentos* son desarrollados a través de lo que denominan *génesis documental*. En la *génesis documental*, los *documentos* son creados y desarrollados, en el tiempo, a partir de un proceso en el cual los profesores construyen *esquemas de utilización* de los *recursos* para situaciones dentro de una variedad de contextos, proceso que se ejemplifica por la ecuación: documento = recursos + esquemas de utilización (Gueudet & Trouche, 2009, p. 205). Para dar cuenta de la variedad y del diseño de *documentos* y la manera en que los profesores los articulan en una variedad de situaciones, los *documentos* se estructuran en *un sistema de documentación*, en donde el *sistema de recursos* del profesor constituye la parte del "*recurso*" del *sistema de documentación.* Es importante señalar que en la *génesis documental* uno de los objetivos es concebir la *actividad* del profesor orientada por objetivos, y conceptualizarla como actividad social. Esta consideración de la *actividad* conlleva a poner atención en los contextos sociales de los diferentes grupos en la que ésta esté presente (Gueudet & Trouche, 2012). De manera particular, los autores hacen referencia a la TA, como la teoría sobre la cual desarrollaron su propia aproximación teórica (Gueudet & Trouche, 2012); y señalan que: "[L]a referencia a la teoría de la actividad también está directamente relacionada con nuestro interés en la mediación y los artefactos mediadores" (Gueudet & Trouche, 2012, p. 24; traducción libre). Es así como se integra la ADD en la presente investigación, para abordar la dimensión didáctica de la pregunta de investigación.

Metodología

Se plantea una investigación cualitativa, mediante estudios de caso (Cohen, Manion & Morrison, 2004). Con la finalidad de establecer las categorías y elementos de análisis se propone el modelo de enseñanza del profesor. Para los objetivos de este artículo se expone el modelo de enseñanza sobre el movimiento de objetos. Este constructo teórico-metodológico se produce a partir de la integración de las teorías expuestas en el marco conceptual (*networking of theories* (Kidron & Bikner-Ahsbahs, 2015)).

El modelo de enseñanza del profesor sobre el movimiento de objetos

Modelo C & Modelo E. Se parte de dos suposiciones. (1) La práctica del profesor considera modos (científicos-institucionales) de acción cognitiva humana y modos de representación: *modelos* [científicos-institucionales] (Wartofsky, 1979). En particular, respecto al movimiento de objetos, se define el *modelo C* como el *modelo* científico –newtoniano– actual que considera cada profesor para producir sus propios *modelos de enseñanza E*: sus prácticas y conocimientos pedagógicos. Es en el *modelo C* que se ubica el contenido físico-matemático de la investigación (e.g., los significados científico-institucionales sobre el concepto de sistema de referencia (SR)). (2) Cada profesor produce, a lo largo de su formación académica y de sus años de práctica docente, un *modelo E* que representa, por un lado, el modo de acción adquirido del *modelo C*, esto es, la manera en que cada profesor ha organizado los símbolos de su experiencia y de su pensamiento en torno al *modelo C* para explicarlo a los estudiantes; y por otro lado, los modos de representación de ese conocimiento adquirido (representaciones y artefactos desarrollados por los profesores). El *modelo E* incorpora el *trabajo documental* de cada profesor, en particular sobre los criterios de selección y *uso* de *recursos*, así como planeación e implementación de clase (planeación e implementación de *sistemas de actividad*).

Sistemas de actividad. Se propone que los *sistemas de actividad principales* y los *sistemas de actividad particulares* (*sub-sistemas de actividad*) son producidos a partir tanto del *modelo C* como del *trabajo documental* (TD) de cada profesor.

Los sistemas de actividad principales y *particulares* se producirán a partir de la *actividad* (interacciones en el salón de clase, *uso* de *artefactos mediadores* y *recursos*) que se desarrolla en el salón de clases a partir de una tarea (e.g. resolución de un ejercicio o discusión de un tema; ambos relacionados con el movimiento de objetos) propuesta por cada profesor durante sus clases. Se da lugar así –a partir de los objetivos de la tarea– a los objetivos principales de la *actividad*. A partir del *sistema de actividad principal* (e.g. encontrar la velocidad final de un objeto) y del *modelo C*, se derivan, también, *sub-sistemas de actividad* (e.g. *sistema de actividad* sobre el SR *y sistema de actividad* sobre el sistema de coordenadas cartesianas); que a su vez están en estrecha relación con el *sistema de actividad principal*, pero que tienen, sin embargo, objetivos particulares diferentes que ayudan a que el *sistema de actividad principal* se lleve a cabo (e.g. determinar un SR y/o utilizar un sistema de ejes coordenados).

Para establecer la manera en que se producen y desarrollan los *sistemas de actividad* se toma la noción de Gal'perin sobre la *base orientadora de la actividad*. La epistemología de Gal'perin "se basa en la noción de que la apropiación de nuevo conocimiento y habilidades es la consecuencia de la acción humana.” (Haenen, 1993, p. 97, traducción libre). Por lo que los procesos de enseñanza-aprendizaje tienen como objetivo la mejora cualitativa del repertorio de acciones presentes y reales (Haenen, 1993). “La optimización de este repertorio depende de las representaciones del alumno, del objetivo, la estructura y los medios de mediación para ejecutar una determinada acción.” (Haenen, 1993, p. 97, traducción libre). El término *base orientadora* se usa para referirse a estas representaciones. De esta manera, los *sistemas de actividad principales* y los *sub-sistemas de actividad* se desarrollan a partir de las decisiones de cada uno de los profesores para representar los significados sobre los conceptos que se abordan.

Existen, por una parte, relaciones didácticas/semióticas (R-α) entre el *modelo C* y cada *sistema de actividad principal*, y relaciones didácticas/semióticas (R-α’) entre el *modelo C* y los *sub-sistemas de actividad*; y, por otra parte, relaciones semióticas (R-β) entre el *sistema de actividad principal* y los *sub-sistemas de actividad*; y relaciones semióticas (R-β') entre los *sub-sistemas de actividad*. A continuación, la representación del esquema del modelo de enseñanza del profesor para el movimiento de objetos (Figura 2).

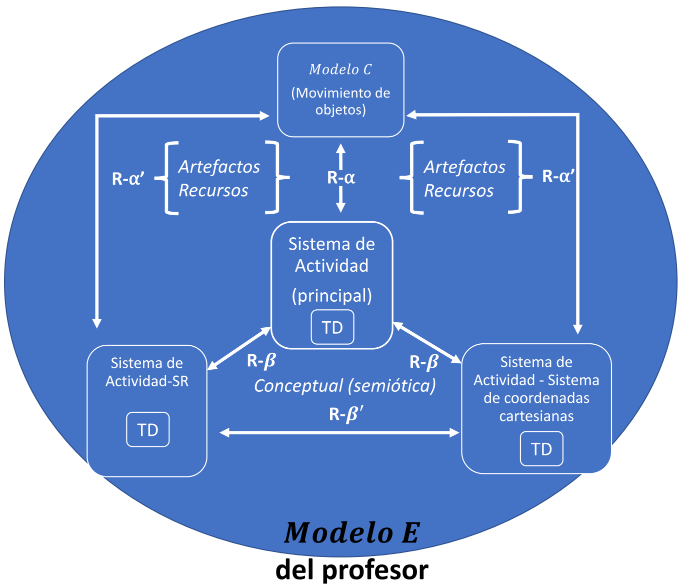

Figura 2: Esquema de las relaciones entre el modelo C y los sistemas de actividad producidos a partir del trabajo documental (TD) de un profesor

Para analizar las características del *modelo de enseñanza* de un profesor novato se trabajó con un profesor de física durante dos etapas, mediante la observación no participativa. El profesor, a quien se denomina Carlos (pseudónimo), contaba con 2 años de experiencia docente al momento de la primera toma de datos, egresado de la carrera de Física. En la primera etapa se videograbaron las clases de Carlos durante el tiempo que enseñó temas de cinemática y dinámica; con el objetivo de identificar los momentos en que abordaba los temas de caída libre y el concepto de SR. Se le observó un total de 20 horas de clase. Se hicieron transcripciones de extractos seleccionados. En la segunda etapa se volvió a realizar videograbaciones de las clases de Carlos, pero ahora solamente cuando enseñó temas particulares seleccionados de la primera etapa, con el objetivo de analizar cambios en su manera de enseñar después de dos años de experiencia docente. En esta segunda etapa se le observó durante 4 horas de clase. Se realizó, al final de la segunda etapa, una entrevista semiestructurada para tener más elementos de su *trabajo documental*.

Resultados y discusión

Para caracterizar el *modelo E* de Carlos se analizan las relaciones entre el *modelo C* y los *sistemas de actividad* (Figura 2). El análisis toma en cuenta tanto los *artefactos* como los *recursos* usados por Carlos. De manera que en lugar de analizar cada elemento (artefactos y recursos) de manera aislada, se realiza un análisis multimodal en donde se considera la estrecha relación entre ambos para establecer las relaciones antes mencionadas. Así, dos elementos importantes para analizar estas relaciones son, por un lado, los artefactos –en particular los gestos– que usa Carlos y que dan cuenta de su pensamiento (estructura cognitiva); y por otro lado el *trabajo documental* (uso de recursos) de Carlos que nos proporciona elementos de la componente pedagógica. Si se determina que en el *modelo E* de Carlos las diferentes relaciones (R-α, R-α’, R-β y R-β') se llevan a cabo de manera satisfactoria, entonces eso se representará en el esquema con una flecha continua. De lo contrario, en caso de haber dificultades para llevar a cabo las relaciones se representará con una línea punteada.

Se presentan algunos resultados de las características del *modelo de enseñanza* (modelo E) de Carlos. En la primera etapa, cuyos datos no se muestran en este artículo, Carlos tuvo dificultad al trabajar con el concepto de SR. En la segunda etapa, continuaron esas dificultades. A continuación, se muestran dos extractos que tuvieron lugar durante una clase de Carlos en la segunda etapa. Su análisis permite caracterizar su modelo de enseñanza. En la clase, Carlos abordó el tema del signo de una cantidad vectorial, en particular la aceleración de la gravedad [g]. El *sistema de actividad principal* de Carlos corresponde a su explicación sobre el significado del signo de la aceleración (se incluye a la aceleración de la gravedad). Así, después de que en la clase Carlos escribió en el pizarrón diferentes ecuaciones para analizar el movimiento de objetos, él dirigió la atención de los estudiantes hacia el significado del signo de la aceleración.

> L1 Carlos: Puede que ustedes [*dirigiéndose a los estudiantes*] tengan que determinar esa aceleración. Pero esa aceleración al momento de determinarla, luego puede que salga un menos, ¿ok? O sea que puede que aquí [*señala las ecuaciones en el pizarrón en las cuales la aceleración puede ser negativa; Figura 3*] tengan un más o un menos en el resultado. Pero ¿que significa eso de un más o un menos? (…) puede haber una aceleración o una desaceleración. Eso es lo que significa cuando les de un menos o un más, ¿ok? (…) por ejemplo, si les da más [*el resultado positivo de la aceleración*], quiere decir que de nueve metros sobre segundo [9 m/s] aumentó a treinta metros sobre segundo [30 m/s]. Y si les da menos [*el resultado negativo de la aceleración*], quiere decir que va frenando. Hay una desaceleración. Entonces quiere decir que de 30 [m/s] baja hasta 9 [m/s], ¿ok? No se les tiene que olvidar ese menos.

Figura 3: Carlos señala los signos de la aceleración

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

Desde un inicio, Carlos dirige la atención de los estudiantes hacia el significado del signo de la aceleración (L1). Sin embargo, en su explicación confunde el significado del signo negativo de la cantidad "aceleración" con el significado de "desaceleración". Es importante señalar que en el *sistema de recursos* de Carlos se encuentra un libro de texto, cuyo autor es Giancoli (2006), que Carlos usa como apoyo [*recurso*] durante el desarrollo de sus cursos. En este libro de texto se señala el cuidado que se debe tener de no concebir el signo negativo de una aceleración como una desaceleración. Más adelante en la clase, Carlos aborda el tema del signo en relación con la caída libre de objetos:

> L2 Carlos: Ahora, en el eje vertical, la diferencia es que esta aceleración que ustedes están viendo aquí [*se refiere a la segunda ecuación de arriba para abajo; Figura 3*] que es una constante siempre (…) pero en el eje vertical, esa aceleración ya no la van a tener que buscar. ¿Por qué?, porque esa aceleración va a ser la de la gravedad. (…) Entonces lo voy a poner así [*escribe en el pizarrón:* $a=g=-9.8\ m/s^2$]. (…) Quiero que siempre le pongan el signo menos.

En L2 se observa cómo Carlos se auxilia del sistema de coordenadas cartesianas para situar el fenómeno físico de la aceleración de la gravedad. Así, se puede ver que se introduce otro *sistema de actividad*: *sistema de actividad–sistema de coordenadas cartesianas* (Figura 4). Este *sistema de actividad* debiera estar relacionado en el contexto del SR, es decir con el *sistema de actividad principal-SR*. Esto daría significado a los signos que se usan en el contexto del movimiento de objetos (*Modelo C*). Sin embargo, Carlos nuevamente, tal como lo hizo hace dos años, dice que "g" debe ser siempre utilizada con el signo negativo (L2).

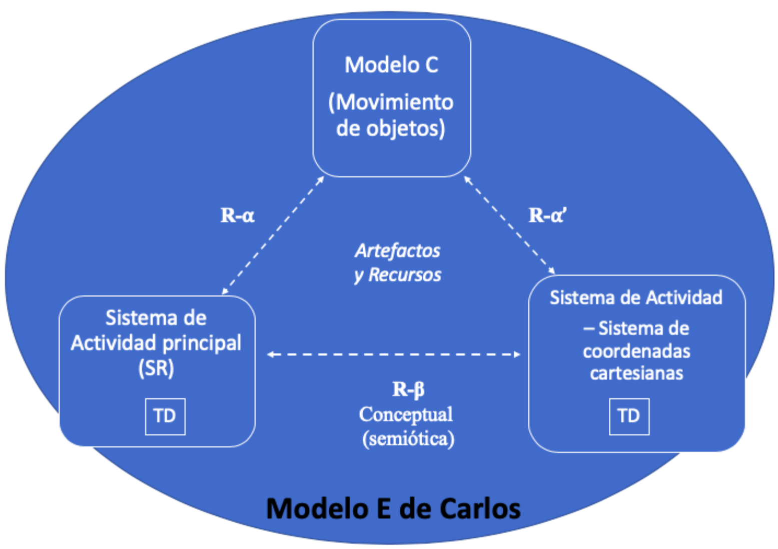

Figura 4: Esquema del modelo E del profesor Carlos

Respecto al *sistema de actividad principal* de Carlos, se observa que éste incorpora al *sistema de actividad-SR* (Figura 4). Sin embargo, se observa la dificultad, por parte de Carlos, de llevar a cabo una relación R-α, entre el *sistema de actividad principal* y el *Modelo C* (institucional). En esta dificultad, el uso del libro de texto –como *recurso* y como *artefacto*– adquiere especial importancia.

Conclusiones

En este artículo se expusieron elementos teóricos y metodológicos para analizar la práctica de los profesores. Se presentó el *modelo de enseñanza* como herramienta teórica y metodológica para analizar las practicas de enseñanza. En particular, se presentaron características del *modelo de enseñanza* de un profesor novato. En el caso de Carlos –un profesor con 4 años de experiencia [antigüedad docente] al momento de que finalizó la segunda parte de la toma de datos– se concluyó, para los resultados presentados, que él tiene un *modelo E* representado por el esquema de la Figura 4. En el nivel epistemológico, este *modelo* se caracteriza por no estar presentes de manera conjunta las relaciones entre el contenido y los objetivos de los *sistemas de actividad principales* –producidos a partir de un *trabajo documental* y derivados a su vez de un *modelo científico-institucional* (*Modelo C*), sobre el movimiento de objetos (relación R-α; Figura 4)– tanto con un *sistema de actividad* sobre el SR (perteneciente al contexto físico), como con un *sistema de actividad* sobre el sistema de coordenadas cartesianas (perteneciente al contexto matemático). Estas relaciones (R-β; Figura 4) permiten dar cuenta de los significados conceptuales que están presentes entre un *sistema de actividad principal* y otros *sistemas de actividad* (*subsistemas de actividad*) que surgen durante la actividad.

THEORETICAL AND METHODOLOGICAL ELEMENTS TO ANALYZE TEACHER PRACTICE: THE TEACHING MODEL

In this article we present and discuss some theoretical and methodological elements of a wider research that analyzes the teaching practice of two teachers—novice and expert—from a semiotic theoretical approach. The conceptual framework of this work allows for addressing the epistemological and didactic dimensions of the teaching practice. Three concepts are particularly emphasized: sign, artefact, and mediation. Furthermore, we propose, through the networking of theories (Kidron & Bikner-Ahsbahs, 2015), the teacher's teaching model as a theoretical-methodological construct to analyze the teaching practice. This work reports the teaching model for the phenomenon of a free-falling object, in which the close relation between mathematics and physics is addressed. Some results on the application of the teaching model are presented for the analysis of a novice teacher.

Keywords: Models, Artefacts, Resources, Activity Theory.

This work is supported by research analyzing the teacher's practice (e.g., Adler, 2000; Pepin, Xu, Trouche & Wang, 2017; Sfard, 2005; Stockero et al, 2018) and seeks to position mathematics and science teaching as mediated activity (e.g., Dobber & van Oers, 2015; Mariotti, 2009). Moreno-Armella and Sriraman (2010) state that access to [mathematical] objects occurs through mediators as language. Then, the relation object-subject does not take place directly.

Two elements [*mediators*] that allow the subject to interact with mathematical objects, both historically and within the cultural context, are the *sign* —as defined by Vygotsky (2009)— as a psychological instrument and *artefacts*— according to Wartofsky (1979)— as representations of *activity* modes. Both elements appear in turn as *mediators* between the subject and the environment. *Signs* are characterized not by their representational nature but by their functional role as means of external regulation or self-control material. They [*signs*] are used by individuals to control their own activity and influence that of others (Kozulin, 2000). Therefore, when placed between the subject and the environment, language and other means of cultural significance [*signs*] make the subject perceive the environment not in its 'pure' state but as one transformed by the action inevitably exerted by the lens of culture. The notion of *artefacts* is presented in the next section.

This is how the role of *mediation* as a key element to the analysis of teaching-learning processes is emphasized. It must be noted that this research considers the notion of *mediation* is not enough to analyze teaching practices. To locate *mediation* in the pedagogical level, we have added an approximation that highlights the *use of resources* in teaching practice: *Documentational Approach to Didactics* (DAD, Gueudet & Trouche, 2009; 2012). The present work addresses the phenomenon of free-falling objects and their representations through

Cartesian planes to analyze how teachers structure and represent their knowledge in the classroom. In their research, Salinas-Hernández and Miranda (2018) analyze how Cartesian planes are culturally included on the understanding [of ways of doing and thinking] of object displacement. Then, we propose the following research question: Which are the characteristics of a novice teacher's teaching *model* regarding the teaching of free-falling objects?

Conceptual Framework

The conceptual framework of this research includes elements of the *Activity Theory* (AT) in the work by Engeström (2001), the use of *artefacts* and the notion of *models* (Wartofsky, 1979), and the *use* of *resources* (Gueudet & Trouche, 2009; 2012). These theoretical approximations are integrated around a common objective: To interpret teaching practice as a concrete *activity* focused on objects (motifs), through the *mediation* of *signs*, *tools/artefacts*, and *resources*. Furthermore, this framework provides a theoretical approach that allows for focusing on the epistemological and didactic dimensions of the research question. The epistemological dimension is associated, on the one hand, to the sociocultural analysis of the concept of *reference system* —within the processes of production of meanings that occur in the classroom— to analyze the free-fall phenomenon. On the other hand, epistemology is associated to the analysis of the teachers' knowledge on the same concept. Additionally, we follow an approach that places knowledge under social practices that are socially and culturally constituted. The didactic dimension of the research question is related to the criteria and the way (from teachers' experiences and own knowledge) the novice teacher represents the concept of *reference system* in front of the class.

Activity Theory through Engeström's Work

What distinguishes the approximations of AT between them is: What constitutes the essence of *activity*. The most import is that the three elements —why an individual [teacher or student in the education context] takes part in the "doing mathematics" *activity*; with whom the individual carries out the *activity;* and which *tools* the individual uses to do so— cannot be separated and analyzed in themselves but integrally. Particularly, Engeström (2001) expanded Vygotsky's approach on *mediation* through *signs* and *tools* and Leont'ev's on *labor* to multiple ways of *mediation* in what he called *activity system*. Now, the units of analysis are, at least, two activity systems interacting with each other (Figure 1).

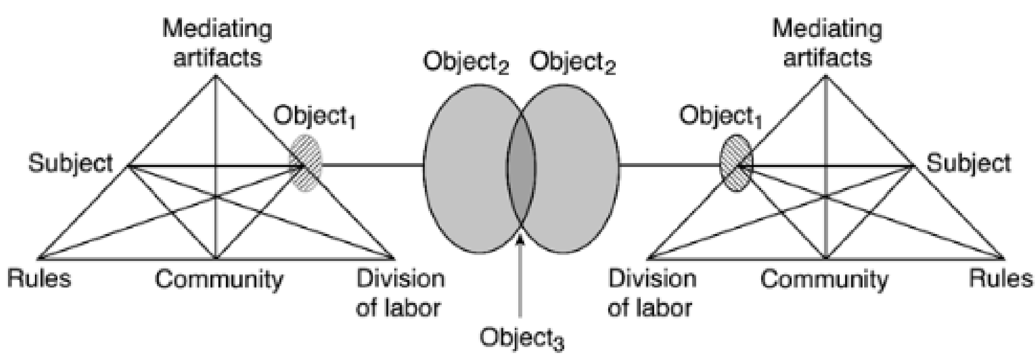

Figure 1: Engeström's Representation on *Activity Systems,* Based on Mediation and Leont'ev's work

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* St Louis, MO: University of Missouri.

An Approximation on the Use of Artefacts: The Notion of Models

Wartofsky (1979) stated that the basic characteristic of human cognitive practice is the ability to create representations. He considers that, unlike non-human animals, human beings create the means of their own cognition: *artefacts*. Besides taking into account language, Wartofsky (1979) introduces ways of social organization and interaction, production techniques, and the acquisition of abilities as *artefacts*. The latter represent not only the use but the way of activity in which they are used or the way their own production [representation modes] occurs. That is, the *artifact* is both a *cognitive medium* and a *representation mode*. Therefore, the production of *artefacts* creates *representations* through which the human being achieves knowledge. In the scientific field, the production of [cognitive] *artefacts* produces *models*. Wartofsky (1979) defines *models* as *representations* for us regarding what we do, want, and expect. They are acquired modes of action. In Wartofsky's (1979) words:

> [T]he model is taken to be a construction in which we organize symbols of our experience or of our thought in such a way that we effect a systematic representation of this experience or thought, as a means of understanding it, or of explaining it to others. (p. xv)

Therefore: (1) there is no knowledge without *representation* and (2) *representations* and *artefacts* are elements that evidence human knowledge (in our research, the teacher's knowledge).

Documentational Approach to Didactics

Gueudet and Trouche (2009; 2012) propose a close theoretical approach in the conceptualization of *resources*, from Adler's proposal (2000). However, they expand the notion of *resources* to all those participating in understanding and solving problems, not restricted to those from material objects. They structure their theoretical proposal under the name of *Documentational Approach to Didactics* (DAD). In this proposal, the *documentational work* (DW) is the core of the teachers' *activity* and professional development. It comprises all the teachers' interactions with their choice of *resources* and the work with them.

The authors distinguish between *resources* and *documents*. Then, *documents* are developed through what they call *documentational genesis*. In the *documentational genesis*, *documents* are created and developed in time from a process in which teachers build *schemes of utilization* of *resources* for situations within a number of contexts. This process is represented by the equation: document = resources + schemes of utilization (Gueudet & Trouche, 2009, p. 205). To provide an account of the variety and design of *documents* and the way teachers articulate them in different situations, *documents* are structures in a *documentational system*, in which the teacher's *resource system* constitutes the "*resource*" part of the *documentational system*. It must be noted that one of the objectives of *documentational genesis* is to consider the teacher's *activity* as goal-oriented and conceptualize it as a social activity. This consideration leads to paying close attention to the social contexts of the different groups in which the *activity* is present (Gueudet & Trouche, 2012). Particularly, the authors refer to AT as the theory from which they developed their own theoretical approach (Gueudet & Trouche, 2012) and state that: "The reference to activity theory is also directly connected with our interest in mediation and mediating artefacts" (Gueudet & Trouche, 2012, p. 24). This is how DAD is integrated into this research to address the didactic dimension of the research question.

Methodology

We propose a qualitative research through case studies (Cohen, Manion & Morrison, 2004). To establish the categories and elements of analysis, we also propose the teacher's teaching model. To achieve the objectives of this article, we present the teaching model on object displacement. This theoretical-methodological construct is produced from the integration of theories presented in the conceptual framework (*networking of theories*, Kidron & Bikner-Ahsbahs, 2015).

The Teacher's Teaching Model on Object Displacement

Model S & Model T. Two suppositions are assumed. (1) The teacher's practice considers (scientific-institutional) human cognitive action modes and representation modes: [scientific-institutional] *models* (Wartofsky, 1979). Particularly, regarding object displacement, *Model S* is defined as the current scientific —Newtonian—*model* that all teachers consider to produce their own *teaching models T*: their practices and pedagogical knowledge. Within m*odel S* is located the physico-mathematical content of the research (e.g., the scientific-institutional meanings on the concept of reference system, RS). (2) Throughout their academic education and their teaching practice years, teachers produce a *model T* representing, on the one hand, the action mode acquired from *model S*; that is, the way in which the teachers have organized the symbols of their experience and thought regarding *model S* to explain it to students. On the other hand, the representation modes of that knowledge acquired (representations and artefacts developed by the teachers). *Model T* adds the *documentational work* of each teacher; especially that on the selection criteria and *utilization* of *resources*, as well as planning and class implementation (planning and implementation of *activity systems*).

Activity systems. We propose that *main activity systems* and *particular activity systems* (*activity subsystems*) are produced from both *model S* and the teacher's *documentational work* (DW).

Main and *particular activity systems* will be produced from the *activity* (interactions in the classroom, *utilization* of *mediating artefacts* and *resources*) taking place in the classroom from a task (e.g., solving an exercise or discussing a topic, both related to object displacement) proposed by the teacher during class. This is how —from the objectives of the task— the main objectives of the *activity* arise. From the *main activity system* (e.g. finding the final velocity of an object) and *model S*, *activity subsystems* are derived (e.g. *activity system* on RS and *activity system* on the Cartesian coordinates system), which are, in turn, closely related to the *main activity system* but that have different particular objectives, allowing for the *main activity system* to be carried out (e.g., determine a RS and/or utilizing a coordinate axes system).

To establish how *activity systems* are produced and developed, we consider Gal'perin's notion on the *orienting basis of the activity*. Gal'perin's "epistemology is based on the notion that the appropriation of new knowledge and skills is the outcome of human action" (Haenen, 1993, p. 97). Then, teaching-learning processes aim to qualitatively improve the repertoire of present and actual actions (Haenen, 1993). "The optimization of this repertoire depends on the pupil's representations of the goal, the structure and the mediational means to execute a certain action" (Haenen, 1993, p. 97). The term *orienting base* is used to refer to such representations. In consequence, *main activity systems* and *activity subsystems* are developed from the decisions made by the teachers to represent the meanings of the concepts addressed.

On the one hand, there are didactic/semiotic relations (R-α) between *model S* and every *main activity system* and didactic/semiotic relations (R-α') between *model S* and *activity subsystems*. On the other hand, there are semiotic relations (R-β) between the *main activity system* and *activity subsystems* and semiotic relations (R-β') between *activity subsystems*. Below is the representation of the scheme of the teacher's teaching model for free-falling objects (Figure 2).

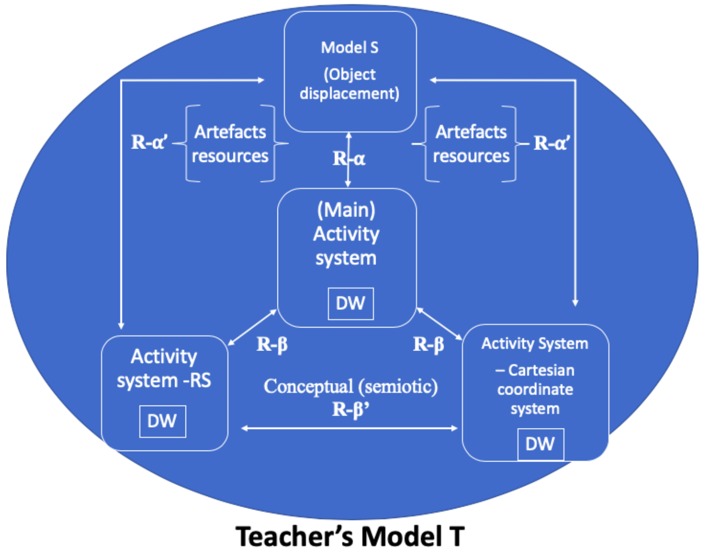

Figure 2: Scheme of Relations between Model S and Activity Systems Produced From a Teacher's Documentational Work (DW)

To analyze the characteristics of a novice teacher's *teaching model*, we worked with a physics teacher in two stages through non-participative observation. The teacher, Carlos (pseudonym), had majored in Physics and worked two years as a teacher when the first round of data was collected. In the first stage, Carlos' classes were video-recorded as he taught kinematics and dynamics topics to identify when he addressed free-fall topics and the concept of RS. The observation comprised 20 hours of class and transcriptions of selected excerpts were done. In the second stage, the teacher's classes were video-recorded as well, but only when Carlos taught specific topics selected from the first stage to analyze changes in the way he taught after two years of teaching experience. The observation in this stage lasted four hours of class. At the end of this stage, a semi-structured interview was conducted to acquire more elements of the teacher's *documentational work.*

Results and Discussion

To characterize the teacher's *model T*, we analyze the relations between *model S* and *activity systems* (Figure 2). The analysis considers both *artefacts* and *resources* used by Carlos. Then, instead of analyzing each isolated element (artefacts and resources), a multimodal analysis is carried out, considering the close relationship between both elements to establish the relations previously described. When analyzing these relations, there are two key elements to consider: the artefacts (particularly gestures) used by Carlos that provide account of his thought (cognitive structure) and his *documentational work* (utilization of resources) that provides elements of the pedagogical component. If the different relations (R-α, R-α', R-β y R-β') are carried out satisfactorily in Carlos' *model T*, then this is represented by a continuous arrow in the scheme. In contrast, it is represented with a dotted line if there are difficulties to carry out the relations.

Below, we present some results of the characteristics found in Carlos' *teaching model* (model T). In the first stage, whose data are not shown in this article, Carlos had difficulties while working with the concept of RS. Those difficulties continued along the second stage. Below are two excerpts from one of Carlos' classes from the second stage. The analysis of these excerpts allows for the characterization of Carlos' teaching model. In the class, Carlos addressed the topic "sign of a vector quantity", especially acceleration of gravity [g]. Carlos' *main activity system* corresponds to his explanation on the meaning of the sign of acceleration (acceleration of gravity is included). Then, after writing different equations to analyze object displacement, Carlos directed the students' attention to the meaning of the sign of acceleration.

> L1 Carlos: [*addressing the students*] You might have to determine this acceleration. But when determining it, we might get a minus sign, ok? That means that here [*points at the equations on the board in which acceleration might be negative; Figure 3*] you might get plus or minus in the result. But, what does plus or minus mean? (…) for example, if you get plus [*positive result of acceleration*], that means that it increased from nine meters per second [9 m/s] to thirty meters per second [30 m/s]. And, if you get minus [*negative result of acceleration*], that means it is slowing down. There is a deceleration. Then, this means that it lowers from thirty [30 m/s] to nine [9 m/s], ok? Don't forget that minus.

Figure 3: Carlos Points at Signs of Acceleration

From the beginning, Carlos directs the students' attention towards the meaning of the sign of acceleration (L1). However, his explanation mistakes the meaning of the negative sign of the quantity "acceleration" for the meaning of "deceleration". It must be considered that within Carlos' *resource system* is a textbook by Giancoli (2006), which Carlos uses as support [*resource*] during his courses. This textbook emphasizes one must be careful not to conceive the negative sign of an acceleration as a deceleration. Later in class, Carlos deals with the topic of the sign and its relation with free-falling objects:

> L2 Carlos: Now, in the vertical axis, the difference is that this deceleration that you see here [*he refers to the second equation from top to bottom; Figure 3*], which is always a constant (…) but in the vertical axis, you will not have to look for this deceleration. Why? Because this deceleration is going to be the deceleration of gravity (…) So, I will put it this way [*writes $a = g = -9.8\ m/s^2$ on the board*]. (…) I want you to always write the minus sign.

In L2, we observe how Carlos is helped by the Cartesian coordinate system to place the physical phenomenon of acceleration of gravity. Then, he evidently introduces another *activity system: activity system-Cartesian coordinate system* (Figure 4). This *activity system* should be related to the context of the RS; that is, to the *main activity system-RS.* This would provide meaning to the signs used in the context of object displacement (*Model S*). However, Carlos says again, just like he did two years before, that “g” must always be used with a negative sign (L2).

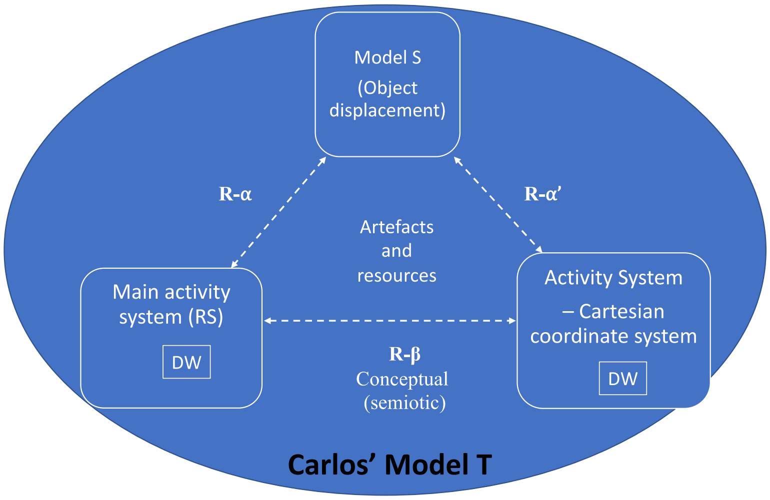

Figure 4: Teacher Carlos’ Scheme of Model T

Regarding Carlos’ *main activity system*, we observed it includes the *activity-RS system* (Figure 4). However, Carlos’ difficulty to carry out a relation R-α, between the *main activity system* and *Model S* (institutional) is evident. Because of this difficulty, the use of the textbook as a *resource* and *artefact* becomes especially important.

Conclusions

In this article, we have presented theoretical and methodological elements to analyze teachers’ practices. We presented the *teaching model* as a theoretical and methodological tool to analyze teaching practices. Particularly, we presented characteristics of a novice teacher’s *teaching model*. In the case of Carlos —a teacher with four years of experience [teaching seniority] at the time the second part of the data collection was completed— we concluded that, according to the results presented, he shows a *model T* represented by the scheme in Figure 4. At the epistemological level, this *model* is characterized by the fact that the relations between content and objectives of the *main activity systems* —produced from a *documentational work* and derived from a *scientific-institutional model* (*Model S*) regarding object displacement (relation R-α; Figure 4)— with an *activity system* on the RS or the Cartesian coordinate system (belonging to the mathematical context) are not present. These relations (R-β; Figure 4) allow for reporting the conceptual meanings present in a *main activity system* and other *activity systems* (*activity subsystems*) that arise during the activity.

The establishment of learning trajectories has become a key area of research in mathematics education, but there remains a need to characterize the role of instruction on students' developing concepts. This paper offers a way to establish a connection between student concepts, tasks, and pedagogical supports. We draw on two constructs, the epistemic student and DNR-based instruction, and articulate how these constructs can work in concert to inform the three phases of design, enactment, and analysis of learning trajectories. We close with an example from a learning trajectory of middle-school students' understanding of quadratic growth.

Keywords: Algebra and Algebraic Thinking, Learning Trajectories (or Progressions)

The Need to Situate Learning Trajectories Research in Instructional Settings

Learning trajectories have become an important area of research in mathematics education (e.g., Clements & Sarama, 2004; Fuhrman, Resnick, & Shepard, 2009; Sarama, 2018). The influence of this strand of research is evident in the development of the Common Core State Standards in Mathematics (National Governor's Association, 2010), in curricular materials (Confrey et al., 2018), and in special journal issues and reports (Daro, Mosher, & Cocoran, 2011; Duncan & Hmelo-Silver, 2009). There is a need, however, to address the role of instruction in the development of learning trajectories.

The notion of a learning trajectory has different meanings for different researchers. Simon's (1995) original definition described a hypothetical learning trajectory as consisting of "the learning goal, the learning activities, and the thinking and learning in which students might engage" (p. 133). Clements and Sarama (2004) depicted a learning trajectory as a description of children's thinking and learning in a particular mathematical domain, along with a "conjectured route through a set of instructional tasks designed to engender those mental processes or actions hypothesized to move children through a developmental progression" (p. 83). Connections to teaching are typically constrained to a consideration of learning activities or instructional tasks.

We offer a way to establish a connection between students' changing conceptions and instructional supports. Students' conceptual development does not occur in response to tasks alone, but also occurs in a specific setting, in concert with peers, a teacher, and particular material and conceptual artifacts (Voigt, 1995). We articulate two constructs for bridging the gap between student conceptions and the instructional environment: the epistemic student (Steffe & Norton, 2014), and DNR-based instruction (Harel, 2008a; 2008b). Below we describe how these constructs can together inform the design, enactment, and analysis of learning trajectories.

Two Theoretical Constructs: The Epistemic Student and DNR-Based Instruction

The Epistemic Student and the Mathematics of Students

Students who participate in learning trajectory research efforts differ in their mathematical experiences, dispositions, and positioning. A learning trajectory presents an account of students' concepts and the transitions from one concept to the next – but which students? We have found it

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

useful to frame a learning trajectory as offering a plausible sequence of concepts for the *epistemic student*. Grounded in Piaget's (1966) notion of the epistemic subject, an epistemic student is a hypothesis of the mathematics of students, consisting of a set of mathematical concepts and operations that can explain students' characteristic activity (Steffe & Norton, 2014). Epistemic students are models to describe, explain, and predict the mathematical actions of similar students who may be operating at a similar level (Steffe & Norton, 2014). A critical goal of learning trajectory research is to engender and explain students' productive thinking. By distinguishing our personal mathematics from students' mathematics, we recognize that students bring significant knowledge and competencies to bear. The job of establishing a learning trajectory then becomes one of explaining students' thinking in a manner that portrays it as meaningful, logical, and internally consistent.

DNR-Based Instruction

DNR is an acronym for the three instructional principles *duality*, *necessity*, and *repeated reasoning* (Harel, 2008a; 2008b). The duality principle addresses two forms of knowledge, Ways of Understanding (WoU) and Ways of Thinking (WoT). WoU can be understood as specific subject-matter knowledge, consisting of definitions, theorems, proofs, and mathematical relationships. WoT, in contrast, are more general conceptual tools, such as deductive reasoning, heuristics, and beliefs about mathematics (Harel, 2013). The duality principle states that students develop WoT through the production of WoU, and, conversely, the WoU they construct are afforded and constrained by their WoT (Harel, 2008a).

The necessity principle states that in order for students to learn the mathematics we intend to teach them, they must experience an intellectual need for it (Harel, 2008a; 2013). Teachers can engender intellectual need through problems that necessitate the creation of the target concept in order to be resolved. Relatedly, the repeated reasoning principle addresses the need for teachers to ensure that their students internalize, retain, and organize knowledge (Harel, 2008a). Repeated experience is a critical factor in achieving this goal, but Harel is careful to emphasize the importance of multiple opportunities to practice mathematical reasoning, rather than the drill and practice of routine problems.

Below we offer an example articulating how the constructs of the epistemic student and DNR-based instruction can inform the design, enactment, and analysis of a learning trajectory. This example draws on a teaching experiment with a group of 6 middle-school students who investigated quadratic growth phenomena, and it highlights the manner in which these constructs can establish a connection between students' changing conceptions and the instructional supports that occur within a particular teaching-and-learning context.

Methodological Approach: Design, Enactment, and Analysis

We conducted a 15-day videoed teaching experiment (Cobb & Steffe, 1983) with 6 8$^{\text{th}}$-grade students. The teacher-researcher was the first author. Three students were in general 8$^{\text{th}}$-grade mathematics, 2 students were in pre-algebra, and 1 student was in algebra. Each session lasted 1 hour. Each student also participated in one pre-interview and one post interview. Data sources included video and transcripts from the teaching sessions and the students' written work.

Learning Trajectory Design

The design phase includes creating a hypothetical learning trajectory (Simon, 1995) informed by DNR-based instructional principles and existing research. We designed a tentative series of tasks to necessitate the WoU that quadratic functions represent a constantly-changing rate of change between two covarying quantities (Saldanha & Thompson, 1998). A broader goal was to engender a WoT that functions can be representations of covariation (Thompson & Carlson, 2017). With those goals in mind we developed a context in which students could compare the areas, heights, and lengths of proportionally-growing rectangles. Students could manipulate the rectangles in order to determine how the quantities grew in relation to one another.

We developed the following three WoU that we wanted to foster during the teaching experiment: (a) the rate of change of a rectangle's area grows at a constantly-changing rate for each same-unit increase in height (or length); (b) given a height, h, the rectangle's area can be determined by $A = \mathrm{a}h^2$ where a is the ratio of length to height; and (c) the constantly-changing rate of change of the area (A) is dependent on the change in height (Δh). In order to foster these WoU, we devised tasks to encourage repeatedly reasoning through predictions of growth, determining areas for specific height values and vice versa, and deciding whether data tables represented proportionally-growing rectangles.

Learning Trajectory Enactment

One purpose of a teaching experiment is to gain direct experience with students' mathematical reasoning in relation to both tasks and teaching actions. Consequently, our set of tasks was not wholly predetermined, but instead we regularly created and revised new tasks in response to our evolving models of the students' thinking. During and between each session, we engaged in an iterative cycle of (a) teaching actions, (b) assessment and model building, and (c) invention and revision of tasks and other instructional supports. In this manner we continually revised our model of the epistemic student throughout the enactment of the teaching experiment (Steffe & Thompson, 2000).

DNR-based instruction provided guidance for introducing new instructional supports beyond tasks, such as teacher moves, question types, and prompts. For instance, we noticed that the students displayed a WoT of identifying number patterns that were divorced from quantities. This then encouraged an emphasis on changes in y without coordinating with corresponding changes in x. For instance, when discussing the increasing area of a rectangle that grew in length only, Ally said, "It would grow by 7, then 10, then 18." Her language emphasized growth in area, but in a manner that did not connect to the amount of growth in length. Further, units were absent from Ally's description. This WoT constrained the students' abilities to develop a WoU that the growth in area is dependent on the growth in height. We responded to this WoT by a) developing tasks to necessitate the creation of tables with different height increments; b) introducing prompts for students to explain their thinking through drawings, necessitating an attention to height increments; and c) encouraging the students to identify and name quantities.

Learning Trajectory Analysis

In addition to ongoing analysis, we also engaged in retrospective analysis (Simon et al., 2010) to support the revision and finalization of the learning trajectory. We applied the constant comparative method (Strauss & Corbin, 1990) to develop codes identifying (a) students' existing and emerging WoT and WoU, and (b) the instructional supports that preceded and appeared to foster shifts in students' WoT and WoU. All three authors independently coded the first eight sessions, met to reconcile discrepancies, and developed an initial framework, which we then applied to the last seven sessions. After these two rounds, we reached a stable framework, which the first and second authors then used to re-code all sessions.

An Example: The Shift from Implicit to Explicit Coordination

We identified three key shifts in the students' WoU: (1) From single-quantity and uncoordinated variation to implicit coordination of changes in quantities; (2) From implicit coordination to explicit quantified coordination; and (3) From explicit quantified coordination to identifying dependency relations of change. We highlight Shift 2, from *implicit coordination of changes in quantities* to *explicit quantified coordination of changes in quantities*. The students first began to explicitly coordinate changes in co-varying quantities when one quantity changed by 1. One of the instructional supports encouraging this coordination was the prompt to create their own ways of recording data. This activity encouraged explicit attention to how each of the relevant quantities grew in order to systematically track the growth. However, the students overwhelmingly created drawings and tables that incremented the height by 1 cm, which could lead to rendering unit changes implicit. We therefore devised a task in which the students had to first rates of change for the growth in area of a 2-cm by 5-cm rectangle, and then devise their own way to record the growth in order to test their predictions. By not specifying the height's magnitude of increase, we anticipated that the students would identify different rates of change for the area, which would engender a disagreement necessitating more explicit attention to changes in height.

Some students predicted that the changing rate of change for the area would be 5 cm^2, while others predicted 20 cm^2. As anticipated, the students did not initially specify for what change in height their prediction referred to. When testing their predictions, some students created tables with a height increase of 1 cm, while others used a height increase of 2 cm. This difference led to a disagreement. For instance, Bianca insisted that Jim's result of 5 cm^2 was incorrect, and that it should be 20 cm^2, which was Daeshim's result. This caused Jim to realize, "*He's* [Daeshim] going by 2's. But *I'm* going by 1's." Jim introduced the need to attend to the change in height, which caused the group to realize that the magnitude of height increase was relevant. The instructional support of encouraging students to create their own ways of recording data, combined with the ensuing conflict that emerged, fostered the students' attention to coordinated changes in quantities for magnitude increases other than 1 cm. Over multiple instances of repeated reasoning, the students eventually became accustomed to identifying different changes in height as coordinated with changes in length and area.

Discussion

Beyond those in the above example, we identified additional instructional supports that fostered Shift 2, including (a) explicitly drawing attention to and identifying quantities, (b) pressing for quantitatively-based justifications, and (c) introducing tables with increments less than 1 for the independent variable. This latter support fostered a WoU that one can coordinate changes in area with height increments less than 1 cm. However, the introduction of tables with $\Delta x < 1$ would not have been effective on its own. Rather, it needed to occur after the establishment of a socio-mathematical norm that one must explicitly identify the magnitude of height increases. This emphasizes the point that a learning trajectory should take seriously the notion that student learning occurs within a highly-contextualized system. This system includes not only carefully-devised tasks, but also students interacting with one another and with their teacher-researcher, the teacher-researcher engaging in particular instructional moves and encouraging particular forms of discourse, and the students and the teacher-researcher together developing a set of norms. One cannot simply lift a task sequence out of a teaching-and-learning system and expect that it will result in similar student outcomes in the hands of a different instructor who may have different mathematical goals, beliefs, and knowledge. Consequently, part of the challenge of translating learning trajectories research is to emphasize and exemplify the ways in which particular instructional moves can be powerful in relation to task sequences, and are dependent on our understanding of the mathematics of students.

This paper describes the APOS-Slope framework, a tool for studying students' understanding of slope. The paper outlines how this framework merges the theoretical lens of APOS with past work describing multiple conceptualizations of slope. Descriptions of student understanding of slope at each stage of the framework are provided, and implications of the framework for future research are detailed

Keywords: Algebra and Algebraic Thinking, Cognition, Learning Theory, Learning Trajectories

The APOS-Slope framework for studying students' understanding of slope unites the APOS (Action- Process-Object-Schema) theoretical lens with descriptions of multiple conceptions of what slope is and how it is used (Nagle, Martínez-Planell & Moore-Russo, *in press*).

Theoretical and Conceptual Lenses

A brief description of APOS Theory and past slope research are provided.

APOS Theory

APOS provides one possible lens through which data on mathematical understanding may be analyzed (Dubinsky & McDonald, 2001). In APOS, an *Action* is a transformation of a mathematical notion that the student perceives as external. It may be a rigid application of an explicitly available algorithm or the application of a memorized fact or procedure. An *Action* is relatively unconnected from the student's other mathematical knowledge. The student is unable to justify the *Action* and may be limited to using a specific representation. When an *Action* is repeated and the student reflects on the *Action*, it may be interiorized into a *Process* that has meaningful connections to the student's other mathematical knowledge. These connections enable the student to imagine the mathematical transformation, omit some of its steps, and anticipate its results without having to explicitly perform the transformation. The meaningful connections give the student the capability to convert between different representations of the transformation and to justify the *Process*. When encountering novel applications and contexts, the student may feel the need to apply *Actions* on a *Process* in order to deal with new problem situations. When the student is able to view the *Process* as an entity in itself and to apply, or to imagine applying, *Actions* on a *Process*, then it can be said that the *Process* has been encapsulated into an *Object*. A *Schema* is a coherent collection of *Actions*, *Processes*, *Objects*, and other *Schemas* that deal with a specific mathematical notion. The *Schema* is coherent in the sense that its different *Processes*, *Objects*, and sub-*Schemas* are interconnected.

Slope Conceptualizations and Research

Slope serves as a foundational concept in mathematics in part because there are numerous ways to represent and consider the topic across the curriculum (Nagle & Moore-Russo, 2014). Past research has reported 11 ways that students and teachers conceptualize slope (Moore-Russo, Connor & Rugg, 2011): *algebraic ratio* (A), *geometric ratio* (G), *physical property* (P), *parametric coefficient* (PC), *functional property* (F), *trigonometric conception* (T), *calculus*

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

conception (C), *real world situation* (R), *determining property* (D), *behavior indicator* (B) and *linear constant* (L). In the past, researchers have used these slope conceptualizations to describe the most prevalent conceptualizations among students and teachers (Nagle, Moore-Russo, Viglietti & Martin, 2013; Stump, 1999, 2001b) and to document deficits in slope reasoning (Stump, 1999, 2001a, 2001b; Teuscher & Reys, 2010). Carlson, Oehrtman and Engelke (2010) gave examples of how *Action* and *Process* views of slope can play a role in students' understanding of functions. Nagle and colleagues (2016) used APOS theory to describe how the 11 slope conceptualizations could be restructured by considering how slope is viewed (as a Number, Ratio, or Invariant) and how slope is used (to Describe Behavior, Measure Steepness, or Determine Relationships). Deniz and Kabael (2017) applied the APOS framework to analyze clinical interviews with eighth grade students constructing meaning for slope. Their findings provide illustrative examples of student thinking at the *Action* and *Process* stages, focusing on *algebraic ratio* and *geometric ratio*. The APOS-Slope framework presented here extends what is proposed by Deniz and Kabael (2017) to a population of more advanced students.

APOS-Slope Framework

The APOS-Slope framework draws on accounts of students' and teachers' interactions with slope in past research and suggests that the concept of slope may be constructed by interrelating the *geometric ratio* (G), *algebraic ratio* (A) and *functional property* (F) conceptualizations until they merge into the *linear constant* (L) conceptualization. These four conceptualizations (i.e., G, A, F, L) are described as ways of thinking about slope. The remaining seven conceptualizations (see Table 1) describe uses of slope. The following paragraphs detail each of the four ways of thinking about slope at Action, Process and Object stages, while drawing on examples of possible uses of slope at each stage. For additional examples and descriptions of possible transition levels between stages, see Nagle, Martínez-Planell & Moore-Russo (*in press*).

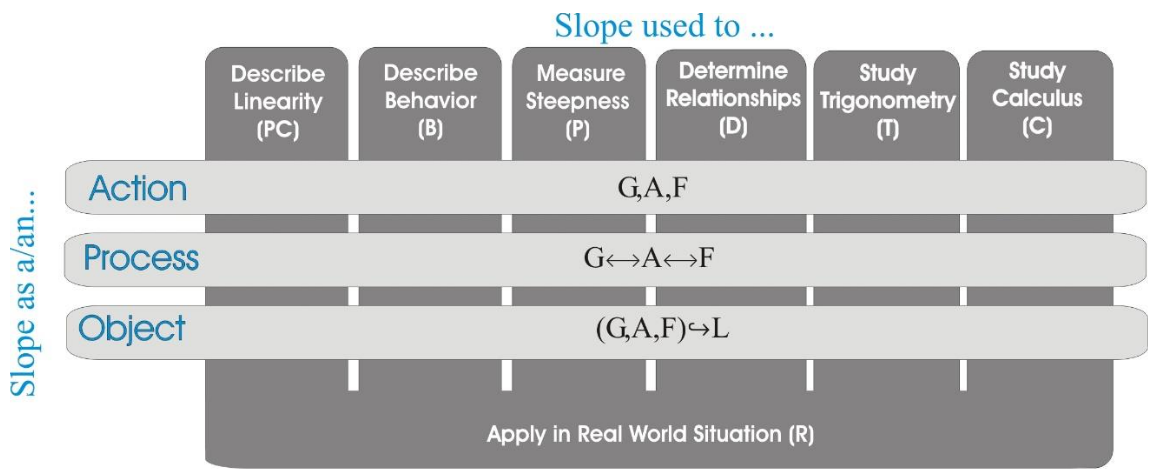

Figure 1: Interrelation between APOS Stages and the 11 Conceptualizations of Slope (from Nagle, Martínez-Planell & Moore-Russo, in press)

Slope as an Action

The *Action* stage can entail thinking of slope as an *algebraic ratio* (A_A), *geometric ratio* (A_G), or *functional property* (A_F). Consistent with Reiken's (2008) "number from a formula", an *Action* stage for the *algebraic ratio* (A_A) would consist of a student being limited to knowing (as a memorized fact) or making use of the formula $\boldsymbol{m} = \frac{y_2 - y_1}{x_2 - x_1}$, without justification or connection to other representations. Like Reiken's (2008) "number form counting", an *Action* stage for the *geometric ratio* (A_G) would consist of a student being limited to thinking about slope as vertical change (rise) over horizontal change (run) with a static mental image and may lead to the incorrect slope for a line graphed on a non-homogenous coordinate system (Zaslavsky, Sela & Leron, 2002). The *functional property* conceptualization involves thinking of slope as the rate of change between two varying quantities. An *Action* stage of *functional property* (A_F) would mean an empty and isolated verbal identification of the word "slope" with the phrase "rate of change" without any ability to further elaborate on what the rate of change represents contextually.

Even if restricted to an *Action* stage understanding of slope, a student might use slope for any of the purposes described in the APOS-Slope framework. For instance, a student who recalls and uses the memorized fact that an equation of the form $y = mx + b$ represents a line will be able to use slope to describe linearity when he or she states that "the graph of the equation $y = 3x + 4$ will be a line because it has a constant slope of 3 and lines have a constant slope." This same student may use slope to describe behavior (e.g., "the line will be increasing because the slope is positive") and measure steepness (e.g., "the line $y = 3x + 4$ is steeper than the line $y = 2x + 4$ because it has a larger slope"). The criteria that place these examples at the *Action* stage involve carrying out of procedures or parroting phrases without understanding of what one is doing.

Slope as a Process

The student showing a *Process* stage understanding of slope would have an understanding that is independent of representation, uniting *algebraic ratio*, *geometric ratio* and *functional property* conceptualizations. The *Process* conception also includes the ability to generate dynamic imagery without having to do explicit computations. Such a student would be able to imagine putting together several slope triangles with unit base to conclude that the vertical change is the slope times the horizontal change, $\Delta V = m\Delta H$. The student would also have the simultaneous awareness that the equation $y - y_1 = m(x - x_1)$ is an instance of this observation.

At the *Process* stage, a student would be able to use dynamic imagery of a line and its equation (see Figure 2) to justify with a geometric argument that any non-vertical line will have an equation of the form $y = mx + b$ (describe linearity) and to relate the sign of *m* in this equation to the increasing or decreasing behavior or the line (describe behavior). This student could also use slope to measure steepness by justifying how the value of slope impacts slope triangles and therefore the steepness of a line.

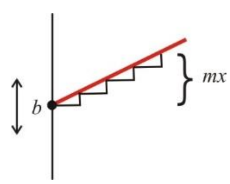

Figure 2: Dynamic Imagery for a *Process* Understanding (from Nagle, Martínez-Planell & Moore-Russo, in press)

Slope as an Object

An *Object* stage understanding of slope results from doing or imagining doing *Actions* on a *Process* of slope as the range of applications extends beyond the context in which it was initially developed. A student who is able to use a *Process* understanding of slope to construct a notion of slope in three-dimensions to think of slopes of tangent planes would be exhibiting behavior consistent with an *Object* stage understanding of slope. Students with an *Object* conception would be able to do *Actions* on their *Process* conceptions of slope to think of slope in units of miles per hour or ounces of juice concentrate per ounces of water or any other combination of units needed for a *real world* application conceptualization. The *linear constant* conceptualization of slope involves thinking of slope as a constant property unique to “straight” figures, independent of representation and thus requires at least a *Process* stage of understanding. Thinking of slope as “a … property” already implies being able to think of the slope *Process* as an entity in itself. In APOS it is conjectured that there might be a stage called *Totality* between the *Process* and *Object* stages (Arnon et al., 2014). *Totality* is proposed to be a stage where the individuals recognize the *Process* as an entity in itself, but they may not yet be able to apply *Actions* on the *Process* (Arnon et al., 2014). We propose that the *linear constant* conceptualization of slope captures the essence of the *Totality* stage of development. That is, the *linear constant* conceptualization implies thinking of slope as a *Process* and as an entity in itself; however the student may not be able to do *Actions* on this *Process*. The ability to do *Actions* on the *Process* is what distinguishes the *Object* from the *Totality* (Arnon et al., 2014).

At an *Object* stage, slope may be used for any of the previously described purposes in a new problem context or setting. While an algebra student may leverage their *Object* stage understanding of slope to a new real-world context such as finding juice concentrate, an advanced calculus student may use it to make sense of slope in three-dimensions.

Implications and Future Research Directions

The APOS-Slope framework provides a lens for interpreting past research while providing direction for future research. Descriptions of possible areas of future investigation follow.

Qualitative Synthesis

A complete qualitative synthesis of past research on slope in light of the APOS-Slope framework would highlight connections between past work describing slope understanding and coverage in the curriculum using a variety of conceptual frameworks. Revisiting this research with the APOS-Slope framework might allow for comparisons that are difficult when authors use different coding schemes and terminology.

Genetic Decomposition

In APOS, a genetic decomposition (GD) is a conjecture of mental constructions students may use in order to understand a specific mathematical concept (Arnon et al., 2014). The APOS-slope framework provides a basis from which to build and refine a GD since it provides detailed descriptions of possible thinking at the *Action*, *Process* and *Object* stages. In addition, because slope is a multi-faceted concept, the APOS-Slope framework describes *Action* stage reasoning where slope can be viewed as an *algebraic ratio*, *geometric ratio*, or *functional property*. Moreover, Nagle, Martínez-Planell and Moore-Russo (*in press*) describe several proposed transitional levels between each of these *Action* stages and a *Process* stage. An important next step is to engage students and teachers in task-based interviews based on the GD, to test and refine these descriptions and the GD itself.

A GD for slope informed by the APOS-Slope framework will provide a new means to analyze the coverage of slope in existing standards documents and curricular materials. One may investigate whether the constructions conjectured in the GD are adequately represented. A GD can also inform the design and implementation of instructional activities intended to help students progress through the GD, resulting in further analysis and refinement. These results can then be used to develop, test and refine an ACE (Activities, Classroom Discussion, Exercise) cycle (Arnon et al., 2014), resulting in pedagogical implications that can inform the teaching and learning of slope throughout the curriculum.

The APOS-Slope framework provides interpretive power to the body of past research on slope and has the potential to inform the direction of future research in the field. Whether used as a research lens or as a guide in curricular development and pedagogical decisions, the APOS-Slope framework has the potential to inform the teaching and learning of slope across the curriculum, from introductory algebra to differential calculus.

A RADICAL CONSTRUCTIVIST MODEL OF TEACHERS' MATHEMATICAL LEARNING THROUGH STUDENT-TEACHER INTERACTION

Biyao Liang
University of Georgia
leungbiyao@uga.edu

I propose a model of student-teacher interaction with attention to teachers' construction and enactment of knowledge of students' mathematics. I adopt the theoretical perspective of radical constructivism to discuss how it enables us to simultaneously account for individual teacher cognition and the dynamics of student-teacher interaction. Specifically, I characterize a mechanism by which student-teacher interaction is generative to teachers' mathematical learning at a cognitive level. I close the paper by discussing the implications for research on teacher decentering and teacher knowledge, and the potential methodological challenges.

Keywords: Cognition, Social Interaction, Teacher Knowledge, Second-order Models

In the past three decades, many mathematics education researchers have built upon Shulman (1986) and proposed a variety of theories of teacher knowledge specific to mathematics teaching. Some researchers in this pursuit have adopted constructivist epistemology (Harel, 2008; Silverman & Thompson, 2008; Tallman, 2016), believing that teacher knowledge is individually-held, while others have followed the sociocultural perspectives, believing that teacher knowledge is collectively-held and distributed (Adler, 1998; Barwell, 2013; Hodgen, 2011; Putnam & Borko, 2000). There are also perspectives that are not based in an explicit epistemology. In such cases, researchers view teacher knowledge as being based in the work of mathematics teaching (i.e., practice-based theory; Ball, Thames, & Phelps, 2008; Fennema & Franke, 1992; Shulman, 1986). A common critique of the constructivist perspectives (or cognitive perspectives in general) on teacher knowledge is that they fail to account for teachers' knowledge sensitive to specific teaching situations (Barwell, 2013; Depaepe, Verschaffel, & Kelchtermans, 2013). Many radical constructivists have argued against these interpretations, claiming that social interaction is at the core of radical constructivism (e.g., Confrey, 1995; Steffe & Thompson, 2000a; Thompson, 2000, 2013, 2014; von Glasersfeld, 1995). The first goal of this paper is to extend these scholars' discussions to elaborate on how radical constructivism can simultaneously explain mathematics teacher cognition and student-teacher interaction.

The second goal of this paper is to unpack cognitive processes involved in teachers' learning of the mathematics of students through social interaction with them. Mathematics teacher educators have emphasized the importance of teachers' *learning through teaching* (Fennema & Franke, 1992; Leikin & Zazkis, 2010; Sherin, 2002; A. G. Thompson & Thompson, 1996). Underlying this proposal is the assumption that teachers' construction of knowledge is a constructive, dynamic, and adaptive process. While the sociocultural and practice-based theories emphasize the situative aspect of teacher knowledge, they do not explain the mechanism by which student-teacher interaction is generative to teachers' mathematical learning. Here, I discuss how radical constructivism can provide a theoretical tool for addressing this limitation.

First-, Second-, and Third-Order Modeling

A central tenet of radical constructivism (von Glasersfeld, 1995) is that *knowledge*, as the product of knowing, is not a representation of objective truth—rather, it functions and organizes viably within a knower's experience and is idiosyncratic to the knower. Under these assumptions, we have no access to anyone else's knowledge; at best, we can construct hypothetical *models* of others' knowledge that are viable with our observation of their behaviors (Steffe & Thompson, 2000b). Radical constructivists clearly distinguish the living experience of the knower herself from the *observer* who is trying to understand the knower's knowledge. This distinction leads to the notions of *first*- and *second-order models*. *First-order models* are "models the observed subject constructs to order, comprehend, and control his or her experience" (Steffe, von Glasersfeld, Richards, & Cobb, 1983, p. xvi)—i.e., the subject's knowledge that no one else can have access to. The first-order mathematics of teachers (or students) are the teachers' (or the students') mathematical *schemes* (i.e., cognitive entities that consist of a collection of mental actions that govern an individual's perception and activity; see Piaget & Inhelder (1968)) that exist in the teachers' (or the students') minds. Because teachers do not have access to their students' first-order mathematics, what we call teachers' knowledge of students' mathematics is at best the teachers' *second-order models* of the students' mathematics. *Second-order models* are, "[the models] observers may construct of the subject's knowledge in order to explain their observations (i.e., their experience) of the subject's states and activities" (Steffe et al., 1983, p. xvi). Teachers' second-order models are the teachers' inferences about the students' mathematical thinking that explain the students' observable actions. To be clear, second-order models are also schemes comprising the teachers' knowledge. There is no way for the teachers, the observers, to confirm if their interpretations match what the students, the subjects, are "actually" thinking. Similarly, the researchers who are attempting to infer a teacher's knowledge of the student's mathematics is engaging in constructing second-order models of the teacher's second-order models of the student' mathematics—i.e., *third-order models* of the student's mathematics. These models consist of the researchers' inferences about how the teacher may interpret her student's mathematics. Figure 1 illustrates these different types of models in the context of student-teacher interaction.

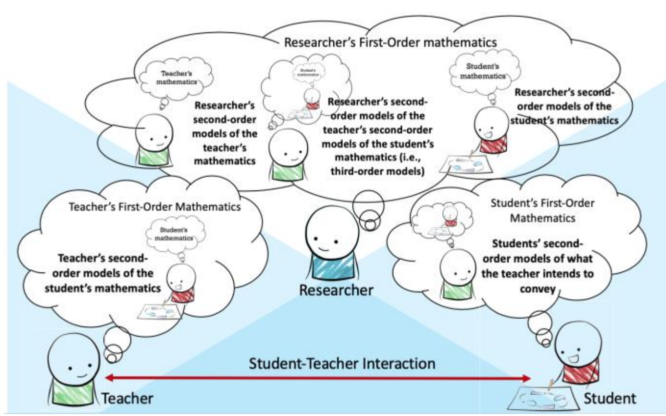

Figure 1: First-, Second-, and Third-Order Models

A Model of Mathematical Learning Through Student-Teacher Interaction

The aforementioned constructs provide the theoretical tools for unpacking the mechanism of student-teacher interaction and teachers' mathematical learning (Figure 2). This proposed model includes components of "teacher activity" (denoted in yellow boxes) and "student activity" (denoted in orange boxes).

I define *teacher actions* as a teacher's observable moves enacted for communicating with her student (e.g., talks, gestures). I limit my definition of *teacher knowledge* to a teacher's mathematical knowledge relevant to her social interaction with students, which includes, among others, the teacher's first-order mathematics and her second-order models of her students' mathematics constructed through *assimilation* and *accommodation* (von Glasersfeld, 1995) (see the bottom blue arrow in Figure 2, left). As the teacher negotiates between these different domains of knowledge, she decides what actions she needs to take to respond to the student (see the left "enact" arrow). Then, the student constructs second-order models of the teacher's meanings by assimilating or accommodating the teacher's actions (see the top blue arrow). The student further enacts her knowledge to respond to the teacher in actions (see the right "enact" arrow), which triggers assimilations and accommodations of the teacher (see the bottom blue arrow). The teacher may also reflect on her previous teaching actions to become aware of how her ways of interacting are consequential to the student's learning and how the student has interpreted her actions (see the left "reflect" arrow).

This interaction cycle continues as the student and the teacher reciprocally and continually assimilate the language and observable actions of the other and construct second-order models of the other's knowledge until (ideally) no accommodations are necessary for successful assimilation (i.e., intersubjective construction of knowledge in social interaction; see Steffe and Thompson (2000a)). In this process, both of the teacher and the student are engaged in interpreting each other's meanings, monitoring and anticipating each other's responses, and correspondingly adjusting second-order models of each other (P. W. Thompson, 2013).

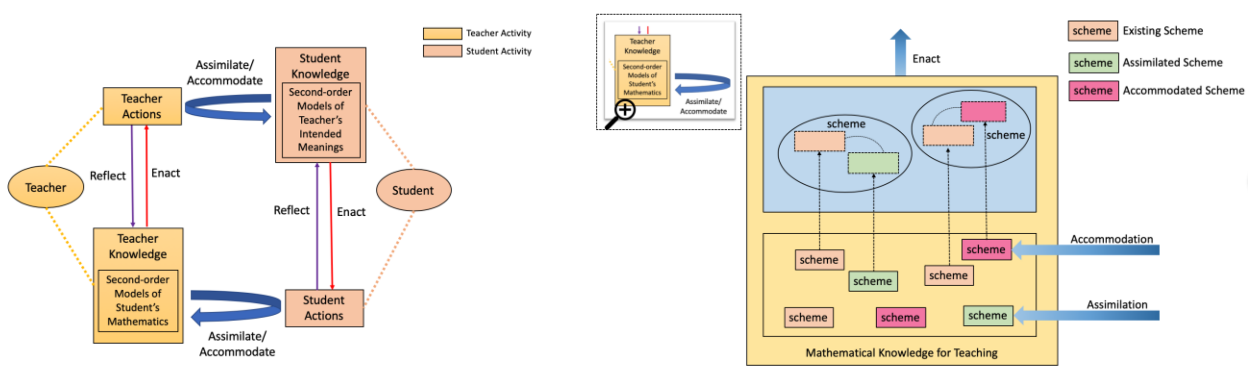

Figure 2: A Model of (left) Student-Teacher Interaction and (right) Teachers' Construction and Enactment of Knowledge of Students' Mathematics

Now I further unpack the mental processes involved in a teacher's construction and enactment of second-order models of students' mathematics during student-teacher interaction (Figure 2, right). I distinguish between three types of schemes of teachers. The first type of scheme (colored in orange) is the teacher's existing scheme prior to her interaction with the student. Constituting the teachers' first-order knowledge, these schemes consist of the teacher's personal mathematical knowledge, her intended mathematical meanings specific to the interaction, and her previously constructed, internalized second-order models of students' mathematics. These schemes are the source knowledge that the teacher leverages to interact with students. The second type of scheme (colored in green) is the scheme to which the teacher *assimilates* the student's actions, hence a subtype of the existing scheme. When the student's actions are similar to the actions that have been abstracted in the teacher's prior learning experiences or prior interaction with students, the teacher recognizes the student's actions by applying her existing schemes. The teacher does not make any significant modifications or reorganizations to her schemes because she does not abstract any novel mental actions from her observation of the student's activity. I note that because no two experiences can be exactly identical at different times and different contexts, assimilation is always accompanied by modest accommodation. The third type of scheme (colored in pink) is the scheme constructed through *accommodation*. When the student's actions generate some perturbations in the teacher, the teacher actively revises her existing schemes to account for the novel features of the student's actions. As a result, the teacher either includes new compositions into her schemes or restructures her scheme system.

As the teacher constructs either type of schemes, she may mentally operate on the different schemes to compare them, identify their relationships, or coordinate them (see the four upward arrows in Figure 2, right). These mental processes have two important outcomes. First, the teacher experiences reorganizations in her schemes and constructs more coherent schemes that consist of a network of related mental actions and operations. The teacher's updated system of schemes may influence her future assimilations and accommodations of the student's actions. Second, by being aware of how the student's ways of operating differ from her own or from the goal understandings, the teacher can determine how to act in ways that are hypothetically beneficial for engendering accommodations in the student.

I note that what types of mental processes come into play is wholly determined by the nature of the teacher's schemes and the teacher's personal ways of organizing and refining her mathematical scheme system in response to her experience of interacting with students—and thus can differ across individuals in face of similar student actions.

Implications for Teacher Education Research

This model characterizes a mechanism that teachers' construction of second-order models of students' mathematics is a process of teachers applying their current schemes to discern students' mathematics and, meanwhile, modifying and reorganizing their own mathematical schemes. This conceptualization can serve as an analytical tool for empirical research aiming at providing a fine-grained analysis of teachers' second-order models or the mental processes involved in their constructions of these models. Relevant findings can (1) help refine the proposed theory of teachers' mathematical learning in relation to student-teacher interaction (i.e., how student-teacher interaction is generative to teachers' mathematical knowledge), (2) provide explanatory power for teachers' decision making during interaction with students, and (3) inform mathematics teacher educators in terms of advancing teachers' sensitivity to students' thinking.

As I have described, a teacher's construction of mathematics of students is an ongoing process that involves continuing scheme assimilation and accommodation. A teacher's second-order models of her students' mathematics can continue to evolve throughout her instruction. I argue that considering the extent to which teachers accommodate their mathematical schemes is crucial to understanding their knowledge growth. I encourage researchers to focus their attention on revealing the constructive and dynamic nature of teachers' knowledge of students' mathematical thinking as it relates to student-teacher interaction. I acknowledge that documenting the evolution of teachers' knowledge of students' mathematics sensitive to their ongoing interaction with students creates methodological challenges. To generate fine-grained third-order models of students' mathematics, researchers may need to triangulate different data sources (e.g., teaching videos, interview videos, written reflections) to test and confirm their hypotheses of teachers' knowledge of students. We may also need to develop methods to document the in-the-moment mental processes involved in teachers' construction of mathematical knowledge of students during their teaching.

Acknowledgments

I thank Kevin Moore and Michael Tallman for their insightful feedback on previous versions of this paper.

TRANSLANGUAGING TO PERSEVERE: BRIDGING METHODOLOGICAL LENSES TO EXAMINE LATINX BILINGUAL STUDENTS' PROBLEM-SOLVING

Hector Morales, Jr.
Northeastern Illinois University
h-morales3@neiu.edu

Joseph DiNapoli
Montclair State University
dinapolij@montclair.edu

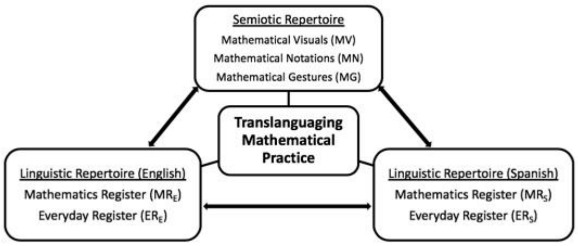
Translanguaging practice has been shown to be an effective resource to support collective perseverance and learning mathematics with understanding. We explore the methodological approach of analyzing the discursive translanguaging and perseverance practices of Latinx bilingual students simultaneously. We found that mapping dialogically tracked components of translanguaging practice to phases of perseverance revealed valuable learning insights.

Keywords: Translanguaging, Equity and Diversity, Classroom Discourse, Latinx Bilinguals

Dehumanizing school practices continue to marginalize the linguistic, social, and cultural capital for Latinx bilingual students in the United States. Research shows Latinx bilingual students can leverage their cultural and linguistic knowledge to construct, negotiate, and communicate about mathematics (Chval & Khisty, 2009; Garcia, Johnson, & Seltzer, 2017; Morales, Jr., 2004), but these resources remain widely ignored in schools that privilege the dominant school language (Langer-Osuna et al., 2016). Reform efforts have made strides toward access for all students to have supports necessary to persevere with challenging mathematics (NCTM, 2014); it is through perseverance in problem-solving that students can learn mathematics with understanding (DiNapoli, 2018). Yet, deficit perspectives on language and culture act as a barrier to knowledge and perpetuate ideas that bilingualism is an obstruction to learning rather than a facilitator (Garcia, 2017; Morales, Jr. & DiNapoli, 2018a). The field of mathematics education must find innovative ways to study how Latinx bilingual students use their bilingualism to learn mathematics with understanding. In this paper, we merge the perspectives of translanguaging and perseverance to posit an analytic method by which this process can be examined.

Translanguaing and Persevering to Learn Mathematics

We draw on translanguaging to reconceptualize bilingualism as a liberating and empowering communicative practice. Translanguaging can be a resource capable of transforming learning that goes beyond the transition to the dominant school language. Translanguaging is more than just a simple shift between two languages. It is a complex and interrelated communicative practice that make up bilinguals' linguistic repertoire (Cenoz, 2017). Garcia (2017) posits, "…speakers use their languaging, bodies, multimodal resources, tools and artifacts in dynamically entangled, interconnected and coordinated ways to make meaning" (p. 258). We extend Garcia's (2017) translanguaging practice framework to accommodate how bilingual students use the mathematics discourse including other linguistic repertoire such as the everyday register, mathematics register, mathematical artifacts (visuals and mathematical notations), and multimodal repertoire to make meanings as they persevere with challenging mathematical ideas (Moschkovich, 2000, 2015; O'Halloran, 2015). Within this Translanguaging Mathematical Practice (TMP) (Figure 1a), participants engaging within the mathematics discourse deploy fluid movement between mathematical and everyday speaking across Spanish and English by using everyday linguistic features and mathematics register resources in dialogically entangled ways with the intention to make meaning (Garcia-Mateus & Palmer, 2017; Morales, Jr. & DiNapoli, 2018b).



(a)

Three-Phase Perseverance Framework (3PP)

Entrance Phase	
Clarity (C-0)	Objectives were understood
Initial Obstacle (IO-0)	Solution pathway not immediately apparent
Initial Attempt Phase	
Initiated Effort (IE-1)	Engaged with task
Sustained Effort (SE-1)	Used problem-solving heuristics to explore task
Outcome of Effort (OE-1)	Made mathematical progress
Additional Attempt Phase (after perceived setback(s))	
Re-initiated Effort (IE-2)	Engaged with task
Re-sustained Effort (SE-2)	Used problem-solving heuristics to explore task
Outcome of Effort (OE-2)	Made mathematical progress

(b)

Figure 1: Frameworks for Translanguaging and Perseverance in a Mathematics Context

In the context of working on a challenging mathematical task, perseverance is initiating and sustaining in-the-moment productive struggle in the face of one or more obstacles, setbacks, or discouragements (DiNapoli, 2018). The Three-Phase Perseverance Framework (3PP) (Figure 1b) is an analytical perspective by which perseverance can be qualitatively described and measured (see DiNapoli, 2018 for detailed framework). The 3PP reflects perspectives of concept, problem-solving actions, self-regulation, and making and recognizing mathematical progress. It considers first if the task at hand warrants perseverance for students (Entrance Phase), considers next the ways in which students initiate and sustain productive struggle (Initial Attempt Phase), and considers last the ways in which students re-initiate and re-sustain productive struggle, if they encounter a perceived setback as a result of their initial attempt (Additional Attempt Phase).

Perseverance is vital for learning mathematics with understanding, so it is important for educators to encourage perseverance via their classroom practice. As such, NCTM (2014) advises for teaching practices that "consistently provide students, individually and collectively, with opportunities and supports to engage in productive struggle as they grapple with mathematical ideas and relationships" (p. 48). However, it is still unclear how perseverance might manifest in students working across two languages. An essential next step in this line of research is to consider the ways in which we recognize how Latinx bilingual students leverage their communicative and linguistic repertoires to build understandings (Martinez, Morales, & Aldana, 2017). Next, we describe an analytic process to recognize the ways in which Latinx bilingual students use translanguaging practice to persevere with challenging mathematics.

Recognizing Translanguaging to Persevere: A Methodology

The question of this study involves the nature of mathematical meaning constructions while Latinx bilinguals work collaboratively around a challenging task. Our analytic method consolidated, reduced, and interpreted collective dialogic interchanges to make explicit the interplay of translanguaging and perseverance experiences.

Tier 1: Coding for Translanguaging Mathematical Practice

The goal of this coding is to demonstrate the dialogic nature of the meaning making process. Bilingual students are afforded the possibility of engaging in a translanguaging practice. Students draw on their home and school languages increasing the potential for students to make connections between everyday and mathematical registers across both languages (Bose &

Clarkson, 2016). The main objective was to understand the meaning-making process and to identify the translanguaging resources that students made connections to as a result of this process. Video transcripts were coded so that we could identify which linguistic resources students used across both English and Spanish and non-verbal resources, including the everyday register (ER) and mathematics register (MR) in both English ($_E$) and Spanish ($_S$). Given the nature of communicating mathematically to negotiate meanings, we also identified moments when students transitioned to non-verbal mathematical representations that include visual-graphic (MV) and symbolic representations or notations (MN).

Tier 2: Coding for Perseverance in Problem-Solving

After coding the small group interaction data from the perspective of translanguaging practice, the same video transcripts were considered through a perseverance lens. The Three-Phase Perseverance Framework was used to capture the ways in students collectively persevered, or did not, during their engagement with a challenging mathematical task. The Entrance Phase captured whether the group of students understood the entirety of what a task was asking (C-0) and if the group immediately knew how to solve the problem (IO-0). The Initial Attempt Phase examined whether and how a group of students initiated (IE-1) and sustained (SE-1) their effort, and the outcome of such effort (OE-1) as they worked toward solving all parts of the problem. In the event the group did not solve the problem after making a first attempt, the Additional Attempt Phase aimed to capture if and how the students amended their original problem-solving plan (IE-2, SE-2), and the outcome of such efforts (OE-2) as they worked to overcome setbacks.

Tier 3: Overlay Analysis of Translanguaging to Persevere

We used a multi-tier code mapping process (Anfara, Jr., Brown, & Mangione, 2002) to identity and tag evidence of translanguaging and perseverance practice in the dialogic interchanges. Then, we conducted a constant comparative overlay analysis of both Tier 1 and Tier 2 coding (Glaser & Strauss, 1967), which facilitated the simultaneous analysis of Latinx bilingual students' translanguaging practice during key moments of their problem-solving when perseverance was necessary. Inductively, we analyzed the ways in which evidence of translanguaging practice occupied different phases and components of perseverance. Such analysis results in a theoretical sampling of patterns and themes that help describe the meaning-making actions in those moments of collective problem-solving.

Sample Analysis of Bilingual Students' Perseverance and Discussion

We present a brief example of our method to illustrate how a group of Latinx bilingual students leveraged their translanguaging practice to persevere with a mathematics task (Table 1). The task referenced an exponential relationship within *Alice in Wonderland*. The group had already demonstrated evidence of understanding the goal of the task (C-0) (to describe the mathematical relationship), but did not immediately know a solution pathway (IO-0).

Table 1: Sample Group Vignette with TMP and 3PP Coding

Transcript *(English Translation)*	**Translanguaging**	**Perseverance**
JESSICA: ¿Qué era la primera, se hace así? *(What was the first one, do you do it like this?)* If [*Alice*] eats one ounce, that means that she grows twice, dos ¿qué? *(two, what?)* Double, no double, two…See, so when two is four, and then three is six, and four is eight, y así, y así	**MR$_E$**: Describing and representing how height grows: "grows twice" **MR$_E$ & MR$_S$**: Dos-Double-Two, "Two is four, three is six, four is eight" **MG**: Graphical gesturing **MR$_S$**: Describes the shape verbally:	**IE-1**: Making sense of context **SE-1**: Exploring doubling

vamos hacer la graph *(like this, and this is how we are going to make the graph)*. Going like that (gesturing), para arriba *(up)*. You get it? **ELENA: Um hmm. Pero *(But)*, how to times it?**	"para arriba"	
JESSICA: Porque mira *(look)*, two, times two. Well no…Double it by, nomas *(just)* double the number of ounces, so if she takes… **ELENA: Two times two, y luego *(and then)* four times two, y luego *(and then)* six times two, is that what you are saying?**	**ER_S & MR_E**: Combines everyday and mathematics register: "Porque mira", "nomas double the number of ounces." **MR_E & ER_S**: Everyday and mathematics registers: "Two times two, y luego, four times times two…"	**IE-1**: Making sense of context **SE-1**: Exploring doubling
JESSICA: Más o menos como sumando el mismo número. *(More or less like adding the same number.)* **CARINA: Pero es lo mismo de sumando si lo multiplicas por dos. *(But it is the same as adding if you multiply by two.)***	**MR_S**: Representing doubling with operations: "como sumando el mismo númer"	**SE-1**: Exploring doubling **OE-1**: Better understanding doubling
INES: Lo que parece es como hicimos un in/out table y ya lo sacamos. *(It looks like we just did an in/out table and that's it).* In x 2 = Out In | x | 1 2 3 4 5 6 7 8 9 10 Out | y | 2 4 6 8 10 12 14 16 18 20 **CARINA: Yeah. In times two equal out… ¿Ya no tenemos que hacer su altura? *(We don't have to use her height?)***	**MV**: Tabular representation of the doubling relationship **MN**: Expressing the equation symbolically	**SE-1**: Revisiting representations of function **OE-1**: Recognizing interpretation mistake

This group initiated their effort (IE-1) toward differently expressing what doubling meant to them. Jessica used her linguistic and multimodal repertoire to express her understanding of doubling in a variety of ways: "grows twice," "dos," "double," "two," a sequence of number relationships, and graphical gesturing. Yet, the group did not immediately realize they were multiplying the number of ounces of cake by two instead of by *Alice's* height. Jessica and Elena dialogically moved between everyday and mathematics register (ER & MR) to explore the relation algebraically. Carina and Jessica leveraged the mathematics register in Spanish (MR_S) to agree that doubling is the same as adding the same number or multiplying it by two. They also represented the relationship symbolically as an equation (MN). Exploration of these points of view is evidence of sustaining their effort (SE-1) to make sense of the function. Their equation correctly spanned the table of values, yet did not model an exponential function. Ines helped her peers realize that they were doubling the number of ounces of cake instead of *Alice's* height (OE-1). In Spanish, Ines reminded the group that they must start with *Alice's* initial height. Ines used her mathematics register (MR_S) to describe how she doubled *Alice's* height as each ounce was eaten. Ines' revelation shows how perseverance can emerge from a group dynamic. This change in strategy marked the exit of the Initial Attempt Phase and entrance into the Additional Attempt Phase. We will depict the remainder of this group's efforts toward understanding in our session.

There is an ongoing demand to learn from the ways Latinx bilingual students communicate mathematically, yet it remains largely underserved in practice as teachers continue to have difficulty authentically engaging bilingual students within the mathematics discourse. We aim to apply our analytic method across contexts in which Latinx bilingual students are productively struggling to learn mathematics. If future research can map the specific ways bilingual students are using translanguaging to collectively persevere, we can help practitioners more progressively design learning environments more supportive of productive struggle across multilingual contexts. By prioritizing the TMP by which meanings can be formed, providing freedom to explore challenges, and lessening the focus on just learning vocabulary, teachers can better support Latinx bilinguals' perseverance toward understanding mathematics.

SUPPOSE A SITUATION: WHAT FOUCAULT HELPS UNCOVER

Travis Weiland
Appalachian State University
weilandtj@appstate.edu

In this paper, I discuss an Archeological analysis of two high school mathematics textbook series in an effort to investigate how actions for the doing of statistics are formed by statements from the statistics lessons the texts. The objective of this paper is not to present all of the findings related to the posed question, but to focus on discussing the methodology employed (i.e. Foucauldian Discourse Analysis), which is relatively novel for analyzing textbooks in mathematics education. One finding will be presented to highlight how the methodology employed can contribute to the field helping to uncover patterns not found using well established deductive frameworks. This methodological discussion is meant to provide an example of how using different methodologies can help to investigate issues in the field and problematize taken for granted norms against a new horizon to embrace the sociopolitical turn.

Keywords: Research Methods, Curriculum Analysis, Data Analysis and Statistics

Objective

In spite of statistics' growing role in the mathematics curriculum and growing importance for citizenship there has been little investigation of the state of the teaching of statistics in K-12 mathematics classrooms (Eichler & Zapata-Cardona, 2016; Shaughnessy, 2007). In an effort to begin to investigate what experiences are made available to students with statistics in the school setting I investigated the research question: How are the actions for the doing of statistics formed by statements from the statistics lessons of two major high school mathematics textbook series? The objective of this paper is not to present all of findings related to the posed question. Instead I am going to focus on discussing the methodology employed (i.e. Foucauldian Discourse Analysis), which is relatively novel for analyzing textbooks in mathematics education and present one finding to highlight how the methodology employed can contribute to the field helping to uncover patterns not found using well established deductive frameworks.

Textbooks in Mathematics Education

In a recent survey of teachers 45% (±2.7) reported using instructional materials for 75% or more of the class time and 74% (±1.5) reported using their text to guide the overall structure and content emphasis of their instructional units (Banilower et al., 2013). This means that classroom texts may largely influence the experiences students might have with statistics in a high school mathematics classroom, particularly in the case of teaching statistics because mathematics teachers often have had little to no past experiences with statistics to draw upon to filter or change the tasks presented in meaningful ways (Shaughnessy, 2007). Up to this point there has been very little work focused on investigating the statistics content of school mathematics texts in the context of the U.S. (e.g. Bargagliotti, 2012; Jones et al., 2015; Jones & Jacobbe, 2014; Pickle, 2012; Tran, 2013). The dearth of research around the statistics lessons of mathematics texts is concerning given that statistics and mathematics are distinct disciplines in spite of statistic's location within the mathematics curriculum meaning there are differences in how it should be taught as well (Cobb & Moore, 1997; Franklin et al., 2007; Groth, 2007).

Theoretical Framework: Discourse

In education the term discourse is frequently linked to talk, language, or other methods of communication (Ryve, 2011). In this study, I draw from Foucault's perspective of discourse (Foucault, 1972); specifically his use of the term "as a regulated practice that accounts for a certain number of statements (Foucault, 1972, p. 80).' The regulated practice is often considered similar to a set of rules, which are generally taken for granted, and also constrain and "specify what is possible to speak, do, and even think, at a particular time" (Walshaw, 2007, p. 19). This makes discourses powerful, producing what is considered knowledge or truth regimes in particular historical, social, and political spaces (Walshaw, 2007). Discourses are important to study because they influence and shape how we see the world around us. They create structures that shape and frame who we are, who we can be, and how the world is perceived. These structures do not represent objective reality, but are socially created and subjective.

Related to the focus of this paper, I am investigating how the discourse of two high school mathematics textbook series, which are from a particular historical, social, and political space produce what is considered the actions for the doing of statistics for readers to take up. Related to textbook analysis in mathematics education, after extensive review I found only two other examples that employed Foucault's notion of discourse and methods; Hottinger (2016) and McBride (1989) both of which focused on how mathematics texts subjectify woman and construct mathematics as a masculine discipline.

Methodology

In this section, I discuss how the methodological considerations taken up in this study. In working towards this end let me first state explicitly the ontological and epistemological assumptions I drew from while conducting this work consistent with the theoretical perspective I discussed earlier drawing from Foucault. For the ontological perspective I reject the existence of knowable, objective, independent reality that individuals can access (Arribas-Ayllon & Walkerdine, 2008; Walshaw, 2007). Objective reality can never truly be known as it is filtered through discourse. Consistent with this ontological perspective I also situate this work in the epistemological where, knowledge or "truth" is viewed as socially constituted by discourses. Various "regimes of truth" are created through rules and regularities in statements in discourses that are historical and situated in context. Rooted in ontological and epistemological stances described I relied upon Foucault's (1972) methodology of Archeology in an effort to answer the research question I posed.

In archaeology, Foucault takes a historical approach to interrogate the "regimes of truth" formed by the rules or regularities of statements in discourse (Walshaw, 2007). In Archeology the unit of analysis is statements from the discourses being investigated and what constitutes a statement changes based on discourse being analyzed (Foucault, 1972). I chose to operationalize statements as sentences as every proper sentence contains at least one verb, which holds the potential to be an action formed for the doing of statistics by the discourse of the text. There is more to discourse than just statements, just as there is more to text than sentences. They may be the building blocks, but there are also rules that function to regulate how statements form and function, similar to grammar in language. These rules are referred to as discursive practices, which operate systematically to form and order objects. Foucault (1972) refers to the 'things' formed by discursive practices as discursive formations. It is regularities in the statements of textbooks that form the actions appropriate for the doing of statistics that are the focus of this study. For example, a statement like "calculate the mean and standard deviation of each data set," functions to position the actions of calculating mean and standard deviation of data sets as actions for the doing of statistics that students can then take up.

For this analysis, regularities in the statements were looked for both within and across lessons in each textbook series. The analysis was iterative through a series of readings of the data with different aspects of the data as the focus of each reading. I used a low bar of three occurrences of an action in the text to constitute a formation to give the benefit of the doubt to the text in terms of the actions formed.

Data Sources

I relied on findings from a survey of a nationally representative sample of science and mathematics teachers in U.S. schools (Banilower et al., 2013) to select texts for analysis. Houghton Mifflin Harcourt and Pearson made of the market share accounting for 35% (SE=1.6) and 30% (SE=2.0) respectively with their traditional Algebra I, Geometry, Algebra II sequence series. I extrapolated from these findings and selected textbook series that explicitly conformed to the CCSSM to make the findings more relevant, selecting the *Houghton Mifflin Harcourt Algebra 1, Geometry, Algebra 2* curriculum (Kanold, Burger, Dixon, Larson, & Lienwand, 2015) and the *Pearson Algebra 1, Geometry, Algebra 2 Common Core* curriculum (Randall et al., 2015). I analyzed all lessons that discussed topics from statistics.

Data Analysis

The analysis was iterative through a series of readings of the data with different aspects of the data as the focus of each reading. The first reading of the data consisted of identifying and recording all the sentences that indicated actions students are intended to perform. Selected statements were then placed in an excel spreadsheet for analysis. The second iteration consisted of taking the sentences identified as relevant statements during the first reading and summarizing the actions constituted in each statement. This process was carried out in the excel spreadsheet where the data from the first reading was recorded. The third iteration consisted of taking all the summarized actions for each statement from the previous iteration and putting them into a word document organized by lesson and then grouping the actions that were similar by lesson. I treated any group that had three or more statements in it as a regularity or action constituted by the discourse of the text. I considered such regularities as a discursive formation consistent with what I described earlier in terms of the methodology of Archaeology (Foucault, 1972). For the forth iteration, I took all the actions formed that met the threshold for being considered a regularity within a lesson into a document and then placed all the statements that did not make the cutoff for being considered regularities within a lesson into a separate document for each textbook. I then looked for regularities that occurred across the lessons that did not come out from the analysis within the lessons. Any regularity found across lessons was then added to those found within lessons in a document.

Findings: Uncovering What Might Be

From the overall analysis I found that the predominant actions formed were associated with analyzing data, which is a narrow view of statistics and how it should be taught. This is a result that has been found by others (i.e. Bargagliotti, 2012; Jones et al., 2015) using deductive frameworks based on the GAISE framework (Franklin et al., 2007). Therefore, the inductive analysis performed supports findings from others using deductive lenses, which helps to strengthen the warrant of those lenses. However, rather than going into detail on the findings that could have been found using deductive frames I will focus on a specific finding that was uncovered that would not have been uncovered by commonly used deductive frames to highlight the use of the methodological approach I took.

The action formation of *supposing a situation* appears frequently in statements throughout lessons in all of the textbooks analyzed. Statements indicative of this action formation typically begin with "suppose …" and go on to describe some sort of fictional situation that students were being given to consider. For example, consider the following example of a series of statements from the text:

> Suppose you asked, "Do you work out every day like a healthy person, or are you a lazy couch potato who only works out once in a while?" Do you think the results of your survey would change? Explain your reasoning. (Randall et al., 2015, p. 752).

Supposing a situation was the most prevalent action formed by the discourse of the textbooks. This action is not specific to dealing with data as this action can be used in any case where students are asked to consider a fictional situation or to take information for granted that is given. One of the most common settings it was formed in was probability settings. For example, consider the following excerpt of statements from the texts:

> 1. A bag contains 12 red and 8 blue chips. Two chips are separately drawn at random from the bag. Suppose that a single chip is drawn at random from the bag. Find the probability that the chip is red and the probability that the chip is blue. Suppose that two chips are separately drawn at random from the bag and that the first chip is returned to the bag before the second chip is drawn. Find the probability that the second chip drawn is blue given the first chip drawn was red. (Kanold et al., 2015, p. 743)

It is not inherently problematic that the discourse of the texts position students to suppose they are in a specific situation or performing a particular task. The problem lies in that students are positioned this way so often. If students are always supposing situations when are they ever investigating actual situations from their own world and reality? In other words how does having students predominant supposing situations when are they being positioned to read and write the word and the world with mathematics (Gutstein, 2006) with statistics (Weiland, 2017)?

Scholarly Significance

The main goal of this paper is to elaborate on how drawing methodologically from Foucault can help uncover realities that may not be visible from using well developed deductive frameworks. Though it is good to have deductive frameworks to help structure analyses and potentially frame what the field values, it is also good to employ inductive analyses to potentially uncover realities that may be hidden to more traditional and structured lenses. Foucault's perspectives are also powerful for interrogating and problematizing the taken for granted values and practices of the field of mathematics education that deductive analysis can be blind to (Kollosche, 2016). Furthermore, using Foucault and the epistemological stance that comes with it helps to make visible the power that textbooks hold in shaping the reality students experience and what is considered knowledge. The prevalence of the discursive formation of "suppose a situation" would not have been laid bare by the frameworks used in previous analyses of statistics lesson in mathematics texts, nor have I found this discussed more broadly in the mathematics education literature. At the same time I hypothesis that this formation is not surprising to anyone reading this who is familiar with mathematics texts. That is the power of this type of analysis is to interrogate taken for granted regimes of truth. As the field begins to realize the sociopolitical turn in mathematics education (Gutiérrez, 2013) it is important more work acknowledges the power that exists in discourse to construct our ways of knowing and being in the world and how they shape how and what people learn as mathematics.

In this theoretical paper, we introduce analytic pragmatism (Brandom, 2008) as a paradigm that allows for the simultaneous discussion of findings from different theoretical traditions. We illustrate the use of this paradigm by examining literature about teaching and learning fractions. This novel approach is particularly well suited for the body of fraction research because in this domain the same terms are used differently across traditions, historical periods, and discursive levels. Moreover, different terms are sometimes used in the same way. We assume that the mathematical activity of learners is stable and, using analytic pragmatism (Brandom, 2008), we illustrate how analytic pragmatism can be used synthesize research across time, tradition, and discursive level. We discuss the utility of our approach for the field of mathematics education.

Keywords: Literature review, Analytic pragmatism, Metatheory

Objectives

While conducting a comprehensive literature review of articles focused on fractions and decimals from forty years of research, we discerned ontologically incompatible frameworks that referred to the same phenomena (disagreements) and ontologically compatible claims that argued a particular phenomenon was more nuanced than was previously understood (refinements). In order to bring disagreeing theorists into conversation with one another, we adopted the ontologically agnostic perspective of analytic pragmatism (Brandom, 2008), which splits discourse into two necessarily related components: meaning and use. We argue that Meaning Use Analysis (MUA) can precisely locate disagreements and refinements.

Because the MUA metatheoretic construct is not in common use in mathematics education, we begin by introducing some terminology used in the subsequent analyses. Then we briefly review literature that provides different accounts of students' initial use of (improper) fractions. We follow by applying the MUA framework to this case to locate disagreements and refinements in the literature. We conclude by discussing implications of the framework and method of analysis for the field of mathematics education research.

Theoretical Framework: Analytic Pragmatism, Meaning, and Use

The broad project of analysis, not only in the tradition of analytic philosophy (Brandom, 2008) but also in scientific efforts in general (Habermas, 1971), can be conceptualized as relationships between *vocabularies*. We often talk about understanding a phenomenon as the ability to explain the phenomenon using a different *vocabulary* taken to be more fundamental. For us, vocabularies are subsets of all the words in a language (i.e., English) over which semantic relationships can be defined, including the syntactic components of any associated non-verbal representations (e.g., reading number lines). Brandom's focus is on reducing exceptionally broad types of vocabularies to a single *normative* vocabulary of *commitments* and *entitlements*. We adopt Brandom's approach to study the acquisition of much narrower, math-specific vocabularies, e.g. "fractions," and place no emphasis on category reduction. However, the language of *commitments* and *entitlements* is broadly applicable to the project of mathematics education. Commitments are assertions like "$\frac{1}{2} < \frac{3}{4}$", but we can program computers to spit out that string or train parrots to vocalize that assertion. What makes those assertions become more than marks on a page or vibrations in the air is that we can ask "what must one be able to do to count as saying '$\frac{1}{2} < \frac{3}{4}$'", that is, "what entitles someone to the commitment that $\frac{1}{2} < \frac{3}{4}$". These entitlements are also assertions, like "$\frac{1}{2} < \frac{3}{4}$ because $\frac{2}{4} < \frac{3}{4}$," but they are grounded in *practices-or-abilities* (defined below). As math educators, we find particular value in the notion that one must be able to do one thing to count as saying something else. Adopting the language of commitments and entitlements could make the injunction to "show your work" less opaque in K-12 situations and could possibly lead to more satisfying responses in teacher education where the form of the question is to "explain your answer". That is, teachers and teacher educators are already in the practice of asking learners to express both their commitments and entitlements. In the present paper, we take it as given that some kind of doing is necessary for a mathematical utterance to count as a commitment (i.e., to have meaning).

What makes analytic pragmatism unique and powerful is that vocabularies are treated as separable from the *practices-or-abilities* that give them meaning. It is common to think of word meanings as the kinds of mappings from one vocabulary onto another vocabulary, like what one finds in a dictionary, where a word is associated with a set of words in direct Vocabulary-Vocabulary (VV) relationships. The point of analytic pragmatism is to break out of direct VV relationships and instead consider meaning as mediated by use. Consequently, we are concerned with VV relationships as mediated by sets of *practices-or-abilities*, and we define meaning as coordinated VPV relationships.

Practices-or-abilities (P) are intended not as observable behavior but rather in a discursive sense as the repeatable rules (algorithms) that specify how to use a particular vocabulary. Brandom uses "practices-or-abilities" because analytic pragmatism is ontologically agnostic and seeks to be able to describe practices like "creating common denominators" alongside abilities like "mentally rotating an isosceles triangle", and thus we argue that both positivist and constructivist traditions (as well as others) can be modeled within this paradigm. For us, *algorithms* include mathematical processes such as a standard computational algorithm but can also refer to mental schemes (e.g., Steffe, 1983). In the MUA paradigm, algorithms need not be standardized across individuals or even consistent for an individual; algorithms merely refer to repeatable discursive rules that, by their discursive nature, are specified by a higher-order vocabulary. The vocabularies that describe the algorithms, which constitute practices-or-abilities mediating VV relationships, are called *pragmatic metavocabularies* (henceforth *metavocabularies*). Linking back to our objectives, we can now say that disagreeing theorists use competing metavocabularies in their descriptions of the same practices-or-abilities, whereas refinements occur as researchers critique whether or not a metavocabulary is sufficient to precisely describe the practices-or-abilities associated with a specific domain.

Literature Review

We focus on frequently-cited literature in the well-researched domain of fractions so readers are more likely to be familiar with the issues, and thus might better understand the relevance of MUA. It is important to clearly state that this is but one case, and a similar analysis would be as

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

fruitfully applied in any area of mathematics education that has been addressed in more than one time and from more than one perspective.

Children learn about fractions over a long period of time and with widely differing outcomes in terms of the mathematical knowledge they develop. The issue of how knowledge of fractions is related to knowledge of whole number is a central theme of research in this area, and we summarize three accounts of students' initial use of fractions. The *interference hypothesis* (e.g. Behr, Wachsmuth, Post, & Lesh, 1984) posits that whole number knowledge is thought to interfere with developing knowledge of fractions, and for example, students inappropriately treat the digits of fractions as if they were whole numbers. In disagreement, Steffe (2002) argues with the reorganization hypothesis that whole number knowledge is a resource that is recruited and reorganized to serve fraction knowledge. Whereas Steffe (2002) argued the splitting operation is sufficient for making sense of improper fractions from whole number knowledge, Hackenberg (2007) provided a refinement by identifying the role of coordinating three levels of units.

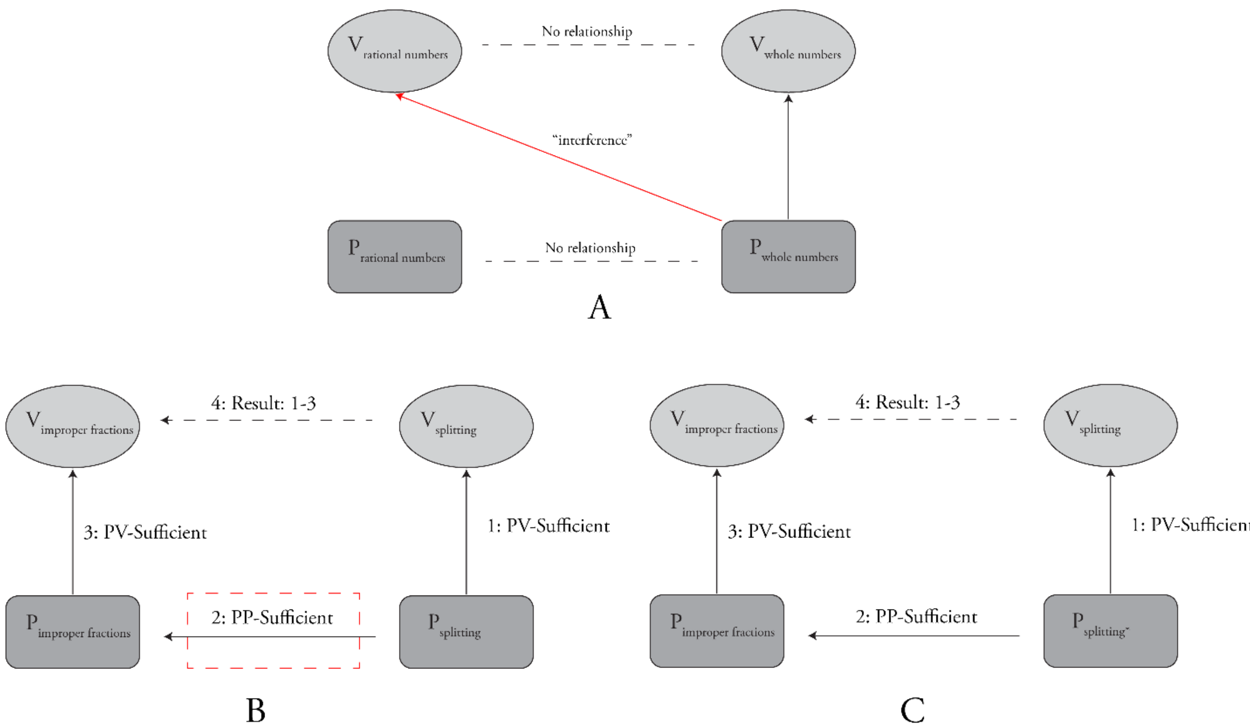

Figure 1: (A) The *Interference Hypothesis* Takes Different Mathematical Vocabularies to be Independent of Each Other; (B) Steffe (2002)Argues that Splitting is Sufficient to Deploy Improper Fractions; (C) Hackenberg (2007) Argues that Splitting Together with the Ability to Doordinate Three Levels of Units (denoted *splitting), is Sufficient to Deploy Improper Fractions**

Results

The results of this project are communicated in Figure 1. Analytic pragmatism allows for a rearticulation of these core perspectives in mathematics education. The interference hypothesis essentially amounts to a claim that children have to develop a new rational number vocabulary, that is independent of their whole number vocabulary. When children deploy a rational number vocabulary under the rules (i.e., practices-or-abilities) associated with their whole number vocabulary, Behr et al. claim that the whole number vocabulary is interfering with the rational number vocabulary. The constructivist alternative to this story is that the practices-or-abilities associated with earlier stages can be elaborated into new practices-or-abilities. In particular, Steffe argues that once learners have established the ability to split, they can deploy a fraction vocabulary to answer questions like "Here's a picture of my stick, which is five times the length of yours. Can you make your stick?" then they have essentially constructed improper fractions, which is to say that they can meaningfully deploy an improper fraction vocabulary. Hackenberg refines Steffe's claim by arguing that the splitting operation that Steffe describes is not sufficient to deploy an improper fraction vocabulary. In terms of MUA, this is taking issue with the second relationship in Figure 1B. Hackenberg argues that a new splitting operation that includes the ability to coordinate three levels of units (denoted *splitting** in Figure 1C) is sufficient to deploy an improper fraction vocabulary. Thus, we demonstrate that MUA allows for the simultaneous discussion of results from traditions that have different ontological commitments, allowing for disagreements and refinements to be located relative to each other with precision.

Discussion

There are two potential contributions of this work. First, reading math education research literature is a high-inference activity because each researcher can approach related phenomena from very different theoretical perspectives. MUA explicates those inferences, which allows readers to lay the arguments of each author side by side. Second, because analytic pragmatism is ontologically agnostic, it is an appropriate tool for synthesizing research across traditions. By looking at the discursive structure of the research reports, disagreements and refinements are readily apparent. Because MUA operates on the most basic elements—words and meaning—no unifying theory is required to bring disparate perspectives into conversation. In a field as rich in theory as is mathematics education, MUA has a great deal of promise.

METAPHORS BEHIND THE CONCEPT OF TANGENCY

Francisco Sepúlveda
CINVESTAV, IPN, México
francisco.sepulveda@cinvestav.mx

Although a group of students already has advanced knowledge of differential calculus, the first definition they give of a tangent line to a curve remains influenced by the tangent line to a circle. A diachronic analysis on tangency through the conceptual metaphor framework shows how metaphors determine mathematical procedures and definitions and help to understand the possible cognitive obstacles presents on the concept of a tangent line.

Keywords: Precalculus, Advanced Mathematical Thinking, Communication, Geometry and Geometrical and Spatial Thinking

While the word “tangent” comes from the Latin tangere and means ‘to touch’, the word “secant” comes from the Latin secare and means ‘to cut’. As many words, both have a metaphorical etymology that shows, from a modern perspective (e.g., Lackoff & Núñez, 2000), how those terms are cognitively conceived. Many authors (e.g., Font, Bolite & Acevedo, 2010; Talmy, 2000) assert that there is an object metaphor and a fictive-motion phenomenon that pervade conceptions of the tangent and of the secant line. Even though, taking a synchronic approach, those words are not really metaphorical, fictive-motion remains one of the indispensables approaches to make sense of those terms. ¿How metaphors are intrinsically related to modern conceptions of the tangent line?

Methodology

From a reputed Mathematics Education Master in Mexico, we choose seven students and future high school professors. They answered a brief inquiry, from which we expose only two questions. On the first question teachers are asked to write on their own words the definition of a tangent line to a curve on a point P. On the second question they are asked to plot a cubic function on Geogebra and approximate the tangent line on a point P to the curve through a secant line PP’. The abscissa of P’ depends on a slider that goes through an interval between 0.001 and 0.1, with a 0.001 step. This slider permits to simulate the limit concept transforming a hand movement on a displacement of the point P’ to P approximating the tangent line by secants lines. Then students are asked to put the slider on its minimum, and, because the 0.001 value of the slider gives the line the appearance of a tangent to the curve on P, declare if the obtained line is a tangent or not, and justify the given answer.

Results

Five of the seven students mention geometrical properties of a tangent line to a circle in defining a tangent line on a point to a curve, as, for example, “a line that touches only in one point to the curve”, “a line that does not traverse the curve” or “a perpendicular line to the curve on a single point”. Only three future teachers use in their definition the calculus paradigm mentioning the limit of secant lines or the derivative number. On the second question, when they are asked if the line that seems to be the limit of secant lines is a tangent to the curve on point P, they all answer correctly that this is not a tangent. However, of the seven future teachers, four justify their answer by arguing that the line obtained touches more than at one point of the curve, one responds with ambiguity writing that the line obtained "tends to be the tangent line" and only one teacher uses the word "converges" avoiding in this way the argument of the double intersection.

Discussion

A chronological approach to the tangent line shows how the Euclidean Elements influenced Descartes to obtain the algebraic equation of a tangent to a polynomial curve. If the Descartes method is analyzed from a conceptual metaphor frame, then some interesting facts come to the front. Figure 1 represents the simplest method to trace a tangent to a circle, given that the tangent in P to the circle of center A is perpendicular to the radius AP.

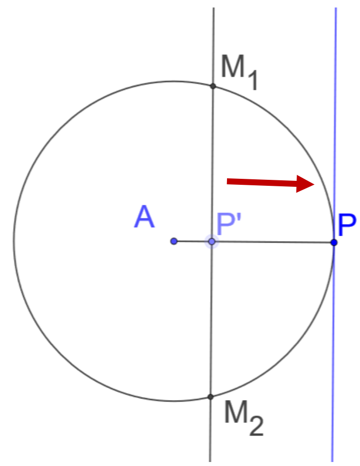

Figure 1: The Trace of a Tangent Line to a Circle by a Perpendicular Displacement of Line M_1M_2

The process in Figure 1 starts with the secant line perpendicular to the radius in P'. This line cuts the circle on two points M_1 and M_2. Then this line is displaced until reach the border of the circle on P. As in this figure, Euclides defined the tangent line through its perpendicularity to the radius, so when Descartes looked for an algebraic equation of the tangent to a curve his first thought was to search for a circle with a radius perpendicular to that curve. Part of Descartes's process is described below where C and E are the two intersections of the supposed circle with the curve.

> The more those two points C and E are close to each other, the less difference there is between its two roots; and finally, they are entirely equal, if they are both joined, that is to say if the circle passing through C touches at C the curve CE without cutting it. (own translation from Descartes, 1637, p. 37)

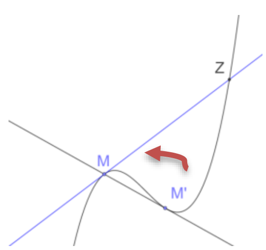
His method is not more used, but the circle that Descartes proposed is called today an osculating circle, or, looking for the initial metaphorical romantic meaning of the verb osculate, a "kissing circle". While this metaphor is not transcendent on the process used by Descartes, three other metaphors are very important on his strategy that come from trying to replicate the method described in Figure 1 on a curve. The first metaphor is the perpendicularity to the radius of a circle replicated on a curve, the second is the fictive motion of the points M_1 and M_2 that approximate to each other, and the third is the coexistence of these two points at the tangency point reinforced algebraically by the double root. Those three metaphors are intrinsically related on the Descartes method, and combined show his cognitive underlying process.

This historical chronology echoes on the mathematics curriculum by introducing first the tangent line to a circle. But, the tangent line to a curve results later from another modern and effective definition of a tangent line to a curve based on the derivative number. In fact, in some curriculums, the derivative of a function at a given point M is introduced as the limit of the slopes of lines passing through M and another point M’ of the curve when M’ tends to M. This process is illustrated in Table 1.

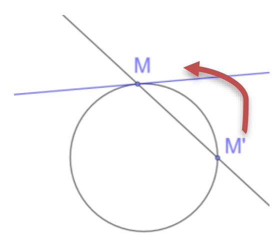
The relationship between tangent and derivative can generate a logical problem representing an obstacle to students (Vivier, 2010). From a linguistic perspective both terms, tangent and secant, are opposed, but in calculus the way to define the tangent line at a given point is as the limit of secants passing through the point. Conceptual metaphors of the calculus paradigm that help to understand the limit concept, and so the tangent concept, are those of collapse and approximation (Oehrtman, 2009) that are related to the Basic Metaphor of Infinity proposed by Lakoff & Núñez (2000). However, as our enquiry and some other researchers supports (e.g., Canul, Dolores, & Martínez-Sierra, 2011; Vinner, 1991; Vivier, 2010), the students’ mental image of the tangent line still influenced by the circle. Let’s analyze on Table 1 which metaphors are behind the calculus paradigm in defining a tangent line.

Table 1: Fictive Motion and the Limit of Secants on a Curve and a Circle

<table>
<tr><th>Limit of secants on a curve</th><th>Limit of secants on a circle</th></tr>
<tr><td>



On the calculus paradigm, to introduce the tangent line to a curve we use the fictive motion metaphor of a point M’ that approximates a fixed-point M. The process could also be understood as a sequence of secant lines that in some point (the limit) becomes the tangent.</td>
<td>



Analogous, this situation can be considered as a fixed-point M and a displacing point M’ that approximates M creating a sequence of secant lines; or as a fixed secant line that rotates around M until it becomes a tangent line.</td></tr>
</table>

This table, in contraposition with Figure 1, helps to understand the cognitive problems behind the conceptualization of the tangent line with a limit paradigm. First, the perpendicular property that was used by Descartes to obtain the tangent line is completely lost. Second, the coexistence of two points on the same place is one impossible phenomenon from the particle’s perspective adopted by Newton and Leibnitz. Moreover, in some cases, the tangent line obtained in one point could remain a secant to the curve (as seen in the left column of Table 1) creating a cognitive paradox and detonating the necessity of a local vision that was not present in the case of the circle.

Finally, a very different fictive-motion metaphor can help to conceptualize a tangent line, not present in the Descartes exposed method neither on the calculus paradigm. That is to interpret the tangent line as the trace of a particle that describe a straight trajectory and “graze” the curve on one point. This interpretation is closer to the original etymology of the word ‘tangent’ and has an algebraic correspondent methodology proposed later by Descartes that consist of searching the equation of a line that intersects twice on the same point with a curve. This approach is closer to the definition of a tangent line as the best linear approximation of a curve on the proximity of a point. Some researchers argue that this definition is the best of a tangent line on mathematics education (De la Rosa, 2009).

Conclusions

A conceptual metaphor approach to the tangent line has served to expose how some of the cognitive process involved on its original conceptualization are lost on the traditional teaching. On the one hand, this historical perspective confirms the power of conceptual metaphors lying in big areas of mathematics to influence procedures and definitions. On the other hand, all the long this article we described different types of motion that can be used to explain properties of the tangent line, accordingly to the sensible approach proposed by Tall (2011, p. 53). As said in the introduction, motion is inherent to the conceptualization of the tangent, however, that does not imply that there is only one cognitive way in which this concept could be introduced. In fact, it is no argued that teachers must use one or other metaphors in classes, but that they may consider a conceptual metaphor approach to some classical delicate concepts before teaching, in order to go deeper and better understand the cognitive processes that were necessary on their conception.

METAFORAS DETRAS DEL CONCEPTO DE TANGENCIA

A pesar de que un grupo de estudiantes goza de conocimientos avanzados de cálculo diferencial, la primera definición que dan de una recta tangente a una curva permanece influenciada por la recta tangente a un círculo. Un análisis diacrónico de la tangencia a través del marco de la metáfora conceptual muestra cómo las metáforas determinan los procedimiento matemáticos y las definiciones y ayuda a comprender los posibles obstáculos cognitivos presentes en el concepto de recta tangente.

EXPLORING QUALITIES OF A COMMUNITY OF INQUIRY IN A SYNCHRONOUS ONLINE COURSE

Jeffrey Choppin

We studied an online course designed to provide rural mathematics teachers access to high quality professional development. The online course emphasized productive discussions related to high-leverage discourse practices. We applied a community of inquiry framework, which emphasizes deep intellectual work, and its three tenets: cognitive presence, social presence, and teaching presence. In this paper we focus on cognitive presence. A major contribution of our study is the use of mediating processes to characterize cognitive presence; this allowed us to conceptualize the interaction between the three presences (social, teaching, and cognitive) and their connections to our design conjectures.

Online platforms and learning environments are emerging as important contexts for providing opportunities for teachers to engage in professional development (Johnson et al., 2018; Keengwe & Kang, 2012; Means et al., 2009), and thus as sites of research. We argue that *synchronous* learning environments have the potential to provide impactful professional learning experiences for teachers and to incorporate many important features of face-to-face models, but there needs to be an increased focus on the methods to do so. In this study, we explore one component of a three-part online professional development model for middle grades mathematics teachers in rural contexts. We apply a community of inquiry framework (Garrison, Anderson, & Archer, 2000) because of its assumptions about engaging participants in demanding intellectual work, and connect it to *design conjectures* (Sandoval, 2014). Specifically, the mediating process component of design conjectures provides a way to characterize and analyze the cognitive presence in a community of inquiry, which has been an outstanding methodological problem in studying online contexts (Akyol & Garrison, 2011).

Online Professional Development Modules

We designed a three-part online professional development model with the goal of providing rural mathematics teachers access to high quality professional development. Our project utilized a series of synchronous online experiences, including online course modules, teaching labs (akin to demonstration or fishbowl lessons), and online video coaching. The online course modules emphasized discourse practices that facilitate mathematically productive classroom discussions (Smith & Stein, 2011), including anticipating, monitoring, selecting, sequencing, and connecting. The modules also emphasize key aspects of lesson planning, such as goal-setting, in addition to having teachers solve and discuss high-cognitive demand tasks. The modules involved a combination of synchronous and asynchronous work, in order to minimize the amount of time teachers virtually met together (Robinson, Kilgore, & Warren, 2017). We conducted the OMD course in Zoom, which allowed for synchronous whole class and small group interactions. In

addition, we simultaneously used Google docs and Google draw, which allowed participants to collectively develop and share artifacts, including approaches to mathematical problems. The instructor presented challenging tasks to the participants, who then worked in virtual breakout rooms to create a document in a common workspace that they shared with the other groups.

Framework

We draw primarily from the community of inquiry framework (Garrison, Anderson, & Archer, 2000), that identifies three components of online learning environments: cognitive presence, social presence, and teaching presence. Garrison and Cleveland-Innes (2005) define a community of inquiry in terms of deep learning that extends beyond simple interactions, stating that a community of inquiry is a place where "ideas can be explored and critiqued; and where the process of critical inquiry can be scaffolded and modeled" (p. 134).

The Three Presences

While not a part of this current analysis, the *social presence* component focuses on the ability of participants to project themselves to establish personal and purposeful relationships (Garrison, Anderson, & Archer, 2000). Rourke, Anderson, Garrison, and Archer (2001) state that the three main components of social presence are affective responses, interactive responses, and cohesive responses. *Teaching presence* defines multiple roles for the teacher, including designer, facilitator, and subject matter expert who provides direct instruction (Anderson, Rourke, Garrison, & Archer, 2001).

The focus of this analysis is on the *cognitive presence*, described as "the extent to which learners are able to construct and confirm meaning through sustained reflection and discourse in a critical community of inquiry" (Garrison, Anderson, & Archer, 2001, p. 11). Garrison (2007) adds that cognitive presence involves the processes of "the exploration, construction, resolution and confirmation of understanding" (p. 65). Akyol and Garrison (2011) elaborate these processes by listing four phases of cognitive presence in online environments: a *triggering event* involving a well-designed activity; *exploration* in which participants seek out relevant information and explanations; *integration*, in which there is a focus on meaning making and integration of ideas; and *resolution*, in which ideas are evaluated. We focus on these aspects to explore the extent to which our participants engaged in meaning making and reflection in an online context.

Using mediating processes to characterize cognitive presence. Because cognitive presence has been harder to define than the other two presences (Akyol & Garrison, 2011), we turn to an aspect of design research, *conjecture maps*, to articulate how cognitive presence can be operationalized analytically. According to Sandoval (2014), "*Conjecture mapping* is a means of specifying theoretically salient features of a learning environment design and mapping out how they are predicted to work together to produce desired outcomes" (p. 19) and is intended to reify the conjectures regarding the learning environment and how they interact to promote learning. There are four main elements to a conjecture map. The first element involves *high-level conjectures* about the learning context and how it supports learning. Those conjectures are then operationalized in the *embodiment* of the learning design, which is the second element. In the third element, this embodiment in turn is intended to generate *mediating processes* that produce desired *outcomes.* To analyze cognitive presence, we turn to the third element, the mediating processes.

Mediating processes focus on the interactions between learners and the learning environment. These interactions can be in the moment and observable or are evident in artifacts that reify learners' engagement in the learning environment. Mediating processes represent the intellectual practices in which we want participants to engage in the online learning context. For example, one mediating process is for participants to explore and discuss the cognitive demand of tasks (i.e. Smith & Stein, 2011); the extent to which participants are able to explain and justify their reasoning is an indicator of cognitive presence. Because mediating processes reflect the immediate aims of the design of the learning environment, they provide a strong articulation of the cognitive presence designers hope to engender.

Our research question was: What were the qualities of participants' cognitive presence, as signaled by an analysis of the mediating processes in which they engaged?

Methods

We video recorded each of the OMD sessions, six in total, using screen capture technology. For each session, we video recorded the host computer as well as each of the breakout rooms, creating up to five video files for each session. We used Panopto so that we could record the Zoom window and simultaneously any Google docs the groups were creating.

We parsed each video into clips, labeling each clip according to whether it was an introduction (e.g., launch, agenda-setting, directions), exploration phase (break-out room in which participants conducted an activity in small groups), or summary discussion (post-breakout room whole-class discussion). We delineated clips by changes in activity structure (e.g., from introduction to breakout room, breakout room to whole group summary, and so on). We then transcribed the clips for the breakout rooms (one for each breakout room) and summary discussions using Transana video analysis software.

Analyzing cognitive presence. For each clip, we created a list of mediating process claims. Subsequently, we sorted the clips into categories we developed according to our design conjectures and emergent categories after an initial pass of the data. Based on our work developing conjecture maps for the OMD course, the categories that we attended to in this analysis include *pedagogical insights*, *instructional practices*, *accounts of instructional episodes*, *analysis of tasks,* and *problem solving strategies*. These categories involved participants engaged in meaningful learning through exploration, joint construction of explanations, and resolution of ambiguities and approaches with the assistance of the instructor. We then tabulated the instances of mediating claims in those categories to understand the content involved in the cognitive presence. However, this did not indicate the extent to which cognitive presence went beyond basic participation in the activity (e.g., rating the cognitive demand of a task) to include more complex forms of participation (e.g., justifying cognitive demand of tasks by explaining features that relate to given levels of demand). To capture the quality of cognitive presence, we sought instances in which participants went beyond low-level types of participation, such as reporting a fact or procedure, providing an opinion, or evaluating a peer's response. These types of participation can be accomplished easily and were not the goal of the project, though we recognize that much of the time, these are how people contribute to conversations. Thus, we coded a participant's contribution as *high cognitive presence* if there was an explanation in which the participant made connections across topics and provided evidence for those connections.

Results

Participants engaged in the mediating processes identified in our conjecture mapping process in a large number of instances, at least at a superficial level. To capture the most robust instances of cognitive presence, we place more weight on the third column in Table 3, which represents the strongest evidence of participants' meaning making, sustained reflection, and inquiry-oriented discourse, key attributes of cognitive presence (Akyol & Garrison, 2011). These instances occurred across the exploration, integration, and resolution phases identified by Akyol and Garrison. We noted that some activities were more likely to facilitate instances rated as involving high cognitive presence. One explanation is that these activities were more explicitly linked to the conceptualization of cognitive presence. For example, explanations of problem solving strategies provided opportunities for participants to make connections between strategies and between mathematical topics within a strategy, which involves exploration and integration. These opportunities were available due to the selection of mathematical problems for the activities and directions by the instructor to develop multiple strategies, indicators of teaching presence. Many of the instances not rated as high cognitive presence involved simpler explanations, evaluations, or reporting of steps. See Table 1.

Table 1: Cognitive Presence as Characterized by Mediating Processes

Mediating Process Types	Number of instances	Number rated as high
Accounts of instructional episodes	63	14
Analysis of tasks	133	27
Instructional practices	32	0
Pedagogical insights	41	5
Problem solving strategies	90	35

Discussion and Implications

Using the mediating processes from our conjecture mapping process to characterize cognitive presence was critical in conceptualizing a rigorous way to explore cognitive presence in online contexts. The specific articulation of these processes derive from our goals related to the design of the learning environment, as evident in the design conjectures from the conjecture mapping process (Sandoval, 2014). In our case, we felt that the mediating processes represented a continuum of ways of showing cognitive presence, with some participants' contributions categorized as a participating in a mediating process even though the contributions did not signal deep reflection or inquiry, and others represented a higher degree of reflection and inquiry, and thus a stronger indicator of cognitive presence. Simple engagement in a mediating process did not always rise to the level of cognitive presence we desired, as was evident in the large number of instances not coded as high. A question that derives from this finding is whether the frequency of instances of high level of cognitive presence was sufficient to engender learning. Our findings indicate, nevertheless, that our instructional design and the instructors' facilitation and direct instruction (the three components of teaching presence) were associated with a considerable number of instances in which participants engaged in reflection and inquiry. Thus, our framing and use of mediating processes provides evidence that we developed in a synchronous online context a community of inquiry that adhered to the assumption of intellectual rigor. A major contribution of our study is the use of mediating processes to characterize cognitive presence. This allowed us to examine the nature of our design conjectures (i.e., to see if our designed learning environment resulted in the desired intellectual activity) in a way that allowed us to conceptualize the interaction between the three presences (social, teaching, and cognitive) and our design conjectures, which helped us to assess more meaningfully our design conjectures.

CONCEPTUALIZING A FEMINIST POSTSTRUCTUAL DISCOURSE ANALYSIS STUDY: AN APPROACH TO GENDER RESEARCH

Julia Przybyla-Kuchek
University of Georgia
juliapk@uga.edu

The increased use of poststructural theories in mathematics education provides a pathway for novel methodological approaches. In this paper, I introduce feminist poststructural discourse analysis (FPDA) as a methodology to study the intersection of gender and racial inequities in mathematics education. Specifically, I explore one example of a conceptualization of such a study to understand gendered, racialized, mathematical discourses in a middle school classroom.

Keywords: Gender, Research Methods, Discourse Analysis

Poststructural and postmodern theories have been suggested as possible theoretical frontiers in identity and equity research in mathematics education (Darragh, 2016; Langer-Osuna & Esmonde, 2017; Stinson & Bullock, 2015; Stinson & Walshaw, 2017). Some researchers have begun to take up these theories to study gender and race inequities (e.g., Stinson, 2013; Walshaw, 2005). Yet, theories of gender in mathematics education predominately remain unchanged in recent years (Damarin, 2008), with feminism not always being seen as relevant to mathematics education. More specifically, few researchers are taking up feminist *and* poststructural theories in their research (e.g., Parks 2009; Mendick, 2006; Walkerdine, 1998; Walshaw, 2001, 2005). In this paper, I introduce feminist poststructrual discourse analysis (FPDA) as a methodology from both feminism and poststructrual theory that has potential to build upon prior feminist and poststructural work and open spaces for new equity research. Below, I present the theoretical underpinnings of feminist poststructuralism and describe their methodological implications. I then present a conceptualization of a FPDA study.

Feminist Poststructural Theory

Feminist poststructural theory emerged out of and in response to liberal and radical feminisms with/through poststructural theory (Gavey, 1989; St. Pierre, 2000). Some feminists were critical of essentializing tendencies of radical feminism, where "women's" *experience* tended to be generalized from White, middle and upper-class women's experiences, and side-lined women's experiences across race, ethnicity, sexual orientation, age etc. (Davies & Gannon, 2005; St. Pierre & Pillow, 2000). When we put limits on, confine and define what it means to be "woman," we are always excluding someone's experiences and crushing the potential for different work to be done (St. Pierre & Pillow, 2000). Thus, projects of poststructuralism feminism show the complex, contradictory, multiple, and shifting meanings of language, how discourses come into being, become "normal" while others are excluded, and how power operates (St. Pierre, 2000). Feminist poststructualists break from humanist ways of knowing and producing research (i.e., theories assuming a human is a rational, conscious being with agency) in their framing of fundamental constructs, including language, discourse, self, and identity.

Language

Humanist perspectives posit that language is innocent, functioning to *identify* and name natural, present objects/subjects; language *mirrors* the "real" world. (MacLure, 2003; St. Pierre,

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.* St Louis, MO: University of Missouri.

2000). Poststructural theory posits that language *produces* the "real" world. By organizing language, we create something more than meaning; language produces real world effects (Walkerdine, 1989). For example, *girl* has no inherent meaning. Instead, *girl* is created from its "position and function within the discourse itself" (Walkerdine, 1989, p. 271). *Girl* becomes meaningful in difference from *boy,* where what is means to be *girl* is a product of a particular organization of practices, such as how one performs *girl* and identifiably not *boy*. Language creates binaries and hierarchies, of which *girls* end up at the bottom (St. Pierre, 2000). Feminist poststructuralists seek to expose what discourses produce and open them up to new discourses. For example, Walkerdine (1989, 1998) demonstrates how language structures are harmful and gendered. She shows that *girl,* through practices in a mathematics classroom, is in a relation to *passivity, rote-learning, rule following,* and *real understanding*. These practices work together in a system of similarity and difference. Walkerdine (1998) argues that, *passivity, rote-learning, and rule-following* exist in similarity, while *real understanding* exists in difference from the previous practices that are often not assigned to *girl* but assigned to *boy*. The ways people talk about subjects in classrooms *produce* real effects as to what learning participants can access.

Discourse

Discourses are traceable and historically constructed "forms of knowledge or powerful sets of assumptions, expectations and explanations, governing mainstream social and cultural practices. They are systematic ways of making sense of the world by inscribing and shaping power relations within all text" (Baxter, 2003, p. 7). Discourses regulate how we interact, how we be "ourselves" (i.e., *subjectivity*), what we know (i.e., truth), and power relations (MacLure, 2003). They allow certain things to be said/done and simultaneously not others (St. Pierre, 2000); they are both constraining/limiting and enabling/generative. Walkerdine argues that the organization of the language into *discursive practices* allows *girls* to do mathematics in particular ways (e.g., rote-memorization) and not others (e.g., real understanding). Furthermore, discourses become so pervasive they become "natural" (St. Pierre, 2000).

Feminist poststructural theory posits that *gender differentiation,* a discourse distinguishing people by gender and positioning them into binary, hierarchical categories, is pervasive in many societies (Baxter, 2003, 2008; Walshaw, 2001). It is discursively produced through modern sciences and maintained through modern social apparatuses, such as school, family, church, etc. (Walshaw, 2001; Walkerdine, 1990). Feminist poststructuralists are interested in how gender differentiation functions, is produced and regulated, and its social effects (St. Pierre, 2000).

The (Human) Subject

A *subject* (i.e., person) in feminist poststructural theory decenters humanist assumptions about the existence of "self." Feminist poststructural theorists do not believe that there is an 'essential self' residing in every human. Walkerdine (1989, 1990) presents the subject as a product of a complex and contradictory system of *discursive practices*—a body of anonymous rules and practices that are constantly changing. Discourses operate simultaneously, not interchangeably, to produce a subject, allowing subjects to be fragmented and even contradictory. A subject is simultaneously "girl" and "student" and "child" and these *subject positions* can be contradictory within the same moment (MacLure, 2003). Discourses impact the ways a subject can be read (i.e., perceived/seen) as "student" and as "girl" differently than how boys are read as "student" and "boy." In being read differently as "boy" and "girl," discourses themselves become gendered. Similarly, being read differently as "black" or "white" simultaneously with "boy" or "girl" discourses are gendered and racialized. Furthermore, a subject does considerable work (i.e., agency) to take up these discourses (Davies, 2003). But, her "agency" is not occurring because of free will. Her fantasies, fears, desires, emotions, and relations (i.e., *subjectivities*) are constructed and regulated through discourse (St. Pierre, 2000).

Power is produced through discourse and is inherent in the relations *between* subject positions (St. Pierre, 2000). Power is not located in or possessed by an individual nor is it held by dominant groups of people, such as men and Whites, in a static and ever-present sense. Instead, power exists within the discursive relations of different subject positionings (Walkerdine, 1990).

Feminist Poststructural Discourse Analysis Methodology

Because of these dramatic shifts in perspective from humanist to feminist poststructural theories, research methods also shift. Feminist poststructural discourse analysis (FPDA) is one methodological approach to poststructural inquiry. Baxter (2008) defines FPDA as "a feminist approach to analysing the ways in which speakers negotiate their identities, relationships and positions in their world according to the ways in which they are located by competing yet interwoven discourses" (p. 1). FPDA is feminist in its focus on gender and goals to be *transformative*: "to open up spaces for those female voices which have been systematically marginalised or silenced" (Baxter, 2008, p. 10). FPDA is a discourse analysis methodology interested in how people become themselves in relation to others by examining spoken words. Based on MacLure's (2003) and Baxter's (2008) work, I describe three interrelated aims of FPDA below, where gender differentiation is a constant lens avoids essentializing girls and women and thus assumes the intersectionality of gender and other identifiers such as race.

Challenge the Reduction of the (Human) Subject and Subjectivities

Researchers who challenge the reduction of subject and subjectivities seek to demonstrate how humanist perspectives of "self" is reductionist by means of presenting subjects and subjectivities as complex, multiple, contradictory, and fragmented, rather than as unified, singular, and coherent (Baxter, 2008; Maclure, 2003). This aim of FDPA stems from the feminist poststructural conceptualizations of subjects and subjectivities. Furthermore, FDPA emphasizes how human subjects and their subjectivities are produced through discourse (MacLure, 2003).

Disrupting Epistemologies and Research Traditions

FPDA aims to disrupt epistemological and ontological assumptions regarding researchers' relationship to research, the use of written texts, and to insert ambiguity and uncertainty into taken-for-granted frames of research (Davies & Gannon, 2005; MacLure, 2003). The poststructural conceptualization of truth impacts how one conducts FPDA research, specifically related to how to treat and re-present data. Data is not proof or evidence of a certain kind of "reality." Rather, "accounts or descriptions or performances of gendered ways of being reveal *the ways in which sense is being made of gender*, or *the way gender is being performed* in that particular text" (Davies & Gannon, 2005, p. 319). That is, the data we collect/produce illustrate how discourses work through/on us, our participants and research, and demonstrates the discursive construction of reality. We cannot position ourselves outside the production of knowledge as objective knowers of truth (Baxter, 2003; Davies & Gannon, 2005). Throughout the research and writing process FPDA self-reflexivity is necessary (MacLure, 2003).

Social Transformation

Rather than the perpetually oppressed position of women in a critical perspective, the feminist poststructural perspective gives rise to a more complex and optimistic perspective of subjects. Feminist poststructural theory seeks to disrupt gendered binaries altogether (Baxter, 2002, 2008; MacLure, 2003). Thus, FPDA aims to be *transformative*, rather than emancipatory.

Deconstructing gendered discourses opens possibilities for new discourses within/between contradictory subject positions making social transformation possible (Walkerdine, 1998).

One Conceptualization of a FPDA Study

Adapting the work of Judith Baxter, I designed a FPDA study around the aims of FPDA to study how discourses operate in a middle school mathematics classroom. Although feminist poststructual theory appears to focus on gender, I consider the intersectionality of gender and race. The study sought to answer the following research questions: (a) What mathematical, gendered, and racialized discourses operate in a middle school mathematics classroom? (b) How do discourses constitute and regulate students' gendered and racialized subject positions and subjectivities in mathematics? (c) How do students resist gendered, racialized, mathematical subject positions and create sites for production of new and generative subject positions?

For 12 weeks I collected daily fieldnotes and video and audio data in a public, gender and racially diverse 7th grade mathematics classroom to track changes in students' subject positions across time, mathematical content, group dynamics, and instructional formats. Classroom observations address two aims of FPDA. First, I *challenged the reduction of subjects* by observing the multiple and contradictory subject positions in which participants are foisted into and take up across classroom interactions over time. Second, daily observations allowed me to note ways in which students resisted restrictive subject positions and discursive practices in local, unpredictable, and constant ways (i.e., *social transformation*). Furthermore, the extended observation time coupled with audio and video recordings allowed for both a broad level analysis of discursive practices and subject positions, as well as detailed moment-by-moment analysis of utterances and non-verbal routines. This broad level and fine-grained analysis differs from other discourse analysis methods which are often restricted to more turn-by-turn speech analyses.

Additionally, this FPDA design makes use of unique interviewing methods to seek out the various contradictory and complex subject positions participants performed. Through interviews with the classroom teacher and small groups of students (usually self-grouped by gender and race), I gained access to students' subjectivities related to mathematics by focusing on students' view of and feelings towards mathematics, experiences and routines in the classroom, and perspectives of narratives told about who does mathematics and what it means to do mathematics. In addition to interview responses, their interactions in the interview—how they positioned each other in relation to mathematics—provided a second level of material to analyze.

A second round of interviews was conducted near the end of the semester that made use of the video data obtained from the classroom. I selected a lesson I believed students resisted gendered, racialized, mathematical discourses. I created a series of clips to represent lesson events, which the teacher and groups of students then watched. As they watched, I encouraged them to stop the video at any time to share their reactions to and interpretations of the events. I sought to uncover why students performed in particular ways of doing mathematics. In doing so, I opened the analysis to multiple possible readings so there was no one authoritative voice determining the "truth" about the interactions in the classroom. That is, the researcher, teacher, and several groups of students provided analyses of the interactions with no one reading claiming the truth. This unique interviewing technique *challenged the reduction of subjects* and *disrupted epistemological assumptions* about the subject positions of researchers and participants. This interview approach challenges the discursive practices by which research produces truth.

Discussion

I have presented but one conceptualization of a FPDA study. This is by no means “the” way to conduct feminist poststructural research or even make use of FPDA—this work is always left undefined. This one example contributes to the ongoing discussion of theoretical and methodological innovation in mathematics education, particularly related to equity research and presents a starting point for generative ways of conducting feminist postructural research.

PSYCHOMETRIC MODELING AND REASONING ABOUT FRACTION ARITHMETIC

İbrahim Burak Ölmez
University of Georgia
i.burakolmez@hotmail.com

The purpose of this study was to coordinate psychometric modeling with reasoning about fraction arithmetic. Recent research has demonstrated the existence of three distinct latent classes in a nationwide sample of in-service middle grades teachers based on psychometric analysis of responses to survey data. The survey focused on four components of reasoning about fraction arithmetic: Referent units, Partitioning and iterating, Appropriateness, and Reversibility. The present study sought to better understand the three classes by interviewing 8 future teachers and comparing to what extent characteristics based on the three latent classes were associated with reasoning evidenced during interviews about fraction arithmetic. The psychometric analysis and qualitative analysis provided consistent results about the reasoning of these future teachers' facility with fraction arithmetic.

Keywords: Rational Numbers, Reasoning and Proof, Research Methods

Having highly qualified teachers is a main goal of many Western, institutionalized systems of education because teachers are responsible for creating classroom environments in which students share observations, make and justify arguments, connect ideas, and use appropriate representations (National Council of Teachers of Mathematics [NCTM], 2000). Because one cannot teach what one does not know, having sufficient mathematical knowledge is one obvious qualification that teachers need to possess. One content area with which teachers and students experience considerable difficulty is fractions, which have been known to be critical for success in mathematics at later grades and further study in mathematics (e.g., Hackenberg & Lee, 2015).

Although recent curriculum standards such as the Common Core State Standards for Mathematics (e.g., National Governors Association Center for Best Practices & Council of Chief State School Officers, 2010) have emphasized the necessity of developing reasoning about fraction arithmetic when solving problems embedded in situations, the present study lies at the intersection of two challenges. One challenge is to support teachers' reasoning about fractions in terms of quantities. Despite most teachers' computational fluency with multiplying or dividing two fractions, numerous studies have pointed out the difficulties that teachers experience in reasoning about products or quotients of fractions in problem situations (e.g., Jansen & Hohensee, 2016). A second challenge is to study reasoning in large samples because most research on reasoning is based on detailed case studies with small samples.

In response to these challenges, several recent studies have used traditional item response theory (IRT) models (e.g., Lord, 1980), which use survey item responses to locate teachers on unidimensional scales to measure teachers' mathematical knowledge. These studies include the Learning Mathematics for Teaching (LMT) project (e.g., Hill, 2007) and the Diagnostic Mathematics Assessments for Middle School Teachers (DTAMS) project (Saderholm, Ronau, Brown, & Collins, 2010). Traditional IRT models assume that all examinees in a given sample belong to a single population. Some recent studies (e.g., Izsák, Orrill, Cohen, & Brown, 2010; Izsák, Jacobson, de Araujo, & Orrill, 2012), however, have reported the existence of distinct latent classes of middle grades teachers when it comes to reasoning about fraction arithmetic in terms of quantities. Existence of distinct latent classes violates local independence, a key assumption of traditional IRT models. In this case, different psychometric models need to be used such as the mixture Rasch model (Rost, 1990), which is an appropriate model to use when distinct latent classes are present. For the present study, distinct latent classes correspond to distinct patterns of strengths and weaknesses in middle grades teachers' reasoning about fraction arithmetic as evidenced by different patterns of correct and incorrect responses to survey items.

To measure teachers' capacities for reasoning about fraction arithmetic, Bradshaw, Izsák, Templin and Jacobson (2014) developed the Diagnosing Teachers' Multiplicative Reasoning (DTMR) Fractions survey and reported on content and item-level validity of the survey. Recent research (Olmez & Izsák, Under Review) analyzed responses from a nationwide sample of 990 in-service middle grades teachers to the survey using the mixture Rasch model. Olmez and Izsák reported the existence of three distinct latent classes, and identified strengths and weaknesses of each class with respect to reasoning about fraction arithmetic. The results from the nationwide sample led to the present study that focused on interview data of 8 future middle grades teachers recruited from each of the three classes. I asked to what extent were strengths and weaknesses associated with each class detected by the mixture Rasch analysis consistent with the 8 future teachers' reasoning about fraction arithmetic across multiple survey items and related tasks?

Theoretical Framework

My theoretical framework considers middle grades teachers' reasoning about quantities and focuses on using drawings (e.g., number lines and area models) to learn and teach fraction arithmetic. I think that reasoning, which goes beyond computational fluency, requires a teacher to make sense of quantities in fraction arithmetic problems using drawings. Thus, a teacher's capacity to reason about quantities with drawings depends in turn on paying particular attention to distinct components such as *Referent units*, *Partitioning and iterating*, *Appropriateness*, and *Reversibility* — each of which is grounded in past research. Moreover, I take the stance that reasoning depends on context. That is, a teacher might use any one of these components appropriately in one situation, but not another, depending on the wording of the situation, the arithmetic operations required, or the representations provided. Hence, it is important to examine teachers' capacities to employ particular components across a range of problem situations.

The DTMR survey measures four components of reasoning about fraction arithmetic: *Referent units*, *Partitioning and iterating*, *Appropriateness*, and *Reversibility*. *Referent units* deals with reasoning about units when numbers are embedded in problem situations and includes *Norming*, *Referent units for multiplication*, and *Referent units for division*. *Norming* refers to the formation of standard units for measurement and occurs either in case of selecting a standard unit from alternate choices or making at least two different choices for a measurement unit in a given situation (i.e., renorming). *Referent units for multiplication* and *Referent units for division* concern the problem situations that can be modeled by the equation $M \bullet N = P$ where M and N refer to different units. *Partitioning and iterating* refers to separating a quantity into equal-sized pieces and concatenating unit fractions, and consists of three sub-components: *Partitioning in stages*, *Partitioning using common denominators*, and *Partitioning using common numerators*. *Partitioning in stages* refers to repartitioning to obtain a desired partition. *Partitioning using common denominators* and *Partitioning using common numerators* refer to using common denominators or numerators to obtain common partitions. *Appropriateness* concerns identifying situations that can be modeled by multiplication and division and includes three sub-components:

Identifying multiplication, *Identifying partitive division*, and *Identifying quotitive division*. *Reversibility* deals with returning to an original state.

Latent Classes Based on Mixture Rasch Analysis

The mixture Rasch analysis (Olmez & Izsák, Under Review) found three latent classes, each with strengths and weaknesses. Specifically, Class-C teachers performed well only on *Appropriateness*, but they had persistent difficulties in the remaining three components of fraction arithmetic. Class-B teachers performed well on *Appropriateness* like Class-C teachers and also on *Reversibility*, but they struggled with items that measure certain aspects of *Referent units* such as *Referent units for multiplication*, and *Partitioning and iterating* such as *Partitioning using common denominators* and *Partitioning using common numerators*. In addition to having the strengths of Class-B teachers, Class-A teachers performed well on *Partitioning using common denominators* and *Partitioning using common numerators* (*Partitioning and iterating*). At the same time, teachers in all three latent classes were not proficient on renorming in the presence of improper fractions (*Referent units*).

Methods

I administered the survey to a cohort of 18 future middle grades teachers at the beginning of a number and operations course offered in Fall 2017. The course focused on reasoning about fraction arithmetic in terms of quantities. The future teachers completed the survey as the first homework assignment during the first week of the course. I used the item parameters generated by the mixture Rasch analysis to analyze the item responses and estimate latent class membership for all 18 future teachers. Of the 18 teachers, 10 were in Class-C; 4 in Class-B; and 4 in Class-A. I then selected 8 future teachers (4 in Class-C; 3 in Class-B; and 1 in Class-A) to be focal participants for this study. To insure strong warrants for class membership, I recruited the participants who had a high probability (over .90) of being a member in a particular class. The survey consists of 27 items (19 multiple choice and 8 constructed response) that measure *Referent units*, *Partitioning and iterating*, *Appropriateness*, and *Reversibility*.

One week after completing the survey, I conducted one individual video-recorded interview with each of the 8 focal participants (8 interviews in total). Each interview consisted of two parts. In the first part (about 45 minutes), I went through items from the survey and asked follow-up questions such as "Why did you select the choice you did?" The focal participants did not experience instruction in fractions between completing the survey for homework and the interview. During the second part (about 45 minutes), I presented additional tasks that were not part of the survey to obtain further information about future teachers' reasoning.

For each participant, I analyzed the interview data by listing item-by-item evidence for and against the proficiency of each component of reasoning. Among the three categories of coding ("for"; "against"; and "other comments"), I included evidence for and against proficiency wherever I found it in the interviews. I used "1" to indicate evidence consistent with proficiency, "0" to indicate absence of evidence for proficiency, and "X" to indicate cases where there was too little evidence or there was a mix of contrary evidence for and against the proficiency of each component. I then focused on 5 of the sub-components that characterize and distinguish the three classes, and used the results of the mixture Rasch analysis to predict each of the 8 teachers' strengths and weaknesses on these sub-components using a "1" or a "0".

Results

My research question asked to what extent strengths and weaknesses associated with each of the three latent classes detected by the mixture Rasch analysis were consistent with the 8 future middle grades teachers' reasoning during the interviews. I compared latent class membership for each participant based on analysis of interview data with latent class membership as diagnosed by analyzing survey item responses using the mixture Rasch model. In other words, while interview data were based on a subset of item responses from the survey and additional tasks, the mixture Rasch analysis was based on responses to the complete set of survey items.

Table 1 presents latent class memberships for the 8 focal participants as diagnosed based on the interview data and as diagnosed with the mixture Rasch analysis. Each column indicates a diagnosis of proficiency (1), non-proficiency (0), or uncertain proficiency status (X) for each component of reasoning. Given 8 focal participants and 5 (sub)-components of reasoning that each interview has addressed, there existed 40 cases. I assigned a 1 in 15 cases, a 0 in 19 cases, and an X in the remaining 6 cases. Of the 15 cases where I assigned a 1, my diagnoses and the class memberships generated by the mixture Rasch analysis agreed in 11. Of the 19 cases where I assigned a 0, my diagnoses and the class memberships agreed in 13. Of the 6 cases where I assigned an X, indicating uncertain proficiency status, the mixture Rasch analysis diagnosed proficiency in 1 case and non-proficiency in 5 cases. The results indicate reasonable consistency between the analysis of interview data and the mixture Rasch diagnoses. This, in turn, suggests that latent classes based on the mixture Rasch model do reflect relative strengths and weaknesses in reasoning about fraction arithmetic in terms of quantities. This result provides significant additional evidence for the validity of our interpretation of the three distinct latent classes.

Table 1: Diagnoses Based on Interview Data and the Mixture Rasch Analysis

Component	Sub-component	Stu-1		Stu-2		Stu-3		Stu-4		Stu-5		Stu-6		Stu-7		Stu-8	
		Int	MR	Int	MR	Int	MR	Int	MR	Int	MR	Int	MR	Int	MR	Int	MR
RU	Norming	0	0	1	1	1	1	1	0	1	0	0	0	X	1	1	1
RU	RU for Multiplication	0	0	X	0	X	0	X	0	1	0	0	0	0	0	1	1
PI	Partitioning Using Common Numerators	0	0	0	0	X	0	0	0	X	0	0	0	0	0	1	1
APP	Identifying Multiplication	0	1	0	1	1	1	1	1	1	1	0	1	0	1	0	1
REV	Reversibility	0	0	1	1	1	1	0	0	1	0	0	0	0	1	1	1

Note. RU=Referent Units; PI=Partitioning & Iterating; APP=Appropriateness; REV=Reversibility.
Int=Diagnosis based on interview data; MR=Diagnosis based on the mixture Rasch analysis.

Discussion

I found reasonable consistency between the class memberships generated by the mixture Rasch analysis and the qualitative analysis based on the interview data of the focal participants. These results demonstrate that psychometric models applied to data gathered with appropriately designed surveys can capture information about strengths and weaknesses in reasoning, particularly in the critical domain of fraction arithmetic. Regarding the high number of qualitative research using small samples in mathematics education, coordination of contemporary psychometric models with qualitative studies is promising to illuminate fine-grained components of reasoning on core issues in the teaching and learning of mathematics. The approaches in the present study can provide helpful diagnostic information to mathematics educators in teacher preparation programs about strengths and weaknesses of each future teacher, and educators can plan instruction accordingly by focusing on those weaknesses. Future research should focus on generalizing these results to other cohorts of future teachers.

Qualitative research studies are used in our field to explore the complexity of teaching and learning. There are, however, persistent barriers to using results from qualitative research to inform policy in schools. There is a growing interest in education for integrating findings across qualitative empirical studies to unpack common threads that can serve as actionable recommendations for practice. We describe qualitative synthesis and its relationship to other research synthesis methods, identify a specific method, meta-aggregation, used to integrate research into practice, and share a critical appraisal protocol for in this method.

Keywords: Research Methods

Qualitative research studies are frequently used in our field to explore the complexity of teaching and learning in mathematics and can generate deeper understandings of teacher and student knowledge and needs. With a wide range of qualitative methods and results, it can be difficult for educators to look across a set of studies to integrate their findings into teaching practices. There are also persistent barriers to using results from qualitative research to inform policy related to teaching and learning in schools (Tierney & Clemmons, 2011). Thus, there is a growing interest in mathematics education, and education in general, in integrating findings across qualitative empirical studies to deepen our understanding of evidence-based practices and to unpack common threads across a related topic (Thunder & Berry, 2016; Yore & Lerman, 2008) that can serve as actionable recommendations for practice in learning environments.

Qualitative synthesis is a methodology for pooling qualitative research data and drawing conclusions on the collective meaning of the research (Bearman & Dawson, 2013). It is a methodology that is still evolving (McCormick, Rodney, & Varcoe, 2003; Noyes & Lewin, 2011). Thunder and Berry (2016) suggest that fields such as mathematics education can benefit greatly from qualitative synthesis, but we need to formalize this process and recognize it as providing important findings that cannot be generated from quantitative synthesis (i.e., meta-analysis) or a single qualitative study. In this paper we identify a specific qualitative synthesis method, meta-aggregation synthesis, used to integrate research into practice, and share a tool we have developed for use in this method.

What is Qualitative Synthesis

Qualitative synthesis is not merely a qualitative version of meta-analysis (Mohammed, Moles, & Chen, 2016). It provides: (a) an accumulative understanding of how qualitative research contributes to our understanding of a studied phenomenon; (b) new insights into the existing theories and knowledge; (c) research-based evidence for the development, implementation and evaluation of intervention; and (d) directions for policy, public perception, and future research (Campbell et al., 2011; Mohammed, et al., 2016; Nye, Melendez-Torres, & Bonell, 2016; Suri & Clarke, 2009; Tong, Flemming, McInnes, Oliver, & Craig, 2012). A qualitative synthesis is a specific type of systematic review that differs from other types of narrative review because of its explicit intent to treat reported findings in individual studies as *data* for analysis to derive a new theory or interpretation from original findings. It requires a systematic and transparent process for analysis and interpretation of the findings from selected studies. While a literature review can take weeks to months to complete, a qualitative synthesis can take six months to two years (Khangura, Konnyu, Cushman, Grimshaw, & Moher, 2012).

Meta-aggregation as a Tool for Informing Practice

Meta-aggregation has gained attention as an effective qualitative synthesis methodology for bridging research findings to practice (Aromataris & Munn, 2017). It involves analyzing empirical qualitative findings across multiple studies to understand evidence-based practices and unpack common threads (Thunder & Berry, 2016; Yore & Lerman, 2008). Meta-aggregation informs practical-level theory or lines of action that are directly applicable to decision-making practices in, for example, a classroom (Lockwood, Munn, & Porritt, 2015). It serves an *integrative* purpose in the synthesis, focused on developing recommendations in response to a defined area of interest (Heyvaert, Hannes, & Onghena, 2017; Lockwood et al., 2015).

Why Focus on Meta-aggregation?

Meta-aggregation is a rigorous process of synthesizing qualitative data that moves beyond the production of theory and attends to the practicality and applicability of results (e.g., specific recommendations for teachers) (Hannes & Lockwood, 2011). Developed by the Joanna Briggs Institute (JBI), it has been used in the fields of nursing and medical science, but a limited number of methodologically sound qualitative syntheses are currently available in the field of education (e.g, in our review of 25 studies identified as qualitative syntheses in education since 1988, only two have used a meta-aggregation approach). However, according to Hannes, Petry, and Heyvaert (2018), meta-aggregation is important to educational research because, “the conceptual clarity in many educational research subdomains invites review authors…to accurately summarize the existing empirical evidence in that domain in order to inform and advise policy and practice. (p. 292). We see meta-aggregation as a useful and needed tool in mathematics education for building bridges between research and practice.

Meta-aggregation Synthesis Procedures

We outline below a detailed procedure for using the meta-aggregative approach, drawing on work from the JBI (Aromataris & Munn, 2017) and a recent example from Hannes et al. (2018) to explain the steps involved in this research method.

Finding potential data for the synthesis. A meta-aggregation synthesis begins with identifying a research question or purpose for the study. The question drives the search for qualitative studies to include to in the synthesis. Before searching for existing studies, we must set criteria for consideration in the search. The reviewer sets this criteria and systematically tracks what databases and keywords used to search for and find potential studies for inclusion.

Appraising the data for inclusion. A quality appraisal, also referred to as quality assessment, validity assessment, and assessment of risk of bias (Higgins & Green, 2008; Hong & Pluye, 2018), is the systematic process used to judge the trustworthiness of reported findings in studies and their relevance to the synthesis goal. After collecting potential qualitative studies for inclusion, researchers then should use a critical appraisal protocol (Aromataris & Munn, 2017; Lockwood et al., 2015) and evaluate how findings are supported with data (e.g., direct interview quotes, observation notes). Studies identified as “unsupported” are excluded from the synthesis pool. Selected studies become the collection of primary studies that now serve as data for the meta-aggregation (we expand on our development of a critical appraisal tool useful for meta-aggregation studies in a later section). Following recommendations for sufficiency and manageability of data (Major & Savin-Baden, 2010) and a review of 12 recent qualitative syntheses, it is reasonable to include 10-20 studies as data.

Analyzing the data. Using the pool of existing research studies chosen for inclusion, the researcher then analyzes the findings from these papers as "data" for the meta-aggregation study. Findings are extracted from individual qualitative studies and coded for literal descriptions of themes, categories, or metaphors reported by the original authors using pre-determined coding protocols and memo (Aromataris & Munn, 2017; Major & Savin-Baden, 2010). Key components in the coding protocols are *general information* about the context and methodological characteristics of a primary study and *interpretive findings*, which serve as the main data for the synthesis. Researchers also use *coding memos* to record reactions to the reported findings, reflect subjectivity, and identify potential impacts on synthesis validity.

It is important to seek supporting evidence, such as interview quotes, work samples, or rich descriptions of observed practices to understand the derivation and trustworthiness of findings for synthesis. Findings are classified into three categories: (a) *unequivocal (not open to challenge)*, (b) *credible (open to challenge)*, or (c) *unsupported by data*. Unequivocal or credible findings are grouped inductively for conceptual and descriptive similarities. This is referred to as *first stage clustering*.

Synthesizing the findings. The fourth step in the meta-aggregation is to take the clustered categories and move them to "lines of action" or particular recommendations (for educators, administrators, policy makers, etc.). These are called the *synthesis findings*. Following Hannes et al. (2018), we see the core purpose of the recommendations as to try and fix problematic situations, and their value lies in the practical usefulness of accepting them or and interrogating them. As a final determination of the robustness of the recommendations, the reviewers should return to the critical appraisal results. Previously excluded unsupported studies are returned to the analysis to evaluate if the developed recommendations for lines of action remain the same with their inclusion. We next share a specific critical appraisal protocol that our team has developed (through modification of existing tools) as one that is useful for meta-aggregation.

The Development of Critical Appraisal Protocol in Meta-aggregation

Explicit use of the results from an appraisal form during data selection and synthesis is unique for meta-aggregation compared to other methods of synthesis, and is used to enhance the credibility of synthesis results. While a variety of appraisal tools are available, few have documented evidence of their validity and reliability (Katrak, Bialocerkowski, Massy-Westropp, Kumar, & Grimmer, 2004). Hong & Pluye (2018) indicated in their conceptual framework that, when doing an appraisal, reviewers may look for three dimensions of a piece of qualitative research: (a) methodological quality (trustworthiness), (b) conceptual contribution (insightfulness), and (c) reporting practices (accuracy, transparency and completeness). Assessments of methodological quality and conceptual contribution, however, are more complex than the assessment of reporting practice because they involve reviewers' thorough understanding and operationalization of how to evaluate and what they look for in the trustworthiness and insightfulness in each primary study. The evaluation of trustworthiness and insightfulness, by nature, is more likely to be affected by the reviewers' own ideological and theoretical perspectives, preferences and experiences (Sandelowski, 2015).

In our own meta-aggregation work using existing *quality appraisal* forms adapted from existing sources (e.g., Blexter, 1996; Hannes & Lockwood, 2011; MacEachen, Clarke, Franche

& Irvin, 2006; Thunder & Berry, 2016), we found our coding was inconsistent because we provided multiple interpretations when making a judgment of quality of a particular component of the research. Quality checklists have, in the past, been found to generate low inter-rater reliability scores even among experienced qualitative systematic reviewer (Dixon-Woods et al., 2006). We also found that dissertation studies, which have little space limitations, were meeting all measures of quality simply because they had the room to detail their work, while journal articles often had to skip reporting certain quality elements due to page limits. Thus, our measures of methodological quality were based on our assumptions of what they "probably" did. We began to wonder how we might limit assumptions and inferences needed by the reviewers.

Through four rounds of pilot testing and discussions and revisions, we made the following decisions on the revision of our appraisal form: (a) the form should avoid adjectives in the appraisal questions to minimize a room for inferences and subjective judgment by reviewers, (b) not all criteria in the form are equally important for appraising a study; some serve as useful information about the study, and others are critical for deciding on the inclusion in the synthesis, and (c) we did not need to measure the methodological quality and conceptual contribution of the study, but rather focus on the transparency and completeness of the information provided to understand their findings. We therefore followed other's examples of labeling the resultant appraisal form as a *critical appraisal form* to remove a sense of subjectively judging quality of the primary studies. Our new critical appraisal tool has questions that can be used as key questions for pre-screening that address the "What?" and "How?" regarding the study (shown in Table 1); and optional additional questions that can be used for data gathering that address *why* the researchers chose the ideas, tools and processes for their study. These additional questions allow the form to produce general information findings for the meta-aggregation.

Table 1: Critical Appraisal Form Key Questions

Criteria	**Question**
Purpose of Study	1. Did author(s) provide clear research questions? If not, is there a clear purpose statement to guide the investigation?
Research Design	2. Is a qualitative research design appropriate for addressing the research purpose? (This may include considering the qualitative component of a mixed-methods study)
Sampling	3. Did author(s) describe the setting/context for data collection?
	4. Did author(s) describe the specific sample of the population being studied? (e.g., Administrators; Secondary science teachers; 4-6th grade math students; History textbooks before 2010; etc.)
Data Collection	5. Did author(s) provide any description of the data collection procedures? (*e.g., If interviews were used, are there details on how they were conducted*)
Data Analysis	6. Did author(s) provide description of data analysis procedure? (*e.g., If thematic analysis is used, is it clear how the categories/themes were derived from the data*?)
	7. Were the findings explicit and clear?
Findings	8. In the concluding sections, did the author(s) describe implications for teaching/learning/practice AND/OR implications for future research?

Summary

We encourage researchers interested in qualitative synthesis review in mathematics education to consider the method of meta-aggregation as a useful and productive approach. Through our own work, we have developed a new research tool that is supported by reliability and validity to enhance the quality of meta-aggregation studies and thus help take us a step closer to move beyond knowledge generation to knowledge application in our *field*.

The present report summarizes the analyses of the calibration data for the electronic Test of Early Numeracy (e-TEN), an adaptive, iPad-based test of early numeracy achievement. A total of 794 children age 3 years to 8 years-11 months from two states were tested. Items were designed to map onto seven theoretical domains: verbal counting, numbering, numerical relations, numeral literacy, single-digit calculation, multi-digit calculation and base-ten place-value. Analysis indicated a strong single factor—a unidimensional structure across all domains. A Wright map of calibrated item difficulty indicated that items were fairly evenly distributed along the entire continuum of the early numeracy.

Keywords: Assessment and Evaluation, Early Childhood Education, Number and Operations

Purpose and Background

The primary aim of the calibration analysis is to develop the adaptive and scoring algorithm that is psychometrically sound yet feasible to implement through standard programming (e.g., for the iOS platform). Secondary aims include (a) examination of the dimensionality, (b) refinement of the item or sublevel scoring rule, (c) item calibration, and (d) identification of "problematic" items. This report addresses these four secondary aims, which are prerequisites for achieving the primary aim.

Methods

Sample

For each 6-month interval between 3.0 to 8.99 years (12 age groups), data were collected with a total sample size of 794 (55 young 3s, 77 old 3s, 66 young 4s, 80 old 4s, 88 young 5s, 72 old 5s, 56 young 6s, 56 old 6s, 57 young 7s, 61 old 7s, 60 young 8s, and 66 old 8s). This sample size was chosen to allow appropriate use of the item response theory (IRT) model, our primary analytic framework.

Procedure

Participants were administered all items deemed appropriate for their 6-month age group regardless of their individual performance to determine the success rate for each item for each age group. The number of items scored per age group ranges from 17 (young 3s) to 28 (older 6s).

Results

Dimensionality

Dimensionality & issue of age. Among the seven proposed dimensions, all three "calculation-2" items loaded on the calculation-1 dimension. Collapsing calculation-1 & -2 resulted in a 6-dimensional model. All items loaded on a single dimension, except two (writes 2-

and 3-digit numbers), which loaded on both the “grouping-and-place-value” and the “numeral literacy” dimensions.

Multi- versus unidimensionality. Table 1 compares the goodness of fit information across models. By comparing model 1 and 3 (unidimensional vs. 6-dimensional Rasch), the 6-dimensional structure is slightly more favorable (smaller AIC and BIC). All dimensions are highly correlated, with pairwise correlation between grouping and place value and the other five dimensions being the lowest (ranging from 0.78 to 0.90). The remaining pair-wise correlations arranged from 0.90 to 0.99. Exploratory factor analysis on the estimated correlation matrix suggests a strong single factor (eigenvalue = 5.48, with the remaining eigenvalues all less than 1), which is consistent with what the correlation matrix indicates. Therefore, **a unidimensional structure across all domains is most appropriate** (see Purpura, 2010; Ryoo et al., 2015)**.**

Table 1: Summary of Model Fit Statistics.

Model #	Item Score	Dimension	Age regressor	Deviance	AIC	AICc	BIC	# Parameters
1	Full credit or not	1	No	16778.8	16886.8	16880.1	17139.4	54
2	Full credit or not	1	Yes	18042.3	18152.3	18145.3	18409.5	55
3	Full credit or not	6[a]	No	16160.9	16308.9	16296.5	16655.0	74

[a] Calculation-1 and Calculation-2 were collapsed into one dimension, because Calculation-2 was not well identified. A Monte Carlo method was used to estimate the 6-dimensional model.

Refinement of Partial Credit

We started with the finest partial credit scoring based on content area expertise, and refined the scoring rules using item analysis. In particular, we relied on mean-square fit statistics (MNSQ), an item misfit index frequently used in Rasch analysis that signals the amount of distortion in the measurement system due to mis-specification (i.e., misfit between data and model). Values greater than 1.0 suggest unmodeled noise in the data (i.e., something in the data is not yet explained by the model), whereas values less than 1.0 imply that the item is not very informative (i.e., the item may not provide much unique information above and beyond other items). Items with greater MNSQ values are more of a concern in our case, and we revised such items’ scoring to improve the fit. In particular, we collapsed sublevels that were not well differentiated with adjacent sublevels. Two examples: (a) Item “composing & decomposing ten & base-10 equivalents of ten” contained two trials: “10 ones=ten” and “ten=10 ones.” As the vast majority of students were incorrect or correct on both, we removed the original partial credit of being correct on one trial, so a student either receives a full credit if he is able to do both, or no credit. (b) The original scoring for subtraction items (e.g., “subtract to 18”) entailed correctness and fluency (i.e., completion within 3 seconds). However, even the oldest group (old 8) in our calibration sample showed little evidence of fluency. In the revision, we removed the reference to fluency, and considered correctness solely for scoring.

Item Calibration

Figure 1 summarizes the calibrated overall difficulty levels of the items. As expected, the sample is fairly evenly distributed along the entire continuum. Items are located across the entire continuum, implying good coverage of the full spectrum of the developmental levels. Item “blocks” by domain are located, in general, consistent with the developmental orders predicted by theory. For instance, “numbering” appears in the low end of the scale, signaling that it is one of the first few things that a young child learns about numeracy, whereas "grouping and place-value knowledge" and "calculation-2" appear in the high end, implying that they are most

Domain 1: Verbal Counting
- Item 1: Verbally counts to "52" (Set 1A)
- Item 2: Number after to 9 with a running start (Set 1B)
- Item 3: Number-after to 9 without running start (Set 1C)
- Item 4: Number-after: 2-digit numbers to 100 (Set 1D)
- Item 5: Number-after: 100 terms (Set 1E)

Domain 2: Numbering
- Item 6: Subitizes 1 & 2 (Set 2A)
- Item 7: Subitizes 3 (Set 2A)
- Item 8: Subitizes 4 (Set 2A)
- Item 9: Counts sets to 5 (Set 2B)
- Item 10: Cardinality principle to 5 (Set 2B)
- Item 11: Counts sets to 10 (Set 2C)
- Item 12: Cardinality principle to 10 (Set 2C)

Domain 3: Numerical Relations
- Item 13: Identifies "more" sets 2:1 (2.0 x) apart (Set 3A)
- Item 14: Identifies "more" sets 3:2 (1.5x) apart (Set 3A)
- Item 15: Identifies "more" sets 4:3 (1.33 x) apart (3A)
- Item 16: Identifies "more" verbal 1-10 far apart (Set 3B)
- Item 17: Identifies "more" verbal neighbors 1-5 (Set 3C)
- Item 18: Identifies "more" verbal neighbors 6-10 (Set 3D)

Domain 4: Numeral Literacy
- Item 19: Relates numerals to sets of 1 to 3 (Set 4A)
- Item 20: Relates numerals to sets of 4 to 9 (Set 4A)
- Item 21: Reads numerals 1 to 5 (Set 4B)
- Item 22: Reads numerals: 6 to 9 (Set 4B)
- Item 23: Reads teen numerals (Set 4C)
- Item 24: Reads numerals 20-99 (Set 4D)
- Item 25: Reads 3-digit numerals (Set 4E)
- Item 26: Reads 4-digit numerals (Set 4F)

Domain 5: Calculation-1 (single digit)
- Item 27: Concrete add/subtract – basic (2+1, 3–2) (Set 5A)
- Item 28: Concrete add/subtract – intermediate (3–1 & 3+1) (Set 5A)
- Item 29: Concrete adds/subtracts – difficult (4–3 & 2+2) (Set 5A)
- Item 30: Accurately solve addition word problems to 10 (Set 5B)
- Item 31: Fluency with add-1 facts to 9 (Set 5C)
- Item 32: Fluency with doubles facts to 9 (Set 5C)
- Item 33: Fluency with near doubles to 18 (Set 5D)
- Item 34: Fluency with add-9 to 18 (Set 5D)
- Item 35: Accurate with subtraction doubles to 18 (Set 5E)
- Item 36: Accurate with other differences (Set 5E)
- Item 37: Accurate with 2-digit differences (Set 5F)

Domain 6: Grouping and Place-Value Knowledge
- Item 38: Writes 2-digit numerals (Set 6A)
- Item 39: Composing/decomposing 10 & equivalents of 10 (Set 6A)
- Item 40: Equates 2-digit numbers with groups(s) of 10 & 1s (Set 6A)
- Item 41: Strategic counting by tens and ones (Set 6A)
- Item 42: Strategic counting by 10s and 1s with renaming (Set 6A)
- Item 43: Writes 3-digit numerals (Set 6B)
- Item 44: Composing/decomposing 100 & equivalents of 100 (Set 6B)
- Item 45: Equates 3-digit numbers to groups(s) of 100, 10, 1 (Set 6B)
- Item 46: Strategic counting by hundreds, tens, and ones (Set 6B)
- Item 47: Strategic counting by 100s, 10s, and 1s with renaming (Set 6B)
- Item 48: Composing and decomposing 1000/equivalents of 1000 (Set 6C)
- Item 49: Strategic counting by 1000s, 100s, 10s, and 1s (Set 6C)
- Item 50: Strategic counting by 1000s, 100s, 10s, and 1s with renaming (Set 6C)

Domain 7: Calculation-2 (multiple digits)
- Item 51: Accurate 2-digit + & - /no renaming (Set 7A)
- Item 52: Accurate with 2-/3-digit addition/renaming (Set 7B)
- Item 53: Accurate 2- & 3-digit subtraction with renaming (7C)

-5 to 4+ indicates item difficulty along the same continuum of early numeracy.
X = Estimated Person Abilities; Each X represents 3.2 cases
Colored numbers = Calibrated item difficulty

Figure 1: Wright Map of Calibrated Item Difficulty

challenging and most challenging and typically achieved by older and more capable children. Within each domain block, items spread across a range, suggesting varying degrees of abilities that such items try to capture. This also gives us leverage to further develop the adaptive algorithm, so that given a child's performance on earlier items, we will be able to choose the next best item that is closest to the child's true ability along the continuum.

Conclusions

All six dimensions were highly inter-correlated, and a unidimensional structure was strongly supported by the data. These results are not surprising given the interdependency of numeracy knowledge.

Item scoring originally provided partial credit for reasonable answers (e.g., incorrect answers that at least honored the meaning of an operation and were in the right direction), indicated a child basically understood how to determine an answer but slipped up and was off by 1 or 2, or could at least make a reasonable estimate of an answer (i.e., off or within 25% of a correct answer). However, such reflections of "operation sense" occurred so infrequently that they had to be eliminated as a candidate for partial credit.

The item calibration provides reassurance that the e-TEN assesses the whole range of numeracy ability. Some similar items, such as Items 25 (reads 3-digit numerals) and 43 (writes 3-digit numerals) and Item 33 (fluency with large near doubles such as 8 + 7) and Item 34 (fluency with combinations involving 9) had the highly similar or even the same level of difficulty. In such cases, one item may be eliminated to shorten testing times.

The item calibration largely corroborated the developmental trajectories on which items were ordered. For example, consistent with previous research (Huttenlocher, Jordan, & Levine, 1994; Levine, Jordan, & Huttenlocher, 1992), success on a nonverbal addition/subtraction task emerges in a step-like manner (with collections of 1 and 2 first, then those involving 3, and finally with 4 items; Items 27, 28, and 29, respectively) and does so before children are successful with verbally presented word problems (Item 30). The results confirmed that the small doubles such as 3 + 3 and 4 + 4 (Item 32) are among the easiest of combinations and, in something of a surprise, were even slightly easier than the highly salient add-1 combinations (Item 31; cf. Baroody, Purpura, Eiland, & Reid, 2015). Moreover, the large doubles such as 8+8 (Item 33) were as difficult as combinations involving adding 9 (Item 34). Another unexpected result was that Item 42 (strategic counting by 10s and 1s with renaming) proved as easy as Item 41 (strategic counting by 10s and 1s). Theoretically, flexibly counting representations of tens and ones by tens and then by ones should be easier than doing so when there are more than 10 representations of ones, which requires regrouping them into a ten (Chan, Au, & Tang, 2014). Moreover, in something of a surprise, Item 42 (strategic counting with 1s and 10s with renaming) was easier than Item 40 (equating 2-digit numbers with groups of 10s & 1s). (It is less surprising that Item 41 (strategic counting 1s and 10s without renaming) was easier than Item 40 or that Item 46 (strategic counting with 1s, 10s and 100s without renaming) was somewhat easier than Item 45 (equating 3-digit numbers with groups of 100s, 10s & 1s), because flexible enumeration may or may not involve understanding grouping and place-value ideas). Additional research is needed to see if these curious result holds and, if so, why.

GTAS' LIVED EXPERIENCE IN THEIR DUAL ROLE AS STUDENTS AND TEACHERS OF MATHEMATICS

Nate Jewkes
North Carolina State University
njjewkes@ncsu.edu

Karen A. Keene
North Carolina State University
kakeene@ncsu.edu

As both students and teachers of mathematics, graduate teaching assistants' (GTAs') identities are shaped by their experience in both learning and teaching. Through interviews with four GTAs in a large mathematics department, the purpose of this pilot study was to gain insight into their identities and lived experience as they fulfill these two roles simultaneously. Preliminary findings highlighted GTAs' perceptions of other GTA peers' prioritization of teaching and schoolwork, navigation of relationships with and expectations from faculty, and the maintenance of a week-by-week balance between teaching, research, and coursework.

Keywords: Graduate teaching assistants, Doctoral education, Undergraduate-level mathematics

Purpose

The challenges that departments of mathematics face in preparing graduate teaching assistants (GTAs) to teach undergraduate mathematics served as the motivation behind this pilot study. The need for better support for this unique group of novice teachers first requires a better understanding of "who [G]TAs are… and how their communities help define themselves and their profession" (Speer, Murphy, & Gutmann, 2009, p. 7). This study aimed to gain insight into the identities and lived experience of mathematics GTAs as they fulfill both roles of *student* (i.e., their own coursework and research) and *teacher* (i.e., teaching and/or recitation responsibilities for undergraduate mathematics courses). The guiding question of this research was: What is the interplay between GTA student and teacher roles, and to what extent does each role play in defining their lived experience and identities?

Literature Review

The literature surrounding mathematics GTAs' identities and lived experience is still developing. Much of the research on mathematics GTAs addresses their challenges (e.g., Hauk et al., 2009; Meel, 2000; Park, 2004), their preparation for teaching (e.g., Belnap & Allred, 2009; Deshler, Hauk, & Speer, 2015; Kung & Speer, 2009; Speer, Gutmann, & Murphy, 2005), and their knowledge and beliefs related to teaching (e.g., Musgrave & Carlson, 2017; Speer, 2008; Speer & Hald, 2008; Speer, King, & Howell, 2015; Speer, Strickland, Johnson, & Gucler, 2006; Speer & Wagner, 2009; Wagner, Speer, & Rossa, 2007). Alternatively, more research is found about GTAs' identities and experiences when searching for work about GTAs in other disciplines (e.g., science, business, humanities, etc.). The following sections draw on both bodies of research.

GTA-Faculty Relationship

GTAs' identities are partially shaped by their relationship with faculty that teach and mentor them. GTAs often experience role ambiguity, or difficulty knowing faculty's expectations for their teaching, student, and research responsibilities (Duba-Biederman, 1991; Park, 2004). Furthermore, because GTAs have dual roles, so do the faculty that advise and supervise them. While many faculty members are adept advisors (i.e., advising GTAs as students about courses, research, etc.), some may lack supervisory skills (i.e., supervising and providing feedback to GTAs in their teaching roles) (Duba-Biederman, 1991; Nyquist & Wulff, 1996). GTAs often report positive relationships with faculty, but they also express the need for more feedback and support (Duba-Biederman, 1991; Latulippe, 2009; Meel, 2000). GTAs may rely on their GTA peers more than faculty for information and support about their multiple roles (Duba-Biederman, 1991; Park, 2004), or when planning to teach (Winter, DeLong, & Wesley, 2009).

GTA-Student Relationship

In pre-semester trainings, GTAs are often advised on how to maintain professionalism with the students they teach (Deshler et al., 2015). Because GTAs are often novice teachers (Speer et al., 2005), and relatively close in age to the undergraduates they teach, establishing professional relationships with students can be a challenge. Nyquist and Wulff (1996) describe how beginning GTAs may feel a desire to become close friends with their students, sometimes to the point of "becoming advocates for undergraduates who are experiencing what they feel to be unjust practices by faculty members" (p. 24). On the other hand, GTAs might resent their emotional investment in their students' welfare after students miss class, fail to hand in homework, or perform lower than expected on exams (Nyquist & Wulff, 1996).

GTAs' Experiences and Challenges

Research on the experiences of mathematics GTAs reveals that they struggle with balancing home, instructor, student, and junior researcher roles, searching for jobs, learning about potential responsibilities as a future faculty member, classroom management issues, and creating an active learning environment (Hauk et al., 2009; Meel, 2000). They often feel lack of autonomy in their teaching and perceive their teaching duties are need-based and not planned out (Austin, 2002; Park & Ramos, 2002).

Methods

The purpose of this phenomenological study (Moustakas, 1994), is to begin to capture the "essence" (Creswell & Poth, 2018, p. 80) of GTAs' lived experience as both students and teachers of mathematics, as well as how the challenges associated with these roles shape their identities. We use Gee's (2001) *institutional* and *affinity* identity sources. This conception is useful since GTAs have designations of "graduate student" and "teaching assistant" bestowed upon them by an institution, which establishes their *institutional* identity. GTAs also engage in common practices and share common interests in mathematics and teaching, which helps define their *affinity* identity.

Participants and Data Collection

Two of the GTAs identified as female, two as male, and all GTAs described themselves as White, with one identifying as Latina (Sarah). Sarah and Greg were recitation leaders and graders for Calculus I, David was a lecture assistant and grader for Calculus III, and Heather was the instructor of record for a large-lecture section of Precalculus. All were doctoral students in mathematics at a large, public research institution in the eastern United States. Consistent with the primary data source in phenomenological studies (Moustakas, 1994), semi-structured interviews with the four mathematics GTAs were conducted near the end of the Fall 2018 semester. Two of the interview questions were given to the participants beforehand to allow interviewees time to think about specific examples of student- and teacher-related challenges they had experienced as GTAs. During the interview, GTAs were asked to respond to questions such as: What do you think is a struggle or challenge that most mathematics GTAs deal with in balancing their roles as both students and teachers? The interview questions were meant to gather data leading to a "textual and structural description" (Creswell & Poth, 2018, p. 79) of the GTAs' common experiences of being a teacher and student of mathematics and were modeled after Moustakas' (1994) broad questions that solicit participants' experience with a phenomena.

Data Analysis

Each interview was audio-recorded, and subsequently transcribed verbatim by the primary author. The transcripts were analyzed (also by the primary author) through the process of *horizontalization* (Moustakas, 1994), where 18 preliminary themes were generated from identifying and grouping significant statements that captured the essence of balancing roles as both students and teachers, and how GTAs' described their experiences related to their institutional and affinity identities (Gee, 2001). The second author then examined the preliminary themes and corresponding significant statements, and together we consolidated them into eight emergent themes.

Researcher Positionality and Bracketing

As a former mathematics graduate student with teaching assistant experience, and as a current mathematics education student with continued GTA duties, the primary author can identify with many of the experiences that the GTA participants shared during the interviews. As part of the phenomenological lens, the primary author thus attempted to *bracket* (Moustakas, 1994) himself from the study by identifying and setting aside his own experiences with the phenomena in order to "take a fresh perspective toward the phenomena under examination" (Creswell & Poth, 2018, p. 78).

Preliminary Findings

While the interviewed GTAs said many things that related to the student or teacher roles separately, we constructed themes focusing on those statements that specifically addressed the phenomena of being a student and teacher of mathematics simultaneously, or the balance between these two roles. All eight themes are listed in Table 1 but due to space constraints, we highlight just three of the themes.

Table 1: Emergent Themes

Theme	**GTAs whose statements were coded for the theme**
Week-by-Week Balance	Sarah, Heather, Greg, David
Mixed Messages from Faculty on Role Prioritization	Heather, Greg
Other GTAs Prioritize Research and Coursework Over Teaching	Sarah, Heather, Greg, David
Maintaining Professionalism with Undergraduate Students	Greg, David
Relying on GTA peers	Sarah, Heather, Greg
Feeling Out of Place	Sarah, Heather, Greg, David
GTA-Faculty Relationship	Sarah, Heather
Sitting on Both Sides of the Table	Sarah, Heather, Greg, David

Mixed Messages from Faculty on Role Prioritization

Heather perceived some incongruence in how teaching duties are assigned and how her advisor and other faculty members tell her that her teaching role is not as important as her own studies:

> Heather: So like when someone says 'teach a 200-person class, but teaching isn't your first priority', that doesn't compute in my brain, like I'm going to have to pour myself into this to really be successful.

Feeling Out of Place

In discussing challenging coursework and teaching responsibilities in her first semester, Sarah felt displaced.

> Sarah: I felt uh, what does everybody call it? Imposter syndrome?... It was hard to get used to, living in a new place not knowing anyone, feeling like you don't belong.

Other GTAs Prioritize Research and Coursework Over Teaching

Even though only two of the participants said that they plan to teach for a career (Sarah and David), all four GTAs expressed a love for teaching and a desire to be helpful to students, and all four also described how they feel that not all GTAs share that same positive attitude towards teaching.

> David: Maybe it's just me who kind of feels concerned about that; about maybe wanting to improve like attendance in office hours, you know? Other [GTAs] might see it as more of a blessing or something. They get their hour or two back.

Greg, a recitation leader for Calculus I, shared his perception of his peers' prioritization of the two roles.

> Greg: The majority of students are here for careers in research and then teaching is what pays the bills getting to that point.

Limitations

One of the limitations of this pilot study is the small, voluntary sample that may not be representative of all mathematics GTAs. For example, the GTAs who agreed to participate may have also been those more likely to enjoy their teaching roles. It would be enlightening to interview GTAs who express dislike for teaching and how that affects their experience. All four GTAs identified as White with one identifying as Latina, and there were no international GTAs. A larger and more diverse group of GTAs would yield a more authentic description of GTAs' lived experience and identity.

Discussion and Conclusion

The lived experience of being a mathematics GTA with both student and teacher roles is complex. The GTAs in the study expressed a love for teaching and a desire to positively impact students but acknowledged that time and energy dedicated to their teaching and student roles can sometimes be out of balance. Like the findings of Winter et al. (2009), the GTAs relied on peers for assistance in both roles, especially in teaching. This suggests that professional development programs for GTAs should leverage the natural environment of peer-centered support and collaboration. The identities of mathematics GTAs that fulfill multiple roles is equally complex. In GTAs' minds, their institutional designations of 'student' and 'teacher' may be partly defined by the emphasis that faculty place on these roles. The GTAs in this study felt like they received mixed messages regarding the proper balance of these institutional identities. This suggests that faculty members that supervise and advise graduate students should be mindful in the way that the prioritization of these roles is discussed, and that neither role should be devalued even if the student role is the primary focus of a GTA's experience. In conclusion, this pilot study yields new information that contributes to all GTA professional development work by hearing from the GTAs themselves. As mentioned before, those involved in improving GTA support could benefit by building on this pilot and future work in this area.

The practice of prototyping is challenging to novice designers as they underutilize insights that prototyping offers to solving design problem. Central to this challenge is the abstract nature of design concepts like idea representation, iteration, and problem solution-space exploration. A unique opportunity from mathematics education presents itself for design educators and facilitators; that is, teaching with manipulatives. We seek to transfer such practices in mathematics education to design education and practice. Challenges exist for design researchers to carefully craft activities in design education mainly because of the open-endedness of problems, the decision-making that takes place while designing, and the inherent uncertainties in the design problems. Ultimately, the goal is to develop students' ability to flexibly transfer expertise to other contexts and new design challenges.

Keywords: Prototyping, Manipulatives, Design education, Mathematics education

Objective: Navigating the Prototyping Challenge in Design Education

Engineers build and create with materials ("stuff") to fashion new designs. The practice of prototyping in the design process can be challenging for novice designers however. Students learning to become engineers often underutilize prototyping as a step for their design process (Ali & Lande, 2018). The abstract and nebulous nature of what and how to prototype is central to this challenge. We propose to navigate the prototyping challenge within design education with insights from mathematics education.

Theoretical Perspective: Prototyping in Design Education Against a New Horizon

Drawing parallels for design education from the manipulative "prototyping" literature within mathematics education we glean insight into the learning and teaching of abstract notions and processes. Borrowing teaching with manipulatives as a pedagogical approach from mathematics education presents a unique opportunity for design educators and facilitators. In mathematics education, modeling mathematical ideas with manipulatives has been demonstrated to be effective in teaching students abstract concepts and processes of mathematics, like addition and subtraction (Carpenter, Fennema, Franke, Levi & Empson, 2015), fractions (Cramer, 2002, 2003) and bases of ten (Dienes, 1960), and function (Arcavi, Tirosh & Nachmias, 1989). Established theories of mathematics learning (Dienes, 1960; Bruner, 1963) support the practical development of activities to introduce abstract mathematical ideas to students by means of manipulating physical objects while reasoning about the represented mathematical abstraction (Thompson & Thompson, 1990; Arcavi, 2003). Students are able to complete sophisticated mathematical processes with understanding through this visual externalization of their "thinking with" tangible items (Carpenter et al., 2015). We map such practices in mathematics education to transfer to design education and practice. Specifically, we aim to develop examples of scaffolded prototyping in manipulatives as a way to move from concrete representations of prototypes to abstract understanding of design.

There are parallels between the conceptualizations of prototyping within the “design” and “mathematics” education literature. Within each domain, there is a specific subject-matter content to be applied: mathematical ideas applied through algebraic symbols, built and tangible creations applying scientific and engineering principles. The phenomena of thinking moving from concrete to abstract though is similar. Both design artifacts and manipulative representations provide conceptual affordances otherwise difficult to access for learners.

Within engineering design, a prototype provides a means for feedback (Jørgensen, 1984), between the designer and the material (Lim, Stolterman & Tenenberg, 2008), amongst the design team (Hartmann, 2009; (Hollan, Hutchins & Kirsh, 2000; Hutchins, 1995; Star & Griesemer, 1989), or between the team and the user (Buchenau & Suri, 2000; Kelley & Littman, 2006; Schrage, 2013). Similarly, the function of the “prototype” physical embodiment (manipulative representation) of an abstract mathematical idea is to feature certain aspects of the mathematical notion, ideally in a one-to-one correspondence between mathematical objects, processes, and relations. Representational theories of mathematics learning (Dienes, 1960; Bruner, 1963) posit that humans learn abstract ideas (no matter the field) not from the abstraction or symbolization itself but through generalizing the abstract idea from multiple concrete representations of it. No single “prototype” (aka manipulative representation or concrete embodiment) will ever fully depict a mathematical abstraction. But from each prototypical manipulative representation, the learner gleans an aspect of the abstraction not captured in the same way by the other prototypical manipulative representations. From this collection of concrete (prototypical) representations, the learner generalizes the abstract mathematical concept. There are clear connections to a design artifact and mathematical education research provides language to more precisely develop mindful design learning experiences and expectations for physical prototyping.

Like aspects of prototypical engineering thinking, algebraic thinking involves the practices of representation; pattern finding and generalizing functions from the relationship between quantities; modification; and abstraction (Kieran, 2006). These are practices that are transferrable to the abstract representation of ideas in design prototyping and defining the relationships between shapes and functions in prototypes. One key misconception in the teaching and learning of design is that students approach prototyping as a final product, as opposed to intermediate steps to learn about the design problem (Cross, 2018), gain insight (Lawson & Dorst, 2009), and reflectively learn design (Beckman & Barry, 2007). Moreover, the focus, in teaching design currently, is not on simplifying the approach to the solution, nor attempting to find the most efficient one; rather to breakdown the process and make it visible, with the ultimate goal for students to take this learning to other contexts. Thus, just as the literature on mathematical knowledge for teaching recognizes that being able to “do” mathematics is different from being able to “teach” mathematics (Ball & Bass, 2002), design instructors would do well to recognize the same for engineering and engineering design. Similar to the expectations for a mathematics instructor, the design instructor should be able to carefully plan the lesson, creating a range of possible, yet expected, paths that the students may take.

Modes of Inquiry: Results on the Horizon

Design educators do well on encouraging students to be creative, but they do not take this to the next step of actually teaching design, harnessing this creativity, and guiding the process. There is a gap, beyond students sharing their ideas and methods in the class, to actually learn design. The questioning approach to teaching is very much needed (Boaler & Humphreys, 2008). A design educator should build on these teaching practices, as intermediate milestones, asking questions, and using the artifact to elicit understanding (Cramer, 2003). There is an opportunity to use case studies to capture such moments in design education, which is often beyond simply characterizing students' behavior or observing current practices in teaching.

The overarching research question for this research design is as follows: *How can the utilization of object representation of mathematical concepts in mathematics education be transferred to object representation in scaffolded prototyping in design education?*

Preliminary Research Design

Overview and Participant Characteristics

In order to conduct the research study, our strategy involves creating a case for building prototypes in a controlled observation environment. The research design emphasizes producing relevant and meaningful results through substantiated rationale and supported by evidence from the collected data. In the preliminary stage of the research, participants of four students from four different disciplines (design, engineering, business and sustainability) will be recruited to complete a structured design task. Because different disciplines emphasize different epistemologies and practices, the setting will evoke the unique utilization of manipulatives as boundary spanning objects between the different participants. The research design will aim for case creation and comparisons across multiple groups of participants. Ideally, design projects span multiple months; however, the controlled task setting in a laboratory setting will allow a focused laboratory-based study.

Characterizing the Design Task

The participants will be provided an open prompt accompanied by a carefully selected set of manipulatives. Observations of group interactions will be video- and audio-recorded to allow for careful analysis. Control for the objects that participants will have access to should allow for augmentation of the underlying cognition and the corresponding exhibited behavior by participants. In order to select the manipulatives that participants will have access to, key considerations should be provided for the following issues surrounding prototyping (Lewrick, Link & Leifer, 2018):

- What are the basic functions for the user?
- What hasn't the user taken into consideration at all yet?
- How has nobody ever done it before?

The manipulatives should allow physical modeling to represent products, spaces and environment, in a way that provides an executable version of the design but with only the most necessary functions. In addition, the observatory lab setting should allow the reproduction of specific situations with team members doing physical acting.

Example. In an attempt to pilot the study to understand students' approaches to prototyping, we asked students to create three different prototypes of "an exercise machine that saves time and space." In this project, the idea was to push the students beyond the machine itself, thinking about larger contexts of exercising and healthy living—a readily available machine in a dorm room, for example, can save time for the students not needing to walk for the gym if it is designed in a way not to take much space as well.

Contextualizing the Design Task

Generally, the prompt that will be provided to the students should be planned to cross the boundaries between their different areas of expertise. More specifically, it should be framed to push the students to construct a collective, shared understanding in a very direct and visual manner. The *directness* and *visibility* of the idea representations should be a center in the design activity, so that playful insights are attained across multiple interactions with the objects. The goal is to provide a deeper, shared understanding of the solution vision while prompting collaboration and discussions. The design task tentatively has the following structure, which moves participants in a series of divergent and convergent modes of thinking:

- Given a set of provided initial solution scenarios, identify which one you would like to test. In the process, you should ponder which functions are absolutely critical
- Think about which variant should be built
- At this point, an intervention on how to allow the "objects to talk" should be perceived
- The built prototypes should allow feedback, moving to the next phase of essential features and solutions in a scaffolded manner. Breaking the groups of four into pairs should allow some variety for testing ideas
- Finally, revised new variants of prototypes should be conceived.

Example. In our pilot study of the "exercise machine," students were expected to combine analytical thinking with creative synthesis. Looking ahead at the implementation of the study, a promising opportunity exists because the learning objectives of the design course are aligned with the mathematical and physical knowledge that the students have acquired at this stage. For example, students are expected to utilize springs as means to achieve the desired functionality in their proposed design. This presents an opportunity to develop course modules, using manipulatives, to present the different behavior of springs to the students. Once they understand and are able to mathematically analyze the behavior of the spring, they can start using it in their prototype that is directed to fulfill the need of a user. Figure 1 below provides an example of the students' work in the pilot study.

Figure 1: Sample of a Students' Prototype in the Pilot Study: "Resistive Core Trainer"

Conclusions and Future Work

Ultimately, the goal is to allow students to flexibly transfer the learned expertise in the proposed activities to other contexts and new design challenges. Building on the understandings for learning from mathematics can have useful implications for the teaching and learning of engineering design. Furthermore, the outcome of this study could guide future bidirectional studies by benefiting not only design education, but also mathematics education, especially at the college-level courses.

Research on quantitative and covariational reasoning has emerged as a critical area of study in recent decades. We extend this body of research by introducing the construct of an abstracted quantitative structure. In addition to introducing the construct, we illustrate it by presenting empirical examples of student actions. We close with implications for research and teaching.

Keywords: Cognition, Algebra and Algebraic Thinking, Calculus, and Learning Theory

Steffe and Thompson enacted and sustained research programs that have characterized students' (and teachers') mathematical development in terms of their conceiving and reasoning about measurable or countable attributes (see Steffe & Olive, 2010; Thompson & Carlson, 2017). Thompson (1990, 2011) formalized such reasoning about measurable attributes into a system of mental actions and operations he termed *quantitative reasoning.* In this paper, we extend this work by introducing the construct *abstracted quantitative structure*: a system of quantitative relationships a person has interiorized to the extent they can operate as if it is independent of specific figurative material (i.e., representation free).

Background

Thompson (2011) defined quantitative reasoning as the mental operations involved in conceiving a situation in terms of measurable attributes, called *quantities*, and relationships between those attributes, called quantitative relationships. One form of quantitative reasoning involves constructing relationships between two quantities that vary in tandem, or covariational reasoning (Carlson, Jacobs, Coe, Larsen, & Hsu, 2002; Saldanha & Thompson, 1998; Thompson & Carlson, 2017). Carlson et al. (2002), Confrey and Smith (1995), Ellis (2011), Johnson (2015a, 2015b), and Thompson and Carlson (2017) are a few researchers who have detailed frameworks and particular mental actions associated with students' covariational reasoning. We narrow our focus to that of Carlson et al. (2002), who identified five mental actions associated with covariational reasoning. A critical mental action of their framework, especially for differentiating between various function classes, is to compare *amounts of change* to draw inferences about quantities' covariation (**Figure 20**).

Piagetian notions of *figurative* and *operative* thought (Piaget, 2001; Steffe, 1991; Thompson, 1985) differentiate between thought based in and constrained to figurative material (e.g., perceptual objects and sensorimotor actions)—termed *figurative thought*—and thought in which figurative material is subordinate to logico-mathematical operations and possibly their transformations—termed *operative thought*. Quantitative and covariational reasoning are examples of operative thought due to their basis in logico-mathematical operations (Steffe & Olive, 2010). Moore, Stevens, Paoletti, Hobson, and Liang (online) illustrated figurative graphing meanings in which prospective secondary teachers were constrained to constructing graphs with particular perceptual features (e.g., drawing a graph solely left-to-right) even when they acknowledged those features did not enable them to viably represent a conceived relationship. In contrast, Moore et al. (online) described that a prospective secondary teacher's graphing meaning is operative when perceptual and sensorimotor features of their graphing actions are persistently dominated by the mental operations associated with quantitative and covariational reasoning.

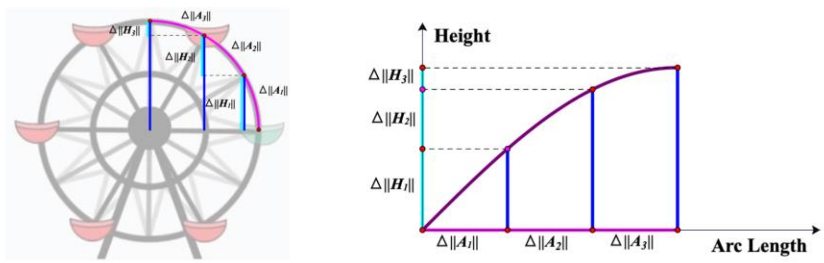

Figure 20: For Equal Increases in Arc Length (counterclockwise direction from the 3 o'clock position), Height Increases by Decreasing Amounts

Abstracted Quantitative Structure

We define an abstracted quantitative structure as a system of quantitative relationships a person has interiorized to the extent he or she can operate as if it is independent of specific figurative material. An abstracted quantitative structure can also be re-presented to accommodate novel contexts or situations permitting the associated quantitative operations. Our notion of an abstracted quantitative structure is an extension of von Glasersfeld's (1982) definition of concept to the context of quantitative and covariational reasoning. von Glaserfeld defined a *concept* as, "any structure that has been abstracted from the process of experiential construction as recurrently usable…must be stable enough to be re-presented in the absence of perceptual 'input'" (p. 194). An abstracted quantitative structure entails both of these features; an abstracted quantitative structure is recurrently usable beyond the initial experiential construction and it can be re-presented in the absence of available perceptual (or figurative) material.

An abstracted quantitative structure can accommodate novel situations through another process of experiential construction within the context of figurative material not previously experienced in the context of using that structure. This action is a hallmark of operative thought due to the action entailing an individual using the operations of their quantitative structure to accommodate novel quantities and associated figurative material. It is in this way that the quantitative structure of an abstracted quantitative structure is abstract; mathematical properties are understood as not tied to any particular two quantities and associated figurative material.

Indications and Contraindications

The way we have defined abstracted quantitative structure presents an inherent problem in characterizing a student as having abstracted a quantitative structure: it is impossible to investigate a student's reasoning in every situation in which an abstracted quantitative structure could be relevant. For this reason, we find it necessary to discuss a student's actions in terms of indications and contraindications of her or him having constructed an abstracted quantitative structure. What follows are examples that we use to illustrate contraindications or indications of students having constructed abstracted quantitative structures.

Lydia and re-presenting. Lydia was a prospective secondary teacher in a teaching experiment focused on trigonometric relationships and re-presentation (Liang & Moore, 2018). Lydia initially engaged in a task in which she constructed incremental changes compatible with those presented in Figure 20 (left). We took her actions to indicate her reasoning quantitatively and presented her the *Which One?* task. The task (Figure 21, left) presented Lydia with numerous red segments that varied in tandem as the user varied a horizontal (blue) segment, which represented the rider's arc length traveled along the circle. We designed only one red segment to covary with the blue segment in a way compatible with the vertical height and arc length of the rider. Lydia's task was to choose which, if any, of the red segments represented that relationship. Lydia chose the correct red segment by re-orienting it vertically and checking whether the heights matched pointwise within the displayed circle (Figure 21, middle). We then asked her if the chosen segment and blue segment entailed the same covariational relationship constructed in her previous activity involving the Ferris wheel (see Figure 20, left) (from Liang & Moore, 2018):

> Lydia: Not really…Um, I don't know. [*laughs*] Because that was just like something that I had seen for the first time, so I don't know if that will like show in every other case…Well, for a theory to hold true, it like – it needs to be true in other occasions, um, unless defined to one occasion.
> TR: So is what we're looking at right now different than what we were looking at with the Ferris wheel?
> Lydia: No. It's – No…Because I saw what I saw, and I saw that difference in the Ferris wheel, but I don't see it here, and so –
> TR: And by you "don't see it here," you mean you don't see it in that red segment?
> Lydia: Yes.

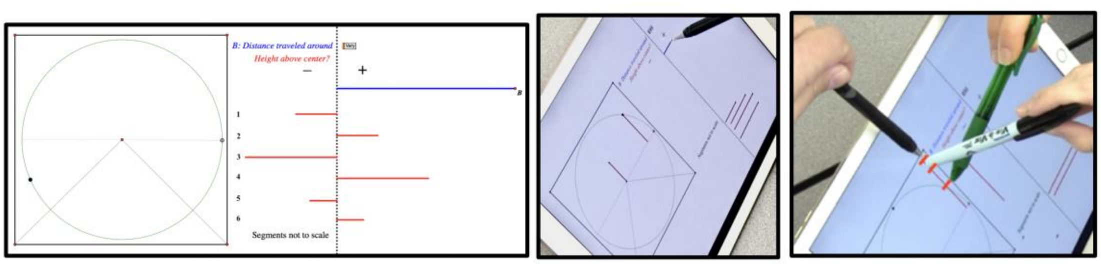

Figure 21: (left) Which One?; (middle) Lydia Checking Segment Pointwise; and (right) Lydia Attempting to Re-present a Quantitative Structure

Lydia's actions are a contraindication of her having constructed an abstracted quantitative structure during her previous activity. Specifically, she could not re-present the activity she engaged in with respect to the Ferris wheel situation (Figure 20, left) when provided with what was to her novel figurative material in the *Which One?* task. As a further contraindication of her having constructed an abstracted quantitative structure, it was only after much subsequent teacher-researcher guiding and their introducing perceptual material using their pens (**Figure 21**, right) that she was able to conceive the red and blue segments' covariation as compatible with the relationship she had constructed in the Ferris wheel situation.

Noli and the inverse sine relationship. We draw on a prospective teacher's response to the graphs in Figure 22 (left and middle). We presented a graph consistent with Figure 22 (left) to

Noli, a prospective teacher, as hypothetical student work and asked whether the graph represents the inverse sine (or arcsine) function. Noli identified that Figure 22 (left) can be thought of as representing the inverse sine function by considering the vertical axis the input of the function (see Figure 22, right). In response, we presented Figure 22 (middle) and explained that a hypothetical student claimed Figure 22 (middle) represents the inverse sine function rather than Figure 22 (left). Noli claimed that both graphs could represent the inverse sine function (completed work in Figure 22, right):

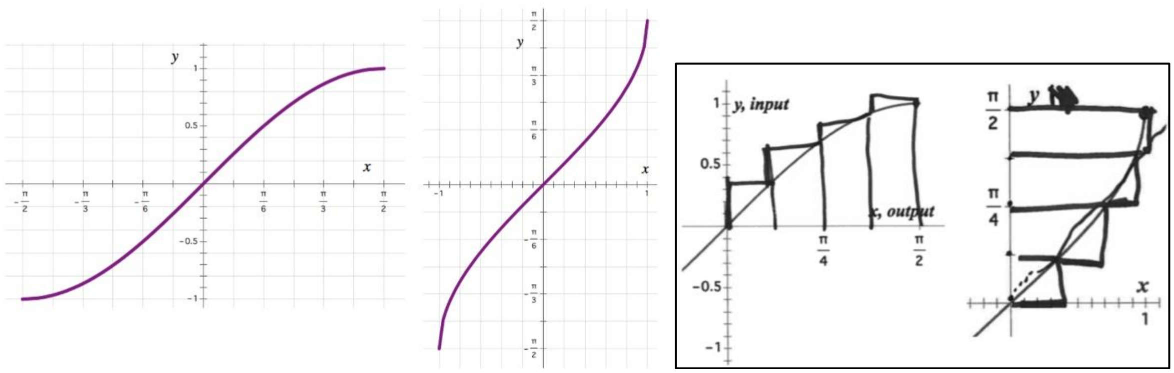

Figure 22: Graphs of (left) $x = \sin^{-1}(y)$, (middle) $y = \sin^{-1}(x)$, and (right) Noli's work.

> Noli: [*Noli has identified that Figure 22, left and middle, represent $x = \sin^{-1}(y)$ and $y = \sin^{-1}(x)$, respectively*] They're both representing the same thing just considering their outputs and inputs differently [*referring to axes*]…So it's like here [*referring to Figure 22, middle, $y > 0$*], with equal changes of angle measures [*denoting equal changes along the vertical axis*] my vertical distance is increasing at a decreasing rate [*tracing graph*]…here [*referring to Figure 22, left, $x > 0$*] it's doing the exact same thing. With equal changes of angle measures [*denoting equal changes along the horizontal axis*] my vertical distance is increasing at a decreasing rate [*tracing graph*]…this one looks like it's concave up [*referring to Figure 22, middle from $0 < x < 1$*] and this one concave down [*referring to Figure 22, left from $0 < x < \pi/2$*], it's still showing the same thing.

We interpret Noli's actions as indicating her having constructed an abstracted quantitative structure that she associates with the "inverse sine function…sine function." Noli understood each graph as representing equivalent covariational properties despite their differences in shape; she understood that both "concave up" and "concave down" graphs represent one quantity increasing by decreasing amounts for equal successive variations in the other quantity. Furthermore, she flexibly moved between re-presentations of this covariational relationship, adjusting for the alternative coordinate orientations, which is a contraindication of her reasoning being dominated by figurative aspects of thought.

Implications

The construct of an abstracted quantitative structure provides a specified criterion for claims about students' and teachers' quantitative and covariational reasoning. In our previous work (e.g., Moore, 2014), we made claims about a student constructing a particular function or relationship based on her or his activity in one, or at most two, contexts. If we frame the construction of a function or relationship in terms of an abstracted quantitative structure, then our evidence within those previous studies is insufficient to make such claims. Making such claims requires studying a student's actions in a variety of contexts in which her or his actions can provide indications or contraindications of such a structure. Likewise, and transitioning our focus to teaching, it is speculative at best to claim one has taught a function or relationship concept if one has not explored their students' reasoning in more than one context and relationship.

UNIT TRANSFORMATION CAPACITY: ASSESSING COGNITIVE DEMAND WITH UNITS COORDINATION AND WORKING MEMORY

Understanding student cognition has been a crucial part of mathematics educational research for decades. The construct of units coordination has proven to be central in students' mathematical development. The psychological construct of working memory has also been shown to have an important role in cognitive development. This report combines units coordination and working memory to create a new theoretical construct called unit transformation capacity, aimed to capture nuances in modeling students' mathematics.

Keywords: Cognition, Research Methods, Learning Progressions

Motivation

Understanding students' struggles and cognitive development in mathematics is important in developing better curricula that foster mathematical foundations. Building models of students' mathematics provides an avenue for understanding what cognitive structures are needed for students to progress in mathematics. Scheme theory has been a primary mode for modeling students' mathematics, through describing assimilatory processes, mental actions, and expected results. The construct of schemes has been applied to various mathematical domains in K-12 (Steffe, 1992; Olive & Çağlayan, 2008; Olive & Steffe, 2010) and post-secondary schooling (Akkoç & Tall, 2002; Arnon et al., 2014; Cottrill, Dubinksy, Nichols, Schwingendorf, Thomas, & Vidakovic, 1996).

In research on primary school education, units coordination (UC) provides a particularly valuable construct for modeling mathematical cognition. UC has been shown to be connected across several mathematical domains including students' construction of number sequences (Ulrich, 2015, 2016), fractions knowledge (Hackenberg & Tillema, 2009; Izsák, Jacobson, de Araujo, & Orrill, 2012; Norton & Boyce, 2013; Steffe, 2010), and algebraic reasoning (Hackenberg & Lee, 2015; Olive & Çağlayan, 2008). Since UC is an integral component of students' mathematics, it is beneficial to continue to investigate how to engage students in tasks that facilitate mathematical development.

This report characterizes a new theoretical framework that combines UC and working memory as a research tool for building models of students' mathematics, and as possible assessment tools for designing tasks and curricula.

Theoretical Framework

Our proposed theoretical framework utilizes the mathematics-specific construct of UC (Hackenberg & Tillema, 2009; Steffe, 1992; Ulrich, 2015) and the psychological construct of working memory to better capture students' mathematics. UC describes students' engagement with various levels of units in mathematical tasks (Steffe, 1992). Pascual-Leone (1970) developed the psychological construct of M-capacity to model working memory. This report presents a new construct that combines UC and working memory to capture and explain nuances in students' engagement in mathematical tasks.

Units Coordination

UC describes students' ability to construct and transform various levels of units in mathematical tasks across mathematical domains. This construct emerged out of Steffe's (1992) research on children's construction of whole number knowledge: "I think of units coordinating as the mental operation of distributing a composite unit across the elements of another composite unit" (Steffe, 2001, p. 279). For example, for a task to be classified as multiplicative, there needs to be at least two levels of units that are coordinated so that one composite unit is distributed over the second composite unit. In the task of 7 times 5, the composite units are the 5 composed of five 1s and the 7 composed of seven 1s. A student could solve this task by distributing seven units of 1 across each single unit of 5 to produce a new unit of 35. In this case, the student sees 35 as composed of five units of seven units of 1 (Figure 1).

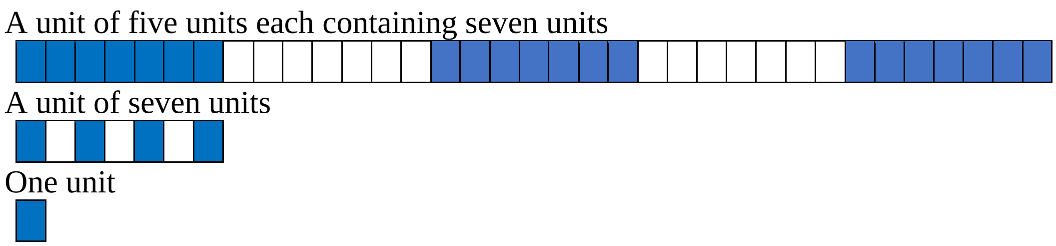

Figure 1: An Example of Coordinating Composite Units in the Problem of 7 Times 5

UC is classified in three stages depending on the number of levels of units the student is able to take as given and operate on. For example, a Stage 2 student is able to take a composite unit, or two-level structure (e.g., a unit of seven units of 1) as given without needing to construct the composite unit in activity. The stages are representative of the psychological structures and schemes with which the students operate (Piaget, 1970). Students build new structures by acting on different units in a task either imaginatively or through sensori-motor activity. A students' success on a particular task will depend on the cognitive demand of the task and, in part, on the student's UC stage. The cognitive demand of a task not only depends on the number of units in the problem but also the mental actions and relationships between the units. Thus, to know whether the cognitive demand of a task exceeds the cognitive capacity of a student, researchers and teachers must identify the units and mental actions needed to transform them successfully, in order complete the task. The psychological construct of working memory can account for the additional cognitive strain of accounting for units and actions, or relations between units, when modeling students' mathematics.

Working Memory

Working memory is involved in retrieving, maintaining, and sequencing the information a person must hold in mind and work on at any moment in time. It has been shown to be crucial in recalling numerical facts, updating and maintaining numerical representations, and implementing mathematical problem solving strategies (Bull & Lee, 2014). Working memory has also been shown to be a predictor of children's mathematical achievement levels (Blankenship, Keith, Calkins, & Bell, 2018). This paper uses the following definition of working memory: "Working memory involves the process of holding information in an active state and manipulating it until a goal is reached" (Agostino, Johnson, & Pascual-Leone, 2010, p. 62). There are several models for working memory; however, Pascual-Leone's (1970) M-capacity model aligns with the Piagetian scheme theory associated with UC.

In the context of UC, a student's working memory holds the units and transformations between units in an active state in order to perform the mental operations required to solve a task. M-capacity refers to the number of separate schemes a person can actively hold in their mind at a time (Pascual-Leone, 1970). However, Pascual-Leone's schemes are simpler than Piaget's, referring to a single action, such as the construction or transformation of a unit. If a person is able to mentally keep track of five units or actions between them, that person would have an Mcapacity of five. Pascual-Leone (1970) empirically found that children ranging in age from 5-11 years-old have M-capacity from 1.723 to 4.149; therefore, elementary school students typically can hold between 2 to 4 units/actions at a time when working on a problem. With a constraint on the number of units a students can hold in mind, having two and three-level units structures helps explain why Stage 2 and 3 students can handle more advanced mathematical tasks. The integration of M-capacity and UC may help describe students' mathematics and explain the power of higher-level mental structures.

Unit Transformation Capacity

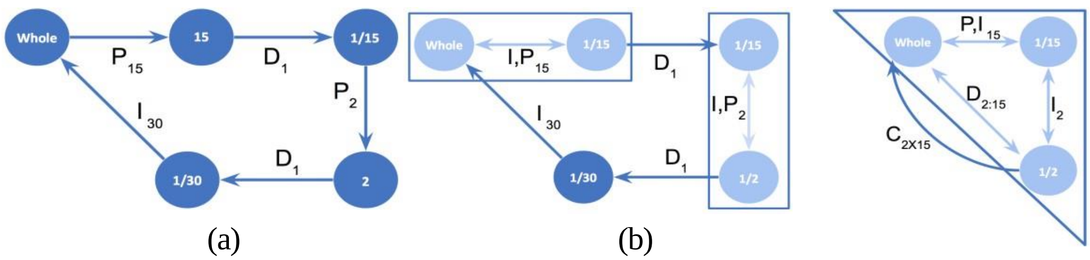
The theoretical framework proposed here combines UC and M-capacity to create an analytical tool for modeling students' mathematical cognition. We believe that students' ability to solve cognitively demanding tasks depends on their stage of UC and M-capacity. This codependence motivates the need for the Unit Transformation Capacity (UTC) construct, which we define as the number of units and transformations of units a student can mentally sequence while solving a task; units may be chunked into two and three-level structures. Thus, the UTC framework accounts for two kinds of mental resources available to a student when predicting whether that student will be successful on a task or not.

To model students' UTC, we began by ranking the cognitive demand of mathematical tasks found in the literature in the domains of whole number arithmetic, fractions, and algebraic reasoning. Rankings were based on hypothetical solutions, developed independent of student work, and assuming the student would be operating at UC Stage 1. Analyzing the tasks from the perspective of a Stage 1 student allowed for unpacking all the different units and transformations required to solve a particular task. The total number of units and transformations involved in a task became the rank of that task, which we call unit demand. We developed a diagraming system to model such solution paths (see Figure 2 below).

The diagrams incorporate units (circles), transformations (arrows), and chunking higher-level structures (boxes, triangles). Each transformation is explicitly identified with a corresponding letter: P=partition, I=iterate, D=disembed. The subscripts on the transformations indicate how many of each transformation occurred. For example, in Figure 2, P_{15} represents the student partitioning a unit into 15 equal pieces. The two models in Figure 2 are theoretical models built from the following task based off Hackenberg and Tillema's (2009) cake problem: "Imagine a rectangular cake that is cut into 15 equal pieces. You decide to share your piece of cake fairly with one other person. How much of the whole cake would that person get?" (p. 7). This task was analyzed to be a task of rank 10 because there are five units and five transformations is the diagrammed solution (Figure 2a).

A student would need to have a UTC of at least 10 to solve this task. For a Stage 1 student to solve this task without relying on figurative material they would need an M-capacity of 10.

Because Stage 1 students aren't able to chunk units and transformations into two- or three-level structures, each unit and transformation taxes their M-capacity. However, Stage 2 students are able to take some units and transformations together as given within two-level structures, represented by boxes, which allows for off-loading of working memory. Thus, a Stage 2 student would only need an M-capacity of 6 to solve the task (see Figure 2b). For a Stage 3 student, a single three-level structure contains many of the units and transformations so that only an M-capacity of 2 is needed to solve this task (see Figure 2c). Note that, for a Stage 3 student, demand is further reduced because there is no need to disembed units within the three-level structure. In fact, the three-level structure captures all units and transformations except for the need to compute the final result.



(a) (b) (c)

Figure 2: Student Diagrams for (a) Stage 1; (b) Stage 2; (c) Stage 3

Conclusion

The UTC framework explains why it is advantageous for student to develop higher-level structures in mathematical development. This added power of working with two or three-level structures has been demonstrated across several domains in mathematics (Hackenberg & Lee, 2015; Hackenberg & Tillema, 2009; Norton & Boyce, 2013) and is captured in our diagrams. These findings fit with Hackenberg and Tillema's (2009) results showing a Stage 1 struggling to solve the cake task without figurative material while a Stage 2 student was able to solve the problem with little figurative material or teaching support.

The diagraming also helps capture nuances in student's mathematics found in the literature. For example, Hackenberg and Tillema (2009) documented a Stage 2 student who was able to solve the task of finding 2/5 of 1/3 but was unable to solve the mathematically equivalent task of finding 1/3 of 2/5. Our analysis finds that the 2/5 of 1/3 task has a rank of 12 while the 1/3 of 2/5 task has a rank 14. The added unit demand is accounted for in having the extra unit of 2 at the beginning of the task instead of at the end. The Stage 2 student solved the 1/3 of 2/5 with an answer of 1/15 indicating that the factor of 2 was lost during her solution path. This fits with what our model would predict for a Stage 2 student with an M-capacity of 5 or less, which is consistent with the student's age.

Our framework and models aim to capture nuances in students' mathematics by integrating UC and working memory. The models offer new psychological perspective on why higher-level structures allow for more advanced mathematics, which is a common theme throughout the literature (Hackenberg & Lee, 2015; Hackenberg & Tillema, 2009; Norton & Boyce, 2013). The diagraming has also provided researchers with a tool for investigating different nuances about how students are thinking about mathematics. We hope to continue to capture nuances in students' mathematics that are consistent with the literature and help explain where students struggle with particular types of tasks. We are currently analyzing behavioral data from a pilot study with pre-service teachers to test the framework's utility in predicting student outcomes on fraction tasks. From this study, we hope to refine our framework and elucidate its use as a tool for researchers and teachers in selecting appropriately cognitively demanding tasks for students.

Overall, the goal for this new framework is to continue to build models of students' mathematics and broaden the scope to encompass multiple age groups and mathematical domains beyond fractions.

A major challenge for elementary STEM teacher educators is incorporating social justice considerations across the span of professional program coursework. Recognizing that standards and policy documents are pressing for diversity and inclusion in STEM education, there is a growing need to support preservice teachers' learning about critical theories and how to develop an equitable vision of teaching. This paper describes ongoing research on our University's elementary STEM teacher education program. We focus our discussion on instrument development and the methods we used for eliciting preservice teachers' understandings of equity and diversity issues related to teaching STEM content. We designed a number of math, science, and technology scenarios in tandem, as means of building coherence across disciplinary boundaries; this report focuses on math teaching and learning.

Keywords: Qualitative Research Methods, Data Collection Instruments, Preservice Teacher Education, Equity and Diversity

Background & Goals: Building Coherence in STEM Learning Opportunities for PSTs

Commonly in teacher preparation programs, preservice teachers (PSTs) learn math and science content, technology in education, and teaching methods separately. Similarly, multi-cultural issues and the historical, sociopolitical foundations of schooling are also typically discussed separate from other topics and subject matter domains, if covered at all. There are known challenges with this lack of coherence and fragmentation in teacher education programs (Sirotnik, Goodlad, & Soder, 1990; Howey & Zimpher, 1989; Zeichner, Gore, & Houston, 1990). Broadly speaking, this fragmentation can lead PSTs to encounter contradictions or a lack of common language, and is overall an inefficient use of their time that can hinder PSTs in developing a clear vision of equity and the work of teaching.

Building on prior calls for coherent teacher education programs (Darling-Hammond & Bransford, 2005; Ritchie, An, Cone & Bullock, 2013), we are currently engaged in a long-term teacher education project aimed at building coherence in PST learning opportunities across disciplines and departments in undergraduate elementary teacher education STEM coursework. Our research team is comprised of math education experts, STEM content experts, and critical-theory scholars. Together, we have been working on a larger project and developing a vision of coherence based on theories of learning, cross-cutting concepts in math and science, as well as principles for fostering equity and social justice. In this paper, we focus on how we created, theorized, and piloted math tasks and in-class activities for the larger project.

Approach and Purpose of Study

Our research team has developed a class activity using a set of hypothetical teaching scenarios. These scenarios feature disciplinary content, student thinking, instructional design, and principles and dispositions around equity and social justice. These activities combine written tasks and prompts for group dialogue, through which PSTs engage in critical discussions that encompasses different aspects of classroom teaching and learning.

Using these tasks and in-class activity, we are collecting data in the form of PSTs' written work and transcripts of group discussions involving these teaching scenarios. With these data, we hope to survey teachers' prior knowledge, experiences, and assumptions pertaining to math content, student thinking, and, equity and social justice in math education. We seek to answer the following questions: What do PSTs already know? What are their productive resources and intuitions related to equitable teaching specifically in math? How do PSTs make sense of complex relational situations that they will likely encounter in future practice?

The Design and Rationale for Multi-Discourse Problematized Teaching Scenarios

During the Fall 2018, the research team designed and piloted instruments for eliciting and analyzing preservice teachers' knowledge related to equity and justice in math education. These instruments involve a number of specially designed tasks, each reflecting a *multi-discourse problematized teaching scenario* (MDPTS). Each MDPTS is a group activity for pre-service teachers and designed to elicit their perceptions and attitudes concerning a hypothetical, yet realistic, classroom scenario. MDPTS design was informed by previous research based on critical and sociocultural theories of math education (see below) and combines different elements highlighting various dimensions of classroom teaching such as content learning, social context, and power dynamics (cf. R. Gutiérrez, 2009).

The MDPTS were loosely inspired by existing work on scenario or case-based assessments in teacher education (e.g., see Shaughnessy & Boerst, 2018; Selling et al., 2015). Each MDPTS was designed to elicit different types of discourses, from about content, to classroom practice, to equity-based dialogue. Where applicable, MDPTS were designed to align with relevant math and science standards for elementary grades. Furthermore, some MDPTS were inspired by scholarship focused on equity, gender, and race in math education (e.g., R. Gutiérrez, 2009; Leyva, 2017; Martin, 2009).

MDPTS Example: "Mathematical Equivalence"

The mathematical equivalence problem presented in this scenario (Figure 1) is intended to build on student prior knowledge, and it creatively combines (and goes beyond) two core standards from earlier grades, namely, CCSS-M Standards 1.OA.6 and 1.OA.7 (National Governors Association Center for Best Practices & Council of Chief State School Officers, 2010). This scenario aims to highlight the intersection of mathematical content, cognition, and gendered dynamics as a means of examining PSTs' knowledge within and across these areas.

Specific elements of "Mathematical Equivalence" were designed by adapting transcripts of utterances and emulating the tone of social interaction and mathematical behavior of students appearing in existing empirical work (Gutiérrez, Brown, Alibali, 2018; Heyd-Metzuyanim & Sfard, 2012). Specifically, it was designed to foreground mathematical content and cognition on the one hand, and gendered dynamics on the other. The psychology literature involving equivalence problems indicates the importance of noticing the location of the equal sign on individual strategy use and learning outcomes (e.g., Alibali, Crooks & McNeil, 2018). The hypothetical student (“Pat”) wants to point out the (accurate) location of the equal sign, which is the crux of the reasoning exhibited by the students in the scenario. The prompting strategy we chose for this scenario is intentionally open-ended for the PSTs to interpret the mathematical as well as the social factors that shape the interaction. Pat is not gender-identified, thus we hypothesize that the PSTs’ interpretations of this scenario will vary according to whether/how they assign a gender to Pat.

Mathematical Equivalence

A class of 3rd graders is in the middle of an explorative unit on the equal sign that incorporates the following goals:

- Accurately notice the location of the equal sign in equations involving addition and subtraction
- Generate and compare different strategies for determining the unknown number that makes an equation true

A group of three students are working on solving the following equivalence problem:

$$\mathbf{8 + 5 + 4 = 4 + \_\_\_}$$

A teacher overhears the following conversation:

Rebecca:	I’m not sure what to do. I’m confused. Do I fill in the blank?
Pat:	This is so easy guys! The answer is just 13.
Rebecca:	I don’t think it’s easy. That was rude Pat.
Gabe:	Plus, I don’t think you did it right Pat. I think the answer is 17. 'Cause 8 plus 5 plus 4 is 17.
Rebecca:	Yeah. That seems smart.
Pat:	You guys are so dumb. You have to pay attention to the equal sign...
Gabe:	Don’t act like the boss of us. You always act bossy.
Rebecca:	I think it’s 21. Cause I added it all up.
Pat:	If you guys would just listen I could teach you how to do it.
Gabe:	We can figure it out ourselves. Thanks anyway.

Imagine you are an observer in the classroom. Please discuss the following questions:

1) What is the dynamic between the three students?
2) How do you think the dynamic came about?
3) If you were the teacher, when would you intervene? How? What would you do?

Figure 1: MDPTS– “Mathematical Equivalence”

There are subtle elements that were designed into this scenario which might allude to either stereotypical female or male gender roles in mathematics, which adds further complexity to our analysis of the PSTs' perceptions of gender and math. At first read, one might assume Pat is a boy given the ways "he" asserts himself in the beginning and finds the solution procedure "easy." Yet, whereas these aspects of Pat's behaviors are aligned with dominant narratives of a masculine mathematician (Hottinger, 2016), Pat's behaviors also exhibit a feminine quality that resist this stereotype. Through it all, Pat wants to teach Rebecca and Gabe, and *teaching* mathematics is not typically associated with the historically gendered role of the masculine mathematician (cf. Hottinger, 2016). Another element in the scenario that could elicit PSTs' perceptions of not only gender and math, but also race, is the fact that it refers to Pat as "bossy." The term bossy can be perceived as a gendered as well as racialized term in math contexts (Langer-Osuna, 2011; McGee & Bentley, 2017), and these troubling narratives should be better understood in teacher education.

Preliminary Analytic Approach for Examining PSTs' Responses to MDPTS

We recently collected audio recordings and written work of 15 small groups (2-4 undergraduates in each group) of PSTs engaging with a set of four MDPTS, including the one presented in this paper. We started the process of open coding, reducing data, and articulating a preliminary analytic approach (Saldaña, 2013).

In Figure 2, we provide a few data excerpts of statements made from one group of PSTs during the activity and our tentative codes for those utterances. These data examples are not meant to be "final products," instead they represent our initial step toward a systematic and rigorous analysis and interpretation of our data. We include them to illustrate the range of codes that might be possible that highlight the multiple intersecting discourses elicited from one group of PSTs in response to "Mathematical Equivalence."

: [*responding to prompt no. 2 in Math Eq.*] It came about because Pat told them it was super easy. : [1]They were all like Pat you're a jerk! Stupid idiot! : [2]Because saying it's easy is ob--like ob-ject-ive, right? : Yeah, objective.	[1]STUDENT BEHAVIOR - JUDGEMENT [2]OBJECTIVITY/ MASCULINITY
: 'Cause I mean they're like none of them are *wrong* because [3]eight plus five plus four is= : Is seventeen. : =seventeen.	[3]STUDENT MATH THINKING
: I don't know if Pat is a boy or a girl but I feel like if they're both boys [*lower volume*] it could have been [4]toxic masculinity. 2 & 3: [5][Laughing] : Just throwing that out there. PST 2: [5]Yeah!	[4]GENDERED DISCOURSE [5]JEST

CAPTURING INSCRIPTIONAL PRACTICES IN DIGITALLY COLLABORATIVE CLASSROOM SETTINGS: A FOCUS ON CONSTRUCTING

Representations often refer to the information in material form on paper or computer screen such as written text, graphical displays, tables, equations, diagrams, maps, and charts. The term, representation, is ambiguous because it also refers to a learner's internal or mental thought; while internal representations can serve as a resource for learning, they are not publicly accessible or directly available to others. From a situative learning perspective, knowing and learning mathematics are "situated in social and intellectual communities of practice, and for their knowing of mathematical knowing to be active and useful, individuals must learn to act and reason mathematically in the settings of their practice" (Greeno, 1988, p. 482). Therefore, the term inscription builds on the situative perspective and refers to external representations of thinking that exist in material form where meanings are developed in social settings.

As a part a four-year design research study that explores student learning and engagement with digital technologies, we advance an analytic framework to capture middle grades students' inscriptional practices in collaborative settings. As called for in the PME-NA 2019 Conference Theme, "...against a new horizon," the examination of inscriptions in mathematics classrooms invites new opportunities to consider the expansion and growth of mathematics education research through shifting attention from focusing on representations of the individual mind towards viewing representations as a social practice (Roth & McGinn, 1998).

The purpose of this presentation is to advance an analytic framework to capture inscriptional practices in middle grades mathematics classrooms. In this poster, we focus on the practice of constructing because it (a) foregrounds the relationship among people and their use of digital resources being developed in the larger project, (b) builds on empirical research on the teaching and learning of mathematics, and (c) provides the project with insights on how students use inscriptions to develop, communicate, and retrieve their understandings.

The framework was developed using a two-phase iterative process. The first phase involved identifying, compiling, and incorporating inscriptional practices that existed when reviewing empirical studies in the educational literature. The second phase involved engaging in iterative cycles of axial coding (Strauss & Corbin, 1998) and discussion to reach consensus.

MODELING MATHEMATICS STUDENTS' TASK SOLUTION PROMULGATION

Thomas E. Ricks
Louisiana State University
tomricks@lsu.edu

Keywords: Classroom Discourse, Research Methods, Technology

Challenging tasks focused on the big mathematical concepts of the mathematics curriculum provide a core set of experiences from which students can develop powerful mathematical meaning (NCTM, 2000). As social beings, students notice and adopt the more efficient strategies of their peers, leading to natural mathematics learning with minimal teacher-talk. This paper continues previous research (Ricks, 2017) that models student engagement in challenging tasks and tracks the spread of student solutions across the classroom landscape by simulating classroom mathematics learning using discreet numerical analyses (various computer models simulate how student solutions to a central, challenging task promulgated across a classroom of twenty students arranged in five rows, each four seats deep). Over 14 million task completions were modeled, across varied parameters, such as an idea-spread ratio to adjacent desk locations and overall task difficulty. Results corroborate previous findings, and suggest that even in the most simple modeling, promulgation behavior is chaotic—hinting that current neo-liberal reform attempts to corporate-ize education, strip students of their humanity by transforming education into industrialized production of human capital, and reduce schooling to quality-control programs is problematic. When properly contextualized, this data contributes to furthering the goals of mathematics education in a variety of ways, including differentiating instruction for specific student needs, making mathematics accessible to all students, encouraging positive mathematics dispositions, learning to talk about personal mathematics understanding and make sense of others' mathematical thinking, and increasing the rigor of mathematical tasks. Educators, educational researchers, and educational policy-makers are increasingly being asked to improve the schooling process with progressively limited resources. We can do more with less—through better design. Proper reform of schooling to align with the various interests of standards-pressures can be recast as engineering problems—the role of the computer modeler then becomes a student of maximization and optimization. Modeling students' mathematical task solution promulgation across the classroom terrain can contribute to reform attempts to optimize pedagogical approaches. Computer modeling holds promise to augment the possibilities of reform by testing at accelerated rates various pedagogical practices for recent reform proposals. As these models become more sophisticated and simulate actual classroom behavior with greater fidelity, various reform scenarios can be tested virtually to see which ones educators might wish to adopt for their specific classrooms to differentiate instruction for their own students. As this study is limited in scope, more research is needed to understand how these models can be improved to better simulate real class dynamics.

EFFECT OF NUMBER CHARACTERISTICS ON PERFORMANCE IN COMPUTATIONAL ESTIMATION

Coskun Erden
Iowa State University
cerden@iastate.edu

Keywords: Cognition

Computational estimation is a form of mental arithmetic which requires the temporary storage of initial information and partial results, retrieval of information from long term memory and the use of a variety of calculation strategies that determine solution sequences. Research revealed that computational estimation skill positively correlates with a variety of measures of mathematical ability including SAT score (Paull, 1972 as cited in Siegler & Booth, 2004) and arithmetic fluency (Dowker, 2003). However, previous research mainly focused on understanding the strategies participants use and the development of computational estimation skills. Only a few studies have examined the effects of problem characteristics on the performance of participants. Ganor-Stern (2015) showed that the certain characteristics of the numbers used in computational estimation have substantial effects on the performance. The purpose of the present study is to contribute to the knowledge base on the effects of number characteristics on the performance in computational estimation. This study examines the effects of values in the ones' digits of numbers on university students' performances in computational estimation. To this end, two-digit by two-digit multiplication problems are characterized by two main aspects: the values in ones' digits of the numbers (homogeneous-lower, homogeneous-upper, or heterogeneous) and the sum of distances of ones digits to nearest tens values (adjustment size of 3,4,5,6, or 7). For example, 64 x 23 is a homogeneous-lower problem with adjustment size 7 as both ones' digits are less than 5 and the sum of the differences between each operand and the nearest tens value is 7. On the other hand, 37 x 82 is a heterogeneous problem with adjustment size 5. The main question in the present research was "How do homogeneity type and the adjustment size of a computational estimation problem affect participants' performances in terms of accuracy and reaction time?"

The author developed a computational estimation test (CET) consists of 30 two-digit by two-digit multiplication problems as a tool of data collection. Thirty undergraduate students (20 female and 10 male) at a Midwestern university in the United States participated in the study. To address the research question, a two-way (3x5) repeated measures ANOVA and two Chi-square goodness of fit tests were conducted. The results revealed a significant main effect for adjustment sizes on reaction time, $F(4, 116) = 4.090$, $p = .004$; no main effect for homogeneity on the reaction time $F(2, 58) = 0.221$, $p = .802$; no main effect of homogeneity on accuracy, $\chi 2(2, N=30) = 0.69$, $p = .966$; and no main effect of adjustment size on accuracy, $\chi 2(4, N=30) = 0.031$, $p = .994$.

The results show that reaction times differ significantly in problems with different adjustment sizes. The results can be used to gain an insight into the amount of cognitive loads different types of problems exert on the participants. Research indicates that reducing the cognitive load of mathematics problems improves students' performance (Gillmor, S.C., Poggio, J. & Embertson, S., 2015). Thus, findings of this study may have implications for mathematics education.

A THEORETICAL MODEL FOR THE DESIGN OF EQUAL SHARING PROBLEMS

Keywords: Problem solving, Equal sharing, Fractions, Measurement

Our research examines the effects of different types of equal sharing problems on children's solution strategies. In a recent study (Foster & Osana, 2018), we assessed whether the familiarity level of the item being partitioned in the problem had an effect on the strategies used by fourth graders. Children had more difficulty partitioning objects that were semi-familiar (e.g., thread) than familiar (e.g., brownies). The results were difficult to interpret, however, because of two confounding variables. First, all the semi-familiar problems involved partitioning length models, whereas all the familiar problems involved partitioning area models. The second confound was the type of unit – that is, the familiar items used arbitrary units of measure (e.g., one brownie) and the semi-familiar problems involved standard units of measure (e.g., one meter).

In this poster, we present a more specified theoretical model for investigating problem-related factors that impact children's solutions to equal sharing problems. The first dimension of the model involves the attribute of the object being partitioned (e.g., length, area). Children's partitioning of brownies, for example, may involve different challenges than partitioning lengths, such as ribbons. Evidence suggests that children's understanding of measurement and their partitioning strategies vary across attributes (e.g., Curry et al., 2006; Hiebert & Tonnessen, 1976). The second factor in the model involves distinguishing between standard and arbitrary units. In our own research (Foster & Osana, 2018), we found that children's intuitive partitioning strategies were compromised as soon as the term "meter" was introduced. Indeed, children's measurement strategies depend on the type of unit used, and this relationship looks different depending on the attribute (Bouton-Lewis et al., 1996; Nunes et al., 1993).

Finally, while familiarity remains a factor in the model, it is not sufficient because it overlooks the potential moderating effects of "groundedness," or the extent to which the to-be-partitioned quantity refers to a physical object in the real world (Belenky & Schalk, 2014; Fyfe & Nathan, 2018). When children are familiar with the items being partitioned, the extent to which the items are grounded may not matter: Children can reason appropriately about mathematical relationships even when representations are abstract (Mix et al., 2017). In contrast, groundedness may have an impact when items are unfamiliar (Koedinger et al., 2008).

In sum, our model can serve as a framework for future research on children's strategies for solving equal-sharing problems. Identifying the types of equal sharing problems that optimize the development of students' problem-solving strategies and fractions knowledge will be informative in the design and implementation of classroom instruction.

Keywords: Instructional leadership, Policy, Frames, Institutional setting

Teacher quality, educational funding, and curricular resources differ across urban, suburban, and rural settings (Bouck, 2004; Harmon, Gordanier, Henry, & George, 2007). Recognizing that context matters, we acknowledge that practitioners' perspectives on key issues in mathematics education may vary with respect to communities' size and proximity to metropolitan centers. For instance, Bouck (2004) described two districts, one metropolitan and one non-metropolitan, that faced a similar teacher quality challenge, but framed it differently—the former as a problem of teacher retention and the latter as a problem of teachers' educational preparation. In an effort to learn about and ultimately address school districts' challenges with respect to mathematics education, we talked with district leaders, administrators, and teachers about their mathematics-related challenges and identified commonalities and differences across metropolitan and non-metropolitan districts.

Our sample included 50 Missouri school districts, 23 metropolitan and 27 non-metropolitan. We interviewed one representative in each district, 46 of whom were district leaders (e.g., superintendent, assistant superintendent of curriculum and instruction, mathematics curriculum coordinator) and 4 of whom were middle and/or high school mathematics teachers. All interviews were audio recorded and summarized. For this poster, we focus only on the responses for questions regarding districts' problems and instructional approaches for mathematics. In our analysis of interview summaries, we identified a primary problem and a primary instructional approach, if any, for each school district. We then revisited the results of our initial pass to identify whether different framings were related to metropolitan or non-metropolitan classifications, and to refine our characterizations of the categories.

Our findings revealed that non-metropolitan districts, as compared to metropolitan districts, were more likely to articulate student outcomes problems and less likely to promote a particular instructional approach. The most common problem for mathematics was student outcomes, though participants framed outcomes (e.g., standardized test scores; course-taking patterns) and ways to improve outcomes (e.g., through teaching; through curriculum adoption) in different ways. For 48 school districts, 22 promoted a particular approach to mathematics instruction (e.g., direct instruction, inquiry-based instruction, etc.); 26 did not. Both metropolitan and non-metropolitan districts that did not promote a particular instructional approach were also more likely to articulate a student outcomes problem for mathematics. We will also discuss implications for research and policy.

A HYPOTHETICAL LEARNING TRAJECTORY FOR PRIME DECOMPOSITON

Courtney Vahle
Southern Illinois University Edwardsville
courtneyvahle@gmail.com

Keywords: Learning Trajectories, Number Concepts and Operations

In my research, I created a hypothetical learning trajectory (LT) for the concept of decomposing numbers into products of primes. In the context of an after-school math league aimed at providing enrichment for students who perform in the bottom quartile, I gained insight into the complex way that students consider prime and composite numbers, divisibility, and decomposition of numbers. Through the league, I examined and tracked students' understanding related to these big ideas.

Theoretical Perspective and Research Questions

This research employs an LT (Clements & Sarama, 2004) as a lens through which to view children's concepts and strategies for prime and composite numbers, divisibility, and decomposition of numbers. An LT is defined in terms of three constituent parts: a mathematical instructional goal, a likely path for learning, and instructional tasks that help move students along that path. Thus, this study seeks to address the questions: How can students' responses to questions regarding prime number decomposition be sorted into an LT? How do students' concepts and strategies surrounding prime number decomposition grow in response to instructional interventions?

Data Collection and Analysis

Using a review of related literature, a hypothetical LT was created prior to the selection of students for the math league. Thirty-eight students in the league were given a pre-test before practices began in three leagues around the country. For comparison, students from a school in the Midwest were also given a pre-test before they started a prime factorization unit in their classroom. I then used thematic analysis (Jin & Anderson, 2012) to refine and revise the LT using pre-test results. Post-test results were analyzed by sorting student responses into the revised LT to trace students' growth along the LT over the course of the program.

Results and Conclusions

Preliminary results suggest that most students' responses to questions regarding prime decomposition can be sorted into the hypothetical LT. Findings suggested that level two required two sub-levels. The revised LT consists of the following three levels:

1. Students understand whole number divisibility and factors.
2. (a) Students apply concepts of divisibility to break down known factors and create more factors of the number; they can recognize prime numbers as an outcome of factoring (its only factors are one and itself) or by exclusion (the number is not composite, so it is prime) (Zazkis & Liljedahl, 2004).
   (b) Students recognize that these prime numbers, multiplied together, create a separate representation of the number.
3. Students understand the implications of the Fundamental Theorem of Arithmetic and manipulate alternate representations of a natural number such as its prime factorization.

Ryan Gillespie
University of Idaho
gill6762@vandals.uidaho.edu

In this working group, we continue with previous efforts to consider design and research methodologies related to teacher learning in online professional development contexts. We then describe an innovative project designed to support the development of middle school mathematics teachers, with a focus on three distinct forms of online learning: digitally communicated teaching lab lessons, an online course, and online video coaching. Given recent technological advances and demands to support teachers in various contexts, we contend that researching and understanding these online models, as well as other online models is important for the broader field of mathematics education. As a result, Year Three of this proposed discussion group will combine whole-group and subgroup time to converse about: (a) the challenges of online professional learning experiences, (b) research tools, methods, and analyses, (c) the connections among different projects and studies, (d) scaling up online models, and (e) future collaborations and research.

Keywords: Teacher Education-Inservice/Professional, Research Methods, Learning Theory

All teachers need access to high quality professional development in order to meet the needs of students and to teach rigorous mathematics as outlined in college and career-ready standards (Marrongelle, Sztajn, & Smith, 2013). Online professional development has the potential to provide access to a wider range of teachers than what is possible face to face. Furthermore, given the propensity of millennials to seek online learning experiences, we feel that more attention needs to be given to the design, dissemination, and research of online professional development. Given the emerging importance and availability of online professional development, we propose the continuation of a working group that met at PMENA 2017 and PMENA 2018. We will continue focus on the design, dissemination, and research on online professional development. The working group participants will analyze current practices in online professional development, including the technology affordances and limitations. Major themes that will be addressed are:

- affordances of online platforms,
- affordances and constraints of synchronous versus asynchronous experiences,
- challenges related to scaling up high-quality online professional development,
- methodologies used to research professional learning in online contexts.

This year the working group will move beyond prior conversations that centered on the specifics of our model to a broader conversation about online opportunities in the greater mathematics education field. Focus will be given to connections among projects, scalability of projects, and future directions for both research on online professional learning and implementation of professional learning. We plan to focus part of the session on the challenges and opportunities of implementing online models in rural contexts. A goal of the working group is to organize a conference to be held in summer, 2020, for which we already have funding.

Importance of Online Opportunities

As schools turn to digital learning contexts, it is inevitable that professional development will follow a similar trend. It is imperative to have research-based models that demonstrate how the features of high quality face-to-face professional development can be matched or augmented in online contexts. As an example of necessity, teachers in rural areas face constraints in terms of accessing the expertise and resources required for high-quality professional learning experiences, often because of a lack of proximity to such resources as institutions of higher education and critical masses of teachers required to collectively reflect on problems of practice (Howley & Howley, 2005). Rural contexts are thus ideal sites for online professional development, which can be offered at a distance and can involve geographically dispersed participants (Francis & Jacobsen, 2013). At the same time, teachers in urban and suburban areas may have more regular access to professional development, but online formats afford conveniences and customized learning opportunities that may not be available in face-to-face settings. Digital learning contexts provide opportunities for connections and visual supports that may otherwise not be accessible in face-to-face professional development. As a result, we consider it necessary to research online professional development and to engage with other mathematics educators and researchers about online professional learning. This working group is intended to advance the practices of designing and researching online professional learning experiences by investigating the challenges of balancing high-quality learning experiences and accessibility for teachers. The focus is also on reconnecting with those in attendance during the 2017 and 2018 conferences for updates on discussions about current happenings and experiences with online learning.

Below we provide an overview of the literature related to professional learning in online contexts. Then we revisit the NSF-funded model of online professional development discussed over the last two years, describing what we have learned in terms of the learning environment and our efforts to research its impact. We will devote part of the first session to providing updates on the project as a means of introducing possible models and methodologies to study online professional development, leaving opportunities over the next working sessions to incorporate discussion of other models and methodologies. We then conclude with aims for the 2020 working group.

Literature Related to Online Professional Learning

Digital Technologies

Online professional learning experiences combine longstanding and emerging digital technologies to provide high-quality, interactive, content-focused professional development. Longstanding digital technologies (e.g., electronic learning management systems) have been used to implement online courses to design and implement professional development for the past couple of decades. Emerging digital technologies involve an internet-based platform to implement online video coaching, or other online communications, in ways that augment the interactivity of face-to-face coaching. Online video coaching emerges from the content-focused face-to-face coaching that the project personnel have engaged in over the last ten years.

Research shows that while online communication lacks some of the modalities (e.g., gestures, facial expressions) and spontaneity of face-to-face communication (Tiene, 2000), there are also affordances unique to its asynchronous and text-based nature. In online asynchronous discussions, communication tends to be more exact and organized (Garrison, Anderson, & Archer, 2001; McCreary, 1990), involve more formal and complex sentences (Sotillo, 2000) and incorporate critical thinking, reflection, and complex ideas (Davidson-Shivers, Muilenburg, & Tanner, 2001; Marra, Moore, & Klimczak, 2004). Research on synchronous online communication – which can include text chat windows and shared space in learning management systems – shows that it is experienced as more social than asynchronous spaces (Chou, 2002). Synchronous sessions induce *personal participation*, which Hrastinski (2008) compared to *cognitive participation* in that personal communication in synchronous spaces “involves more intense interaction … while cognitive participation is a more reflective type of participation supported by asynchronous communication” (p. 499). Furthermore, synchronous communication fosters multiple communication channels based on emerging networks within the larger group, including the use of chat boxes and personal email during synchronous sessions (Haythornthwaite, 2000, 2001). Researchers have reported positive outcomes from professional development involving synchronous exchanges via typing (e.g. Chen, Chen, & Tsai, 2009). However, synchronous verbal online discussions and group activities have not been a focus of research.

Online Professional Development in Education.

Despite the growing popularity of online professional development, there is a continued need for empirical research regarding its quality and effectiveness (Dede, Ketelhut, Whitehouse, Breit, & McCloskey, 2009). Prior research has not demonstrated advantages for online professional development in terms of teacher outcomes (cf. Fishman et al., 2013), in part due to the lack of online professional development contexts that involve teachers in sustained, intensive reflection on their practices. Furthermore, teacher learning in online spaces can be challenging, especially related to complex forms of learning. Sing and Khine (2006) found that a number of factors make it difficult for teachers to engage in complex or difficult forms of learning in an online context, such as teachers’ roles as implementers rather than producers, cultural norms where disagreement is seen as confrontational, and the cognitive demands relative to the available teacher time. Teacher learning in online contexts is discussed in more detail below.

In order to illustrate professional learning in an online context, we present a model that the authors are currently using in a project situated in rural contexts. We present the model to continue the discussion of this model and other potential models, as well as the learning platforms and other features, such as the synchronous or asynchronous nature of learning in online environments.

Outcomes from Implementing a Model of Online Professional Development

During the working group sessions, we will report on outcomes from an innovative professional development model we have implemented for three years. We will provide an overview of findings from each component of the project, and describe dilemmas and challenges related to the implementation of the model. The innovative online professional learning experiences in this project focus on the development of teacher capacity to enact ambitious, responsive instruction aligned with the rigorous content and practice elements of the Common Core State Standards for Mathematics (CCSSM). We use the term *professional learning experiences* to denote that the professional development we employ differs from traditional workshop or other models that are too short or fragmented to be effective (Garet, Porter, Desimone, Birman, & Yoon, 2001).

In the project, we identified three primary research goals, which were to study and understand: (a) the ways online-based professional development can help teachers improve their instructional practices and their ability to notice and respond to student thinking; (b) the characteristics of the cycles in the online coaching, the role of video, and the asynchronous components; and (c) the features of the professional development model that would inform efforts to scale up the model, including the resource commitments, the requisite capacity of the course instructors and coaches, and the logistical requirements of the courses and coaching. We are currently in year three of four years of the project. The following describes the three online components of our project. In the working group, we envision these and other components used by other researchers serving as the catalysts for dialogue around online professional learning and will engage participants with conversation around our learning in the past year while encouraging them to share their recent experiences.

Online Course - Orchestrating Mathematical Discussions

The first component of our project is two online course modules, *Orchestrating Mathematical Discussions Parts One and Two*, aimed at orienting the participants toward high-leverage discourse practices that facilitate mathematically productive classroom discussions (Smith & Stein, 2011). In this course, the participants solve and discuss a series of high cognitive demand tasks, activities that will be accompanied by synchronous and asynchronous discussions around the *5 Practices for Orchestrating Productive Mathematics Discussions* (i.e. anticipating, monitoring, selecting, sequencing, connecting; Smith & Stein, 2011). The courses are designed to develop awareness of specific teacher and student discourse moves that facilitate productive mathematical discussions, to understand the role of high cognitive demand tasks in eliciting a variety of approaches worthy of group discussions, and to further develop participants' mathematical knowledge, particularly the rich connections around big mathematical ideas that are helpful to teach with understanding (Author, 2007a, 2007b; Ball, 1991; Boaler & Staples, 2008; Chapin, O'Connor, & Anderson, 2003; 2014; Herbel-Eisenmann, Steele, & Cirillo, 2013; Ma, 1999; O'Connor & Michaels, 1993).

In order to take advantage of the affordances of both asynchronous and synchronous characteristics of online communication, the course is embedded in a learning management system (LMS) that: allows for synchronous whole class and small group interaction; the sharing of artifacts, including those collectively developed in the LMS; and asynchronous discussion threads. In the online course modules in the LMS, the facilitator verbally presents a challenging task to the participants, which is viewed in a shared work space. The course instructor then assigns participants to virtual breakout rooms, in which the participants work synchronously in a common workspace, creating virtual white boards to share with the other groups. They can talk to each other, work simultaneously in the virtual space, and use the chat window to communicate. The course instructor can listen to and participate in these group discussions to determine when the groups are ready to present their solutions. The course instructor then closes the virtual breakout rooms, which automatically returns all participants to the main room to conduct a summary discussion of the different strategies, in effect modeling the practices in the *5 Practices* book. Asynchronously, the group can continue to go back and reflect and comment on the task and related solutions, as well as on the readings from the *5 Practices* book using discussions threads in the LMS. Participants are also encouraged to share resources, lesson plans, and student work as appropriate. The working group will discuss this format for online professional learning as well as other formats and tools that have proven beneficial for users.

Teaching Labs

In order to address the challenges of engaging teachers in learning complex practices in an online context, we include a component aimed at initiating and reinforcing relationships between participants and project personnel and at helping participants to understand the types of learning experiences and design and feedback cycles that will be the core of the project. Research on lesson study (e.g., Author, 2016; Stigler & Hiebert, 1999) has led to an emphasis on demonstration lessons where teams of teachers collectively plan, enact, and reflect on lessons in ways that make public the features of the lessons and teachers' instructional practices (Saphier & West, 2009). Consequently, one component of our project is a collaborative classroom activity, a Teaching Lab, that builds from the *studio classroom* model developed by the Teachers Development Group (2010), with features consistent with content-focused coaching (West & Staub, 2003). To do this in an online space, we first teach a lesson in a participant's classroom and video record and edit the footage. Then, for each lesson, a group led by project personnel meet to discuss the task of the lesson, which is typically of high cognitive demand. The group explores the task, the mathematical learning goals embedded in the task and anticipated student approaches to solving the task, and the related CCSSM practice and content standards. The group then immediately watches the edited video of the lesson with a focus on productive teaching moves and evidence of student thinking and learning in relation to the lesson goals. In the same meeting, the group collectively reflects on the experience, with a focus on describing evidence for student understanding using the data gathered by the teachers and observers. This process is repeated regularly with participants.

In the beginning of the project all demonstration lesson activities were face-to-face. However, at this point in our project, this component has moved to an online format of synchronous activities. The entire process is held via a video conferencing platform, Zoom, allowing for synchronous engagement in both whole group and small group discussions of the lessons. Discussion in the working group will center on the affordances and constraints of the online teaching lab model and possible modifications to ensure the intended professional development goals are met.

Online Video Coaching

The third – and most innovative – component of our project's professional development program is the online video coaching that builds from models of content-focused coaching (West & Staub, 2003). More recently, thanks to the advent of improved internet-based software aimed at increasing collaboration around video data, the project personnel have begun conducting online video coaching cycles with teachers. The coaching cycles are focused on identifying and unpacking the mathematics with the teacher, while anticipating likely student strategies, conceptions, and misconceptions. The coach helps the teacher identify evidence for demonstrating how students are thinking (from the video as well as from student artifacts) and make connections between different student approaches in order to help the teacher structure the summary discussion of the lesson.

The online coaching experiences involve synchronous and asynchronous components, with the goal of engaging participants in reflective or deliberative practice. The online coaching has features similar to face-to-face coaching, such as video conferencing conversations via Zoom, in which the coach and participant collaborate to plan lessons and reflect on the qualities of lessons. However, the online coaching includes an innovative component that involves asynchronous collaboration and feedback that structures the post-lesson collaborative reflection, features that augment or surpass the kind of feedback that can be given face-to-face. Teachers video-record themselves using Swivl, which allows them to place a camera (iPhone or other device) on a robot that tracks them around the room, allowing for teacher-focused video without the necessity of someone operating the camera. The video is automatically uploaded into a password-protected site and processed, and is immediately accessible to view and annotate. The annotation feature in Swivl allows the coach and the teacher to separately view and annotate the video. For example, a teacher can stop the video by hitting the pause button and type in a comment or question that is synced with the video, so that when the coach watches the video, she can read the comment during the point in the video referenced by the comment. The coach can do the same. The video can be viewed repeatedly, which allows for more thorough reflection and analysis. The notation provides for more in-depth and substantive feedback, pointing to specific instances of practice and student thinking. The discussion group will focus on this model for professional coaching as well as other models or avenues for supporting individual teachers in online professional learning.

Researching Online Professional Learning Experiences

There is a dearth of research on online professional development, especially online professional development that is sustained and intensive. Similarly, while there have been years of intensive efforts to implement coaching in schools, much of the research has revolved around the role and impact of coaches (Coburn & Russell, 2008; Penuel, Riel, Krause, & Frank, 2009), and less around the impact on reflective or deliberative practice. Although coaching has now been around for over ten years, there is limited research on the effectiveness of coaching in terms of improving teacher quality (Matsumura, Garnier & Spybrook, 2012). The greatest dearth of research involves online video coaching in education, as opposed to face-to-face coaching, which has no peer-reviewed research yet associated with it.

Structure of the Working Group Sessions

Within this working group we propose to explore the following questions related to researching online professional learning experiences:

1. What are various platforms and models for online professional development?
2. What theoretical framework and methodologies are salient for researching online digital technologies and online professional learning experiences?
3. What data analysis methods are suited to the data captured in online environments?
4. In what ways can online professional learning experiences help teachers improve their instructional practices and their ability to notice and respond to student thinking?
5. In what ways does the use of video in an online professional learning experience project maximize teacher learning?
6. What features of the professional development model would inform efforts to scale up the model, including the resource commitments, the requisite capacity of the course instructors and coaches, and the logistical requirements of the courses and coaching?

Plan for Working Group

In Session 1, the organizers will present brief update reports on the Author's project, research design, and evolution of the model, as well as a recap of the 2018 working group discussions. Subgroups will be formed to continue conversations around design and implementation efforts with online professional learning experiences from their own research and current efforts in the field; attendees from this working group at PMENA 2018 will provide updates on their respective projects in the small-group setting.

During Sessions 2 and 3 we will provide the subgroups time to continue collaborating on themes identified in the PMENA 2018 working group: a) identifying the challenges of online professional learning experiences that are the most challenging and why—this will include a specific look across the projects presented and with a focus on activities on the last year, b) refining research tools, methods, and analyses, c) exploring connections among different projects and studies for former and new attendees, d) discussing scaling of online project, and e) discussing future collaborations and research. We will close Session 3 with time to review group progress and discuss next steps for our work as shown in Table 1. Meeting notes, work, and documents will continue to be shared and distributed via our Google Folder (set up for this Working Group). The use of Google documents allows members to create an institutional memory of activities during the working group that we will continue to use and add to following the 2019 working group. This shared folder will also provide a shared space for future collaborations and writing projects related to online professional learning experiences within the working group members.

Table 1: Overview of Proposed Working Subgroup Sessions

	Activities:	**Guiding Questions:**
Session 1	1. Introductions and Agenda 2. Brief Presentations of Authors' Project and Research Questions 3. Brief Presentations of former Attendees' and New Attendees' Projects and Research Questions 4. Subgroup formation and initial work time - designing Online PD experiences	1. What are the different forms of online professional development? 2. What research is being done related to online professional development? 3. Which aspects of online professional learning experiences are the most challenging to implement or research? 4. What are new questions that have arisen within the last year?
Session 2	1. Overview of subgroup's work from previous day 2. Subgroup work time - engagement in online professional learning experiences 3. Brief sharing of work in subgroups	1. How can online learning support teacher learning? 2. What are the affordances and constraints of various platforms? 3. What are the affordances and constraints of synchronous and asynchronous experiences?

Session 3	1. Overview of subgroup's work from previous day 2. Subgroup work time - researching online professional learning experiences 3. Brief sharing of work in subgroups 4. Final reflections – future collaborations and research	1. What theories and theoretical frameworks have informed the design of your research project(s)? 2. How might your work inform theory in researching online professional learning experiences? 3. What issues and challenges have you faced in designing studies in this area? 4. What challenges may exist for scaling up high-quality online professional development?

Embodied cognition is growing in theoretical importance and as driving a set of design principles for curriculum activities and technology innovations for mathematics education. The central aim of the EMIC (Embodied Mathematical Imagination and Cognition) Working Group is to connect with inspired colleagues in this growing community of discourse around theoretical, technological, and methodological developments to advance the study of embodied cognition for mathematics education. Our thriving, informed, and interconnected community of scholars organized around embodied mathematical cognition will continue to broaden the range of activities, practices, and emerging technologies that contribute to mathematics teaching and learning as well as to research on these phenomena. This year's proposed EMIC working group builds upon our prior working groups with a specific focus on collaboratively creating embodied activities for mathematics learning that utilize different types of physicality, from full-body to gestural movements. In particular, we aim to develop and evaluate novel activities that apply principles of embodied cognition to foster mathematics learning through engaging in the enactment of carefully crafted movement. Our ongoing goal is to connect researchers and educators as we all create activities which can be implemented in mathematics classrooms.

Keywords: Learning theory, Cognition, Technology, Instructional activities and practices

Motivations for This Working Group

Empirical, theoretical, and methodological developments in embodied cognition and gesture studies provide a solid and generative foundation for the continuation of the established, **regularly held Embodied Mathematical Imagination and Cognition (EMIC) Working Group** for PME-NA. The central aim of EMIC is to attract engaged and inspired colleagues into a growing community of discourse around theoretical, technological, and methodological developments for advancing the study of embodied cognition for mathematics education, including, but not limited to, studies of mathematical reasoning, instruction, the design and use of technological innovations, and learning in and outside of formal educational settings.

The interplay of multiple perspectives and intellectual trajectories is vital for the study of embodied mathematical cognition to flourish. While there is significant convergence of theoretical, technological, and methodological developments in embodied cognition, there is also a trove of questions that must be addressed through formulating and implementing experimental design principles. As a group, we aim to (1) synthesize the work of leading scholars into a coherent theory of EMIC, (2) identify the most promising ideas for opportunities for methodological and technological integration, (3) curate and disseminate a set of evidence-based design principles for enhancing mathematics education and broadening participation in STEM fields, and (4) articulate a future research agenda in the growing area of embodied design.

We aim to address basic theoretical questions such as, *What is grounding?* And practical ones such as, *How can we reliably engineer the grounding of specific mathematical ideas?* We want to understand how variations in actions and perceptions influence mathematical reasoning, including self-initiated vs. prescribed actions, and actions that take place in intrapersonal versus interpersonal interactions; how gestural point-of-view when enacting phenomena from a first-versus-third-person perspective, including how gestures move through space, influences reasoning and communication; how actions enacted by oneself, observed in others, or imagined influence cognition; how gestures connect with external visual representations, and how gestures are used to forge collaborative thinking (Abrahamson, 2018; Abrahamson & Bakker, 2016; Alibali & Nathan, 2012; in press; Walkington et al., in press).

From an applied level, we are also witnessing the emergence of a new genre of educational technologies and interventions for promoting STEM, rooted in theories of embodied cognition. These new uses of technology, in turn, offer novel opportunities for students and scientists to engage in math visualization, symbolization, intuition, and reasoning. In order for these designs to successfully scale up, they must be informed by research that demonstrates both ecological and internal validity. As technology becomes more affordable, more integrated in mathematics education spaces, and more common in classrooms, we need the proposed intellectually rigorous synthesis of theory and design principles to help shape approaches and activities that help make mathematics education accessible to a wider range of students.

Focal Issues in the Psychology of Mathematics Education

Emerging, yet influential, views of thinking and learning as embodied experiences have grown from several major intellectual developments in philosophy, psychology, anthropology, education, and the learning sciences that frame human communication as multimodal interaction, and human thinking as multi-modal simulation of sensory-motor activity (Clark, 2008; Hostetter & Alibali, 2008; Hutto, Kirchhoff, & Abrahamson, 2015; Lave, 1988; Nathan, 2014; Newen, Bruin, & Gallagher, 2018; Varela et al., 1992; Wilson, 2002). As Stevens (2012, p. 346) argues in his introduction to the *JLS* special issue on embodiment of mathematical reasoning, “it will be hard to consign the body to the sidelines of mathematical cognition ever again if our goal is to make sense of how people make sense and take action with mathematical ideas, tools, and forms.”

Four major ideas exemplify the plurality of ways that embodied cognition perspectives are relevant for the study of mathematical understanding: (1) *Grounding of abstraction in perceptuo-motor activity as one alternative to representing concepts as purely amodal, abstract, arbitrary, and self-referential symbol systems.* This conception shifts the locus of “thinking” from a central processor to a distributed web of perceptuo-motor activity situated within a physical and social setting. (2) *Cognition emerges from perceptually guided action* (Varela, Thompson, & Rosch, 1991). This tenet implies that things, including mathematical symbols and representations, are understood by the actions and practices we can perform with them, and by mentally simulating and imagining the actions and practices that underlie or constitute them. (3) *Mathematics learning is always affective*: There are no purely procedural or “neutral” forms of reasoning detached from the circulation of bodily-based feelings and interpretations surrounding our encounters with them. (4) *Mathematical ideas are conveyed using rich, multimodal forms of communication, including gestures and tangible objects in the world.*

In addition to theoretical and empirical advances, new technical advances in multi-modal and spatial analysis have allowed scholars to collect new sources of evidence and subject them to powerful analytic procedures, from which they may propose new theories of embodied mathematical cognition and learning. Growth of interest in multi-modal aspects of communication have been enabled by high quality video recording of human activity (e.g., Alibali et al., 2014; Levine & Scollon, 2004), motion capture technology (Hall, Ma, & Nemirovsky, 2014; Sinclair, 2014), eye-tracking instruments (e.g., Abrahamson, Shayan, Bakker, & van der Schaaf, 2016), developments in brain imaging (e.g., Barsalou, 2008; Gallese & Lakoff, 2005), multimodal learning analytics (Worsley & Blikstein, 2014), and data logs generated from embodied math learning technologies that interacts with touch and mouse-based interfaces (Manzo, Ottmar, & Landy, 2016).

Past Meetings and Achievements of the EMIC Working Group

The first PME-NA meeting of the EMIC working group, "Mathematics Learning and Embodied Cognition," took place in East Lansing, MI in 2015. Our group has been growing ever since. In addition to the PME-NA meeting each year, there are a number of ongoing activities that our members engage in. We have built an active website which connects members, provides updates on projects, and hosts resources. We have also created a space for members to share information about their research activities – particularly for videos of the complex gesture and action-based interactions that are difficult to express in text format. In addition, we have a common publications repository to share files or links (including to ResearchGate or Academia.edu publication profiles, so members don't have to upload their files in multiple places). Our members collaborate on ongoing projects and have presented at other conferences and workshop events annually. Several research programs have formed to investigate the embodied nature of mathematics (e.g., Abrahamson 2014; Alibali & Nathan, 2012; Arzarello et al., 2009; De Freitas & Sinclair, 2014; Edwards, Ferrara, & Moore-Russo, 2014; Lakoff & Núñez, 2000; Melcer & Isbister, 2016; Ottmar & Landy, 2016; Radford 2009; Nathan, Walkington, Boncoddo, Pier, Williams, & Alibali, 2014; Soto-Johnson & Troup, 2014; Soto-Johnson, Hancock, & Oehrtman, 2016; Walkington et al., in press), demonstrating a "critical mass" of projects, findings, senior and junior investigators, and conceptual frameworks to support an ongoing community of like-minded scholars within the mathematics education research community.

In order to sustain collaboration and connect emerging and established scholars, eight of our members will also host an NSF funded Synthesis and Design workshop at the University of Wisconsin–Madison (UW–Madison) in May 2019. This workshop will bring together leading scholars in mathematical reasoning, teaching, and learning who work on embodied design with the goal to form a ten-year research agenda that will provide a coherent set of evidence-based design principles for enhancing mathematics education and broadening participation in all STEM fields. The organizers will seek to attract an interdisciplinary set of 30 scholars from education research, cognitive science, the learning sciences, developmental psychology, movement science, computer science, and mathematics, as well as 6 teachers. The research presented will span K–16 topics in content areas such as arithmetic and algebra, proportional reasoning and fractions, geometry, complex numbers and functions, statistics, and calculus. It will focus on design of systems for classroom learning settings, with attention to equity and access for underrepresented groups, while examining evidence of learning both in *and* outside of school. The reach of such an endeavor can extend to studies of mathematical intuition and reasoning, learning in and outside of formal educational settings, professional development, classroom instruction and assessment, and STEM integration. The hope is that the 2019 PME workshop can serve as a time to follow up, disseminate, and extend what was learned from this workshop.

Current Working Group Organizers

As the Working Group has matured and expanded, we have a broadening set of organizers that represent a range of institutions and theoretical perspectives (and is beyond the limit of six authors in the submission system). This, we believe, enriches the Working Group experience and the long-term viability of the scholarly community. The current organizers for 2019 are (alphabetical by first name):

- Candace Walkington, Southern Methodist University
- Carmen J. Petrick Smith, University of Vermont
- Caro Williams-Pierce, University at Albany, SUNY
- David Landy, Indiana University
- Dor Abrahamson, University of California, Berkeley
- Erin Ottmar, Worcester Polytechnic Institute
- Hortensia Soto–Johnson, University of Northern Colorado
- Ivon Arroyo, Worcester Polytechnic Institute
- Martha W. Alibali, University of Wisconsin-Madison
- Mitchell J. Nathan, University of Wisconsin-Madison

Some of **our collaborative accomplishments** since last year's PME-NA working group include:

1. A successful proposal to host a three-day NSF Synthesis and Design workshop for researchers and teachers on "The Future of Embodied Design for Mathematical Imagination and Cognition" with 8 members serving as organizers https://www.embodiedmathematics.com/
2. Invitation by Springer to write a book on our collective work on Embodied Cognition in Mathematics for the "Research in Mathematics Education" Series
3. Submission of an additional NSF Workshop Proposal to host a 3 day Workshop in 2020 on Embodied Cognition for K-16 math educators)
4. Several members creating and teaching Embodied Cognition and Gesture seminars at their institutions.
5. Several grants awarded by IES CASL program to study embodied cognition, including the role of action in pre-college proof performance in geometry (Funded 2016-2020 for Nathan & Walkington) as well as the use of perceptual learning technology to study algebra learning (Ottmar & Landy, 2018)
6. Expanding a group website using the Google Sites platform to connect scholars, support ongoing interactions throughout the year, and regularly adding additional resources/activities https://sites.google.com/site/emicpmena/home
7. Extending the embodied-design agenda into special education in dialogue with Universal Design for Learning (Abrahamson, Flood, Miele, & Siu, in press)
8. Some senior members joining junior members' grant proposals as Co-PIs and advisors

EMIC 2019: Creating Embodied Instructional Activities for Mathematics

Last year, the EMIC working group focused on extending theoretical frameworks of embodied cognition (Melcer & Isbister, 2016) as well as exploring the role of technology in assessing and assisting mathematics learning. This year, we will continue this discourse as we effectively transition from theory-driven discussion and research to application in mathematics education. Specifically, we will continue to focus on theoretical frameworks which tie various perspectives on embodiment to different forms of physicality in educational technology (Melcer & Isbister, 2016; see Figure 1 below) as foundations to collaboratively design novel activities for mathematics education which utilize action, objects, and the surrounding environment in distinct ways. We will follow up on several of the discussions from the workshop held at UW-M, plan the proposed 2020 workshop, and explore the ten-year research agenda that aims to provide a coherent set of evidence-based design principles for enhancing mathematics education and broadening participation in all STEM fields.

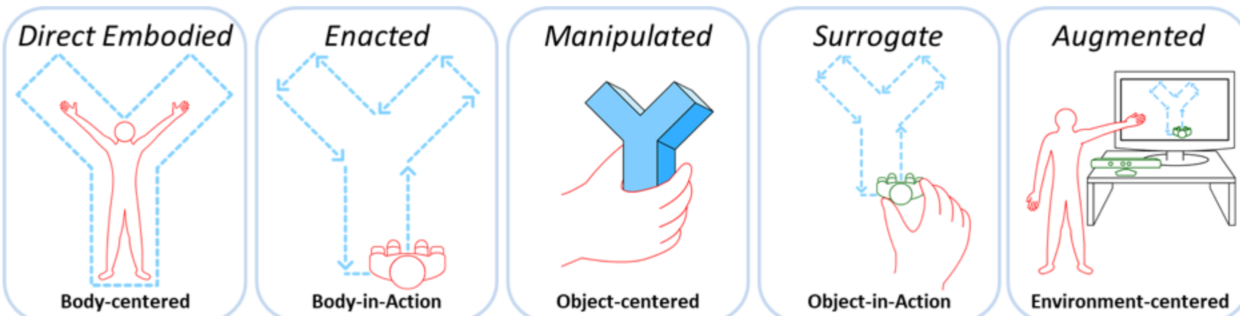

Figure 1: Five Distinct Approaches to Facilitating Embodiment through Bodily Action, Objects, and the Surrounding Environment in Educational Technology

In previous years, participants experienced theory-driven embodied instructional activities for mathematics learning. Two years ago, the EMIC working group focused on embodied instructional activities in geometry and most recently, the group focused on instructional activities which emphasize gestures through novel technologies. Examples include exploring mathematical transformations while using a dynamic technology tool (Ottmar & Landy, 2016), playing and creating embodied technology games to teach mathematics and computational thinking (Arroyo et al., 2017; Melcer & Isbister, 2018; Nathan & Walkington, 2017); using dual eye tracking (Shvarts & Abrahamson, 2018), and a teacher guiding the movements of a learner exploring ratios (Abrahamson & Sánchez-García, 2016). From experiencing these embodied activities, we explored questions such as: what role does technology play on supporting connections between the brain, body, and action? Even as we continue to bear these formative questions in mind, this year, participants in our EMIC workshop will shift from experiencing such activities and reflecting on the roles of physicality, technology, and collaboration to applying their perspective of embodied cognition to the creation of future novel activities for research and/or learning contexts.

Figure 2: A Small Selection of Embodied Activities Created by EMIC Organizers and Experienced by EMIC Participants

Plan for Active Engagement of Participants

In the past years of PME-NA working groups, we successfully engaged participants in open-ended math activities at the beginning of each session that steered our discussions towards elements of mathematics that the group found most provocative. This year, we intend to engage participants by facilitating one central open-ended activity that places participants in the driver seat for their working group experience—collaborating in small groups to design novel embodied instructional activities for mathematics (Figure 3).

On **Day 1,** we will focus on introductions and goals for the three sessions. After introductions to one another as well as an overview of the EMIC working group, we will discuss the goals for PME-NA 2019. The overarching goal will be to design and demonstrate a small collection of embodied activities for mathematics learning that utilize the enactment of goal-oriented movement in unique ways. This will give way to a discussion of the theoretical framework of physicality in embodied activities (Melcer & Isbister, 2016), which will drive the structures of our instructional activities. We will divide into small groups which will work together over the course of three days to create an instructional activity. The groups will mix educators, researchers, and students to create synergistic groups with different interests and knowledge of mathematics education. After a brainstorming session in small groups, the EMIC working group will close with a general discussion of ideas for instructional activities. On **Day 2**, we will primarily work in our small groups to continue designing embodied instructional activities. Towards the end of the session, groups will share their progress on activity design and participate in a guided discussion about the role of physicality, technology, and collaboration in the designed activities to reflect on how the structure of the activity contributes to connections between the mind, body, and action. **Day 3** will be focused on finalizing the created activities among small groups as well as planning for continued engagement and the dissemination of these activities.

Figure 3: Agenda Outline for the 2019 Embodied Mathematical Imagination and Cognition Working Group

Building on the diverse work in embodied cognition and among our group members, possible topics for these activities may include:

1. Grounding Abstractions
    1. Conceptual blending (Tunner & Fauconnier, 1995) and metaphor (Lakoff & Núñez, 2000)
    2. Perceptuo-motor grounding of abstractions (Barsalou, 2008; Glenberg, 1997; Ottmar & Landy, 2016; Landy, Allen, & Zednik, 2014)
    3. Progressive formalization (Nathan, 2012; Romberg, 2001) and concreteness fading (Fyfe, McNeil, Son, & Goldstone, 2014)
    4. Use of manipulatives (Martin & Schwartz, 2005)
2. Cognition emerges from perceptually guided action: Designing interactive learning environments for EMIC
    1. Development of spatial reasoning (Uttal et al., 2009)
    2. Mathematical cognition through action (Abrahamson, 2014; Nathan et al., 2014)
    3. Perceptual boundedness (Bieda & Nathan, 2009)
    4. Perceptuomotor integration (Ottmar, Landy, Goldstone, & Weitnauer, 2015; Nemirovsky, Kelton, & Rhodehamel, 2013)
    5. Attentional anchors and the emergence of mathematical objects (Abrahamson & Bakker, 2016; Abrahamson & Sánchez–García, 2016; Abrahamson et al., 2016; Duijzer et al., 2017)
    6. Mathematical imagination (Nemirovsky, Kelton, & Rhodehamel, 2012)
    7. Students' integer arithmetic learning depends on their actions (Nurnberger-Haag, 2015).
3. Affective Mathematics
    1. Modal engagements (Hall & Nemirovsky, 2012; Nathan et al., 2013)
    2. Sensuous cognition (Radford, 2009)

4. Gesture and Multimodality
    1. Gesture & multimodal instruction (Alibali & Nathan 2012; Cook et al., 2008; Edwards, 2009)
    2. Bodily activity of professional mathematicians (Nemirovsky & Smith, 2013; Soto-Johnson, Hancock, & Oehrtman, 2016)
    3. Simulation of sensory-motor activity (Hostetter & Alibali, 2008; Nemirovsky & Ferrara, 2009)
5. Universal Design for Learning in Special Education (Abrahamson et al., in press)

Follow-up Activities

Unique to this year, the EMIC working group intends to focus on collaboratively creating instructional activities for mathematics education. By the end of the third session, we aim to have a collection of novel activities for mathematics classrooms that utilize action and movement in various ways. After the conclusion of the working group, participants will be invited to assist the organizers with the dissemination of these activities on the EMIC website, in journal articles, and other math education forums.

Beyond dissemination of our instructional activities, we envision an emergent process for the specific follow-up activities based on participant input and our multi-day discussions. As in previous years, we will continue to develop a list of interested participants and grant them all access to our common discussion forum and literature compilation. Additionally, the EMIC organizers will continue to plan workshops that continue this line of work. All EMIC participants will be invited to attend these events.

In the past several years, we have seen a great deal of progress. This is perhaps best exemplified by the development and continuation of the EMIC community, the NSF workshops, the website, the ongoing collaborations between members, and the annual PME-NA workshops that draw participants from across the country. We will strive to explore ways to continue to reach farther outside of our young group to continually make our work relevant, while also seeking to bolster and refine the theoretical underpinnings of an embodied view of mathematical thinking and teaching.

This working group continues to develop a research program on the practice of launching mathematical tasks and its resulting impact on learners. Our research agenda contains two strands of inquiry exploring (1) theory and framework building concerning effective launches and (2) empirical examination of the link between launching and opportunities for students to engage in "productive struggle" while solving worthwhile mathematical tasks. Participants will (a) examine empirical data collected from K-12 mathematics teachers in order to further develop our emerging Launch Framework and (b) discuss the next steps to be taken in the development of an empirical research agenda examining launching and high demand tasks. Participants will collaborate to shape the development of the emerging research agenda and plan future research and dissemination.

Keywords: Classroom Discourse, Instructional Activities and Practices, Curriculum, Problem Solving

The new *Standards for Preparing Teachers of Mathematics* calls for supporting new teachers in building a foundation of "effective and equitable mathematics teaching practices" including introducing, or "launching" demanding tasks (AMTE, 2017; p. 6; 14). When doing so, teachers need to activate prior knowledge, ensure understanding, establish expectations, and remove barriers to productive engagement (Van de Walle, Lovin, Karp, & Bay-Williams, 2014). However, there is little research that describes, in detail, what effective teachers do when launching, and how what they do changes in response to changes in their teaching context.

Research has given some guidance to teachers seeking to launch tasks effectively. Initial descriptions of effective launches stress the importance of clear expectations (Stein, Smith, Henningsen, & Silver, 2009) and creating a shared understanding of the problem and the problem's context (Ball, Goffney, & Bass, 2005; Lubienski, 2000). Jackson and colleagues (2013) found that launches which supported students in developing a taken-as-shared understanding of the key ideas and quantities as well as a shared vocabulary to describe those ideas produced greater opportunities to learn in subsequent mathematical discussion. Despite this guidance, teachers and teacher educators continue to struggle with what constitutes an effective launch. Teachers wrestle with how to give exactly the right amount of support that provides access to students without taking over mathematical thinking (González & Eli, 2017). In addition, different goals for the launch may conflict with each other (González & Eli, 2017; Jackson & Shahan, 2013). Furthermore, the features and goals of a specific launch may depend on the task, the learning goal, and the needs and strengths of a specific group of students. In the face of this complexity, continued examination and discussion about the purpose and features of effective launches are necessary in order to help guide teachers and teacher educators as they work to develop launching expertise.

History of Launching Working Group

While the launching working group first officially met at PME-NA 2018 in Greenville, SC., this meeting was an important culmination of sorts for the group and its interests. The original impetus for the formation of this working group is based upon the work of mathematics methods instructors who designed a module to support prospective teachers' ability to launch cognitively demanding tasks. As these researchers sought to examine the theoretical underpinnings behind launching tasks it became evident there was a dearth of research or theory on the subject. "There were few common images of effective launches in the research literature, nor were there descriptions of the kinds of problems that students and teachers experienced during launches" (Wieman, Perry, et al., 2018, p. 1501). As a result, the content and design of the module was not a representation of "professional knowledge" which is established by the research community or as a result of empirical studies, but rather "practical knowledge" which is built by teacher educators as a result of doing the work of teaching and reflecting upon that work (Arbaugh & Taylor, 2008, p. 2).

At PME-NA 2016, the designer-researchers presented some early results of their empirical examination of their methods course module (Wieman & Jansen, 2016). The session was well attended and included a spirited discussion concerning the salient features and non-features of an effective launch. Several attendees shared examples of launches from their own methods course work, examples that contrasted starkly with each other, and the launch depicted in the module. Both presenters and several attendees continued the conversation after the conclusion of the session. After the conference the session organizers collaborated with a group of mathematics teacher educators to propose a symposium session at AMTE 2018 on launching (Wieman, Jansen, et al., 2018). This symposium brought together researchers who had studied launches, teacher educators who were teaching teachers to launch effectively, and professional developers with extensive experience in schools. In this session, we began a discussion that moves the field towards an explicit, shared understanding of how to effectively launch demanding tasks, including (1) What is the purpose of a launch? (2) What are the elements of an effective launch? and (3) What are common challenges in launching? Again, this symposium was well attended, and generated extensive discussion, as well as a striking diversity of thought and experience. Clearly, there was a need among mathematics teacher educators to examine the practice of launching more closely.

PME-NA 2018 Working Group

The launching working group was formed to give educational researchers and practitioners and opportunity and space to work toward the following long-term goal:

> Create shared, empirically-based knowledge about launching cognitively demanding tasks, that would support mathematics teachers in launching tasks effectively, mathematics teacher educators in supporting teachers learning to launch, mathematics education researchers in

generating knowledge about launching, and curriculum writers in supporting teachers' launching. (Wieman, Perry, et al., 2018)

The three working group sessions at PME-NA 2018 were consistently attended by a group of 10-12 mathematics teacher educators. Across the three sessions, participants engaged in a series of activities and discussions designed to answer the following questions:

- What is the purpose of an effective launch?
- What challenges do teachers face when planning, enacting and evaluating launches?
- What are typical experiences for students in launches?
- How do we support teachers and pre-service teachers in developing skill in planning, enacting and reflecting on launching (and how might we improve these efforts)?
- How do we support teacher educators and professional developers in helping others get better at launching (and how might we improve these efforts)? (Wieman, Perry, et al., 2018)

Day 1. After orienting participants to the prior work of the group, organizers and participants shared interests and questions concerning launches. After identifying some common questions and themes, participants were introduced to the following mathematical task:

Last year the national weather service recorded _____ tornadoes in the United States. They recorded some tornadoes in other parts of the world. They recorded a total of ____ tornadoes. How many tornadoes were in other parts of the world?

(18, 28) (26, 48) (22, 75) (83, 150) (95, 194) (101, 183)

We asked participants to consider and discuss how a teacher might launch this task and what other questions they might have about launching this task. We then viewed a video of a teacher launching this task to a class of second graders. While they watched, we asked participants to consider the following:

- What do you notice about the launch that you found especially interesting or surprising?
- What does the teacher think the purpose of a launch is?
- What supports does the teacher use to help students, and the teacher during the launch?
- What is the impact of this launch on students? How do you know?
- What mathematical activity do you predict the students will engage in?
- How might you evaluate the effectiveness of this launch?

After discussing these questions in relation to the launch of this task, we introduced participants to a second task, "*Write an equation that you can use to find the number of one foot by one foot square tiles you would need to make a one-foot fringe around an "n x n" square pool".* Participants then discussed how a teacher might launch this task, and viewed a video of a teacher launching this task in an 8th grade classroom, considering the above set of questions. This was followed by a discussion in which attendees compared and contrasted the two launches, and how they informed our original interests and questions.

This final discussion resulted in five salient questions moving forward: (1) How do teachers balance support with maintaining the cognitive demand while launching? (2) What might be the role of a “Precursor Task” and when should one occur? (3) Can students “internalize launch routines” or develop the capacity to make sense of problems? (4) Are there routines, steps, or structures for launches? (5) How do features of a task relate to features of a launch?

Day 2. In Day 2 we took up two versions of the final question listed above, “What is the relationship between key features of tasks and key features of launches?” and “Are there certain launch structures that go with certain tasks?” In order to begin examining these questions participants worked in small groups to sort a collection of 10 mathematical tasks according to how they would launch them – they were group together tasks that they would launch in a similar way and be ready to explain how that type of launch would support students doing that task. Once participants had come to a consensus within groups, we engaged in a gallery walk, in which groups struggled to make sense of other group’s categories. The ensuing discussion illuminated a great diversity of ideas about task features, launch features, and the lack of a shared language or understanding about the details of launching.

Day 3. Our final session began with a review of the prior day’s sorts in which we created a list of possible problem features and a list of launch types or structures which might be appropriate for the given tasks (e.g. three reads, act out the story/process, make a prediction, etc.)

Participants then were given this set of launch types and worked in groups to sort a second set of tasks according to which launch type they would use to launch it. From the discussions generated by the two task sorts we were able to begin work on a launching moves framework to support teachers’ practice of effective launching for demanding tasks. We present these in our next subsection.

Progress Since 2018 Working Group

We extend our work from 2018 by presenting preliminary ideas related to the question, “What is the reciprocal relationship between central features of demanding mathematical tasks and central features of launches? or “What types of launches are effective for what type of problems?” One result of the discussions in the working group was a *Launching Framework*, which serves as an initial attempt to describe key features of different types of launches, as well as key features of demanding tasks that may inform choices about launching. We first unpack and define the key features of important launching types (Table 1). We then identify specific problem features and give illustrative examples (Table 2).

Table 1: Launch Types

Launch Types	Example/Description
Act out the process	Eric the sheep: Act out Eric skipping two places whenever a sheep gets sheared.
Provide a visual representation of the context	Create a representation of the task - i.e. showing a picture of two punch bowls with different amounts of Orange Juice and Ginger Ale next to them for a comparing rates problem (Which tastes more like Orange Juice?)
Noticing	Three-act lesson: Show a video, ask what they notice, what they wonder

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

Three Reads	First Read: What is this about? Second Read: What is the question? Third Read: What is important information/quantities?
Make a prediction or conjecture	Ask students to make a guess about the answer
Evaluate an incorrect answer	Johnny had some money, he went to the store and worked until he had twice as much as he started with. Then he went to the diner and had dinner, for $12. He now has $34. How much did Johnny start with? I say he started with $50. Am I right or wrong? How do you know? Then how much DID he start with?
Engage students in Precursor Tasks: (i.e. a number talk or routine for reasoning)	Contemplate then calculate: What do you notice about this figure? How many tiles in this figure without counting? Then, can you come up with a rule for the number of tiles in the "nth" figure?
Set Expectations	Remind or create expectations for how to work together in a group, how to address logistical concerns, and the nature of the final product

Table 2: Problem Features and Sample Tasks/Descriptions

Problem Features	**Description and Sample Task**
Process with end-point given	Golden Apples (Start with some apples; Meet three trolls, each one takes half your apples and two more. You end up with 3 apples. How many did you start with?
Process with beginning point given	Eric the sheep is 50^{th} in line to get sheared. Each time a sheep gets sheared, Eric cuts two sheep in line. When will Eric get sheared? (How many sheep will get sheared before Eric is at the front of the line?)
Graph/Diagram Focused	Match the picture of people at a bus stop with a graph of age versus height.
Familiar context	Context that draws on student experiences
Unfamiliar context	Context that may be foreign and confusing to students

Context free problem	Explain why cos(x) = sin (90-x)

An Illustrative Example

As an example, suppose a teacher wanted to pose the Eric the Sheep problem:

It's a hot summer day, and Eric the Sheep is at the end of a line waiting to be shorn. Each time the shearer takes one sheep from the front of the line, Eric sneaks past two sheep to get closer to the front.

1. Suppose there are 10 sheep in front of Eric. How many sheep will be shorn before Eric gets to the front of the line.
2. Suppose there are 25 sheep in front of Eric. How many sheep will be shorn before Eric gets to the front of the line?
3. Suppose there are 50 sheep in front of Eric. How many sheep will be shorn before Eric gets to the front of the line?
4. How could you predict the answer for any number of sheep in the line?
5. What happens if Eric sneaks past 3 sheep? 4 sheep?
6. What happens if there are 2 shearers? 3 shearers? (Driscoll, 2001).

The teacher may anticipate that students may have trouble making sense of this particular situation, so she may decide to act out this specific situation, having students take the place of sheep, and physically acting out the process of getting shorn, moving up in line, and, for Eric, cutting in line each time a comrade is shorn.

This task would be categorized as a *Process with a beginning point given*. A process is described and students are asked to explain what will happen as this process unfolds. The teacher employs an "Acting it out" launch, by having her students act out the shearing. One could also argue that the task itself employs a "precursor task" structure, asking students to solve specific cases of the process before engaging in the task of generalizing. It is key however to consider what number(s) might make for good examples without reducing the cognitive demand of the task. For example, if Eric is in a line with 6 sheep, 2 will be shorn before him. If Eric is in a line with 7 sheep, there are still 2 sheep shorn before him. Revealing the idea that multiple starting numbers have the same answer in the launch of the problem would not be beneficial as it can be a somewhat surprising outcome and one students have to consider when answering the generalizable questions in the task. If the teacher wanted to show an odd number example and an even number example, 7 and 8 would be better number choices than 6 and 7.

Once we have begun to identify important launching types and important problem features, we can begin to empirically determine if curriculum writers and teachers tend to launch problems with specific features using specific types of launches. For instance, we can ask teachers to engage in the same kind of sorting exercise as we described above, and then keep track of their responses on a grid.

Figure 1: Launch Framework - Matching Problem Features and Launch Types

Launching Framework		Launch Types							
		Act out process	Provide a visual representation of the context	Noticing (I notice, I wonder)	Three Reads	Prediction/ Conjecture	Evaluate an incorrect answer	Precursor Tasks	Setting Expectations
Problem Feature	Process with Starting Point Given								
	Process with Ending Point Given								
	Graph/Diagram focused								
	Familiar Context								
	Unfamiliar Context								
	Context Free								
	Other								

Plan For PME-NA 2019 Sessions

Day 1

Prior to the meeting we will send potential attendees a file of mathematical tasks along with instructions how to complete the launching task sort described above. The goal of this is to help those unfamiliar with the sort to understand the task sort activity prior to our first session. We will begin session 1 with a quick introduction of the participants and their interests in examining the practice of launching demanding tasks, followed by an orientation to the previous work and progress of the group. Our main activity for the first session will be to engage participants in examining data and or/results from an enactment of the launching task sort activity with inservice teachers. Our session organizers are planning a professional development activity in the spring of 2019 in which they will engage a group of K-12 in-service mathematics teachers in the launching tasks sort activity, and collecting data on the choices they make and their rationales. This will enable leaders and participants to both make sense of the launching framework and examine teacher perspectives on launching. We also hope to discuss revisions and additions to the framework based on this data analysis.

Day 2

On the second day of our working group we intend to engage participants in two different launch related activities. In the first activity participants will utilize the *Launch Framework* to engage in small group examination of a curriculum series to identify relationships between high demand problem features and prescribed launches. Each group will examine the same curriculum materials so a common base of discussion can be had. Through this activity we hope to generate a protocol for utilizing the framework for curriculum analysis that could be used to continue this work in the months following the conference. The second activity will afford participants an opportunity to examine videos of teachers launching the same task utilizing different launch types and to consider the initial discussion of students following/during the launch. Discussion of this activity will help conceptualize a follow up study examining the relationship between categories of selected launch move, teacher enactment of launch move, and student reaction to the launch. At the end of the session participants will be asked to consider the two different lines of inquiry and to select one to discuss in small group the following day.

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

Day 3

The third day will begin by forming special interest groups (SIGs) (i.e. curriculum analysis, effect of launch types on student learning, etc.). Each group will be provided time to begin planning a research project to be carried out over the upcoming months for their topic. At the end of the session groups will have selected a SIG leader and will submit a brief outline of their plans moving forward including possible timeline. Each group will share these plans with the group as a final activity. We will encourage SIGs to plan for proposals to present at AMTE 2021 (proposals usually due in mid-May 2020).

Focus on Specific Framework: Rationale

Given the wide range of initial questions about launching that this working group was interested in, we have chosen to focus on examining and developing a specific framework related to launching structures and features of tasks for several reasons. First of all, we hope that a more focused discussion will provide access to new members of the working group while pushing the work of the group forward. Second, we think that this focus on launch types, task features, and the connections between them will provide numerous opportunities to talk about other important and interesting questions. For instance, we believe that discussing features of problems and launches will also involve discussing student thinking and creating hypotheses for the kinds of struggles students and teachers experience during the launch phase of a lesson. We think that anchoring these discussions in specific problems and launches will help participants more rigorously articulate questions and hypotheses that can drive research.

Connection to Conference Theme

The conference theme for the PME-NA 2019 Annual Conference, "Against a New Horizon," is an explicit acknowledgement of how a quest for progress can also reinforce systematic exclusion. The extant research has demonstrated that a teacher's launch has the ability to provide or deny opportunity and access for students to engage in worthwhile mathematics and as such it is paramount we understand what constitutes effective launch practices. The promise of problem-based learning remains unrealized for many mathematics students, especially those who have traditionally been under-served by larger educational institutions and systems. While we have come to understand there exists an unexplored variety and complexity to launching cognitively demanding tasks, we have been able to agree that the underlying goal of any launch is to provide "access and opportunity for ALL students to grapple with challenging mathematics" (Wieman, Perry, et al., 2018, p. 1502). In addition to access and opportunity, launching is also, fundamentally, about agency and empowerment. Effective launches support all students in drawing on their own funds of knowledge (Moll, Amanti, Neff, & Gonzalez, 1992) to make sense of problems, provides them with opportunities to engage in the productive struggle that results in deep conceptual understanding, and empowers them to decide for themselves what solution strategies to pursue. Learning more about launches will help us empower all of our students so that they can all build on the knowledge and experience they have to construct new mathematical understandings, and engage powerfully in a diverse mathematical community.

Anticipated Follow Up Activities

Following the completion of our working group sessions we foresee several follow up activities. Our first priority will be the completion and submission of a National Science Foundation DRK-12 Conference Grant Proposal for a 2020 conference focused on launching for teachers and teacher educators. Second is the empirical examination of our hypothesized framework. We have three lines of inquiry for this: (1) Through collection and analysis of empirical data examining tasks, launches and student reactions to them we will attempt to verify and/or refine the framework in terms of student effectiveness; (2) We intend to utilize a survey approach to gather more Launching Task Sort data from MTEs in order to further refine the *Launch Framework*; and (3) We will continue the empirical examination of curriculum materials begun at this working group. As mentioned above we will be encouraging members of the SIGs forms at this working group to plan proposals for AMTE 2021.

SIMULATIONS OF PRACTICE FOR THE EDUCATION OF MATHEMATICS TEACHERS

Heather Howell
Educational Testing Service
hhowell@ets.org

Yvonne Lai
University of Nebraska - Lincoln
yvonnexlai@unl.edu

Carrie Lee
East Carolina University
leecarr16@ecu.edu

This working group addresses the challenge and opportunity presented by the use of simulations of teaching practice as an educative tool for preservice and practicing teachers. We focus particularly on the development of teachers' skills in enacting the content-intensive work of teaching, including how simulations may be able to cultivate or reveal teacher MKT, either as propositional or applied knowledge or as an essential component of a larger teaching practice in which MKT is activated.

Keywords: Mathematical Knowledge for Teaching, Teacher Knowledge, Teacher Education-Preservice, Teacher Education-Inservice/Professional development

History of Topic and Elaboration of the Problem Space

We situate this working group in two complementary strands of work, one focusing on teacher knowledge and the other on teaching practice. Since Shulman (1986) introduced the construct of pedagogical content knowledge, scholars have identified specialized mathematical knowledge in and for teaching (e.g., Ball & Bass, 2003; Krauss et al., 2008; Thompson & Thompson, 1996). With this scholarship have come efforts to focus teachers' education on learning this specialized knowledge (e.g., Ball, Sleep, Boerst, & Bass, 2009; Ghousseini, 2017; Silverman & Thompson, 2008). This knowledge, sometimes identified as mathematical knowledge for teaching (MKT), coordinates purposes and reasoning from both mathematics and teaching. Developing teacher MKT has increasingly become a core component of teacher preparation for mathematics teachers (e.g. Association of Mathematics Teacher Educators, 2017; Conference Board of the Mathematical Sciences, 2012) with assessment of MKT generating a body of scholarship (e.g., Gitomer, Phelps, Weren, Howell & Croft, 2014; Herbst & Kosko, 2012; Hill, Schilling & Ball, 2004; Krauss et al., 2008) and recently crossing over into mainstream licensure tests (see https://www.ets.org/praxis/about/ckt/).

MKT is, by definition, knowledge that is demanded in response to the content-intensive work of teaching (Ball, Thames & Phelps, 2008) and has been described by scholars as *practice-based*, or more closely grounded in teaching practice than other forms of mathematical knowledge (Ball & Bass, 2003). Other scholars have noted that the examination of MKT as it is learned by teachers or used in teaching benefits from more clearly articulated conceptualizations of how that knowledge is held, enacted, activated, or drawn on. (Heid, Wilson, & Blume, 2015; Rowland, 2013) The Knowledge Quartet work, for example, provides a framework designed "to guide attention to, and analysis of, mathematical knowledge-in-use within teaching", the purpose of which is to help teachers reflect and learn from their teaching (Rowland & Ruthven, 2011, p.85). Ghousseini (2017) similarly distinguished between propositional knowledge and knowing as a form of action, and Heid et al. (2015) described mathematical knowledge in terms of proficiency and activity. These lines of work arguably push toward understandings of MKT as it is used in teaching in ways that are even more closely aligned to the practice of teaching.

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

A complementary line of practice-based research has emerged that seeks to conceptualize critical teaching practices and to understand how teachers learn to engage in them effectively. Recent years have seen widespread effort to identify and prioritize teaching practices (e.g., http://www.teachingworks.org/work-of-teaching/high-leverage-practices, https://www.corepracticeconsortium.com/), shifting the field toward the systematic description of the most critical competencies for teachers to develop during preparation. At the same time, theories such as the Grossman, Hammerness, and McDonald (2009) pedagogies of enactment help to describe learning opportunities likely to support teachers' development of those competencies. A number of studies utilizing simulations of teaching practice are grounded in this theory, which describes the key pedagogy of *approximation of practice* as "opportunities to rehearse and enact discrete components of complex practice in settings of reduced complexity" (p. 283).

We situate this working group proposal at the intersection of these two lines of work. While not all simulated teaching is content-intensive, the simulation of content-intensive teaching practices may provide us with opportunities to observe, develop, and measure MKT, as recommended across elementary (e.g., Ball & Cohen, 1999; Hill, Sleep, Lewis, & Ball, 2007; Stylianides & Stylianides, 2013 and secondary levels (e.g., Ticknor, 2012; Wasserman, Weber, Villanueva, & Mejia-Ramos, 2018). And increasing attention to how MKT is activated and used in the practice of teaching can help us to better understand the relationship between knowledge and practice and how a teacher's MKT may relate to the quality of his or her practice or opportunities to learn from practice.

Enacting this approach brings a number of challenges. When working with simulations, teachers' attention can emphasize pedagogical concerns, "eclipsing" the intended specialized knowledge (Creager, Jacobson, & Aydeniz, 2016, p. 3); and at other times teachers may attend to mathematical ideas in a way that sidelines pedagogical reasoning (e.g., Schilling & Hill, 2007; Suzuka et al., 2009). In enactments of these activities, whether teachers' attention slides away from mathematics or away from pedagogy, the opportunity for using mathematics and pedagogy to inform each other is lost. In other words, one challenge facing the simulation designer is that of focus. The proposed working group will provide opportunities for simulation designers to work toward clearly defining objectives and determining which simulation design characteristics are critical in creating circumstances likely to meet those objectives.

A second challenge is that of common vocabulary. As Grossman, Compton et al. (2009) noted, simulations such as approximations of practice "can vary significantly, both in terms of comprehensiveness and authenticity" (p. 2065), ranging from responding to written cases to role-playing in mixed reality settings. In addition, the simulations under consideration vary significantly with respect to factors that matter in simulation design such as the level of interactivity or the types of records in which the practice is made visible. This variability in turn may amplify the potential for confusion across lines of work. Lesson planning, for example, might be considered a teaching practice to be simulated by one project, or as a part of the preparatory cycle for a simulation of interactive teaching by another, and it is likely to be conceptualized, supported, standardized, recorded, related to teacher knowledge, and attended to in very different ways as a result. The proposed working group will provide opportunities to work toward a common vocabulary or way of describing simulations of teaching practice

Rationale for the Working Group

This working group is timely and critical. The field is still at the early stages of developing a robust understanding of the ways in which practice-based professional preparation occurs within teacher education, especially in terms of how to leverage simulated environments to productively develop teachers' competencies (Sykes & Wilson, 2015). Recent years have seen multiple nationally-funded efforts to improve the mathematical preparation of teachers by developing materials with simulations of teaching practice for use in mathematics and methods courses. Most of these efforts build on the success of small-scale pilot studies (e.g., Lischka, Strayer, Watson, & Quinn, 2017; Straub, Dieker, Hynes, and Hughes, 2015; Wasserman, Fukawa-Connelly, Villanueva, Mejia-Ramos, & Weber, 2017).

While approximations of practice such as role playing or peer teaching are common practices in teacher preparation, more systematic approaches such as those using trained actors to provide standardization of opportunity (e.g., Dotger, Masingila, Bearkland, & Dotger, 2014; Shaugnessy & Boerst, 2018) are relatively rare, and investigators have noted the novelty and rarity of the very idea of incorporating technologically-supported simulations into mathematics courses (e.g., Ensley & Fiorini, 1998; Lai & Patterson, 2017; Wasserman et al., 2017). As noted in the 2018 PME-NA call, such technologies create opportunities to "explore how technology can be used in the service of mathematics education and research," (Hodges, Roy, & Tyminski, 2018) both by allowing us to explore best practices around the use of such technologies and because of the windows of opportunity they create to observe teacher learning in more systematic ways.

There is thus an emerging community of mathematician and teacher educators who are interested in attending to teachers' mathematical development through simulations of practice. For example, one of the NSF-funded projects listed previously supported a recent conference on the topic of simulation use in teacher education attended by one of the working session co-leads, who reported that major learning from sessions included (1) a significant variation across models of implementation, structure of cycles of enactment, and purposes and (2) a need expressed among expert panel members for the field to describe the parameters of simulation task design in a way that helps to build mappings between those parameters and task design.

Focus of Work

This working group seeks to explore the following questions:

1) How can we conceptualize the theories of action by which teacher learning is expected to result from engagement in simulation activities in contexts such as mathematics and methods coursework?

Theories of how teacher learning occurs, characteristics of simulation activities, the role of MKT, and how the activities are evaluated differ in substantial ways across projects. For instance the ULTRA project (Wasserman et al., 2018) is based on a learning theory of transfer and has revised its simulations in tandem with revising decompositions of teaching practice, whereas the MODULE(S^2) project (Lai, Strayer, & Lischka, 2018) is based on a learning theory of decentering and has revised its simulations in tandem with revising an adaptation of the Knowledge Quartet framework for use with simulations. This working group will invite comparison of theories of action and explore the variability in how researchers are conceptualizing simulation.

2) How can we articulate design principles rising out of or grounded in the theories of action identified in question 1?

Many simulation projects utilize iterative cycles of design to revise and refine simulation tasks. That is, simulations are designed based on a provisional theory of action, the simulations are then enacted in instruction, the enactments and instruction are studied in relation to intended outcomes, and action is taken to revise the simulations and underlying theory based on studying enactments.

This revision process is the foundation for a growing understanding of how characteristics of simulations provide opportunities for teachers to develop their teaching practice. But we lack a common language for what these characteristics are, and how they differ by context. Without a common language, it is difficult for the field to build systematically on this emerging base and capitalize on interest. So now is the time to contextualize what different educators are doing, how they draw on theory, and the rationale for choosing these theories. As Kennedy (2016) argued, the rationale matters more than the particular actions, because it's the reasoning that can change practice.

3) How can we measure the development of MKT, teaching practice, or other valued outcomes through the use of simulations?

Simulation use is additionally diverse in the varying degree to which it focuses on assessment and with respect to the targets of that assessment. Shaughnessy and Boerst (2018), for example, describe a program designed to measure preservice teachers' skill in eliciting student thinking through the use of a standardized on-demand interactive simulation. While the context of their work is indisputably content-intensive and they note that skill in eliciting may interact with MKT, the primary focus of their study is the teaching moves involved in elicitation. One could easily imagine, however, analyzing such data for evidence of MKT in use, similar to the approach taken by Lai et al. (2018). In contrast, Mikeska, Howell, & Straub (2017) acknowledge and propose to study the potential relationship between MKT and the targeted teaching practice of leading small group discussions in mathematics, but provide preservice teachers with preparatory materials in advance of the interactive simulated teaching to support their ability to make sense of the student work samples they will be discussing. Of note across these examples is that despite similar conceptualizations of MKT and a common understanding that it relates to the teaching practices simulated, MKT holds a very different role in what each project seeks to measure.

Organization and Plan for Active Engagement

The overall goal of this new working group is to create a community in which researchers and practitioners can explore how simulations of practice can be optimized to provide opportunities for teacher learning. Prior to convening in Missouri, we see value in collecting information from participants through a short survey on participants' conceptualizations of simulations of practice and how they use them in their teaching and/or research. This information will help create a canvas in which to begin to co-create our community.

The working group will consist of three sessions during the conference followed by virtual meetings through the following year. Across the three sessions participants will engage with facilitators to examine the learning theories that ground current work in simulations of practice, identify key design principles of the simulation tasks, and analyze our methods of assessing the impact of this work. In each session, participants will engage with simulation tasks of their own or from the facilitators, make explicit the areas they want to dive into deeper, and link with others that want to dive in with them.

Session 1: Exploring our Simulations of Practice

For the first session we will use information from our short survey to ensure that we are anticipating how different researchers and practitioners are conceptualizing simulations of practice. We will introduce our conceptions of simulations of practices within our own work and expand to include those from the survey. Next, small groups will be formed based on common interpretations, and group members will participate in an activity to map features of simulations to the issues of teacher learning that they are attempting to address. These simulations of practice will be provided by attendees' own work or examples from co-leaders' projects.

This mapping activity will result in a working document of simulation characteristics linked to the objectives they are intended to meet. This mapping will also allow outlets for us to problematize the simulation space. These activities are intended to surface commonalities and differentiations in our theories of action and our intended use of simulations.

Session 2: Analysis of Design Elements of Simulation Tasks

For the second session we will continue utilizing the working document from the first session and delineate the characteristics or design elements of the simulations that provide opportunities for teachers to enact MKT and teaching practices. Participants will begin by placing examples of simulations on a continuum of authenticity and completeness in relation to their approximation of teaching (Grossman, Hammerness, et al., 2009). This activity will lead to group efforts to identify key components of simulations that afford or hinder teachers' opportunities to learn. From this we will identify common themes in how simulations are designed for particular contexts. This record of design characteristics will be the beginnings of our efforts to create a collection of design principles for simulations that will inform the field and help link theory to practice. Session participants will apply this preliminary collection of design principles to revise or write simulations of practice to incorporate these characteristics. Through this process we will also identify issues of congruence and contrast within the design process.

Session 3: Assessment of the Impact of Simulation Tasks

In the last session of the working group we will again employ the working document to dive deeper into how learning objectives are measured active projects represented by attendees. In our efforts to identify key components of simulations that afford learning we need to be transparent in what outcomes we are measuring as learning and how they align with the underlying theories guiding the simulation development. Outcomes and metrics used within projects by co-facilitators will be presented and examined as a starting point for this session. Next, participants will identify their outcomes and metrics within their own work and consider any possible revisions. The power of utilizing a consistent working document is that we will have a record of the revision processes and analyses that will further inform future simulations and underlying theory.

In the closing segment of this session we will collect contact information from participants, document subgroups and their future research interests, and share next steps.

Follow-up Activities

This working group is a key step in establishing a network of teacher educators and researchers that are engaged in utilizing simulations of practice to develop teaching knowledge and practice. Subgroups formed during the sessions will be encouraged to continue collaborations on co-constructed areas of inquiry. The facilitators will support the continuation of collaboration by hosting virtual meetings through the year to check-in. We anticipate subgroups pursuing design revisions, creating simulations, exploring learning theories, examining the impact of simulations across varying contexts, and other emerging themes.

One of the future priorities of this working group is to channel the productivity of our sessions into a proposal for a special issue in the *Journal of Mathematics Teacher Educator*. In 2007 there were a series of special issues in *JMTE* that described the field's then-current understanding of mathematics-related tasks for the education of mathematics teachers. Those special issues highlighted the development process around task and as a result the editors saw "how the focus on tasks leads to 'meta-tasks' through which knowledge in and of teaching grows in practice through a research process" (Jaworski, 2007, p. 201). We see simulations as a form of "meta-task" and envision this special issue as a platform to describe our current understanding of simulations of practice for the education of mathematics teachers. Subgroups formed during the working group will be well positioned to contribute and advance this work.

The Gender and Sexuality in Mathematics Education Working Group convened in 2018 with a focus on (1) language use, multidimensional understandings of gender and sexuality, and influences of these on methods, results, and interpretations; (2) interactions between gender/sexuality and students' self-perceptions; and (3) the roles of curriculum, pedagogy, and teacher education in students' experiences of gender and sexuality. The 2019 Working Group will continue with these foci, but with an added dimension of learning through examination of work in gender and sexuality in mathematics education across the world, including country/culture-specific studies, and cross-cultural studies.

Keywords: Gender and Sexuality; Equity and Justice; Affect, Emotion, Beliefs, and Attitudes

The Gender and Mathematics Working Group (GMWG) began more than 20 years ago at PME-NA 20 in Raleigh, North Carolina. At this conference, mathematics education scholars came together "in order to weave together the findings of various strands in research and understanding of issues in gender and mathematics" (Damarin et al., 1998, p. 78). The GMWG continued to meet from 1998 to 2007, with the exception of the 2003 joint conference between PME and PME-NA in Honolulu, Hawaii**.** The group also reconvened for the 2011 PME-NA conference in Reno, Nevada. The GMWG's past discussions have involved reviewing the scholarship surrounding gender and mathematics, defining research strands, determining gaps in the literature, and establishing directions for future work. Some notable accomplishments of this group have been creating a visual representation of the field of gender and mathematics and the social and psychological complexities of the topic (Erchick, Condron, & Appelbaum, 2000) and publishing a monograph on gender and mathematics research as a joint project with scholars from the International Group for PME (Forgasz, Becker, Lee, & Steinthorsdottir, 2010).

The Gender and Sexuality in Mathematics Education Working Group convened in 2018 at PME-NA 40, after a hiatus of a seven years and with an updated title to reflect current trends in the field. Prior to the conference we identified preliminary themes across our work, including (1) the choice of language that we as scholars use when conducting research on gender and sexuality in order to be inclusive of all individuals and to reflect a multi-dimensional understanding of gender and sexuality, and how our choices of language and methods may affect

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

our research results and interpretations; (2) interactions between gender/sexuality and students' perceptions of themselves as mathematical learners, including experiences inside classrooms, in less formal learning spaces (e.g., summer camps, homes); and (3) the role of curriculum, pedagogy, and teacher education in the study of gender and sexuality in mathematics education.

Much of our time during the 2018 conference was spent becoming familiar with one another's recent work, and more broadly exploring the experiences and interests of the working group participants, including both the co-authors and others in attendance. Dr. Ana Dias, who was not a co-author for 2018, gave a presentation to the working group about the current social and political context of education, gender, and sexuality in Brazil. In addition, two of the co-authors (Dr. Elizabeth Kersey and Dr. Jennifer Hall) led the group in a very informative presentation and discussion about language and methodology in gender and sexuality research. We also welcomed and heard from new participants who joined us on the final day due to previous unavailability, and we considered opportunities for sharing resources and collaborating in the future. Based on the work of these three days, and to further develop and contextualize our knowledge and research related to gender, sexuality, and mathematics education, the working group leaders decided to propose for 2019 a focus on how these topics are experienced by students and teachers, and studied by researchers, outside of the U.S. In addition to work conducted within the U.S., among our 2019 proposal co-authors are individuals who have studied gender and/or sexuality as related to mathematics education in Australia, Brazil, and Israel. In addition, for this proposal, we have examined the literature from China, Ghana, Jordan, and Saudi Arabia. Short summaries of this work are provided below.

Rebecca McGraw, University of Arizona

Rebecca McGraw's work related to equity, gender, and mathematics includes co-facilitating a residential summer math camp for middle grades girls (led by Lynda Wiest, a co-author of this paper), studying teacher classroom practice from an equity perspective (e.g., distribution of images by gender in classroom resources, patterns of participation, course-taking, and achievement), and investigating pre-service secondary teacher preparation (Bay-Williams & McGraw, 2008; Eli, McGraw, Anhalt & Civil, forthcoming; McGraw & Lubienski, 2007; McGraw, Romero & Krueger, 2009; Rubinstein-Avila et al., 2014). Currently, Rebecca McGraw is particularly interested in the development of teacher and student beliefs about mathematics and learning, and the development of middle/high school students' mathematical identities. Recently, she has begun working with several colleagues, including one at King Saud University, to plan a year-long mathematics education program for Saudi teachers. This program would be modeled, in part, after the Building Leadership for Change through School Immersion (Khbrat) programs currently happening across the U.S. In the following paragraphs, Dr. McGraw has summarized some of the recent research related to mathematics, gender, and sexuality in Saudi Arabia.

According to Abu-Hilal et al. (2014), public schooling in Saudi Arabia began around 1930 with girls beginning to enroll in the 1960s. Rapid progress was made thereafter in terms of the number of girls enrolled, reaching 50% of the total students enrolled in 2000, according to the Ministry of Education. The school system, policies, and curriculum are strongly centralized, and teaching methods are frequently targeted towards rote learning, and not particularly oriented towards skills needed for a global economy (Hein, Tan, Aljughaiman, & Grigorenko, 2015). Pre-college education is entirely single-sex; however, a co-educational university, King Abdullah Science and Technology University, opened in 2009. As of 2018, enrollment included 35% Saudi students (65% international students) and the student body was 37% female (https://www.kaust.edu.sa/en/about/media-relations#part3).

In many countries around the world, researchers have found that mathematics self-concept is highly related to achievement (Mohammadpour & Ghafar, 2014). In Saudi Arabia, boys exhibit a higher self-concept while girls exhibit higher achievement (Abu-Hilal et al., 2014; Marsh, et al., 2014). Some researchers have argued that differences in the ways that boys and girls are raised in Saudi Arabia and in their expected future roles in society, lead boys to have a higher, or even inflated, self-concept, while girls are motivated to prove themselves academically and secure places at local universities through achievement (Abu-Hilal et al., 2014). To some extent, the Big Fish Little Pond Effect (Marsh & Parker, 1984) may be at play, with boys comparing themselves to only to other boys and girls to other girls (Abu-Hilal et al., 2014; Marsh, et al., 2014). Research on Saudi Arabian teacher practices by gender is sparse; however, in one study of teachers' Mathematical Knowledge for Teaching (MKT), researchers found that female teachers scored significantly higher than male teachers on both number and operation content knowledge and knowledge of content and students scales of a translated version of the Learning Mathematics for Teaching (LMT) (2008) instrument (Haroun, Ng, Abdelfattah, & Alsalouli, 2016). This difference may explain some component of the difference found in students' achievement scores by gender.

With regard to student interest in future careers, it is in the more gender-egalitarian countries (such as the U.S. compared to Saudi Arabia) that boys and girls are *less* interested in careers involving mathematics, and in which researchers find gender differences in interest in such careers, with girls significantly less interested than boys (Goldman & Penner, 2016). The research of Charles and Bradley (2009) suggests that gender-egalitarian contexts can "encourage girls and boys to express societally approved gender ideals as part of their gender performance…. Education in these contexts [serves] . . . an expressive function, so that students' educational choices are thought to reflect important aspects of who they are." (Goldman & Penner, 2016, p. 415). Currently, Saudi Arabian women have access to higher education exclusively through women's colleges (with the exception of King Abdullah Science and Technology University). These colleges are on completely separate campuses that are attached to male-only universities. The one exception is the all-female Princess Nourah Bint Abdulrahman University. Founded in 1970, it currently serves approximately 60,000 women, making it the largest women's university in the world. Altogether, women currently account for over 60% of all Saudi university students (Islam, 2017); however, access to jobs is very limited. For example, in 2015, 57% of science graduates were women, but their share of the total labor force was only 16% (Islam, 2017). As in a number of other places throughout the world, gender discrimination in STEM workplaces, and particularly in computer science and engineering, as well as the masculine gendering of STEM, continue to create barriers to entry and advancement (DeBoer & Kranov, 2017).

Katrina Piatek-Jimenez and Ana Dias, Central Michigan University

Katrina Piatek-Jimenez's research interests focus on what motivates women to study mathematics at the undergraduate level and what influences their decisions whether or not to continue in mathematical careers, including factors such as the development and role of one's mathematics identity (Cribbs, Piatek-Jimenez, & Mantone, 2015; Piatek-Jimenez, 2015), images of mathematicians (Piatek-Jimenez, 2008a), knowledge of mathematical careers (Piatek-Jimenez, 2008b), and equity within mathematics textbooks (Piatek-Jimenez, Madison, & Pzybyla-Kuchek, 2014). Ana Dias's research interests include the politics of mathematics education, adult numeracy, ethnomathematics, and mathematics in vocational education and training. Ana Dias and colleagues have conducted comparative studies of professional education curriculum in the U.S. and Brazil (Gonçalves & Dias, 2017), Freirean mathematics education (Gonçalves & Dias, 2016), and the history of professional education in Brazil (Gonçalves, Pires, Dias, & Monteiro, 2013a; 2013b; 2013c). In the following paragraphs, these scholars summarize some of the recent work on gender and mathematics in Jordan.

Drs. Piatek-Jimenez and Dias chose to study the country of Jordan for two reasons. First, Jordan is a country in which girls repeatedly score higher in mathematics on standardized exams than boys. Given that this is not the case in the United States, these scholars decided that it would be interesting to learn more about Jordan's culture and educational system to better understand what influences girls to be more successful on standardized examinations in mathematics. Second, Central Michigan University (CMU) has a large number of Jordanian students in the doctoral program in mathematics. Since the program's first PhD graduates in the year 2000, CMU has had 21 students from Jordan earn their PhD from the mathematics department. Given that from 1995 to 2015 only 90 students from Jordan earned a PhD in mathematics in the United States (National Science Board, 2018), CMU has awarded a large percentage of those degrees. Further, CMU's mathematics department currently has eight Jordanian students pursuing PhDs in mathematics. Therefore, these scholars wanted to learn more about the country of Jordan and its culture, with the intent to design a qualitative study to better understand gender and mathematical interest and achievement in the country of Jordan.

A substantial amount of research shows that girls in Jordan score higher than boys on standardized exams in mathematics. This is true not only with large-scale international assessments, such as the TIMSS (Innabi & Dodeen, 2006, 2017), but also with a national exam developed by the Jordanian Ministry of Education (Al-Bursan et al., 2018). Although these researchers found that certain nuances exist based on specific variables, such as the mathematical content or context of items, or whether the students attended coeducational or single-sexed schools, a clear pattern that shows girls achieving higher overall than boys on mathematics assessments exists.

This is not the case only for the subject of mathematics. In Jordan, "girls outperform boys at all levels and in all subjects" (Education Reform for Knowledge Economy Project II (ERfKE), 2014). At the collegiate level, a larger percentage of the female population attend college than the male population (UNESCO Institute of Statistics, 2019). According to one report (Ripley, 2017), at the University of Jordan, which is the country's largest university, women outnumber men by a ratio of almost two to one in their undergraduate programs. Amongst the students in the sciences, the division is even greater, with women outnumbering men by a ratio of almost 3.5 to 1 (University of Jordan, 2012). Despite these advances in their education, women consist of just under 20% of the actual workforce.

There may be multiple reasons why girls in Jordan academically outperform boys. One conjecture could be that it is because the girls have fewer freedoms and more restrictions put on them by their parents and therefore spend more time studying than the boys; if true, this may not the whole story (Ripley, 2017). A difference in the quality of schooling may play a role as well (ERfKE II, 2014; Ripley, 2017). In the public school system in Jordan, children attend coeducational schools only until third grade. After that point, boys and girls are filtered into separate single-sex schools, and, where difference exists in the quality of teachers, this may likely play a role in achievement differences. In Jordan, because of societal expectations, women rarely work jobs that require long hours or evening hours, or that involve close involvement with men (Kawar, 2000; Shteiwi, 2015). As such, the teaching profession is common for women because the hours are conducive to societal expectations and it is an all-woman environment in the single-sex schools. On the contrary, teaching is not a preferred profession for many men. Due to cultural norms, men are expected to be primary breadwinners, yet the pay for teachers in Jordan is quite low. Therefore, many male teachers work two or three jobs to help earn enough money to pay their bills. This leads to lower job satisfaction for male teachers (ERfKE II, 2014). Further, the boys' schools tend to be more violent than the girls' schools, which also leads to a less conducive environment for learning (ERfKE II, 2014; Ripley, 2017). Although the government has acknowledged these differences between the boys' and girls' schools and generally place strong women teachers in the lower elementary grades so that boys can develop a stronger foundation during their initial co-educational years (Ripley, 2017), in many ways these differences have not yet been systemically addressed.

Lynda Wiest, University of Nevada, Reno

Lynda Wiest's scholarly interests involve understanding factors that influence gender differences in mathematics, including those that relate to dispositions and beliefs, and strategies and opportunities for supporting and encouraging females in mathematics. Dr. Wiest has particularly focused on the role that out-of-school-time (OST) learning can play in this regard because it is an area of rising scholarly interest in education, especially in STEM education (e.g., McCombs et al., 2012; Slates, Alexander, Entwisle, & Olson, 2012). Dr. Wiest developed and has directed a residential summer math program for middle school girls for 20 years, conducting research in association with the program and recently publishing the first book of its kind on OST STEM programs for females (Wiest, Sanchez, & Crawford-Ferre, 2017). Dr. Wiest has worked for multiple years with graduate students from Ghana at University of Nevada, Reno, which has spurred her interest in mathematics education in that country. In the following paragraphs, Dr. Wiest summarizes some of the recent research related to mathematics, gender, and sexuality in Ghana.

Gender equality in Ghana is promoted not only as a human rights issue but also as one that is vitally linked to the pursuit of sustainable national development, such as one that has the potential to increase the socioeconomic well-being of all people (Zaney, 2014). Some gender issues in education in Ghana include the fact that only two girls for every three boys graduate from senior high school, that girls are more likely than boys to be over-age for their grade level and to drop out of school, and that females have a higher adult illiteracy rate than males (Camfed Ghana, 2012; UNESCO, 2016). Despite barriers to girls' education in Ghana, improvements have been made due to the joint efforts of governmental and nonprofit organizations, which have included eliminating school fees and providing training for school counselors and teachers (Eppenauer, 2018).

Nevertheless, Ghanaian males outperform females in school mathematics, only a little more than half as many females as males pursue elective mathematics in secondary school, and males far outnumber females as college mathematics/statistics students (Asante, 2010; Baah-Korang, Gyan, McCarthy, & McCarthy, 2015; Frempong & Asare-Bediako, 2016). Reasons offered for these differences are sociocultural, such as societal stereotypes that lead to greater familial financial investment in boys' education due to a greater expectation for social mobility for boys, whereas girls are generally expected to preserve current traditions and are more subject to early marriage (Asante, 2010). Such social pressures, as well as a lack of female role models in mathematics, also contribute to weaker mathematics-related dispositions, such as self-esteem and self-confidence, for females in Ghana (Asante, 2010, 2012). Girls who do break with this pattern and pursue elective mathematics seem inclined to do so based on their higher social status, which includes family support and role models (Baah-Korang et al., 2015; Boateng, 2017). The minimal research conducted on gender in mathematics education in Ghana has been conducted at the upper academic levels (secondary, tertiary), with little attention to the younger grades, where the roots of gender inequity might first take hold.

Ana Dias, Central Michigan University, and Harryson Gonçalves, State University of São Paulo

As previously stated, Ana Dias's research interests include the politics of mathematics education, adult numeracy, ethnomathematics, and mathematics invocational education and training. Harryson Gonçalves's background and research are in the area of curriculum studies and mathematics education, in particular diversity and inclusion or curricula as gendered and racialized texts. In the following paragraphs, Ana Dias and Harryson Gonçalves describe some related research from Brazil.

Previous research on Brazilian mathematics education has focused on comparing boys' and girls' scores on standardized international tests (Machado, 2014), examining gender stereotypes and gendered discourse in mathematics education (de Souza & Fonseca, 2010), and analyzing mathematics textbook illustrations and story problems in relation to gender stereotypes (Casagrande, 2006). Our focus is on research that encompasses a non-binary view of gender and sexuality. Diversity in gender expression and sexual identities is a reality in Brazilian schools, and teachers, including mathematics teachers, often find themselves unprepared to fight homophobia, transphobia, bullying, and other problems that directly affect students, often resulting in school dropout, self-mutilation and suicide attempts.

Examining the public policies and legislation in Brazil, three distinct moments are evident; naming, recognizing, and including (Pinto, 1999). In many schools there are efforts to name and classify (e.g., activities clarifying or defining gender and sexuality, different gender and sexual expressions and identities); efforts and strategies to recognize (e.g., who the different groups are, how they organize, what their political and social demands are), and mechanisms of inclusion (accepting, respecting, and valuing diversity, respecting human rights, combating school drop-out and violence against minorities). However, as Seffner (2013) points out, policies of inclusion inevitably generate procedures of labeling, and end up acting as mechanisms of oppression, even when guided by good intentions. Seffner (2013) addresses the challenges faced when schools attempt to promote mechanisms of inclusion and of respect towards sexual and gender diversity.

Even with the best intentions, sometimes these mechanisms have unintended results, and Seffner (2013) argues that this is due to a certain naïveté in relation to the ways in which heteronormativity works. In his school ethnography he describes five cases, in one of which he found that students responded to a campaign to value diversity by mocking the campaign slogan "value diversity" by changing it to "value Arthur" (Arthur is a pseudonym that the author uses for a homosexual student in the school). The slogan was later spread around as "value the literature teacher" in reference to the school's literature teacher who was openly gay. In another case described by Seffner (2013) a student, here called Renato, complained that in two situations, when the teachers invited a gay leader for a collective interview and showed some videos with anti-homophobia campaigns, the classmates – both boys and girls – claimed that the event was happening “just because of Renato.” A friend of Renato´s said that she would “rather attend a math class than talk about stuff like that,” leaving Renato in an awkward position.

How prepared is the mathematics teacher to deal with such situations? What is the role of mathematics in the curriculum? Although it may seem that these topics are outside the field of mathematics education, they directly affect students and teachers of mathematics. When the student said that she would rather have a math class than hear a speaker talk about inclusion, she was not necessarily referring to how much she enjoys her math classes, but probably also signaled the fact that students will be held accountable for their mathematics performance in exams at school, and especially, in the “vestibular” exams which determine entrance into higher education institutions in the country.

A few authors, such as Peralta (2019), have questioned how school mathematics may reinforce labeling, categorizing, and comparing social groups. Peralta’s focus is in preschool mathematics activities, which consist mainly of seriation, classification, and ordination. We believe that adequate preparation of mathematics teachers in gender and sexuality issues need to move beyond examining stereotypes about women in mathematics textbooks (which is currently the emphasis of the literature used in Brazilian teacher preparation programs). Further efforts need to a) promote educational efforts in partnership with social movements, and not only scholars; b) create curricular materials that focus on the hegemonic mechanisms of heteronormativity, instead of focusing on homosexuality (that is, problematizing the norm itself and not those presently out of the norm); and c) avoid activities that have as sole focus defining different gender and sexual identities, which end up being almost like an effort in taxonomy and often result in labeling.

Jennifer Hall, Monash University

Jennifer Hall has long had an interest in “gender issues” research in mathematics education. Dr. Hall began formally investigating this topic through a Master’s degree research project, in which was an exploration of the experiences of women mathematics majors at a Canadian institution (Hall, 2010). More recently, Dr. Hall has conducted research in Australia and Canada (Hall & Jao, 2018a, 2018b) about the general public’s views of gender and mathematics. Notably, for this study, the data collection instrument from a previous, similar study by Forgasz and Leder was altered (1) to make all the questions non-binary (e.g., “For which gender…”) and (2) to add questions that explicitly queried the participants’ views on gender. In another recent project, Dr. Hall and colleagues (e.g., Hall, Robinson, Flegg, & Wilkinson, in press) investigated the supports and challenges faced by undergraduate mathematics majors in Australian universities. This project has an explicit focus on gendered aspects of the students’ experiences, and, like the previous project, gender-related data are collected in non-binary ways. Data collection is complete for both projects, and analysis and writing are underway.

In Australia, there is a long tradition of “gender issues” research in mathematics education, primarily linked to the work of Helen Forgasz and Gilah Leder, the latter of whom is the winner of the 2009 Felix Klein Award. Forgasz and Leder have widely published in the area of gender and mathematics for decades, with notable publications such as *Mathematics and Gender* (Fennema & Leder, 1990), *International Perspectives on Gender and Mathematics Education* (Forgasz, Becker, Lee, & Steinthorsdottir, 2010), and *Towards Equity in Mathematics Education: Gender, Culture, and Diversity* (Forgasz & Rivera, 2012).

With regard to achievement on international large-scale assessments, such as the Programme for International Student Assessment (PISA), which assesses 15-year-old students, no statistically significant gender differences in mathematical literacy were found between Australian boys and girls from 2003 to 2015 (Thomson, De Bortoli, & Underwood, 2017). In contrast, on the Trends in International Mathematics and Science Study (TIMSS; Thomson, Wernert, O'Grady, & Rodrigues, 2016), gender differences in mathematics achievement in favoring boys were found in 2015 for Grade 4 students; this marks the first statistically significant gender difference since the 1995 iteration of the test. No statistically significant gender differences were found in 2015 for Grade 8 students, and there has only been one such difference since 1995 (in boys' favor).

With respect to participation at non-mandatory levels of study, women remain a minority of students in university programs in the mathematical sciences, and women's proportion of the enrolments has been declining in recent years (Australian Academy of Science, 2016; Johnston, 2015). For instance, in 2014, only one-third of the students who graduated with an honors bachelor's degree in the mathematical sciences were women (Johnston, 2015). Over the past 15 years, there has been a slight downward trend in the number of women, compared to a substantial upward trend in the number of men, graduating with honors degrees in the mathematical sciences (Johnston, 2015).

Angie Hodge, Northern Arizona University, with contributions by Dakotah Wilkey, Northern Arizona University

Angie Hodge's research interests lie at the intersection of active learning (Ernst, Hodge & Yoshinobu, 2017) and gender equity in the STEM disciplines. Most recently, Dr. Hodge conducted research on a four-week summer camp for underrepresented middle school girls (Hodge, Matthews, & Squires, 2017). In addition, Dr. Hodge conducted a research study on why some women choose STEM fields and what has made them successful in such majors (Weber & Hodge, 2012). In the following paragraphs, Angie Hodge, with contributions by Dakotah Wilkey, has summarized some of the recent research related to mathematics, gender, and sexuality in China.

In China, gender equity has been a common topic studied in mathematics education research as mathematics has been seen as a male dominated field of study. The achievement levels of girls in mathematics have not been found to be significantly different than boys, except that the highest scorers on the college entrance examinations are more likely to be boys (Tsui, 2007). Based on findings such as this, some researchers have advocated for analyses of societal factors, including home and school backgrounds, to further investigate male domination of mathematics-related fields (Zhu, Kaiser, & Cai, 2018). For example, researchers conducted a study in poor, rural areas of China in which they aimed to measure the factors of health, nutrition, and background and how these factors might affect children (Zhou et al., 2016). These researchers concluded that health and nutrition did not seem to be related to engagement with mathematics fields later in life; however, girls were found to have lower levels of self-efficacy and self-esteem, and higher levels of anxiety (Zhou et al., 2016), which may contribute to their opting out of certain academic areas and/or making different career choices than boys do.

The lack of a gender difference academically in China may be related to the recently changed policy that formerly allowed families to only have one child. Prior to this law, boys were found to have more value placed on their education than girls. There was a time where the laws were more relaxed, leading to some children having siblings. In one study, researchers found that having a male sibling negatively impacted female students potentially due to parents having a male preference (Kubo & Chaudhuri, 2017). Chinese parents often depend on their children when they grow older, so seeing their children succeed is crucial, regardless of gender. Parents who only have one child have expectations that are more gender-neutral, removing competition and value placed on some children over others (Tsui, 2007). In fact, having a single, female child may lead to more educational spending to ensure that the child is successful in the competitive job market, leading to more success in academic endeavors. This may be related to the ways gender, achievement, and selection of mathematics-related careers is experienced by students in China.

Betsy Kersey, University of Northern Colorado

Betsy Kersey is primarily concerned with ways that we can research gender without reinforcing the gender binary. In her dissertation study, she used a narrative framework to analyze the experiences of transgender students in STEM fields, some of whom were nonbinary, in order to gain insight into how the treatment of students in mathematics and other STEM fields are gendered, both for those within and those who transcend a binary notion of gender. Several interesting findings emerged. Perhaps most surprisingly, those participants who were assigned male at birth and then transitioned to align their presentation with their gender identity as women reported that being treated as male, even though it meant they had more social power, felt uncomfortable and sometimes even insulting. Once they transitioned and others in their programs perceived and treated them as women, they had less social power, but experienced this as affirming of their identity and saw it as an improvement in their circumstance. This suggests that there are subtleties in how we regard gender-based privilege and discrimination to which we should attend.

Betsy Kersey is collaborating with Rowen Thomas, a colleague pursuing their doctorate in Higher Education and Student Affairs, to propose a variety of ways that researchers can ask their participants about gender to provide some structure without reducing gender to a binary. The first model is the gender oppression plane (Kersey, 2018). The second model is a pictorial model based on the color wheel that would allow participants to select both what gender(s) they identify with and to what degree, if any, they identify in that direction. These models would be best suited for qualitative research. The first model focuses on how participants are perceived by others and how their treatment varies based on their perceived gender; the second model focuses on how an individual identifies. The third model is a Likert-scale adaptation of the model for gender used by the Gender Unicorn (Trans Student Educational Resources, 2017) and would be best suited to quantitative research. This model is also readily adaptable to asking about sexual/romantic attraction. Finally, Dr. Kersey is collaborating with Jennifer Hall on an article about the ethics of studying gender. The work of these researchers draws from relevant statements from professional organizations in mathematics and mathematics education around the world, as well as previous work conducted by researchers in other fields, such as science education. This work focuses primarily on the collection and analysis of data, how to avoid forcing participants to choose a category that does not fit them, and some considerations when analyzing data related to gender.

Laurie Rubel, University of Haifa and City University of New York

Laurie Rubel's current research focuses on the educational experiences of women Palestinian citizens of Israel (Arab Israelis, who represent 25% of the population of Israel). Arab Israelis are a minority group with limited access to opportunity and resources and lower socioeconomic standing in Israel (Bar-Tal & Teichmann, 2005; Zuzovsky, 2010). Arab Israeli girls outperform boys in mathematics (Rapp, 2015) and have been found to have beliefs about success in mathematics different from Western or Westernized peers (Forgasz & Mittelberg, 2008). It has been hypothesized that girls appropriate academic success to overcome the lower status that they hold, as a minority in Israel as Palestinians exacerbated by their role as women in a patriarchal society (Rapp, 2015), and as an unintended consequence of less diversity among course offerings in Arab high schools (Ayalon, 2002).

Laurie Rubel's research methodology consists of life-story interviews with Arab Israeli women in undergraduate and graduate programs in mathematics education, from diverse Arab ethnic groups and geographies, in which they are asked how they understand and interpret the effects of local racialized narratives in relation to learning, how they interpret their achievement and others' lack of achievement, and which factors they identify as supporting or inhibiting their success. Dr. Rubel's analysis will pursue the educational experiences of these women, as told in their own stories and counterstories, with particular attention to how these stories converge or contrast with Western narratives. The commentary will include analysis of researcher positionality (Milner, 2007) and Dr. Rubel will discuss methodological tensions inherent to research about equity in mathematics in relation to social groups known to espouse conservative, patriarchal, and homophobic ideologies.

Plans for Active Engagement During the Conference

During sessions 1 and 2 we plan to begin our work with a series of short presentations by the working group authors about research that has been or is being conducted across the various parts of the world described previously. We will focus on situating the research within the respective cultures, and we will explore the ways gender and sexuality are constructed and re-enforced, especially, but not only as they relate to mathematics education. We believe it is important to attend to cultural contexts, and, where possible, we will include short, publicly available video highlighting stories of the experiences of individuals within these cultures and/or artifacts of student/teacher work. We will highlight themes that emerge across cultures and discuss ways in which we see our own cultures anew based on studying the experiences of others. We will also include time for non-co-author participants who have engaged in mathematics-education related work outside of the U.S. to share their work and experiences. It is important that this time is both informative and interactive, and thus will likely take us well into the second session. During sessions 2 and 3, our time will be devoted to break-out group work, followed by a large group-sharing session at the end of Session 3. Break-out groups will be arranged according to individual interest, with the goal of generating questions to be investigated and creating (small) sets of online resources and potential collaborators. One aim is to begin to consider opportunities for cross-cultural collaborations, leveraging our own connections and those of other participants. Each break-out group will generate a plan for moving the work forward, and collectively we will determine a timeline for engaging in this work after the conference ends. These sessions might initiate a process for developing materials that could lead to an edited volume.

The goal of the proposed working group is to create a space for those interested in researching issues around the teaching and learning of statistics to meet, discuss, synthesize past research, and begin to strategize ways of leveraging multiple perspectives and expertise to identify and address current challenges in statistics education. The nature of statistics being a methodological discipline make it such that statistics education is made up of a diverse array of people from various backgrounds, disciplines, fields, interests and expertise. We propose this working group to create a space for dialogue among people with diverse perspectives to tackle important issues in the teaching and learning of statistics. Diverse perspective help to look at problems in new ways and come up with new solutions. However, we also want to pragmatically make progress towards a goal, which requires some common direction as well. To balance these tensions we frame our work in the notion of learning environments as a way of organizing past work as well as ideas for future projects into a meaningful structure. Additionally we are layering on the consideration of teachers and teaching in the design and enactment of learning environments.

Keywords: Data analysis and statistics

Introduction

Creating opportunities to develop statistical literacy in public schooling is crucial for education in the 21st century in data centric societies, and thus a top priority for statistics education (Franklin et al., 2007; Steen, 2001). The focal point of statistics education, an interdisciplinary field, is the teaching and learning of statistics and can trace its beginning to the early eighties (Zieffler, Garfield, & Fry, 2018). While statistics education has emerged as a discipline in its own right, it evolved from statistics and mathematics education drawing on the practice of statisticians, theories of learning and development, as well as methods of inquiry (Ben-Zvi & Grafield, 2008; Garfield & Ben-Zvi, 2008; Zieffler et al., 2018). In chronicling the emergence of statistics education, Ben-Zvi and Garfield (2008) identified core areas of importance in this emerging field: statistical literacy, challenges related to learning and teaching statistics, development of the field of statistics education, collaborations among statisticians and mathematics educators, and the relationship between statistics and mathematics. They argue that statistics can be perceived as a bridge connecting mathematics and science.

While much progress has been made to establish statistics education as a discipline, there are still many challenges that educators and researchers face in order for the field to evolve as a collective community of practice. Because of the interdisciplinary nature of statistics education and its roots in statistics, mathematics and science education, statistics educators come from a diverse array of disciplines, backgrounds, and expertise and, as such, have a wide variety of visions for the direction of statistics education. This is no surprise to anyone who agrees with Cobb and Moore's (1997) characterization of statistics:

> Statistics is a methodological discipline. It exists not for itself but rather to offer to other fields of study a coherent set of ideas and tools for dealing with data. The need for such a discipline arises from the omnipresence of variability (p. 801).

While having a diversity of perspectives is a strength, it is also a challenge. Another challenge for statistics educators is that the teaching and learning of statistics is often situated within the mathematics curriculum and in mathematics departments. Perhaps as a result, statistics is often still positioned as a branch of mathematics as opposed to a distinct discipline that draws heavily upon concepts and practices from mathematics (Cobb & Moore, 1997; Franklin et al., 2007; Groth, 2015).

The goal of the proposed working group is to create a space for those interested in researching issues around the teaching and learning of statistics to meet, discuss, synthesize past research, and begin to strategize ways of leveraging multiple perspectives and expertise to identify and address current challenges in statistics education. Organizing within the North American Chapter of the International Group for the Psychology of Mathematics Education (PME-NA) acknowledges the roots of statistics education in mathematics education, and acknowledges the importance the authors place in drawing from educational theories, research, and practices in studying the teaching and learning of statistics. Additionally, PME-NA is also well known for promoting and stimulating interdisciplinary research; thus, it would be an ideal space for mathematics and statistics educators to work and collaborate, along with mathematicians, statisticians and scientists, on issues relating to the teaching and learning of statistics. Furthermore, in line with the conference theme, in a world where we are saturated with data in our daily lives, we view the new horizon as a place where we have the opportunity to prepare individuals to critically engage with data and make evidence-based decisions. This new horizon points to the critical need for fostering statistical literacy among all members of society to critically make sense of the world around them (e.g., Arnold, 2017). The new horizon also holds great potential for the future, with the explosion of interest in statistics and statistics education from the many fields it offers a coherent set of ideas and tools for dealing with data.

Statistics Education as a Field

In an effort to start a new working group focused on issues of teaching and learning statistics, we begin by briefly discussing the past history and current status of the field of statistics education in conjunction with mathematics education—particularly because of PME-NA's situatedness in mathematics education. We also use this section to make explicit some of the major challenges that statistics education currently faces as a field. This section serves as both a background and as a rationale for the work of the group.

Statistics Education and Mathematics Education

Mathematics education and statistics education have quite a long and, some might argue, complicated history. Mathematics education can trace its origins back to such writings as Thorndike (1922), Moore (1923), and *The First Yearbook* by the NCTM (Smith, 1926). In the US, although the National of Council of Teachers of Mathematics (NCTM) was established in

1920 (NCTM Board of Directors, 2017), the field of mathematics education was not formally recognized in the academe until 1962 when it was included as an option for doctoral graduates to choose as their primary field of study in the Survey of Earned Doctorates—a survey that has been used in the US to track earned doctorates since 1920 (Shih, Reys, & Engledowl, 2017). Historically, statistics has been included as part of the mathematics curriculum—dating back to at least 1923 in the US (National Committee on Mathematics Requirements, 1923).

It wasn't until the 1950s and 60s that statistics began to form its own identity apart from mathematics. For instance, although the American Statistical Association was founded in 1839 (ASA, 2019a)—49 years before the American Mathematical Society (AMS, 2019) and 76 years before the Mathematical Association of America were founded (MAA, 2019)—a separate department for statistics did not exist at Harvard until 1957, when founded by Frederick Mosteller (Powell, 2006). Further recognizing the distinct disciplines of mathematics and statistics, in 1968, the ASA and NCTM formed the *ASA/NCTM Joint Committee on the Curriculum in Statistics and Probability*, chaired by Frederick Mosteller (Scheaffer, 1982)—the outgoing ASA President. This first joint committee set out to produce a book that would "help the layman, and those in charge of secondary school mathematics curricula, understand the uses of statistics and probability" (Mosteller, 1971, p. 341). The committee went on to publish two curricula: *Statistics by Example* and *Statistics: A Guide to the Unknown* (Scheaffer, 1982)—the former of which was well received, with one book review stating that "from the point of view of interest and motivation, these problem sets are far superior to what has been used previously" (Greenhouse, 1975, p. 483). This relationship between NCTM and ASA would result in supporting roles in curriculum standards documents, such as the *Curriculum and Evaluation Standards* (NCTM, 1989), *Principles and Standards* (NCTM, 2000), and the *GAISE* report (Franklin, et al., 2007), and it played a role in the development of probability and statistics content in NSF-funded curricula, such as *Connected Mathematics Project* (Franklin, et al., 2015). Moreover, the *GAISE* report made a lasting impression on the field at large, and played a leading role in the probability and statistics standards included in the *Common Core State Standards for Mathematics* (NGA & CCSSO, 2010; Franklin et al., 2015). The joint committee is still in existence, and its charge still the same:

> To provide national leadership for the inclusion of statistics and probability in the Nation's mathematics curriculum; to promote awareness programs and quantitative literacy among teachers; and to support the development of appropriate curriculum materials. (ASA, 2019b, para. 1)

The current 6 members of the committee (3 from ASA, 3 from NCTM, Chair alternates between NCTM and ASA) are listed in Table 1 (taken from ASA, 2019b).

Table 1: Current ASA/NCTM Joint Committee Members

Name	Position/Affiliation	Term
Perrett, Jamis	Chair/ASA	2019–2019
Bargagliotti, Anna	NCTM	2016–2021

Gould, Robert	ASA	2018–2020
Maddox, Kathleen	NCTM	2014–2019
Miller, Stephen	NCTM	2015–2020
Tyson, Douglas	ASA	2016–2021

Through some of the efforts of ASA and NCTM described above, as well as others, there was a general recognition in the 1980s that statistics should be included in the school curriculum and improved at the tertiary level (Garfield & Ben-Zvi, 2008). In 1982, the first International Conference on Teaching Statistics (ICOTS) was held in order to improve statistics education at all levels, from elementary school to the training of professionals. Zieffler et al. (2018) suggest that statistics education can trace its roots as a discipline to the first ICOTS. ICOTS has continued to be held every four years ever since.

Past History of Working Group

While PME-NA 41 will be the inaugural meeting of this working group, past working groups have focused on a closely related topic, the teaching and learning of probability. Although probability plays an important role in statistics education, past working groups have placed more emphasis on probability rather than statistics. The first group's work centered on learning to reason probabilistically (Maher, Speiser, Friel, & Konold, 1998) and has convened at ten annual conferences up to 2006 (Lee, Tarr, & Powell, 2005; Maher & Speiser, 1999; 2001; 2002; Powell & Wilkins, 2006; Speiser, 2000; Stohl & Tarr, 2003; Tarr & Stohl, 2004). In 2009, Lee, Lee, Wilkins, and Angotti extended the focus of the working group to include statistics by exploring ideas related to learning to reason probabilistically and statistically through experiments and simulations. The following year, the focal point of the working group returned to using technology to teach and learn probability (Radakovic, Karadag, & McDougall, 2010).

Challenges of the Field

Mathematics and statistics. Though both mathematics and statistics are part of the mathematical sciences, statistics is its own distinct discipline—not a sub-discipline or branch of mathematics (Cobb & Moore, 1997; Franklin et al., 2007; Gattuso & Ottaviani, 2011; Groth, 2013). As Steen (2001) points out, "Although each of these subjects shares with mathematics many foundational tools, each has its own distinctive character, methodologies, standards, and accomplishments" (p. 4). Statistics relies heavily on mathematics, but there are distinct practices and habits of mind in statistics which are non-mathematical as well (Groth, 2007, 2013). Part of this reliance is through probability, which is necessary for statistical inference and firmly a part of mathematics (Fienberg, 1992).

There is a strong literature base that discusses important differences that should be considered between the discipline of mathematics and statistics in undergraduate and school settings (Cobb & Moore, 1997; Franklin et al., 2007, 2015; Gattuso & Ottaviani, 2011; Groth, 2007, 2015; Scheaffer, 2006; Usiskin, 2014). The most prominently discussed differences include the treatment of context, variability, inductive versus deductive reasoning, and uncertainty. Scholars generally support the location of the teaching of statistics in the mathematics curriculum (Gattuso & Ottaviani, 2011; Scheaffer, 2006), and some scholars also point out it should also be distributed cross the teaching of all disciplines (Usiskin, 2014). This situatedness can also be viewed in the earlier discussion of the relationship between mathematics and statistics education.

While there are interrelations between mathematics and statistics, differences in the disciplines mean there are some important differences in the thinking and reasoning encouraged in both disciplines, which relates to teaching and learning. For example, mathematics primarily relies on deductive reasoning using definitions, axioms, and theorems, in a logical chain of reasoning, to come to a conclusion. A student could use Euclid’s definition of a circle and his first and third postulates to construct an equilateral triangle. At the same time, Euclidean geometry is based on certain unprovable assumptions such as the parallel postulate, which if changed creates an entirely new type of geometry and way of viewing the world (Katz, 2009).

Statistics, on the other hand, begins with a question for which data is collected to answer (Franklin et al., 2007; Wild & Pfannkuch, 1999). It is from the data that information is empirically derived. This can lead to issues in teaching statistics, as teachers who have had few experiences with statistics may attempt to deduce solutions from rules and assumptions rather than inducing them from the data. Such differences in teaching result in the need for the investigation of issues relevant to the teaching and learning of statistics, which may differ in some regards to the teaching and learning of mathematics. It is these differences that have fueled the need for the field of statistics education. However, As Groth (2015) cautions,

Although the evolution of a statistics education community of practice can be viewed as a positive development for research on the teaching and learning of statistics, there is also a danger that the disciplines of statistics education and mathematics education may become increasingly insular and non-communicative with each other. Sustained boundary interactions are vital to preventing insularity from contributing to the stagnation of interrelated communities of practice. (p.5)

This caution is why a working group such as the one being proposed is so important—to create a community of practice that focuses on sustained boundary interactions between mathematics and statistics education. The need for such a space is discussed in the section that follows.

Collaborating and communicating across fields and disciplines. Statistics education as a discipline has established its own organizations, conferences and journals. At the international level, the International Association of Statistics Education (IASE) serves as an organizing body, which also houses the Statistics Education Research Journal (SERJ) to help disseminate the work of its members. The IASE also helps to organize a number of events and research conferences, both on a yearly basis in conjunction with the International Statistics Institute, and every four years for the main research conference (i.e., ICOTS). In the US, the ASA disseminates scholarly work through the *Journal of Statistics Education* (JSE).

While these organizations, conferences and journals make important contributions to the knowledge base of scholarly work and best teaching practices, we conjecture that work may not be as widely accessed by mathematics educators and researchers, or others, who do not identify as statistics educators and scholars. In turn, statistics educators and scholars, especially those who identify more broadly as mathematics educators, science educators, learning scientists, mathematicians, or statisticians likely publish their work outside of journals such as SERJ and JSE. Thus, the interdisciplinary nature of statistics education contributes to challenges in disseminating work through organizational efforts, conferences and scholarly publications. We argue that while it is a challenge to access research across different fields and disciplines, it is necessary to build on all contributions to move statistics education forward.

An additional challenge to collaborating and communicating about important issues in statistics education is the multitude of stakeholders with vested interests in improving the teaching and learning of statistics: K-12 mathematics teachers, university and community college mathematics and statistics instructors, statisticians, mathematics education researchers, statistics education researchers, mathematics teacher educators, learning scientists, as well as others. When statistics educators and scholars disseminate their work, they are faced with the challenge of appealing to such a wide audience.

Lastly, another challenge in working across disciplines is the relationship between science education and statistics education. Statistics has very strong roots in science, and as a methodological discipline is drawn upon heavily by all the sciences, which has implications for standards. For example, the new Next Generation Science Standards (NGSS Lead States, 2013) includes science and engineering practices that are deeply connected with the practice of statistics, such as analyzing and interpreting data and engaging in argument from evidence. While there are strong disciplinary boundaries between mathematics and science at the K-12 level in the US, we argue that there should be stronger ties between these communities. The work of Lehrer and Schauble (e.g., Lehrer, Kim, & Schauble, 2007; Lehrer & Schauble, 2000, 2004; Petrosino, Lehrer, & Schauble, 2003) around data modeling is an exemplar of how drawing on multiple fields can contribute to improving the teaching and learning of statistics. Work along these boundaries holds much promise for the future, particularly given Ben-Zvi and Garfield's (2008) call for statistics to serve as a bridge between mathematics and science. It is our hope that the proposed working group will foster a space for such boundary work to occur, and to consider how best to disseminate that work to the various stakeholders and audiences of interest.

Researching the Teaching and Learning of Statistics

The challenges of the field we describe in the previous section are part of the reason why it is so important to form spaces to bring together people from various backgrounds, disciplines, fields, interests and expertise to tackle important topics in the teaching and learning of statistics. We propose this working group for that very purpose, to create a space for dialogue among people with diverse perspectives. Diverse perspective help to look at problems in new ways and come up with new solutions. However, we also want to pragmatically make progress towards a goal, which requires some common direction as well. To balance between acknowledging and drawing from diverse perspectives and working towards a common goal we have decided to take the approach of framing our work as a way of organizing past work as well as ideas for future projects into a meaningful structure.

To frame the activities of the working group, we draw on Ben-Zvi, Gravemeijer, and Ainley's (2018) recommendations in taking a holistic approach to investigating the teaching and learning of statistics by focusing on learning environments and drawing from a multitude of theories from various levels of generality. They call for more researchers to take up a holistic perspective of investigating many or all of the factors of a learning environment, and furthermore ask researchers to consider which supports for teachers and teacher education are necessary for creating and facilitating such learning environments. Their work highlights the importance of understanding how various dimensions of learning environments are interrelated.

Responding to the call of Ben-Zvi et al. (2018), the initial goal of the working group is to review what the field knows about each of the components of a learning environment described, and to also conceptualize the role of teaching and teacher education in relation to learning environments and synthesize the literature related to that as well. The rationale for this approach is to synthesize the literature through this new lens to identify areas of need and have a basis for identifying specific problems for the working group to brainstorm ways of investigating and form collaborations for future work around. To frame the work of the working group, we briefly describe the factors in learning environments described by Ben-Zvi et al. (2018) below and then begin to conceptualize the role of teaching and teacher education in relation to learning environments.

Learning Environments

Taking a learning environment perspective acknowledges the inherent complexity in a classroom, which is at the intersection of social, cultural, temporal, and spatial dimensions and represents an interactional space that includes the influence of many different stakeholders including students, parents, teachers, administrators, politicians, etc. Such complexity requires design efforts that do not just take a narrow focus on a single element of a learning environment, such as the written curriculum used, but instead focuses on how to take into account many interrelated dimensions of the environment. Ben-Avi et al. (2018) identify key interrelated dimensions that are critical to designing learning environments to support students in developing productive statistical thinking: focus on central ideas, well designed tasks, real or realistic data, technology tools, classroom culture, and assessment to monitor and evaluate. Ben-Zvi et al.'s proposed interrelation of these elements can be seen in Figure 1.

Researchers taking up this perspective often take a design research approach (Cobb, Confrey, diSessa, Lehrer, & Schauble, 2003). Our goal in drawing from this framework is not to subscribe to particular orienting or background theories or specific methodologies. Instead our initial goal is to use this framework as a way of organizing past research in a manner that will serve as a starting point for designing research projects that leverage what is known by the field and target areas of need in a holistic manner attending to the learning system as a whole versus only its parts. In framing our review of the literature, we feel it is important to explicitly incorporate the role of teachers, teaching and teacher education in learning environments. We elaborate on these dimensions in the section that follows.

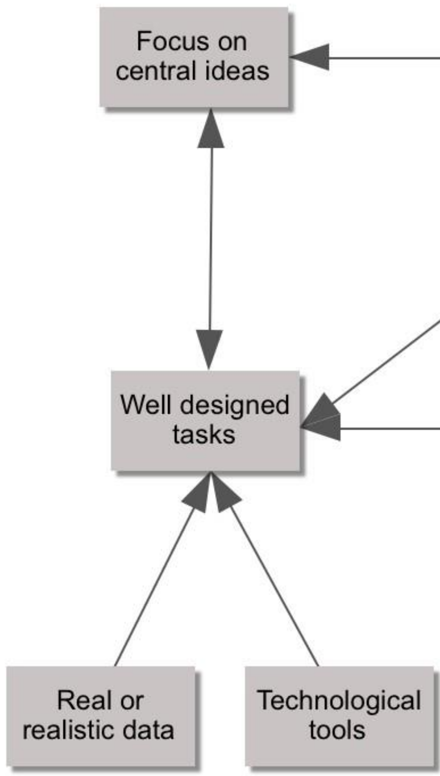

Figure 1: Ben-Zvi et al.'s (2018) Interrelated Dimensions of a Learning Environment

Teaching and Teacher Education

There is a wide variety of models or notions of teaching. In teachers' enactment of their curriculum, they must work as both diagnosticians and river guides (Russ, Sherin, & Sherin, 2011) by both probing and making sense of student learning, and being flexible to navigate the complexities and dynamics of the practice of teaching in the moment. This includes navigating the complex interactions between teacher and student, teacher and content, student and content, and between students situated in learning environments (Cohen, Raudenbush, & Ball, 2003). These interactions are influential in shaping what is taught as mathematics/statistics, how to do mathematics/statistics, and students' identification in relation to mathematics/statistics (Boaler, 2002; Boaler & Greeno, 2000). To be able to navigate these interactions requires that teachers have a strong content knowledge—be familiar with the content they are teaching—as well as have a strong pedagogical content knowledge—be familiar with how to create effective learning experiences for others to learn content knowledge (Ball, Thames, & Phelps, 2008; Baumert et al., 2010; Hill et al., 2008; Shulman, 1986). Furthermore, content knowledge and pedagogical content knowledge are deeply intertwined and are inseparable in the practice of expert teachers (Baumert et al., 2010). As a result it is important for mathematics teachers to not only have a strong understanding of the mathematics they teach, but to also have powerful pedagogical practices for effectively teaching mathematics content to students from diverse backgrounds (Chao, Murray, & Gutiérrez, 2014).

Scholars argue that merely discussing teaching in terms of the interactions Cohen et al. (2003) describe, does not give enough credit to the historical, cultural, societal, and political environments that learning environments are situated in and influenced by (Chazan, Herbst, &

Clark, 2016). Classrooms are situated at the intersections of many different contexts, such as the specific social norms, policies, and physical layout of the classroom and school within which such interactions are occurring, as well as larger community and societal environments within which the school is situated (Davis & Sumara, 1997; de Freitas & Sinclair, 2014).

The importance of statistics education has gained traction in K-12 school settings in the US with the CCSSM (NGA Center & CCSSO, 2010). However, a common issue related to this is the teaching of statistics and the statistical education of teachers (Franklin et al., 2015). As Shaughnessy (2007) pointed out over a decade ago, and Horizon has found is still the case from two separate nationally representative surveys of K-12 mathematics teachers (Banilower et al., 2012; Banilower et al., 2018), many mathematics teachers have had little to no prior experiences with statistics. This is an issue because, as Cobb and Moore (1997) describe, the teaching of statistics has some differences from that of mathematics and this position has been echoed by a number of others since (Franklin et al., 2007; Gattuso & Ottaviani, 2011; Groth, 2007). More recently, the Horizon surveys found teachers across K-12 are not confident in teaching statistics in general (Banilower et al., 2012; Banilower et al., 2018), and, regarding specific statistics content, Lovett and Lee (2017) found that secondary teachers are not confident in their ability to teach a number of the new statistics and probability standards they are expected to teach. The consideration of teachers and teaching is crucial to developing statistics education in school settings. Teaching is however a complex social practice at the intersection of many different communities of practices and influencing factors.

To incorporate the consideration of teachers and teaching the working group will include considering the knowledge and pedagogy necessary to create and enact learning environments as well as how teacher education may need to be modified to help prepare teachers for such roles. These layers will be considered in addition to the learning environment framework from Ben-Zvi et al. (2018).

Plan for Active Engagement of Participants

The working group meetings at the PME-NA 2019 conference will be organized to introduce members to one another, explore frameworks for synthesizing statistics education research, synthesize findings from statistics education research, and make connections with researchers that have a similar focus within statistics education research. To make the most of our time together during the conferences the meetings will be organized as described below.

Session 1

- Participants introduce themselves to the group and share research focus in statistics education
- Working Group leaders introduce the focus of the group and share initial framework from Ben-Zvi and elaborate on components
- Participants break out into small groups to discuss and engage with the framework considering guiding questions provided by the working group leaders
- Participants share summary of their small group discussion and the group as a whole refines the framework and goals of the group

Session 2

- Participants brainstorm in small groups dimensions that are not in the Ben-Zvi framework that would be important to consider
- Groups share out and Working Group leaders facilitate discussion to build shared framework

- Participants identify areas of the framework that align with their expertise and/or interest

Session 3

- Participants work in groups to identify sources for literature within each dimension of the framework and brainstorm a plan for systematically reviewing the literature
- Participants share out sources of literature and thoughts on a plan for reviewing the literature
- Group refines plan for reviewing the literature
- Outline of draft of publication created
- Participants plan meeting times and shared work for after conference
- Possible venues for publication of work are discussed

After conference

- Small groups follow the plan for searching for literature along different dimensions of the framework
- Small groups add literature to google sheet repository
- Working Group leaders curate literature and write synthesis for each area
- Teams work on adding to the outlined draft
- Working group leaders plan 2020 conference time

It is our hope that this working group will serve as a basis for a sustainable working group that can continue on in later PME-NA conferences and serve not only to connect scholars currently in the field, but to also provide an environment that welcomes in early career scholars and graduate students interested in investigating issues around the teaching and learning of statistics.

This working group will engage PMENA members to better understanding the nature of mathematical modeling in the early grades while considering the student perspective and recognizing the importance of teachers knowing their students and the contexts that are meaningful to their students. We will investigate how PK-6 teachers demonstrate the interdisciplinary nature of mathematical modeling, the diversity of mathematical approaches taken by student modelers, and the multiple pathways the teacher can use to elicit students' mathematical thinking. We will explore how mathematical modeling bridges equity and social community in teaching and learning mathematics for all students. Exemplar tasks that emphasized local contexts and tapped into students' funds of knowledge and student artifacts will be shared to illustrate the child's perspective and the developmental progression. These topics will facilitate group discussions exploring the learning progression for mathematical modeling thinking and habits of mind that can develop for emergent mathematical modelers from an early grade. Finally, based on the interests of the participants, we will devote work time to finding synergistic collaborative topics to pursue for future research and practice.

Keywords: Mathematical Modeling, Elementary Education, Teaching Practices, Professional Development, Learning Progressions, Knowledge of Content and Pedagogy

Overview of the Working Group

This working group began at the 2017 PMENA in Indianapolis, IN and continued its meeting in 2018 in Greenville, SC. We proposed that this working group have a special focus on early mathematical modeling and continue to build on PMENA's long tradition of working groups on

Models and Modeling. Through the 2017 and 2018 working group meetings, we found that there are researchers and practitioners with a keen focus on broadening the access of mathematical modeling to diverse learners in the elementary grades and advancing the field's collective understanding of the interrelated processes of mathematical modeling in the elementary grades and beyond. Although there has been a long history of mathematical modeling at PME and PMENA, the focus was primarily middle, high school and university levels. We believe it is critically important to understand the learning progression of mathematical modeling from early elementary to secondary grades to ensure coherence and rigor in the mathematics curriculum.

In our first year, the working group leaders proposed an edited volume and a special issues journal venue for MM where participants interested in submitting manuscripts could work together to provide a comprehensive research trajectory documenting the progression of mathematical modeling from emergent levels to more sophisticated levels of modeling. We are excited to share that this working group was able to secure a contract with Springer to publish an edited volume on this very topic. In our second year of the working group, one of our lead facilitators announced an exciting networking meeting at the upcoming MSRI meeting in 2019 focused on modeling and the connection to community and cultural contexts. It is clear that this PMENA working group is facilitating ways to bring synergy among researchers across North America, and we hope to continue this working group so that we can invite more mathematics educators to take part in the important research of MM in the early grades.

Implementing MM in the elementary grades is not just going "light" with the high school math modeling curriculum. Instead we advocate integrating aspects of mathematical modeling in the early grades effectively to enhance student learning and to help build their competency in real-world problem solving using their current mathematical knowledge. The latter content knowledge is expected to develop and evolve as students progress towards high school and beyond. So what does mathematical modeling look like in the elementary grades? Why focus on early grades? In addition to the direct benefits of modeling, the elementary school environment affords many advantages that complement work in mathematical modeling. Elementary students often rely on concrete referents such as objects, drawings, diagrams, and actions that can support the conceptualization and construction of carefully formulated arguments to solve a problem. Such arguments can make sense and be correct, even though they are not generalized or made formal until later grades (CCSSO 2010). Young students have great potential to become fluent – native speakers, thinkers, and dreamers of mathematics. Thinking creatively may come more easily to children first learning and exploring mathematical concepts. Kindergarteners can use manipulatives to independently solve traditional multiplication or division problems they have never seen before, which is evidence that students come with knowledge--it is not necessary to wait to incorporate modeling activities until we have "shown them how" to do everything. Because early grade teachers are generalists, they can address several subjects simultaneously through modeling activities. Mathematical modeling is of interest and relevance to the mathematics education community especially because it connects to the need for professional development focused on MM in the elementary grades.

We are also interested in focusing on different research methodologies used in mathematical modeling research. Some of our researchers use Design-Based Implementation Research methodology, DBIR (Fishman, Penuel, Allen, Cheng, & Sabelli, 2013) to examine the design of the professional development and to study and enhance the design through feedback from iterative implementation cycles. Each year at our working group meetings, we meet researchers who are also using Networked Improvement Communities (NICs) collaborating with school districts working with diverse populations to examine what works, for whom, and under what conditions, which helps us better understand the nature of MM in the elementary grades with diverse learners across geographic regions. For example, in one of our NSF-funded projects, each university site worked with the collaborating district's teacher leaders to co-plan the professional development. Teachers became co-designers of the MM curriculum for the elementary classrooms. In our project, we engaged elementary teachers in MM using real world tasks that contained several of the following attributes: (a) Openness; (b) Problem-posing; (c) Creativity and choices; d) Iteration and revisions.

Through our work, we are gaining a better sense of teaching practices and classroom routines that support modeling. We are contributing to the understanding of what is possible in early elementary grades and how these processes support the development of critical 21st century skills. As we continue in our research to consider what constitutes the practice of Mathematical Modeling (MM) and how it could be implemented in classrooms at different grain size, we invite the larger PMENA community to build on this knowledge. Over the past decades, working group leaders have individually, and in subgroups, been theorizing and collecting, analyzing, and reporting on data relating to mathematics modeling. This Working Group builds on and extends the work of previous Model and Modeling traditions by discussing current work from leading scholars from diverse perspectives.

Relevance to Psychology of Mathematics Education

In the spirit of exploring the theme of 2019 PMENA "Against a New Horizon," we will offer differing views of "expansion" and "growth" in relation to ways mathematical modeling can provide opportunities for learners, families, and their communities to engage in mathematics and supporting *all* students through a concerted focus on equitable teaching practices. In addition, this working group will attend to the interdisciplinary nature of mathematics and how it connects to social justice, STEM, and civic responsibility for our citizen in our country. Finally, we invite researchers from different countries in North America to broaden our understanding of how different national curricula attend to mathematical modeling as mathematical literacy, situational problem solving, and other curricular initiatives that develop critical thinking skills.

The purpose of this working group is to invite individuals across the research community interested in synthesizing the literature and collaborating on research focused on mathematical modeling along the developmental continuum. Our goal of mapping a learning progression of mathematical modeling from K-12 education, particularly starting from elementary to middle grades, is critically important to provide coherence in the mathematics curriculum.

The primary focus for this working group will be centered on the following three goals:

1. Examine current research and discuss the nature of mathematics modeling and detailing the development of teachers' content knowledge, teaching practices, and students' modeling competencies.
2. Map the learning pathways for mathematical modeling and task design for K-6 mathematics education and explore how mathematical modeling can bridge equity and social community in teaching and learning mathematics for all students.
3. Engage in dialogue and collaboration among individuals and groups conducting research on student- and teacher-related outcomes related to implementing mathematical modeling, ways mathematical modeling promotes social justice, 21st century skills, and ways in which early modeling can develop interdisciplinary skills in STEM.

Related Research

Mathematical proficiency, in today's world, moves beyond computational ability. It includes the development of 21st century skills (i.e., critical thinking, creativity, communication, and collaboration), conceptual understanding of mathematics (NCTM, 2014), and mathematics that has practical relevance outside of the classroom (Gravemeijer, Stephan, Julie, Lin, & Ohtani, 2017). Mathematical modeling (MM) is a powerful tool for developing students' 21st century skills (Suh, Matson, & Seshaiyer, 2017), advancing their conceptual understanding of mathematics, and developing their appreciation of mathematics as a tool for analyzing critical issues in the world outside the mathematics classroom (Greer & Mukhopadhyay, 2012). It provides the opportunity for students to solve genuine problems and to construct significant mathematical ideas and processes instead of simply executing previously taught procedures and is important in helping students understand the real world (English, 2010).

There is broad agreement among mathematics educators on the relevance of MM in schools, but the field has yet to come to a consensus on the definition of mathematical modeling or on how it might be taught and learned in schools (Kaiser, 2017). Although mathematical modeling has traditionally been reserved for secondary and college students, its enactment in schools contributes to broad educational goals that are relevant to learners of all ages (Ferri, 2018). In addition, scholars have argued that engaging in mathematical modeling is important for elementary school students (Carlson, Wickstrom, Burroughs, Fulton, 2016).

Mathematical modeling has received increased attention in the United States since the release of the Common Core Standards in Mathematics (the Common Core hereafter) in 2010. Modeling is incorporated as a specific area of expertise that teachers should cultivate in students across Grades K–12. The Common Core's Standards for Mathematical Practice, SMP4 is called *Model with Mathematics.* Although SMP4, as a mathematical practice, cuts across Grades K–12, mathematical-modeling opportunities are not highlighted in connection with the K–8 content standards, presenting an implementation challenge for teachers (Cirillo, Pelesko, Felton-Koestler, & Rubel, 2016). Modeling with mathematics, the topic of SMP4, refers to both modeling mathematics and mathematical modeling. The distinction between modeling mathematics and mathematical modeling is not clear to many teachers (Meyer, 2015), nor is it clear in Common Core documents or in mathematics education literature (Cirillo et al., 2016). The key difference between mathematical modeling and modeling mathematics is where the mathematical activity begins. Modeling mathematics begins in the mathematical world (Van de Walle, Karp, & Bay-Williams, 2016), whereas mathematical modeling begins in the unedited real world (Pollak, 2007). The explicit focus on getting a problem outside of mathematics into a mathematical formulation and explicitly translating the mathematical solution back into the real world is what differentiates mathematical modeling from modeling mathematics. The real-world focus also distinguishes mathematical modeling from problem solving and application problems (Lesh & Caylor, 2007; Schukajlow et al., 2012).

One of the ways the researchers in this working group have approached MM in the elementary grades was to immerse students in a relatable and personally-meaningful real-world situation within their local contexts. In bringing mathematics closer to social community spaces, mathematical modeling became a vehicle that brought teaching and learning mathematics closer to all students. Reforms in mathematics have advocated for mathematics to be more related to students' lives by building on community and cultural knowledge and practices with issues that matter to them, which then helps students view mathematics as a vehicle through which they learn to be active change agents for social justice (Bartell et al., 2017; Civil, 2007).

To keep the initial problem open, students were encouraged to develop the habit of mind of being problem posers by identifying the many questions around the real phenomenon, then defining a mathematical problem that can be solved by way of mathematics. After the identification process of the problem, the modeler makes assumptions, eliminates unnecessary information, and identifies important quantities to develop a solution. The mathematical solution focuses on the usefulness of mathematics to solve a real-world problem. It should be noted that there can be several mathematical solutions for a given real-world situation. After solving the problem, the results are translated back to the real-world and interpreted in the original context. The problem-solver then validates the solution by checking whether it is appropriate or reasonable for the purpose. This process of making assumptions, identifying variables, formulating a solution, interpreting the result, and validating the usefulness of the solution is iterative in nature and modified and repeated until a satisfactory solution is obtained and communicated (Blum, 2002).

It is important to note that teachers play a crucial role in MM and must be able to: (1) find appropriate questions to move students through the modeling cycle, (2) handle discussions in nondirective but supportive ways, (3) allow students time for productive struggle, and (4) provide scaffolding without directing the problem or its solution (Burkhardt, 2006). Teachers also need to develop problem-posing expertise (Suh et al., 2017) and to base their instructional decisions on responses to students’ work (Bleiler-Baxter et al., 2016). Thus, learning to teach MM requires teachers develop multiple knowledge bases. For example, teachers must understand modeling processes and tasks, including the potential mathematical content embedded within tasks; learn about students’ mathematical and personal experiences to predict the strategies they might use when responding to modeling tasks; know what content is on the mathematical horizon to anticipate what mathematical ideas students might construct; and learn to engage individual and groups of students in the modeling process (Blum, 2011; Ferri, 2018).

Previous work with elementary school children demonstrated it is feasible for them to develop a disposition towards realistic mathematical modeling (Verschaffel & De Corte, 1997). One of the issues in implementing MM at the elementary level is that MM can be difficult for both teachers and students to implement (Blum & Ferri, 2009). MM can be difficult for teachers to implement as they must be able to merge mathematical content and real-world applications while teaching in a more open and less predictable way (Blum & Ferri, 2009). Mathematical modeling can be a challenge for students because each step of the modeling process presents a possible cognitive barrier (Blum & Ferri, 2009). As stated in the Common Core Standards for Mathematical Modeling,

“Real-world situations are not organized and labeled for analysis; formulating tractable models, representing such models, and analyzing them is appropriately a creative process. These real-world problems tend to be messy and require multiple math concepts, a creative approach to math, and involves a cyclical process of revising and analyzing the model” (Carter et. al., 2009).

To model, students need support to develop mathematical modeling competency -- i.e., the ability to independently carry out the various phases of the modeling process (Vorhölter & Kaiser, 2016) and its related sub-competencies (Schukajlow et al., 2015). Based on the Standards for Mathematical Practice 4 in the Common Core: Model with Mathematics, Bleiler-Baxter, Barlow, and Stephens (2016) identified the mathematical modeling sub-competencies needed by students as simplification (e.g., making assumptions), relationship mapping (e.g., identifying important quantities and their relationships), and situation analysis (e.g., interpreting results in the context of the situation). In addition, students need to develop a metacognitive modeling competency because it is "indispensable in order to enable students to solve complex modeling problems independently, which is an indispensable part of true modeling activities" (Vorhölter & Kaiser, 2016, p. 279).

Emerging Research on Early Mathematical Modeling

Developing modeling competencies in young mathematicians. English (In press) argues for the importance of incorporating mathematical modelling into the years of early education, where young children's learning potential often remains untapped. She states MM is ideally suited for early learning and should not be reserved for the later school years; Early MM facilitates interdisciplinary learning, in particular, linking the STEM disciplines as well as humanities (e.g., literature). She elaborates on (a) "pre-modelling" experiences (e.g., working with simple data and their representations), (b) mathematical modelling within different disciplinary contexts (e.g., engineering in the production of confectionary for a modelling problem that targeted this topic; using literature as introductory and supporting contexts), (c) the inclusion of supplementary science content, and (d) modelling experiences posed by children.

Anhalt, Cortez, and Aguirre (In press) share a construct for developing competency across grades and propose key modeling competencies that can be targeted for development early on, and thus, classroom activities can be designed with the goal of developing those competencies in students through modeling tasks and through other activities that do not necessarily engage the entire modeling process. They refer to it as *mathematical modeling thinking (MMT)*. In order to define MMT and determine what to include in it, they address the questions: (1) what are key competencies to be successful in mathematical modeling? And (2) what activities are effective at laying the foundation for the development of those key competencies?

Osana and Foster (In press) report on the genesis of modeling in kindergarten and unpack the key ingredients for professional development. The MEA that was orchestrated in the teachers' classrooms invited the children to design their ideal Kindergarten classroom. The activity encouraged the children to answer the questions they themselves generated through modeling (English, 2010), such as "How many tables and chairs do we need for all the kids in the class?" "How big should the tables be and where should we put them?" "How many kids should be at each table and why?" Manipulatives and other tools were made available to the children as they worked through the modeling cycles, and children worked collaboratively on the construction and revision of their models. The results yield valuable insights on the elements that are necessary for professional development in mathematical modeling with young children, particularly in classrooms with at-risk students.

Turner, McDuffie, Aguirre, Foote, Chappelle, Bennett, Granillo, and Ponnuru (In press) provide a description of the Upcycling Jump Rope task and state several important implications for mathematics education researchers to consider. They recommend that given the salience of children's funds of knowledge across all phases of the modelling process, teachers should explicitly elicit students' experiences and perspectives, and position these experiences as resources to support meaningful engagement in mathematical modeling. Second, their findings highlighted pedagogical tensions in mathematical modeling lessons that demand further investigation. For example, while students readily shared experiences related to the broader task context (plastic consumption, recycling, and pollution), teachers had to determine when to encourage this sharing and when to redirect the conversation to key features of the specific modeling task. A third implication is related to more effective engagement with the final phase of the modeling process – generalizing. While generalization of models remained elusive, emerging evidence suggests that teachers can reframe tasks to facilitate shareable and re-usable models for similar situations.

Wickstrom and Yates (In press) analyze students' notions of mathematics as they consider how elementary students define mathematics and view themselves as learners while doing mathematical modeling and also during traditional instruction. Findings suggest that the third-grade students conceptualized math as computations and often compared themselves to peers to determine success in mathematics. In contrast, during mathematical modeling, students discussed that the task was more difficult than traditional mathematics, but also more rewarding and inclusive.

Developing core teaching practices for early mathematical modeling. Suh, Matson, Birkhead, Green, Rossbach, Seshaiyer, and Jamieson (In press) report ways in which researchers are collaborating with teacher designers to develop personally relevant and rigorous MM tasks for elementary students. The essential design skills include : 1) Leveraging problem posing routines to develop questioning skills: When posing an MM problem, teacher-designers adopted instructional routines for problem posing and worked on developing teacher and student questioning competence; 2) Connecting familiar context that engages students: Teachers, as designers, looked for situational features that warranted mathematizing and searched for contexts that were relevant and important to support students' engagement in modeling. In addition, teachers elicited students to think about how their solution was shareable, reuseable, or generalizable in order to evaluate whether a systematic model was created; 3) Connecting context with content: Teachers connected the need for mathematics in a modeling task with the curricular objectives of their grade level; 4) Considering categories of MM tasks: The modeling tasks tended to fall into four general categories (described below) where a mathematical solution or model could be used to describe, predict, optimize, and make decisions about real world situations.

- Descriptive Modeling - Using math to describe, represent, and analyze a situation or a phenomenon.
- Optimization Modeling - Using data to find the "best" by optimizing or in some cases minimizing some variable (i.e., cost, space) in a situation.
- Rating and Ranking - Using a criterion where one assigns weights or mathematical measures as a way to rate and rank options to make decisions.
- Predictive Modeling - Using trends and data analysis to predict an outcome or using patterns (data analysis and algebra) to predict a situation and make decisions. In some tasks, probability and statistical modeling is used to search for patterns in data to explain a phenomenon (i.e., scientific phenomenon used in STEM contexts).

In addition, researchers are examining core practices that are essential in supporting student learning through modeling. Suh and Matson (In press) found four main categories of core teaching practices that emerged as being central to the success of enacting mathematical modeling in the elementary classroom: a) Questioning practices: Developing competence in asking productive questions of students; b) Data Practices: Connecting relevant data by formulating the problem and eliciting student thinking about important variables and assumption in a problem situation; c) Modeling Practices: Building solutions/models that can be communicated and are useable to others through records of student work, concrete tools, written and verbal explanations, number sentences, and pictorial representations; d) Analytic and Interpretive Practices: Facilitating productive analysis of a model for the purpose of refining it.

Carlson (In press) report on teacher knowledge bases for engaging young children in MM. She explores the mathematical and pedagogical knowledge teachers need in order to engage young children in mathematical modeling. Analysis of data collected suggests that teachers developing and implementing modeling tasks draw on three knowledge bases: (1) knowledge of real world contexts around which students might pose and investigate mathematical problems, (2) knowledge of students' mathematical and local knowledge resources, and (3) knowledge of curricular mathematics – including the mathematical tools children may have at their disposal and ideas that are on the "mathematical horizon" and might be constructed during a modeling activity.

Formal and informal learning of modeling across disciplines and settings. Mathematical modelling is central to understanding different disciplinary contexts. Elementary teachers are generalists who teach multiple disciplines. Early caregivers, parents, and preschool teachers also have opportunities to leverage real-world situations to teach mathematics. Gallagher and Jones (In press) describe how elementary teacher candidates were introduced to mathematical modeling (MM) in their math methods course and how one of those candidates implemented a MM task related to economics. Students were asked to make economic decisions on the supplies needed for their classroom based on a list of choices and a budget prepared by their principal. The students chose items they found most necessary within the budget. They discussed how economics, as a field based on MM, provides a natural way to integrate MM into the elementary curriculum.

Yanisko and Minicucci (In press) share design features of a course designed for K-5 prospective teachers and aligned with two curricular goals – that students feel empowered by learning mathematics and that teachers recognize the assets of their students and leverage those assets to improve the effectiveness of mathematics instruction. This acquired knowledge is unpacked through an asset-focused lens and leveraged to build students' capacity for geometric modeling that is aligned with math standards. Additionally, teachers examined how to foster students' personal sense of power by investing them to use acquired math knowledge to positively impact themselves or their community.

Gilbert and Suh (In press) highlight how modeling principles across mathematics, science, and engineering converge toward a construct of integrated STEM modeling. These processes are framed as a disciplined inquiry approach that embrace cross-disciplinary connections to solve problems or better understand real-world phenomena. In particular, this instrumental case study investigated preservice teachers enrolled in a graduate-level integrated STEM course where activities were steeped in modeling tasks surrounding content and pedagogy involved in meaningful integrative processes. Findings suggest that preservice teachers could both prepare and enact integrated STEM approaches, and after teaching children in elementary contexts, recognized the creative freedom and motivation it brought to the children they taught as well as themselves. These researchers propose a model for the convergence of STEM practices and articulate the value for STEM modeling in elementary contexts.

Civil, Bennett, and Salazar (In press) look at ways to encourage MM in informal settings with professional development with families and caregivers. They report on their learning from Modeling with Mothers. They maintain that parents are intellectual resources and have a wealth of knowledge about various topics that interest their children. In alignment with the larger project's overarching goal to bring together parents and teachers, the co-development exercise intertwined the roles of those inside and outside of the classroom, fusing researchers' knowledge of mathematical modeling with parents' funds of knowledge about the school community. Additionally, the mothers' insistence to involve their children signaled to the researchers the importance of collaboration between parents and children in curriculum development.

Plan for Active Engagement of Participants

The working group will meet three times during the conference and virtually during the course of one year. In each session, PMENA members will engage in mathematical modeling while sharing their perspectives in teaching and learning mathematics, considering synergistic areas fruitful for future research and practice, and finding collaborators within our group. At each session, we will have facilitators share a research theme and provide participants time to get into smaller research groups so that participants can join one or visit with three smaller groups to network and find synergistic research interests with others at our working group.

WG-Research Group 1: Student Development Focused: Tapping into Students' Funds of Knowledge and Assessing Student MM Competencies and the Developmental Trajectories

Research Group 1 will focus on better understanding the nature of mathematical modeling in the elementary grades while considering the student perspective and recognizing the importance of teachers knowing their students and the contexts that are meaningful to them. We will investigate how K-6 teachers can assess math modeling in the elementary grades while appreciating the diversity of mathematical approaches taken by student modelers and the multiple pathways the teacher can use to elicit students' mathematical thinking. We will explore how mathematical modeling bridges equity and social community in teaching and learning mathematics for all students. Exemplar tasks that emphasized local contexts and tapped into students' funds of knowledge and student artifacts will be shared to illustrate the child's perspective and developmental progressions. These topics will facilitate group discussions exploring the learning progression for mathematical modeling thinking and habits of mind that can develop for emergent mathematical modelers from an early grade. We will map out productive learning pathways for mathematical modeling and task design for K-6 mathematics education and beyond.

WG-Research Group 2: Teacher Development Focused: Identifying Core Teaching Practices for Early Math Modeling and Unpacking the Knowledge of Content and Pedagogy Needed for Mathematical Modeling in the Elementary Grades

Research Group 2, we will focus on clearly defining modeling teaching practices and competencies needed for mathematical modeling and outlining research goals and objectives to monitor the enactment of these practices. We will detail classroom routines, such as the "organize - monitor - regroup" cycle (Carlson et al., 2017), and the Core Practices for Mathematical Modeling (Suh & Matson, in press) as we share designed activities and lesson vignettes to solicit more ideas around high leverage MM teaching practices. We will explore what mathematical knowledge is needed to "successfully" facilitate mathematical modeling tasks in elementary grades. As we synthesize the current research on early modeling, we will define the nature of mathematics modeling and detail the development of teachers' content knowledge, teaching practices, and students' modeling competencies.

WG-Research Group 3: Professional Development Focused: Detailing PD Research and Development of Tools and Modules for PD & Finding Convergence between PD on Mathematical Modeling and Interdisciplinary Areas

Research Group 3 will focus on detailing components of effective mathematical modeling professional development for educators, examining relevant research methodology and instruments for studying the nature of MM in the early grades, and outlining several 21st century skill frameworks and teaching approaches for mathematics educators, researchers, and practitioners. We will share PD modules designed for elementary teachers that engage learners to use mathematical modeling through problem-based tasks, STEM, and teaching social justice through MM. Connecting interdisciplinary topics across subjects afford modeling opportunities that will help educators value the complementary connections between subjects and common classroom practices that support MM. We will engage in dialogue and collaboration among individuals and groups conducting research on student- and teacher-related outcomes related to implementing mathematical modeling, ways mathematical modeling promotes 21st century skills, and ways in which early modeling can develop interdisciplinary learning.

Anticipated Follow-up Activities and Goals of Working Group

Each session will engage participants to share their research interests related to mathematical modeling and form groups that might pursue research collaboratively based on the interests of the participants. Some of the questions that we will engage in include:

- What defines successful mathematical modeling at different grade levels?
- How does mathematical modeling support each and every learner?
- How does mathematical modeling connect to issues of social justice, STEM, andcivic responsibility of citizens?
- What can we learn from teachers who implement MM regularly in their classrooms?
- How is mathematical modeling ambitious teaching and how can we support teachers enacting MM through lesson plans and other resources?
- How can we map out the learning pathways of MM across grade levels?
- How and what can we learn about models elicited from student artifacts from MM tasks?
- What do “successful” modeling practices look like in our elementary mathematics classrooms? How are they similar or different from practices in secondary classrooms?
- What does it mean to “see the math” in the components of mathematical modeling?
- How do teachers select and/or develop modeling problems? How can Professional Learning Communities or Teacher Study Groups help teachers anticipate how students will answer the MM questions?

Our goal is for the working group leaders to propose an edited handbook or a special issues journal venue for mathematical modeling where participants interested in submitting manuscripts can work together to provide a comprehensive research trajectory documenting the progression of mathematical modeling from emergent levels to more sophisticated levels of modeling.

Mathematical play has a fairly short history, with strong roots further back in time (e.g., Papert, Montessori), and understanding the role of mathematical play from early childhood to adulthood is, as yet, unmapped. This working group will build on the success of last year's working group and continue to provide a community space to explore and discuss mathematical play broadly, ranging from informal to formal contexts and from 3rd grade students to teachers in professional development. We will emphasize physical and digital interactions designed specifically to support mathematical play. Each day will focus specifically on a different approach to and definition of mathematical play. Day 1 will focus on mathematical play and making by 3rd to 5th graders across formal and informal environments; Day 2 will focus on intellectual play within mathematical microworlds; and Day 3 will focus on mathematical play in teacher professional development. Throughout the sessions, we will be examining threads of common ground that will assist in developing a more flexible and appropriate model of mathematical play that can inform design of environments and activities across age groups, content, and context.

Keywords: Instructional activities and practices; Design experiments; Technology

Mathematical play has a fairly short history, with strong roots further back in time (e.g., Papert, Montessori). The majority of research on this topic stems from early childhood research on play and researchers have begun to identify the mathematical play children naturally engage in during open-ended play activities and explores how to further mathematize that play and the consequent learning (see Wager & Parks, 2014, for a review). In addition, researchers have explored how mathematicians in the course of their work engage in mathematical play (e.g., Holton, Ahmed, Williams, & Hill, 2001). Given that young children and mathematicians both engage naturally in mathematical play, there is an intriguingly underexplored area of promise between those two populations. A small number of researchers have examined how to support students in approaching mathematics problems with a playful bent (e.g., Steffe & Wiegel, 1994; Holton et al., 2001), but understanding the role of mathematical play from early childhood to adulthood is, as yet, unmapped.

Following the success of our initial working group at PME-NA 2018, we reached out to new collaborators who will be conducting the activities this year. Our goal is to continue providing a community space to explore and discuss mathematical play broadly, which requires that we extend into new mathematical play activities. In 2018, we had a different focus each day: early childhood mathematical play with wooden blocks (Reimer); middle-school mathematical play with touchpad games (Williams-Pierce); and undergraduate mathematical play with Rubik's cubes (Plaxco). This year, our three foci are: mathematical play in informal makerspaces (Simpson); intellectual playgrounds (Sinclair and Guyevskey); and mathematical play professional development with teachers (Burke and Orrill).

Our goal for the second instantiation of this working group is to continue facilitating mathematical play experiences and discussions around open research questions that transcend our individual lines of research, such as:

- What is the nature of mathematical play across the age/grade bands?
- What are the features, characteristics, and affordances of mathematical play?
- How might context (e.g., physical, digital) influence mathematical play?
- How might content (e.g., fractions, group theory) influence mathematical play?
- How might factors such as gender, race and ethnicity, and parental income/education level influence experience of and access to mathematical play?
- How are mathematical play and mathematical learning related?
- How does mathematical play influence problem solving?
- How do mathematicians (experts) engage in mathematical play, and how might that mindset be fostered for learners (novices)?
- When might a didactical introduction to the content support more productive mathematical play?
- How might mathematical play support or influence learning in other disciplines (e.g., a broader STEM perspective)?

Although answering all of these is beyond the scope of possibility for our working group, we will use these questions to facilitate and orient discussions during each of the three days, and as potential topics for future collaborative investigations. In order to ground the discussions, we will facilitate a mathematical play experience each day, then guide the discussion towards the mathematics at play (pun intended) and the specific characteristics of that mathematical play. During these group discussions, we will regularly orient the conversation specifically towards the open research questions listed above. We will take notes during these conversations and conclude each session by collecting names and emails of working group attendees.

Definitions of Mathematical Play

There are numerous definitions of mathematical play, each emerging from different contexts and with students of different ages. Contexts can range widely, such as digital (Steffe & Wiegel, 1994; Williams-Pierce, 2016, 2017; Sinclair & Guyevskey, 2018), physical (Sarama & Clements, 2009; Simpson, this submission), or paper and pencil-based (Holton et al., 2001). One of the crucial open questions that we highlighted in our discussions at the first working group that we plan to continue discussing is how the definitions may vary in features they prioritize due to the differing contexts. For example, might Holton et al. (2001) and Williams-Pierce (2016) find common ground if they examined similar contexts? Or are their approaches too fundamentally different to ever come to agreement? Or how might Reimer's wooden block activities with young children relate to Plaxco's Rubik's cubes work with undergraduates learning about groups? How might all these examples of play compare to what mathematicians do? We strive to ensure that each session of the working group is oriented around a specific definition and operationalization of mathematical play, so that attendees have concrete experiences grounded in different definitions to facilitate discussion across these different frameworks.

In the below sections - Retrospective (about our initial working group in 2018) and Working Group Schedule and Activities (where we outline the plan for this year's working group) - we describe in more detail our definitions of mathematical play along with activities they inspired.

The History of This Working Group

As mentioned above, this proposal is for a second year of the mathematical play working group, following the success of our first at PME-NA 2018 (Williams-Pierce, Plaxo, Reimer, Ellis, & Dogan, 2018), where we had about 30 attendees each day - most returning each day. We followed the same approximate format for each session: Frame - a brief introduction to the theoretical grounding of that day's topic; Play - a mathematical play activity in order to ground the discussion in a common experience; and Discuss - a broad discussion of the activity, the theoretical underpinnings, and implications for designing and understanding mathematical play and learning. Importantly, we had found in previous working groups (e.g., Nathan, Williams-Pierce, et al., 2017), that beginning with a relevant activity quickly develops fruitful discussions between participants - especially given that working groups tend to have a variety of attendees with wide-ranging expertise in the topic - so we considered the Play component of our format to be crucial for grounding the discussion in shared experiences. One of the crucial goals for our working group was - and is - to ensure that every attendee actually *experiences* mathematical play, and we were delighted that during the 2018 sessions, considerable laughter emerged from our assigned room. However, it is important that we also emphasize the richness of the discussions about mathematical play and learning that emerged alongside the laughter.

The first author was bemused by some of her conversations with PME-NA attendees who did not attend the working group, who often asked, "Are you just playing in the sessions?" An implicit attendant to this question is, "Are people *learning* anything in your working group?" In our retrospectives below, we describe the activities and the discussions that took place, but we would like to take this opportunity to answer this question head-on. First, in order to understand and discuss the role of mathematical play in mathematical learning, we must *experience* what mathematical play feels like. Second, we posit that many PME-NA attendees regularly enjoy their experiences with mathematics, and consequently often engage in some type of mathematical play already in their daily professional lives. Then, discussions about mathematical play can help attendees develop language in order to explicate their own experience with mathematics, and consider new ways in which to introduce elements of mathematical play in their own work with learners. Third, discussion and collaborations that emerged from the relationships established in the working group give empirical evidence that attendees were already considering how play might be infused into mathematical learning - we know of at least four different partnerships that have emerged as a direct consequence of this working group.

Here, we give succinct descriptions of the activities and discussions that occurred in each session last year.

Retrospective - Day 1 (Reimer)

Frame. The first session began with a brief background on early childhood play that highlighted the spontaneous and emergent nature of early play. We focused this session around early childhood play frameworks that emphasize child agency through spontaneous interaction, choice, and opportunities for repeated trials (Wager & Parks, 2014). Because attendees would be engaging in exploratory play in solo and collaborative forms, we also drew on conceptualizations of play that suggest players use novel ways to generate norms, players create new rules in contextual ways to continue play, and play continues through the creation of new meaningful constraints (Di Paolo, Rohde, & De Jaegher, 2010).

Play. We distributed colorful nontraditional pattern blocks (e.g., a mix of both concave and convex hexagons) to participants and encouraged them to begin with individual construction or puzzle play to explore the characteristics of the blocks. We asked them to pay attention to any material constraints that contributed to the ways they developed norms in their individual play. Then we asked attendees to orient each other to their play by explaining their norms and sharing their constructions. This led to opportunities for negotiated play in which participants joined each other in coordinated constructions. Finally, we asked participants to form small groups and bring their shapes together into one as an example of an intertwined sense-making activity. Participants circulated the room and shared the ways their groups had coordinated their play, pointing to specific aspects of their constructions that were made possible by constraints, unexpected possibilities, or the breaking of their established rules.

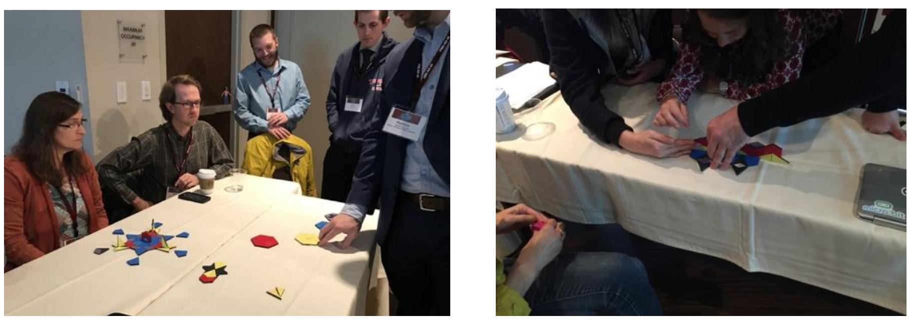

Figure 1: Attendees Orient Peers to Their Play (left) and Negotiate Coordinated Play (right)

Discuss. We offered several questions to guide participants' discussions after their play experiences, including what mathematics learning opportunities emerge in children's play, and how can teachers support children's mathematics learning without disrupting play? Discussions around these questions centered on the role mathematical properties of the blocks played as constraints in construction play. One aspect of these blocks is that they are stable enough to allow construction in an upwards direction (such as in Figure 1), which a small number of participants noticed and then spread to other participants in the room. Participants also noted productive tensions between self-direction in mathematical play and the ways norms and rules of play are emergent and negotiated. For example, one group had a long discussion about their differing views of using symmetry as a design tool - most group members were striving specifically for a fully symmetric shape, while another group member went so far as to (playfully) hide a piece in order to prevent symmetry from being achieved.

Retrospective - Day 2 (Williams-Pierce)

Frame. This session began by defining mathematical play as *voluntary engagement in cycles of mathematical hypotheses with occurrences of failure*, and introducing five features of digital contexts that support mathematical play: (1) consistent and useful feedback; (2) high enough levels of difficulty and ambiguity that players experience frequent failure that is closely paired with the feedback; (3) non-standard mathematical representations and interactions; (4) mathematical notation introduced late or not at all; and (5) the legitimate possibility of alternative conceptual paths for successful progression (Williams-Pierce, 2017; Williams-Pierce & Thevenow-Harrison, in revision). This framework emerges from a blend of scholarship on mathematical learning and videogames research, the latter of which has embraced the conceptualization of *failure* as an important and often enjoyable experience within the realm of gameplay (e.g., Juul, 2009; Litts & Ramirez, 2014), which highlights the importance of a non-threatening environment where mistakes are perceived as natural and appropriate.

Play. We paired attendees and distributed iPads with *Dragonbox 12+* by WeWantToKnow (a commercial learning game that focuses on balancing equations) and a variety of other mathematics learning games. We chose *Dragonbox 12+* for three reasons: it instantiates four of the five features above, and at least partially instantiates the remaining feature, #2; it is highly popular (over a million downloads worldwide, and a *Wired* article that touted the original game's release; Liu, 2012); and because two of the authors (Williams-Pierce and Ellis) had strongly divergent views about how mathematical the play in *Dragonbox 12+* actually is. Figure 2 shows a screenshot of *Dragonbox 12+* and attendees at the working group playing the game together.

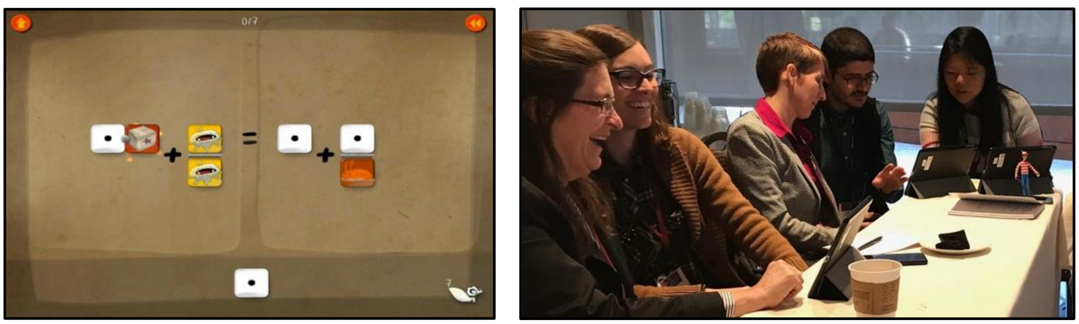

Figure 2: *Dragonbox 12+* (left) and Working Group Attendees Playing Together (right)

Discuss. To support attendees in analyzing their play experiences, we developed broad guiding questions: (1) Where's the math? (2) Where's the learning? (3) Where's the play? Did you experience *voluntary engagement in cycles of mathematical hypotheses with occurrences of failure*? (4) Does the game have all five features for supporting mathematical play? Paired players discussed the game and these questions as they played *Dragonbox 12+* and the discussions grew naturally into larger groups until we were all debating together as a single large group. The primary group discussion focused on the idea of target content - that is, we discussed how the game designers' intended outcomes may differ from the intended content goals of the individual instructor. One insight that developed was that we need to reframe our discussions about mathematics games from "What math games are good?" to "What games are good for *x*?" where *x* represents a specific learning goal or mathematical behavior. For example, while it may be easy to dismiss many mathematics games as digital versions of flash cards, some instructors may have learning goals that involve practicing math facts - and consequently, in that context, digital flashcards can be a good game. We also discussed how the intended learning goals of designers may not be accomplished - for example, while *Dragonbox 12+* was enjoyable for most attendees, there was debate as to whether the game actually teaches the balancing of equations as intended. To that end, we discussed ways in which games that use innovative interactions and representations can be bridged into more formal and rigorous mathematical learning.

Retrospective - Day 3 (Plaxco)

Frame. The Rubik's cube session began with an introduction to the history of the cube, a discussion of some rules governing the cube's movement and arrangements, and an overview of how to communicate moves on the cube (for examples, see Figures 3 and 4). Because research in this area of mathematical play is less developed and we anticipated our participants' unfamiliarity with solving the cube, we focused on first engaging the participants in play intended to support later discussion of the possibilities for educational research.

This play was more structured than the previous days' free play. Given the nature of Rubik's cubes, and how quickly new players can lose their place (mix up the cube), we opted to scaffold working group participants in their interactions by providing simple goals that still supported open-ended playfulness and also provided safety in "failure" to keep the cube solved. The purpose of this variety of structured play was to move participants beyond the typical singular (and often daunting) goal of solving the Rubik's cube in order provide them with alternative goals that would begin and end with the solved cube and other goals that participants could work toward from an unsolved cube. This supported a discussion of how using artifacts of play in alternative ways can open opportunities for creativity and improvisation in play.

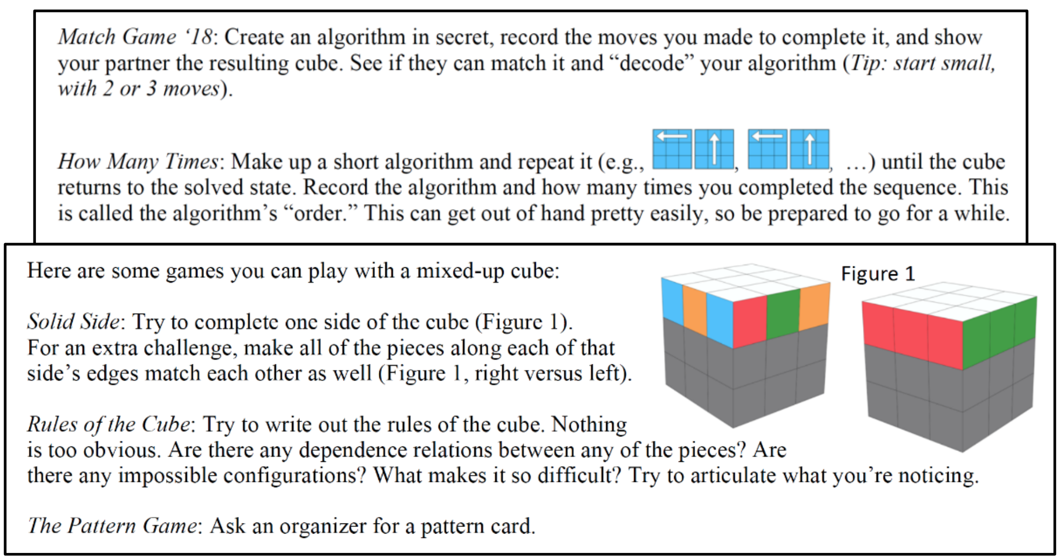

Figure 3: Structured Play Beginning and Ending with a Solved Rubik's Cube

Play. We distributed 50 solved 3x3x3 Rubik's cubes to the working group participants, who engaged in a number of types of structured play. We guided this play with use of a handout that provided a list of games that begin (and hopefully end) with a solved cube (Figure 3, top) as well as some that drew on the likelihood of the participants' eventual mixing up of the cube during the first type of organized play (Figure 3, bottom). Throughout this time, the organizers of the working group walked around to engage with participants as they explored the Rubik's cubes. Very fortunately, a few of the participants happened to have experience solving Rubik's cubes, which allowed for some "safety" in the other participants' *failure* to keep the cube near a solved state. This occurred when participants "lost track" of the moves that they needed to make relative to the moves they had already made. Initially, we had planned to incorporate iPads in the activity so that partners could record each other to help keep track of moves. However, we decided that we could forego this by incorporating tasks and games that could be completed on unresolved cubes. Specifically, we included a "Pattern Game" that tasked participants with matching a face of the cube to an image on a small, numbered card. These cubes were then collected with the cards and used to construct a mosaic (Figure 3, bottom) that read **PME NA 2018**!

Figure 4: The Last Remaining Working Group Participants with a Rubik's Cube Mosaic

Discuss. During the discussion portion of the third day, the organizers brought up a few themes that had continued to emerge throughout the sessions. For instance, the group tried to elaborate on what aspects of the Rubik's cube made play with it mathematical. This included a distinction between an intended content focus of mathematical play and a practice focus of mathematical play. For instance, the Rubik's cube exemplifies the mathematical structure of an algebraic group. However, for many K-12 students who are interested in cubing, the formal construct of a group is unnecessary to engage in and develop their own mathematical practices of problem solving, communicating, generalizing, and reasoning structurally that play with the Rubik's cube can afford. This conversation supported a more general discussion about the values that educators have when focusing on students' mathematical play, specifically the need for an awareness of our focus on content and practices as we develop mathematical play spaces.

Working Group Schedule and Activities

Each day will focus specifically on a different approach to and definition of mathematical play. Day 1 will focus on mathematical play and making by 3rd to 5th graders across formal and informal environments (Simpson); Day 2 will focus on intellectual play within mathematical microworlds (Sinclair and Guyevskey); and Day 3 will focus on mathematical play in teacher professional development (Burke). While each session has distinct differences in their definitions of mathematical play and approaches to fostering such play, there are commonalities across the sessions. For example, the art produced by the Art Bots on Day 1 have distinct similarities to the mathematical microworld focused on in Day 2. Day 2 and Day 3 both highlight the use of open-ended microworlds for supporting mathematical play, although the microworlds focus on different types of content (geometry versus ratio and proportion). By concluding the working group with a session on teacher professional development, we hope to foster conversations about how to support both others and ourselves in fostering mathematical play experiences.

Day 1 Session – Following Williams-Pierce (2016)

The first session will focus on Dr. Simpson's preliminary research on mathematical play of 3-5 graders in making and tinkering contexts across formal and informal learning environments. As such, building upon the scholarship of Williams-Pierce (2016), mathematical play is defined as *voluntary engagement in cycles of mathematical hypotheses, wonders, and curiosities that lead to or stem from occurrences of failure*. Making and tinkering is not a new phenomenon but involves youth in the process of designing, constructing, testing, and revising of physical and/or digital products for play or for purpose. It involves the use of a variety of materials and tools such as low-tech (e.g., conductive tape), high-tech (e.g., 3D printers), household items (e.g., cotton balls), and recyclable material (e. g., yogurt containers). Scholarship on making and tinkering contexts has illustrated youths' engagement in "experimental" play as scientists and engineers (e.g., Simpson, Burris, & Maltese, 2017), but less is known regarding youths' play as mathematicians in such contexts (Pattison, Ruben, & Wright, 2016).

The session will begin by engaging participants in a making activity – participants will make an Art Bot that draws a hands-free art piece (see Figure 5). During and after this activity, we will guide discussions about how (and if) participants felt their experience involves mathematical play. For example, was mathematical play a genuine part of their making experience or did it seem like an add-on or an outlier to their experience? Did mathematizing happen during play, or only afterwards, when we engage in overt discussions about mathematical play? If the latter, can we trace the mathematics brought up afterwards back to the play, to see how the play provoked our own mathematizing and consequent play? We will particularly focus on the role of failure in their experiences of mathematical play, given Simpson's previous work examining failure episodes in makerspaces (e.g., Simpson & Maltese, 2017) and the emphasis on failure in Williams-Pierce's (2016) definition of mathematical play.

Figure 5: Example of an Art Bot (left), and the Resulting Art Piece (right)

Next, Dr. Simpson and Dr. Williams-Pierce will present episodes of how one youth's mathematical play in making and tinkering context span space (e.g., after-school program vs. home) and time. This is a dynamical view of youths' play, as opposed to a "flat" view, as we consider how mathematical play and the physical and abstract objects transcend time (time scales; Lemke, 2000) and environment (boundary crossing; Akkerman & Bakker, 2011). We will conclude this session by seeking feedback on our view of the ways in which mathematical play and learning can transcend contexts, and discussing future research possibilities.

Day 2 Session – Following Featherstone (2000)

The second session, conducted by Dr. Sinclair and Ms. Guyevsky, will focus on Featherstone's (2000) *intellectual play*. Drawing on the work of Huizinga, Helen Featherstone (2000) argues for the central importance of what she calls "intellectual play" in mathematics learning. She finds many parallels between the characteristic features of play and the way mathematicians work. After having observed her students in an elementary classroom engaged in serious mathematical activity in a manner she described as “math in the ludic zone”, Featherstone wondered whether we could help children see mathematics as an arena for play. She is not arguing that play and mathematics are identical, nor that teachers should include play periods as part of their mathematical lessons; instead she is interested in “the moments in which doing mathematics becomes playful and about the ways in which play might expose children to aspects of the discipline that may not ordinarily be visible to them” (p. 16).We conjecture that certain well-designed and open-ended computer-based environments might be especially effective at providing “playgrounds” or mathematical microworlds in which play can occur. As participants engage in playful activities, they will be invited to reflect on how such play might free learners “from the dictatorship of concrete objects,” as Vygotsky (1933/1966) writes, and enable them to “develop the capacity to behave in accordance with meaning” (p.19).

The Web Sketchpad version of *The Geometer’s Sketchpad* (Jackiw, 2012) will provide the digital context for intellectual play. In contrast with traditional definition of a game, the participants will not be offered a set of explicitly prescribed rules that the player has to abide by; rather, the rules of the “game” will be determined by the fixed geometric properties of the figures and communicated to the player via visual feedback as participants engage with the microworld. The player “wins”, if the outcome of the interaction is a robust dynamic construction that behaves according to the criteria of the assigned task. However, being “at play” is more of our focus here than “winning”, as we hypothesize that those participants who “lost” the game have nonetheless come a step closer to understanding a certain geometric concept. We chose a dynamic geometry environment because it offers various modes of feedback that can enable students to experiment, test conjectures and debug without having to appeal to an outside authority, which we think is a crucial aspect of enabling play (Sinclair & Guyevskey, 2018).

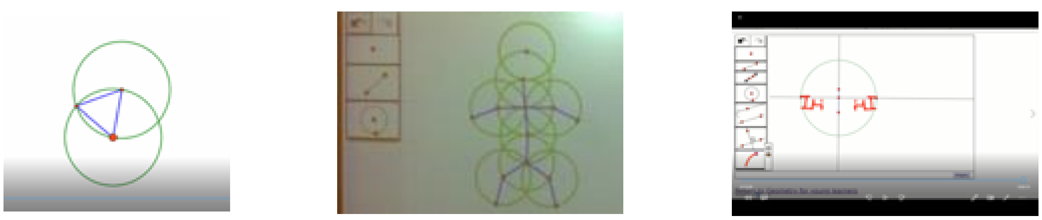

Figure 6: Regular Polygons (left), Stickman (middle), and Mirror Machine (right).

Participants will be asked to engage in computer-based mathematical tasks in which they will explore geometric concepts and relations, and model mathematics in contextualized experiences. Activities will be carried out in pairs. Participants will be offered three different tablet-based activities that are potentially relevant to play. These activities will vary in the level of difficulty, i.e., the geometric relationships involved in a task will range from less to more complex. A progression of tasks will focus on regular polygons, properties of a circle, and the concept of symmetry. In Task 1, Regular Polygons, participants will construct a variety of shapes, beginning with an equilateral triangle, and then gradually tessellating with that triangle to construct a rhombus, regular trapezoid, and regular hexagon (Figure 6, left). In Task 2, Stickman, participants will be asked to construct a stickman in such a way, that the arms are equilateral, and the legs are equilateral. As extension, equilateral fingers could be added, as well as neck, knees and elbows. Participants will need to accommodate for the stickman's ability to grow limbs while maintaining their congruency (Figure 6, middle). In Task 3, Mirror Machine, participants will be shown a picture of Leonardo da Vinci mirror-writing machine that he designed to encode his writings, and then shown a dynamic version of such a machine in web sketchpad. They will be invited to create such a machine themselves (Figure 6, right).

Day 3 Session – Following Burke (2017)

The third and final session, conducted by Dr. Burke and Dr. Orrill, will focus on mathematical play in teacher professional development. Dr. Burke will coordinate an exploration of the environments and tasks of Dr. Orrill's Proportions Playground project. This approach to professional development relies on engagement with digital "toys" designed by Dr. Burke and Dr. Orrill to encourage participants to "play" with mathematics to strengthen their understanding of important aspects of ratio and proportion. The toys we'll be playing with in the workshop were designed to be explored, requiring us to conjecture, justify, and explain as we collaborate. We will focus on using the Bars Toy, which is built around a relatively simple browser-based simulation of two bars of interdependent length that can be edited by dragging. In the PD and in the working group session, we will use three separate scenarios to provide contrasting mathematical relationships that will elicit discussions in which mathematical language and ideas are valuable to differentiate among them.

For our purposes, we define playing with math to mean engaging teachers in problem solving in a way that relies on making and testing conjectures and mathematical arguments that can be reasoned about, tested, illustrated, and explained through the use of dynamic tools. In order for this play to occur, an environment (including the toys and the implementation of the PD) has to allow for playfulness. It has to exist as a space where participation - and consequently play - is a safe activity. We use language and norms to lower the stakes of participation, and provide activities that teachers can immediately explore and use to form conjectures (Burke, 2017).

Central to the goal of our PD were three key ideas of proportionality: quantity, constant, and covariation. When we talk about proportional situations, what quantities do we refer to? What do we identify as remaining constant? How do we, and do we, use covariation to make sense of proportion? As Sutherland and Balacheff (1999) have written, students must learn to use the language of algebraic thinking in order to develop algebraic ways of solving problems. While teachers have shown themselves to be adept at cross-multiplying missing value problems, we want them to be able to see a ratio as a comparison between two quantities (Lamon, 2007). In particular, we want them to be able to talk to students about proportional situations as ones in which "the ratio of one quantity to the other is invariant as the numerical value of both quantities change by the same scale factor" (Lobato & Ellis 2011, p. 11). To this end, we developed a PD in which rich discussions about proportional situations can take place, allowing teachers to use their knowledge of proportion together with the key ideas we emphasize.

In this session, after facilitating a mathematical play experience with the Bars Toy, we will highlight some of our unexpected findings or struggles from our PD research, and foster a discussion that feeds into our re-design plans. In particular, we plan to use this opportunity to both share our work on mathematical play with teachers, and to gain insight from a community of deep thinkers about mathematical play in order to further our ongoing PD design. Our broad discussion questions will revolve around the relationship between mathematical play and learning for teachers, and how can support teachers in bridging from their own experiences of mathematical play in the PD to fostering such play with their students.

After Dr. Burke's group activity, we will conclude the working group by discussing our experiences across each of the three days. In particular, we will focus on the three mathematical play approaches emphasized on different days, and how the differing contexts and content may have influenced the development of these approaches, following the open research questions identified above. We will seek to find threads of common ground that will assist in developing a more flexible and appropriate model of mathematical play that can inform design of such environments and activities across age groups, content, and tools. Finally, we will conclude by identifying next steps for the working group members, as outlined in the following section.

Future Plans

In order to establish clear next steps at the working group, we will investigate potential NSF conference proposals in advance, and share a draft submission action plan with attendees, with the goal of collaboratively conducting a workshop that draws across different areas of mathematical play expertise, in order to begin productively synthesizing the phenomenon.

In addition, this working group will continue establishing a network of support for designing and examining mathematical play at all ages. To that end, we will continue curating the listserv we established after last year's session, so that attendees find it convenient and simple to continue the pattern of fruitful collaborations that the first session spawned.

This Working Group builds on the accomplishments of the Working Groups in 2015, 2016, and 2018. We will continue considering multiple aspects of research and practice related to mathematics learning and teaching with English Learners. Our goals for the 2019 Working Group include: (1) sharing an opportunity to publish empirical research related to mathematics and English learners; (2) identifying additional venues for dissemination of mathematics education research on English learners, including novel outlets that connect research to practice; and (3) developing and refining the work that will be shared. In Session 1, the organizers will engage participants in a structured sharing and offer feedback using a protocol. During Session 2, we will engage in a second round of co-working to improve our developing empirical studies. In our final day of the Working Group, we will discuss alternative outlets for sharing our work. We will close with time to review group progress and discuss next steps for our collective and individual work.

Keywords: Equity and Diversity

Introduction/Rationale

English Learners (ELs) are the fastest growing group of U.S. students (Verplaetse & Migliacci, 2008). U.S. schools have seen an increase in the percentage of ELs in all but 10 states between 2000 and 2015 (National Center for Educational Statistics [NCES], 2017). This increase in the population of ELs has created a need for schools and teachers to create inclusive and equitable mathematics classrooms. No longer is supporting ELs a concern only for educators in states like Arizona, Texas and California with traditionally high numbers of EL students. With all but 15 states across the country seeing increases in their EL populations between 2004-05 and 2014-15 (NCES, 2017), there is growing nationwide pressure for support in addressing the needs of these students. (Figure 1).

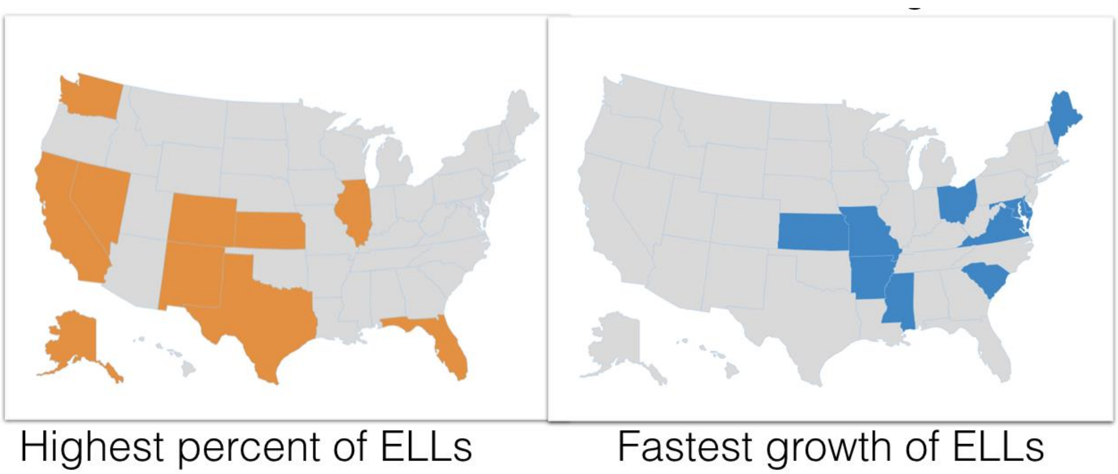

Figure 1: The 10 states with the highest percent of ELs in 2016 (left) and the 10 states with the fastest growth in EL population (right). (Source: National Center for Educational Statistics) https://nces.ed.gov/programs/coe/indicator_cgf.asp

This year, our Working Group aims to look backward to synthesize research related to the mathematics education of ELs, while also looking forward to consider new opportunities to publish research in the field. We will focus on the question: How can we produce empirical research that addresses gaps in the literature related to the mathematics education of English Learners?

In looking back at research that the field has completed, the organizers will share insights from a recently completed a literature review of research on ELs and mathematics education (de Araujo, Roberts, Willey, & Zahner, 2018). We will also discuss the political landscape in relation to this work, as we acknowledge the sociocultural and political dimensions of mathematics, school mathematics, and the complex intersection of language(s) culture and mathematics in multilingual settings (Gutiérrez, 2013). There is still much work to be done; some contexts and critical dimensions of the question of how best to educate English learners in mathematics remain unexamined. During this meeting of the working group, we will look forward as a group to continue to contribute to the field and to consider the contexts, dimensions, and work that still needs to be done related to ELs and mathematics education. The product of this Working Group will be a special issue in a research journal focusing on ELs in mathematics education, which features the empirical research discussed in this Working Group.

Brief History of the Working Group

The facilitators of this Working Group initially came to work together through the NSF-funded Center for the Mathematics Education of Latinas/os (CEMELA). CEMELA brought together researchers from across the country to collaborate on research focused specifically on critical issues related to Latinos/as in mathematics. Prior to CEMELA, researchers interested in such a focus worked mostly in isolation. In considering issues related to Latinos/as in US schools, issues of language and culture were central to CEMELA's work, which often had direct implications for ELs more broadly. While not all Latinos/as are ELs, and not all ELs are Latinos/as, these two groups have significant overlap. For example, about 80% of ELs speak Spanish as a first language, and Spanish-speaking ELs appear to struggle on measures of academic achievement (Goldenberg, 2008).

CEMELA expanded the field's knowledge of ELs in mathematics through conducting interdisciplinary studies that helped researchers and practitioners better understand the reality of Latinas/os and mathematics teaching and learning. CEMELA's research focused on teacher education, research with parents, and research on student learning, resulting in over 50 publications and presentations. Again, several of these studies involved the investigation of questions related to the interplay of language, culture, and mathematics education. CEMELA also had the goal of connecting the network of scholars focused on these issues, as a means to build capacity and sustain the work.

Following the conclusion of CEMELA's funding, Zandra de Araujo, Sarah Roberts, Craig Willey, and William Zahner continued to meet regularly. These meetings focused on examining intersections among these early career scholars' work related to the mathematics education of ELs. To date these meetings have resulted in a number of national presentations at the annual meetings of the National Council of Teachers of Mathematics, the American Educational

Research Association, and PME-NA. Currently, this group is working on several manuscripts and follow-up studies related to the preparation of teachers to work with ELs. Perhaps most notable is an extensive review of the international literature focused on mathematics and ELs (de Araujo et al., 2018).

The Mathematics Education and ELs Working Group met at PME-NA in 2015 (de Araujo et al., 2015), 2016 (de Araujo et al., 2016), and 2018 (de Araujo et al., 2018). At those meetings, we brought together a diverse group of about 30 researchers who started working together on several projects related to the mathematics education of ELs (see descriptions of these projects in the section below titled *Previous Work of the Group*). Our aim for the 2019 Working Group is to provide a space for these scholars to continue their work, to focus on producing and sharing products from our research, and to bring new scholars into the fold.

Previous Work of the Group

The 2015 and 2016 Working Groups (de Araujo et al., 2015, 2016) began with whole group discussions aimed at examining five aspects related to the mathematics education of ELs including: a) Student Learning; b) Family and Community Resources; c) Language Perspectives; d) Teacher Education; and e) Curriculum. In the following sections we briefly summarize our discussions and subsequent work in each of these areas.

Student Learning

Building upon situated and sociocultural perspectives (Moschkovich, 2002), the student learning group started from the premise that ELs, like all students, learn mathematics through a process of appropriating discourse practices, tool use, and perspectives of mathematics. In reviewing the literature on the mathematics learning of ELs, we have identified a need to better understand how research in mathematics education at large is connected with research on the mathematics learning of ELs. Much of the content-focused work in mathematics education is isolated from research on how ELs develop specific mathematical understandings. Previous discussions at this Working Group have supported ongoing research and development efforts focused on bridging the literature on supporting ELs in mathematics classrooms and the literature on students' mathematics learning through focused instruction.

Family and Community Resources

Families and communities can serve as resources for ELs in their mathematics learning in myriad ways. Families can advocate for their children and provide and support learning experiences both in and out of the classroom. Communities can also provide a wealth of support mechanisms and learning possibilities. Moll, Amanti, Neff, and Gonzalez (1992) described how students studied candy making and selling within their neighborhood to explore mathematics within this context, such as discussing and analyzing production and consumption. In doing so, the teachers and students acknowledged the value of these community experiences. Additionally, Civil and Bernier (2006) explored the challenges and possibilities of involving parents in facilitating workshops for other parents around key math topics. These studies and others like them illustrate the promise of family and community resources in fostering ELs' mathematics learning. At our 2015 meeting, Civil shared her recent work on how school language policies impact ELs' engagement and how teacher educators can draw on family and cultural resources in support of ELs. We followed up on this work during our 2016 with small group discussions.

Language Perspectives

Teachers' and researchers' conceptions of language, second language acquisition, and bilingualism affect teaching and learning mathematics for ELs. In 2015, Judit Moschkovich shared her work, highlighting how perspectives of language, second language acquisition, and bilingualism appear in both theory and practice. We also discussed, in particular, how work focused on ELs can draw on current work on language and communication in mathematics classrooms, classroom discourse, and linguistics. Looking for these intersections and connections was crucial, because it ensures that work in mathematics education is both theoretically and empirically grounded in relevant research, preventing researchers from reinventing wheels.

Teacher Education

Much of the prior work on teacher education related to ELs has focused on more general strategies (e.g., sheltered instruction, as in Echevarria, Vogt, & Short, 2007), such as using visuals, modifying texts or assignments, and using slower speech. We argue there is a need for content-specific support for mathematics teachers of ELs. At our previous meetings, we explored ways to support teachers, both pre-service and in-service, in better understanding students' strengths and meeting the needs of ELs in the mathematics classroom.

During the 2015 and 2016 Working Groups, the teacher education subgroup focused on the primary issues that arise in the preparation of teachers to teach ELs at the various institutions. As a group, we recognized that there were few attempts to include the teaching and learning of mathematics to ELs beyond the states where there was a high population of ELs. Given that some of the group members were meeting for the first time, a significant portion of the allotted time was spent sharing the details of the research we did and our interest in being part of this particular subgroup. One of the members shared a survey about examining preservice teachers' conceptions about teaching mathematics to ELs, and the other members agreed to administer the survey at their locations. Together, the responses could provide us with some insight about possible conceptions that need change and the steps we can take to make that happen. The group stayed in touch online and continued the discussions about potential collaborations.

Curriculum

In 2015, the curriculum subgroup focused on the role of textbooks, specifically teachers' guides and student work pages, in demonstrating how one might approach supporting ELs in building mathematical understanding and developing mathematics language. We inquired about the process publishers undergo to incorporate and offer support to teachers. What assumptions do they make? Who do they consult? What motivates them to invest in serving ELs better? What is/are their end goal(s)? The group decided to conduct an analysis of various middle grades curriculum to ascertain what supports and guidance are offered to teachers. It was suggested that we might build on the work of Pitvorec, Willey, and Khisty (2010), who explored the features of Finding Out/Descubrimiento (FO/D) that proved to be successful with bilingual children of migrant families in the 1980's and partially contributed to the development of complex instruction (Cohen, Lotan, Scarloss, & Arellano, 1999).

At the 2016 meeting, this group continued to examine textbooks to understand better the supports they provide for ELs. Participants considered language issues in mathematics texts for ELs, especially as related to word problems and assessment items. We shared a short literature review of relevant research on linguistic complexity and vocabulary for mathematics word problems. Based on that research, we summarized recommendations for addressing language complexity and vocabulary in designing word problems for instruction, curriculum, or assessment. We then used examples of released sample Smarter Balanced Assessment Consortium items to illustrate how to apply those recommendations to design word problems and to design supports for ELs to work with word problems. Several of the participants have continued this work examining curriculum accommodations for ELs and are completing a research study based on the work started at the 2016 Working Group.

2018 Working Group

The 2018 Working Group was an opportunity to share recent empirical work from members of the group and to provide participants with a chance to engage in discussions around data collection and analysis. During the first half of the working group, several members presented current research. For example, Erin Smith presented her work on curriculum supports for ELs in elementary mathematics classrooms. Marta Civil introduced the Working Group to the forthcoming National Academy's (2018) *English Learners in STEM Subjects* report, on which she had contributed. Sarah Roberts shared a framework she and a colleague have developed for supporting ELs that they use in their content methods course. Such presentations represented topics from a variety of researchers who conduct research across the spectrum of grade bands and contexts of research previously mentioned. Zandra de Araujo wrapped up these presentations by sharing an overview of the findings of the literature review of de Araujo et al. (2018). These presentations provided an overview of a variety of research taking place in the field around English learners and mathematics, and with the literature review presentation and the National Academy report, some of the research that is currently lacking.

The second half of our 2018 Working Group was dedicated to a *data dive*. In the first part of the activity, participants learned about Bill Zahner's NSF CAREER study. He then introduced the group to a framework he has developed for linguistic and mathematical demands (Zahner, Milbourne, & Wynn, 2018). The group used this framework to analyze a task and interviews from his study, entering into the *data dive*. The Working Group considered transcripts, the accompanying audio, student work, and the original task.

Sharing this existing work along with participating in the data dive engaged the Working Group in conversations around data. Our discussions and activities during the 2018 Working Group allowed us to model and to discuss analysis and data collection. Now members of the Working Group have works in progress that they are getting ready for dissemination. In 2019, we will focus our efforts on dissemination, providing structured time together for improving the products of our research. Between March 2019 and November 2019, the Working Group organizers will be proposing a special issue to journal editors to lay the foundation for this group publication.

Aims for the 2019 Working Group

Previous meetings of this Working Group have brought together a large and diverse group of attendees. For example, in 2016 there were approximately 30 attendees including teachers, preservice teachers, researchers, graduate students, and teacher educators from a range of institutions. In 2018, the Working Group attendees included experienced leaders in the field, mathematics education faculty with experience in the topic of English learners in mathematics who were still at the early stages of their careers, and graduate students and faculty who were new to the topic of English Learners in mathematics. During the 2018 meeting, we successfully shared some of our existing and in-progress research in the form of presentations. For the 2019 iteration of this Working Group, we propose to narrow our focus and to home in on the goal of producing high-quality scholarship in widely accessible venues. Our goals for the 2019 meeting include: *(1) sharing an opportunity to publish empirical research related to mathematics and English learners; (2) identifying additional venues for dissemination of mathematics education research on ELs, including novel outlets that connect research to practice; and (3) developing* *and refining the work that will be shared.* The goal for 2019 will be realized through specific activities and interaction formats. These activities include: (1) structured time for participants to share their existing work; (2) structured feedback protocols through which participants can offer constructive feedback with the goal of advancing the quality of our research, and (3) concrete discussions of timelines and plans for publication of our work in a refereed journal as well as alternative forms of dissemination.

Plan for the 2019 Working Group Sessions

During the three sessions in 2019, participants will engage in collaborative efforts related to dissemination and the production of research based on the prior research of Working Group participants. Each meeting of this Working Group at PMENA will have a narrow focus. Prior to the Working Group, we will contact past participants and invite them to come to the 2019 Working Group with a paper in progress for discussion and feedback sessions. We will also send out an email to the PMENA list-serv and offer this as an option to new participants, to capture individuals who may be working on papers and would fit in the session.

Participants who wish to receive feedback on their manuscripts in progress will be asked to upload draft work ready to be shared and workshopped in a working group format before the first meeting. Aware that some members will be new in 2019, we will invite new members to join in the shared writing and editing efforts using Google Docs or a similar tool to share files as appropriate.

Session 0 (Pre-PME-NA): Propose Special Issue & Virtual Study Group

The summer before PMENA 2019, we will propose two special issues on ELs in mathematics to peer reviewed journals. One issue will be written for a research audience and the other will address teachers. We will also build momentum for the working group before the PMENA meeting by organizing a virtual study group in which potential Working Group members can participate. Over the course of six sessions, we will meet monthly and organize a study space around translanguaging in mathematics classrooms. The group will be open to anyone who is interested in learning more about translanguaging to inform their teaching and/or scholarship. This will also allow us to provide an introduction to the special issue and possible contributors.

Session 1: Introductions and Brief Reports

The initial session will include some time to allow participants to meet fellow attendees and to share current perspectives on extant research related to mathematics and English learners. The organizers will present a brief report on the outcomes of prior working groups. Then we will share goals for this year's iteration of the Working Group. After this preliminary step, we will devote a substantial amount of time to sharing and workshopping three manuscripts that are close to completion.

Activities

- Brief (re)introduction to the Working Group.
- Sharing of 3 papers by potential contributors to the special issue.
- Structured feedback to authors.

The structured feedback will happen in small groups. Participants in the Working Group will be divided into groups and invited to read an excerpt of each authors' work and then offer constructive feedback that can be used to refine the manuscripts in development. Feedback will be structured to maximize the probability that the feedback is useful to authors. Guiding Questions for the feedback will be:

1. What does this paper add to the literature on mathematics education and English learners?
2. Are the frameworks (theoretical and conceptual), research questions, methods, analysis, and claims aligned? If not, how can the author bring these elements into alignment?
3. Are the discussion points illuminating in relation to the literature review and the existing state of knowledge in this field? Is there anything that should be added to the discussion to make it more powerful?

At the end of session 1, the authors who will be sharing work in session 2 will give a brief (1 minute) precis of their work. Participants will be divided into groups and assigned to one author. The author will give these participants access to a manuscript in progress that they will read before Session 2.

Session 2: Continued Workshopping

Session 2 will have a structure similar to Session 1. In Session 2, three more potential contributors to the special issue will share their work. This will follow a format similar to the format of Session 1: Each potential author will give an overview of their work in the form of a short Powerpoint. Then the Working Group will divide into subgroups in which the members of the Working Group provide structured feedback to authors.

We will conclude Session 2 with an overview of some of the general themes of the articles and the feedback that authors are receiving. This work is twofold. First, it helps to begin to organize the special issue topically. Second, it helps the authors to consider some of the major feedback that authors are receiving and how that might support their writing moving forward. What are some of the missing pieces across the manuscripts? With what are authors conceptually struggling? How can we make our methods stronger to make arguments stronger? These conversations will help us wrap-up our second day.

Session 3: Consider Alternative Modes of Sharing Work

Aware that much of our work winds up in journals that are only read by other researchers, on Day 3 of the Working Group, we will convene a discussion of potential alternative modes of sharing the work we produce. We will consider the following outlets: video exemplars, blog posts, op-eds, apps, curriculum production/development, professional development. We will invite a panel who has completed such work to share their experiences, challenges, successes, and suggestions. This will take the first half of the last day of our Working Group.

During the last half of our final day of Working Group, we will create a timeline for our collective and individual next steps of the special issue and for participants' individual manuscripts.

Follow-up Activities

We anticipate that this Working Group will again attract other researchers interested in issues related to the mathematics education of ELs. Therefore, an important component of this fourth meeting of the Working Group will be to maintain current relationships while also continuing to establish connections with other interested researchers in order to build opportunities for future collaborations. We will provide space for new researchers to contribute to our collective work, to suggest new directions, and to add to the growing body of research on mathematics and ELs. At the first session of our Working Group, we will share our ongoing online Google Community, which uses Google applications (Hangout, Groups, Drive, etc.). Google's applications are freely available and allow for a number of collaborative opportunities, including video conferencing, group messaging, collaborative document development, and shared web and social media space. Through this collaborative Google Community, we have organized follow up meetings both virtually and at conferences such as TODOS and the NCTM Research Conference.

Our long-term goal is to publish a special issue on ELs and mathematics. We hope to take the articles that are workshopped during Working Group 2019 and continue to work with participants to develop a full-fledged special issue. We currently plan to co-edit two special issues in two different journals: *TEEM (Teaching for Equity and Excellence in Mathematics)* and *Qualitative Studies in Education.* This work will be the culmination of four PME-NA working groups and can provide a product of the work from bringing individuals together who are committed to completing work around ELs and mathematics.

Students' construction, coordination, and abstraction of units underlie success across multiple mathematics domains. Structures for coordinating units underscore notions of numbers as composite units (e.g., five is a unit of five and five units of one). In this working group, we seek to facilitate collaboration amongst researchers and educators concerned with units construction and units coordination. The aim for this working group is two-fold: (1) to extend our research around units construction and coordination to new grade levels; and (2) to collaborate with researchers who investigate students with learning differences in school settings to determine diverse students' mathematics learning trajectories.

Keywords: Number Concepts and Operations, Learning Trajectories, Learning Theories

In Steffe's 2017 plenary for PME-NA, he substantiated particular needs for investigating how children develop operations when constructing and coordinating units. The Complex Connections: Reimagining Units Construction and Coordination working group began at PME-NA 2018, with the aim of facilitating collaboration amongst researchers and educators sharing Steffe's concerns about units construction and coordination for all learners. The main goals of the working group are to extend research around units construction and coordination to new grade levels and to facilitate collaborations with researchers who investigate students with learning differences in school settings to determine diverse students' mathematics learning trajectories. We frame this proposal to continue this working group by first providing a background about units construction and coordination. We next describe our progress toward meeting our goals stemming from our inaugural meeting. Lastly, we describe our goals and plans for continuing this work at PME-NA 2019.

Background and Theoretical Perspective: Composite Units – Old and New

We provide a theoretical background for units construction and coordination, focusing on the role of units coordination in students' number sequences (Steffe, 1992), multiplicative concepts (Hackenberg & Tillema, 2009), and fractions schemes (Steffe & Olive, 2010).

Units Construction and Coordination

Unitizing, or setting an object (a unit) aside for further action or activity (Steffe, 1992), is the basis for units construction. Students initially rely on concrete, pictorial, fingers, symbolic numerals, and language to evidence internalized (being able to mentally re-imagine contextual actions) or interiorized (being able to draw on de-contextualized actions) actions. Consider the construction of additive reasoning as an example. When considering how to add eight and seven, students might not yet see the cardinality of eight, counting a set of objects to create eight, then another set of objects to create seven, and finally combining the two sets, beginning at one to quantify the total. Should students see the cardinality of eight, they might use it as an input for solving the problem. They will count on from eight, using objects (cubes, fingers) to keep track of the addition (e.g., 8…9 [raises a finger], 10 [raises another finger]…). The double counting involved in this activity (e.g., 8…, 9 (1), 10 (2), 11 (3), 12 (4), 13 (5), 14 (6), 15 (7)) promotes a coordination of the start value and the stop value. That is, eight, seven, and 15 are taking on some meaning as composites (8 and 7) and a unitized whole (15). Evidence of this meaning includes the breaking apart of one or both of the numbers to arrive at the total (e.g., 8 is 5 and 3; 7 is 5 and 2; 8 + 5 is the same as 5 + 5 + 3 + 2, or 15). This type of units coordination can be explained through the type of numerical sequence students produce and rely upon.

Number Sequence Types (INS, TNS, ENS, GNS)

Steffe and Olive (2010) described four different counting sequences that children may develop and evidence when solving mathematics tasks: (1) Initial Number Sequence (INS), (2) Tacitly-Nested Number Sequence (TNS), (3) Explicitly-Nested Number Sequence (ENS), and (4) Generalized Number Sequence (GNS). Each number sequence can illustrate stages of children's development of units coordination.

Initial number sequence. Steffe (1992) explained that children who segment and interiorize number sequences have developed Initial Number Sequence (INS). Children who develop an INS are characterized by their counting of single units and then their segmenting of a numerical sequence (evidenced through "counting on" activity). When children segment numerical sequences, they are interiorizing patterned templates for counting, which allows them the ability to count on from a composite unit (e.g., developing one composite unit to use when counting on, 4…5-6-7-8). Thus, through counting actions, numerical patterns are developed and become interiorized (evidenced through less reliance on sensory-motor experiences; e.g., verbalizing counts, using fingers, or tapping) before being segmented into a composite unit.

Tacitly-nested number sequence. Once children have developed composite units through their INS activity, they can begin to coordinate these composite units, treating the result of counting activity as both a unit to count on from and one to keep track of when counting. These actions evidence children's development of a Tacitly-Nested Number Sequence (TNS). Steffe (1992) explains that when children have a numerical sequence interiorized and segmented they can use their segmented numerical sequence as material for making new composite units within these numerical sequences. The awareness of one number sequence contained inside another, or double-counting, is an indication of TNS, as is a skip count (i.e., 4, 8, 16,…) to solve early multiplicative kinds of problems, such as how many 3's are contained in 12.

Explicitly-nested number sequence. Children who are described as having part-whole number reasoning in place are capable of disembedding parts from wholes and developing iterable units of one. These children are described as reasoning with an Explicitly-Nested Number Sequence (ENS) (Olive, 1999; Steffe, 1992; Ulrich & Wilkins, 2017). Children capable of multiplicatively understanding a single unit and a composite (whole) unit without disrupting either are said to be operating with an ENS (Ulrich & Wilkins, 2017). The two given composite units (e.g., parts and whole) provide children material to coordinate while constructing a third composite unit; e.g., a unit of units of units (Steffe, 1992). This part-whole reasoning with abstract units provides children multiplicative number structures.

Generalized number sequence. Children capable of developing iterable composite units where units of units of units can be coordinated, are described as operating with a GNS. For example, Olive (1999) explained that when children are asked to find common multiples, they are required to keep track of two series of composite units (e.g., 3, 6, 9, 12; 4, 8, 12; 12. The LCM of 3 and 4 is 12). Children evidencing successful completion of tasks like this are described as reasoning about two iterable composite units (e.g., 3 and 4), while keeping track of the common composite unit in each sequence. At the root of much of this number sequence development, units construction and coordination explain how and why children are capable of transitioning from additive/subtractive operative structures towards multiplicative/division operative structures towards rational number understanding.

Multiplicative Levels of Units Coordination

A student is said to assimilate with one level of units when she conceives of multiplication situations, such as seven iterations of four, by counting on from the first or second set of four by ones and double-counting the number of fours to reach a stop value (e.g., 4, 8,…9- 10-11-12; 13-14-15-16; 17-18-19-20; 21-22-23-24; 25-26-27-28). Here, the child has to model or carry out the situation by using internal (e.g., subvocal counting) or external (e.g., fingers or objects) representations. This is referred to coordinating two levels of units in activity. Units coordination in activity is ephemeral: in a follow-up task, such as how many ones are in eight iterations of four, the student would likely need to repeat a similar process rather than count-on four more from 28.

A student's use of strategic reasoning in such situations may be evidence that she assimilates the situation with two levels of units. For example, a student assimilating with two levels of units might conceive of seven iterations of four as five iterations of four plus two iterations of four (e.g., five 4s is 20; 21-22-23-24; 25-26-27-28). As opposed to modeling the entire coordination, the child can anticipate breaking apart the composite unit of seven into five and two and use each of those parts to solve the problem. For a student assimilating with two levels of units, the result of operating is simultaneously 28 ones and 7 fours; hence a follow-up task of finding the number of 1s in 8 fours would not require building up from 5 fours again.

A student is said to assimilate with three levels of units when she can conceive of a situation such as seven iterations of four as resulting in three distinct yet coordinated units: (a) one unit of 28 that contains (b) seven units of four, each of which contains (c) two units of two. Students assimilating with three levels of units have flexibility to reason strategically with each of the units. For instance, a student assimilating with three levels of units might solve the task, "How many more twos are in 32 than in 28?" by reasoning that 32 is one more 4, which is thus two more 2s. This reasoning involves assimilating three levels of units, multiplicatively.

Norton, Boyce, Ulrich and Phillips (2015) conducted a cross-sectional analysis of 47 sixth-grade students' reasoning in whole number multiplicative settings in clinical interviews. Figure 1 displays descriptors of attributions of students' activities Norton and colleagues identified as corresponding with students' reasoning with one, two, or three levels of units. For instance, they describe students' activity when transitioning from reasoning with one level of units to reasoning with two levels of units with descriptors G-K (Norton et al., 2015, p. 62).

Though there are commonalities with descriptions of students' counting schemes (e.g., descriptors C and J), the focus of the descriptors are more generally about how and whether students are able to flexibly reverse and reflect on their multiplicative reasoning.

Descriptors			
A. Iterates units of 1	E. Works with at least one level of units within a figurative three-level structure	I. Works with at least two levels of units within a figurative three-level structure	M. Assimilates three levels of units within a task
B. Builds composite units	F. Indicates a reciprocal relationship between the size and number of parts in a whole	J. Distributes composite units	N. Reflects on all levels within a three-level structure
C. Iterates composite units	G. Reverses multiplicative relationships	K. Immediacy of response	O. Conflates or confuses units
D. Uses multiplicative relationships	H. Builds a three-level structure	L. Flexibly works with a three-level structure	P. References the structure of units

Figure 1: Descriptors of Sixth-grade Students' Units Coordinating Activity as They Progress from Coordinating 1 Level of Units to Coordinating Three Levels of Units, as Discussed in Norton et al.'s (2015) Findings

These stages of units coordination, as delineated in Norton et al.'s (2015) findings, comprehensively explains transitions children make from additive operations to multiplicative operations. These findings also provide fundamental explanations for fractional unit development, as recursive units coordination in which to act upon and explain how students develop fractions as mental objects.

Fractional Units

Reasoning with fractional units requires unitizing a fractional size, 1/nth. When children first conceptualize fractional units, Steffe (2001) posited that they would reorganize natural number schemes to develop fractional schemes. Olive (1999) and Steffe (2001) argued that they would have to re-interiorize their units coordination operations, to consider a fractional unit as a result of *equi-partitioning* a unit whole into a size that, when iterated *n* times, would result in the size of 1. This re-interiorization of schema requires students to recursively construct and coordinate new composite units relationships (Olive, 1999). Thus, children's production of numerical sequences and their associated units coordination provide children necessary operations for their fractional units coordination.

To conceive of a fraction *m/n* as a number, one must understand m/n as equivalent to *m* 1/*n*ths, n of which are equivalent to 1. In the case of $m > n$, the meaning of 1/*n* must transform from thinking of 1/*n* as one out of n total pieces (*a parts-out-of-wholes scheme*) to thinking of *1/n* as an amount that could be iterated more than *n* times without changing its relationship with the size of 1 (*an iterative fraction scheme*). This measurement conception of fraction (Lamon, 2008) involves coordinating three levels of units of nested units: 8/3 is 8 times (1/3), 1=3/3 is 3 times (1/3), thus an 8/3 unit contains both a unit of 1 and a unit of 1/3 within 1 (Hackenberg, 2010). Students in the intermediate stages of constructing such a measurement conception may reason about the size of proper fractions of form m/n by counting the number of parts of size 1/*n* within a whole of *n/n*. Such students are not yet iterating the amount of 1/*n*, which limits their ability to iterate unit fractions beyond the size of the whole (Tzur, 1999).

Issues Related to the Psychology of Mathematics Education

Steffe's 2017 plenary included both a summary of contributions and important extant problems for mathematics educators pertaining to units coordination. Given these advances in research surrounding K-8 students' units construction and coordination, our mathematics education field is still limited by the context in which students' units construction and coordination develops and how preschool and high school students' units construction and coordination may inform these trajectories. Further, Steffe (2017) proposes that about 40% of first grade students have very different learning trajectories than their peers, suggesting a need to develop alternative means in which units construction and coordination may be developed by children. Finally, Steffe suggests that our field would benefit by investigating children's transitions in scheme development. For instance:

> It is especially crucial to investigate possible changes that indicate *fundamental* transitions between reasoning with two levels of units and three levels of units induced in the construction of quantitative measuring schemes and their use in the construction of multiplicative and additive measuring schemes (Steffe, 2017, p. 46).

One of our intentions for this working group is for researchers from different backgrounds to collaborate to work toward solving such problems. Consider that in their review of research preparing the recent (2016) compendium chapter on quantitative reasoning, Smith and Barrett (2017) note the following:

> [We] found it striking how often the same conceptual principles and associated learning challenges appear in the measurement of different quantities… Despite the clear focus in research on equipartitioning, units and their iteration, units and subunits… curricula (and arguably most classroom teaching) focus students' attention on particular quantities and the correct use of tools, as if each was a new topic and challenge. (p. 377).

Consistent with Arbaugh, Herbel-Eisenmann, Ramirez, Knuth, Kranendonk, and Quander's (2010) call to "develop mathematics proficiency in various school, cultural, and societal contexts" (p. 13), our goal is to connect research programs involving units construction and coordination with research programs that stem from other theoretical perspectives.

Unfortunately, many students with mathematics learning difficulties do not transition from two levels of units to three levels of units at the same pace as their more successful peers. In fact, the construction of ENS is one pervasive mathematical impediment for students with mathematics difficulties (Landerl, Bevan, & Butterworth, 2004). Compared to students without mathematics difficulties, students with mathematics difficulties develop less sophisticated strategies for number computation problems over time, suggesting a lack of a conceptual basis for ENS engagement that actually plays a part in their later disability identification (Butterworth, Varma, & Laurillard, 2011). Therefore, particular research programs with these foci are desperately needed to nurture multiplicative and rational number conceptions (Boyce & Norton, 2017; Grobecker, 1997; Kosko, 2017) and operations (Grobecker, 1997; Grobecker, 2000; Norton & Boyce, 2015) for students who need our support.

Alignment with Conference Theme

By designing interventions with children's mathematics and their units construction and coordination at the center, the field has grown over the years, yet there is much opportunity for improvement. Relations between cognitive factors and test performance may be important, yet these relationships are only one way to conceptualize "cognition." Instead of focusing on aspects of students' working memory or processing, researchers can revolutionize access for students by intervening on the malleable cognitive factors that can be improved upon through students' own development. Research stemming from units coordination and construction is "*against* the new horizon" in the sense that the goal of supporting students' units construction and coordination does not align with goals or initiatives that focus entirely on helping students to meet grade-level, task-based learning objectives. We argue that equitable instruction for all students begins with increased opportunities to adapt their own thinking grounded in a construction within their own mathematical realities. When well-intentioned educators provide children interventions that promote procedures and actions, not only are they not serving their children's mathematics learning needs, they may be preventing them from engaging in learning situations that support the children to adapt their thinking structures and advance their learning.

Research Designs and Methodologies

The primary methodology for investigating units construction and coordination has been the radical constructivist teaching experiment (Steffe & Thompson, 2000). A main role of these teaching experiments is to generate (and refine) epistemic models of students' mathematics – models for how students with common underlying conceptual operations learn within a particular mathematics domain (Steffe & Norton, 2014). Such teaching experiments involve close interactions with a teacher-researcher modeling the dynamics of students' ways of operating longitudinally. Teaching experiment methodology is also used as part of design research (Cobb, Confrey, diSessa, Leher, & Schauble, 2003), to inform instructional approaches or interventions that could be "scaled up" to heterogeneous classroom settings.

Results from analyzing teaching experiments have also informed methods for assessing a child's ways of constructing and coordinating units at a particular moment. In addition to task-based clinical interviews (Clement, 2000), Norton and Wilkins (2009) created written instruments for assessing middle-grades' fractions schemes and operations associated with units coordination. These instruments have been used to validate conjectured learning trajectories for children's construction of schemes for coordinating fractional units (e.g., Norton & Wilkins, 2012). These instruments currently serve as tools for selecting research participants in teaching experiments with middle-grades students (e.g., Hackenberg & Lee, 2015).

Consideration of these methodologies for researching units construction and coordination suggests areas for collaborative work to build our understanding not only of the research programs Steffe (2017) described, but also opportunities and needs regarding related research domains. For instance, Norton and Wilkins' (2009) written instruments have been modified to assess units coordination with fractions with prospective elementary teachers (Lovin, Stevens, Siegfied, Wilkins, & Norton, 2016). Thus, research development with these methodologies are better served in collaborative designs to allow for more perspectives in the design and analyses to more closely determine students' mathematics.

First Aim: Extending Units Construction and Coordination Research

The first aim of this working group proposal is to extend units construction and coordination research to investigations that include both older students and younger students. For instance, questions regarding whether differences in secondary students' units coordination persist beyond eighth grade, and, if so, how these differences manifest in older students' learning, remain underexplored. In interview and teaching experiment settings, Grabhorn, Boyce, and Byerley (2018) have found that students enrolled in university-level calculus do not necessarily coordinate three levels of units. Further expanding understanding of students' units coordination beyond eighth grade would contribute to the development of "coherent frameworks for characterizing the development of student thinking" (Arbaugh et al., 2010, p. 15).

In addition to studies focusing on relationships between units coordination and older students' mathematics, studies of pre-kindergarten children's units construction are also warranted. For instance, Wright (1991) found that students entering kindergarten had a wide variance in their number knowledge, which suggests critical mathematics learning may occur prior to the elementary school experience. With a significant dearth of research studies in the early childhood years (De Smedt, Noel, Gilmore, & Ansari, 2013) we posit that studies of how young children construct their earliest units are a critical area of research. Another potential need regards equity and access in mathematics education.

Researchers might investigate whether analyses of students' units construction and coordination provides insight to the mathematical reasoning of diverse and underserved populations. We envision collaborations around similar conceptual principles and learning challenges, to investigate units construction and coordination of children enrolled in different grade levels and representing different population groups (i.e., special education, early childhood, secondary education, teacher education), which would allow more coherent mathematical learning theory and practical means with which to link research to classrooms.

Steffe (2017) estimated that about 40% of first grade students rely solely on perceptual material when counting all items (Counters of Perceptual Unit Items – CPUI) and that 45% of first grade students are capable of counting figurative unit items (CFUI), a necessary precursor for interiorizing counting actions and developing "counting-on" (e.g., INS) (see Figure 2). Steffe posits that these distinct groups of children require different learning trajectories due to the differences in their construction of units.

With more U.S. students attending preschool programs and an increase of 48% in national funding towards preschool programs, it would be advantageous to develop research that could directly inform early childhood mathematics curricula (Diffey, Parker, & Atchison, 2017; Sarama & Clements, 2009). Also, given the need for these curricula should be coherently aligned with elementary grade mathematics curricula initiatives, it would serve early childhood curriculum designers to bridge research programs around number development in early elementary grades to preschool grade levels. For instance, one author found in a case study that one preschool student may be using subitizing activity to construct prenumerical units (MacDonald & Wilkins, 2019). Investigating how early, perceptual actions may relate to students' actions and operations development around units construction and coordination would serve these foci. Thus, our first aim is to extend research around units construction and coordination to new grade levels.

Grade/N Seq.	CFUI or INS	ENS	GNS
First	≈ 45 Percent	≈ 10 to 15 Percent	≈ 0 to 5 Percent
Second	≈ 30 Percent	≈ 25 to 30 Percent	≈ 0 to 5 Percent
Third	≈ 5 Percent	≈ 45 to 50 Percent	≈ 0 to 10 Percent

Figure 2: Steffe's (2017) Estimated percentage of Students Capable of Counting Figurative Unit Items (CFUI), Engaging with Initial Number Sequences (INS), Engaging with Explicitly-nested Number Sequence (ENS), or Engaging with Generalized Number Sequence (GNS) p.41).

Second Aim: Widening Units Coordination Research

Our second aim is to widen units coordination research by collaborating with researchers who investigate students with learning differences, from diverse cultures, and from low-socioeconomic households to determine diverse students' mathematics learning trajectories. For instance, one author who works closely with students with learning differences in case study research uncovered three important challenges students experience as they work toward more sophisticated coordination of units. First, when engaging in tasks that support the construction of composite units, the use of memorized fact combinations or teacher taught strategies eclipsed the use of one student's natural reasoning (Hunt, MacDonald, & Silva, in press) yet supported a second's (Hunt, Silva, & Lambert, 2017). Both students evidenced initial or tacit reasoning; one reverted to pseudo-empirical abstractions, tricks, or algorithms that she could not explain to solve the tasks. Conversely, the second student leveraged his knowledge of number facts and alternative representations to advance his fractional reasoning and compensate for his perceptual motor differences (2017). For both students, teacher encouragement and support to engage in each student's own ways of reasoning was imperative. Second, Hunt & Silva (in press) found evidence that confirms previous research (Geary, 2010) that one student sometimes lost track of counting during a count on, possibly due to working memory. Hunt & Silva (in press) conjectures that this learning difference interferes with the move from counting on to more sophisticated additive reasoning due to sequential (as opposed coordinated) counting. Yet, the problem was alleviated through opportunities for within-problem reflection through experiences that the child had to construct addends involved in number problems through reprocessed figurative counting (e.g., closing the firsts to recognize ten), sweeping small numbers as lengths, and improving the usability of small composites like 2, 4, 3, 5, and 6. Hunt's research is currently conducting cross-case analysis to discern whether the students' activity is indicative of similar or unique trajectories in number and/or fractional reasoning to students without learning differences.

Specific Goals and Aims

To extend and widen units construction and coordination research this working group intends to accomplish the following: (a) delineate tasks used in various areas of units construction/coordination research/teaching, (b) critically consider student reasoning associated with necessary task features, (c) explore develop means to organize tasks and cross reference with associated study, means for perturbation, materials, etc., (d) discuss webpage revision and creation to house organized tasks, and (e) embark upon collaborations leading to reading groups, research endeavors, and funding opportunities.

Goals and Outcomes from 2018 Working Group

The Complex Connections: Reimagining Units Construction and Coordination Working Group was well attended each day at PME-NA 2018. Including the organizers, there were 16 participants attending all three sessions who also provided their email contact in order to foster continued collaborations.

Session 1: Concept Formation

GOAL: Generation of research questions that are important to the group and/or sub-groups

ACTIVITIES: Introduce focus for the working group by asking "what types of problems would members like to explore?", by viewing/discussing short video clips of students working through various mathematical concepts to better understand the students' thinking, and developing potential research foci (e.g., overall purpose/goals of this working group, ties between composite units, coordination of units, and particular mathematics content). Finally, subgroups will be developed to form research questions that can cross-domains and use questions to form collaborations based on each members' area of interest and expertise.

OUTCOMES: Participants spent a bulk of the session defining terms and discussing students' responses to tasks designed to assess units construction/coordination. Small groups foci included participants' experience in this field with teaching/research.

Session 2: Theoretical Frameworks and Methodologies

GOAL: Explore appropriate research methodologies.

ACTIVITIES: Formulate plans for research and collaboration across group members by examining a variety of methodologies. Means for these examinations would include but not be limited to the following: (a) view videos of work already conducted to highlight possible methodologies for future studies; (b) discuss other potential methodologies not highlighted during the video viewing; (c) discuss how to design robust collaborative studies. Small group would entail: (1) work already done; (2) research agenda development; Large group would entail: (1) sharing of small group discussions; (2) delineate session 3 goals

OUTCOMES: Foci shifted in the session to include task development and website organization.

Session 3: Planning and Writing

GOAL: Embark on collaborations.

ACTIVITIES: Small group will entail: (1) work on written product of research agenda; (2) develop shared conceptual framework and the relationship of our framework to what is currently being done; (3) identify target journals and outlets or grants and funding sources. Large group will entail: (1) share progress and commitments from small group discussion; (2) finalize a plan for individual groups to continue updating progress to the larger group; (3) creation of working group website or blog

OUTCOMES: Collaborative plans around theoretical questions related to particular tasks were developed including task development/organization and webpage development.

Anticipated follow-up activities

Throughout the year, the members of this working group will continue working on research problems of common interest. They will contribute to a common website in which they will update other members of the working group about the progress of the various research collaborations. In the future, this working group will propose a special issue to a leading journal in the field and/or construct a grant proposal to a nationally recognized funder.

Results from 2018 Working Group

Resulting from the 2018 working group were development of three projects (extending to Calculus students, Preservice teachers, early elementary students; widening to special education), five manuscripts, and 11 conference proposals at four (inter)national conferences. Discussions from the 2018 working group further informed nuances in manuscript and project development while also including at least two new members to research initiatives in the units construction/coordination field. The webpage has become further developed to improve organization and include more readings.

Goals and Plan for 2019 Working Group

We primarily plan to build upon the successes of the inaugural Working Group, with two exceptions. We realized during the 2018 working group that the term "unit" needed to be discussed further. This year, we include distinction between research focusing on units construction (to include pre-numerical activity) and research focused on interiorized units coordination. We also plan to spend more time in the first meeting setting up the research paradigm and inviting participants to engage in task-based units coordinating activity themselves (rather than merely watching video excerpts of students' reasoning).

Session 1: Task Organization and Constructivist Groundings

GOAL: Describe main tenets of the Constructivist paradigm; generation/organization of units coordinating tasks set in this paradigm. Introduce focus for the working group by delineating particular assumptions of constructivism:

1. Knowledge is actively created or invented by the child, not passively received from the environment,
2. Children create new mathematical knowledge by reflecting on their physical and mental actions,
3. No one true reality exists, only individual interpretations of the world,
4. Learning is a social process in which children grow into the intellectual life of those around them,
5. When a teacher demands that students use set mathematical methods, the sense-making activity of students is seriously curtailed (Clements & Battista, 2009, p. 6-7).

To draw parallels between these tenets and this working group, members will actively engage with tasks while reflecting on their actions. In particular, they will consider "how did you respond to this task?," "how might students respond to this task?" and "why are these tasks effective for teaching/research purposes?." By breaking into groups to engage with tasks, which exemplify various units construction/coordination, participants can reflect on their own actions to determine how students may develop units and coordinate units through their engagement. Finally, subgroups will come together and discuss possible relationships between student actions and task features when examining students' units construction/coordination.

Session 2: Student Reasoning Relative to Units Construction/Coordination Theories

GOAL: Connect student reasoning to units construction/coordination learning theories.

ACTIVITIES: Participants will discuss students' responses to tasks and explanations relative to appropriate learning theories: (a) documenting anticipated student responses to categorize intended outcomes for tasks; (b) connecting details for student actions to theories in units construction/coordination; (c) documenting learning theories with tasks and references. Small group would entail: (1) task/student actions organization; (2) learning theory discussion to explain importance of particular student actions; large group would entail: (1) sharing of small group discussions; (2) delineate session 3 goals.

Session 3: Webpage Expansion

GOAL: Organize tasks on the webpage. Small group will entail: (1) collaborative webpage expansion by organizing tasks and possible student responses on the webpage; (2) associate each task with intended perturbation/assessment, reference, learning theory, etc. Large group will entail: (1) share progress and commitments from small group discussion; (2) finalize a plan for individual groups to continue updating progress to the larger group; (3) further creation of working group website or blog.

Anticipated Follow-up Activities

Throughout the year, the members of this working group will continue working on research problems of common interest and develop several reading groups. They will contribute to a common website in which they will update other members of the working group about the progress of the various research collaborations and discussion from reading group ideas. In the future, this working group will propose a special issue to a leading journal in the field and/or construct a grant proposal to a nationally recognized funder.

Historically underused methodologies in mathematics teacher education such as narrative inquiry, self-study, and autoethnography (i.e., self-based methodologies) are becoming a more frequent choice of mathematics teacher educators (MTEs). This has opened new challenges for MTEs as they try to disseminate their findings in mathematics education journals. Building from our working group at PME-NA 2018, we respond to the need for creating spaces (communities) where MTEs can feel supported in their study design, implementation, representation of findings, and publication using self-based methodologies. This year, we shift our focus from discussion to mentoring and scholarship on self-based methodologies. We invite MTEs with research projects in any stage of preparation to join us to in discussions meant to promote growth, sustainability, and continued insight into the use of self-based methodologies.

Keywords: Mathematics Teacher Educators, Research Methods, Narrative Inquiry, Self-study, Autoethnography

Significance and Historical Context of the Working Group

Mathematics teacher educators (MTEs) are responding to calls to employ research approaches less often used in mathematics education (e.g., Bullock, 2012; Stinson & Walshaw, 2017). Spaces to support scholars in the design of studies, implementation, representation of findings, and publication of findings using these approaches is needed. In this proposal, we continue our effort begun in 2018. Influenced by the work of Hamilton, Smith, and Worthington (2008), we have adopted the language of *self-based methodologies* (Chapman, Kastberg, Suazo-Flores, Cox, & Ward, 2019 in press) to refer to narrative inquiry (Clandinin & Connelly, 2000), self-study (LaBoskey, 2004), and autoethnography (Ellis & Bochner, 2000). These research methodologies focus on self-understanding based on personal professional experiences and are promoted in teacher education to enhance practice. These methodologies are often used in teacher education (e.g., Grant & Butler, 2018; Ross, 2003; Sack, 2008; Samaras & Freese, 2009) and are growing in use in mathematics education (e.g., Chapman, 2011; Chapman & Heather, 2010; Grant & Butler, 2018; Kastberg, Lischka, & Hillman, 2018a). However, MTEs interested in these methodologies tend to attend conferences or workshops outside of mathematics education that are more supportive of these ways of conducting research (e.g., Self-study of Teacher Education Practices (S-STEP) International Biennial conference, or Invisible College). Although some MTEs have been successful in conducting and publishing research under self-based methodologies (e.g., Chapman, 2011; Chapman & Heather, 2010; Grant & Butler, 2018; Kastberg et al., 2018a), incorporating "outsider" practices to the mathematics education field is not an easy task. Yet, we cannot dismiss this need as every year PME-NA accepts more studies using self-based methodologies (Kinser-Traut, 2018; Lischka, Kastberg, & Hillman, 2018; McGraw & Neihaus, 2018).

Another challenge to creating access to less used research approaches (e.g., Bullock, 2012; Stinson & Walshaw, 2017) is the dissemination of studies in peer reviewed mathematics education journals. Challenges are usually related to describing methodologies that are new to editors and reviewers. Resulting frustration might motivate MTEs to publish their research in "outsiders" journals. For instance, Ross (2003) and Sack (2008) have backgrounds in mathematics education and their narrative inquiry studies are published in teacher education journals.

We see a need to create a community of practice (Lave & Wenger, 1991) to support conducting and publishing results of studies using self-based methodologies. Some of us have experience conducting and disseminating work using self-based methodologies and being editors of well recognized journals in mathematics education. Our experiences conducting studies using these methodologies have allowed us to inquire into our practices (Chapman et al., 2019 in press), learn about ourselves (Cox, D'Ambrosio, Keiser, & Naresh, 2014; Cox & D'Ambrosio, 2015; Grant & Butler, 2018; Kastberg, Lischka, & Hillman, 2018b), and become more empathetic researchers (D'Ambrosio & Cox, 2015). The development of a community of practice would support colleagues with similar methodological interests.

History of the Working Group

The work of this group began as a desire to build a network of MTEs using self-based methodologies (Suazo-Flores, Kastberg, Ward, Cox, & Chapman, 2018). We reasoned that such a group could support scholars at different points in their professional learning and research by creating a community of practice dedicated to understanding and using self-based methodologies. We share an overview of our PMENA 2018 working group sessions (90 minutes each), that included Melva Grant, to outline the history of our working group.

Session one provided background about each of the methodologies, including terminology, and common tools used across the methodologies. Methodologies were described by outlining (1) communities of practice, (2) focus, (3) characteristics, (4) methods. Olive engaged the group in the role and use of stories in mathematics education research from an analytic and an empathetic approach.

Session two addressed the nuances of each methodology. Melva and Jennifer described their experiences conducting studies using self-study and autoethnography methodologies, respectively, and participants were invited to add their own questions or concerns to the discussion.

Session three addressed participants' lingering questions and discussions of possible physical or virtual spaces to continue our collaboration.

PME-NA 2018 working group participants had a variety of questions and interests related to the self-based methodologies. Some attendees were interested in learning about theoretical underpinnings and differences among self-based methodologies: How do I align these [methodologies] with a theory/positionality? What is the difference between autoethnography and ethnography? How do we use these [methodologies] to help/support teachers (prospective/in-service) capture growth over time? What are the connections between the methodologies? Is there danger in too much blending between these methodologies? What is the meaning of "truthful" within the methodology of autoethnography? Truthful –relative to what and to whom? Others wanted to know about methods that can be used under these methodologies: What are effective prompts, tasks, artifacts, contexts for engaging adolescents in narrative inquiry/autoethnography? How do you find a critical friend? Finally, attendees were also interested in learning about dissemination of studies conducted using these methodologies: Who is publishing? How is this research valued? Can I be promoted and tenured using these methodologies to inform my research? How do I prove "quality/significance/impact"? How are the conclusions/discussions different with these methodologies?

Progress Since 2018 Working Group

When we presented our working group proposal for PME-NA 2018, our intention was to gauge mathematics education researchers' interest in self-based methodologies. This goal informed the decision to structure the 2018 working group sessions to provide information about each methodology and share our experiences conducting studies. For the first two days of the 2018 working group we had approximately 20 attendees. We created an email list and during the year have maintained communication. Many of our working group participants are early career scholars with a passion for learning about self-based methodologies and a desire to gain experience conducting such studies. Therefore, we see a need for building a community of practice for scholars in all stages of career to be academically supported. Over the last year, we have worked to build a network of scholars. Central to our role as organizers and facilitators of such a network is our continued communication about and use of self-based methodologies in the research community. One vehicle for such communication is our co-authored book chapter in the *International Handbook of Mathematics Teacher Education* (Chapman et al., 2019 in press).

Each author has continued present and publish using self-based methodologies. Kastberg, Lischka, and Hillman (2018a) explored MTEs' use of written feedback and MTEs' use of questioning (2018b). In addition, the trio presented findings from their use of self-study methodology to explore MTE questioning at Association of Mathematics Teacher Educators (AMTE) 2019 conference.

Dana has continued to explore the role of empathy in her teaching and scholarship. Empathy for others in that work is supported by the use of narrative inquiry as a methodology. This positions her participants, be they teachers or students, as partners and knowledgeable people from whom she learns, and together construct new understandings of mathematics and its teaching (Cox & D'Ambrosio, 2015). She has used narrative inquiry as a methodology to explore and communicate experiences working with her students on problem solving and posing in technological environments, and mathematical design (Cox & Harper, 2017). After engaging with this working group in 2018, she was inspired to write a personal narrative about her professional trajectory (Cox, 2019) that revisits an earlier call for empathetic methodologies (D'Ambrosio & Cox, 2015), but also conceptualizes *rough draft spaces* (Jansen, Cooper, Vascellaro, & Wandless, 2017) in mathematics teacher education.

Elizabeth continued building from her dissertation study using narrative inquiry and self-study methodologies. A manuscript narrating an eighth-grade mathematics teacher's personal practical knowledge (Elbaz, 1981, 1983) was submitted to *Journal for Mathematics Teacher Education*. Another manuscript describing her experiences working with an eighth-grade mathematics teacher was accepted for presentation at American Educational Research Association 2019 annual meeting. Elizabeth lead a group of graduate students and postdoctoral fellows to explore their experiences conducting narrative inquiry studies in mathematics education (Suazo-Flores, Kersey, Bloome, Richardson, & Burdick, 2018). Signe, Elizabeth and a colleague presented findings from a study of MTEs' motivations for using mathematics autobiographies (Drake, 2006) in mathematics courses at AMTE 2019 and have a manuscript focused on unpacking these motivations (Kastberg, Suazo-Flores, & Richardson, 2019).

Following PME-NA 2018, Jennifer has been using her experiences teaching mathematics for social justice with young children to explore how this informs her work with prospective teachers in mathematics methods focused on grades K-2. A current focus has been reflecting on her scaffolding of prospective teachers to engage in equity based mathematics teaching in their field placements. Jennifer has been disseminating her dissertation research focused on experience and the lessons she implemented including sharing her findings at 2019 National Council for Teachers of Mathematics conference and submitting proposals for 2019 National Association for the Education of Young Children conference. She has built from her 2017 (Ward, 2017) work examining her experience in teaching mathematics for social justice from a critical lens. This involves her looking at the times she missed opportunities to engage in conversations with her students during the study; revisiting these moments to reflect on what could have been done to enhance conversations around social justice.

Olive has used narrative inquiry as a research methodology in studies of her teaching and mathematics teachers, a research tool to obtain phenomenological data in studies with mathematics teachers, and an approach to in-service and prospective mathematics teachers' learning. With the goal of understanding mathematics teachers from a holistic context that considers their perspectives, Olive has been communicating mathematics teachers' personal meanings (Chapman, 1994; Chapman, 1997) and teachers' agency on their practice change (Chapman & Heater, 2010; Chapman, 2011; Chapman, 2013). Olive has also used narratives as a research tool and pedagogical tool. When working with prospective teachers (Chapman, 2008a), Olive has asked them to write and share narratives of teaching mathematics and re-write them later in the course. This pedagogical tool has triggered prospective teachers' reflection of mathematics teaching practices. Olive's research and teaching experience using narrative inquiry and narratives to approach teachers in different stages of their career had brought her to lead one of the PME 2017 plenary session, chapters in handbooks (e.g., Chapman, 2008b; Chapman, 2009), and discussion groups at 12th International Congress on Mathematical Education, PME, and ICME (Beswick & Chapman, 2015; Beswick, Chapman, Goos, & Zaslavsky, 2012; Beswick & Chapman, 2013) that focused directly or indirectly on mathematics teacher educator knowledge and learning that included narratives and self-study. Olive recently gave a presentation on self-based methodologies in mathematics teacher educators' learning at the International Symposium on Mathematics Teacher Education in UK (Chapman, 2019) and has a paper in press on mathematics teacher educators' use of narrative in research, learning and teaching (2019, in press).

We invited Melva to join our working group as a presenter and organizer in 2018. Signe became familiar with Melva's work at the Self-study of Teacher Education Practices (S-STEP) International Biennial 2018 conference. Melva has brought together her Black feminist and post-structural academic formation with self-based methodologies in mathematics education and higher education. Professional experiences in higher education led to an auto-ethnography study where she explored the construct of epistemic oppression (Grant, 2019 in press). As an entry into self-study research, Melva explored teacher educators' motivations to conduct self-study as she learned and practiced the method collaboratively (Grant & Butler, 2018). She is currently engaged in self-study work with Signe and others to explore ways to improve elementary teacher preparation using instructional technology. The technology afforded her online mathematics method students opportunities to teach within a virtual environment and includes a small group of student avatars (i.e., virtual students). Melva is trying to determine ways to leverage the instructional technology to improve prospective teachers' capacity to facilitate productive math talk for developing student's mathematics understanding (Lamberg, 2013). In 2019, she plans to share findings through conferences and journal publications related to: (a) developing the instructional technology for improved teacher preparation; (b) prospective teachers' learning and teaching; and (c) professional learning emerging from her own practice. This line of inquiry started in spring 2018 and has spanned several elementary mathematics methods courses taught in both online and face to face settings. Melva plans to continue this self-study research until she is satisfied that her elementary method students' learning is not hindered because her teaching is maximally effective.

Energizing MTEs has been identified as critical to sustaining the field of mathematics teacher education (e.g., Whitcomb, Liston, & Borko, 2009). Our individual and collective work conducting studies under self-based methodologies have created such feelings of energy. Wilson (2006) described, being a "teacher educator-researcher requires understanding the practice of teacher education and the practice of teacher education research" (p. 316). Yet, defining a teaching and research path involves negotiating internal passions with external factors such as institutional structures, and funding policies. This could constrain MTEs' practices making them feel that academic life is unsustainable. We argue that this working group could be the beginning of a community of practice where MTEs interested in conducting studies using self-based methodologies feel sustained and empowered in their professional practices (Jaworski & Wood, 2008). Below is our plan for the 2019 working group.

Outline of Working Group Session

Our focus on participant discussion in our first year as a working group enabled us to build an emerging community of practice around the foundation of self-based methodologies (Suazo-Flores et al., 2018). Given the personal nature of that work, it was paramount that we create an atmosphere of trust and care. Extensive time was spent on setting norms, getting to know one another and our research foci, but also getting to know the methodologies and setting goals, both individual and collaborative, for our group going forward.

In 2019, we shift our focus from discussion to mentoring and new scholarship. We welcome new and returning members to our working group, thus we will begin again by building norms and (re)establishing an atmosphere of trust and care. The remainder of our work together will be oriented around project and manuscript review teams, with the long-term goal to start outlining a potential book. Working group participants are encouraged to bring works-in-progress to the group for feedback. Each day will focus on different phases of the work: Day One will focus on projects in progress, Day Two will focus on beginning projects, and Day Three will be devoted to discussing the year-long book project.

Beginning with projects in process on Day One is an intentional choice. By starting with projects with a defined methodology and whose research questions or goals are identified, we set the stage for productive mentoring and feedback cycles for beginning projects on Day Two. Sharing the origins of scholarship with others can be daunting and these ideas are the most fragile. Beginning with established projects may 1) assure new authors that their ideas will be handled gently, 2) give new authors a chance to hear the ways these methodologies shape potential studies, and 3) give us a chance, as a community, to review the tenets of each methodology in an educative way.

Day Two will start with a progress update from each of the authors who shared work on Day One. These project updates will include where projects are going next and action(s) scholars hope to take in 2019-2020. The group will take time to consider and adjust the ways we provide (as well as the nature of) feedback to respond to the needs of participants. The remaining time will be devoted to projects that are in initial or introductory stages. These projects could include those that are still being conceptualized, those where data is still being collected, or those that still feel fragile to authors. Encouraging participants to share their work publically within our community of practice may help crystalize or generate ideas. In a whole-group setting, we will support participants as they give an overview of their current work/idea and invite us to give feedback on data sets, research questions, relevant literature, or early writing. Feedback can and should focus on specific areas identified by the author, so as to respect the fragility of these ideas and give the author agency to ask for what they need.

Discussion of a year-long project designed to support scholars in different career stages and to disseminate findings from studies using self-based methodologies will be a focus of Day 3. Building on the ideas shared in the previous two days, we will identify themes that will comprise the table of contents of a book. Before the conference, we solicited manuscripts from those who attended our 2018 working group. We have maintained contact with those participants and have continued to develop our community including scholars who expressed an interest in joining us following PME-NA 2018. Manuscripts will also be shared with the members of our email list in advance of the conference and distributed to mini review groups (2-4 people). 2019 PME-NA working group participants can also propose studies or share manuscripts designed under self-based methodologies to be included in the potential book.

Conclusion

As MTEs use self-based methodologies, spaces (communities) are needed to support their practices including study design, implementation, representation of findings, and publications in mathematics education journals. This working group intends to be such a space (community) where over time MTEs feel sustained in their use of self-based methodologies.

Embracing the theme of this year's meeting, we seek as a community to consider the role of expansion, displacement, and growth in mathematics education in the privileging of some and marginalizing of others. Following on the topics discussed at the Working Group between 2009-2018, this year the focus is on balancing the need to reflect and collect around issues of equity and diversity in mathematics education and orienting toward action. Each session is designed to address the needs of (or to create opportunities for) attendees interested in equity, generating and brainstorming new subtopics, potential projects, and/or working to establish standalone working groups dedicated to furthering research on equity. The purpose being to encourage a move away from "big-tent" equity thinking and toward more productive working collectives.

Keywords: Equity and Diversity

Brief History

This Working Group originates from the Diversity in Mathematics Education (DiME) Group, one of the Centers for Learning and Teaching (CLT) funded by the National Science Foundation (NSF). DiME scholars graduated from one of three major universities (University of Wisconsin-Madison, University of California-Berkeley, and UCLA) that comprised the DiME Center. The Center was dedicated to creating a community of scholars poised to address critical problems facing mathematics education, specifically with respect to issues of equity (or, more accurately, issues of inequity).The DiME Group (as well as subsets of that group) has engaged in important scholarly activities, including the publication of a chapter in the *Handbook of Research on Mathematics Teaching and Learning* which examined issues of culture, race, and power in mathematics education (DiME Group, 2007), a one-day AERA Professional Development session examining equity and diversity issues in mathematics education (2008), a book on research of professional development that attends to both equity and mathematics issues with chapters by many DiME members and other scholars (Foote, 2010), and a book on teaching mathematics for social justice (Wager & Stinson, 2012) that also included contributions from several DiME members. In addition, several DiME members have published manuscripts in a myriad of leading mathematics education journals on equity in mathematics education. This working group provides a space for continued collaboration among DiME members and other colleagues interested in addressing the critical problems facing mathematics education.

It is important to acknowledge some of the people whose work in the field of diversity and equity in mathematics education has been important to our work. Over time, the Working Group has encouraged building on and featuring senior scholars' work, including Jo Boaler (Boaler, 2002), Walter Secada (Secada, 1992), Marta Civil (Civil, 2007; Civil & Bernier, 2006; González, Andrade, Civil, & Moll, 2001), Eric Gutstein (Gutstein, 2003, 2006; Gutstein & Peterson, 2013), Jacqueline Leonard (Leonard, 2007; Leonard & Martin, 2013), Danny Martin (Martin, 2000, 2009, 2013), Judit Moschkovitch (Moschkovich, 2002), Rochelle Gutiérrez (2002, 2003, 2008, 2012, 2013) and Na'ilah Nasir (Nasir, 2002, 2011, 2013; Nasir, Hand & Taylor, 2008; Nasir & Shah, 2011). We have as well been building on the work of our advisors, Tom Carpenter (Carpenter, Fennema, & Franke, 1996), Geoff Saxe (Saxe, 2002), Alan Schoenfeld (Schoenfeld, 2002), Megan Franke (Kazemi & Franke, 2004), and Anita Wager, (Wager & Stinson, 2012) as well as many others outside of the field of mathematics education.

Previous iterations of this Working Group at PMENA 2009 – 2013, and 2015-2016 have provided opportunities for participants to continue working together as well as to expand the group to include other interested scholars with similar research interests. Experience has shown that collaboration is a critical component to this work. These efforts to expand participation and collaboration were well received; more than 40 scholars from a wide variety of universities and other educational organizations took part in the Working Group each of the past six years. Starting in 2017, an effort was made to “reset” the group toward providing opportunities for a new generation of scholars whose work intersects with issues of equity/inequity, diversity/inclusion, privilege/oppression, and justice in mathematics education research, practice, and development.

Focal Issues

Under the umbrella of attending to equity and diversity issues in mathematics education, researchers are currently focusing on such issues as teaching and classroom interactions, professional development, prospective teacher education (primarily in mathematics methods classes), factors impacting student learning (including the learning of particular sub-groups of students such as African American students or English learners), and parent/family/community perspectives. Much of the work attempts to contextualize the teaching and learning of mathematics within the local contexts in which it happens, as well as to examine the structures within which this teaching and learning occurs (e.g. large urban, suburban, or rural districts; under-resourced or well-resourced schools; and high-stakes testing environments). How the greater contexts and policies at the national, state, and district level impact the teaching and learning of mathematics at specific local sites is an important issue, as is how issues of culture, race, and power intersect with issues of student achievement and learning in mathematics. There continues to be too great a divide between research on mathematics teaching and learning and concerns for equity.

The Working Group has begun and will continue to focus on analyzing what counts as mathematics learning, in whose eyes (and for whose benefit), and how these culturally bound distinctions afford and constrain opportunities for traditionally marginalized students to have access to mathematical trajectories in school and beyond. Further, asking questions about systemic inequities leads to methodologies that allow the researcher to look at multiple levels simultaneously. This research begins to take a multifaceted approach, aimed at multiple levels from the classroom to broader social structures, within a variety of contexts both in and out of school, and at a broad span of relationships including researcher to study participants, teachers to schools, schools to districts, and districts to national policy.

Some of the research questions the Working Group will continue to consider are:

- What are the characteristics, dispositions, etc. of successful mathematics teachers for *all* students across a variety of local contexts and schools? How do they convey a sense of purpose for learning mathematical content through their instruction?
- How do beginning mathematics teachers perceive and negotiate the multiple challenges of the school context? How do they talk about the challenges and supports for their work in achieving equitable mathematics pedagogy?
- What impediments do teachers face in teaching mathematics for understanding?
- How can mathematics teachers learn to teach mathematics with a culturally sustaining approach?
- What does teaching mathematics for social justice look like in a variety of local contexts?
- What are the complexities inherent in teacher learning about equity pedagogy when students come from a variety of cultural and/or linguistic backgrounds all of which may differ from the teacher's background?
- What are dominant discourses of mathematics teachers?
- What ways do we have (or can we develop) of measuring equitable mathematics instruction?
- How do students' out-of-school experiences influence their learning of school mathematics?
- What is the role of perceived/historical opportunity on student participation in mathematics?
- Whose mathematics is accepted? (displaced?) across a variety of local contexts and schools?
- How are students' out-of-school experiences valorized in their learning of everyday mathematics?
- How do we make space for this work to continue with open opposition to critical approaches to mathematics education?

We believe the continued support of this working group provides a partial response to the last question. Specific to the intent of this year's Working Group, we will organize around questions like the ones above in order to create specific, targeted working groups that are charged to address and act around such questions.

Plan for Working Group

Based on feedback from the previous year and the emergence of new working groups related broadly to "equity," this working group has shifted toward a renewed focus on facilitating "collaboration within the growing community of scholars and practitioners concerned with understanding and addressing the challenges of attending to issues of equity and diversity in mathematics education." We have reconfigured the working group toward being a catalyst for new spaces instead of a "destination" for the inclusion of equity discourse within the PME-NA organization. To put it differently, our vision for the working group is to bring together attendees toward developing their own agendas and specific working groups related to equity-oriented themes--or toward themes that push the field beyond traditional equity discourses yet adhere to the needs and challenges of inequity within mathematics education.

Our plans for PMENA 2019 will proceed as follows. Each session will build on previous sessions, beginning with a facilitated conversation around the previously stated purpose of the working group. The format for the sessions will include:

- DAY 1: Opening up a day of reflection: Welcome, Introductions, Norm Setting. We will then ask each attendee to reflect on their experiences and write out examples of displacement, expansion, and growth in mathematics education that privileged some and marginalized others. Session attendees can generate examples from any time period. To encourage a wide variety of examples, we will ask attendees to think about these experiences as they relate to K-12 classrooms, with preservice teachers (methods or content courses), in student teaching, in undergraduate mathematics courses, in professional development settings, in the media, etc. From there, we will devote time to trying to categorize all of the examples (written on sticky notes) by themes to identify what types of categories emerges from this activity. We will conclude Day 1 by engaging in a whole group discussion where we will operationalize the ways in which mathematics has been used as tool to displace and marginalize. After operationalizing these examples, we will generate guiding questions to be used throughout the conference. As a collective, we will use (and ask) these questions at plenary sessions, individual presentations, etc to ensure that the conference theme remains at the forefront for all attendees.
- DAY 2: Finding common ground: Developing problem trees. Utilizing emerging themes from day 1, we will engage participants in an activity problematizing issues in mathematics education. The activity, a problem tree (Cammarota, Berta-Avila, Ayala, Rivera & Rodriguez, 2016) is used to distinguish between superficial symptoms and underlying root causes of societal issues, towards the development of a research question. Participants will work in small groups to create their own problem trees, generating a research question that will be presented to the whole group further enriching the collective discussion on issues of equity and diversity in mathematics education and resulting in potential collaborations to be built on in Day 3.
- DAY 3: Working working groups: Newly established subgroups will “take flight” and initiate plans to support their chosen topics/research questions through continued collaboration.

Previous Work of the Group

The Working Group met for productive sections since 2009. In 2009, participants identified areas of interest within the broad area of equity and diversity issues in mathematics education. Much fruitful discussion was had as areas were identified and examined. Subgroups met to consider potential collaborative efforts and provide support. Within these sub-groups, rich conversations ensued regarding theoretical and practical considerations of the topics. In addition, graduate students had the opportunity to share research plans and get feedback. The following were topics covered in the subgroups:

- Teacher Education that Frames Mathematics Education as a Social and Political Activity
- Culturally Relevant and Responsive Mathematics Education
- Creating Observation Protocols around Instructional Practices

- Language and Discourse Group: Issues around Supporting Mathematical Discourse in Linguistically Diverse Classrooms
- A Critical Examination of Student Experiences

As part of the work of these subgroups, scholars have been able to develop networks of colleagues with whom they have been able to collaborate on research, manuscripts and conference presentations.

As a result of the growing understanding of the interests of participants (with regard both to the time spent in the working group and to intersections with their research), we began to include focus topics for whole group discussion and consideration and continued to provide space for people to share their own questions, concerns, and struggles. With respect to the latter, participants have continually expressed their need for a space to talk about these issues with others facing similar dilemmas, often because they do not have colleagues at their institutions doing such work or, worse yet, because they are oppressed or marginalized for the work they are doing. These concerns, in part, informed the focus topics for whole group discussion and consideration. For example, in 2009 research protocols (e.g., protocols for classroom observation, video analysis and interviewing) were shared to foster discussions of possible cross-site collaboration. In 2012, the Working Group explicitly took up marginalization in the field of mathematics education with a discussion about the negotiation of equity language often necessary for getting published; this was done in the context of the 'Where's the mathematics in mathematics education' debate (see Heid, 2010; Martin, Gholson, & Leonard, 2010). Dr. Amy Parks was invited to join Working Group organizers to share reflections on their experiences. In 2013 the Working Group hosted its first panel in which scholars (Dr. Beatriz D'Ambrosio, Dr. Corey Drake, Dr. Danny Martin) shared their perspectives on the state of and new directions for mathematics education research with an equity focus. In recent years, we have had collections around topics that have resulted in several proposals for sessions and working groups for PMENA.

The Models and Modeling Working Group at PME-NA has provided a forum for discussing and collaborating on projects fundamental to research on mathematical modeling since the first PME-NA conference in 1978. We propose to convene this Working Group at PME-NA 41 with a dual purpose: (1) to build on a theme begun in Greenville, holding a focused workshop to pursue innovations in activity design to connect modeling activities to mathematically rich, socially-engaged inquiry into questions from the world outside of school; and (2) to continue to invite newcomers to the Models and Modeling Perspective (MMP), giving them an introduction to this design research tradition.

Keywords: Modeling, Problem Solving, Design-Based Research, Design Experiments

The Models and Modeling Working Group was initiated in the inaugural year of the PME-NA conference in 1978, and it has met frequently since then. Over the 41 years of its existence, the working-group format has offered a vehicle for coordinating substantial research efforts and for fostering collaborations and mentoring relationships within the “Models and Modeling Perspective” (MMP). The MMP takes a pragmatic approach to fundamental questions in mathematics education, such as “What ... beyond having a mathematical idea ... enables students to *use it* in everyday problem-solving situations?” (Lesh, Landau, & Hamilton, 1983, qtd. in Lesh & Doerr, 2003, p. *i*., emphasis added). Such questions foster interdisciplinary collaborations connecting a broad range of theoretical perspectives.

A function of the Working Group has been to pursue innovations in design-based research (cf, Kelly, Lesh, & Baek, 2008) – to discuss and extend the ways in which a focus on models and modeling can be used both to support learning in STEM, and to study such learning processes in action. Indeed, calls for STEM integration (English, 2016; English & King, 2015) and for attending to Engineering perspectives (Diefes-Dux, Moore, Zawojewski, Imbrie, & Follman, 2008; Roehrig, Moore, Wang, & Park, 2014) have only increased the potential of this long-standing tradition to contribute to efforts to innovate in teaching and research.

This year, we propose to convene the working group to pursue an area of innovation in activity design for STEM integration. We aim to connect a signature *genre* of mathematical modeling activity created by the MMP, Model-Eliciting Activities (MEAs), with real-world modeling contexts that engage with important broader societal questions. In particular, we will workshop a particular MEA, refining it (and/or creating a cluster of thematically related MEAs), and connecting it with (a) related Citizen Science projects; (b) resources and information housed in centers for informal learning (e.g., zoos and museums); and (c) bearing on deep issues of social and ecological justice.

History of the Working Group

Early in its history, the Group focused heavily on the design and analysis of particular, self-contained activities that enabled groups of learners to engage realistic and deep forms of modeling and that produced an auditable trail of thinking, exposing their thought processes to teacher and researcher observers. Thus, this initial line of research pursued modeling activities as research instruments, analogous to group-level versions of Piaget's interview tasks. In this phase of the field's development, a primary effort involved elaborating design principles for these and documenting images of *idea development* that they promoted.

Quickly, these activities were recognized for their potential as powerful learning environments, yet this "turn" raised questions about how different student groups' work on open modeling problems could be "processed" by the whole class, bringing out common themes and connecting them to more conventional mathematical terminology, algorithms, and procedures. Gradually over time, researchers associated with the Group expanded their perspectives to consider implementations and curricular sequences that had longer time-duration, and that integrated models and modeling into the experience of learning mathematics in more extensive ways.

Several broad patterns in this more extensive and disseminated approach to modeling in the curriculum have emerged, and there is no sense that the MMP has yet exhausted the space of possibilities. These broader perspectives open both exciting opportunities and significant challenges. On the one hand, new questions can be researched, opening the way for new forms of contact and interaction with classroom practice and with learning outside of school; on the other, the approach raises new challenges at the level of methodology, data analysis, and forms of evidence that are convincing backings for claims about learner activity.

We propose convening the Group at PME-NA 41 to continue a style of work that has characterized the Group's collaborations over the past several years. In particular, based on our experiences in 2015-2018, we propose a work-session structure that can serve two dual purposes: (a) making substantive progress in work on a particular cluster of Model-Eliciting Activities, exploring how to use activities in the MEA genre to spark student connections with citizen science and ecological conservation; while also (b) integrating newcomers to Models and Modeling as a research area.

For this Working Group, these two goals are ***both*** essential: we propose to gather, not as a closed expert group, but as a broad group of educators and researchers. To welcome newcomers and new perspectives into the group, the structure we are proposing for the Working Group will provide initial introductions to the approaches and characteristics of the MMP and the activity designs the tradition has developed, but we also plan to engage both newcomers and returning participants in the work of continuing the refine the MEA structure in general and the Pelican MEA in particular to address issues of equity, sustainability, and environmental stewardship, which represent urgent opportunities and problems of research and practice in mathematics education.

In the following sections, we provide a very brief overview of the field of research represented by the Models and Modeling Perspective; we outline patterns in research efforts that have extended modeling activities over longer timescales; and we describe our plan of work in detail, illustrating how these goals are addressed as well as how we plan to productively integrate newcomers to the Group over the three working sessions offered in the Conference.

The Models and Modeling Perspective (MMP)

Since the 1970s, MMP researchers and educators have engaged in design research directed at understanding the development of mathematical ideas among groups of learners. A key principle behind this work has been that learners' ideas develop through, and in relation to conceptual entities called *models*. The core construct of a "model" and the activity of "modeling" are both central to the MMP; and they are also multidimensional, playing multiple roles in the MMP theory.

Models & Modeling Working Group founder Dick Lesh and Helen Doerr provide the following working definition of *models*:

> conceptual systems (consisting of elements, relations, operations, and rules governing interactions) that are expressed using external notation systems, and that are used to construct, describe, or explain the behaviors of other system(s)—perhaps so that the other system can be manipulated or predicted intelligently (Lesh & Doerr, 2003, p. 10)

In this spirit, "being a good modeler is in large part a matter of having a number of fruitful models in one's 'hip pocket.'" (Lesh, 1995, personal communication, qtd in Lehrer & Schauble, 2000).

But the term "model" not only applies to features of "target knowledge" that are built through learning: the interpretive systems that people *bring* to problems are also "models." When explicitly expressed through representational media, such models—personal interpretive systems—can provide illumination into how students, teachers, and researchers adapt, formulate, and apply relevant mathematical concepts in particular situations or contexts (Lesh, Doerr, Carmona, & Hjalmarson, 2003). In fact, "models" are the shape and vestment of most all knowledge—whether this knowledge appears as the patterns of perspectives and pre-conceptions that learners bring with them "in the door"; the shared ways of thinking that a group of learners build in solving a problem; or the systematic accounts of phenomena that represent the normative views of a scientific discipline at a given moment in its history.

An early finding of research in the Models and Modeling Perspective (MMP) was that, under appropriate conditions, groups of learners can be supported in producing external representations of the models they bring to a situation, and that when these groups put their initial models into conversation with one another and in contact with the real world, they can be supported to revise, and refine them in rapid and iterative cycles, building toward a more robust model that reflects their achievement of a shared way of thinking. In particular, when individuals and groups encounter problem situations with specifications that demand a model-rich response, their models can be observed to grow through such relatively rapid cycles of development toward solutions that satisfy these specifications.

While the elicitation of initial ways of thinking is valuable, MMP researchers' interest quickly turned to this process of model refinement—that is, to the dynamics of model***ing*** (as opposed to the statics of mod***els***), and to the features of activity environments that foster modeling and make it visible for teachers and researchers. The dynamics of modeling represent, for the MMP, an account of *idea development*, as observed in the discourse and other representations produced by groups of learners as they iteratively work to mathematize and formulate a solution that meets the needs of a concrete *client* in a realistic setting.

Thus, the MMP tradition became focused squarely on local conceptual development (Lesh & Harel, 2003): that is, on investigating the micro-evolution of ideas in groups of students (and teachers). The resources and tools its researchers produced were first and foremost designed to study idea development and the range of possibility for this mode of learning activity. The results of this work include a body of *Model-Eliciting Activities* (MEAs), in which students are presented with authentic, real-world situations where they repeatedly express, test, and refine or revise their current ways of thinking as they endeavor to generate a structurally significant product—that is, again, a *model*, comprising conceptual structures for solving the given problem. These activities differ markedly from some other environments dedicated to applications of specific mathematical concepts and procedures. In contrast, MEAs give students the opportunity to create and adapt mathematical models in order to interpret, explain, and/or predict the behavior of real-world systems (Zawojewski, 2013). An extensive body of MMP research has produced accounts of learning in these MEA environments (Lesh, Hoover, Hole, Kelly, & Post 2000; Lesh & Doerr, 2003), design principles to guide MEA development (Hjalmarson & Lesh, 2007; Doerr & English, 2006; Lesh, et. al., 2000; Lesh, Hoover, & Kelly, 1992) and accounts and reflections on the design process of MEAs (Zawojewski, Hjalmarson, Bowman, & Lesh, 2008).

As an example of the activity-type of Model-Eliciting Activities (MEAs), consider the Pelican Colony problem (Moore et al, 2015; Pompei, 2010) (below, and **Figure 1**). In this problem, the client is Alice Heart, a Wildlife Biologist from the U. S. Fish and Wildlife Service. The problem provokes students to grapple with notions of area, and for many (though by no means all) groups it prompts them to invent a measure analogous to “nest density” in the context of a pelican conservation effort to arrive at a procedure that the client can use.

An excerpt from the client letter, which includes the “call to action” for students, is given below:

> The U.S. Fish and Wildlife Service needs a procedure to estimate the number of nests at each pelican colony. Because pelicans are very sensitive to disturbances while they are incubating their eggs, we are not able to physically walk through every colony and count nests (this would also take too much time and cost too much!). We have hired pilots to fly our biologists over nesting colonies so they can take aerial photographs of the sites. As pelican colonies can be quite large (hundreds or thousands of nests), each photograph shows only a portion of the entire site. We have maps based on satellite images that are taken annually, which show us the shape and size of each colony site. We are enlisting your team’s help to create a procedure that will allow us to estimate the number of nests in a pelican colony, based on the photograph that shows a sample of the colony, and a map that shows the size and shape of the entire site.

Students are provided with aerial photographs and colony outlines (Figure 1) for two sample pelican colonies. The client would like to be able to determine the size of a colony (in terms of the number of nests) from these pieces of data, and students are tasked with developing a procedure to 1) compare the sizes of different nests and 2) estimate the size of a nest based on an aerial photograph and an outline of the colony.

Student groups iteratively develop solutions to this problem in the time allotted—usually 50-60 minutes for this MEA. Afterwards, groups may present their work for a discussion of the modeling possibilities of these presentations (see Brady & Jung, 2019a; b, for suggestions of the value of such presentations); the students solutions can be used as a springboard for a class discussion following the five-practices structure described by Stein, Engle, Smith, and Hughes (2008); or the teacher may organize a “poster session” for the groups to share and learn from each others’ solutions (Lesh, 2010). In one version of this activity structure, one member of each group hosts a presentation of the poster showing their results. The other students circulate to learn about other groups' solutions, using a Quality Assurance Guide to assess the results produced by others in the class. These instruments are submitted to the teacher and contribute to assessment in various ways, providing evidence for the achievements of both individuals and groups.

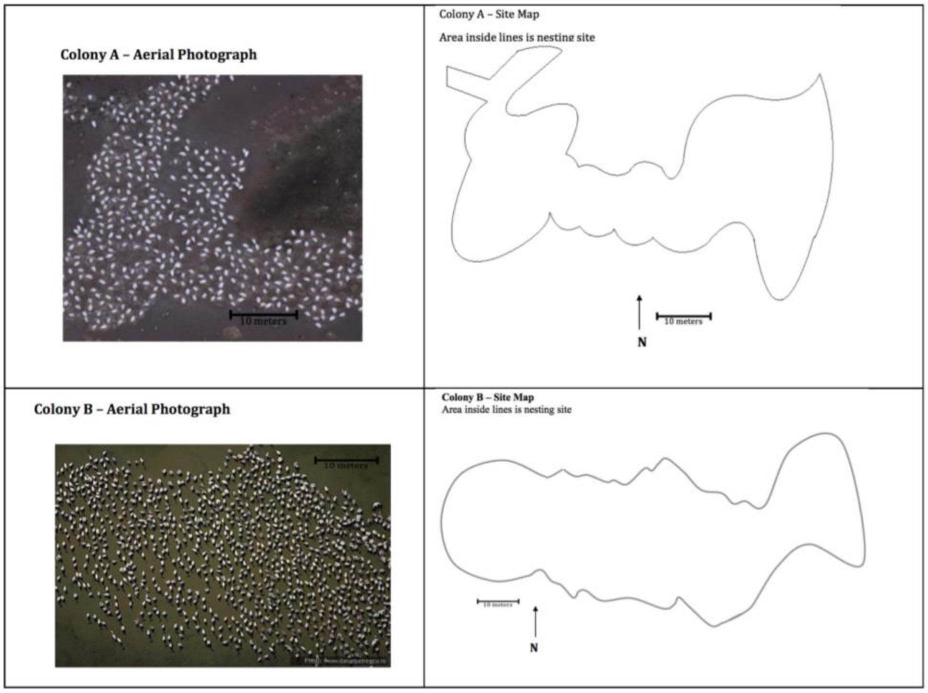

Figure 1: Two Pelican Colonies. Outlines, and Aerial Photographs.

MEAs like the Pelican problem present learners with situations where familiar procedures, ways-of-operating, and constructs may be *applicable*, but where they are also *insufficient*. In this sense, they support a learning environment that has a "low threshold" but a "high ceiling" (cf Papert, 1980). That is, on the one hand they are accessible to learners from a wide range of levels of ability, experiences, or knowledge (from upper elementary school through graduate school). On the other hand, learners encountering these problems find that they have no ready-made solution they can apply to address the client's needs. As a result, groups learners must engage in sense-making and solution-construction processes that position them as mathematical creators and also put them off balance in comparison to typical school-mathematics tasks. Indeed, this uncertainty is part of the design of MEAs, illuminating fundamental conceptual issues associated with the core mathematical structures involved.

MEA Design Principles

As individual MEAs emerged, an intense period of design research ensued to understand them as a genre of learning tasks that could (a) stimulate mathematical thinking representative of that which occurs in contexts outside of artificial school settings (Lesh, Caylor, & Gupta, 2007; Lesh & Caylor, 2007); (b) enable the growth of productive solutions through rapid modeling cycles; and (c) leave behind "auditable trails" - researchable traces of learners' ways of thinking during the process (Kelly & Lesh, 2000; English et al., 2008; Kelly, Lesh & Baek, 2008). The

Otten, S., Candela, A. G., de Araujo, Z., Haines, C., & Munter, C. (2019). *Proceedings of the forty-first annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. St Louis, MO: University of Missouri.

success of MEAs as an activity genre and as research tools was both enabled by and illustrated by the MMP's articulation of a set of six design principles (Lesh & Harel, 2003; Lesh et al., 2000; Hjalmarson & Lesh, 2007). These principles indicate essential elements of MEAs and their classroom implementations, enabling them to serve as rich contexts for student problem solving. Table 1, below, also indicates "touchstone" tests for whether each of these six principles has been realized in a given implementation setting.

Table 1: Six Design Principles for MEAs and Touchstones (see also Brady et al, 2017)

Principle	Touchstone Test for its Presence
Reality Principle	Students are able to make sense of the task and perceive it as meaningful, based on their own real-life experiences.
Model Construction Principle	To solve the problem, students must articulate an explicit and definite conceptual system (model).
Self-Evaluation Principle	Students are able to judge the adequacy of their in-process solution on their own, without recourse to the teacher or other "authority figure".
Model Generalizability Principle	Students' solutions are applicable to a whole range of problems, similar to the particular situation faced by the "client" in the MEA.
Model-Documentation Principle	Students generate external representations of their thinking during the problem-solving process.
Simplest Prototype Principle	The problem serves as a memorable representative of a kind of mathematical structure, which can be invoked by groups and by individuals in future problem solving.

Nested Levels of Modeling: Multi-Tiered Design Research

In parallel with learner-focused research using MEAs, researchers also have observed that *teachers'* efforts to understand their students' thinking involve yet another process of modeling: In this case, teachers engage in building models of student understanding. Although these teacher-level models are of a different category from student-level models, students' work while engaged in MEAs does provide a particularly rich context for teachers' modeling processes. Following this line of inquiry, the MMP community has also produced tools and frameworks that can be useful to teachers in making full use of MEAs in classroom settings, while also providing *researchers* with insights into *teachers'* thinking.

Finally, at a third level of inquiry, researchers' own understandings of the actions and interactions in *curricular activity systems* (Roschelle, Knudsen, & Hegedus, 2010) involving students, teachers, and other participants in the educational process can also be studied through the lens of model development. Multi-tier design experiments in the MMP tradition have done precisely this, involving researcher teams in self-reflection and iterative development as well (Lesh, 2002). Therefore, the MMP version of multi-tier design research can involve at least three levels of investigators— students, teachers, and researchers—all of whom are engaged in developing models that can be used to describe, explain, and evaluate their own situations, including real-life contexts, students' modeling activities, and teachers' and students' modeling behaviors, respectively. The situation can be further enriched by considering other educational stakeholders and learning settings, such as interactions between academic coaches and teachers (Baker & Galanti, 2017), and between schools and community organizations, and between students and parents.

Constructing Curricular Materials to Support Modeling at Larger Timescales

Over the past 15 years, MMP researchers have continued this direction of work in their own teaching and in partnerships with K-12 classroom teachers. Within the domain of statistical thinking in particular, this effort has produced resources and tools sufficient to support *entire courses* in several versions and including accompanying materials related to learning and assessment aimed at both student and teacher levels.

In their work on MEAs, students have rich but idiosyncratic mathematical experiences that need to be *unpacked* and placed into relationship with each other and with more canonical concepts, practices, and procedures from the discipline. To investigate such matters, MMP researchers attend to learner activity beyond the scope of single MEAs, formulating tools and designs for Model Development Sequences, or MDSs (Arleback, Doerr, & O'Neil, 2013; Doerr and English, 2003; Hjalmarson, Diefes-Dux, and Moore 2008; Lesh, Cramer, Doerr, Post, & Zawojewski, 2003). Work here includes approaches for extending the modeling dynamics that MEAs foster and for unpacking and making explicit learners' ways of thinking, so that they are available to be reflected upon by the classroom group as a whole and systematized in relation to big ideas in the discipline (see also Brady, Eames, & Lesh, 2015 for tentative MDS design principles).

Because the courses supported by these materials were designed explicitly to be used as research settings, for investigating the interacting development of students' and teachers' ways of thinking, the materials were modularized so that important components could be easily modified or rearranged for a variety of purposes in different implementations. In particular, by selecting from and adapting *the same core collection of MEAs*, and surrounding them with MDS activities tailored to the learning goals and emergent ideas of different classrooms, parallel versions of the course have been developed for: (a) middle- or high-school students, (b) college-level elementary or secondary education students, and (c) workshops for in-service teachers. Existence-proof versions of these courses have produced impressive gains (see, e.g., Lesh, Carmona, & Moore, 2009).

As a result of the breadth of the MMP, other models for engaging with MEA-style modeling at larger timescales have also emerged. These larger structures reflect other professional and theoretical interests and concerns, such as a commitment to iterative design-based inquiry (Eames, et al, in press); a focus on socio-mathematical norms (Yackel & Cobb, 1996), or the dynamics of coaching (Baker & Galanti, 2017).

Connecting to Themes Supporting Sustained Inquiry

While Model Development Sequences and other MEA-based approaches (cf Eames et al, in press) explore ways to sustain authentic modeling experiences over longer timescales, we have recently become interested in ways to build upon the *thematic* interests that MEAs awake in learners. Entering the world of the MEA's client, learners become deeply engaged in a world-view, and they are positioned as assisting in a cause or concern that they adopt for the duration of the problem, often quite energetically. We are asking ourselves, how might teachers or educators at a larger scale (e.g., schools, districts) build upon student interest in MEA clients' problems to offer sustained inquiry into the issues and concerns raised there? And the reciprocal question, how might important social issues (e.g., questions of social or ecological justice), or movements (e.g., citizen science or citizen activism projects) be a fruitful source for MEA design, yielding not only opportunities for rich mathematical modeling but also entry points for engaging of the student population with these out-of-school themes, contexts, and groups.

Research and Discussion Themes to Guide the Working Group

In the past several, our previous PME-NA working group meetings in East Lansing, Tucson, Indianapolis, and Greenville have brought together over 40 participants from the US, Canada, and Mexico. Participants have described ongoing implementation and research across a wide range of grade levels and educational settings. In their work, attendees reported that they apply a variety of interpretive lenses and frameworks to modeling, and they situate their work in a variety of ways with respect to other current trends in mathematics education research. Moreover, in pursuing their practice, they developed definitions of core MMP constructs that were both broadly compatible (enabling productive discussion) and differently specialized and exemplified (enabling illuminating debate).

We have thus found Working Group meetings to offer unique opportunities to connect research voices and viewpoints, spurring conversations between research groups that have common inspiration and compatible interests, but very diverse local experiences and perspectives. The Working Group meetings have also consistently been a vehicle for connecting "old timers" with "newcomers." Some of the giants in the PME-NA community (e.g., Dick Lesh, Lyn English, Helen Doerr, Margret Hjalmarson, Jim Middleton, Tamara Moore, Eric Hamilton, and others) have also been leaders in the MMP, and in each of our sessions, we have invited participation from one or more of these leaders to offer perspectives on our thinking and on the field as a whole. We see these interactions as an important aspect of newcomers' (and old-timers') experience of the conference as a site for the exchange of wisdom, perspective, and enthusiasm among participants.

In our planning leading up to the Greenville we identified a compelling opportunity to experience and workshop an MEA that was still being designed. Thus we configured our work as a "researcher-level MEA" – where our "client" was the research team preparing the MEA for its first implementation, and where we experienced the problem as learners (working on the problem together during session 1) and as researchers (reflecting on our experiences and work-shopping possible revisions or additions to the activity).

As we learned more about the work of our "client" through workshopping the MEA, we became interested in the subject matter of the problem (which involved Box Turtles and conservation efforts surrounding them), and we identified connections between the way conservation efforts and issues entered into this problem and into work that members of our group had done in their own MEA designs. Our client's connections with a major ecological foundation were distinctive, but we felt that the idea of building an MEA that would awaken students' interest in ecological or social issues was not only compelling but possibly a repeatable and generalizable approach. This year, we aim to prove out that emergent conjecture. Specifically, we aim to explore how conservation and sustainability can serve as a context for authentic mathematical modeling—and how such modeling efforts can stimulate interest and concern for conservation and sustainability.

Session Outline: Advancing the Research Agenda while Building Community and Capacity

The working group will meet in three sessions over the course of the conference. As the organizers and facilitators do the preparatory work for the conference, these plans will be refined, but the broad outlines here reflect our current thinking.

As mentioned above, our experience of the working group over the past three PME-NA conferences has highlighted the value of these meetings for both (a) establishing and "hashing out" plans for innovative collaborative research, and (b) inviting interested newcomers to the

MMP, providing them opportunities to engage with its principles and practices and to interact with some of its founding members. Although it imposes an intense challenge for organizing and facilitating the working group, we aim to continue to support these two strands of activity. In part, we are committed to both because we recognize the importance to the MMP both to advance its agenda and rejuvenate its participant group. But in addition, we recognize that these two threads are in fact inseparable. Some of our most interesting theoretical discussions have come out of the friendly challenges from newcomers/outsiders, and we aim to cultivate and integrate rather than cordon off these voices and perspectives.

Key among the preparatory efforts for the facilitator group will be to select the focal MEA. One proposal is to return to the Box Turtle MEA workshopped last year, and use the session to explore adaptations and variations that could enable learners from diverse geographic settings to connect with local conservation efforts and/or citizen science projects. An alternative would be to pursue another of the design efforts emerging among others in the facilitator group, which also combine conservation, community engagement, and citizen science. In either case, the focus will be on creating MEA-style activities that foreground the mathematical modeling challenges inherent in pursuing such efforts. Below, we describe the session plan assuming the "Box Turtle" choice; changing the focal MEA will change the details but not the high-level purpose of each session or the "story arc" of the Working Group overall.

Session One

Our goal in Session One is to equip a diverse attendee group to participate in workshopping the focal MEA. With Box Turtles, this will involve a slightly time-compressed experience of the MEA as learners, followed by a report of the implementations since last PME-NA of this activity, and patterns in both students' modeling work and in the interests that students and teachers have expressed in conservation topics.

Sessions Two and Three

The goal of these sessions is to make substantive contributions to the effort to identify opportunities to connect the MEA with local conservation efforts, and to provide suggested structures for activating those connections. For instance, one of the emergent themes in our prior work with the Box Turtle MEA was the challenge of structuring observations (of turtle's features) and converting observed phenomena into measurable quantities (and into a *procedure* for measuring them). This is both an important theme in the history and philosophy of science (Daston and Lunbeck, 2011) and a theme recognized as appropriate and valuable for science learning, even at a young age (Eberbach & Crowley, 2009). Moreover, as Trumbull et al (2005) describe how identifying and stabilizing clear and repeatable procedures for observation is critical efforts like those central to organizing successful citizen science efforts.

A possible goal, then would be to refine the design of this MEA so that it (1) uncovers and delves into an important issue and practice involved in participating in citizen science projects, and (2) raises awareness and interest in the social and ecological themes that often *inspire* participation in citizen science projects. Together, these features of a refined MEA could both motivate and prepare students to engage in conservation projects, preparing them to experience citizen science through the lens of modeling, and modeling through the lens of engaged citizenship.

Session Three will be dedicated to making concrete research plans for continuing work after the Conference. This will include plans for multiple implementations of the revised focal MEA and other thematically-connected MEAs. We will foreground implementation opportunities, identify opportunities for cross-institution IRB proposals and additional collaborations to create new MEAs that exhibit similar connections with social issues and movements.

Acknowledgements

Proposing and facilitating this Working Group is a highly collaborative effort. Authors after the first contributed equally, and their authorship order has been determined at random.
