The few studies of children's decimal multiplication often focus on students' procedural, not conceptual, understanding. Hiebert and Wearne (1985) conjectured students learn decimal multiplication procedurally and disconnected from underlying concepts. They found that "students' procedures are indeed syntactically based" (p. 200), with decimal operations viewed by students as moving symbols around on paper. Yet, there were several instances where students deviated from Hiebert and Wearne's (1985) predicted error types. Specifically, students used the Decimal Placement Rule inconsistently, leading Hiebert and Wearne (1985) to state "we cannot explain the conditions under which such a rule is applied" (p. 193). More recently, Larsson et al. (2017) reported case studies of two students followed from fifth to seventh grade. Despite both students' competence with multidigit whole number multiplication, they consistently had difficulty explaining decimal multiplication. Indeed, one student described decimal multiplication as "a completely different system not susceptible to distributivity" (Larsson et al., 2017, p. 10). Others have observed children's difficulty with decimal multiplication (Greer, 1987; Lortie-Forgues et al., 2017; Tian et al., 2021) but provide similarly limited descriptions of children's multiplicative reasoning therein. Rather, the literature suggests that place-value is an issue, but there is no indication of differences in how children coordinate multiplicative units in such contexts. The central goal of the current study is to examine children's approaches and reasoning with multidigit whole number and decimal multiplication when these children are at different documented levels of multiplicative reasoning.

Overview and Research Questions

This paper explores the intersection of two understudied areas of scholarship: multidigit multiplication (Hickendorff et al., 2019) and decimal multiplication (Larsson et al., 2017). Scholars generally agree that many students apply the Decimal Placement Rule rotely (Hiebert & Wearne, 1989) and that students' difficulties with decimal multiplication are often associated with their conceptions of multiplication and place value in decimal multiplication (Larsson et al., 2017; Lortie-Forgues & Siegler, 2017). Given that children's ability to engage with partial

products is facilitated by their multiplicative reasoning (Gill et al., 2025), we sought to better understand how children's ability to engage with partial products corresponded to how they engaged with their multiplication of decimals. Thus, we sought to answer the following question: *How do students reason mathematically when engaged in decimal multiplication tasks, and how do their actions correspond to their multiplicative reasoning?*

Methods

Participants & Protocol

Participants included 28 fifth and sixth grade students enrolled in different schools in a Midwestern US state. Participants were part of a larger study of 1,451 students across grades 4-6. Students completed grade-level specific written packets that included the Multiplication Reasoning Assessment (MRA) to assess which multiplicative concepts students operated. The MRA includes substantial validity evidence, including analysis of students' written work and interviews relating their scores to their reasoning with multiplication and division tasks (Kosko, 2019). The packets also included 10 multiplication tasks that had four common items across grade levels. Fifth and sixth graders completed: 21×4; 19×16; 37×34; 86×49; 789×382; 81×0.36; 24×0.32; 5.7×93. Fifth graders also completed 457×21 and 2083×35 while sixth graders completed 1.43×0.006 and 0.15×0.85. We used MRA scores, as well as written responses to canonical multiplication tasks, to purposefully sample a cross-section of 18 fifth and 10 sixth grade students. Participants wore Pupil Neon eye-tracking glasses to capture eye gaze data. Students were asked to solve a set of tasks one at a time and then to explain their reasoning for how they solved each task. Fifth grade (14×2, 8×42, 43×38, & 0.54×25) and sixth grade students (8×42, 43×38, 0.54×25, & 0.81×2.4) solved both whole number and decimal multiplication tasks. Follow-up questions focused on students' procedures, the place-value meaning of certain digits, and/or how the child might visually represent their procedures.

Analysis & Findings

We implemented a transformation variant mixed methods design where qualitative themes were transformed into ordinal data for quantitative analysis (Creswell & Plano Clark, 2018). This study emphasizes the qualitative findings, while the quantitative analysis provided statistical support for observed trends in qualitative analysis.

Qualitative Analysis & Findings

We used a descriptive-interpretive qualitative approach to examine interview data from video recorded with mobile eye-tracking headsets (Elliott & Timulak, 2021). Specifically, we examined students' approaches to solving multiplication problems, focusing on observable actions that included writing/drawing, discourse, gesture, and eye-gaze behavior. Each author conducted multiple rounds of open coding before the research team discussed observations and developed initial themes based on this analysis. Four dominant themes emerged across all 28 participants: Arithmetic Decimal Operator (n = 10); Rote Decimal Counter (n = 11); Multiplicative Decimal Operator (n = 5); and Meaningful Decimal Counter (n = 2). Below we describe four brief cases of each theme focusing on Josefa, Irven, Hunt, and Faith.

Arithmetic decimal operator. Ten students relied on arithmetic approaches to solve decimal multiplication problems and in placing the decimal in the product. Quite often, this involved multiplying numbers by column, doubling, or repeated addition before placing the decimal in the product directly below where it was aligned in the multiplication problem. Such actions mimicked rules used in decimal addition. Josefa, a sixth grade student operating at MC1, provides a useful case of students demonstrating this theme. At MC1, Josefa could anticipate one level of units and construct the second level in activity. For example, early in the interview

Josefa used doubling approach to solve 8×42 by writing four pairs of 42 and adding each pair until eventually finding a sum of 336. The approach demonstrated an ability to iterate the composite 42 eight times but through a process of partitioning the multiplier into four 2s. However, Josefa did not demonstrate an ability to partition the multiplier by place value, which is typically associated with students at MC2 (Gill et al., 2025). Instead, for tasks where multiplicands included more than one digit, she typically would stack the numbers vertically and multiply within a column. This was evident in her decimal multiplication. For 0.54×25, Josefa placed 0.54 above 25, aligning the 4 and 5 digits on the right (see Figure 1) and multiplied the digits within each column. Josefa confirmed this approach explaining "…Five times four is twenty so you put the two over the five. Then, five times two [points to the 5 and 2 in column] is ten plus two is twelve.". When a decimal was present in both multiplicands, Josefa would align by decimal in both her written work and in the interviews. Across the decimal tasks, Josefa's eye gaze consistently moved along the column structure of tasks (see Figure 1). For example, for 0.81 ×2.4, Josefa multiplied 1×0 (inferring a 0 below the 1), 8×4 within that column, and so forth. Her eye-gaze follows the same pattern when placing the decimal between the 5 and 2 in her product. Josefa explained her decimal placement stating, "…they are always supposed to line up." Based on Josefa's and other students' interviews, we infer this approach to be a direct application of rules learned for decimal addition and subtraction. Interestingly, the approach was most common amongst pre-multiplicative and MC1 students.

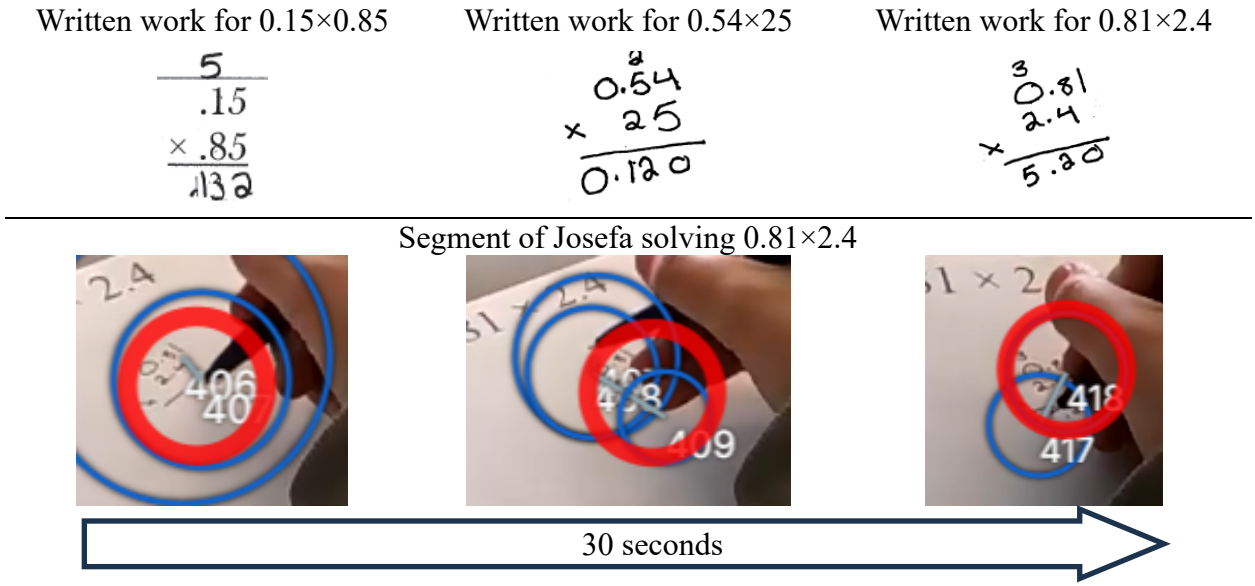

Figure 1: Written Work and Segments from Interview for Josefa (MC1)

Rote decimal counter. This theme describes students' actions wherein they used the Decimal Placement Rule (whether such actions were mathematically correct or not) but could not provide a rationale for it. Irven, a sixth grader, was one of 11 students demonstrating this theme. He operated at MC2, meaning he anticipated two levels of units and constructed three in activity. For example, early in the interview when multiplying 8×42 with the Box Method, he was able to break 42 into 40 and 2 to multiply each by 8 via disembedding by place value. This was evident in his explanation for why 8×40 allowed him to "add a zero" for 320. With 40 aligned by place value directly above 320, he stated "it is like a 10, but you don't really see it…"

As he stated this, his eye-gaze quickly went between the two 0s which we inferred was evidence of him disembedding 40×8 as (10×4)×8 because the 40 was simultaneously described and treated as four 10s as well as 40 without the need to construct the relationship in activity. This allowed Irven to also solve whole number problems with four partial products by operating on one set of two partial products at a time. When solving the decimal multiplication tasks, Irven solved these tasks as he did whole number multiplication tasks, until it was time to place the decimal point. Irven's eye gaze shifted to the expression 0.81×2.4 as he focused first on the 81 in .81 and then on the 2 in 2.4. As he did this, his eye gaze shifted back and forth between the given expression and his calculated product. He then counted from left-to-right and paused his pen and eye gaze between the 4 and 4in 1944 before counting from right-to-left and placing a decimal for an answer of 1.944. When asked about why he chose the latter of the two places, he indicated it was a rule that he had learned. When pressed why the rule worked, he said, "I just know you're supposed to do this" and motioned with his pen three counted spaces from right-to-left on the digits 1944. Thus, Irven knew the Decimal Placement Rule, but was not consistent in the directionality for counting. We infer this to mean he did not understand the role of place value in the Decimal Placement Rule but did understand the role of place value for partial products.

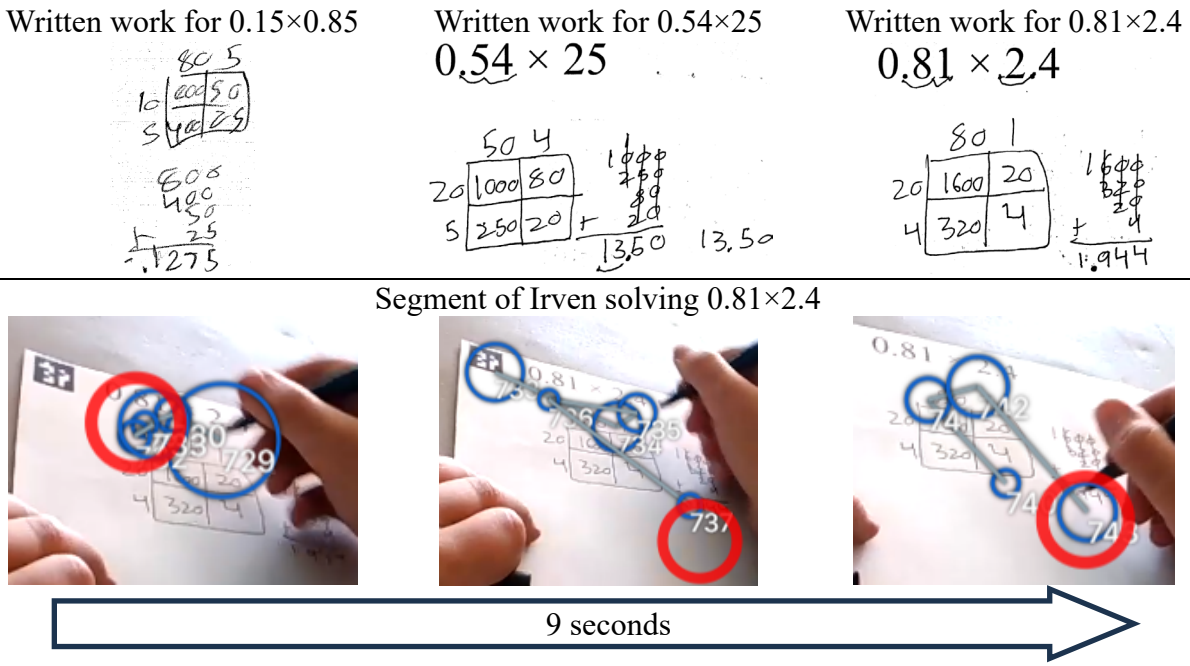

Figure 2: Written Work and Segments from Interview for Irven (MC2)

Multiplicative decimal operator. Students demonstrating this theme did not rely on counting the number of decimal places to determine the position of the decimal point, but instead attempted to solve the problem using place value. Hunt, a fifth grader operating at MC3, was one of five students demonstrating this theme. Thus, Hunt was able to anticipate three levels of units. For example, when solving 43×38, Hunt disembedded 38 into 30 and 8, and 43 into 40 and 3, according to their place values, and then wrote down the expressions for each partial product. As he explained this procedure in the interview, his eye-gaze shifted between the corresponding digits in 38 and 43, indicating he considered the 3 digit in 38 as 30 and the 4 in 43 as 40,

simultaneously. When solving the decimal multiplication tasks, Hunt solved tasks as he did whole number multiplication tasks, until it was time to place the decimal point. For example, when solving 0.54×25, he wrote four partial products: 0.50×20, 0.04×20, 0.50×5, and 0.04×5. When focusing on the partial product 0.04×5, he quickly wrote down 20 and spent about 3 seconds (see Figure 3) focusing on the particular location of the digits in relation to the decimal's location before placing the decimal before the 2 for 0.20. Important here is that Hunt's gaze did not move in a counting motion but instead moved between the whole number product produced (20) and the location of decimals in the other multiplicand. In explaining his work, Hunt referenced the whole number place value of the product as a rationale for where the decimal would be placed, which appeared similar to approaches used by Rote Decimal Operators, but with a focus on the place value meaning of multiplication.

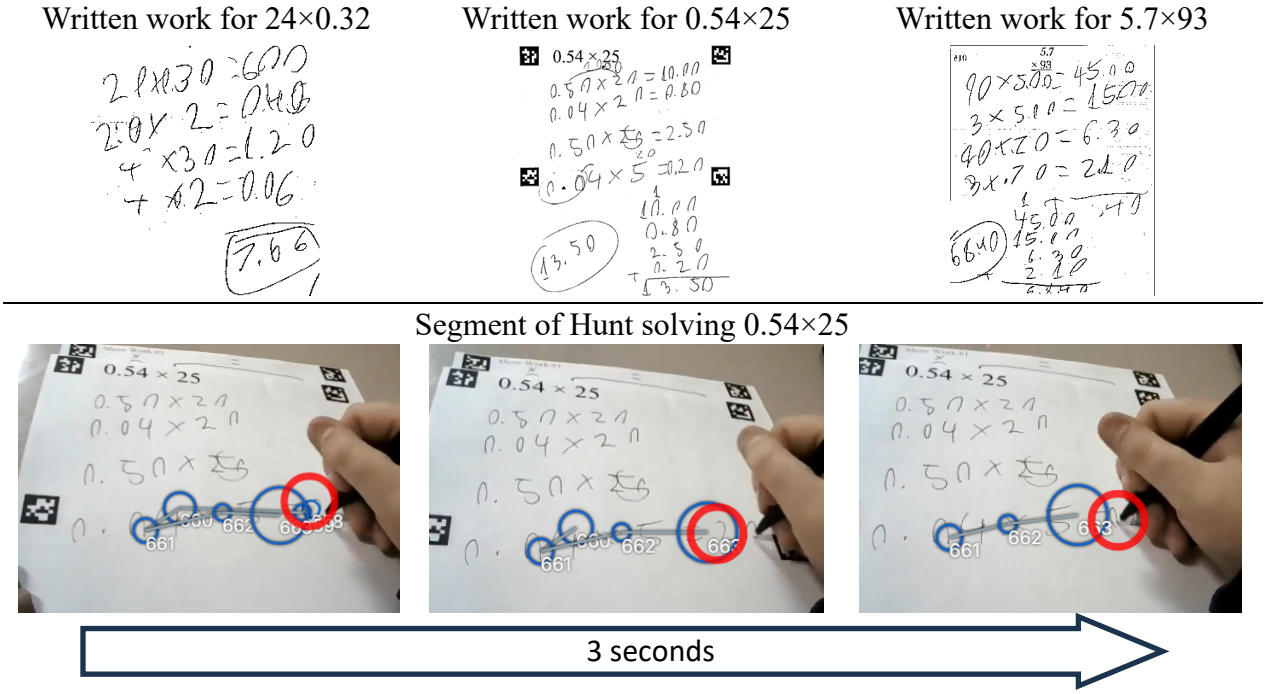

Figure 3: Written Work and Segments from Interview for Hunt (MC3).

Meaningful decimal counter. This theme describes students' actions in which they used the Decimal Placement Rule, but were able to provide a place value related rationale for it. Faith, a sixth-grade student at MC3, was one of only two students demonstrating this theme. At MC3, Faith could anticipate three levels of units and demonstrated this earlier in the interview when solving 43×38 using the standard algorithm. In explaining her approach, she consistently referenced the place value meaning of all digits without the need to explicitly write or construct them. For example, she explained "8 times 3 is 24. So you regroup the 20 and put it up there" to explain what the regrouped 2 meant, and then later explained "then you add a 0 [for the second row of products] because it's not a 3 [you're multiplying by], it's a 30..." While Faith's MRA scores also suggest she operated at MC3, we inferred her actions here as confirmatory because she could describe the place value meaning within the algorithm and identify all four partial products within the two rows of products. This latter aspect is evidence of simultaneous

disembedding of relating two partial products (43×8 & 43×30) to four (40×8, 3×8, 40×30 & 3×30). Faith was able to articulate the same reasoning and procedures for decimal multiplication, while consistently applying the Decimal Placement Rule. For example, solving 0.54×25, Faith's eye-gaze shifted to the 0.54 and moved just ahead of her pen as her eyes moved between the 4 and 5 indicative of counting each digit in 0.54 before doing so in the product. When probed about this, she explained that after summing her partial products "…you would get 1,350. But since it's two decimal – it's a hundredth and it's not in the one's place. You'd have to add the two decimals or…I don't know…It's divided by 100 sort of." We infer from Faith's actions and explanations that she understood that place value served a role in why the Decimal Placement Rule worked, and this was evident of a meaningful understanding of it.

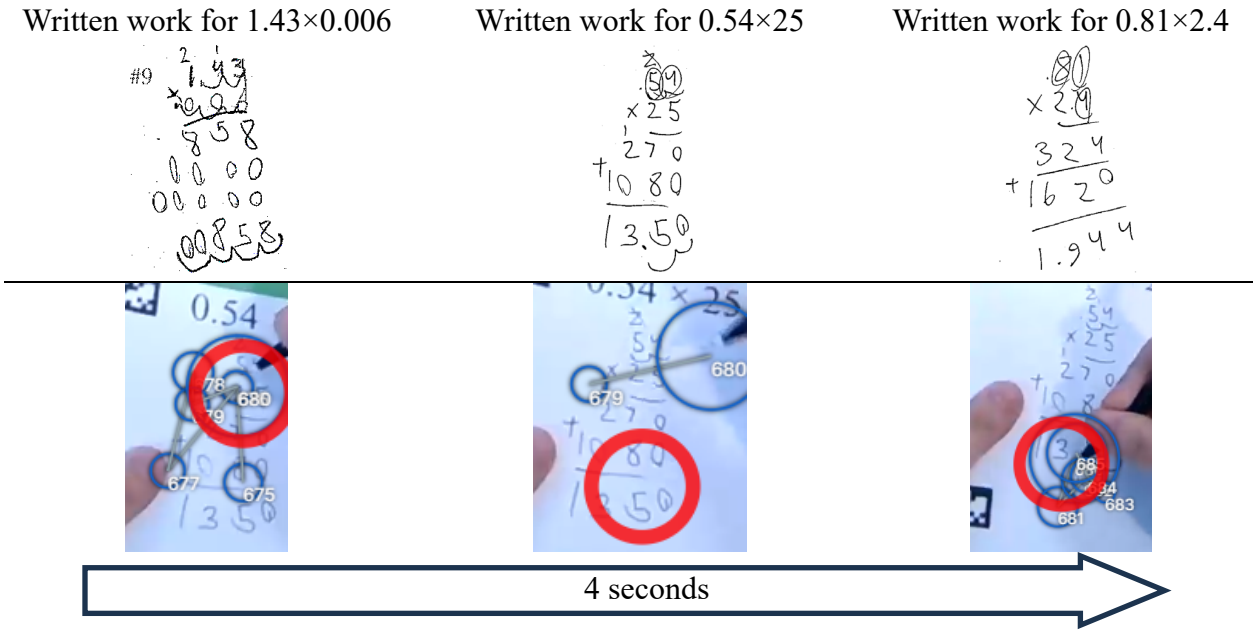

Figure 4: Written Work and Segments from Interview for Faith (MC3)

Quantitative Analysis & Results

Themes from qualitative analysis were quantified into ordinal data (1 = Arithmetic Decimal Operator; 2 = Rote Decimal Counter; 3 = Multiplicative Decimal Operator; 4 = Meaningful Decimal Counter). Qualitative descriptions of children's reasoning with decimals provided the necessary rationale for this order. Specifically, Arithmetic Decimal Operators focused neither on partial products nor the multiplicative meaning of the decimal, whereas Rote Decimal Counters typically focused on the meaning of partial products, but not on the multiplicative meaning of the decimal. Multiplicative Decimal Operators focused on partial products, while often having to construct the multiplicative meaning of decimal placement. Only Meaningful Decimal Counters provided place value explanations related to the Decimal Placement Rule. Next, we calculated a Gamma Statistic, which is a nonparametric measure of association between two ordinal variables (Siegel & Castellan, 1988). The calculated Gamma of .805 ($p < .001$) was both strong and statistically significant, suggesting that knowing either the level of multiplicative reasoning or decimal multiplication actions would reduce one's error in prediction by 80.5% (see Table 1).

Table 1: Contingency Table for Themes and Multiplicative Concepts

	Arithmetic Decimal Operator	Rote Decimal Counter	Multiplicative Decimal Operator	Meaningful Decimal Counter	Total
PreM	2	1	0	0	3
MC1	6	0	0	0	6
MC2	1	3	1	0	5
MC3	1	7	4	2	14
Total	10	11	5	2	28

Discussion

Most of the scholarship on decimal multiplication has focused on students' written procedures or task format (Hiebert & Wearne, 1985; Lortie-Forgues & Siegler, 2017; Tian et al., 2021), with relatively few examinations of children's reasoning through such tasks (Larsson et al., 2017). For example, Hiebert and Wearne's (1985) seminal study noted that students applied the Decimal Placement Rule inconsistently but could not explain why. Findings reported in the present study provide four distinct ways in which students engage with decimal multiplication, and these are strongly associated with their multiplicative reasoning. Initially, students engage with decimal multiplication in ways similar to decimal addition/subtraction, but with multiplication of digits within columns. As students begin to understand partial products (MC2 & MC3 reasoning), they begin to engage in the latter three themes.

Although there is some variance in alignment between multiplicative reasoning and decimal multiplication themes (i.e., a pre-multiplicative student can learn the Decimal Placement Rule by rote), findings suggest students at MC2 and higher are more likely to apply the Decimal Placement Rule. Yet, the meaning behind this rule is still being constructed. Irven could apply the rule, but sometimes mixed up the direction he counted the decimal places, and this inconsistency may be what Hiebert and Wearne (1985) observed in their own interviews. Multiplicative Decimal Operators seldom used the Decimal Placement Rule, but did focus on the place value meaning of multiplication with decimals. Although Hunt demonstrated correct approaches, other Multiplicative Decimal Operators demonstrated meaningful reasoning that led to incorrect solutions. Notably, we observed only two students able to provide a conceptual explanation of the Decimal Placement Rule and both of these students were at MC3. Findings here are preliminary but highly significant, as they go beyond models of examining students' rote procedures (Hiebert & Wearne, 1985) and extend models of their reasoning across a range of multiplicative reasoning (Larsson et al., 2017). Additional analysis is needed to both confirm and extend observations here, but these findings provide important insight into how children reason with decimal multiplication.

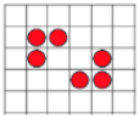
Subitizing supports early number development, yet we know little about how children coordinate rapid quantity apprehension with visual structuring across representations. Using a procept lens, we analyzed preschool and kindergarten children's responses (N = 20) to brief presentations of six-dot in random, growing, canonical array, structured, structured and growing, canonical array and structured, and ten-frame layouts (fivewise, doublewise). Coding 159 instances across eight tasks identified nine activity forms from counting and estimating to conceptual subitizing and number structuring. Random displays more often elicited estimation and unstable drawings; whereas, structured arrays and ten-frames supported explicit part–whole composition. Many children reorganized random dots into canonical groupings, and some showed "groups of groups" and reversible reasoning, suggesting early pathways toward multiplicative thinking.

Keywords: Number Concepts and Operations, Early Childhood Education, Learning Theory, Learning Trajectories and Progressions



The literature is incomplete in describing when and how children subitize and structure items visually in mathematics classrooms and how this can be leveraged to support early forms of number development. *Subitizing*, a quick apprehension towards numerosity when shown a small set of patterned items (Kaufman et al., 1949), has been found to explain early forms of children's counting development (Wilkins et al., 2022). Sarama and Clements (2009) distinguished between perceptual subitizing (subitizing patterned stimuli with verbal number associations) and conceptual subitizing (subitizing and composing units conceptually). Ellemor-Collins and Wright (2009) describe children's subitizing with base-ten frames as number structuring (conceptualizing number relations). Given this, we wondered how these constructs could further explain how varying arrangements of six items shown to children may relate to their number understanding. The focus here is on the different ways preschool and kindergarten students subitize when shown a random six, an array of six (with/without structure), a staircase of six (with/without structure), and a ten-frame of six (fivewise and pairwise; see Table 1).

Theoretical Framework

To examine young children's number understandings concerning their subitizing activity, we examine number abstraction through the lens of a procept (Gray & Tall, 1993; Gray et al., 2000). Fundamental to a procept is the notion that "abstraction is drawn not from the object that is acted upon, but from the action itself" (Piaget, 1970, p. 16). Gray et al. (2000) define a *procept* as children's reification and coordination of their processes to form mental objects. A procept characterizes flexible reasoning, explaining how children move back and forth between their processes and mental objects. In this study, we considered processes children used when

describing parts of a whole and mental objects they used to conceptualize parts and their respective wholes. We considered children's re-presentations (i.e., drawings, finger patterns) as foreshadowing potential future processes and object development.

4		Structured	Interview 3
5		Structured and Growing	Interview 3
6		Canonical - Array and Structured	Interview 3
7		Ten-Frame - Fivewise	Interview 4
8		Ten-Frame - Doublewise	Interview 4

Subitizing and Number Structuring

Kaufman et al. (1949) first named and operationalized subitizing, providing educators constructs to examine in children's reasoning and to inform curricula (Sarama & Clements, 2004), pedagogical practices (Parrish, 2010; Sun et al., 2018), and children's entertainment (e.g., https://www.ncetm.org.uk/classroom-resources/ey-numberblocks-support-materials/). Resulting from Kaufman et al.'s work, scholars distinguish subitizing as operationally unique from estimation, as individuals evidenced significantly faster and more accurate response times when subitizing items one through three versus when they estimated four or more items.

Perceptual subitizing, first defined by Clements (1999), refers to the process by which children develop simple perceptual associations between canonical patterns (e.g., with dots, fewer than three or four) and number words. When perceptually subitizing, children often describe the shape made by the dots or identify subgroups without identifying the total group (MacDonald & Wilkins, 2016). Comparatively, *Conceptual Subitizing* describes children as uniting several perceptually subitized groups of items to form larger groups (e.g., "I saw five because I saw two, two, and one!"), especially with canonical patterns. This activity has been found to explain more sophisticated activity and requires children to partition the canonical pattern and develop part-whole additive relationships between the subitized units (Clements et

al., 2019). *Number Structuring* or Spatial Structuring explains networks of units, often after children are quickly shown arrays (Bajwa et al., 2023; Ellemor-Collins & Wright, 2009). MacDonald and Wilkins describe many constructs preschool children may utilize when subitizing (i.e., ascending towards the group, descending from the group, perceptual subgroup subitizing), but does not include varying aspects of number structuring. We will partially frame subitizing with these constructs to explain procept development. In this proceeding, we aim to utilize these constructs to explain children's access to varying number and operation understandings when subitizing unstructured dot arrangements, canonical patterns, ten frames, and arrays (Bajwa et al., 2023).

Methods

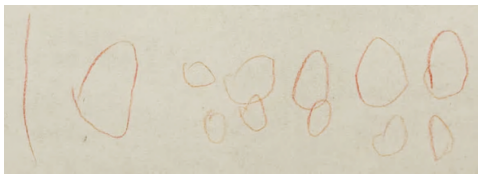
Part of a larger study, this paper examines the type of subitizing activity of 20 children (9 preschool students; 11 kindergarten students) evidenced across three 15-minute interview sessions. Participants were enrolled in schools in the midwestern portion of the United States. Each participant engaged with tasks that drew from random, canonical, unstructured, structured, growing, and ten-frame arrangements of dots (see Table 1). Dots were shown in a span of three-second intervals. Because preschool participants were a year younger, they were shown arrangements with relatively fewer dots than the kindergarten participants' tasks. However, in this paper, we present results on dot patterns of six that all participants saw.

For broad data organization, the authors watched and transcribed the videos before organizing the data in Excel. For each participant, we placed transcriptions in rows (a new row per speaker change). We then included columns for notes, images of participants' drawings, descriptions, and/or images of their finger use, descriptive codes (i.e., describing groups and then the total), and constructs (i.e., ascending towards the group) used to operationalize procepts. Through this initial data analysis, we wondered how children re-presented arrangements for six in different ways. As such, we organized in a new Excel spreadsheet children's language around groups used and drawings related to different arrangements for six shown to them.

Results

From the eight tasks across three interviews, the 20 students had the potential to evidence 160 types of activity, with 159 instances documented. Given the space of this proceeding, we describe a portion of these instances. From our analysis of these instances, we found nine themes (*counting, estimating, perceptual subitizing, perceptual subgroup subitizing, ascending towards the group, descending from the group, counting and subitizing, conceptual subitizing,* and *number structuring*), evidencing relations between subitizing and procept development.

Counting



When one preschool student, Bluey, used counting, he seemed to either re-present the shape shown to him or the number of items he counted. After showing Bluey a random arrangement and asking him to draw what he saw, Bluey started drawing a vertical column of six circles (see Figure 1a), while verbalizing, "Two, three, four, five, six" as he drew each additional circle. Bluey is capable of producing six and abstracts the six drawn items with his written symbol "6."

When shown a typical canonical pattern of six dots (an array of two rows of three dots), Bluey immediately started counting to six as the picture was taken away and then declared it to be 10. Bluey seems to be focusing on the image shown to him and considers this primary and his counting secondary. This is evidenced when Bluey draws an array of two rows of five dots (see Figure 1b), suggesting his use of number is dependent on the shape shown to him. For instance, he drew his first dot at the right side of the paper, saying, "One," and then drew three additional

dots to the left while counting them, "two, three, four." He drew his fifth dot, "five" above the fourth one, and then drew the next three to the right of that one, "six, seven, eight," making an array of two rows of four dots each. He continued drawing "nine" to the right of his eighth dot and paused. When asked if that's what he saw, he reiterated, "Well, it WAS ten," and he drew another dot, "ten," under the ninth dot. When counting, Bluey used a remembered image similar to what was shown to him, allowing him access to all the items to count. This suggests that Bluey was relying on actions for future mental processes and objects (Gray & Tall, 1994).

b) Canonical Array, Task 3

Figure 1: Bluey's Drawings, When Shown Arrangements in Tasks 1 and 3 (see Table 1)

Estimating

Kaufman et al. (1949) describe *estimating* as when individuals express a relatively lower confidence level, degree of accuracy, and speed in response. We found that participants estimated more often when shown random arrangements (40% estimation) than canonical patterns (5–10% estimation) (Moscoso et al., 2020). We coded students' activity as estimating when they did not describe groups, arrangements, or operations that supported their response. As the students estimated, we found that they were, at times, accurate (four instances) and at times, inaccurate (seven instances). When students drew what they saw, they often re-presented arrangements shown to them in a horizontal arrangement (see Figures 2b–2d). This suggests they may have been engaging in an Approximate Number System (Norton & Alibali, 2019; Dehaene, 2011) because they may have been keeping track of their number sequence as they drew the items, and stopped once they reached an implicit number, informed by the shape and/or the space taken up by the arrangement.

a) Random Arrangement, Task 1

b) Random Arrangement, Task 1

c) Growing Pattern, Task 2

d) Ten-Frame, Five-wise, Task 7

Figure 2: Drawings Evidencing Estimating (see Table 1)

Two students, one a preschool student (see Figure 2a) and one a kindergarten student, drew the arrangement in a shape dissimilar from the one they were shown. This may indicate that, even though they did not explicitly mention shape in their response, they were implicitly relying on the movement their eyes engaged in when estimating (cf. MacDonald et al., 2012).

Perceptual Subitizing

When students relied heavily upon shape to accurately describe the number six, we described this as perceptual subitizing. Sarama and Clements (2009) describe children transitioning

towards conceptual subitizing when shown six items. However, MacDonald and Wilkins (2016) describes some young children relying on perceptual activity when shown six items. As such, when participants described seeing six items and seemed to explicitly rely on the shape shown to them or a shape associated with their understanding of six, we considered this to be perceptual subitizing. For instance, even though three students (one kindergarten student and two preschool students) perceptually subitized the random arrangement of items, they all seemed to draw from their association with six in an array format (similar to Task 3, see Table 1). This suggests that when perceptually subitizing, participants may have been implicitly drawing on a grouping structure to reorient the items in this way, but could not yet explicate this. We also observed participants re-presenting a similar arrangement shown to them, suggesting that the features of the shape (i.e., structures, canonical groups) allowed them access to not yet explicated groups and/or patterns, which in turn allowed participants to access the number represented by the arrangement of items (see Figure 3). Finally, one student, Manesh, considered the ten-frame pairwise arrangement (see Task 8, Table 1) as a character from a television show he had seen, Numberblocks (see Figure 3f). He drew the character next to the arrangement that he had seen, but was not able to explain the subgroups that made this arrangement six. This suggests that previous experiences can inform perceptual subitizing activity and inform opportunities for future mental objects to develop (Gray & Tall, 1994).

Figure 3: Drawings Evidencing Perceptual Subitizing (see Table 1)

Perceptual Subgroup Subitizing

Perceptual Subgroup Subitizing fundamentally explains a participant's ability to partition a group of items and subitize each subgroup, but not use these subgroups to accurately describe the total number of items (MacDonald & Wilkins, 2016). For instance, when shown structured arrays or dots in ten frames, Moana, one of the preschoolers, identified subgroups and drew the two groups of three (see Figure 4c), before putting up three fingers on each hand and counting her fingers to determine there were six dots. Likewise, when shown the structured and growing arrangement of six, she called it "stairs" and accurately drew one dot, then two dots in the next column, and then three dots in the final column (see Figure 4d). However, she once again needed to count them to name the group as six. We found 13 instances of when participants engaged in perceptual subgroup subitizing (see Figure 4). Students demonstrated perceptual subgroup subitizing when they could subitize subgroups and connect this to a total group developed through their counting and/or estimating. By allowing participants opportunities to re-present the items shown to them in subgroups, they were able to count or estimate to determine the total number of items shown to them. When students engaged in perceptual subgroup subitizing, they often developed partitioned patterned images for future procept development (Gray & Tall, 1994).

Figure 4: Drawings Evidencing Perceptual Subgroup Subitizing (see Table 1)

Ascending and Descending Towards/From the Group

When participants used groups in their subitizing activity, they either described the subgroups and then the total items in the group (*ascending towards the group*) or described the total number of items and then described subgroups (*descending from the group*; MacDonald & Wilkins, 2016). The distinction between this activity and conceptual subitizing was that the participants did not seem to concurrently understand the subgroups and the total, but could either subitize the subgroups and then the total or vice versa. This suggests participants were capable of conceptualizing part-whole numerical relationships, but could not anticipate and coordinate these relationships when quickly shown the arrangement of items.

In particular, when ascending towards the group (see Figure 5), we observed two instances, I which kindergarten students described subgroups and then explained the total number of items in the group. It seemed two students changed the number of items in each of the subgroups each time, until determining the subgroups and then using this activity to construct the total number of items in the group. John (see Figure 5a) explains he saw five and two, and then as he draws the circles, he changes his response to five and one before describing the total amount as "six."

A: Growing Pattern, Task 2

B: Structured, Task 4

Figure 5: Drawings Dvidencing Ascending Towards the Group Subitizing (see Table 1)

When descending from the group, Olasa, one of the preschoolers, saw the six in the ten-frame doublewise and quickly stated that she knew it was six. She was unable to say how she knew it was six; instead, she drew a grid with several empty boxes. Although her grid was eight by three, she still drew her six dots in pairs (vertically instead of horizontally, see Figure 6), noticing, "There's a two and a two, and a two." Her responses indicate that she only considered the subgroups of the dots after considering her drawing. This evidences participants' flexible activity between objects and actions, informing future procept development (Gray & Tall, 1994).

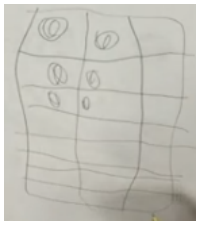

Figure 6: Olasa's Drawing of Six When Shown the Arrangement from Task 8 (see Table 1)

Counting and Subitizing

There were also three instances when participants coordinated their sequential activity through their counting with their grouping structures through their subitizing. For instance, when shown the growing pattern in Task 2 (see Table 1), Finn (a kindergarten student) quickly states that he saw "three … six", suggesting his grouping structures for three were distributed along his number sequence. This is very different from stating that he saw three and three and this is six, as he may not have been explicitly aware of two groups of three. After showing Bluey the arrangement from Task 8 (see Table 1), he first says, "one, two, three, four, five, six." He then draws the image he saw, while drawing the eight additional dots outside of the rectangle he drew to show what had been "eaten." It seems Bluey is experiencing conflict as to which to attend to: his grouping structure and the shape shown to him, an experience where he is "eating something," or his counting. Hence, students coordinated their past experiences with their grouping and counting structures or switched between them. Here, participants drew from counting actions to further inform relationships between their mental objects for "six" and their processes related to "six" (Gray & Tall, 1994).

Conceptual Subitizing

There were 50 instances where participants demonstrated conceptual subitizing. Given the space of this proceeding, we only focus on three different types of conceptual subitizing (with random arrangements, with patterned arrangements, and explicit operations). The preschoolers we worked with demonstrated conceptual subitizing only when the dots were structured in grids or ten frames. When shown random arrangements, four kindergarten students demonstrated conceptual subitizing, suggesting relatively greater reliance on more abstract operations (Moscoso et al., 2020). Finally, both kindergarteners and preschoolers explained some groups in the form of an operation ("three plus three equals six").

Cinderella talked about the arrangements in terms of lines, indicating that the ten-frame fivewise was a "straight line [of five] and one down" (see Figure 7b). Scarlet also described this arrangement as "one group of five and another group of one." Then, when shown Task 8 (see Table 1), Cinderella explained the two rows of three as "two lines" with "two at the top, four at the bottom" (see Figure 7a). Here, her drawing matched her explanation, not the visual.

A: Ten-Frame, Pairwise, Task 7 B: Ten-Frame, Doublewise, Task 8 C: Random Arrangement, Task 1 D: Canonical Pattern, Task 3

Figure 7: Drawings Evidencing Conceptual Subitizing (see Table 1)

When four different kindergarten participants were shown the random arrangement of six (Task 1, see Table 1), they seemed to describe or utilize groups when subitizing. This was often re-presented in their drawings, where John (see Figure 7c) drew two groups of three and described these groups. This suggests that some students organized items shown to them in a way that allowed them to anticipate subgroups coordinated with the total number. We also found that eight participants drew from addition operations when shown arrays, growing patterns, and structured patterns. For instance, when shown a canonical pattern of six as an array, Bella (see

Figure 7d), a kindergarten student, described seeing six because she knows "three plus three equals six." Participants develop procepts when conceptually subitizing, allowing them resources to develop structural relationships in future activity (Gray & Tall, 1994).

Number Structuring

When students discussed and/or demonstrated groups of groups understandings, we described this as number structuring, explaining early forms of more complex relations fundamental to multiplicative reasoning (Bajwa et al., 2023; Ellemor-Collins & Wright, 2009). Of the 18 instances of accurate number structuring, one student, Stephen, described the groups of groups (i.e., "three twos") while also anticipating the sections he would need to draw (i.e., "I will need to draw two lines for this") to re-present these structures (see Figure 8a, 8b, 8e, 8f). Three of these instances described structuring that utilized reversible operations. For instance, Bella (see Figure 8i) used the seven items shown to her beforehand to subtract one from, explaining that she "took one from the one before." Finn used the three-by-three array arrangement of nine items shown to him beforehand to subtract three from the nine, saying, "It was minus three," and it was "like the nine … three times three…. minus three." These instances explain how participants engaged in reversible activity, as they reversed their reasoning to operate within this structure and make sense of the subsequently shown dot arrangement. When structuring number, participants were developing structural relations with procepts, further informing their capabilities to develop axiomatic concepts (Gray & Tall, 1994).

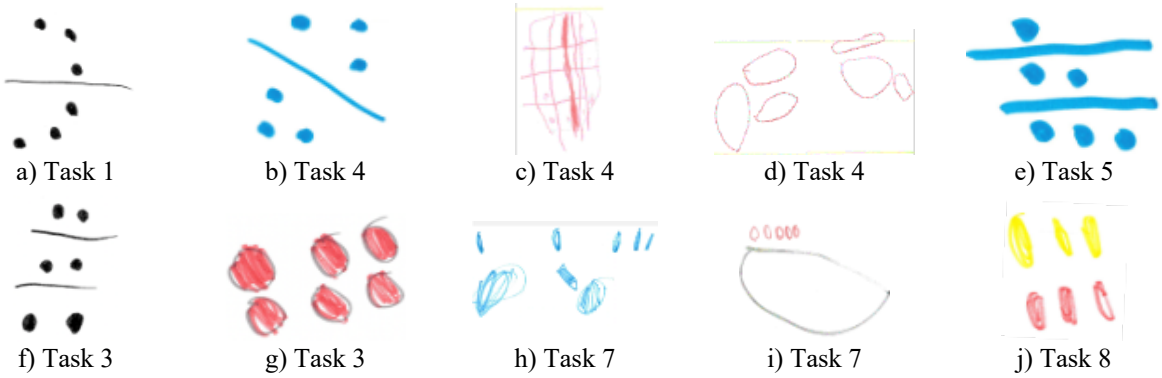

Figure 8: Drawings Showing Accurate Number Structuring (see tasks from Table 1)

Conclusion

Random displays more often elicited estimation and unstable drawings, whereas structured arrays and ten-frames supported explicit part–whole composition. This echoes Moscoso et al.'s (2020) findings, as they explained more sophisticated subitizing is grounded in individuals' ability to draw from operations such as addition and multiplication versus features of the arrangements. Many children reorganized random dots into canonical groupings, and some showed "groups of groups" and reversible reasoning, suggesting early pathways toward multiplicative thinking. As students demonstrated relatively rudimentary activity (i.e., counting, estimating, perceptual subitizing) and coordinated this activity (i.e., perceptual counting subitizing, ascending towards groups, descending from groups), they demonstrated opportunities for procept development through their conceptual subitizing and number structuring (Gray & Tall, 1994).

Digital learning platforms, while prevalent, often lack practice problems closely aligned with research on how visual models and contextual features support conceptual understanding in mathematics. In this study, we investigated which modified models and/or contexts may better support Grade 6 students' proportional reasoning. We conducted one-on-one cognitive interviews in which 63 students solved 24 variants of ratio and proportion items on the ASSISTments digital platform. We present results on the proportions of responses exhibiting different forms of reasoning across model and contextual variants. Preliminary analysis indicates that students were more likely to demonstrate proportional reasoning with context modifications combined with informal or formal iconic models. Results will be used to generate items for interventional purposes.

Keywords: Mathematical Representations, Rational Numbers and Proportional Reasoning

Introduction and Theoretical Framework

Digital learning platforms have emerged as prominent tools for delivering digital curriculum in mathematics education (Doan et al., 2022). As these platforms evolve, it is important to ensure practice problems they provide not only target CCSS-M standards (National Governors Association Center for Best Practices, Council of Chief State School Officers, 2010), but also are closely aligned with research on how visual models and contextual features support students' conceptual understanding (e.g., Fyfe & Nathan, 2019; Küchemann et al., 2011).

This may be especially important in proportional reasoning, a content area widely recognized as challenging for students. Their understanding often begins with unsophisticated strategies, like non-coordinated units reasoning or an incorrect additive approach instead of the necessary multiplicative relationships (Carney et al., 2022; Carney & Crawford, 2016; Misailidou & Williams, 2003; Steinthorsdottir & Sriraman, 2009). With support, students can progress to developing composed unit reasoning and applying increasingly sophisticated strategies for scaling ratios. The goal is for students to progress to an "operating within ratio" strategy, indicating they recognize both the scalar and functional relationships. However, it is unknown how proportional reasoning practice items offered in digital learning platforms are designed to support this conceptual progression.

Mathematics education researchers have identified various models that effectively support students' proportional reasoning (e.g., Booth & Koedinger, 2012; Karplus et al., 1983; Küchemann et al., 2011; Lamon, 2007; Misailidou & Williams, 2003; Tourniaire & Pulos, 1985). These models exhibit varying degrees of abstraction (Fyfe & Nathan, 2019), with different models potentially affording different types of reasoning. For example, informal iconic models, like pictorial and bar models, represent relationships visually. Formal iconic models, such as tape diagrams and double number lines, progressively emphasize iteration and

multiplicative relationships. Whereas, ratio tables and formal symbolic models highlight scalar and functional relationships using mathematical notation.

Research has also identified two contextual aspects of problems that may influence students' understanding of proportional situations: (a) the imaginability of the contextual setting, and (b) the chosen number sets. For example, the imaginability of proportional relationships can make tasks more accessible by grounding mathematics in known experience (Fyfe & Nathan, 2019). Furthermore, number sets can influence students' abilities to reason proportionally based on whether the numbers and multipliers in the task are integers or non-whole rational numbers (Carney & Crawford, 2016; Lamb et al., 2018; Tian & Siegler, 2018).

In this study, we selected and modified four ratio and proportional reasoning practice problems from the ASSISTments digital learning platform to increase their alignment with the research findings noted above. The purpose of this study was to investigate the effects of these modified digital practice problems, enhanced with a variety of models, accessible number sets, and imaginable contexts, on Grade 6 students' proportional reasoning.

Method

Item Development

We identified four practice items from the ASSISTments platform that involve ratio and proportional reasoning for Grade 6 students. For each item, we developed a range of models (e.g., informal iconic, formal iconic, and informal symbolic) and modified the context (e.g., by simplifying the number set or adding context to a bare problem). By crossing model types with contextual variants (including the original item), we generated eight possible variants per item. From these eight, we selected six variants for each item, resulting in 24 total variants.

Participants

We recruited Grade 6 teachers from three schools (one rural, one suburban, one urban) in the Western U.S. to offer the variants to their students (63 of whom participated). We developed a planned rotation of implementation in which each participant solved one of the six variants of each of the four items, yielding 10–11 responses per variant.

Data Collection and Analysis

Using cognitive interview procedures, students individually solved each of the four problems assigned to them and described their thinking to an interviewer. Video recording equipment was set up to capture students' written work. Our study produced codable videos of students solving 241 problems.

Our coding protocol included 24 deductive codes describing correctness, strategy use, reasoning, and explanation features. This report presents inferences about proportional reasoning–evidenced by the codes "multiplicative comparison" or "composed unit,"–and non-proportional reasoning–evidenced by the codes "non-coordinated units" or "none" (i.e., guessing or using a memorized algorithm). Six coders iteratively refined descriptors in the codebook across nine videos. Interrater reliability was established on four additional videos, yielding 75% agreement across all 24 codes and Krippendorf's alpha = 0.82. After coding, frequencies were tabulated for reasoning types across model types, context modifications, and their combinations.

Results

Student Reasoning Across Model Types and Modified Contexts

As shown in Figure 1, responses were coded according to the types of mathematical reasoning students used in the presence of different types of contexts and models. When comparing context modifications, students evidenced proportional reasoning (i.e., multiplicative

comparison or composed unit) more often in response to contexts that had been modified (71%) compared to their original form (57%). When comparing model types, we found that students evidenced proportional reasoning (i.e., multiplicative comparison or composed unit) at the same rate (66%) for problem variants that offered (a) informal iconic models, (b) formal iconic models, and (c) no models. In contrast, informal symbolic model variants elicited fewer responses evidencing proportional reasoning (56%), and the only model with no evidence of eliciting multiplicative comparison. These findings suggest that informal symbolic models may be less likely to elicit proportional reasoning than other types of models, whereas context modifications may be more likely to elicit it for some students.

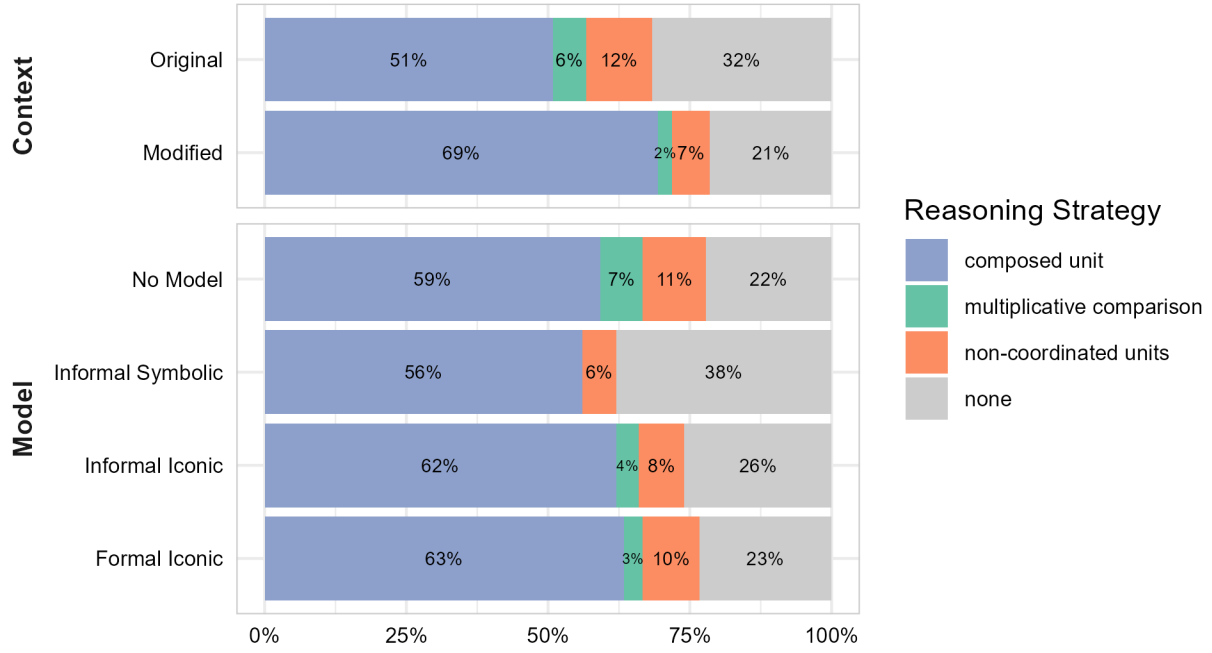

Figure 1: Student Reasoning by Context and Model

Student Reasoning Across Model and Context Combinations

As seen in Figure 2, students evidenced proportional reasoning (i.e., multiplicative comparison or composed unit) at varying rates across the eight problem variants that combined model and context modifications, ranging from 40% (original context with informal symbolic models) to 80% (modified contexts with formal iconic models). These findings corroborate those noted above but also highlight a potential advantage of formal iconic models that was not previously identified. Additionally, modified context variants with models showed the fewest non-coordinated unit responses (3–5% compared to 10–15%), possibly indicating that models and contexts supported unit coordination.

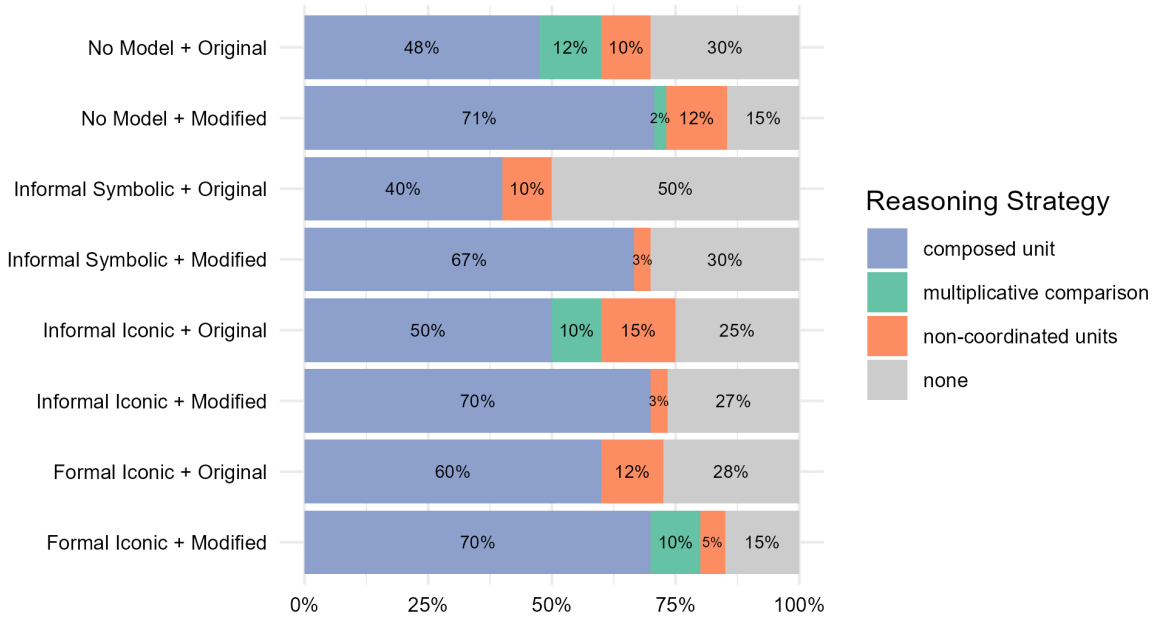

Figure 2: Student Reasoning by Pairings of Model and Context

Discussion and Conclusion

Our preliminary results suggest that model and context modifications influence students' proportional reasoning. Modified contexts consistently elicited higher rates of proportional reasoning than original contexts, and the combination of modified contexts and formal iconic models achieved the greatest success (80%). This suggests context modifications combined with informal or formal iconic models may be most likely to elicit proportional reasoning for some students. This aligns with research indicating that imaginable contexts and appropriate visual representations can support conceptual understanding (Bruner, 1966; Freudenthal, 1983; Fyfe & Nathan, 2019). However, the lower instance of proportional reasoning with informal symbolic models was unexpected, particularly when combined with original contexts (40%). This may indicate that Grade 6 students require more scaffolding or instruction to effectively use these representations, or that the symbolic nature of these models creates additional cognitive demands that interfere with proportional reasoning for some learners. Furthermore, the substantial reduction in non-coordinated units reasoning within modified context variants with models (3–5% vs. 10–15%) suggests these modifications may help students move beyond additive thinking toward multiplicative comparison and composed unit strategies. This finding supports the design principle of aligning practice problems with students' learning trajectories (Carney et al., 2022).

These results suggest digital learning platforms might better support proportional reasoning by incorporating imaginable contexts and formal iconic models into practice problems. However, the variability across model types indicates that careful alignment with research on student reasoning progressions remains essential. Future work should examine whether these patterns persist across different problem structures and with larger, more diverse samples.

FIFTH-SIXTH GRADE STUDENTS' ALGORITHM USE, RESPONSES, AND ERRORS IN MULTI-DIGIT MULTIPLICATION

Temitope F. Egbedeyi
Kent State University
tegbedey@kent.edu

Karl W. Kosko
Kent State University
kkosko1@kent.edu

This study reports empirical evidence of the algorithms commonly used by 814 fifth- and sixth-grade students. The goal was to understand what algorithms children use for multi-digit multiplication and how they engage with them. This study examined fifth-grade (n = 618) and sixth-grade (n = 196) students enrolled in 36 different teachers' classrooms in a Midwestern US state. The results showed that the Box Model, Partial Products Algorithm, and Standard Algorithm were the most prevalent. Moreover, the Standard Algorithm recorded the most correct answers across the three algorithms. Meanwhile, arithmetic, multiplication, and partial-product errors were common across all algorithms, though some were more prevalent in certain algorithms. Implications are discussed, but a call is made for future analysis and examination of these trends.

Keywords: Elementary School Education, Number Concepts and Operations

Many scholars argued that multi-digit multiplication is an important and cogent component of upper-elementary mathematics simply because it requires complex mathematical skills, such as students' ability to coordinate place value, number decomposition, as well as multiplicative reasoning (Egbedeyi & Kosko, 2025; Carpenter et al., 1996; Young-Loveridge & Mills, 2009). Despite significant scholarship on other arithmetic operations, such as multi-digit addition and subtraction, research on multi-digit multiplication has been relatively limited, especially regarding the use of algorithms (Egbedeyi & Kosko, 2025; Fuson, 2003; Harrison, 2013; Hickendorff et al., 2019). Evidence of students across grades using different algorithms to solve multiplication has been properly documented in research, for instance, counting strategies (Lampert, 1986), arrays (Izsàk, 2001; Barmby et al., 2009), the Area Model (Izsàk, 2001), the Lattice Algorithm (Speiser et al., 2012), and others (Hickendorff et al., 2019). For instance, Egbedeyi & Kosko (2025) reported in their study on fourth-grade students that the Standard Algorithm (Alanazi, 2024) was the most frequently used strategy, followed by the Box Model (Kosko, 2024) and the Partial Products Algorithm (Flores et al., 2020; Speiser et al., 2012), while repeated addition and doubling algorithms were infrequently used.

Previous studies comparing multiplication algorithms have shown mixed but informative patterns regarding students' correctness. For instance, both the early and later quasi-experimental studies revealed that fourth-grade students who used the Lattice Method were more likely to obtain correct answers than those who used the Partial Products Algorithm (Hughes & Burn, 1975; Speiser et al., 2012). Furthermore, research indicates algorithms grounded in concrete or pictorial area models, such as the Box Model and Partial Products, can support students in producing correct solutions by making multiplicative structure explicit (Izsák, 2001; Flores et al., 2020). However, Javornik and Lipovec (2020) reported that there were no statistically significant differences in fifth-grade students' performance when using the U.S. Standard Algorithm, the Box Model, or a combination of algorithms, including the Lattice Method. Although Egbedeyi and Kosko (2025) compared the three algorithms on partial products in fourth grade, there is a need for additional empirical evidence from a larger dataset to determine which algorithm tends to produce correct multi-digit answers among fifth- and sixth-grade students.

One way of examining which algorithms may best scaffold students' learning about multi-digit multiplication is to examine and compare the types of errors often associated. It is important

to note that, in doing so, we are not using these errors to make judgments about the students, but about the algorithms they are exposed to. Errors in multi-digit multiplications are considered to be deviations from accepted strategies and/or algorithms, which likely, though not necessarily, result in an incorrect answer. According to Egbedeyi and Kosko (2025), the deviations include mistakes, misunderstandings, or conceptual errors. For instance, Englehardt (1977) describes inversion errors when students "carry" the wrong number for regrouping and grouping errors, as when students do not add the correct number of 0s in their rows for addition at the bottom of an algorithm. Most of the available literature on multi-digit multiplication errors centered on the standard algorithms, despite the fact that other algorithms, such as the Box Model and the Partial Products Algorithm, are also prone to students' errors. For instance, Egbedeyi and Kosko (2025) found that fourth-grade students' use of the Standard Algorithm, regardless of task type, led to more observed partial product errors than expected by chance. By contrast, the other two common algorithms did not show such a trend, except for the Partial Products Algorithm on tasks with four partial products. Therefore, Egbedeyi and Kosko (2025) argued that the introduction of the Standard Algorithm to students should be delayed until fifth grade and should not be introduced in fourth grade. Based on the call from their study, this study presents a large sample of students' multi-digit multiplication. This preliminary analysis includes data from fifth- and sixth-grade classrooms, with the primary goal of understanding which common algorithms children choose and the errors they typically make when using them. Therefore, this study examines fifth- and sixth-grade algorithm use, its success, and its associated errors.

Methods

Sample, Protocol & Data

Data were collected from 814 fifth- (n = 618) and sixth-grade (n = 196) students enrolled in 36 different teachers' classrooms in a Midwestern US state. Students self-identified primarily as White (75.4%), with others identifying as Black (11.1%), Asian (5.2%), Latine (2.1%), multiple ethnicities (6.5%), or as another ethnicity (0.5%). Additionally, 53.5% identified as female and 46.4% as male (0.1% as non-binary). As part of a larger study, students completed 10 whole number and decimal multiplication items aligned with their grade level. Certain whole number multiplication items for fifth (21×4; 19×16; 37×34; 86×49; 457×21; 2083×35; 789×382) and sixth grade (21×4; 19×16; 37×34; 86×49; 789×382) largely overlapped and are the focus of the current study. Participants' written work was scanned and then analyzed for the algorithm/strategy used, their responses, any errors employed in their work (i.e., arithmetic, multiplicative, partial products, or other), and whether they wrote expressions for partial products in their written work. We used a codebook from an earlier analysis of fourth-grade students' multiplication work (Egbedeyi & Kosko, 2025) to examine 308 of the 814 students' work. Both authors independently coded this subsample, with a Kappa of .97 ($p<.001$) indicating almost perfect agreement. Given this high level of agreement and following data reconciliation in the subsample, the remaining data were split evenly between the two authors for independent coding before proceeding to analysis.

Analysis & Results

We used descriptive statistics to examine students algorithm use, success and presence of any associated errors. Based on the analysis, the following primary algorithms were observed among both fifth- and sixth-graders: Repeated Addition, Doubling, the Box Model, the Partial Products Algorithm, Lattice, and the Standard Algorithm. We identified instances where students used multiple algorithms or employed other algorithms, with notes providing more specific details, such as the use of counting-by-1s.

Partial Products Algorithm | Box Method | Standard Algorithm

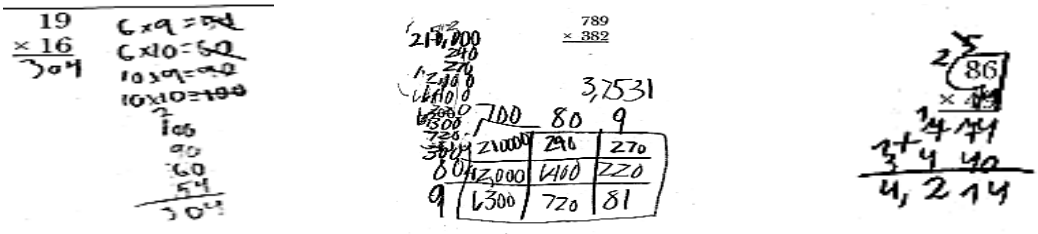

Figure 1: Examples of the Most Used Algorithms Among Fifth- and Sixth-Grade Students

Therefore, this analysis focused primarily on the Box Model, the Partial Product Algorithm, and the Standard Algorithm among both fifth- and sixth-grade students, as well as on the associated errors common to each algorithm. The full details of the analysis are given below

Table 1: Percentage of Usage and Correctness by the Most Common Algorithm Among Fifth- and Sixth-Grade Students

% of Fifth-and Sixth-Grade Students Using Algorithm			
	Box Model	Partial Products Algorithm	Standard Algorithm
Grade 5	19.7%	8.1%	72.2%
Grade 6	31.1%	3.6%	65.3%
% Correct on Task by Algorithm of Fifth-and-Sixth Grade Students			
	Box Model	Partial Products Algorithm	Standard Algorithm
Grade 5	60.9%	58.5%	61.7%
Grade 6	61.8%	66.7%	67.5%

Table 1 shows the percentage of students using each algorithm in the fifth and sixth grades. In both grades, the Standard Algorithm is the most used, while the Box Model is used by a smaller group of students, and the Partial Products Algorithm is rarely used at either level. A notable pattern is that use of the Box Model increases by about 11–12% from Grade 5 to Grade 6, while use of the Standard Algorithm and the Partial Products Algorithm both decline slightly across grades. Further analysis reveals that the Standard Algorithm, which most students use, produced the highest correctness in both grades, but only by a small margin. In fifth grade, it can be inferred that the correctness is almost the same across the three algorithms. Furthermore, in sixth grade, there is an increase in students' algorithmic correctness, with a noticeable increase in the Standard Algorithm and the Partial Products Algorithm, and a slight increase in the Box Model. Therefore, the statistical difference shows that in fifth grade, the Standard Algorithm exceeds the Box Model by only 0.8% and Partial Products by 3.2%, and in sixth grade, the Standard Algorithm is 5.7% above the Box Model and 0.8% above Partial Products; these remain modest gaps, indicating only a slight accuracy advantage for the Standard Algorithm while all three algorithms support broadly comparable levels of success.

We used descriptive statistics to compare the three major errors identified in the written work of fifth- and sixth-grade students across the Box Model, Partial Product Algorithm, and Standard Algorithm, as shown in Table 2. The analysis indicated three primary types of errors in the open coding process: arithmetic, multiplication, and partitioning. Arithmetic errors involved an error with addition or subtraction. Multiplication errors involved reporting an incorrect product in one or more steps when multiplying within the chosen algorithm, or incorrect placement of the place

value with the chosen algorithm. Partitioning errors including regrouping errors, involved miscoordination of partial products, for example, incorrectly partitioning a number using some of the partitioned multiplicands (e.g., 19×16 = 9×6 + 10×10), inability to multiply using the column value, or multiplying partitioned elements inappropriately.

Table 2: Percent of Error Types Made for an Algorithm Used (by Task) Among Fifth- and Sixth-Grade Students

	Fifth-Grade Student Algorithm Errors		
	Arithmetic Error	Multiplication Error	Partitioning Error
Box Model	17.8%	12.0%	5.6%
Partial Products	10.8%	10.8%	22.2%
Standard	5.6%	12.5%	18.4%
	Sixth-Grade Student Algorithm Errors		
	Arithmetic Error	Multiplication Error	Partitioning Error
Box Model	12.8%	17.4%	3.5%
Partial Products	6.1%	12.1%	21.2%
Standard	2.2%	12.6%	14.9%

Table 2 shows the errors comparison among the three primary algorithms used by both fifth- and sixth-grade students. The analysis shows that arithmetic, multiplication, and partitioning appeared across all the algorithms. However, this study specifically compares partitioning error among algorithms. The results indicate that partitioning errors are most frequent when students use the partial products algorithm in both grades. Likewise, the Standard algorithm shows notable partitioning errors, though fewer than the partial products, while the box model produces comparatively few partitioning.

Discussion

This study significantly contributes to expanding the existing body of knowledge on multi-digit multiplication. The results suggest that fifth- and sixth-grade students favor the standard algorithm for multi-digit multiplication among the remaining algorithms, though the box model receives more attention from sixth-graders than other algorithms. This result supports Egbedeyi and Kosko (2025), who found that the Standard Algorithm was the most frequently used strategy, followed by the Box Model and the Partial Products algorithm among fourth-grade students. Furthermore, the results showed that the Standard Algorithm is likely to produced more correct answers than the Box model and the Partial Products Algorithm; however, both the Box Model and the Partial Products Algorithm tended to yield correct answers when students were more exposed to them as alternative algorithms to the Standard algorithm (Thompson, 2008). In addition, the higher partitioning errors with Partial Products and Standard Algorithms, contrasted with fewer in the box model showed that many students might struggle to scaffold their understanding in applying the Partial Products Algorithm to derive partial products in multi-digit multiplication, especially those considered to be complex, while the Box/Area Models scaffold partitioning more intuitively (Anghileri, 2006; Egbedeyi & Kosko, 2025). While this study presents preliminary findings, the study therefore calls for students to have more exposure to the Box Model and Partial Products Algorithms in both the fifth- and sixth-grade classrooms because, despite their small popularity or usage among the students, they were able to produce almost a similar percentage of correctness level to the most commonly use algorithm (the Standard Algorithm) and likewise results of this study are highly significant in pointing toward future study to compare algorithms based on partial product tasks.

Proportional reasoning is foundational to mathematics and science learning, yet many middle school students rely on additive and procedural strategies that obscure relational understanding. This study investigates the development of proportional and covariational reasoning within a nanotechnology-focused integrated STEM summer program. Eleven middle school students engaged in ratio investigations, dimensional scaling, surface-area-to-volume (SA:V) modeling, and engineering design tasks grounded in nanoscale phenomena. Pre/post assessments showed significant gains in proportional reasoning (Wilcoxon $p < .05$, $r = .60$). Learning-trajectory analysis revealed progression from procedural fraction manipulation to multiplicative coordination and, for seven students, emerging nonlinear covariational reasoning in SA:V contexts.

Keywords: Integrated STEM, Learning Trajectories and Progressions, Rational Numbers and Proportional Reasoning, Middle School Education

Proportional reasoning is a cornerstone of middle grades mathematics and a foundational construct for scientific sensemaking, supporting reasoning about rates, densities, concentrations, similarity, and scale (Lamon, 2020; Lesh et al., 1988). Despite its centrality, proportional reasoning remains conceptually challenging for many students (Ayan & Isiksal Bostan, 2018). Research documents persistent reliance on additive comparisons, overgeneralized cross-multiplication, and procedural fraction manipulation that may yield correct answers while masking fragile relational understanding (Tourniaire & Pulos, 1985; Dougherty et al., 2016).

Conceptual proportional reasoning extends beyond computational proficiency to include multiplicative coordination, recognition of invariant scale factors, and interpretation of ratios as structured relationships (Lobato & Ellis, 2010). Students must transition from additive reasoning toward multiplicative coordination, a shift that often remains incomplete even when procedural accuracy is achieved (Vergnaud, 1983). These challenges are amplified in contexts involving dimensional growth and scale. Students frequently apply linear reasoning to area and volume situations despite the inherently nonlinear nature of surface-area-to-volume (SA:V) relationships (Tretter et al., 2006). Reasoning in such contexts requires covariational reasoning—the coordination of how quantities change together (Carlson et al., 2002). While covariational reasoning has been examined in algebraic contexts, its development within middle school STEM environments, particularly in relation to proportional reasoning and scale, remains underexamined.

Standards documents foreground ratio and proportional reasoning in mathematics and identify Scale, Proportion, and Quantity as a crosscutting scientific concept (Common Core State Standards Initiative [CCSSI], 2010; NGSS Lead States, 2013). Yet instruction across mathematics and science often remains fragmented, limiting students' opportunities to develop proportional reasoning in contexts where it is epistemically necessary for explanation (Lehrer & Schauble, 2015). Nanotechnology provides a particularly generative context, as reasoning at the nanoscale inherently involves ratios, dimensional scaling, and SA:V relationships that challenge

linear assumptions and foreground multiplicative and nonlinear structure (Ramsden, 1990). However, empirical research documenting how students' proportional reasoning develops in nanoscale STEM contexts remains limited. Grounded in a learning-trajectory perspective (Simon, 1995), this study addresses this gap by examining how proportional and covariational reasoning co-develop in a nanotechnology-focused STEM program.

Theoretical Framework

This study is grounded in a learning-trajectory perspective, which conceptualizes learning as movement toward a goal state through progressively sophisticated forms of reasoning supported by instruction (Simon, 1995). Within this framework, students' incomplete strategies are viewed as productive transitional reasoning rather than misconceptions. Research on proportional reasoning characterizes development as a progression from additive comparison to multiplicative coordination and invariant-ratio reasoning (Tourniaire & Pulos, 1985; Lamon, 2020). Procedural competence does not necessarily indicate relational understanding (Dougherty et al., 2016). From a learning-trajectory perspective, proportional reasoning is not a fixed endpoint but a construct that can be refined as students encounter contexts requiring more complex coordination of quantities.

Reasoning about dimensional growth introduces additional demands. Students frequently apply linear reasoning to SA:V relationships despite their nonlinear nature (Tretter et al., 2006). Reasoning in such contexts requires covariational reasoning (Carlson et al., 2002). In this study, nonlinear covariational reasoning is conceptualized as a refinement of proportional-reasoning trajectories rather than a transition to formal functional thinking. Students' reasoning remained grounded in ratio and multiplicative structure, even as they coordinated layered multiplicative effects across dimensions. Integrated STEM contexts, particularly nanotechnology phenomena involving SA:V relationships, served as epistemic drivers that foregrounded dimensional structure and supported this refinement (Moore et al., 2014).

Methods

This study employed a design-based research (DBR) approach to investigate the development of proportional and covariational reasoning in an authentic instructional context (Cobb et al., 2003). DBR was appropriate given the study's goal of identifying a realized learning trajectory rather than evaluating program effectiveness. Participants were 11 middle school students (ages 10–14) enrolled in a week-long, university-based nanotechnology STEM summer program that met daily for approximately 7.5 hours. The lead researcher served as the primary instructor, supported by two teaching assistants. Data sources included a 17-item pre- and post-proportional reasoning assessment scored using a 5-point analytic rubric; student artifacts; audio recordings of small-group discussions; and researcher field notes. Quantitative analysis examined pre/post differences using a Wilcoxon signed-rank test with effect size calculated using r. Qualitative analysis involved coding student reasoning as additive, procedural, multiplicative, relational, or nonlinear covariational. Interrater agreement was strong ($\kappa = .81$).

Instructional Sequence

Instructional activities were sequenced to support movement from additive toward multiplicative and nonlinear reasoning. The sequence began with a cornstarch–water ratio investigation that disrupted additive comparison by introducing ratio as a relational comparison. Ratio comparison and scaling tasks then supported the transition from procedural to relational proportional reasoning by maintaining mixture consistency across quantities using invariant scale

factors. Dimensional scaling tasks (length → area → volume) surfaced limitations of linear intuitions as students predicted effects of scaling objects. Surface-area-to-volume modeling with cubes foregrounded layered multiplicative structure and coordination of dimensional growth. Virtual nanoscale simulations connected abstract structure to scientific phenomena, and an engineering design challenge (Alka-Seltzer reaction rate) consolidated nonlinear reasoning through strategic application.

Results

Quantitative Growth

Students demonstrated significant growth in proportional and covariational reasoning. Median rubric scores increased from 3.1 to 4.2, indicating a statistically significant improvement ($Z = -2.80$, $p = .005$, $r = .60$). Gains were strongest on SA:V items, where reliance on linear assumptions decreased substantially.

The analysis of student work, discourse, and design revisions revealed a realized learning trajectory consisting of four phases (see Figure 1).

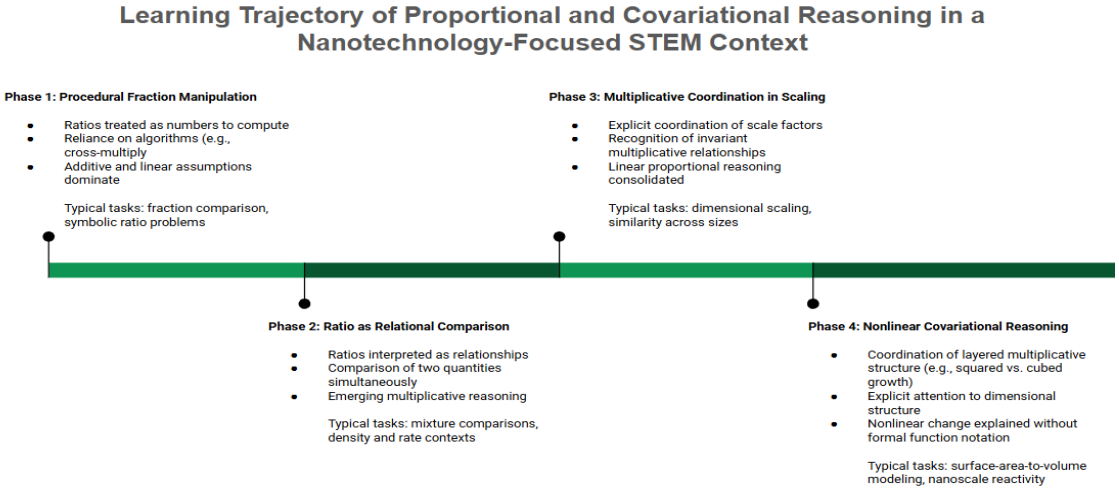

Figure 1: Realized Learning Trajectory of Proportional and Covariational Reasoning in Engineering Design Contexts

Realized Learning Trajectory

Analysis of student work, discourse, and design revisions revealed a learning trajectory consisting of four phases. In Phase 1 (Additive and Procedural Reasoning), students compared quantities additively or applied cross-multiplication without relational understanding. Phase 2 (Emerging Multiplicative Coordination) involved students beginning to recognize scale factors but applying them inconsistently across dimensions. In Phase 3 (Relational Proportional Reasoning), students coordinated quantities multiplicatively and identified invariant ratios. Phase 4 (Nonlinear Covariational Reasoning) involved students coordinating layered multiplicative effects across dimensions, recognizing that scaling effects depend on dimensionality.

Dimensional Revision

One analytic vignette illustrates this progression. During a surface-area-to-volume investigation, a student ("Maya") initially reasoned, "If the side doubles, everything doubles."

After calculating surface area ($SA = 24$) and volume ($V = 8$) for a two cm cube, she revised her explanation:

> "Surface area doubled twice, but volume doubled three times."

Maya then predicted cubic growth for larger cubes prior to calculation, demonstrating explicit coordination of dimensional structure and nonlinear covariation. Seven students demonstrated similar shifts, moving from linear scaling assumptions toward reasoning that accounted for layered multiplicative effects.

Engineering Design Application

All 11 students applied SA:V reasoning in an engineering design task involving Alka-Seltzer tablets. Students justified design decisions, such as crushing tablets to increase reaction rate, by coordinating surface area with reaction speed:

> "More surface touching the water means more reacting at once."

In this context, proportional reasoning functioned both strategically (to optimize performance) and explanatorily (to justify outcomes), indicating transfer of mathematical reasoning from modeling activities to applied engineering contexts.

Discussion

This study extends research on proportional reasoning by showing that middle school students' reasoning can develop beyond linear multiplicative coordination toward nonlinear covariational reasoning when dimensional structure is made epistemically central. Grounded in a learning-trajectory perspective (Simon, 1995), the findings position proportional reasoning not as a fixed endpoint but as a dynamic construct that can be refined through engagement with phenomena requiring coordination of scale, dimension, and rate of change.

Consistent with learning-trajectory theory, students' reasoning progressed through increasingly sophisticated forms as instructional activities disrupted additive and procedural strategies and supported relational coordination. Proportional reasoning developed in response to explanatory and design-oriented demands embedded in integrated STEM activities rather than through isolated symbolic practice. This finding aligns with prior research emphasizing that conceptual understanding is strengthened when mathematical structures are epistemically necessary for explanation (Lehrer & Schauble, 2015; Lobato & Ellis, 2010). Students' early reliance on additive and procedural strategies reflected productive transitional reasoning rather than conceptual failure (Simon, 1995).

The study further contributes by documenting the co-development of proportional reasoning and understanding of scale. Tasks involving dimensional scaling and SA:V relationships challenged students' linear intuitions and required attention to how quantities change across dimensions. Students came to recognize that proportional relationships are not invariant under dimensional transformation and that scaling effects depend on dimensionality. By foregrounding scale as a central organizing structure, instruction supported deeper relational understanding of proportionality (Lamon, 2020) and extends prior findings on persistent linear reasoning in area and volume contexts (Tretter et al., 2006).

Finally, the findings indicate that nonlinear covariational reasoning can emerge as a refinement of proportional-reasoning trajectories when dimensional structure is explicitly emphasized. Seven students coordinated layered multiplicative effects while remaining grounded in ratio-based reasoning. This extends covariational-reasoning research beyond algebraic contexts (Carlson et al., 2002) and challenges assumptions that nonlinear reasoning must be

deferred until secondary mathematics. Instead, nonlinear covariational reasoning appears as a natural developmental extension of proportional reasoning when learning trajectories foreground dimensional growth (Vergnaud, 1983; Lamon, 2020).

The study examined how two students (fourth & sixth grade) conveyed their multiplicative reasoning while solving multi-digit division problems using a Box Method. Both students participated in eye-tracking enabled clinical interviews. Transcripts were analyzed using Systemic Functional Linguistics (SFL) to examine how students interpreted and explained their own mathematical reasoning. Eye-tracking data and gestures were examined in concert with SFL to triangulate conveyed meaning. Findings highlight how differences in algorithm use and the participants' multiplicative reasoning affected their conveyed meaning of division.

Keywords: Elementary School Education, Number Concepts and Operations

Multidigit division can be difficult for students to understand the multiplicative meaning underlying the procedures (Hickendorff et al., 2019; Lampert, 1992; Silver et al., 1993). In particular, understanding the meaning of various digits within division algorithms has historically been found to be difficult for students (Hickendorff et al., 2019; Holland, 1942). Students may initially attempt to solve division tasks through additive reasoning such as via repeated subtraction or fair-sharing strategies (Neary & Nic Mhuri, 2021; Schulz, 2024; van Putten et al., 2005). A turning point in reasoning is marked by students' ability to partition dividends, and by consequence their quotients, by place value (Ambrose et al., 2003; Neary & Nic Mhuri, 2021; Schulz, 2024; Schulz & Leuders, 2018). This concept is known as partial quotients, and is a place value application of the Distributive Property to division (e.g., $177 \div 3 = 150 \div 3 + 27 \div 3$). Various scholars have advocated approaches to support students' learning partial quotients. These include: drawn groups-of models to write different place value components (Lampert, 1992); use of the Partial Quotients Algorithm, which is visually similar to long division, but where the partial quotients are explicitly written and accounted for (Losinski et al., 2021; Irons, 1975; Smith, 1950); and the Box Method for Division, which is an inversion of the same approach for multiplication (Egbedeyi & Kosko, 2025). Across these approaches is an effort to scaffold students' use of partial quotients.

Despite clear evidence of the importance of a conceptual understanding of partial quotients (Ambrose et al., 2003; Neary & Nic Mhuri, 2021; Schulz, 2024; Schulz & Leuders, 2018), and particular approaches meant to support this development (Lampert, 1992; Losinski et al., 2021; Smith, 1950), there is less understanding of the range of reasonings children engage with partial quotients. Multiplicative reasoning, from the perspective of Scheme Theory, emerges when children anticipate one level of units to construct two levels in activity. This first multiplicative concept (MC1) is characterized often through skip-counting, but may also be observed through repeated subtraction for division (Hackenberg, 2010; Kosko, 2019). Children at the second multiplicative concept (MC2) can anticipate two levels of units to construct three levels in activity. Gill et al. (2025) observed that such students can solve tasks like 8×33 by anticipating 33 as also 30 and 3 and then constructing 8×33 by adding 8×30 and 8×3. Yet, Gill et al. (2025) observed it is at the third multiplicative concept (MC3) when students can anticipate doing this with more than one number at a time (i.e., $24 \times 15 = 20 \times 10 + 20 \times 5 + 4 \times 10 + 4 \times 5$). The current study represents a preliminary analysis of students' division who operate at different levels of multiplicative reasoning (i.e., MC1 & MC3) with a goal of examining how these students engage

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

with partial quotients differently. Thus, the current study explores the following question: *How do students with different multiplicative reasoning convey meaning of division when using the Box Method?*

Methods

Participants & Protocol

Participants included two students as part of a larger study on fourth to sixth grade students' multiplication and division. Both analysis and data collection are ongoing at the time of this writing and involved a two-stage process. First, participating students completed a written assessment of their multiplicative reasoning and solving various multidigit division tasks. A subsample of students was purposefully selected from these responses for one-on-one eye-tracking enabled clinical interviews. Specifically, a target sample of 48 interviews is sought with individuals representing a range of multiplicative reasoning and written strategies for division. The current paper reports on the preliminary analysis of Lavada and Kit, who each used the Box Method for division. Lavada is a fourth-grade girl operating at MC1 and Kit is a sixth-grade boy operating at MC3. Both students wore Pupil Neon mobile eye-tracking glasses during the interviews and were tasked with solving each of the following tasks: 609÷3, 2400÷8, 708÷6, 179÷4. The first three tasks emphasize aspects of place value within division (Schulz, 2024) whereas the third task includes a remainder.

Analysis & Findings

Systemic Functional Linguistics (SFL) examines how grammar functions together for meaningful communication (Banks, 2019). Thus, elements of grammar may stem from language, different registers, gestures, and so forth (Jewitt et al., 2025). This analysis examines English grammar within the mathematics register where a register is a particular range of meanings and grammar associated with a specific activity (Halliday, 1975). For the purposes of this study, we examined reference chains to understand how students conveyed meaning about division. Reference chain analysis examines for cohesion of meaning by focusing on how nominal groups (nouns or sets of words that function as nouns) are referenced within and across a text. Meaning of nominal groups can be modified through transitive processes (i.e., verbs) and modality (Banks, 2019; Eggins, 2004). Modality conveys interpersonal meaning (Banks, 2019). Modality can be conveyed via modalization or modulation. Modalization can communicate a person's appraisal of the likelihood or frequency of propositions whereas modulation communicates appraisal of obligations (i.e., norms) or permissibility of propositions (Banks, 2019; Eggins, 2004). For the current analysis, we used transcribed interviews, as well as students video-recorded gestures and eye-gaze to examine their reference chains about division.

Lavada. For each division task, Lavada would draw a box with the same number of partitions as the divisor. She would then write numbers in each of the partitions and subtract the sum of these numbers from the dividend until reaching zero. For example, in solving 179÷4 she first wrote a 20 in each of the four partitions and subtracted 80 from 179. She then wrote a second 20 in each partition and so forth until she had subtracted all the dividend (see Figure 1). Lavada explained her division predominately through polar statements, conveying the truth value of her actions: "… we **do** 20, 40, 60, 80 … we **did** 179 subtracted by 80…" Interestingly, Lavada used modality in situations of uncertainty—particularly in instances when positing a number for one of her partitions in her Box Method. In the transcribed excerpt below, modality is italicized while transitive processes are in bold and nominal groups are underlined. Lavada hedges "you would do 20" while her finger points to and sweeps across the four 20s in Lavada's box method. Her eye-gaze also pauses at each 20, moving slightly ahead of her finger, while she makes this

statement (see Figure 1). Use of modals like *would*, *should have*, and *just* suggests a conveyed adherence to norms. In this case, we infer they are the norms of Lavada's box method where there are the same number of partitions as the divisor. Essentially, Lavada is conveying a skip-counting of four 20s two separate times. Her use of modals suggests these procedures adhere to her version of the box method.

Lavada: So, you *would* **do** 20, (sweeps first row of four 20s) // well you *should have* **done** 80, (circles all four 20s with finger as saying this) // but I *just* **broke** it down to 20. // So, we **do** 20, 40, 60, 80. // So, we **did** 179 subtracted by 80 equals 99. // And then I **did** 20 again, // which I **know is** 80. // I *just* **did** that. // So, 99 subtracted by 80 **is** 19. // And then I **did** four to get 16 // which **equals** three // and **there's not** three spaces.

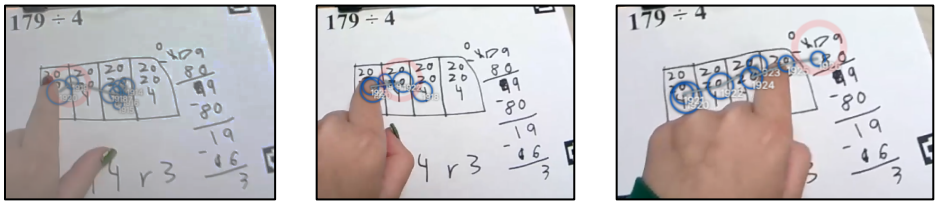

Figure 1: Segment (4 sec) from Interview for Lavada (MC1)

Analysis of Lavada's transcripts illustrates a conveyed goal of subtracting her partial quotients until reaching zero. This is evident in the excerpt above where material transitivity consistently conveys this pattern: "179 subtracted by 80… 99 subtracted by 80… I did four [fours] to get 16… which equals three." Moreover, across these tasks Lavada's box method focused on the value of the divisor instead of place value, which conveyed a groups-of meaning of division instead of a focus on partial quotients.

Kit. For each division task, Kit would quickly draw a box and place the divisor on the left side and write the digits by place value in the partitioned sections of his drawn box. He described this process clearly on the first task (609÷3) describing 609 as the dividend and 3 as the divisor. In describing his procedures, Kit would reference the digits, such as stating "six divided by three equals two." When the interviewer asked "is that actually a six?" Kit quickly said, "No, it's a 600" and the quotient there would be "200." Thus, Kit's reference chains consistently connected to the place-value meaning of the digits he acted upon. Most of Kit's statements were polar statements conveying a truth value related to his procedures: "then you **subtract** it… that **gives** you four… then you **carry** over the four." Use of modals appeared to be reserved primarily for contexts where the digits for one place value would have to be regrouped to another. For example, the excerpt below comes from Kit's explanation for solving 708÷6. As with Lavada's transcript, transitivity is in bold, key referents are underlined and modals are italicized. Within this excerpt, Kit initially uses *can* and *can't* to modulate statements about what is allowed to do with division in his box method. Later, he continues using such modals noting for the 700 that he "*can only* **divide** it by six one time," which again signals modulation within the context of regrouping quotients by place value.

Kit: So, you *can* **divide** seven by six one time. // So, you **put** the one above it, // but you *can't* **divide** it fully. // So, you **subtract** it // and then you **get** a one

Teacher: And the 1 stands for?

Kit: Oh, [1 **stands** for] 100. // And then you **carry** the one over to the 10 space // and since there**'s** zero there, // it *would* **equal** still as a 10 or whatever. // And then you **divide** it by six one time // it *can only* **divide** it by six one time // and then you **subtract** it // and that **gives** you four // And then you **carry** over the four // and the six divided by 48 **equals** eight.

Analysis of Kit's eye-gaze data confirms SFL analysis of his reference chains. Figure 2 illustrates an 8 second clip from the transcription above. As Kit explains dividing 700 by 600, his eye-gaze shifts to the tens column. As he states "and then you get a one" his eye-gaze centers on the 10 written in the 10s column. This action, coupled with his linguistic reference chain, suggests that Kit is conveying the "1" as a 10, but specifically a 10 in the tens place value. When prompted, Kit states that this 1—or 10 tens—also "stands for" 100. Throughout his explanation and observed actions in the interview, Kit reference place value, but uses modals when having to regroup digits in his quotients. This suggests Kit is appealing to his version of the box method, which emphasizes partitioning the dividend by place value.

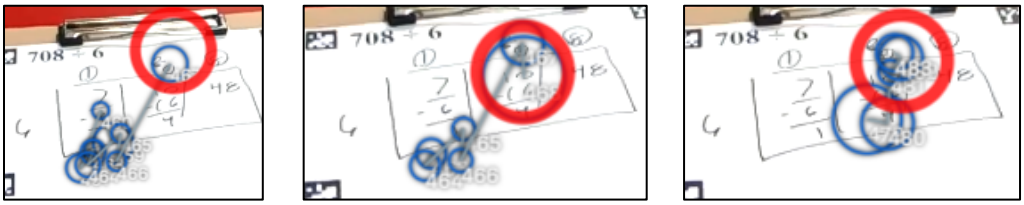

Figure 2: Segment (8 sec) from Interview for Kit (MC3)

Discussion & Conclusion

Various scholars have observed that partial products are important in students' multidigit division calculations (Hickendorff et al., 2019; Holland, 1942; Lampert, 1992; Silver et al., 1993). However, there is less research on students' reasoning with partial quotients. The purpose of this exploratory study was to examine how students conveyed multiplicative meaning when engaging with problems involving partial quotients. Findings indicated that Lavada and Kit used modals to convey an appeal to the norms of their algorithms, but these specific norms differed due to differences in the box methods used. Lavada's reference chains focused on repeated subtraction while her box method conveyed a groups-of approach to division (modified for place value). She hedged when placing quotients in each partition of her box method. By contrast, Kit's reference chains focused on the interplay of place value, and he hedged when having to regroup by place value. Important to note is that Lavada was operating at MC1 and was at the first half of fourth grade while Kit was operating at MC3 and was in the second half of sixth grade. Thus, these findings highlight key differences in students' reasonings with and exposure to multidigit division. For example, while Lavada did not explicitly reference place value in her explanations, she utilized it in her work. Thus, students at MC1 may be able to engage with place value in division but may convey different meanings than students at MC2 or MC3. Additional analysis is forthcoming, but findings provide important insights into differences in how students convey multiplicative meaning of their multidigit division algorithms.

DEVELOPING COMPUTATIONAL FLUENCY THROUGH A VISUAL "HOW MANY" ROUTINE

The How Many routine, in which an image of objects is used to elicit a variety of solutions, provides accessible, engaging computational practice. Yet, number sense routines are considered a "black hole" in mathematics education research, characterized by the lack of research directly studying the routine (Matney et al., 2020). This study examines the efficacy of How Many activities for promoting fluency development in elementary grades. A nine-lesson sequence of How Many tasks was taught in four second and third grade classrooms, and pre- and post-assessment interviews were conducted with 32 participants. Analysis of the interview responses via a multi-faceted fluency framework indicated statistically significant growth in fluency despite the brevity of the intervention.

Keywords: Number Concepts and Operations, Instructional Activities and Practices

Supporting all students to acquire computational fluency continues to be a challenge, as "many educators find that children, even in the upper grades, continue to draw tally marks and count by ones as their dominant solution approach in solving problems" (National Council of Teachers of Mathematices [NCTM], 2020, p. 82). Over the past 50 years, studies have shown that students who learn arithmetic via a focus on strategies as opposed to rote memorization consistently outperform their traditional counterparts (Thornton, 1978; Cook & Dossey, 1982; Henry & Brown, 2008; Brendefur et al., 2015). Yet many schools still rely on the rote practices of drill, worksheets, and timed testing, despite the overwhelming evidence that such practices do more harm than good (NCTM, 2020; Henry & Brown, 2008; Baroody, 2006).

Over the past two decades in an attempt to address this, number sense routines—brief, discourse-based routines focused on recognizing quantities and developing flexible mental computation strategies (e.g., addition, multiplication)—have gained prominence in elementary classrooms (MAISA, 2023). These routines reflect a shift to a contemporary definition of computational fluency as comprised of flexibility, accuracy, efficiency, and appropriate strategy use (National Research Council [NRC], 2001; NGA & CCSSO, 2010). Despite this, number sense routines have been characterized as a "black hole" in mathematics education research, meaning "an instructional practice for which there is a scarcity of blind-peer-reviewed research evidence supporting its efficacy, yet has attained critical gravity in the teaching field" (Matney et al., 2020, p. 247). Matney et al. (2020) explain that such "black holes" form when there is substantial tangential research that supports elements of the teaching practice, yet little-to-no research *directly* studying the efficacy of the practice itself. This study explored one such black hole: the How Many number sense routine.

The Multiplicity Lab (https://multiplicitylab.northwestern.edu/) at Northwestern University hosts a wealth of potential How Many activities (see Figure 1). The How Many routine consists of three components: (1) show an image to the class and ask, "How many do you

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

see?," (2) provide children time to think, and (3) facilitate class discussion of as many different solutions as possible. This routine bears some resemblance to the number sense routine of number talks (Humphreys & Parker, 2015). While there is mathematical overlap between the concepts and practices that students might engage in through the How Many and Number Talks routines, one key difference is the entry point. In How Many, students are offered a *visual*, rather than a computational, mathematical prompt, and in most cases, multiple answers are defensible (e.g., total number of dice, total number of pips on the dice, identical sets of dice). For example, in the first image above, some children might count the dots, one by one, or add them in their visual order. Others might rely on their knowledge of combinations of 10 and doubles to group the 6 with a 4 to make 10, the two 5s to make 10, and then add the 8 from the two remaining 4s to reach 28. Still others may think multiplicatively, particularly about the three groups of 4. As students are exposed to the variety of strategies shared by their classmates, there are opportunities for them to develop flexibility, choose appropriate strategies, and move towards greater efficiency.

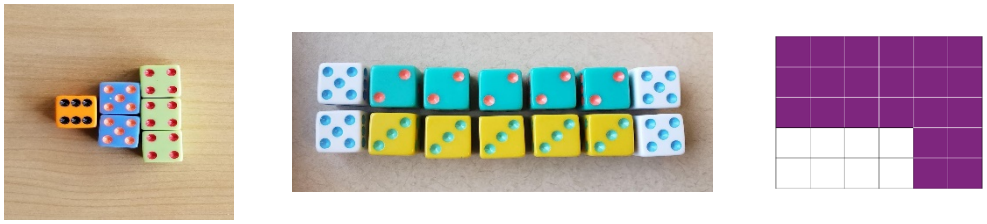

Figure 1: Three Different How Many Images

Defining procedural fluency in the complex way described above warranted new frameworks for fluency development. With respect to single-digit computation, a Three Phase basic fact fluency framework developed by Baroody and others (e.g., Baroody, 2006; Baroody et al., 2009; Baroody & Tiilikainen, 2003) is useful for assessing student progression as it distinguishes between deriving and knowing facts, a distinction that is often collapsed in other frameworks (e.g., Carpenter et al., 1993). According to Baroody's framework, students begin in Phase 1 with counting-based strategies (e.g., modeling and counting, mental counting, skip counting), then progress to Phase 2 where solutions are derived from known facts (e.g., $6 \times 8 = 5 \times 8 + 1 \times 8$). Phase 3, mastery, is demonstrated by highly efficient production of answers, either through recall or highly efficient strategy application. While the framework is critical for understanding fluency development with two addends or factors, it raises questions of how to assess fluency in the context of more complex tasks like those in How Many.

The purpose of our research was to explore the efficacy of How Many activities for promoting greater fluency development in elementary school children, and in doing so to develop analytic tools that build on earlier frameworks to allow us to assess fluency when many values are involved. In the current study, we ask: Do How Many activities promote fluency in elementary school students?

Methods

Setting, Participants, and Study Design

The study took place across four rural midwestern classrooms (two second grade and two third grade) and consisted of a week of pre-interviews with 32 participating students, three weeks of instruction, and a week of post-interviews. One researcher taught three lessons in each

classroom per week, for a total of 36 lessons (9 lessons/classroom x 4 classrooms). Each lesson lasted 30 minutes and utilized 1–2 images such as those shown in Figure 1, engaging students in whole class discussion as they shared different ways they might determine How Many.

Data Sources and Analysis

Data for this study include the pre- and post-assessments, which were video recorded. Our interview assessments, both pre and post, included the three images shown in Figure 1 as well as the computation problem 6 + 3 + 6 + 7. Children were presented with each task, asked "How many do you see?" and were provided with as many copies of the task as they wished to utilize in their responses. During the assessment, two research assistants took fieldnotes recording student strategies and solutions. These three sources, two sets of fieldnotes and the video records, were coordinated to analyze students' fluency before and after the How Many intervention.

By creating a list of indicators for the four components of fluency (NRC, 2001), we developed the fluency framework shown in abbreviated form in Figure 2 to measure participant growth and provide an indication of the potential efficacy of the How Many routine. This framework was developed iteratively by the research team and each task was scored by two coders; all coding differences were resolved through discussion with the entire research team. Each task on the interview could be scored up to four points on the framework; each task in which the student provided an accurate answer was given an additional point. Across all four tasks, each participant received a composite pre- and post-assessment score of up to 20 points. These composite scores as well as mean scores of individuals across the four tasks (up to five points) were tested for statistically significant growth using paired t-tests of the mean differences.

Level 1	Level 4
Efficiency: Relatively inefficient strategies that took a longer time than other available strategies. Flexibility: A single strategy is used throughout, without regard to the opportunities in the numbers. Appropriate Strategy Selection: Strategy did not take into account the particular numbers involved or the structures available.	Efficiency: Efficient strategies used exclusively throughout. The strategies coordinated maximize the structures available for efficiency. Flexibility: Students combined and moved between multiple strategies throughout the task. Appropriate Strategy Selection: Strategies fully accounted for features of the particular numbers involved or structures available.
Level 2	Level 3
Efficiency: Partial increase in efficiency, often at the beginning, but then primarily relied on inefficient strategies. Flexibility: Either a single strategy is used throughout that attended to one feature of the numbers, or students used such a strategy and then moved to an inefficient strategy for the remainder of the task. Appropriate Strategy Selection: Strategy took into account one feature of the particular numbers involved or the structures available.	Efficiency: Primarily relied on efficient strategies, but finished with or included a less efficient strategy for a portion of the task, OR used a large collection of strategies such that coordinating or moving between them was inefficient *(not maximizing use of structure)*. Flexibility: Students used more than one efficient strategy that attends to features in the numbers or their structure. Appropriate Strategy Selection: Strategy took into account more than one feature of the particular numbers involved or the structures available.

Figure 2: Abbreviated Fluency Scoring Framework

Findings

Our analysis found statistically significant growth in students' fluency from the pre- to post-assessments after the nine-lesson How Many intervention. The mean total score on the pre-assessments was 10.53 (out of 20; 5 points for 4 tasks), or a mean score per task of 2.63. On the post assessments, the mean total score was 13.63, or a mean score per task of 3.41. The pre- to post-assessment difference was highly statistically significant at the $\alpha = 0.05$ level ($p = 0.0008$). These differences were similar in both second and third grades.

Analyzing the shifts at the student level, we found that the number of students with a mean per task score lower than 3 shifted from pre- to post-intervention (see Table 1). In the pre-assessment, seven students had a mean score below 2 and another 12 students had a mean score of at least 2 but less than 3, for a total of 19 students with a mean fluency score per item below 3. In the post-assessment, the number of students in this group was more than cut in half; only one student had a mean per item score below 2 and eight scored in the next highest tier, for a total of nine students with mean scores below 3. Proportion testing indicated that this was a statistically significant shift at the $\alpha = 0.05$ level as well ($p = 0.0117$).

Table 1: Fluency Shifts Pre- to Post-Intervention

Mean Fluency Score (per task, out of 5)	Number of Students (Pre-Assessment)	Number of Students (Post-Assessment)
Score ≥ 4	2	8
$3 \leq$ Score < 4	11	15
$2 \leq$ Score < 3	12	8
Score < 2	7	1

Discussion

Our results indicate that the nine-lesson How Many intervention, despite its brevity, may have encouraged fluency development for the participating second and third graders. The duration of this intervention was bound by practical constraints at the end of a school year; our findings raise questions about what additional gains might be possible if this routine were truly routine, even once or twice a week, across a school year. Additional research is needed to explore this possibility, as well as to investigate the potential for supporting fluency development in both younger and older students. Furthermore, given the limited research on fluency frameworks involving multiple addends and factors, we posit the framework shared in Table 1 has scholarly significance as well. Indeed, we believe that these types of tasks may offer unique opportunities for developing appropriate strategy selection, flexibility, and efficiency, given the multiple entry points available when the number of addends stretches to six, ten, or more. We next seek to investigate the nature of the discourse and facilitation of the intervention itself to inform how others might seek to implement the How Many routine for future research and in practice.

This study investigates how Dynamic Measurement for Area (DYME-A), an approach that engages students in exploring models of area as a dynamic sweep of a line segment over a distance, can support students' multiplicative reasoning. We report on a design experiment with one third-grade student to illustrate how experiences with generating and manipulating dynamic area models supported the student in constructing multiplication expressions as dimensionalized objects of base × height, that could be dynamically stretched, partitioned, and iterated, fostering flexible multiplicative reasoning.

Keywords: Cognition, Design Experiments, Number Concepts and Operations, Technology

Area models have been a key visual representation for several forms of multiplication, including whole numbers, fractions, and binomials (e.g., Kwon et al., 2019; Lischka & Stephens, 2020; Pratt, 2017). An area model is a visual representation of a rectangular area filled with a grid of rows and columns (e.g., Figure 1a) or split into unequal area parts (e.g., Figure 1b) (Kwon et al., 2019). For example, to find the product of 3×4, a student can draw a rectangle of three rows and four columns (Figure 1a) and count the total number of squares units.

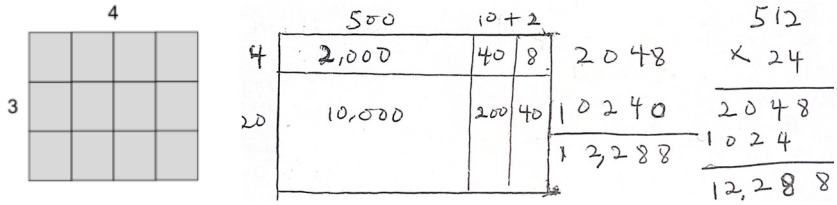

Figure 1: Area Models of Multiplication

Area models provide several benefits for multiplication including supporting students in making connections between quantities and operations (Kwon et al., 2019), developing mental images that help students reason abstractly (Englert & Sinicrope, 1994; Schultz, 1991), and reasoning about continuous quantities (Lischka & Stephens, 2020; Smith et al., 2013). Englert and Sinicrope also note that area model representations make the parts of partial product multiplication visible and support students to notice patterns relating the area models to the computations. Additionally, area models are particularly useful in visually representing real-world experiences such as "carpeting, fabrics, paint, wall coverings, and lawn and gardening products" (Schultz, 1991, p. 42). Lischka and Stephens (2020) argue that "developing an understanding of the area model in the elementary grades lays a foundation for understanding other concepts involving multiplication in later grade levels" (p. 187). These include ratios,

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

probability, even covariational reasoning and algebra in later years of schooling (e.g., Ellis et al., 2020; Fyfe et al., 2017; Lischka & Stephens, 2020; Lovin, 2020; Pratt, 2017).

Because of these benefits, the state learning standards (NGA, 2010; NJDoE, 2020) include area models in numerous mathematics standards for whole number multiplication and fraction operations and students are expected to be able to use them to represent, illustrate, explain, and justify their reasoning. Despite emphasis in the curriculum, the NAEP report (USDoE, 2022) shows that fourth-grade students struggle in both area measurement and multiplication. One reason for these struggles is that existing approaches lead students to focus on the number of parts rather than the area of the parts in an area model (Čadež & Kolar, 2018; Smith et al., 2013; Van de Walle et al., 2013). As a result of treating area as the count of discrete squares and not a multiplicative relationship, when area models are used for multi-digit partial product multiplication (Figure 1b) or the distributive property, students may "not be sure if numbers used for factors represent the lengths of sides of a given rectangle or the numbers of rows and columns in the model" (Kwon et al., 2019, p. 364). Therefore, students struggle with creating area models without grids for multiplying larger numbers (Figure 1b). Consequently, Kwon et al. (2019) call for more research to determine the essential ideas embedded in the use of area models for multiplication, as well as on the different kinds of area models and how students use them.

In this paper, we discuss how we reconceptualized area models through Dynamic Measurement for Area (DYME-A), an approach that engages students in exploring models of area as a dynamic sweep of a line segment over a distance (Panorkou, 2020a). Our conjecture was that this approach can engage students in dynamically generating and transforming area models and support them in developing more flexible multiplicative reasoning through a deeper connection with measurement. Specifically, we examined: (a) What kind of DYME-A model design can support students' multiplicative reasoning? and (b) What forms of multiplicative reasoning do students exhibit as they interact with DYME-A area models?

Area Models: What We Know and Pushing Forward

There are two distinct types of area models in the literature (Kwon et al., 2019): the area-to-area model and the lengths-to-area model. The area-to-area model starts with an area unit as an initial quantity and emphasizes its change through the one- or two-dimensional arrangement of area units in groups (Figure 2a). It is a model that is analogous to the traditional array model. In contrast, the lengths-to-area model conceptualizes an area unit as the product of two coordinated lengths of one unit each (Figure 2b) and generates area in terms of a specific length and width (i.e., factor × factor). While textbooks usually focus on the first type, the lengths-to-area model can support students to understand how lengths can generate and define an area.

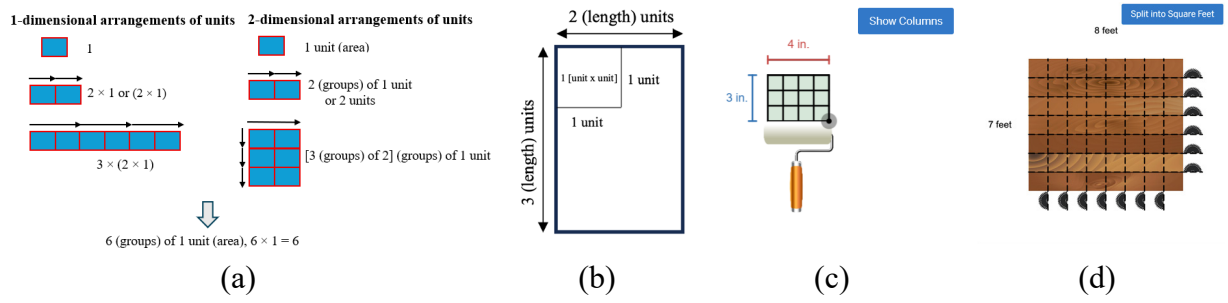

Figure 2: a) Area-to-Area and b) Lengths-to-Area Models Adapted from Kwon et al. (2019); c) Generating Area Models and d) Splitting Area Models into Square Units

In addition to the two models, we also considered the *containment* and *generation* perspectives of measurement (Panorkou, 2020b; Panorkou & Pratt, 2016) and how these may apply to how area models are drawn, manipulated, and conceived. The containment perspective entails conceptualizing an area model as a 2D space that contains other 2D (square units) and 1D parts (length, width), while the generation perspective entails conceptualizing that the area model can be generated by tracing a length over a distance, or by iterating other area units. In our study, we aimed to provide students with opportunities to experience both generation and containment perspectives. For instance, we had students construct area models by using draggable points to generate a specific length (e.g. 4 in.) then drag that length over various width measures and visualize how the area grows simultaneously (Figure 2c). To help students connect the 1D parts (length and width) with the 2D parts (square units) of the rectangle, we made use of features that allowed students to toggle between continuous area models (only showing the dimensions) and discrete area models with square units. We also had students dynamically cut rectangles into the contained square units given the dimensions of the rectangle (e.g., Figure 2d).

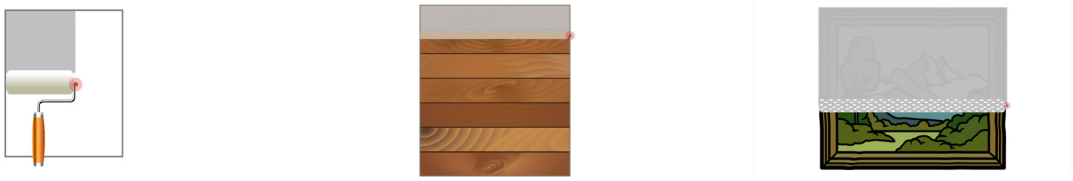
Theoretical Framework: Studying the Interplay Between Area and Multiplication

Over the years, research on students' measurement and multiplicative reasoning has developed along separate paths. A study that aimed to connect the two was the Elkonin-Davydov Curriculum (Davydov et al., 1999) and its US adaptation Measure-Up (Dougherty et al., 2004) that studied measurement with multiplication as a change of unit measures. The difference in the DYME-A approach is that students construct a unit of measure as a dimensionalized object (Thompson, 2000) that depends on the specific length and width. For instance, in Figure 2c, the construction of an area (e.g., using the length of 4 in. dragged by 1 in. to create an area of 4 square in.) can be perceived as a dimensionalized object that can be iterated by 3 in. to generate a total area of 12 square in. In constructing our framework, we focus on students' possible mental processes as they generate and act upon those dynamic area models. We hoped that this approach will give us insights into their early multiplicative reasoning that will be constructed and developed as they interact with these different models. Table 1 presents the mental processes that we considered while we were open for any others not reported on that list.

Table 1: Possible Mental Processes During Students' Area Models Explorations

Mental Process	Definition
Equipartitioning	Cognitive behaviors that have the goal of producing equal-sized parts of wholes (Confrey et al. 2009).
Re-assembling	Recombining equal parts to produce the original whole as "n times as many" or "n times as much" as a single part (Wilson et al., 2012)
Iterating	"Repeatedly instantiating a part of a unit in order to make a larger amount" (Hackenberg, 2010, p. 385)
Decomposing	Breaking a whole into non-equal parts (Sarama & Clements, 2009)
Composing	Recombining non-equal parts to produce the original whole (Sarama & Clements, 2009)
Stretching	Changing the whole by multiplicatively changing the base or the height by a factor greater than 1.
Compressing	Changing the whole by multiplicatively changing the base or the height by a factor between 0 and 1.

These processes illustrate an integration of the containment and generation perspectives. To elaborate, growing the base or the height to grow area presumes a conceptualization of area as both containing those objects and being generated by these objects. In a similar manner, equipartitioning an area into square units or re-assembling square units to produce area involves a conceptualization of area as containing square units and being generated by these square units.



Methods

This paper reports on the findings from a design experiment (DE) (Cobb et al., 2003) with a third-grade student, Alexa, to initiate the discussion around the qualitative different mental processes and varied forms of multiplicative reasoning that are possible as students interact with the DYME-A tasks as well as the type of design (tasks, questioning) that might support these forms of reasoning. This DE is part of a larger design-based research study where we conducted a series of 10 DEs with pairs of third- and fourth-grade students aiming to study the interplay between design and students' reasoning. The particular DE presented here was part of our second iteration and lasted for 13 sessions. Each session ranged between 38–85 minutes.

The activities on area models and multiplication were designed using the Amplify (formerly Desmos) classroom platform due to its dynamic tools. Each session was video-recorded and student screen activity was recorded. All recordings of the sessions were multimodally transcribed (Chanier & Lamy, 2017) to capture verbal language, gestures, and student actions. First, we analyzed the transcriptions to identify episodes of student reasoning about area and multiplication based on our theoretical framework described previously. Each member of the research team coded the transcripts and then met to discuss the coding. In this paper, we report the second stage of analysis that included constructing a chronological account of student reasoning episodes to describe the relationship between their mental processes and their activity.

Findings

In terms of prior knowledge, Alexa was familiar with the term area, but she did not "really know what it means." She could also find the products of expressions such as 10×9 by using arrays and equal groups. She acknowledged the challenge with using arrays with big numbers, stating, "I won't have enough space" on the whiteboard to construct one. The initial tasks of DYME-A asked students to dynamically sweep a line segment over various distances and reason about the space generated using contexts such as painting, bubble wrap rolling, or carpet rolling (Figure 3). To create common language, we introduced the terms *base* (measure of one side), *height* (measure of a side that is perpendicular to the base), and *area* (measure of the surface generated).

(a) (b) (c)

Figure 3: Dynamic Sweep of a) a Paint Roller, b) a Carpet Roller, c) a Bubble Wrap

After dragging a roll of bubble wrap to cover a painting (Figure 3c), Alexa was asked how we could make the area bigger. She responded, "By making that height bigger, we can stretch," illustrating a dynamic conception of height as a quantity that can "*stretch*" and influences the area. We then prompted, "We cannot stretch the base?" and she acknowledged, "Yes, we can."

To support students to quantify the area, we then introduced the notion of square units by using a step-by-step animation (Figure 4) that illustrates how an area model for whole number multiplication can be generated, beginning with a single square unit (Figure 4a), then a row of five square units (Figure 4b), and rectangle of eight rows (Figure 4c) that dynamically forms a 40-unit rectangle. When Alexa was asked what she noticed about the animation, she stated, "The purple one is one unit, and the other one is five units because it is the base." She then continued, "The height got bigger, seven more," and "the total is 40 square units." Alexa's response shows that she constructed the 1-square-unit as an area unit, then quantified the one row based on those area units by looking at the measure of base. Then she quantified the large rectangle as 40 square units by considering the increase in the height and *iterating* the row seven times. Next, we asked Alexa to draw and label a 7×5-unit rectangle herself on a digital grid and find its area. She responded that to find the area of a rectangle, "we need to know how big is the base and the height," illustrating that she began connecting the base and height to the square units.

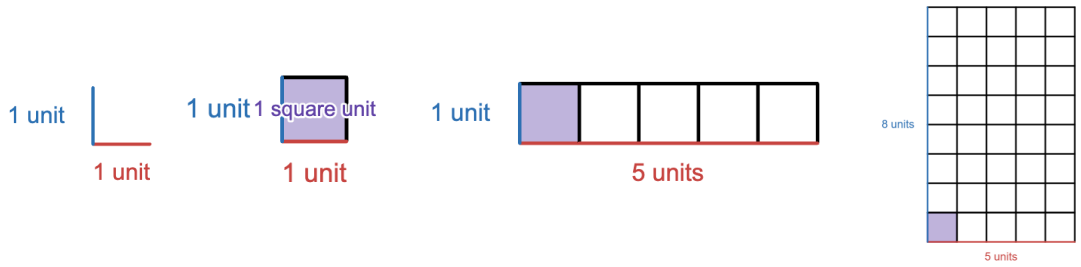


Figure 4: Construction of a) One Square Unit, b) Base Row of Units, and c) Entire Rectangle

To support the connection between lengths-to-area and area-to-area models further, we introduced a task using draggable paint rollers to generate rectangles. She dragged a paint roller to create a 4in. × 3 in. rectangle and stated, "This is four, this is three, so that is like, so that's 12," referring to the area (Figure 5a).

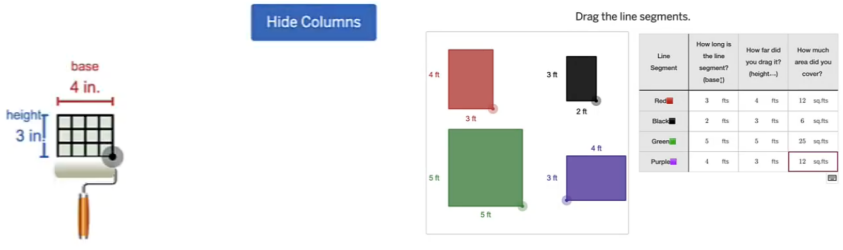

Figure 5: a) Hide/Show Columns Feature, and b) Dragging Line Segments

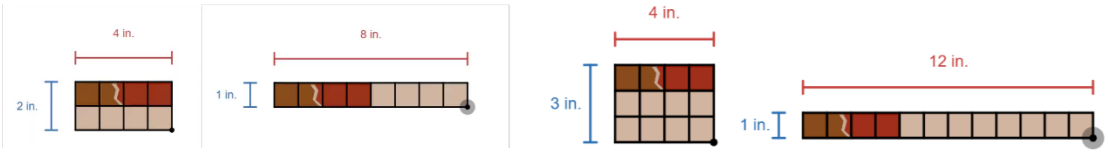
Next was an 8 in. × 3 in. rectangle and Alexa immediately stated, "So this one is 24," without generating the digital rectangle. When asked how she knew the 8 in. × 3 in. dimensions would result in a rectangle with an area of 24, she replied, "Because I can multiply the base and the height because it will equal to 24 since it's multiplication." We interpreted this as an early indication of her conception that area is determined by the product of base and height, connecting multiplication to the area model. Alexa then began working on dragging line segments to generate rectangles (Figure 5b). At this time, the "show columns" feature, which enabled students to see the square units, was no longer accessible and she was able to find the area of each rectangle. At the end of the activity, Alexa was asked, "How do we find area?" and Alexa stated, "By multiplying the base and the height," suggesting that the absence of square units in the design supported her shift between discrete and continuous models of area.

Our next goal was to support Alexa in recognizing the multiplicative coordination between base, height, and area. Alexa was asked to double the area of a 4 in. × 1 in. candy bar (Figure 6a). She first doubled the area of the rectangle by first *iterating* the area and connecting it to *stretching* the height. Alexa explained, "because if I add four more [square units], this [circles 1in height in her drawing] change into two [inches]." When asked to do it differently, she *stretched* the base. Then she was asked, "Based on what you did, how would you explain to someone how to double the area of the rectangle?" and she responded that she "can use the base or the height." She was then asked to triple a 4 in. × 1 in. rectangle and she *stretched* the height to create a 4 in. × 3 in. rectangle (Figure 6b). She then did it a second way by incrementally *stretching* the base to create an 8 in × 1 in. and then a 12 in. × 1 in. rectangle. She was then asked to triple the area again and stated that multiplying either the base or height by three would make the area "three times bigger." She was then prompted to reason about larger factors, such as "if I make the height ten times bigger, what will happen to the area?" She explained that when we make the base or height ten times bigger, the area will also become "ten times" bigger. Her reasoning shows that she connected the act of *stretching* with multiplication, recognizing that *stretching* either the base or height by a factor results in *stretching* the area by the same factor.



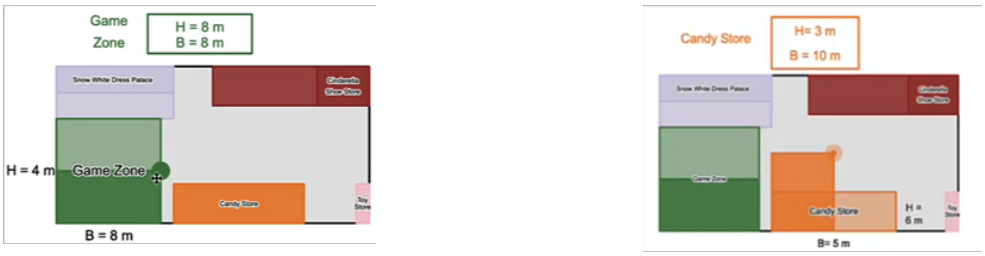


Figure 6: Alexa (a) Doubled and (b) Tripled the Height or the Base of a 4 sq. in. Candy Bar

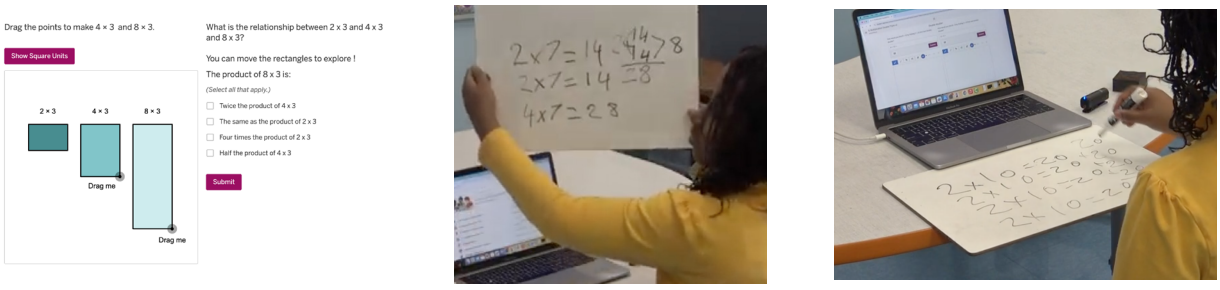
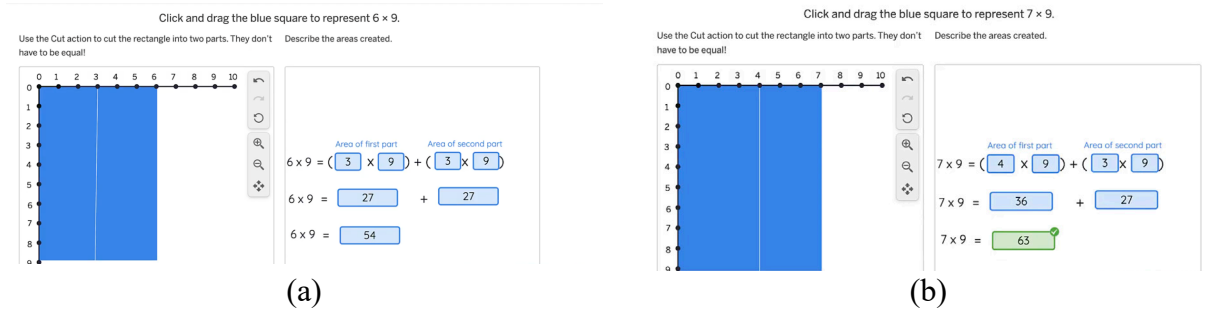
The tasks that followed also focused on the multiplicative coordination of base, height, and area but illustrated change in continuous models where the square units were not visible. In one task, we asked Alexa to multiplicatively change the dimensions of various stores in a shopping mall and reason about the change in area. When we asked her to halve the height of the 8 m × 8 m game zone (colored green, Figure 7a), she *compressed* the area and stated that the height and area each "got two times smaller."



(a) (b)

Figure 7: a) Alexa Halved the Height, b) Alexa Doubled the Height and Halved the Base

Alexa was then asked to double the height and halve the base of a 10 m × 3 m candy store (colored orange, Figure 7b) and she replied, "It changed because it was like, first this [points at the original area], and it got longer [points at the new area], and the area and the base got smaller. But it still equals the same; it's still equal to the same area." Alexa's responses indicate that she was able to coordinate the change in length, base, and area flexibly, even when both dimensions changed, without the need of visible square units.



Subsequent tasks aimed to extend students' experiences with dynamic area models to multiplication by asking them to investigate relationships between factors that are multiples of two, with the goal to help them recognize that multiplying a quantity by four or eight is equivalent to doubling that quantity twice or three times, respectively. For instance, students were asked to drag the height of a 2×3 rectangle to generate 4×3 and 8×3 rectangles and explore questions such as, "What is the relationship between 2×3 and 4×3 (or 8×3)?" (Figure 8a). Students could also overlap the rectangles to compare them or toggle the square units. This series of tasks supported students in finding larger products by *equipartitioning* and *iterating*. For instance, when Alexa was asked to find 4×7, she stated, "I can use 2×7. So, I put 2×7, two times. It equal to the same number" (Figure 8b). We interpret Alexa's reasoning to show that she constructed 4×7 as a dimensionalized object that she split in half to a smaller dimensionalized object with a familiar product. She then doubled the 2×7 to *reassemble* the original. Similarly, when she was asked to find 8×10, she stated, "I can use 4×10 to do 8×10 since it will be easier." She continued, "I am going to use 2×10, four times, since it's double-double." (Figure 8c). Like before, we characterize her reasoning to illustrate that she constructed 8×10 as dimensional object that she *equipartitioned* in four smaller dimensional objects with a familiar product. She then *reassembled* the original by quadrupling the 2×10 part.

(a) (b) (c)

Figure 8: a) Relationship Between ×2, ×4, ×8; b) Alexa's 4×7 Work, c) Alexa's 8×10 Work

Likewise, Alexa was then asked to find products with factors ×6 and ×12 but she struggled to mentally coordinate the processes associated with *partitioning* and *iterating* these dimensionalized objects. To support her, we designed a partitioning task that she could actively manipulate from both generation and containment perspectives. We asked her to create rectangles using dragging (e.g. 6×9 in Figure 9a) and then use the Cut tool to split it into equal parts and determine each part's area. This task supported her exploration of how multiplying a quantity by 6 is equivalent to multiplying the same quantity by three and then doubling it. For instance, Alexa explained, "You can just use rectangles to find the answer, and you can just split a rectangle in half. Which is half of the area, you can use any area that can be split and after, you can use the area of the first part and the second part. You can add them up together to make it the product." The task allowed Alexa to equipartition the rectangle into smaller, more manageable dimensionalized objects.

(a) (b)

Figure 9: Cutting Rectangles Task for Finding (a) 6×9, and (b) 7×9

Subsequently, we introduced multiplication sentences with both factors odd (e.g., 7×9) to examine whether students could *decompose* dimensionalized objects. Alexa was able to *decompose* seven into three and four (Figure 9b) stating, "So what I did was cut the rectangle in four. And it doesn't equal to a half, because it's an odd number, but it doesn't have to be equal. So, the area of the first part is four times nine, in the second one is three times nine. And when I add the area of the first part it's 36 and the second part is 27." Alexa was able to *decompose* a bigger dimensionalized object into two smaller and more manageable dimensionalized objects and then *composed* them to find the total area. These *decomposition/composition* processes supported her to find more complex products later such as two-digit by one-digit, three-digit by one-digit, and two-digit by two-digit.

Concluding Remarks

Our tasks allowed students to work with area models as a combination of area-to-area and length-to-area models (Kwon et al., 2019) through the dynamic generation of both base and height, and square units. First, our findings show that the dynamic generation of area models allowed Alexa to see that the area of a rectangle depends on the base and the height. Then, Alexa demonstrated that the tasks supported her construction of the multiplicative relationship between base, height, and area as well as the connection to the square units used to measure area, illustrating the containment of space. Alexa also generated both 1D and 2D area models that supported her construction of the multiplicative coordination between base and height and area. These experiences provided Alexa with the opportunity to construct multiplication expressions (e.g., 8×7) as dimensionalized objects (Thompson, 2000) of base × height. These

dimensionalized object expressions modeled areas that could be stretched or compressed dynamically to generate larger or smaller areas. They can also be equipartitioned or decomposed to smaller manageable dimensionalized objects, which can be reassembled, iterated, or composed back to find the total area of the original. Shifting between discrete and continuous area models and between containment and generation (e.g., Panorkou, 2020b; Panorkou & Pratt, 2016) in the area model design could be a new perspective to support students' flexible multiplicative reasoning through measurement.

THREE-DIMENSIONAL CONSTRUCTION THAT DEVELOPS SPATIAL VISUALIZATION IN YOUNG CHILDREN

Satoshi Watanabe
JISSEN Women's University
watanabe-satoshi@jissen.ac.jp

This study analyzed the spatial visualization abilities of 41 five-years children through their cube construction strategies and the mental manipulation of nets. Four types of cube construction strategies were observed. Mental manipulation of cube nets was difficult for children. The children were observed to tend to judge whether they could build a cube based on appearance alone. However, four children used gestures and took a long time to complete mental manipulation. Two of these four children created cubes using strategies that utilized the relative positions of the faces. For these two children, a correlation was considered to exist between cube construction and mental manipulation.

Keywords: Spatial Reasoning, Spatial Visualization, Mental Folding, Geometry

Introduction

Spatial reasoning is broadly defined as the ability to mentally represent, organize, and transform objects and their relations (Linn & Petersen, 1985; Newcombe & Shipley, 2015). Spatial reasoning plays an important role in predicting overall mathematics success with even greater predictive power than general mathematics scores (Farmer et al., 2013). Spatial skills are strongly related to success in Science, Technology, Engineering, and Mathematics (STEM) educational pursuits and career choice (Wai et al., 2009). However, this is a particularly underdeveloped area of current mathematics curricula, especially in Japan.

Theoretical framework

Spatial Reasoning that Operates on Transformations Between 2D and 3D Objects

Two object-based spatial skills that frequently appear in mathematics research are mental rotation and spatial visualization (Harris, 2023). Mental rotation skill is the ability to mentally rotate a two- or three-dimensional geometric figure quickly and accurately; and spatial visualization is associated with the ability to recognize complicated, multi-step manipulations of spatial presented information (Uttal et al., 2013). Spatial visualization has been singled out by cognitive scientist as a central metric of spatial reasoning (Jansen et al., 2013). In this article we discuss what we mean by spatial visualization, why constructing solids can foster spatial visualization in young children. Spatial visualization involves understanding and performing imagined movement of 2D and 3D objects (Uttal et al., 2013). Many studies have reported that educational interventions have improved spatial visualization in young children (e.g. Bruce & Hawes, 2015). Even at an early age, some children can mentally construct planes using spatial visualization and imagery. Furthermore, the children with lower levels of spatial visualization skills have improved through educational intervention (Uttal et al., 2013). However, the detailed reasons for this have not been reported, and there is no clear explanation for the relationship between spatial visualization, imagery, and intervention experiences in young children. Several spatial visualization tests have been studied to date (Davis, 2015). For example, both surface development tests (a 2D to 3D transformation task) and the paper folding tests (a mental folding task) may require dynamic spatial manipulation abilities and visuospatial working memory capacity. These tests require children to engage in dynamic thought processes related to a single

object. However, there is little detailed research on experiences and training to improve spatial visual abilities in young children. Currently, there is relatively little research focusing on spatial thinking and the environmental factors that influence its improvement.

This paper focuses on surface development tasks in young children. Creating three-dimensional objects from two-dimensional planes is a common activity in young children's play. Clements (2004) suggests that young children with extensive experience in creating three-dimensional objects have high spatial abilities. Creating three-dimensional objects is an enjoyable activity for young children. However, the way they approach it varies from person to person. We hypothesized that this experience might influence spatial visualization. Therefore, we decided to study the relationship between the strategies used when creating a cube from a two-dimensional plane and the strategies used when imagining folding the net of a cube. Based on the above, we address the following research questions.

- What types of strategies do young children use to construct a cube from six faces?
- What is the relationship between young children's cube-construction strategies and their mental manipulation of cube-nets?

First, we will study the process by which young children create cubes using six faces and define the process by which they understand how to create a three-dimensional cube from a two-dimensional plane. Next, we will study the process by which young children imagine a three-dimensional cube by mentally folding the net of a two-dimensional cube and identify the difficulties they face. Finally, we will study the relationship between the strategies of making a cube by hand and mental manipulation.

Method

A total of 41 five-year-old children participated. Each participating child (n=41) was individually interviewed by author in a quiet location at school. We observed and recorded how the children responded to the tasks. First, we placed a cube in front of the children, with squares of the same color facing each other. Next, we gave each child six squares (2-red, 2-yellow, 2-green). Then we told them, “Use these six squares to create the same cube as before.” Each child assembled a cube based on the color information. We observed, recorded, and categorized how each children assembled their cube. Second, we prepared a cube one top face missing and its net, and asked the children, “If you make this cube net, will it become the cube in front of you? Think about it in your mind and try to guess whether it will or won’t.” The children answered “Yes,” “No,” and “I don’t know.” The reason we used a net with one face missing was that the results of mental folding tests using six-faces and five-faces nets of the same shape were similar from first grade to sixth grade. The children worked on seven different nets (Figure 1).

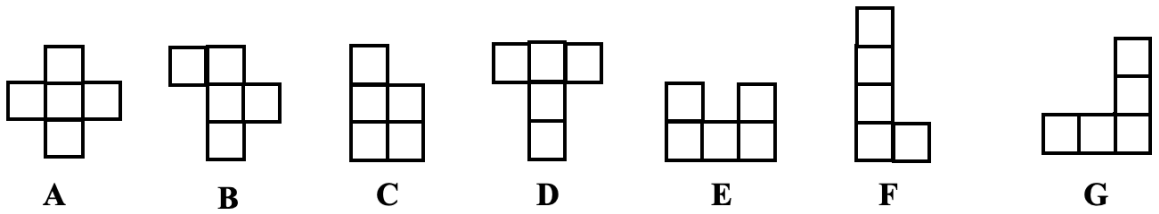

Figure 1: Seven Kinds of Cube Nets

The difficulty level of the thought processes for each type of cube net was analyzed based on the correct answer rate. In addition, the thought processes of students with high correct answer rates were observed and analyzed, their relationship to cube construction strategies examined.

Results

Two children were ultimately unable to assemble the cube. One child tried to make a cube by connecting six squares in straight lines to form a ring, while the other tried to make a rectangle by connecting two squares vertically and three squares horizontally, then folding that to make a cube, but both ultimately failed. Four strategies for constructing the cube were observed. First strategy to construct a cube was using three faces attached to one apex. Children who used this strategy connected three different colored faces and placed them on the sample cube, ensuring that the same colors corresponded. Eleven children used this strategy. Second strategy was to set faces of the same color on the bottom face. Nineteen children used this strategy. These children could construct a cube with the help of observation of sample cubes. In the third strategy, children first joined four side faces to form a cube, then attached two bases. In this case, children alternated between attaching two different colored faces and then bent them to see if faces of same color were facing each other. They already knew that when the cube was unfolded, the four sides of the cube would line up in a skip position. Four children used this strategy. Forth strategy is to construct a cube from cube net of cross shape. In this case, children had already known how to construct a cube from a cross-shaped cube net. Five children used this strategy, and these children already understand where the faces of a 3D cube fit onto the 2D cube net.

Next, we will discuss the characteristics of the cube net that make it easy and difficult for young children to mentally manipulate it. The average number of correct answers is 1.74 out of 7 questions. In the case of plane A, 95.1% of children said the correct answer. The next highest correct answer rate after plane A was plane E at 43.9%, and the lowest correct answer rate was plane G at 21.9%. Thus, most children could not imagine cube nets other than plane A. The incorrect answers demonstrate the difficulty in mentally manipulating the shape is their mind. Plane B can be constructed correctly, but 20 children answered “No.” After they answered, they tried to make this cube, but stopped when they raised one face. Because children had no experience moving two faces together. So, they couldn’t construct plane B in their mind.

Many of the children were not observed to be engaging in mental operation. However mental operation was observed in four children (Table 1). These four children were observed to approach the problem in a way that was clearly different from the other children. First, they do not answer immediately. They were observed thinking carefully while moving their hands. Ehrlich et al. (2006) suggested that gestures thus provide useful information about children’s spatial strategies.

Table 1: Answers of Four Children Observed Using Mental Operations

	A	B	C	D	E	F	G	Total of correct answer
Child A	✓	X	✓	✓	✓	✓	X	5
Child B	✓	X	✓	✓	✓	X	X	4
Child C	✓	✓	X	✓	✓	X	X	4
Child D	✓	X	✓	✓	✓	X	X	4

The average number of correct answers for 37 children, excluding the four children, was 1.7. Therefore, these four children got far more correct answers than the other children. Two of the four students looked at the sample cube and constructed a cube by placing faces of the same color opposite each other on the bottom. One of the four children first connected two pairs of same-colored faces in a skip position to complete a side and then added a top and bottom face to create a cube. Another one of the four children made a cube using the cube nets of cross. It was observed that these two children already knew how the faces of a 3D cube would be positioned when unfolded. A correlation was observed between the strategy of constructing a cube using the relative positions of the cube's faces and using mental rotation to create a cube in these two children.

Discussion

This study observed four strategies for constructing cubes. Young children relied on visual information, such as opposite faces being the same color or three faces meeting at a single vertex, to construct cubes. They also utilized knowledge such as alternating face colors and arranging faces in a cross shape to form a cube. Furthermore, it was found that it was extremely difficult for young children to mentally manipulate various shapes' nets. They did not appear to judge whether a net would form a cube based on its appearance, nor did they seem to engage in any mental manipulation. In particular, it was observed that children immediately recognized symmetrically arranged nets as cubes. Figure B (Figure 1) is a net that has a low success rate not only young children but also students from first to sixth grade of elementary school. It is thought that students pay more attention to this net than other because it required the mental operation of bending each face in a different direction, thus demanding more working memory. While many young children answered immediately, four children were observed taking their time, working with their hands and mentally considering the movement of faces in the net. One of these children knew that four squares arranged together form the four sides of a cube. Another student knew that unfolding a cross-shape cube net would results in a cube. It was observed that the spatial visualization of these four children were supported by knowledge gained through concrete manipulation of various three-dimensional objects. For children to be able to manipulate the movement of objects in their minds, they need to form the basis of images trough concrete experiences. Therefore, using concrete manipulation experiences and the use of images are essential for strengthening spatial visualization. Future research is expected to involve observing and coding the specific operations and mental processes of more students, conducting research

through actual learning experiences, and clarify what kinds of activities will foster students' spatial abilities.

Keywords: Number Concepts and Operations, Preservice Teacher Education, Rational Numbers and Proportional Reasoning, Teacher Knowledge

Multiplication involving rational numbers has long posed ongoing conceptual challenges among teachers and students (Alghazo & Alghazo, 2017; Olanoff et al., 2014; Young & Zientek, 2011). Purnomo et al. (2022) noted that multiplication has sometimes been seen by learners to result in larger numbers, but this idea does not hold for multiplying a rational number between 0 and 1, as multiplication in this case results in a number smaller than the original value. Research has shown that in-service and prospective teachers (PTs) often find it challenging to create coherent meanings for such operations, and this indicates that this cognitive conflict extends beyond learners at the elementary grades (Depaepe et al., 2015; Kang, 2022; Son & Lee, 2016).

In this study, we examined PTs' reasoning about the multiplication of a positive number and a rational number between 0 and 1. We utilized Mathematical Knowledge for Teaching (MKT) as our framework (Ball et al., 2008) in this research. In addition, we grounded our work in literature on conceptual and procedural understanding of mathematical concepts to analyze PTs' understanding of rational number multiplication (Hiebert & Lefevre, 1986). Together, the MKT framing as well as this literature guided our interpretation of the findings related to PTs' understanding of multiplication of rational numbers. This literature further helped us identify some misconceptions that PTs had (Alghazo & Alghazo, 2017; Depaepe et al., 2015).

This study took place in a northeastern U.S. university where PTs were taking a mathematics course taught via problem solving. There were two sections with two instructors and four graduate mathematics education students who served as interns. Also, there were 30 PTs whose data were complete, and thus were used in reporting the findings of the study. In order to gain insight into how PTs conceptualize multiplying positive number and a rational number between 0 and 1, we used a qualitative technique using an interpretative paradigm. We further used three data collection tools. We used pre-unit and post-unit assessments that focused on PTs' thinking around multiplying a positive number by a rational number between 0 and 1. We prompted the PTs to describe whether the outcome was a smaller or larger value. A third data collection method we used were memos written by interns based on their observations and PT interactions.

The findings from the study indicated that most PTs were able to determine that multiplying a positive number by a rational number between 0 and 1 gives a result smaller than the positive

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

number. However, the explanations for this varied among PTs as some of them demonstrated conceptual understanding and others relied more on procedures. At the beginning of the unit, some PTs had misconceptions; however, by the end most of the responses were void of erroneous explanations. Through this study we discuss particular junctures at which some misconceptions hindered conceptual understanding and procedural fluency. We further recommend that instruction should thoughtfully combine visual and contextual models, such as number lines, area models, and scaling scenarios, to assist future teachers as well as students in developing an understanding of the rationale behind the rules for multiplying rational numbers.

GESTURE, INSCRIPTION & PROPORTIONAL REASONING: A PILOT STUDY

Angela R. Crawford
University of Idaho
arcrawford@uidaho.edu

Keywords: Rational Numbers and Proportional Reasoning, Assessment, Cognition

Objective & Theoretical Framework

This study investigated how students' gestures and inscriptions during proportional reasoning tasks might signal mathematical reasoning. The following question guided the pilot study: *Are specific types of gestures or inscriptions associated with more sophisticated proportional reasoning?*

Grounded and Embodied Learning (Nathan, 2022) encompasses the many embodied and situated ways students build and demonstrate mathematical understanding. This suggests assessment should attend to gestural and representational activity as meaningful evidence of reasoning. The long-term goal is to develop empirical foundations for technology-mediated, embodied assessment systems capable of detecting mathematical reasoning through gesture and inscriptions—moving beyond static, decontextualized assessment formats.

Method

Sixty-five grade 6 students were video recorded as they completed between 1–4 proportional reasoning problems and explained their thinking. These videos were coded for gesture, inscriptions, correctness, and proportional reasoning sophistication. Analyses focused on frequencies, proportions, and chi-square tests of association, interpreted as exploratory given the nested data structure.

Results & Implications

Gesture was present in 74% of attempts and more common during explaining (70%) than solving (22%). Gestured attempts were more likely to involve proportional reasoning than those without (71% vs. 46%; $\chi^2(1) = 11.37$, $p < .001$, $\varphi = .22$). Inscriptions were present in 41% of attempts and more likely to accompany proportional reasoning (74.5% vs. 57.3%), yet slightly more common in incorrect attempts (37.8%) than correct ones (34.7%), suggesting no straightforward relationship between inscription use and success. Creating number lines or ratio tables was associated with the highest proportional reasoning rates (85% and 77%), while annotating a given model showed the lowest (25%).

These exploratory findings suggest that gestures and inscriptions carry diagnostic information about proportional reasoning that correctness alone does not reveal. The pattern of inscription use occurring more often with proportional reasoning but not necessarily with correct answers warrants further investigation. This pilot study points toward explanation-phase gesture and student-generated representations as potentially meaningful signals for assessment purposes. Future work will examine whether these patterns hold across larger and more diverse samples, and what they mean for the design of technology-mediated assessment systems capable of detecting reasoning through gesture and inscription in real time.

WHEN "COUNTING BY TENS" ISN'T "COUNTING BY TENS"

Karl W. Kosko
Kent State University
kkosko1@kent.edu

Maryam Zolfaghari
Kent State University
mzolfagh@kent.edu

Keywords: Elementary School Education, Number Concepts and Operations

Place value is an important concept that children begin to develop early in elementary school (NGAC & CCSSO, 2010). From a Scheme Theory perspective, students first internalize number after constructing the Initial Number Sequence (INS), which involves the ability to count-on to other numbers by 1s (Steffe, 2025). When students develop the Tacitly Nested Number Sequence (TNS), they can anticipate one level of units to operate on, including skip-counting by 10s (Osana et al., 2023; Steffe, 1992). Thus, a child at TNS can simultaneously conceive of a 10 as one unit and also as ten 1s units (Silveira, 2000). Yet, practitioner literature includes examples of counting by 10s that are not considered as skip-counting (Battista, 2012; Wright et al., 2011). Such instances often occur in first grade (Hiebert & Wearne, 1992). Thus, the purpose of this study is to examine one first-grade child's construction of number in the context of place value.

A six-year-old, first grade student participated in this study. His performance was consistent with INS, as demonstrated by his ability to count onto by ones on Task 2 (see Figure 1). Across tasks, he relied primarily on these counting-on strategies, progressing sequentially from one tick mark to the next. Confirmatory evidence in the form of eye-gaze movement and gesture reinforced these observations. In several instances, he appeared to count by tens based on his verbal references to decade numbers (see Task 8 in Figure 1). However, closer analysis revealed disconfirmatory evidence suggesting that he treated each position as a single countable unit while labeling place value positions with decade names, rather than coordinating tens (or hundreds) as composite units. For example, when asked to interpret quantities composed of tens and ones, he stated that 6 tens and 30 ones equals 36, and 2 tens and 4 ones equals 60. These responses indicate that although he used decade terminology, he did not coordinate tens and ones according to place value structure. Thus, these findings illustrate that apparent counting by tens may occur without the construction of composite units, highlighting that verbal decade references alone are insufficient evidence of TNS development.

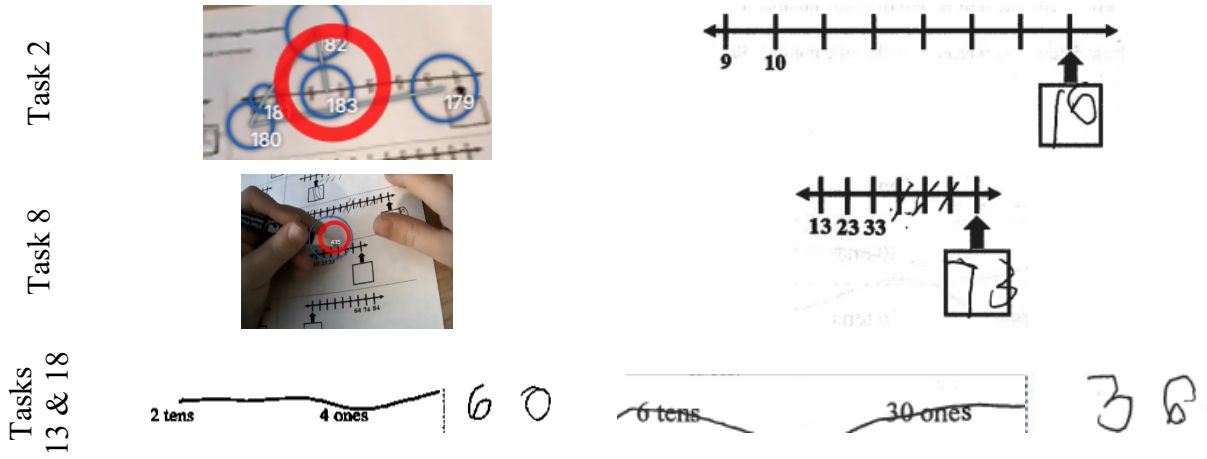

Figure 1: INS-Level Counting and Eye-Gaze Coordination During Number Line Tasks

A STUDENT'S CONVEYED REASONING OF TWO VS FOUR PARTIAL PRODUCTS

Jie Wang
Kent State University
jwang89@kent.edu

Karl W. Kosko
Kent State University
kkosko1@kent.edu

Keywords: Elementary School Education, Number Concepts and Operations

Partial products involves partitioning factors in multiplication by place value (Ambrose et al., 2003; Baccaglini-Frank et al., 2023; Hinton & Flores, 2024). They are the basis for algorithms of multidigit multiplication (Ambrose et al. 2003). There is preliminary evidence in the literature about the reasoning required for engaging in partial products (Gill et al., 2025), but more scholarship is needed. This study reports on an analysis of one student's conveyed meaning of multiplication when engaging with two and four partial products.

Systemic Functional Linguistics (SFL) was used to examine how one fifth-grade student, Hunt, conveyed meaning about partial products in different multiplication tasks. SFL analyzes grammar in text for how ideational meanings are conveyed by speakers (Banks, 2009). In this study, we examined transitive processes (verbs) and modality (hedging) in Hunt's transcribed text alongside his written work and physical actions (i.e., gestures). Hunt solved various tasks (14 × 2, 8 × 42, 43 × 38), but we focus on his explanation for 43 × 8 (see Figure 1). Across all tasks, Hunt engaged in partial products effectively. When solving 43 × 38, Hunt partitioned 38 into 30 and 8 two times and drew a line between both sets. He then partitioned 43 into two 40s and two 3s, placing them in both halves for the partitioned pairs of 38, respectively. Examining his transcribed interview, Hunt consistently referenced these partial products, but in pairs: "30 and eight … two 40s … the threes." Alongside his linguistic pairing of two partial products at a time, he used a series of transitive processes to convey his partitioning: "If you **break** …, then you **break** up … and you **put** …" Recall that Hunt drew a line between the first and the last two equations, thus conveying two pairs of partial products. Moreover, in explaining his procedures, he noted that when he had solved 8 × 42 that it "is a one-digit times a two digit," but that 43 × 38 was different because "you *have to* **do** the same exact thing [twice]." Both in his written work and spoken discourse, Hunt consistently conveyed his operating on four partial products as two sets of two partial products. Yet, Hunt lacked confidence in his understanding of the approach stating "I **don't know** how the strategy works; I *just* **learned** it." Despite this conveyed uncertainty, Hunt's description of four partial products as a pair of two partial products is appropriate. It may be indicative of a key transition between students' understanding two and four partial products.

So, I **don't know** how the strategy works, // I just **learned** it. //
If you **break** up the 38 and the 43, // then you **break** up the 30 //
and you **put** 30 and 8 // and then [**put**] 30 and 8 down here. //
And then you **put** two 40s on one of this half //
and then [**put**] on the other half // you **put** the threes
(motions to written 30×3. And 8×3)…

Mathematics education doctorates perform various tasks and play versatile roles. However, the field lacks consensus on what doctoral programs prepare future mathematics education doctorates for, or what preparation they need to perform their jobs. In this paper, we focus on the work and doctoral preparation of mathematics education doctorates, using interviews with 35 recent graduates. The results revealed that the work of mathematics education doctorates is far more complex than the traditional research/teaching dichotomy suggests. Doctoral programs need to be flexible to meet individual needs/goals, given each student's background. Some recommended experiences in doctoral programs include interdisciplinary collaborations, professional networking, and policy work. Gaps between the work and preparation for mathematics education doctorates are highlighted, and recommendations are provided.

Keywords: Doctoral Education, Doctoral Preparation and Training, Work of Mathematics Education Doctorates, Doctoral Competencies

Three National Conferences on Doctoral Programs in Mathematics Education in 1999, 2007, and 2022 focused on the competencies required for doctorates in mathematics education and on their preparation in doctoral programs. After each of the first two conferences, an edited volume was published to summarize the discussions and capture various ideas about doctoral preparation and competencies (Reys & Kilpatrick, 2001; Reys & Dossey, 2008). The Association of Mathematics Teacher Educators (2003) also published *Principles to Guide the Design and Implementation of Doctoral Programs in Mathematics Education*, listing and elaborating on the required competencies, such as mathematics and research. Since the first conference, several studies have been conducted on doctoral preparation, primarily using survey data to profile current doctoral preparation across programs and to call for further research (e.g., Reys & Reys, 2016; Reys et al., 2019).

Our work on mathematics education doctorates' competencies and doctoral preparation consists of a survey study with 218 recent graduates and a follow-up study in which we interviewed 35 of the participants about the work they performed in their current positions and the preparation they received in doctoral programs. The goal was to unpack and elaborate on the competencies needed for mathematics education doctorates, which we posit informs doctoral programs to better prepare them for their work and roles. We report the competencies recommended for mathematics education doctorates elsewhere. In this paper, we focus on the following two research questions and the related data analyzed.

1. What roles do mathematics education doctorates perform?
2. How well did the doctoral programs prepare them for their roles?

Framework

Mathematics education doctorates presumably perform various tasks and play versatile roles. However, the field lacks consensus on what doctoral programs prepare future mathematics education doctorates for, or what they need to learn or prepare to perform their jobs (Chinen & Din, 2024; Reys et al., in press). To answer these questions, we need to examine the interplay among mathematics education doctorates' work, the competencies required to perform that work, and the doctoral preparation needed to develop those competencies. Our work is grounded in this interplay among the three (see Figure 1).

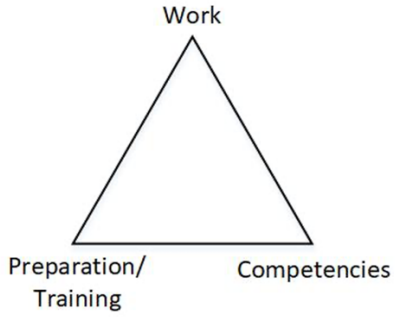

Figure 1: Interplay among Mathematics Education Doctorates' Work, Competencies, and Preparation/Training

Drawing on the definitions of Durette et al. (2016), we view competencies as attributes and resources that enable competent action, including knowledge, skills, and dispositions. Besides the core knowledge and skills in a specific field, the doctorates need general but critical competencies, such as communication, the ability to collaborate and work in a team, and the capacity for adaptation (Durette et al., 2016). Examining the nature and scope of the work and the roles that mathematics education doctorates perform is pivotal for determining the competencies required and for better designing doctoral programs. Hiebert et al. (2008) argued, "Answering questions about essential competencies requires describing clearly the work of mathematics educators. It makes no sense to design doctoral programs that are not aligned with the kind of work graduates actually do" (p. 246). The work that mathematics education doctorates do evolves; so do the competencies needed, and the preparation and training must evolve as well. Continued training is needed after graduation, as in any other job. Doctoral programs need to provide core experiences and training to support this evolution and the growth of mathematics education doctorates throughout their careers. This study examines the work experiences of recent graduates and reflects on current doctoral preparation.

Literature Background

The literature on doctoral programs and doctoral preparation, and on the competencies (including knowledge and skills) required for mathematics education doctorates, is of two kinds: (1) positions and recommendations based on professional conversations, authors' perspectives, and related literature; and (2) empirical studies that relied on surveys. A body of literature, including the reports and articles in the edited volumes after the National Doctoral Conferences (e.g., Ferrini-Mundy, 2008; Middleton & Dougherty, 2008; Zbiek & Hirsch, 2008), discusses and recommends what mathematics education doctorates need to learn and experience during doctoral training (e.g., Kilpatrick & Spangler, 2016). Typically, this line of literature lists

categories of core knowledge and skills and elaborates on them, discussing what preparation/training can help doctoral students acquire those competencies.

Chinen & Din (2024) reviewed and summarized the literature (articles or reports) on the knowledge and skills doctoral students need to learn through doctoral programs, from the perspective of educating future mathematics teacher educators. They found only a limited number of empirical studies on doctoral preparation, whereas other literature was mostly based on authors' perspectives. Existing empirical studies relied heavily on surveys to investigate aspects of doctoral preparations in mathematics education. In particular, Reys and his colleagues profiled doctoral programs using various aspects, such as the number of doctoral graduates and the number and types of courses (e.g., Reys & Reys, 2016), as well as special niches in doctoral programs recognized by peer faculty (Reys et al., 2021). Although surveys are useful tools for gathering large datasets and condensing the information efficiently, the method is limited in capturing the depth and specifics of the information. We also used a survey to gather the input from recent graduates. As we analyzed the survey data, we confirmed the need to follow up on their responses (Kim et al., 2024). One study collected data through a combination of a survey and interviews with a subset of participants. Glasgow (2000), in addition to a survey, collected data through interviews with 12 respondents about their doctoral preparation and current work. His criterion for selecting interviewees with a strong scholarly record (publications, presentations, etc.) was to hear from the "successful" doctoral recipients. In our study, we aimed to gather diverse voices from across positions.

Both types of literature described above focused on doctoral preparation for academia mostly. Centering on the role of mathematics education doctorates in higher education, the literature highlighted typical recommendations, such as research and teaching (e.g., Chinen & Din, 2024; Kilpatrick & Spangler, 2016; Shih et al., 2020). Glasgow (2000) gathered data from K-12 position holders and the commercial sector, as well as from faculty in higher education, yet his view of "successful" doctorates was limited to scholarly activities. As mathematics education doctorates play versatile roles, this study aimed to examine "the nature of the professional practice" of various groups of mathematics education doctorates.

After more than two decades of discussions and research on doctoral preparation in mathematics education, Reys et al. (in press) continue to report a lack of research on doctoral preparation. They call for descriptive research and case studies on doctoral programs (e.g., specific elements of doctoral preparation). This study, drawing on the voices of 35 recent graduates, describes their doctoral preparation, including the strengths and weaknesses of their doctoral studies and experiences. Reys et al. (in press) also suggest we examine what other fields do in doctoral preparation (e.g., science education). Durette et al. (2016) highlight a shift in doctoral education from a doctoral degree as a product to a degree as "a process, that is, a training providing the necessary competencies" (p. 1355) to become a competent worker. This study examines the recent graduates' work and doctoral preparation/training, which can illuminate the competencies needed and the continued training in their careers.

Methods

This study is part of the ongoing work on competencies that mathematics education doctorates need to perform their work, and the doctoral training needed for those competencies. This study drew on data from that project to answer the research questions.

Data Collection and Participants

The research team distributed a survey to mathematics education doctorates who graduated in the past 10 years to gather data on their work, doctoral preparation, and how they apply their

knowledge and skills in their current positions. As part of the survey, respondents were asked whether they would be willing to participate in an interview to elaborate on their responses. Out of 218 survey respondents, 72 volunteered to participate in an interview. Among the volunteers, 35 completed an interview either in a focus group (e.g., post-doc group) or individually during the summer of 2024. Focus group interviews were intended to capture both consensus and distinctions within each group, rather than interviewing everyone individually. Focus group interviews help capture detailed information and insights from the participants at a deeper level as they listen to others and articulate their thoughts (Eliot, 2005). Despite the benefits of the focus group interviews, we interviewed seven participants individually due to scheduling conflicts. The interview participants held positions across a range of professional contexts, including tenure-track, non–tenure-track, postdoctoral, and K-12 (see Table 1), thereby meeting our goal of hearing diverse voices. The interview questions focused on the participants' work, the competencies they used, and their doctoral preparation and experiences. We developed an interview protocol using guidelines for conducting focus group interviews (Eliot, 2005; Krueger & Casey, 2002) and were trained prior to the interviews. The first four authors conducted 14 interviews virtually (seven focus group interviews, each group consisting of two to six participants, and seven individual interviews), lasting 1 to 1 2/3 hours each.

Table 1: 35 Interview Participants

Position	# of participants	Percentage
Tenured	12	34.3%
Pre-tenured	7	20.0%
Non-tenure track	7	20.0%
Post-doc	4	11.4%
K-12 education	4	11.4%
Research Scientist	1	2.9%

Data Analysis

Following the interviews, the interviewers checked the accuracy of the AI-generated transcripts and cleaned them while watching the interview recordings. Each interview transcript was then converted to a tabular form and categorized by participants' professional positions (e.g., tenure-track) for analysis. The research team then color-coded and summarized the participants' responses in meaningful chunks. First, each team member independently coded the data (e.g., comments on the mathematics education doctorates' work and roles played in purple, and comments on their doctoral preparation in green) and summarized the main idea in each meaningful chunk. Afterward, the team met to review and ensure consistency among the coders, and to discuss the main themes from individual chunks and across chunks. Any discrepancies in coding and main themes were discussed until consensus was reached. Once gaining confidence in coding consistency after four interviews that we all coded and discussed, we coded the remaining interviews in pairs. After coding each interview, we summarized the main themes and the unique yet significant aspects of participants' responses in the categories of their work, preparation, and competencies in use from each interview.

Finally, we condensed the themes from each interview into the main categories in a large spreadsheet to notice common themes in the mathematics education doctorates' work, competencies, and doctoral preparation across all the interviews. Connections among the themes

across the 14 interviews were examined to identify significant emerging patterns. Additionally, comparisons were made across different professional groups (e.g., postdoctoral, tenure-track) to examine consistency and variation in themes and patterns. This study employed a purely qualitative approach, focusing on the participants' perspectives and experiences. For triangulation, the findings were compared across participants' reported competencies, doctoral preparation, and professional work. The themes of the mathematics education doctorates' work and doctoral preparation and their relationships are elaborated on in the following sections.

The Work Mathematics Education Doctorates Do

Doctoral preparation in mathematics education is often framed around specific professional roles, such as teaching, research, and service. Yet focus group interviews with mathematics education doctorates revealed that their lived professional work is far more complex. The participants represented a wide range of professional positions, including tenure-track and non-tenure track faculty positions, postdoctoral appointments, and K-12-based roles, reflecting the diverse institutional contexts in which math education doctorates work. The data show that they engage in highly diversified, context-dependent work that we have clustered into four interrelated domains: teaching, research, service, and integrated work.

Across roles, teaching emerged as a core responsibility. However, teaching expectations varied widely, with reported loads ranging from one course per year to 2-2 and 4-4 configurations, and with teaching ranging from a minor role to a primary responsibility. Participants described teaching preservice teachers, graduate students, in-service educators across elementary, middle, and secondary fields, and K-12 students. They reported teaching mathematics content courses at the undergraduate and graduate level, as well as methods and pedagogy courses in general education, math education, science education, STEM education, and research methods. However, teaching was not limited to course delivery and often involved substantial work with clinical supervision and mentoring, instructional coaching, course design and redesign, curriculum alignment, coordinating courses, supervising TAs, advising graduate students, and serving on doctoral committees.

Research expectations varied widely, ranging from clearly defined annual publication targets to roles where research was encouraged but not required. Some participants experienced formal pressure to publish and secure funding, particularly in postdoctoral and tenure-track positions, while others engaged in research more informally in clinical or teaching-focused roles. Research activities included study design, data collection and analysis, collaborative writing, grant development, and project management. Participants described research-related work that extended beyond traditional scholarship to include educator training, curriculum work, research literacy, technology-mediated inquiry, graduate mentoring, and professional development facilitation. Respondents in K-12 positions reported they collected and analyzed data to inform policy decisions rather than publishing research findings. Many participants described conducting research outside of formal workload allocations, highlighting tensions between research expectations and time available. As a result, research work was shaped as much by institutional context as by scholarly interest.

Service and leadership constituted a third major area of work and were described as both extensive and largely invisible. Participants reported engaging in departmental service, program coordination, accreditation and assessment efforts, mentoring students and colleagues, and acting as a liaison between departments, colleges, and external partners. This work required significant relational and organizational expertise but was rarely acknowledged as specialized work of doctorates.

Participants described "other work" as a practice-based and service-oriented activity that connected research, teaching, leadership, and policy. Mathematics education doctorates consistently described work involving interaction with a variety of stakeholders, including extensive engagement with K-12 schools and districts, state and accreditation agencies, and university communities, through leadership, service, research, curriculum work, and educator support. This included translating research for practitioners and adapting disciplinary knowledge for varied audiences. These responsibilities often operated outside formal workload categories but were central to mathematics education doctorates' roles.

Doctoral Program Preparation and Work

The doctoral preparation that the participants had varied within and across institutions. Aspects of their preparation that were discussed included general program descriptions and specifics related to the suggested competencies for mathematics education doctoral students. These included, but were not limited to, DEI, technology, teaching and research experiences, professionalism, networking, and collaborations.

Doctoral programs vary; however, at their core, they focus on math, research, and education. Some institutions place equal emphasis on all three, whereas others emphasize one or two areas, expecting training in the other core components to have been completed during Master's programs (e.g., math courses). Experiences within programs typically include coursework, practical experiences, often teaching and/or research opportunities, and integration into the field through collaborations with faculty and attendance at conferences. Many felt that their programs largely prepared them for positions at research institutions or in academia. Additionally, doctoral students needed to be self-sufficient and independent in their own learning, as well as proactive in taking initiatives to better themselves as students and scholars by pursuing additional coursework to become more versed in topics impacting education.

Teaching and Research Experiences

Teaching and research experiences varied and largely came in the form of assistantships or apprenticeships during one's doctoral program. Teaching included GTA or GA positions that involved being a graduate assistant or teacher of record for undergraduate courses, supervising student teachers, a university field instructor, or mentoring a course with a faculty member for a semester. Several participants noted that their teaching experience(s) gained in doctoral programs allowed them to use their teaching abilities in their current positions, even when it involves skills like teaching writing, which they may not have done before.

Research experiences also varied, with some noting that their only research experience consisted of readings and discussions about research in courses. Others noted that they were a research assistant on a grant and/or had opportunities to work closely with their major advisor or other faculty members on a research project. Those involved in these experiences were also more likely to have opportunities to travel to and present at conferences, to be involved in developing grant proposals, to write articles for publication, and to gain insight into the IRB process.

Teaching and research were often siloed within a program, with no connections between the two. Several interview participants noted a noticeable mismatch between the instructor's teaching methods and their research, highlighting gaps in the alignment of teaching practices and academic expertise. Additionally, several participants noted that their programs had a strong emphasis on teaching rather than research. Those in programs with a strong research focus reported that their research experiences were more focused on educational research than on teacher education research. Many expressed a lack of confidence in their research abilities, as the program primarily prepared them for teaching roles. At the same time, one participant noted that

their current job is teaching-focused and that their career goal is to teach future educators, so they felt the program's limited research preparation was not an issue for them. Teaching and research experiences were valuable to all participants; however, not all the experiences they received necessarily adequately prepared them for their current role.

Preparation for Current Work

Several participants noted varying degrees of connection between their doctoral preparation and their current work. Some felt their research training, although not extensive, was helpful in their current roles, particularly when assisting faculty and conducting research. Knowledge of policy and IRB procedures, as well as experience with policy during their doctoral training, provided confidence in adapting to potential future changes. Those with teacher education apprenticeships and teaching assistantships found their training valuable in their current positions. However, some felt their doctoral programs did not adequately prepare them for certain aspects of their careers, which are discussed in more detail in the next section. One participant mentioned that their program did not focus on the specialized field of teaching math for social justice, which they had to define and expand on their own as a graduate student.

Gaps and Strengths

Mathematics education doctorates varied in their overall satisfaction with their doctoral programs. Despite varying program experiences and pursuing a wide range of post-graduation career paths, participants shared common perceived gaps and recommendations for mathematics education doctoral programs. While the gaps stemmed from unmet needs and expectations, recommendations arose from positive experiences that participants wanted future doctoral students to share.

Doctoral Preparation Gaps

The most significant concern expressed by the participants was a lack of preparation for the academic job market. Participants reported feeling underprepared in several key areas, including research, scholarly writing, and professional networking. Research opportunities were described as uneven across doctoral training, and some participants noted limited integration between quantitative methods and mathematics education research. Participants highlighted the lack of guidance in research originality and emphasized the need for more authentic writing experiences. For example, one participant from the tenure-track group noted, “Something I didn’t get in my doctoral training that I wish I had a little more of was just experience writing grants. My professors had grants and I worked on them … but I never got experience writing them.” Overall, participants expressed a desire for greater exposure to writing and publication processes before entering the job market.

Although insufficient preparation in research and writing has been previously documented among postdoctoral scholars, our findings also revealed another significant area of concern: professional networking. Multiple participants cited feeling unprepared to engage with the broader mathematics education community and described challenges in building professional connections. Some also experienced a sense of disconnection within their own programs, citing insufficient mentorship and limited faculty support.

Doctoral Preparation Strengths

Overall, the participants emphasized the benefits of tailored advising, authentic teaching, and diverse professional experiences during their doctoral preparation. Since doctoral students come from diverse backgrounds, the participants praised programs that personalized content to fit students’ individual needs and goals. Many also advocated for opportunities to teach or supervise courses, with one participant stating, “If you’re going to leave a [doctoral] program and take a

faculty position, you need to know how to teach at the college level … it's just essential." Participants also stressed the importance of teaching doctoral students how to provide feedback to teachers and prepare doctoral students "to be part of the larger mathematics education community." Several recommended that doctoral students gain professional experience through service and leadership opportunities, including peer-reviewing for journals, attending conferences, writing grants, and supervising classroom teachers.

Participants also advocated prioritizing specific content areas within required coursework, such as diversity, equity, and inclusion (DEI), assessment, and curriculum. Several participants noted that, while their programs offered these topics as optional courses, they proved instrumental for their future work and should be required for doctoral preparation. One participant also suggested that instead of addressing DEI through an isolated course, it should be woven through all courses within the program.

Discussion

This research showcases that doctoral work in math education is more complex than traditional, single-role models or linear career trajectories suggest. Doctoral work often involves integrating research, teaching, service, and leadership across numerous contexts. Beyond teaching and research, mathematics education doctorates engage in curriculum work, leadership, mentoring and supervision, accreditation and policy work, grant and project management, translating research to practice, interdisciplinary collaboration, and networking. All of this requires preparation that centers on boundary-crossing, relational, and networking expertise, professionalism, and attention to diversity, equity, and social justice alongside traditional research and teaching competencies.

The data revealed a meaningful distinction between research producers and research consumers, with many roles requiring not only the generation of scholarship but also the interpretation and translation of research for different audiences. Also, teaching experience needs to encompass curriculum development, course design, and preparing others (e.g., TAs) to teach. Professionalism, networking, and interdisciplinary collaboration emerged as critical competencies, yet the participants described these areas receiving little or no attention in doctoral preparation.

This study is limited by its reliance on self-reported experiences of 35 recent U.S. graduates, and its findings may not generalize to all contexts. However, by centering the diverse professional roles of math education doctorates, this study provides insight into the evolving nature of math education doctoral work. Preparing future doctorates requires moving past a traditional teaching-research-service model toward models that recognize the integrated, relational nature and boundary-spanning roles embedded in mathematics education doctoral work. Alignment between doctoral preparation and current work differed across professional contexts. Given the diversity of career trajectories among our participants, the findings suggest that a single model of doctoral preparation may not be adequate to address the range of roles that math education doctorates assume.

Lastly, considering the high attendance of graduate students, doctoral advisors, and mentors at PME-NA, the topic of this study is highly relevant to the audience and informative for both students and faculty in mathematics education doctoral programs.

CONSTRAINTS AS A TOOL TO DEVELOP CURRICULAR DECISION-MAKING IN MATHEMATICS METHODS INSTRUCTION

Alyson E. Lischka
Middle Tennessee State University
Alyson.Lischka@mtsu.edu

Signe E. Kastberg
Purdue University
skastber@purdue.edu

Existing research on mathematics teacher educators as curriculum designers has identified factors that influence design, principles to guide design activities, and professional pedagogical structures used in design. In this paper, we report our use of self-study to improve our curricular design activities drawing from primary sources including designed activities, weekly instructor reflections, and analytic dialogues to develop awarenesses of curricular design informed by our commitment to relational constructivist teaching. Findings explain the emergence of constraints as a design consideration mathematics teacher educators use to surface evidence of preservice teachers' curricular decisions. We argue that mathematics teacher educator imposition of intentional constraints in designing instructional activities provides opportunities to observe and engage preservice teachers in discussions of their curricular decision-making.

Keywords: Teacher Educators, Curriculum, Instructional Activities and Practices, Pre-Service Teacher Education

Problem Statement

A growing field of research in mathematics education focuses on learning and growth of mathematics teacher educators (MTEs). Within the complex work of teaching preservice teachers (PTs) to teach mathematics (Li & Castro Superfine, 2018), MTEs' research of their own practices should have a goal of "self-understanding and professional development" (Chapman, 2008, p. 132) as well as contributing knowledge for other MTEs. Within the specific practice of curriculum design, MTEs design learning activities (Ackermann, 2012; Li & Castro Superfine, 2018) to support PTs as curricular agents (Felton & Koestler, 2015). Research on MTEs' design of curriculum has focused on PTs' reading (Drake et al., 2014) and use of curricular resources (Zaslavsky & Sullivan, 2011), with emphasis on principles (Saclarides et al., 2022) and factors impacting design, however insight into MTEs' work as curriculum designers is limited (Li & Castro Superfine, 2018).

As MTEs in US universities, we (the authors) faced challenges supporting PTs to develop curricular decision-making skills. We are relational (Kitchen, 2005) constructivist (Steffe & D'Ambrosio, 1995) MTEs who engage in inquiry into our practice through "reciprocal" critical friendship (Guilfoyle et al., 2007; Stolle et al., 2019, p. 23). In Fall 2023, we began to explore our MTE curriculum design practices for mathematics methods courses as an extension of our prior research and in response to legislative shifts related to teachers' curriculum use. We focused our inquiry on the question: How do MTEs design tasks to support PTs' development of curricular decision-making? Through our self-study inquiry (LaBoskey, 2007), we learned to use constraints (Coles, 2020) as a pedagogical tool which led to PTs' discussions of their curricular decisions and personal experiences and ideas informing their choices. We argue imposing intentional constraints on MTE designed tasks provides opportunities to both observe and bring into discussion PTs' curricular decisions, thus developing PTs' curricular decision-making.

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

Background: Literature and Theoretical Framing

We, Alyson and Signe, practice relational (Kitchen, 2005) constructivist (Steffe & D'Ambrosio, 1995) teacher education in our mathematics methods courses. With this perspective, we strive to know our PTs' problems, convey respect and empathy, and grow in relationships (Kitchen, 2005) as we use their ideas and experiences to develop PTs' teaching practices. Ackermann (2012) described:

> Constructivist teachers need to support their students' initiatives by creating a "learning culture" in which the active contributions of every participant can become a valuable piece within a broader learning experience. They need to help the group of learners as a whole become its own critic, and learn when and how to overcome some perceived limitations. (p. 342)

Learning takes place as PTs engage in central activities of the teaching community, such as lesson planning, and are supported to contribute to their own growth (Ackermann, 2012).

To create a constructivist learning environment, we flow between facilitating learning and researching MTE knowledge (Zaslavsky, 2008) as we develop tasks with potential to support PTs to hone their teaching practices. The cycle of facilitating learning and researching MTE practice centered around MTE tasks creates possibilities for pedagogies of practice that push beyond representations, decompositions, and approximations of practice (Grossman et al., 2009) to the creation of pedagogical tools (e.g., discussion) that make it possible for PTs to examine their own curricular decision-making.

Li and Castro Superfine (2018) defined *design* as "the process in which decisions are made about the content, curriculum materials, instructional strategies, and assessments used to support learning in pursuit of instructional goals" (p. 180). MTEs as designers take up knowledge of the field and knowledge of learners to design tasks with goals of addressing themes important for the preparation of mathematics teachers, such as developing adaptability, selecting appropriate tools for teaching, and overcoming barriers to student learning (Li & Castro Superfine, 2018; Zaslavsky, 2008). As constructivist designers, we focus on designing activities that support PTs to build on their own experiences as they learn (Ackermann, 2012).

The flow between facilitating learning and conducting practitioner-based research (Borko et al., 2007; Zaslavksy, 2008) that occurs as designed tasks are used and redesigned in iterative cycles supports MTE's learning and the refinement of designed tasks (Zaslavsky, 2008). Such refinements include imposing constraints, which we define as boundaries on PTs' activities with the goal of focusing pedagogical inquiry. Through such iterations, PTs' responses make visible how they navigate intentional and unintentional constraints in their interpretations of the tasks. Constraints both bound the tasks and create space for PTs to express their ideas (Ackermann, 2007; Coles, 2020). In this paper we extend Li and Castro Superfine's (2018) account of MTEs as designers to provide an exemplar of MTEs coming to know and use constraints in supporting PTs to develop as curriculum decision-makers.

Methods

For over 12 years, we have met remotely each week in critical friend conversations (Schuck & Russell, 2005) to share our teaching practices, discuss task design, and reflect on our MTE practices. Adopting LaBoskey's (2007) conceptualization of self-study as self-initiated, improvement-aimed, interactive, and involving validation via trustworthiness, we approach self-study as open, collaborative, and involving reframing (Samaras & Freese, 2009). We engage in perspective taking cycles through design, teaching, and weekly analytical dialogues (Placier et

al., 2005) where we analyze alignment between our activity designs and relational constructivist principles (The Arizona Group, 1996).

For this study, our primary data sources included designed activities particular to developing PTs' curricular decision-making, weekly instructor reflections, and analytic dialogues from 2023, 2024, and 2025. Secondary data sources included PTs' work samples, recordings of class conversations, and conference proposals and proceedings encapsulating our curriculum design processes. We engaged in dialogic analysis, with the goal of becoming conscious of our design decisions and improving our design processes aimed at supporting PTs' curricular decision-making. Dialogic analysis revealed the role of constraints as pivotal in our curricular design. To support the dialogic analysis (Placier et al., 2005), we also reviewed course documents from each year to note changes in our designed activities and instructor journals and meeting recordings to note discussion of constraints applied to tasks. Findings are generated from both authors' practices and data, but we report only from Alyson's practice here due to space restrictions.

We are mathematics methods instructors at two different U.S. universities. Both of us are experienced MTEs with backgrounds in teaching mathematics prior to transitioning to teacher preparation. Alyson teaches methods courses for secondary PTs and Signe teaches methods courses for elementary PTs. Alyson and Signe are connected by their commitment to relational constructivist teaching (Kitchen, 2005; Steffe & D'Ambrosio, 1995).

Alyson's practice, from which we draw the data for this report, takes place in a UTeach replicate program (Hughes et al., 2020) in which PTs matriculate as a cohort and are in classrooms beginning in their first semester in the major. Alyson's methods course typically occurs in the semester prior to student teaching. Though the course does not have a field placement component directly connected to it, PTs have a field placement for another course during the same semester. This is the second of two mathematics methods courses in the program. The focus of this course is on unit planning (i.e., connected lessons encompassing more than two days of instruction) and the Mathematics Teaching Practices (National Council of Teachers of Mathematics [NCTM], 2014).

Findings

To share our findings, we describe Alyson's layers of 2023 methods course activity (Kastberg et al., 2024) related to curricular decision-making. We then share the evolution of our curricular design to support PTs' curricular decision-making in 2024 and 2025 to highlight the emergence of constraints as a productive design element.

Contextual Grounding: Layers of MTEs' Designed Activities

In 2023, as we concluded prior inquiry into our discussion practices (Kastberg et al., 2024), we were drawn to emerging questions about PTs' curricular decision-making amid changing local contexts. Legislation impacting teachers' curricular agency was enacted in Alyson's state and her partner school district adopted new curriculum. As constructivist MTEs, we started by engaging PTs in sharing their thinking. We wanted to understand what our PTs were bringing with them to this aspect of practice. Alyson asked PTs to create a concept map showing how they thought about lesson planning. PTs drew maps connecting constructs such as standards, curricular resources, technology, and scope and sequence documents to questions such as *What do students know?* and *How is the mathematics sequenced?* (PT submitted work, 10/10/2023). Using this and other reflective prompts, Alyson formed models of PTs' curricular decision-making, acknowledging differences among the authorities PTs leveraged in their planning. For example, some PTs gave authority to textbook authors to set the order of presentation of concepts whereas other PTs took internal authority to rearrange concepts or change the

facilitation of activities. Though our attention was shifting to making sense of PTs' models of curricular decision-making, our activity design lived within existing structures for courses and thus we did not alter major components of the course.

The existing structure of Alyson's course included two major activities: writing unit plans and rehearsals of teaching. PTs wrote two unit plans (one for three days of instruction and one for five days of instruction). PTs were provided with curriculum materials and other virtual resources for an assigned high school content goal and were required to produce lesson plans for consecutive days of instruction including all materials a teacher would need to teach the lessons. The PTs also engaged in three rehearsals of teaching. For each rehearsal, a PT prepared and taught a ten-minute portion of a lesson to classmates as learners for the lesson. Each rehearsal was video recorded and then watched by the whole class to support collaborative debriefing regarding the teaching decisions enacted in the rehearsal. These activities spanned the semester (see Table 1). In addition to these major activities, there were readings and shorter assignments that supported PTs to develop understanding of the Mathematics Teaching Practices (NCTM, 2014) and reflect on their own teaching practices as enacted in class assignments. Throughout all tasks, PTs engaged in self and peer feedback cycles and received feedback from Alyson.

Table 1: Layers of Instructional Activities for Curricular Decision-Making Development

Week	Description of Task
Week 1	PTs map the content taught in high school mathematics and explore high school standards
Week 2	Unit plan 1 topic assigned; introduction to the Mathematics Teaching Practices (MTP) (NCTM, 2014)
Week 4	Introduction to curriculum resources (PTs are provided with the teacher's edition for unit plan 1)
Week 6	Rehearsal 1 with video and debriefing (launch a provided task)
Week 7	Final draft of unit plan 1 submitted
Week 8	Unit Plan 2 topic assigned (5 day plan)
Week 8	Rehearsal 2 with video and debriefing (lesson launch using Unit Plan 2 provided curricular resources)
Week 11	Rehearsal 3 with video and debriefing (discussion following a technology enhanced lesson)
Week 14	Final draft of unit plan 2 submitted

Understanding Our Goals for PTs' Curricular Decision-making

The first mention of "constraint" in Alyson's meeting notes, "What are the constraints I impose?" (Meeting Notes, 1/8/2024), arose from a dialogue about centralization of curriculum as we wondered about our goals for PTs:

> Alyson: My goal is that as my PTs build lessons, they make decisions based on what is going to help their learners make sense of mathematics. And that they are reaching for different documents to make that happen. The document might be the textbook or internet resources or ideas they have about how they understand a concept. I want them to feel they have the agency to do that. … But the current legislative shifts are restricting the choices they have. (Critical Conversations, 1/8/2024)

We continued to discuss constraints PTs would experience in their future careers, such as limits to curricular materials, imposed scope and sequence for courses, and requirements to teach scripted lessons with fidelity. In our conversation, we acknowledged constraints we imposed. Alyson dictated the number of days unit plans were to span, assigned mathematical content as the focus of the plans, and provided descriptions of students in class contexts for which the plans were to be written. Rehearsals included constraints for PTs including tasks, required materials, and assigned standards. Constraints were present in our design, but at this time we only considered them to be ways to bound the tasks we assigned to PTs. Further, we were concerned with PTs' agency as curricular-decision makers and experienced a tension between constraining designed tasks and impacting PTs' autonomy (Critical Conversations, 1/15/2024)

Possibilities Offered by Constraints on Tasks

In 2024, supplied with ideas of how PTs' might approach curricular decision-making through the models we had constructed in 2023, we delved further into improving our design practices. Signe said, "We know how we are designing activities on some level" (Critical Conversation, 8/14/2024) however, we struggled to explicitly describe our design practices. Clearly articulating our curricular decision-making practice would support us to improve this aspect of our practice.

As we planned for the Fall 2024 semester, we asked questions during our weekly meetings like "How do we support our students to be wonderers about teaching?" and "How do we make decisions about constraints on tasks?" (Meeting Notes, 8/14/2024). In our August 14 meeting, amid final planning for courses to begin the next week, we shared planned questions for PTs about curricular decision-making, our goals for PTs' discussions of curricular decision-making and explored constraints we were imposing on activities. Alyson's Fall 2024 course would have three PTs enrolled: Carrie, Denny, and Whitney.

As a result of our dialogic conversations, Alyson adjusted constraints on rehearsals in her course. For the 2024 course, Alyson changed rehearsal requirements so that rehearsals were embedded in the unit plans PTs were assigned to write in the course. Other structures of rehearsals remained the same as in 2023. Alyson posited that rehearsals derived from plans PTs had written could produce more productive debriefing discussions with her PTs. For the first rehearsal, PTs were now required to launch a lesson from their first plan using provided curriculum materials. For the second rehearsal, PTs rehearsed presenting a strategy to support language learners drawn from their second unit plan. The third rehearsal did not change from the 2023 course and still required PTs to engage the class in discussion following the implementation of a mathematics action technology task.

Following the conclusion of the first round of rehearsals, Alyson provided example strategies PTs could use to support language learners in mathematics class including Frayer diagrams, color coding techniques, discussions about language use, use of examples and non-examples, and others. After PTs engaged as learners in short mathematics lessons including these strategies, Alyson displayed tasks PTs had launched for their first rehearsal (Figure 1, Class Files 10/10/24) and asked PTs how they might modify their tasks to include language learner supports.

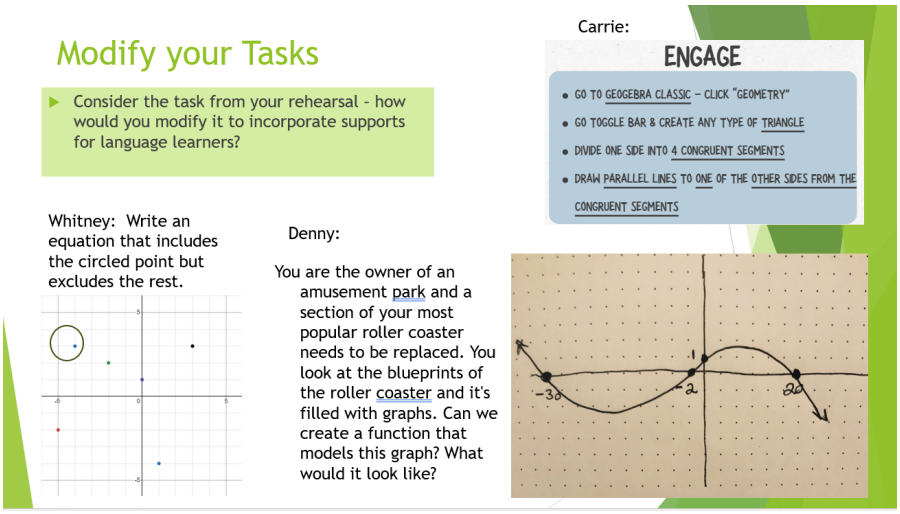

Figure 1: Slide of PTs Rehearsal 1 Tasks for Modification for Language Supports

After a few minutes of think time, Alyson asked PTs to discuss their curricular decision-making. Denny, whose task included a paragraph explaining a rollercoaster as a polynomial function, suggested removing the rollercoaster context from the task completely so language learners would not have to read the explanation. The other PTs continued:

Carrie: You could play a 30-second clip of a rollercoaster and say, "There is a function for this. What do we think it looks like?" That way you could keep the context, which might help them. I would also just simplify the language—they don't need all the information you included.

Whitney: You don't have to remove the context. Try displaying a rollercoaster [track] on your whiteboard and drawing the graph over it.

Discussion continued with Carrie suggesting she could create a video or set of image driven instructions to replace written directions for her task (see Figure 1). To which Whitney added, "you could use screen capture and get rid of the problematic words completely," encouraging Carrie to find a way to reduce the language difficulty for language learners (Class recording, 10/10/2024). The discussion continued with PTs offering each other a variety of adaptations with little input from Alyson.

In later critical conversations, Alyson would hold up this class discussion as an example of what was possible for PTs' discussions about curricular decision-making. However, during this semester, Alyson's concerns were focused on constraints imposed by PTs' mathematical content knowledge. She wrote in her meeting notes, "My students' lack of desire to work with the mathematics imposes a curricular constraint that is internal" (Meeting Notes, 11/18/2024).

At the conclusion of the 2024 Fall semester, Alyson and Signe engaged in dialogic analysis of activities in their courses and recognized constraints emerging as a tool that could be used to support development of PTs' curricular decision-making. Critical conversations included ways context constrained our decisions (Meeting Notes 2/24/2025), and wonderings about how PTs could make sense of self within our intentional constraints (Meeting Notes, 6/3/2025). In Alyson's 2024 course, she wrestled with constraints imposed by PTs content knowledge and constraints that supported productive discussions, helping us to see constraints could be helpful

and good (i.e., language learner constraint) or unproductive (i.e., PTs' content knowledge; Meeting Notes, 2/24/2025).

Successes and Challenges with Imposing Intentional Constraints

Reflecting on Fall 2024 led Alyson and Signe to shift their conversations regarding constraints on curricular design. Critical conversations in preparation for the start of the Fall 2025 semester included using common reflection questions for PTs as well as considerations for how constraints might be included in the planned tasks for courses. Alyson's class included five PTs in Fall 2025 and Signe's course maintained its larger population between 15 and 20 PTs. To accommodate her larger classes, Signe pushed for thinking about whole class constraints that might be implemented to develop PTs' curricular decision-making, explaining:

> The central takeaway for us at that time [2024] was trying to understand the different constraints that the preservice teachers were operating under with the different knowledge structures that they had. So we had evidence of their curricular reasoning, but then we hadn't really incorporated the idea of the constraints and how those might potentially affect that reasoning. We talk a lot about individual meetings [with PTs] and how those take a role. And I think when we were discussing this, we were talking about the fact that each one [PT] is different, and that makes it hard to have an instructional activity design that's going to capitalize on those differences or address them. (Critical Conversation, 9/29/2025)

Alyson reframed how she thought about the design of activities aimed at developing PTs' curricular decision-making. Particularly, Alyson thought about how adjusting constraints might encourage reflection and discussion about curricular decision-making.

To describe the second rehearsal for Fall 2025, Alyson explained that PTs must incorporate a strategy to support language learners in their class for their second unit plan. She described this requirement to the class as an intentional constraint that was authentic to what they may experience in schools (Class recording, 10/7/2025). During the second rehearsal, Matthew, the last PT to present his rehearsal, used a Frayer Diagram as a tool for developing understanding of exponential function graphs. He began his rehearsal by asking classmates to record the pieces they felt were important to the definition of an exponential function on a Frayer Diagram he provided. Matthew drew out classmates' ideas, recording them on the board and easily discussing different notations classmates had chosen. At the end of his rehearsal, Matthew asked if a negative value for b in $f(x) = a \cdot b^x$ would be possible. His explanation faltered. During the whole class debriefing conversation the PTs pointed to their lack of understanding related to the restrictions on b in the definition of exponential functions (Class Recording, 11/04/2025). The whole class worked through understanding why b must be positive. Then Matthew had an opportunity to meet with Alyson individually to further refine his understanding of the definition of exponential functions and improved his written lesson plans based on this learning. Alyson's intentional constraint to use language supports led to open discussion about mathematical knowledge and its role in curricular decision-making.

However, not all constraints led to success. Alyson continued her practice with her third rehearsal to require PTs to hold a whole-class discussion following the implementation of a mathematics action technology task. PTs engaged in each other's technology tasks prior to the start of the third rehearsal. Then rehearsals were conducted in which each PT led a discussion to summarize the concepts learned in the technology task. Throughout the preparation for and enactment of these rehearsals, Alyson was disappointed in PTs' lack of interest in holding a whole-class discussion and puzzled about why PTs seemed resistant to the activity. PTs

expressed frustration and said they would not necessarily hold a whole-class discussion following their activities (Class recording 11/18/2025). In her debrief, PT Kourtney reflected on her rehearsal saying:

> I didn't love this rehearsal, but I guess I could have asked more guiding questions to make it a more student-centered discussion. But the way I have this structured is that we are going to do four slides and then stop and talk about it. I guess I could have had a guided notes summary page to summarize after the fact. (Class recording, 11/20/2025)

Alyson's imagined class structure for implementing technology rich tasks with mathematics learners included a whole-class discussion of the concepts following the activity. However, this constraint for her task design was not aligned with PTs' visions for how using a technology task would take place in their classes. In this debrief, PTs critiqued the activity rather than discussing their curricular decision-making.

Alyson and Signe continued to meet weekly throughout Fall 2025 and collaboratively planned constraining activities to experiment with intentional constraints as supports for discussions of curricular decision-making among PTs. Signe experimented with changing the time constraints for teaching and inspired Alyson to plan an activity she called "What if it snows?". At the end of the semester, following completion of their second unit plan which encompassed five days of instruction for 90-minute class periods, Alyson asked PTs to edit their unit plans to remove 1 ½ days of instruction (imagining schools were closed due to a winter weather event). After making decisions, Alyson engaged PTs in discussion:

Alyson:	Talk to each other—How did you make the decisions you were making?
Fiona:	So, I just slid some things together. I cut out a couple of think-pair-shares and an entrance ticket. I also got rid of something I didn't really like. I cut out the walk-through of a poster presentation.
Deborah:	I did something like that too. I looked for things that were connected together. Like you can do hyperbola and ellipses together pretty easily. With a little less practice and putting ideas together it could work.
Reanne:	So rather than removing the sense-making, it sounds like we put connected ideas together and moved some homework to outside of class time. I did that too.
Kourtney:	Me too. Some of the days of practice could be grouped together differently. (Class recording, 12/2/2025)

The discussion continued as PTs built on each other's ideas and compared their reasons for the curricular decisions they made. Alyson noted it a success that PTs were discussing curricular decisions as a community with little input from her, though sometimes finding agreement where it did not fit, as in Deborah's connection to Fiona's statement.

Discussion and Conclusion

We set out to investigate how MTEs engage in curricular design to support PTs' curricular decision-making. Our account provides an exemplar of how MTEs engage in design, adding to research literature on MTEs' design practices (e.g., Li & Castro Superfine, 2018; Zaslavsky, 2008). The key finding from our study was MTEs' intentional use of constraints to productively support PTs' development of curricular decision-making through discussion. Constraints ranging from assigning PTs particular standards to identifying learner needs for PTs to address had always been part of our curricular design. However, cycling between facilitator and researcher

(Zaslavsky, 2008) supported reflection on incidental constraints (format and bounding) and intentional constraints (technology use and temporal) as design elements. This reflection shifted our attention to the content of PTs' reasoning regarding their curricular decisions. We saw something different about our PTs' curricular decisions than we were able to see before. Through discussions, we gained insight into the rationales PTs provided for their decisions.

We began to see constraints as offering possibilities to learn about PTs' curricular decision-making through class discussion. These possibilities extended the learning culture in our classrooms through the intentional use of constraints to create the basis for discussions with active contributions from every PT (Ackermann, 2012). As Coles (2020) stated, "A boundary is offered, in each case, in the belief that the constraint will occasion freedoms and learning in future communications" (p. 20). Originally, constraints were a way to bound activities so PTs would produce similar products. Now we view boundaries as making space for growth, as in Matthew's experience with exponential function definitions, and creating possibilities for discussions about PTs' curricular decision-making.

This brief report examines how fellows in the APLUS (Alabama Practitioner Leaders in Underserved Schools) in Math Master Teacher Fellowship used program opportunities and translated learning into leadership beyond their classrooms. Using maximum-variation case selection, we analyze three fellows with contrasting preparation pathways and initial professional capital. Data include interviews and artifacts from Teacher-Led Community (TLC) planning and facilitation, preservice teacher mentoring, and a schoolwide student initiative. Within-case journey maps and cross-case thematic analysis trace opportunity uptake and spillover outcomes. Preliminary findings indicate three pathways: (a) iterative district-facing PD design leadership grounded in TLC data use, (b) mentoring-centered leadership evidenced in novice teacher growth, and (c) schoolwide initiative leadership extending across disciplines.

Keywords: Teacher Leadership, Professional Development, Identity/Agency, Systemic Change

Mathematics teacher leadership in underserved schools demands more than improving individual classroom practice; it requires sustained professional development that positions teachers to influence colleagues and contribute to school and district improvement. In APLUS in Math, we designed a five-year, multi-phase curriculum model that integrates graduate coursework, National Board Certification preparation in collaborative professional learning communities, and leadership project development to cultivate secondary mathematics teachers as instructional experts and emerging change agents (Zelkowski et al., 2025a). APLUS was organized around goals targeting instructional expertise, content knowledge, leadership enactment, clinical mentoring capacity, and dissemination through professional venues Prior analyses of the program's first phases documented alignment among evidence sources from the classroom observations of Mathematics Teaching Practices and Student Mathematical Practice engagement (Gleason et al., 2017), National Board component outcomes, and suggested growth in instructional practice and leadership readiness (Zelkowski et al., 2025b). However, outcomes and readiness indicators alone do not explain how different participants take up fellowship opportunities or how learning extends beyond the classroom in distinct ways. Accordingly, this brief research report uses a maximum-variation multiple-case design to examine (1) which aspects of the APLUS project participants identify as most consequential for instructional growth and student learning and (2) what leadership enactments, if any, extend beyond participants' classrooms (e.g., peers, school structures, district professional learning), and how are those enactments described and evidenced.

Perspective & Theoretical Framing

This study adopts the perspective that teacher leadership development that sustains instructional improvement over time is best understood as participation in professionally

organized communities wherein the teacher has an increasing central role over time. APLUS was designed as a structured three-phase curriculum that engages teachers in graduate coursework, collaborative National Board Certification preparation, and leadership project development, with the explicit intention of cultivating professional identity, instructional expertise, and leadership capacity (Zelkowski et al., 2025a). The curriculum is grounded in Wenger's (1998) Communities of Practice and the NBPTS Five Core Propositions (National Board for Professional Teaching Standards [NBPTS], 2016), framing Professional Learning Communities (PLCs), peer mentoring, and shared inquiry as mechanisms through which teachers develop identity and agency alongside increasing responsible teacher leadership.

Within this framing, the fellowship operates as an opportunity structure with a set of designed opportunities aligned to program goals that participants may take up (e.g., collaborative PD task design, facilitation routines, mentoring of novices and preservice candidates, and dissemination through professional venues). We distinguish between program opportunities (structured components of APLUS), program engagement (participants enacted participation in components), and leadership spillover (leadership activity that extends beyond the participant's classroom and beyond routine program participation, evidenced through initiatives, roles or practices taken up in peer, school, or district contexts) rather than changes in beliefs or intentions alone. This focus is consistent with prior reporting that positions APLUS as a multi-phase professional development model intended to prepare teachers for schoolwide or districtwide influence through the combined use of graduate coursework, National Board preparation, and leadership projects (Zelkowski et al., 2025b).

Methods

This study uses a maximum-variation multiple-case design (Patton, 2014) to examine how APLUS fellowship opportunities translated learning into leadership influence beyond the classroom. Three fellows were purposefully selected to represent contrasting entry pathways and professional capital and differing loci of leadership enactment (Figure 1): Teacher A (high initial preparation; district-facing TLC design leadership), Teacher B (limited early preparation opportunities; mentoring-centered leadership with TLC support co-leadership), and Teacher C (elementary-to-middle-grades pathway; schoolwide initiative leadership alongside TLC co-lead).

Data sources included semi-structured interviews focused on perceived high-value fellowship opportunities, uptake episodes, and leadership enactments, as well as artifacts aligned to those enactments (Creswell, 2018). Artifacts included TLC planning materials (agendas, PD task drafts, participant feedback/data instruments), masked mentoring/coaching documentation related to preservice teacher candidates, and initiative-related artifacts connected to Teacher C's implementation role. Participation records were used to corroborate leadership responsibilities.

The three pathways were developed iteratively: we first identified salient enactment episodes within each case, then compared cases by locus of influence (peer/school/district), mechanism of leadership (PD design/mentoring/initiative leadership), and evidence of spillover. Thus, the pathways are provisional analytic claims from this early case analysis rather than a complete typology. Credibility was supported through interview-artifact triangulation and analytic notes documenting how case-level evidence informed cross-case assertions.

Findings

Figure 1 summarizes three contrasting fellow trajectories illustrating how the same fellowship opportunity structures can produce different forms of leadership spillover beyond the classroom. In response to RQ1, fellows identified opportunities as consequential when they

connected individual instructional growth to shared professional work; in response to RQ2, spillover was evidenced through leadership enactments in district PD design, mentoring of novices, and schoolwide initiative leadership. Across cases, spillover was not a generic "outcome" of participation; it was enacted through identifiable mechanisms in forms of PD design routines, mentoring/coaching practice, and schoolwide initiative leadership that were shaped by entry conditions and organizational role access.

Case	Entry conditions	APLUS opportunity structures Goals 1–5	Uptake episodes (illustrative)	Spillover locus / form
Teacher A (HS)	Rigorous preparation; high math capital	**G1** Instructional refinement **G2** Content leadership/legitimacy **G3** Leadership roles **G4** Clinical mentoring network **G5** Dissemination/credentialing	Leads TLC planning cycles; co-designs PD tasks; directs TLC data collection/feedback; sustains candidate supervision	**District:** PD design leadership; stewards' iterative improvement; builds other leaders' capacity **Peer/Clinical:** mentoring pipeline
Teacher B (HS)	Limited early PD; fellowship as access	**G1** Instructional learning via cohort **G2** Content learning/structured reflection **G3** Scaffolded leadership participation **G4** Candidate mentoring entry points **G5** Credentialing/ recognition pathways	Co-leads TLC planning (support role); enacts focused mentoring/coaching; expands mentoring responsibilities	**Peer/Clinical:** mentoring-centered leadership; novice growth episode as marker **District:** support-oriented TLC co-lead
Teacher C (MG)	Elementary → middle grades endorsement; rapid uptake	**G1** Instruction linked to initiative **G2** Endorsement/content pathways **G3** Schoolwide leadership roles **G4** Candidate mentoring entry points **G5** Peer learning dissemination/support	Co-leads TLC planning (hybrid); leads cross-disciplinary Whole Child work; facilitates/supports peer learning; strong mentor of candidates	**School:** initiative leadership across disciplines **Peer/District:** TLC co-lead + facilitation

Figure 1: Cross-case Journey Map Comparing Entry Conditions, Program Opportunities, Uptake Episodes, and Leadership Spillover Across Three Provisional Pathways

Teacher A's pathway foregrounds spillover enacted through collective PD design and iterative improvement. Teacher A assumed primary responsibility for coordinating TLC planning, setting agendas, facilitating co-design of PD tasks, and organizing collection and use of participant feedback to inform subsequent sessions. This trajectory (Figure 1) illustrates how leadership opportunity structures (Goals 3 and 5) were taken up as recurring design and data-use routines that supported district-facing instructional leadership while building other teacher leaders' facilitation capacity.

Teacher B's trajectory illustrates how fellowship participation can function as access to a rigorous professional community and legitimacy for leadership enactment. While co-leading TLC planning primarily in a support role, Teacher B enacted leadership most visibly through mentoring and coaching preservice teacher candidates. The salient enactment marker was the candidate's rapid growth early during student teaching, attributed to structured coaching and feedback routines. Figure 1 characterizes this pathway as mentoring-centered spillover, with TLC participation serving as an on-ramp for leadership participation and identity development.

Teacher C's pathway highlights spillover enacted at the school level, extending across disciplines. In addition to co-leading TLC planning in a hybrid lead/support role, Teacher C served as the school leader for *Whole Child* implementation engaging teachers beyond

mathematics. Figure 1 captures a trajectory in which organizational openings for schoolwide improvement supported translation of fellowship participation into cross-disciplinary leadership.

Cross-case comparison showed that the cases differed not only by participant background but by the locus and mechanism of leadership: Teacher A's influence centered on district-facing PD design and data-use routines, Teacher B's on mentoring/coaching routines, and Teacher C's on schoolwide initiative leadership. Case journey maps (see Figure 1) show how fellows' entry conditions and participation in structured APLUS opportunities are translated into distinct forms of leadership spillover across peer, school, and district contexts. Across cases, the fellows' trajectories can be characterized as three distinct but convergent leadership pathways. Teacher A exemplifies an *iterative PD design leadership* pathway in which leadership spillover is enacted through organizing and steering TLC planning cycles, coordinating collective task design, and using participant data to refine subsequent professional learning. Teacher B illustrates a *mentoring-centered leadership* pathway in which the fellowship functions as an access point to rigorous professional community and legitimacy, with spillover enacted most visibly through coaching and supporting novice development alongside a supportive TLC co-leadership role. Teacher C represents a *schoolwide initiative leadership* pathway in which spillover is enacted through cross-disciplinary improvement work, leveraging organizational openings to lead *Whole Child* implementation while also contributing to TLC planning and facilitation. Taking together, these pathways suggest that APLUS supports multiple routes from opportunity uptake to beyond-classroom influence, with the form of spillover shaped by entry conditions, role access, and local educational supports.

Conclusions and Implications

This brief report extends prior APLUS work by illustrating how a common, multi-phase fellowship design can yield multiple pathways from professional learning to instructional leadership. Across three contrasting cases, leadership spillover was enacted through (a) iterative district-facing PD design routines, (b) mentoring-centered coaching of novices, and (c) schoolwide cross-disciplinary initiative leadership. Rather than treating "teacher leadership" as a single outcome, these cases suggest that leadership development is better understood as opportunity uptake within structured communities (e.g., TLC) that affords legitimacy, role access, and tools for influence beyond the classroom.

For APLUS design, the findings point to several implications. First, TLC structures that emphasize collective task design and iterative improvement informed by participant data appear to function as a high-leverage mechanism for district-facing spillover and capacity building among teacher leaders. Second, mentoring-centered pathways warrant intentional scaffolds—such as coaching routines, protected time, and explicit mentoring roles—to translate instructional growth into novice support and induction capacity. Third, schoolwide leadership pathways depend on organizational openings; engaging administrators and clarifying role authority may increase the likelihood that fellows can lead cross-disciplinary improvement work while sustaining mathematics-specific instructional leadership.

Future research in the larger APLUS study will examine the prevalence and stability of these pathways across the full cohort and across phases of participation, including how entry conditions (e.g., preparation history, prior leadership) and contextual supports (e.g., administrator support, formal roles) mediate spillover. Methodologically, the journey-map approach used here can inform broader analyses by specifying measurable indicators of uptake and spillover (e.g., TLC roles, mentoring enactments, schoolwide initiative artifacts), supporting an account of how teacher leadership develops in sustained fellowship models.

The knowledge and competencies necessary for mathematics education doctoral preparation have received growing attention over the past two decades. Recently, Kim et al. (2024) administered a survey examining the knowledge, skills, and competencies necessary for doctorates in mathematics education as they embarked upon varying career paths. In this report, we examine the interview data of 35 recently graduated mathematics education doctorates who participated in the survey. The findings expand on previous work by revealing additional recommendations for mathematics education doctoral preparation. Specifically, participants highlight the importance of opportunities for professionalism and networking and share experiences from their own doctoral programs. These findings have implications for faculty and university administrators seeking to strengthen their mathematics education doctoral programs.

Keywords: Doctoral Education, Doctoral Preparation and Training, Competencies Required for Mathematics Education Doctorates, Professionalism, Networking

Over the past two decades, research investigating the experiences of graduates from doctoral programs, specifically within the field of mathematics education, has grown significantly. The first National Conference on Doctoral Programs convened in 1999 and sparked conversations about the components necessary within doctoral programs to promote the success of graduates in their future careers. Following the conference, the Association of Mathematics Teacher Educators (AMTE) published the *Principles to Guide the Design and Implementation of Doctoral Programs in Mathematics Education* (2003). This document outlined the essential knowledge necessary for doctorates in mathematics education and provided recommendations for the development of high-quality doctoral programs.

The second National Conference on Doctoral Programs was held in 2007. After almost a decade, scholars continued to address doctoral student preparation and possible program improvements. Reys and Dossey (2008) contributed to this effort by publishing a monograph detailing the core components necessary for mathematics education doctoral preparation. In this monograph, the authors elaborated on the core knowledge necessary for mathematics education doctorates by identifying specific components (e.g., curriculum). Ultimately, Reys & Dossey's (2008) work encouraged others to explicitly define the components necessary for mathematics education doctorates, rather than providing broad overarching recommendations.

The third and most recent National Conference on Doctoral Programs took place in 2022. Following the third conference, the question remained: How can programs ensure that mathematics education doctorates are successful after graduation when there is such a vast spectrum of career paths they might pursue? Kim et al. (2024) sought to address this concern by identifying the scope of work that mathematics education doctorates engage in. Additionally, the authors wanted to know how mathematics education doctorates use their doctoral program

experiences in their current roles (post-graduation). To understand and document these experiences, Kim et al. created a survey to explore the knowledge, skills, and competencies necessary for doctorates in mathematics education.

Core Competencies for Mathematics Education Doctorates

Although early literature examining the necessary components for strong mathematics education doctoral preparation focused primarily on mathematics, research, and teaching, additional competencies began to emerge as research progressed. Beginning in 2002, Reys & Reys (2002) developed a list of essential knowledge that mathematics education doctoral programs should include to promote the success of their graduates. They recommended that programs place an emphasis on the following areas: (1) mathematics content, (2) research, (3) social, historical, political, and economic context of education, (4) learning, (5) teaching and teacher education, (6) technology, (7) curriculum, and (8) assessment (Reys, 2002).

Shortly after the second National Conference of Doctoral Programs was held, Ferrini-Mundy (2008) highlighted the components that she believed to be at the core of mathematics education doctoral programs, expanding the previous work of Reys (2002). These components included mathematics, learning, and research. In addition to these foundational core components, she recommended that "core plus" components be recognized as well. Her findings suggested the inclusion of aspects such as: (1) resources for learning, (2) contexts, (3) diversity and equity, (4) ethics, (5) teacher education, (6) teaching, (7) policy, (8) technology, and (9) international issues (Ferrini-Mundy, 2008). Almost a decade later, Kirkpatrick & Spangler (2016) expanded the list of recommendations further by highlighting the need for teaching experience prior to entering a doctoral program. They emphasized the need for mathematics education doctorates to have experience teaching pure mathematics (K-12 or undergraduate level) and experience teaching mathematics education. In addition to the proposed teaching experiences, Kirkpatrick and Spangler (2016) also advocated for mathematics education doctorates to have access to a wide variety of research experiences during program enrollment.

Although each of these reports contributed to the literature examining the necessary components for mathematics education doctoral preparation, they lacked empirical data, each resulting from either a task force (Reys, 2002) or general noticing within an individual doctoral program (Ferrini-Mundy, 2008; Kirkpatrick & Spangler, 2016). To address this gap, Kim et al. (2024) compiled the collection of recommended competencies into a single list seeking to gather information about each competency that would inform future mathematics education doctoral programs. The preliminary list consisted of 12 core competencies: (1) mathematics, (2) curriculum, (3) research, (4) diversity and equity, (5) policy, (6) standards, (7) teacher education, (8) technology, (9) learner development, (10) assessment, (11) history of mathematics education, and (12) interdisciplinary connections.

Ongoing Study

Despite ongoing discourse related to doctoral student preparation, the question remained: What core components should mathematics education doctoral programs attend to in order to best prepare their doctoral students for success after graduation? In response to this question, Kim et al. (2024) conducted an empirical research study that developed and administered a survey designed for recent graduates of mathematics education doctoral programs. The survey sought to gather information about recent mathematics education doctorates regarding the responsibilities of their current role, experiences prior to their doctoral program, experiences during their doctoral program, and the impact that these experiences had on their current role.

Additionally, the survey gathered input regarding the use of Kim et al.'s list of core competencies. The list was based on existing literature and additional important areas related to the mathematics education doctorates' work, such as assessment.

The survey was administered through Qualtrics, and participants were notified of its opening through email listservs, personal connections, and social media. Survey items were presented in both multiple-choice and open-ended formats. The survey was left open for one month, and at the time of closing, 309 individuals responded. The authors define mathematics education doctorates as "doctoral graduates from a mathematics department or a department/school/college of education, with an emphasis on mathematics education" (Kim et al., 2024). Additionally, participants were only included in the study if their current role was within the area of mathematics education. Out of the 309 survey respondents, 218 completed the most significant portions of the survey (> 85%), and their responses were analyzed. Although all participants were recent graduates of mathematics education doctoral programs, their current roles within mathematics education varied significantly.

Following the survey study, interviews were conducted with 35 of the survey participants to further explore the competencies needed for the work of mathematics education doctorates. The full results on the competencies are reported elsewhere; in this report, we focus on professionalism, which we found significant aspect of the competencies that mathematics education doctorates need to develop. This report explores a subset of the interview data collected during this study. Specifically, it examines the responses of mathematics education doctorates who discussed professional experiences related to professionalism and networking. Professionalism and networking both encompass experiences required to navigate the landscape of mathematics education successfully. However, professionalism opportunities are oriented inward, toward an individual's capacity to function effectively within the profession. While networking is framed through an individual's outward relationship to the mathematics education community. This report seeks to answer the following research question: What professional experiences are most needed for mathematics education doctorates after graduation?

Methods

Data Collection and Participants

The data presented in this report was gathered through an extension of the survey administered by Kim et al. (2024). In addition to completing the survey, respondents were asked if they would be willing to participate in an interview with one of the members of the research team to elaborate on their responses. Out of the 218 respondents, 72 mathematics education doctorates agreed to participate in a follow-up interview. Ultimately, only 35 respondents were able to participate in a follow-up interview. The data discussed in this report reflects the responses of these 35 participants. Each participant was placed in an interview group based largely on their responses to the survey and their self-reported current position (post-doc, tenured faculty, pre-tenured, non-tenure track, post-doc, K-12 educator, research scientist). In total, 14 interviews were conducted either through focus groups of one to five participants or individual interviews. As seen in Table 1, participant positions varied greatly, with tenured faculty representing the largest subset (34.3%).

Table 1: Current Positions of Mathematics Education Interview Participants

	Position					
	Tenured	Pre-Tenured	Non-Tenure Track	Post-Doc	K-12 Education	Research Scientist
Participants	12	7	7	4	4	1
Percentage	34.3%	20%	20%	11.4%	11.4%	2.9%

Data Analysis

Following each interview, the responses were transcribed and the first phase of coding began. To organize and analyze participant responses, our research team developed a series of codes reflecting the trends present within the interviews through open coding. From these trends, five categories emerged: (1) current role or work they do, (2) doctoral program experiences, (3) experiences before their doctoral program, (4) how they use certain skills or knowledge to do their job, and (5) recommendations for future doctoral programs. Each category, seen in Figure 1, was assigned a color for coding to distinguish it within the transcripts. If responses did not fit any of the categories, but appeared to embody a significant trend, they were highlighted in grey.

Color	Categorization	Description
Purple	Current Role/Work They Do	Aspects of their current position: - Job title - Main duties & expectations - Research focus
Green	Doctoral Program Experiences	Experiences within their doctoral program: - Teaching experience - Research experience - Other
Blue	Experiences Before Doctoral Program	Experiences prior to their doctoral program: - Undergraduate experience - Graduate experiences (Master's degree) - Previous career experiences
Yellow	How They Use Certain Skills or Knowledge to do Their Job	Relevance of the core competencies in their current position: - Each core competency - Any additional relevant components
Pink	Recommendations for Future Doctoral Programs	Suggestions for future doctoral programs based on their doctoral program experience: - Helpful experiences included in their program that they would recommend - Experiences that would have been helpful, but were not included within their program

Figure 1: Interview Data Color Coding Sequence

After all codes were established, the research team analyzed several transcripts together to establish a consistent coding scheme. Members would analyze transcripts individually before meeting as a research team to establish reliability within coding assignment. The team discussed all discrepancies in coding to determine specific descriptions of each category in an effort to limit any overlap between codes. Upon establishing descriptions of each code, the team divided into pairs to complete the analysis of the remaining interviews. Each pair was assigned two to three interviews to analyze, coding individually before meeting together to establish reliability in coding.

Following the analysis of each transcribed interview, all coded data was compiled and displayed in a table. The team then identified sub-categories within the broader categories, seen

in Figure 2, and cataloged all responses accordingly. As this process continued, the team decided to merge the category recommendations for doctoral programs (previously pink) with the reported doctoral program experiences (green). Additionally, sub-sets of uncategorized significant trends (grey) began to emerge and were included to represent important responses from participants that did not fall under any previously established category.

Current Role/Work They Do	
- Job Title - Main Duties & Expectations - Research Focus - Research Related Work - Teacher Related Work	- Other Work (Professional Development, School Boards, etc.) - Other Significant Components (Job Satisfaction, Job Fit, etc.)
Doctoral Program Experiences	
- General Program Information - Equity & Diversity Experiences - Technology Experiences - Coursework - Teaching Experiences	- Research Experiences - Comprehensive Exams - *Recommendations for Doctoral Preparation* - Other Significant Components (Professionalism, Networking, etc.)
Experiences Before Doctoral Program	
- Undergraduate Experiences - Master's Program Experiences	- Previous Career - Other Significant Components (Standards, etc.)
How They Use Certain Skills or Knowledge to do Their Job	
- Mathematics - Curriculum - Research - Diversity/Equity - Policy - Standards - Teacher Education	- Technology - Learner & Learner Development - Assessment - History of Mathematics Education - Interdisciplinary Connections - Other Significant Component Recommendations
Additional Important Factors	
- Effects of Educational Political Climate - Effects of Covid-19 Pandemic	- Lack of awareness of possible career paths (outside of higher education)

Figure 2: Interview Data Code Sub-Categorization

Findings

The findings in this report highlight the experiences of mathematics education doctorates as they describe the importance of professionalism and networking opportunities during their doctoral programs. Professionalism experiences emphasized the development of skills needed to perform one's professional role after entering the field. While networking opportunities described the connections individuals had with others both inside and outside their institutions.

Professionalism

As we coded the participants' responses on their doctoral experiences, the topic of professionalism was a recurring theme. Out of 35 participants, 10 explicitly discussed professionalism experiences during their doctoral program. This report defines professionalism as the competencies or skills required to navigate the landscape of mathematics education

successfully. Although less than a third of participants spoke about their professionalism experiences, those who did stressed how valuable these experiences were. One participant praised her "preparing future faculty program" where doctoral students "did all those professionalism things, and a whole bunch of people all got in a room. They're all looking for jobs. We had all those [professionalism] conversations … it was like an extra thing, but so essential, just so essential." For mathematics education doctorates, there are several aspects of professionalism that do not become apparent until they enter the workforce. After using a constant comparative analysis to examine the data, three themes emerged from participants' discussions of professionalism: (1) seeking multiple perspectives, (2) assistantships and apprenticeships, and (3) academic assessment. Excerpts from participants, seen in Figure 3, represent both positive (unshaded) and negative (shaded gray) professionalism experiences. (Please note that the names in Figure 3 here and Figure 4 later are pseudonyms.)

Sub-Category	Example 1	Example 2
Seeking Multiple Perspectives	"There was a preparing future faculty program that was offered at my grad institution that basically did all those professionalism things, and a whole bunch of people all got in a room. They're all looking for jobs. We had all those conversations. There were panels – someone who just knew the structures of universities and how they work, because that's not always a conversation or something that you learn about. And just hearing perspectives from deans writing cover letters and all of that stuff, that was all in a summer course. So it was like an extra thing that I did but so essential, just so essential." - **Claire (Postdoctoral Scholar)**	"I wouldn't have that knowledge necessarily had I not done graduate school. You know through graduate school I got to talk to Matt Larson a few, quite a few times…and that was when he was starting to take leadership roles at NCTM. And he was bringing to these courses that I was teaching and conversations I was getting to have with him, some really interesting perspectives" - **Leslie (Education Department Chair)**
Assistantships & Apprenticeships	"I want to share something that I felt like I have seen as being tremendously helpful for my graduate training related to teacher education. Before I even had a teaching assistantship, I had a semester to apprentice with a tenured professor who had designed the methods course…That was tremendously helpful, for then my own teaching and being able to also make sense of future classes. Instead of 'well, this is the way that I did it, so this is the best way,' I had a model of what that looks like and experienced someone else there to watch what I was doing and give feedback. That I feel like has really strengthened what is now a very core part of what I'm expected to do in my current role." - **Alan (Assistant Professor)**	"I did a little bit because I asked for later in my Ph.D. program more of a research assistantship. But I felt like coming out of the program, I didn't feel like I was prepared for or would be ready to take on a tenure track position" - **Amy (Assistant Professor)**
Academic Assessment	"I never would have thought about it in grad school that the assessment of my colleagues and my peers was something that I would need to be thinking about in my job as a faculty member. But it is a huge part of my job at this point. Whether it's my staff, my lectures, or my faculty, I am assessing a lot of their work, their teaching, their service and their scholarship with my students." - **Leslie (Education Department Chair)**	"I guess the one thing I did not really do or don't have as much experience in is assessing courses and programs for teachers. I've…I don't think I've ever done that. Obviously, I plan and teach courses and I've designed courses, but I've never assessed." - **Nicole (Assistant Professor)**

Figure 3: Professionalism Experiences of Mathematics Education Doctorates

Most participants who discussed seeking multiple perspectives during their doctoral program said that it was not only a positive experience, but one that helped them succeed in their future role. However, the opinions about graduate apprenticeships/assistantships were mixed. Assistantships were generally cited to prepare mathematics education doctorates for teaching but fell short in preparing them for research. Finally, participants unanimously expressed negative feelings regarding their experience with academic assessment. Whether in reference to assessing peers or evaluating courses, participants did not feel that their doctoral program prepared them for this task.

Networking

As participants discussed the experiences they had in their doctoral programs, they also commented frequently on their networking experiences. Out of the 35 participants, only 13 discussed networking experiences (good or bad) during their doctoral program. When asked what she would recommend doctoral programs to focus on, one participant suggested "Maybe professional networking … because it's really what you're doing when you step outside of your university. You're getting involved in other professional organizations. You're learning … you're investing in your field, and you're investing in your profession." Several mathematics education doctorates echoed this sentiment and emphasized the importance of their networking experiences. After using a constant comparative analysis to examine the data, three themes emerged from participants' discussions of networking: (1) student and faculty interactions, (2) proactive process, and (3) conference exposure. Excerpts from participants, seen in Figure 4, represent both positive (unshaded) and negative (shaded gray) networking experiences.

Sub-Category	Example 1	Example 2
Student & Faculty Interactions	"A lot of programs have some sort of… We called it Friday Seminar. But just a time when all of the students and faculty can get together. Maybe it's a semi-structured time, but it's an important time." - **Josh (Research Scientist)**	"And [mentoring] is also something that I was supported to focus on at my doctoral institution, and had great mentors who centered that and their work as well." - **Francis (Associate Professor)**
Proactive Process	"I had to reach out kind of regularly to a handful of professors that I like to work with, and say, 'Hey, what do you have coming up? I'd love to work with you on something' or 'I heard you have something coming up. Do you have space for a GA?' So that's how it worked. It was really like it had to be self-initiated." - **Stephanie (Assistant Clinical Professor)**	"You don't know what you don't know, so I think you have to have somebody to kind of say, 'Hey, like check out these spaces and check out these things.'" - **Amy (Assistant Clinical Professor)**
Conference Exposure	"I didn't really know for many years what conferences to go to because no one had said 'These are math ed conferences' or 'This is what you should be interested in'…I think if I were to mentor doctoral students…I would tell them 'Here are the major conferences you should be interested in [and] this is when the proposals are generally due.' - **Blair (Assistant Professor)**	"You know, grad programs [providing] funding for going to AMTE or NCTM…Maybe that is part of the requirements of [doctoral students], that they're going. Maybe [they're] presenting, but maybe just learning what it's all about. Because if you've never been to one, I don't think you have any idea what to look for." - **Leslie (Education Department Chair)**

Figure 4: Networking Experiences of Mathematics Education Doctorates

Most participants who discussed their interactions with faculty during their doctoral program highlighted both their importance and positive impact on their career. Additionally, while some viewed self-initiated discovery as a positive experience, others critiqued the hands-off nature of their program, with one participant stating, "You don't know what you don't know." Unfortunately, a common negative experience that emerged throughout the discussions of networking was the lack of conference exposure for mathematics education doctorates. While some commented on their lack of knowledge surrounding conferences during their doctoral program, others highlighted the financial burden that conference attendance can have on a doctoral student.

Discussion

Although the literature examining core competencies necessary to promote success among mathematics education doctorates is growing (Hiebert et al., 2008; Reys & Reys, 2016; Shih et al., 2020; Yow et al., 2016), there is a need to continue these discussions through empirical research. The structure of mathematics education doctoral programs has direct implications for

the success of graduates who go on to serve in various roles, including K-12 teaching, curriculum development, research, and higher education.

While discussions of competencies recommended for mathematics education doctorates have largely centered on domains of knowledge, less attention has been given to professional experiences as a critical competency. Since aspects of doctoral preparation, such as professionalism and networking, are discussed less frequently than other components they are often overlooked. However, these "invisible components" present the greatest challenges for mathematics education doctorates upon entering their professional roles. Thus, including professional experiences within the core competencies is essential to better prepare mathematics education doctoral students for the full range of demands they will face in their professional careers.

It would be unrealistic to assume that doctoral programs can prepare their graduates for every possible career path available to them. However, by documenting the most significant core components that contribute to mathematics education doctorates' success, research can inform future doctoral programs and provide recommendations that encourage future faculty to thrive. By taking simple steps, such as encouraging conference attendance through graduate funding or establishing faculty mentorship through graduate assistantships, doctoral programs can promote professionalism and networking experiences and better prepare their graduates for varying career paths. Future research should continue to explore the experiences of mathematics education doctorates as they transition into their professional roles.

This paper examines how multi-tiered research–practice partnerships reason about organizing collaborative design with education systems in efforts to support system-level learning. Drawing on three distinct design situations from a long-standing statewide mathematics RPP, we analyze reflective accounts of design decisions elicited through a structured analytic tool. We identify recurring forms of reasoning about the purposes of design, interpretations of system conditions, configurations of expertise and resources, enactments of design activity, and the tradeoffs these judgments entail. From these patterns, we theorize a methodology for collaborative design with education systems that can inform how other research–practice partnerships reason about organizing design under shifting system conditions.

Keywords: Systemic Change, Research Methods, Design Experiments

Meaningful and sustained instructional improvement at scale in mathematics remains a persistent policy, practice, and research problem. In the U.S., instructional improvement is pursued within education systems where authority and responsibility for change are distributed across multiple levels and organizations, resources and expertise are unevenly allocated across contexts, and sociopolitical dynamics shape which forms of instructional change are prioritized, supported, or contested (Polikoff, 2021). As a result, efforts to improve teaching and learning must extend beyond instructional quality in individual classrooms to contend with variation in local capacity, organizational structures, policy pressures, and political dynamics (National Academies of Sciences, Engineering, and Medicine [NASEM], 2025). Mathematics education research has largely approached instructional improvement through research on teaching and learning and through the development of curricula, instructional tools, and professional learning programs. While this scholarship has generated important insights, it offers limited guidance for efforts aimed at instructional improvement when the unit of change is an education system rather than a bounded setting (i.e., school, district). These realities cast the central challenge of improving mathematics instruction as a problem of organizing and coordinating research and design efforts across roles, organizations, and time under changing system conditions.

Multi-tiered research–practice partnerships (RPPs) (Farrell et al., 2021) have increasingly emerged as key actors in this space (McMahon et al., 2022; NASEM, 2025). Positioned across research institutions, state agencies, districts, schools, and professional organizations, RPPs are uniquely situated to convene diverse expertise, navigate the contours and constraints of education systems, and coordinate research and design efforts that span roles, organizations, and time. For long-term RPPs, this coordination often extends beyond the design of specific resources or interventions to include an intentional organization of relationships, routines, and conditions that support instructional improvement (Penuel, 2019). Yet despite a growing body of scholarship documenting the effects of interventions developed by RPPs and examining

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

partnership dynamics (Coburn & Penuel, 2016; Farrell et al., 2021), there remains relatively little insight into how partnerships reason about organizing collaborative design in response to system conditions. For example, partnerships may elect to address externally imposed problems such as policy mandates that require rapid coordination across levels of the system. At other times, they may engage in negotiated and jointly defined problems that emerge from sustained deliberation and shared commitment. Beyond contextual, such differences call for distinct ways of convening expertise and organizing participation for design activity.

In this paper, we examine how multi-tiered RPPs reason about organizing collaborative design with education systems in efforts to support system-level learning. Our central claim is that, in RPPs focused on system-level learning and instructional improvement, collaborative design is carried out through recurring forms of methodological reasoning about how design activity is organized and sustained under changing system conditions. This study addresses the following research question: *How do multi-tiered research–practice partnerships reason about organizing collaborative design under differing system conditions in efforts to support system-level learning and instructional improvement?* To address this question, we analyze three distinct design situations from a long-standing statewide RPP in order to elicit reflective accounts of how the partnership approached design under differing system conditions. Through this analysis, we theorize a methodology for collaborative design with education systems that specifies the forms of reasoning and judgment through which partnerships organize system-level instructional improvement.

Theoretical Perspective

Our aim in this study is to theorize a methodology for collaborative design with education systems. By methodology, we refer to a set of procedures and the accompanying rationale that guides how they are selected and used. Methodology thus concerns not only activity but also the logics, commitments, and warrants that shape judgments in pursuit of particular goals (Guba & Lincoln, 1994; Kelly, 2009). In contrast to research methodologies, Edelson (2002) characterizes design methodologies as prescriptive theories that are developed through sustained engagement in design. Design methodologies offer guidance for organizing activity when encountering new situations that share salient features and goals with prior design efforts by foregrounding judgments about how roles, expertise, and structures are configured. In situations characterized by multiple and often competing goals, this form of reasoning is less about optimizing toward a single solution than about navigating tensions and balancing incommensurate aims (Tatar, 2007).

By collaborative design, we refer to a range of participatory approaches to educational design that involve researchers and practitioners working together to address practical problems, along with a shared orientation toward joint inquiry, learning, and authority in design. Such approaches are often referred to as co-design (e.g., Penuel et al., 2007) or participatory design (e.g., Bjögvinsson et al., 2012) and typically described as processes and techniques for engaging practitioners in the development of educational innovations. In this paper, we adopt a broader interpretation of collaborative design that extends beyond particular methods or design processes to encompass the commitments, orientations, and judgments through which joint work is organized, including how roles and expertise are configured, how participation is structured, and how design activity is adapted to shifting conditions, goals, and constraints.

This framing of collaborative design foregrounds the forms of reasoning involved in organizing design activity and is especially relevant in multi-tiered RPPs, where design unfolds across roles, organizations, and levels of the education system. In such partnerships, design often extends beyond the development of specific instructional resources or interventions to include

the intentional organization of relationships, routines, and conditions that support instructional improvement over time. This form of long-term, system-oriented activity has been described as infrastructuring, a practice oriented toward shaping the social, organizational, and material conditions that enable the implementation, adaptation, and sustainability of educational innovations (Penuel, 2019). From this perspective, collaborative design in RPPs is both a means of producing artifacts and a strategy for organizing research and design with education systems under changing conditions. This view motivates theorizing a methodology for collaborative design with education systems that accounts for how partnerships reason about organizing design activity, configuring expertise, and navigating tradeoffs as they encounter new but related system-level design situations.

Methods

Context: The Partnership and Design Situations

To develop the methodology presented in this paper, we examined the work of the North Carolina Collaborative for Mathematics Learning, a long-standing, statewide research–practice partnership focused on expanding equitable professional learning opportunities and supporting system-level learning and instructional improvement in mathematics education across North Carolina. Since 2016, the partnership has convened university-based researchers, state and local education agency leaders, school-based instructional leaders, and classroom teachers to collaboratively design professional learning resources and structures that support systemic coherence through a shared instructional vision. These activities unfolded across multiple initiatives, each organized under distinct system conditions, including differences in the broader sociopolitical landscape of the system, the nature of the problem being addressed, the urgency with which action was required, the locations of authority and expertise involved, and the scope of influence the initiatives were intended to have. Drawing on this variation, we selected three initiatives that illustrate meaningful differences in these system conditions. For analytic purposes, we considered each initiative as a distinct design situation that enabled our examination of how collaborative design was reasoned about under contrasting conditions.

Initial design situation. The first design situation occurred in 2016–2017 following North Carolina's adoption and immediate implementation of new high school mathematics standards, a decision that left many districts with little time to prepare. The problem space was initially surfaced by district and state leaders, shaped by political tensions surrounding the state's prior adoption of the Common Core State Standards for Mathematics, and constrained by districts' capacity to respond. Under these conditions, the partnership faced significant pressure to act quickly, with limited opportunity for broad participation or extended deliberation. Given these constraints, it leveraged existing relationships and organized collaborative design around a small group of university-based researchers and trusted district and state partners to develop mathematics professional learning and implementation resources intended for statewide use and broad distribution (see https://www.nc2ml.org/high-school-resources/hs-math-standards). Design decisions were heavily influenced by the compressed timeline, the need to navigate politically charged policy contexts while safeguarding participating organizations, and the need to address multiple levels of the state education system simultaneously.

Second design situation. The second design situation occurred between 2018 and 2020, following North Carolina's adoption of new K–8 and fourth-level high school mathematics standards under a planned yearlong implementation timeline. The problem space centered on the widespread use of locally developed pacing guides that varied substantially in quality, coherence, and alignment with research on student learning. These guides were often created under resource

constraints, used prescriptively, and widely viewed as barriers to supporting high-quality instruction in classrooms. Under these conditions, the partnership faced a challenge of supporting statewide coherence while respecting meaningful differences across local contexts and capacities. In response to this context, the partnership developed 15 grade-level and course-specific curricular and instructional guidance resources that clustered and sequenced the new standards, explained the underlying mathematics and research on student learning, and suggested pedagogical approaches for teaching them in diverse settings (see https://www.nc2ml.org /k-5-resources/#frameworks). It expanded participation to include design teams composed of teachers, instructional coaches, district leaders, and state education agency staff from across the state. Design decisions were shaped by the need to balance inclusion with coherence, position expertise across multiple roles, and support adaptation in local contexts.

Third design situation. The third design situation occurred between 2022 and 2025 with the launch of the partnership's VISIONS Project, a multi-year effort oriented toward system-level instructional coherence. Rather than responding to policy adoption or implementation timelines, the partnership focused on developing a shared vision of high-quality and equitable mathematics instruction as a means of supporting instructional improvement (NC^2ML, 2025). This focus emerged from instructional challenges identified by more than 280 mathematics teachers and leaders during regional listening sessions, partnership leaders' reflections on persistent variation in instructional visions across the state, and the broader post-pandemic context. In this situation, the partnership faced a challenge of engaging the education system around a research-based vision of high-quality, equitable mathematics instruction without the unifying pressure of a policy deadline. In response, the partnership organized collaborative design through multi-year, heavily facilitated grade-band design teams coordinated by a steering committee composed of educators representing diverse roles, regions, and perspectives. Design decisions required ongoing reasoning about how to support inclusive participation, manage complexity across grade bands, and sustain engagement over time while maintaining a coherent system-level orientation.

Together, these three design situations provided contrasting contexts for examining how the partnership reasoned about organizing collaborative design in support of system-level learning. Although each situation involved distinct problems, timelines, and configurations of participants, all required the partnership to make judgments about how its activities should be organized given who was involved, what forms of expertise were needed, and what the effort was intended to accomplish given the constraints and affordances of each situation. Treating these situations as analytically distinct enabled us to examine recurring forms of reasoning about how collaborative design was organized across contrasting situations.

Data Sources and Analysis

To support a systematic examination of these situations, we developed an analytic tool referred to as the BAT. The BAT was designed to elicit reflective accounts of how the partnership configured its activities and reasoned about collaborative design under particular system conditions. It was informed by Edelson's (2002) conception of design methodologies as prescriptive theories that guide decisions about how design activity is organized, what forms of expertise are required, how responsibilities are distributed, and how design processes are enacted. The BAT operationalized this perspective through 11 questions focused on how design problems were defined within particular contexts, how expertise and participation were positioned, and how activity was organized and sustained. Using a common set of questions across multiple design situations, the BAT elicited the judgments, rationales, and tradeoffs

through which the partnership reasoned about collaborative design. Each respondent completed the BAT in a single retrospective session and treated each situation as a distinct case.

The primary data source for this analysis consisted of completed BAT responses from five core members of the partnership who were centrally involved in organizing and sustaining the partnership's efforts across the three design situations. These respondents included partnership researchers and design leaders who had direct responsibility for configuring design activity, facilitating collaboration across roles and organizations, and navigating system-level constraints. In addition to the BAT responses, we used partnership records to support interpretation and ensure accuracy when constructing preliminary accounts of each design situation.

Our analysis proceeded in three stages. First, we constructed analytic accounts for each design situation by synthesizing BAT responses and partnership records with attention to how collaborative design was organized and sustained under the conditions characterizing each situation. These accounts were then circulated among 15 additional designers who had participated in each initiative for scrutiny, correction, and elaboration. Second, we compared these accounts across design situations to identify recurring patterns of judgment that shaped how the partnership organized its work. Third, we synthesized these comparisons to develop higher-level categories that characterize recurring forms of reasoning about collaborative design across system conditions. Throughout this process, we iteratively refined our interpretations through discussion and feedback from designers involved in the initiatives.

Results

Across the three situations examined in this study, our analysis revealed recurring forms of reasoning through which the partnership organized, enacted, and sustained collaborative design in response to shifting system conditions, timelines, and goals for system-level learning. These forms of reasoning shaped what was designed and how the activity itself was configured, including who participated, how expertise and responsibilities were positioned, how work was coordinated across roles and organizations, and which tradeoffs were accepted at particular moments. Examining how these forms of reasoning operated across distinct design situations enabled us to move from describing situated decisions to articulating an empirically derived design methodology that delineates a space for organizing and sustaining collaborative design over time with education systems.

Figure 1 synthesizes the methodology by illustrating how a partnership's orientation toward an education system and the purposes of collaborative design shapes its interpretation of system conditions, configuration of resources and expertise to support design activity, organization of facilitation and participation, and engagement with recurring tradeoffs as conditions and goals evolve. In this way, Design Orientation, Design Conditions, Design Structures, Design Practices, and Design Considerations function as interrelated components that together define a relational space for methodological reasoning across time and initiatives. Each component is elaborated through a set of dimensions that specify ranges along which partnerships reason about how collaborative design should be organized under differing system conditions. In what follows, we elaborate each component by clarifying the forms of reasoning it foregrounds and how it informs decisions about organizing collaborative design for system-level learning.

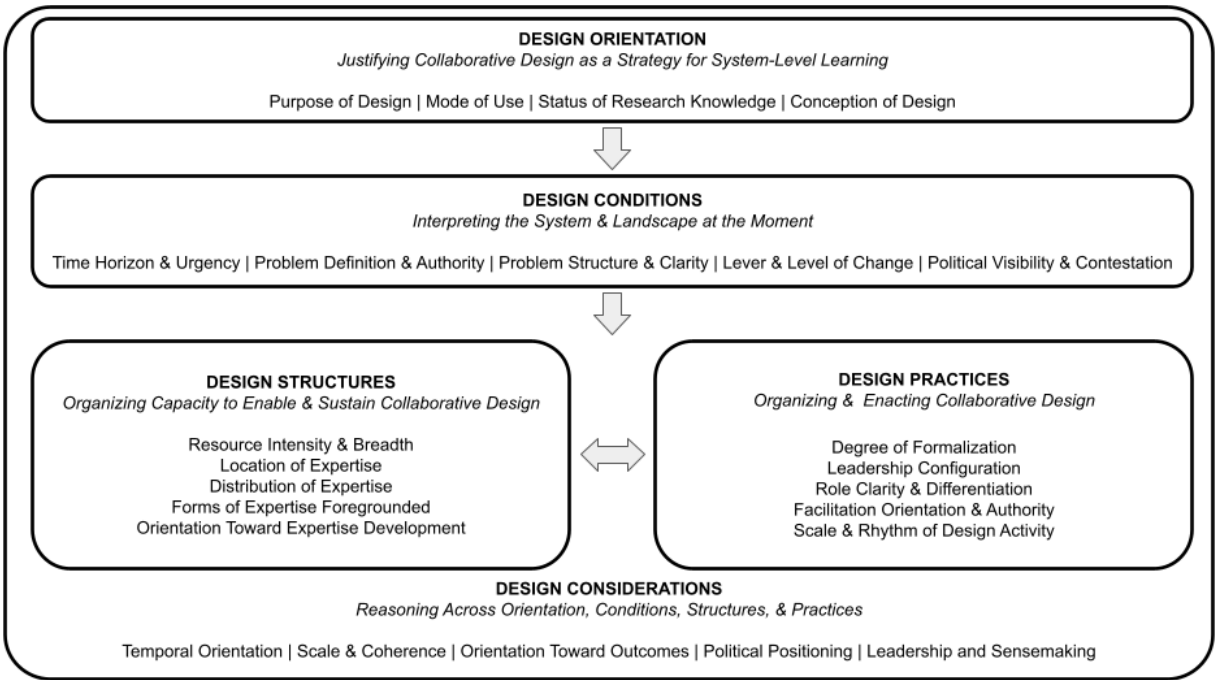

Figure 1: Methodology for Collaborative Design with Education Systems

Design Orientation describes how a partnership reasons about the purposes of collaborative design and its role in supporting system-level learning. It foregrounds a partnership's commitments that shape the kinds of learning that are prioritized (e.g., individual practice, collective sensemaking, or organizational capacity), how progress is understood in relation to system-level goals, and which tradeoffs are viewed as acceptable when organizing design activity. Orientation is elaborated through four dimensions, shown in Figure 1, that define a space for reasoning about why collaborative design is an appropriate response to system-level challenges and how it should be oriented under differing conditions. For example, one dimension concerns the *purpose of design* and captures how partnerships balance an emphasis on producing resources with using design activity as a mechanism for capacity-building, alignment, and coordination across roles and organizations. Where a partnership positions itself across these dimensions informs how system conditions are interpreted and, in turn, how structures and practices are configured and considerations are weighed.

Design Conditions characterize how a partnership makes sense of the education system and broader landscape at a given moment when organizing collaborative design. Rather than articulating commitments or aims, the component highlights features of the system that shape what forms of activity are feasible, constrained, and consequential, including temporal pressures, political dynamics, authority structures, and the nature of the problem being addressed. Conditions are developed through five dimensions that assist partnerships in interpreting the demands and constraints of a given system moment. For example, one dimension concerns *time horizon and urgency* and captures how partnerships reason about the extent to which a situation demands rapid response versus sustained deliberation and sensemaking over time. How a partnership reads system conditions influences judgments about who should be involved and in what roles, how design activity should be coordinated across actors and organizations, and how

quickly design activity should move. In this way, conditions shape how structures and practices are selected and enacted in response to the system.

Design Structures concern how a partnership organizes capacity to make collaborative design with an education system possible and sustainable. This component emphasizes organizational arrangements that shape who can participate and in what roles, how activities are resourced and coordinated, how responsibility for decisions is distributed, and how expertise is positioned and developed. Structures are operationalized through five dimensions that describe ways of assembling capacity to support design activities under particular system conditions. For example, one dimension concerns *orientation toward expertise development* and distinguishes between approaches that treat expertise as a prerequisite for participation and those that treat it as an outcome of participation itself. Where a partnership positions itself along these dimensions influences which forms of activity become feasible, how participation is sustained, and how capacity develops over time.

Design Practices attend to how design activity unfolds over time. This component foregrounds reasoning about how partnerships facilitate and coordinate design activity in practice, including how responsibility is exercised, how participation is organized, and how learning across roles and organizations is supported as conditions and capacity shift. Practices are described through five dimensions that define a space for reasoning about how collaborative design is enacted under particular system conditions and structural arrangements. For example, one dimension concerns *facilitation orientation* and captures how partnerships balance facilitation aimed at coordination and efficiency with facilitation oriented toward collective sensemaking, alignment, and capacity-building. Where a partnership positions itself along these dimensions shapes how design activity unfolds, how participants experience collaboration, and how shared learning and ownership develop over time.

Design Considerations capture persistent tensions that partnerships must reason through when organizing collaborative design under particular system conditions. Rather than describing features of the system or design activity, this component highlights how partnerships weigh competing aims and make tradeoffs across orientation, conditions, structures, and practices. Considerations are elaborated through a set of five tensions that surface persistent dilemmas when designing with education systems and define a space for reasoning about what is responsible, strategic, and sustainable over time. For example, one consideration concerns *scale and coherence* and captures how partnerships reason about supporting system-level alignment while allowing for local interpretation and adaptation. How a partnership engages these considerations informs judgments about how collaborative design is scoped, who is involved and in what roles, how explicit or flexible designs should be, and how alignment and adaptation are balanced under particular system conditions.

Discussion

This study examined how a multi-tiered research-practice partnership organized collaborative design under differing system conditions in efforts to support system-level learning and instructional improvement. Across three design situations, we found that the partnership's approach to collaborative design was shaped by recurring forms of reasoning about how design activity could support system-level learning, how system conditions were interpreted, and how expertise, resources, and participation were configured in response to shifting constraints and possibilities. Together, these forms of reasoning constitute an empirically derived methodology that characterizes how partnerships organize collaborative design in ways that remain responsive to changing system conditions.

This methodology extends existing scholarship on research-practice partnerships by focusing attention on the methodological reasoning partnerships use to organize and sustain collaborative design with education systems. Prior RPP research has documented internal partnership dynamics associated with effective collaboration, including trust, mutualism, and communication routines (Coburn & Penuel, 2016). This study builds on that scholarship by specifying how partnerships make and revise judgments when organizing design as conditions, timelines, and priorities change. In doing so, the methodology complements existing RPP frameworks by foregrounding the tradeoffs and strategic decisions involved in coordinating design work with education systems.

Our findings have implications for how system-level learning and instructional improvement is understood and pursued. In U.S. education systems, governance, expertise, and resources are distributed across multiple levels, organizations, and actors, and improvement therefore unfolds differently across contexts (NASEM, 2025). The methodology presented here highlights how partnerships can reason deliberately about these realities when organizing collaborative design. By attending to orientation, conditions, structures, practices, and considerations as interrelated components, partnerships can use the methodology as a planning and reflective tool to organize collaborative design in ways that remain responsive to shifting system demands while sustaining learning, coordination, and long-term viability.

The methodology developed here draws on a single long-standing statewide partnership and a bounded set of design situations and should be considered with that scope in mind. Our aim was not to offer a generalizable model, but to develop an analytic and practical resource for reasoning about collaborative design with education systems whose value depends on examination, adaptation, and refinement through use across contexts. Future research might examine how similar forms of methodological reasoning emerge in other partnerships or policy contexts, how these forms evolve as partnerships mature or confront new system conditions, and how this methodology is taken up, adapted, and revised as a planning and reflective tool. Such efforts would further develop an empirically grounded theory of collaborative design as a methodological practice for system-level educational improvement.

MATHEMATICAL IDENTITY MAKING, SELF-STUDY THROUGH DUOETHNOGRAPHY, AND TEACHING GEOTECHNICAL ENGINEERING AS A FIELD OF STUDY

Keywords: Mathematical Identity, ADAS, Authorial Voice, Self-Study, Duoethnography, SOAR

Mathematical identity has been extensively researched in contexts of mathematics education. The bulk of this focus, however, was mostly conducted in K-12 settings (Heyd-Metzuyanim & Graven, 2024; Sfard, 2019). While few studies have focused on mathematical identity in university level settings, none, as far as we know, focused on university instructors' mathematical identity experiences. We problematize this gap because this missing piece precludes a view onto the relationship between mathematical identity making and pedagogical approaches in settings of higher education. The study is conducted as part of an interdisciplinary collaboration between two university instructors. We import a four-part framework of mathematical identity making to capture, surface, and discern connections with pedagogical approaches and instructional practices.

We use the ADAS framework (Fellus, 2019), to carve the landscape of one's *Autobiographical* (experiences with learning mathematics), *Discoursal* (how one is spoken to and about as a learner of mathematics), *Authorial* (opportunities one gets to develop ownership, autonomy, and confidence in mathematics), and *Socioculturally* available narratives about mathematics. This approach is aimed at addressing what Graven and Heyd-Metzuyanim (2019) identified as "the implicit unification of different types of identity narratives; and … the neglect … in the field to differentiate between … various identity stories of different authors" (p. 364). The ADAS framework allows us to dive deeply into different types of identity narratives so that we can differentiate between various identity stories and critically reflect on their connections with instructional practices.

We engage in a two-pronged methodology that involves self-study (Kitchen, 2009) and duoethnography (Norris & Sawyer, 2017) to embark on a journey of critical reflection of and awareness to connections between mathematical identity and instructional practices. The data comprise emails between the authors, more than a dozen scheduled recorded dialogic online conversations, and a growing record of the first author's experiences in mathematics and the second author's feedback and follow-up questions. The data were analyzed as sites of inquiry and theory-informed reflections through the second author's role of critical friend.

Several insights pertain to how one's experiences with learning school mathematics project onto one's instructional practices. We showcase how opportunities the first author experienced in taking ownership over mathematical ideas (the second A in the ADAS framework) while strongly associated with the other identity-related experiences (i.e., autobiographical, discoursal, and socioculturally available narratives about mathematics) have also been the catalyst for self-regulation, fluency, and flexibility. We thus offer an identity-making pedagogical approach that pushes to the front opportunities for learners to develop mathematical voices through self-regulation, ownership, autonomy, and research (SOAR).

ROOTED IN PLACE: EXPLORING AFFORDANCES AND CONSTRAINTS OF RURAL MATHEMATICS TEACHER LEADERSHIP

Matthew P. Campbell
West Virginia University
mpcampbell@mail.wvu.edu

Julie M. Amador
University of Idaho
jamador@uidaho.edu

Keywords: Instructional Leadership, Rural School Contexts

Rural schools constitute approximately one-third of public schools in the United States (Showalter et al., 2017) and enroll a student population that is becoming increasingly diverse (Lavalley, 2018; Johnson et al., 2014; Thier et al., 2021). Due to an uneven distribution of economic, social, and political capital, including a lack of specific attention in policy and research, rural schools typically face acute inequities in meeting the educational needs of these student populations (Hartman et al., 2022; Johnson & Howley, 2015). However, rural school contexts also have characteristics of cultural richness, self-reliance, and deep connection to community and place, which all serve as assets to leverage toward educational improvement (Gallo, 2020; McHenry-Sorber et al., 2023).

Rural schools and districts face specific challenges in teacher recruitment and retention, especially in STEM fields, which further exacerbate issues of teaching and learning (Carver-Thomas & Darling-Hammond, 2017; Goldhaber et al., 2021; Ingersoll & Tran, 2023). Opportunities for teacher leadership, and systems that support and leverage teacher leadership, are an effective means for improving teaching and learning in schools and increasing teacher retention (Lumpkin et al., 2014; Shen et al., 2020). Supporting mathematics teacher leadership in rural schools is shaped—through both affordances and constraints—by the place-based, cultural, and geographic contexts of these settings. While a small subset of the literature on mathematics teacher leadership has focused particularly on rural contexts (e.g., Bolyard et al., 2025; Lotter et al., 2020; Nelson, 2022), the place-specific variation across rural contexts necessitates intentional efforts to further understand the development of mathematics teacher leaders and the cultivation of systems that support and leverage mathematics teacher leadership.

We present initial findings from collaboration across two different research studies, one in Idaho and one in West Virginia, that engaged in developing mathematics teacher leaders and supporting their work in school and district contexts. The intent of both studies was to better understand the interplay between aspects of the rural context and teacher leadership, with the aim to articulate affordances and constraints of the journey of becoming and being a teacher leader in a rural space. We intentionally focus on rural contexts across two states in different regions of the United States to highlight the variance of affordances and constraints related to rural teacher leadership, despite the unifying characteristics of rurality.

Findings across both projects highlight shared themes, such as the role of professional networks in validating teacher leader identity and the tension between teacher agency and district-level structures. Notable differences also help further elaborate the nuances of teacher leadership, including how geographic isolation in Idaho and regional cultural norms in Appalachian West Virginia distinctly shape teachers' experiences of and pathways into leadership. This poster represents the beginning of a research collaboration aimed at developing a more nuanced understanding of mathematics teacher leadership in rural contexts, with the goal of building a framework that informs the design of programs and systems that more effectively support and leverage rural mathematics teacher leadership across diverse rural contexts.

Purpose and Methods

In Ontario, Canada, mathematics performance has prompted renewed attention to classroom instruction and implementation of supports for teachers. A directive from the Ministry of Education (2024) has increased funding and classroom supports for roles such as board math leads and central math support educators (2016, 2024). While titles vary, the function is clear: to support teachers through classroom-embedded professional learning (Ellington et al., 2017; McGraw et al., 2025; Walkowiak, 2016). This study examines how MLPs and Math Coordinator perceive and enact their roles within a large urban board. Research questions include:

1. How does the school board define the Math Learning Partner role? How does this align with or differ from the MLPs perspective of their own role?
2. What training and professional learning do MLPs experience? How do these structures prepare them to impact teacher practice and student learning beyond their direct, in-person support?

MLPs are expected to work directly in classrooms through co planning and co-teaching, positioning the role as classroom embedded and partnership oriented (Saclarides, 2022). Research highlights the importance of infrastructure, centralized leadership, time for collaboration and clarity in role expectations (Patel et al., 2021; Walkowiak, 2016), as well as the role of principals in supporting instructional partnerships (West, 2017).

This qualitative study explored experiences of 5 MLPs and one Math Coordinator working in destreamed Grade 9 mathematics. Semi structured interviews focused on perceptions of the role, supports, training, challenges and indicators of success. Data was coded inductively.

Results and Conclusion

Participants described clear expectations related to improving mathematics achievement, particularly aligned with EQAO performance and data use. MLPs were expected to support High Impact Instructional Practices, ensure curriculum fidelity and design professional learning. At the same time, participants reported mixed messaging across levels of leadership and a strong sense of accountability. MLPs navigate a mix of instructional, relational and organizational demands. The role extends beyond pedagogy to include navigating school contexts, building relationships and responding to local needs. Time limitations, systemic barriers and the instability of funding were identified as ongoing challenges. Training includes formal learning, collaboration and shadowing, grounded in current research and supported through team structures. This study highlights the importance of principal partnership, consistent messaging and time for in class collaboration. The findings show that the role is shaped by formal

expectations and relational/organizational demands, contributing insights into how board level teacher educator roles can be supported in detracked mathematics contexts.

COMPUTATIONAL DEGRADATION OF OVERLY-BUREUACRATIZED MATHEMATICS EDUCATION COMPLEX SYSTEMS

Thomas E. Ricks
Louisiana State University
tomricks@lsu.edu

Keywords: Policy, Professional Development, Standards, Systemic Change

The purpose of this research is to better understand how the growing educational bureaucracy of the United States (U.S.) affects mathematics education reform progress. This research extends previous research (Ricks, 2025) describing how initially useful educational bureaucracy (promoting equality and efficiency) stifles reform potential by excessive reductionistic fixation on trivializing metrics and alignment compliance. The original standards-based reform movement has taken a potentially dangerous bureaucratic turn. This new era of reform-by-bureaucracy needs clarifying research about its effects. This study seeks to develop explanatory theory about this phenomenon and to suggest future action for praxis. I followed the four cyclic stages of Glaser's (1965) constant comparative method—comparing, integrating, delimiting, and writing—to perform a meta-analysis across empirical and theoretical material from eight prior bureaucracy-based research studies. I utilized an integrated theoretical framework viewing overlapping, nested mathematics education systems—such as mathematics classes, departments, teachers' learning communities, schools/districts, states' departments of education (some with numeracy divisions), special interest groups, professional organizations, etc.—as *computational* complex systems. All complex systems *compute* as part of their systemic maintenance—e.g., self-emergent agentic rule-bound behavior enfolding through feedback loops determining actual morphological structures—and hence, enact systemic-specific forms of mathematics. The quality of computation is directly linked to the health of the system—i.e., its dynamic adaptability, creative integration of diversity, problem-solving capacity, etc. This perspective illuminates how organizational hierarchies and algorithmic protocols mandated by educational bureaucracies affect the information-processing structures of mathematics education complex systems. The results of this study indicate that overly-bureaucratized mathematics education systems often suffer from procedural limitations to the necessary phase space of morphological configurations needed for reform. I adapt Stein et al.'s (2009) student-based *Mathematical Task Framework* to the super-systemic level, and show how bureaucratized mathematics education systems' behavior is mostly low-level *memorization or procedures-without-connections*. Bureaucratic mandates like forced digital platformization, scripted curricula, value-added teacher accountability, high-stakes disciplinary pressures upon schools/districts, etc. all contribute to constrained computational capacities. This research suggests ways to leverage educational bureaucracy to encourage higher-level systemic computation like *procedures-with-connections* and possibly *doing mathematics* (e.g., administrative supports for teacher professional learning communities like lesson study) to encourage better super-systemic mathematization.

TEXTBOOK CONCEPTIONS AND STUDENT RESPONSES ABOUT PIVOTS IN LINEAR ALGEBRA

This study investigates how students reason about pivots in linear systems, considering both potential conceptions in a linear algebra textbook and students' responses to open-ended questions addressing the notion. Using Balacheff's cK¢ model, we identified problems, operations, representations, and control structures embedded in the textbook explanations. We then analyzed 68 student responses, identifying which control structures were evident. Findings indicate that students frequently mobilized the Zero Row control structure promoted by the textbook, but also activated control structures related to the number of solutions. Some responses lacked the full constraints of the reduced row echelon form. This suggests that students selectively engage with textbook structures and mobilize strategies from related contexts, offering insights that can inform teaching strategies and the design of instructional materials.

Keywords: Undergraduate Education, Algebra and Algebraic Thinking, Integrated STEM / STEAM, Curriculum

This study is situated within PROTEUS (PreTeXt-Runestone: Open Textbooks for Engaging Undergraduates in STEM), a large-scale project aimed at developing interactive questions for open-source textbooks in calculus and linear algebra using the Runestone Academy platform (Mesa et al., 2023). The textbooks and the platform are freely available, allowing instructors to adopt these materials with their students. The questions developed within PROTEUS include mainly open-response items, fill-in-the-blank questions, drag-and-drop activities, matching tasks, and Parsons problems.

A key challenge in this context concerns the interpretation of students' responses to open questions. Unlike automatically graded question types, open responses require instructors to examine each answer individually in order to infer students' thinking and, when desired, provide personalized feedback. This makes understanding patterns in student reasoning particularly important for both instructional and research purposes.

Within this setting, students may rely on the textbook, and potentially other resources, when responding to open questions before formal instruction on the topic. Motivated by this, we focused on tasks related to pivots to identify from how the concept is presented in the textbook the possible conceptions that can emerge and then contrasting student responses to those possible conceptions.

Theoretical Framework

In this study, Balacheff's cK¢ model (Balacheff & Gaudin, 2009) was chosen because it supports the formulation of possible students' reasoning through the identification of control

structures evident in responses to specific tasks. In this model, knowledge refers to the system of constructs that are institutionalized by a social body, such as the mathematical community, while knowing refers to the personal constructs developed by an individual. A conception is defined by the interaction between a subject's knowing and a mathematical milieu in which a mathematical notion is needed.

Instead of assuming the subject's internal mental processes, the model utilizes a quadruplet connecting problems (P), operators (O), representation systems (R), and control structures (Σ) to provide a model for a student's conceptions about a mathematical notion. By applying this model to textbook analysis, prior work has identified the "potential conceptions" that are intended by textbook authors by examining how expository text and examples can guide readers through specific tasks (Mesa, 2010; Gerami et al., 2024).

A major focus in our study is the control structure, which contains the criteria that is used to decide what actions to take to solve the problem, to determine when an answer is reached, and to establish the correctness or plausibility of that answer. When analyzing student responses, the model allows researchers to treat students' justifications as empirical evidence of their internal control structures (Gerami et al., 2024). Gerami and colleagues found that students often employ a wider and more varied range of control structures than those explicitly presented in their textbooks, which suggests that their "knowing" is shaped by a more complex interaction between instructional design and personal experience (see also Deng et al., in press).

Specifically, we examine student responses to three open questions embedded in the textbook to answer the following research questions (RQ):

- What conceptions of pivots can be inferred from the content related to the pivots in an interactive undergraduate linear algebra textbook?
- What control structures are evident in student responses to open questions about pivots?

In this study, we use the cK¢ model to analyze student responses collected via an interactive textbook, focusing on the *Understanding Linear Algebra* textbook (ULA; Austin, 2025) housed in the Runestone learning academics platform. ULA is an open source and interactive resource, it provides a unique milieu in which students encounter interactive reading questions after the expository text and examples; Runestone captures all the responses students type, making them available for analysis.

We analyzed responses to determine the specific control structures that were called for in answering the questions, and contrasted them with the possible conceptions the textbook would have promoted. The contrast allows a differentiation between knowledge (as evidenced in the textbook) to knowings, from students' responses. We can then determine if the students rely on the control structures demonstrated in the textbook, or if they develop alternative control structures to reason and verify their answers.

Analyzing the ULA textbook is important because its interactive format may make available a wider range of mathematical conceptions to students than traditional printed texts. This digital environment can promote the establishment of multiple connections, between representations, procedures, and meanings (Gueudet et al., 2017).

In this sense, the ULA textbook not only presents content, but also structures how students may interpret and justify mathematical situations (Love & Pimm, 1996). Thus the cK¢ model provides a suitable analytical lens to examine these conceptions as they are embedded in the textbook content and to relate them to the control structures evident in students' responses to open-ended questions.

Methodology

We analyzed Section 1.4 of the Understanding Linear Algebra textbook, entitled "Pivots and Their Influence on Solution Spaces." This section presents a definition of pivot positions, six questions in a Preview Activity, an explanation of the existence of solutions, and a discussion of solution uniqueness. It concludes with a summary containing five open-ended checkpoint questions, followed by a final list of exercises.

Three researchers independently analyzed this section using cK¢ model, based on the two fundamental questions the author proposes: the existence and uniqueness of a system linear solution. The unit of analysis was each worked example in the section that addressed these topics, examining how existence and uniqueness were operationalized.

By examining the problem formulations, the representations mobilized, the expected operations, and the associated control structures, we inferred the mathematical conceptions that the textbook makes available for addressing the proposed problems to address the first RQ. Any disagreements were minor and were resolved through consensus among all authors. A table (Table 1) was constructed to systematize this analysis.

While the first part of the study focuses on the conceptions of pivots made available by the textbook, the second part examines how students mobilize control structures when responding to open questions about pivots.

For that, we focused on the first three PROTEUS questions (parts a, b, and c) from a single activity in the section (runestone.academy/ns/books/published/PROTEUS_Year2_ULA_Template/sec-pivots.html) which share the same opening prompt (Figure 1):

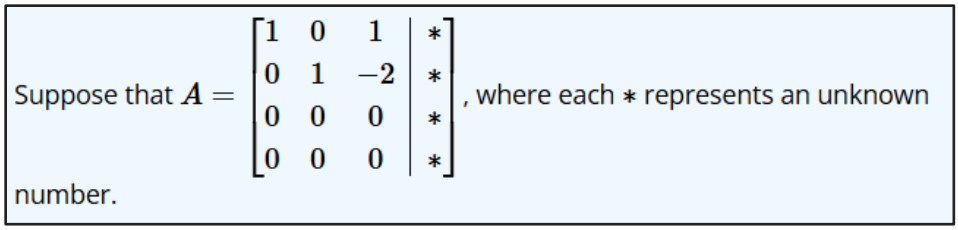

Figure 1: Opening Part of the Prompt

a) If the linear system represented by A is consistent and A is in reduced row echelon form, can we determine any of the unknown numbers? If so, which ones? Explain your thinking.
b) If the linear system represented by A is inconsistent and A is in reduced row echelon form, can we determine any of the unknown numbers? If so, which ones? Explain your thinking.
c) If the linear system represented by A is consistent and A is in reduced row echelon form, can you guarantee that there is a single solution or that there are infinitely many solutions? Explain your thinking.

For space reasons, this paper focuses on the first two questions of the activity. We had access to 82 student responses to these two open-ended questions, collected from courses taught in Fall 2025 by three instructors at different U.S. universities. Responses that did not include an explanation or for which students' reasoning could not be inferred were excluded from the analysis: three from the first question and eleven from the second. The higher number of

exclusions for the second question was related to the question itself, which stated that the matrix was inconsistent; some students therefore appeared to conclude that there was no possible value for the asterisks and did not provide further justification. As a result, the final dataset consisted of 68 student responses.

Based on the textbook analysis and the focus of questions (a) and (b), we identified four control structures relevant to determining the consistency or inconsistency of a linear system. These control structures, their definitions, and illustrative examples from student responses are presented in Table 1.

Table 1: Control Structures Identified and Illustrative Examples from Students' Responses

Name of Control Structure	Definition	Example Response (question, student ID)
Pivot position (CS1_1)	Identify pivot positions in a RREF matrix and determine the corresponding zero and nonzero entries in the same column.	[...] This pivot point must be in R3, because it can be the only nonzero value in its column, and if it were in R4, R3 would contain all zeros, which would not meet the standards for RREF. (Part B, 212I-001-06)
Rightmost column (CS1_2)	Check if the rightmost column has a pivot to conclude consistency/inconsistency.	Either row 3 or 4 would have a number other than 0 in the rightmost column. There would be no solutions. (Part B, 212I-002-04).
Equations (CS2_2)	Translate matrix rows into equations and use their solvability to determine consistency or inconsistency.	If consistent, then the forth column in R3 and R4 have to be 0 for that statement (0 = 0) to be true. I think we'll require more information to determine the other two asterisks. (Part A, 212I-003-02)
Zero row (CS3_2)	Examine zero rows in the RREF matrix to determine consistency based on whether the last entry is 0 or 1.	The 0 rows have to be 0. (Part A, 212I-003-15)

In addition to these four control structures, our broader analysis identified five further control structures related to reasoning about the number of solutions of a linear system (uniqueness versus infinitely many solutions). In the full coding scheme, these control structures were distinguished as CS1_3 through CS5_3.

However, because questions a and b do not address the number of solutions, and instead focus exclusively on consistency and inconsistency, these additional control structures are not examined in detail in this paper. Since they all refer to the same underlying problem, reasoning about solution multiplicity, they were grouped and labeled generically as CS*_3.

The first three authors independently coded all 68 student responses for evidence of the nine identified control structures. Multiple control structures could be assigned to a single response. This analytical process provided the basis for examining how students' reasoning aligned with,

diverged from, or partially reflected the control structures made available in the textbook explanations.

Findings

To address our first RQ related to conceptions of pivots, we examined the textbook explanations regarding pivot positions and the consistency of linear systems. Using the framework, we identified four conceptions embedded in the textbook, three of which are illustrated in Table 2. These conceptions describe the ways in which the textbook guides students to reason about pivot positions and the consistency of systems through specific representations, operations, and control structures.

The first conception corresponds to the Pivot Position control structure (CS1_1), formalized as the following quartet:

P: Determining pivot positions in a matrix.

R: Matrix representation in reduced row echelon form (RREF), with pivot entries visually emphasized.

O: Identify the leftmost nonzero entry in each row of the RREF matrix.

Σ: If row i contains a leading 1 in column j, then (i, j) is a pivot position.

Table 2: Conceptions Presented in the Pivot Section of the Textbook

Elements of the Conception	Conception 1	Conception 2	Conception 3
Problem 2	*Determine whether the linear system is consistent or inconsistent.*		
Representations	Matrix in $R^n \times R^n$ focusing on pivot positions.	Algebraic notation for systems of linear equations.	Augmented matrix focusing on zero rows.
Operations	Find the RREF matrix, find the pivot position.	Find RREF of the matrix, put in terms of variables (x, y, z), and calculate those equations.	Find the RREF matrix, check the 0-row in the coefficient matrix.
Control Structure	There is a pivot position in the rightmost column of the corresponding augmented matrix → conclude inconsistency. There is not a pivot position in the rightmost column of the corresponding augmented matrix → conclude consistency.	If it is possible to relate a row with an equation in the form $0x + 0y + 0z = 1$ → conclude inconsistency. If all the rows related to equations have solutions, like $0x + 0y + 0z = 0$ → conclude consistency.	If there is a 0-row in the RREF matrix in this format $(0 \cdots 0\ 1)$ → conclude inconsistency. If all the 0-rows in the RREF matrix are $(0 \cdots 0\ 0)$ → conclude consistency.

The other three conceptions, illustrated in Table 2, correspond to the control structures Rightmost Column (CS1_2), Equations (CS2_2), and Zero Row (CS3_2). Each describes how students can determine consistency or inconsistency of a system by checking the rightmost column, translating rows into equations, or examining zero rows, respectively.

To address our second RQ, related to the students' control structures, three of the authors independently coded student responses to locate evidence for any of the nine control structures identified across the questions. Multiple codes could be assigned to a single response.

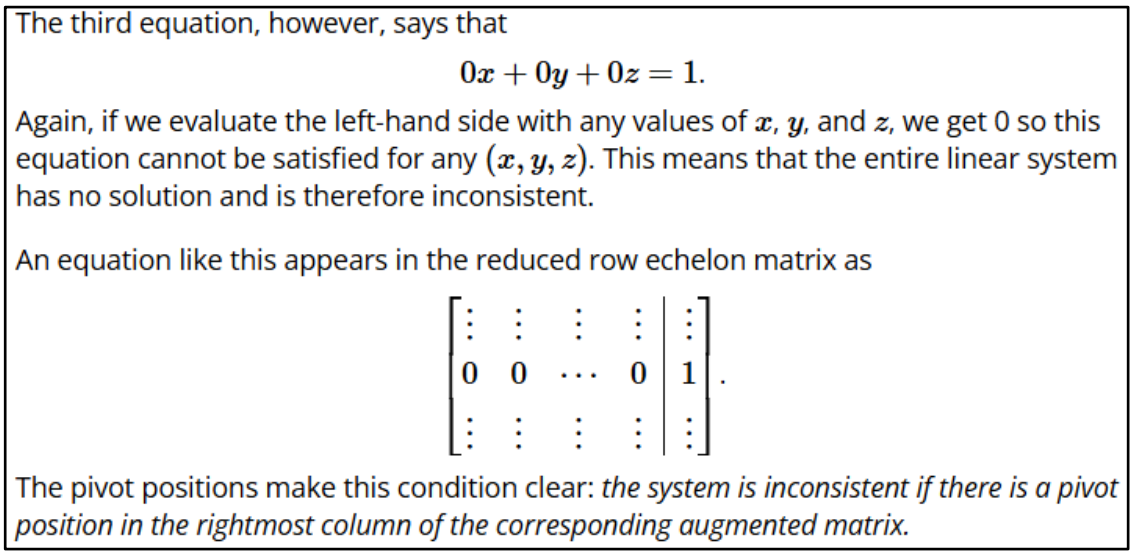
This analytical process provided the basis for examining how students' reasoning aligned with, diverged from, or partially reflected the control structures embedded in the textbook explanations. Across 68 responses, we identified a total of 89 instances of control structures: 52 responses contained a single control structure, 12 contained two, 3 contained three, and 1 contained four.

For instance, one student response for part a illustrates how multiple control structures could be applied in a single answer: "Yes, we can determine a few of the unknown numbers - For the system of A to be consistent the right-hand side of Columns 3 and 4 must be 0 (Rightmost column - CS1_2). The Column 1 and 2 give pivot variables so they can give out numbers (Pivot position - CS1_1)." The frequencies of each code are presented in Table 3.

Table 3: Frequency of Control Structures in the Dataset

Code	Frequency
Pivot position (CS1_1)	8
Rightmost column (CS1_2)	9
Equations (CS2_2)	8
Zero row (CS3_2)	40
Other control structures (CS*_3)	24
Total	89

Looking at Table 3, the most striking observation is that Zero row (CS3_2) was used far more frequently than any other control structure, accounting for over half of the 68 responses. This emphasis mirrors the textbook, where a 0-row is highlighted to differentiate between rows ending in 1 or 0, corresponding to inconsistent or consistent solutions.



This visual highlighted example in the textbook may have influenced student responses (Love & Pimm, 1996). Many student responses focused on this 0-row control structure, describing the values in the last column of Rows 3 and 4 without explicitly connecting these entries to the pivot positions in the RREF matrix.

For example, some responses suggested that the unknown numbers in Rows 3 and 4 could be arbitrary to indicate inconsistency, while the top entries were left unspecified: "We can determine that the unknown numbers in Rows 3 and 4 can be non-zero, since if they are, the linear system cannot be consistent. Apart from that, the unknowns in Rows 1 and 2 can be anything, and it will still be inconsistent" (using Zero row as the control structure).

Considering the pivot positions associated with the RREF matrix would provide additional structure for interpreting the last column, indicating that the first two entries, and the last one should be 0 and that only the Row 3 entry should be 1. In this sense, the responses illustrate reasoning about inconsistency that does not yet fully integrate the RREF structure.

In the textbook, the 0-row ending with a 1 is visually emphasized, while the other entries are represented with dots (Figure 2). These visual cues appear to guide student attention to the last column, highlighting the connection between row structure and consistency, while leaving the other entries open to interpretation. This alignment with Balacheff and Gaudin (2009) reflects how student response patterns can emerge from the textbook's structure, reinforcing the idea that a conception is characterized as a situated knowing.

In addition, the translation of the 0-row ending with 1 into the equation $0x + 0y + 0z = 1$ emphasizes the absence of a solution. This explicit representation may have contributed to reasoning that any nonzero number in that position could generate inconsistency, without necessarily considering how the pivot positions in the RREF matrix constrain the other entries.

The third equation, however, says that

$$0x + 0y + 0z = 1.$$

Again, if we evaluate the left-hand side with any values of x, y, and z, we get 0 so this equation cannot be satisfied for any (x, y, z). This means that the entire linear system has no solution and is therefore inconsistent.

An equation like this appears in the reduced row echelon matrix as

$$\left[\begin{array}{cccc|c} \vdots & \vdots & \vdots & \vdots & \vdots \\ 0 & 0 & \cdots & 0 & 1 \\ \vdots & \vdots & \vdots & \vdots & \vdots \end{array}\right].$$

The pivot positions make this condition clear: *the system is inconsistent if there is a pivot position in the rightmost column of the corresponding augmented matrix.*

Figure 2: Textbook Excerpt Illustrating Control Structures for Linear System Solutions

Another important observation from Table 3 is the high number of responses using CS*_3. Many students applied reasoning associated with the number of solutions of a linear system (CS*_3) when responding to questions about consistency (Parts A and B).

For example, to part a when the matrix is consistency, some stated, "We can't determine the value of a free variable" or "No, because there is a free variable," while when the matrix is inconsistency (Part B), one wrote: "We will not be able to, because if the linear system is inconsistent, there will be no solution."

These responses indicate that students were reasoning from the perspective of the system's solutions rather than focusing on the values of the entries in the rightmost column (the asterisks). In other words, students often mobilized control structures related to the number of solutions to justify what could or could not be inferred about individual entries, showing how these structures can be activated across related but distinct problem contexts.

Discussion and Conclusions

This study examined how pivot positions are presented in an interactive linear algebra textbook and how students activate related control structures when responding to open-ended questions. Regarding our first RQ related to conceptions of pivots, the textbook conveys several conceptions of pivots, emphasizing the identification of pivot positions, the connection between

rows and equations, the role of zero rows, and the significance of the rightmost column in determining consistency. These conceptions are embedded in visual and symbolic representations, which structure the potential ways students may interpret and reason about linear systems (Mesa & Goldstein, 2017).

In addressing the second RQ related to students' control structures, we observed that they activated a range of such structures in their responses. Most responses reflected reasoning about zero rows, and number of solutions. A particularly interesting pattern was that, when asked to reason about consistency, some students mobilized control structures more closely associated with determining the number of solutions. This suggests that students may treat consistency and number of solutions as closely connected, or even interchangeable, even though they involve different levels of classification. While these control structures are mathematically relevant, they were not always directly aligned with the question being asked. This demonstrates how student reasoning can selectively engage structures promoted in the textbook while also suggesting areas where additional scaffolding might be beneficial.

At a broader level, this analysis highlights the alignment and divergence between the conceptions embedded in the textbook and the control structures evident in student responses. This comparison is grounded in the understanding of the textbook as an instrument for acquiring mathematical knowledge (Rezat, 2006). While the textbook provides explicit cues for identifying pivots, student interpretations do not always fully exploit these available frameworks. These insights suggest that instructional support could be enhanced through exercises that explicitly bridge the relationships between pivots, zero rows, and the reduced row echelon form.

While this analysis provides valuable observations, the number of responses analyzed here was relatively small (68 in total), which may limit the generalizability of the findings. However, we anticipate receiving approximately 300 additional responses, which could provide a more comprehensive understanding of the control structures students employ when reasoning about pivots.

Future work should extend this analysis to a larger dataset to examine how control structures are used across a broader sample and to refine our understanding of student reasoning patterns in the context of pivot positions. Such work can also inform the development of teaching interventions and learning materials, providing guidance both for instructors teaching pivots and for textbook authors designing instructional content.

This paper describes a quantitative analysis of students' retention of content knowledge and the predictability of their final grade based on their mastery of content in a standards-based College Algebra course. The sample consisted of semester and final exam mastery data, along with final grades, for 39 students enrolled in a single section of College Algebra. Our analysis consisted of a matched-pairs analysis of students' semester and final exam mastery scores, along with various statistical diagnostics and measures, such as Goodman-Kruskal gamma and Ridge Ordinal Regression, to identify central standards with significant predictive ability for final grade. Our results identify four standards and two themes that exhibit significant predictive power for students' final grades, which we connect to the literature on students' thinking on these topics.

Keywords: Precalculus, Standards, Assessment, Data Analysis and Statistics

Alternative grading (AG) practices (e.g., standards-based grading, specification grading, ungrading) are commonly used in K-12 mathematics settings in the United States and are increasingly used in postsecondary classrooms (Lewis, 2022). Researchers have shown that AG implementation can yield positive affective outcomes for students, such as reduced test anxiety (Harsy & Hoofnagle, 2020; Henrikson et al., 2020) and a re-envisioning of office-hours conversations and assessments as learning opportunities (Collins et al., 2019; Zimmerman, 2020). Various researchers have also shown that AG students perform no worse than their peers in traditionally graded classes on cumulative exams (Harsy & Hoofnagle, 2020; Morris et al., 2024) or standardized tests (Pollio & Hochbein, 2015; Welsh et al., 2013). At the College Algebra level, there is a litany of research categorizing students' thinking about using quantitative reasoning to model real-world phenomena with functions (Pollio & Hochbein, 2015; Welsh et al., 2013), logarithms (Kuper & Carlson, 2020; Weber, 2002), and exponential functions (Ellis et al., 2016). However, there is very little research relating students' performance on individual standards to their success in College Algebra (Eckman et al., in press), retention of knowledge on a cumulative final exam, or the ability of these data to predict final course grade. The purpose of this paper is to present a quantitative analysis of the relationship between students' final grade performance in one section of a coordinated AG college algebra course, their mastery of individual standards during the semester, and retention of content knowledge on a cumulative final exam. Our discussion will be framed around the following research questions (RQ):

1. Which College Algebra standards showed the greatest retention differences from semester to final exam?
2. What is the independent effect of each standard on final grade after controlling for possible statistical interactions between standards?

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

Theoretical Background and Course Structure

The AG College Algebra course (the equivalent of a U.S. high school Algebra II course) that we describe in this paper was constructed using the Four Pillars of Alternative Grading (Clark & Talbert, 2023) and Collins et al.'s (2019) characteristics of Mastery-based Testing (MBT). In this section, we describe the structure of our course using the Four Pillars.

Pillar 1: Clearly Defined Standards

To our knowledge, there is no widely accepted definition among AG proponents for the word "standard." For instance, Clark and Talbert (2023) leave decisions about what content to cover and the determination of mastery benchmarks to the instructor's discretion, and Collins et al. (2019) state that standards should be clearly communicated on study guides and assessments.

To construct the original 18 standards for College Algebra, we evaluated a common final exam using the principles of open and axial coding from grounded theory (Strauss & Corbin, 1998). The process included creating lists of content skills students needed to answer exam questions (open coding) and grouping these skills into topics (axial coding). The 18 standards, included in Table 1 below, addressed four themes: general properties of functions and their graphs (8 F standards), exponential and logarithmic functions (5 EL standards), polynomial and rational functions (4 PR standards), and polynomial theory (1 PT standard). We consider our list of standards to be a work in progress and continually evaluate the need for wording updates, combinations, or new types of standards (e.g., synthesis standards).

Table 1: College Algebra Standards in the Approximate Order of Instruction

Code	Standard Summary
F1	Distinguish and interpret functions and non-functions in various forms.
F2	Recognize parent or toolkit functions in graphical or symbolic form.
F3	Given a function in symbolic, tabular, or verbal form, identify its domain and range.
F4	Identify features of a function graph and describe intervals over which these occur.
F5	Find the inverse of a one-to-one function and interpret it in context.
F6	Identify or compute the average rate of change or difference quotient of a function.
F7	Algebraically or graphically transform a function through scaling or rigid motions.
F8	Perform function arithmetic or composition. Identify the domain of the new function.
EL1	Graph an exponential function and identify algebraic or graphical parts of the function.
EL2	Graph a logarithmic function and identify algebraic or graphical parts of the function.
EL3	Convert between exponential and logarithmic form. Use logarithm properties.
EL4	Solve exponential and logarithmic equations algebraically and provide exact answers.
EL5	Model and solve applications of exponential functions.
PR1	Identify and graph linear, quadratic, and piecewise functions.
PR2	Model and solve applications of linear and quadratic functions.
PR3	Graph or write rules for polynomials using roots, multiplicities, and end behavior.
PR4	Construct graphs of rational functions based on their properties.
PT	Determine the complex zeros of a polynomial and write it in factored form.

Pillar 2: Helpful Feedback

AG College Algebra instructors provide weekly assessment and reassessment opportunities and give specific, targeted feedback to student work on these items. Collins et al. (2019) stated

that the purpose of such feedback is not to penalize students but to help them progress toward mastery of the course material by highlighting areas that require further study.

Pillar 3: Marks Indicate Progress

Instructors use a binary system to provide marks on students' assessments and reassessments: *pass* and *not pass yet* (Clark & Talbert, 2023). Instructors base *pass* marks on conceptual mastery of a topic and utilize *not pass yet* marks to indicate the need for additional reflection on course material, rather than penalizing (often computational) mistakes (Collins et al., 2019).

The number of standards a student masters (passes twice) throughout the semester constitutes the primary measure of final course grade. Table 2 presents the letter grade initially assigned to students before other modifiers, such as homework and final exam performance, are applied. Consequently, students' final letter grade in the course indicates the amount of AG College Algebra content for which they have exhibited proficiency. When we make claims in the results about individual standards and students' retention (RQ1) or final-grade predictability (RQ2), we do so to highlight important topics in a College Algebra class.

Table 2: Letter Grade Scale for Standards Mastered

Grade	A	B	C	D	F
Standards Mastered	17–18	14–16	11–13	9–10	0–8

Pillar 4: Reattempts Without Penalty

A major component of our AG College Algebra class is that students can reassess, outside of class, standards they have previously assessed twice in class but have not yet mastered. Clark and Talbert (2023) call this process *reattempts without penalty*. At our institution, students complete a form to schedule reassessments in a dedicated reassessment room, which student proctors monitor. In this report, we compare students' semester mastery status after (re)assessments with their performance on the same standards on the final exam (RQ1).

Methodology

Data Collection and Final Exam Makeup

Sample description. The students in this sample were enrolled in a single section of College Algebra at a mid-sized public university in the Pacific Northwest during the Fall 2025 semester. The first author served as the primary instructor of this course and was the only College Algebra instructor to offer a cumulative final exam. We collected three types of instructor-provided data: students' semester standard mastery scores based on (re)assessment grades, students' performance on each standard on the final exam, and students' course grades.

Description of assessments, reassessments, and final exam. The course assessments and reassessments were single-page quizzes containing 1–3 questions per standard. In contrast, the final exam was a nine-page assessment in which the standards were clearly labeled, and each question corresponded to a different standard. Unlike regular assessments, the final exam used three evaluation marks: "not pass," "half-pass" (i.e., the problem started appropriately but contained a major error), and "pass" (i.e., the problem was completed with only minor errors).

Predictor variables, response variable, and sample refinement. We determined two classes of ordinal predictor variables based on the instructor's grading scheme. An ordinal variable describes a scale that is logical and ordered, but whose distances between values are

unknown or undefined. First, we developed a four-point scale to assess students' mastery of each standard during the semester (1 = not assessed; 2 = not passed; 3 = partially met; 4 = met). We created a similar four-point scale for students' standard performance on the final exam (1 = not assessed, 2 = not passed, 3 = half-passed, 4 = met). During this process, we removed standard PT from consideration because it was not included in the final exam. We used students' final letter grade in the course as our response variable (i.e., A, B, C, D, F). However, because few students received D's, we collapsed the scale into four levels: Below-C-level, C-level, B-level, and A-level students. Our final sample comprised 39 students and their corresponding final-grade data, which we related to their mastery of two sets of 17 standards (i.e., the semester and final exam).

Data Analysis and Explanation of Statistical Tests and Measures

Our data analysis consisted of two stages: matched-pair analysis to measure students' retention of the ability to meet standards, and the identification and validation of important predictor variables while controlling for small sample size and multicollinearity. We now describe the statistical procedures employed at each stage.

Matched-pair analysis (RQ1). To conduct our matched-pair analysis, we computed the difference between each student's mastery level at the end of the semester and their mastery level on the final exam. We then calculated the mean change in mastery per standard across the observations. A negative change indicated that, on average, students' mastery scores were lower on the final than their semester mastery scores.

Identifying and validating important predictor variables (RQ2). We used several statistical methods to identify significant standards whose semester mastery values predicted students' final grades. Due to the small sample size and multicollinearity (e.g., some standards covered similar topics), we employed four levels of analysis. First, we calculated the Goodman-Kruskal gamma (γ) for each standard and used Fisher's Exact test to identify significant predictors of final grade while ignoring multicollinearity. Second, we examined multicollinearity among these standards by evaluating the correlation matrix, computing variance inflation factors (VIFs), and using alias detection to identify variables that are nearly perfectly correlated. Third, we used the Least Absolute Shrinkage and Selection Operator (LASSO) to remove variables with high multicollinearity and Ridge Ordinal Regression to construct a model to predict students' final grades. We note that we chose to use these modeling methods rather than the standard multinomial model due to our small sample size. Finally, we performed a partial correlation analysis to reconcile paradoxes and determine the independent effect of each standard. Through our analysis, we identified two standards that showed substantial loss of retention between semester-standard mastery and the final exam and were important predictors of final course grades. We report these standards in the results of this paper.

Results

RQ1: Retention Differences Between Semester Mastery and Final Exam Performance

Our analysis of the mean mastery level difference per standard on the final exam and during the semester revealed a negative overall and relative change for all but one standard, implying that students' final exam mastery levels were lower, on average, than their semester mastery level (e.g., 4 = mastery during semester, 3 = half pass on final). We did not find this result surprising. Still, the level of retention loss varied by standard, as evidenced by Tables 3a and 3b below. We draw two conclusions from this data. First, standards related to functions covered early in the semester (e.g., F1, F4–F6) generally exhibited higher retention loss, and standards covered late in the semester (e.g., EL2–EL4, PR3–PR4) exhibited lower retention loss. Second, two standards, EL5 and PR2, were covered late in the semester and showed a high relative loss

in retention. This implied (to us) that standards EL5 (exponential modeling problems) and PR2 (linear modeling and optimization) merited further analysis regarding their impact on final-grade predictability.

Table 3a: Lowest Retention Standards

Standard	Mean Semester Mastery	Mean Final Mastery	Relative Change
F6	3.41	2.68	–21.41%
F1	3.90	3.27	–16.15%
PR2	3.13	2.64	–15.65%
F5	3.49	2.96	–15.19%
F4	3.90	3.34	–14.36%
EL5	3.31	2.84	–14.20%

Table 3b: Highest Retention Standards

Standard	Mean Semester Mastery	Mean Final Mastery	Relative Change
EL2	3.05	2.87	–5.90%
PR4	2.59	2.46	–5.02%
EL4	3.00	2.90	–3.33%
PR3	2.92	2.90	–0.68%
EL3	3.08	3.14	+1.95%

RQ2: Independent Effects of Standards on Final Grade Predictability

Identifying an initial list of important predictor standards. Our initial determination of the Goodman-Kruskal gamma (γ) and use of Fisher's Exact Test for each student's standard semester mastery level in relation to their final semester grade indicated that standards EL2–EL5 and PR2 were likely important predictive standards whose mastery level could help predict final grade. The gamma values for standards F1, F2, and F4 were extremely high (near 1), but Fisher's Exact Test showed these standards were not statistically significant ($p > 0.05$), indicating that these standards could be aliased, meaning they are linearly dependent. In the context of our work, the term "aliased" implies that removing all but one of the aliased standards (i.e., F1, F2, F4) from the model would not affect the model's predictive power.

Addressing multicollinearity with the identified predictor standards. We used three multicollinearity diagnostics to refine further our list of important predictor standards: the correlation matrix, VIF, and alias detection. Through these diagnostics, we determined that standards F1, F2, and F4 were indeed aliased, that standards PR2 and EL5 were highly correlated ($r = 0.795$), and that standard PR2 had a high VIF score (VIF $=$ 5.94; any VIF score higher than 5 is considered significant). Consequently, when we used LASSO and Ridge Ordinal Regression to identify important standards to include in our model, we found a paradoxical result. Specifically, the LASSO model selected standards PR2 and EL5, but the Ridge Ordinal Regression only identified students' semester mastery level for standards EL2, EL4, and EL5 as having significant independent effects on a model to predict students' final grades, claiming that the independent effect of standard PR2 was not significant ($p = 0.119$). Since we considered PR2 and EL5 to be topically different (optimization, exponential modeling) but to share some problem-solving similarities (constructing a function to model a real-world scenario), we elected to further investigate standard PR2 by conducting a partial correlation analysis.

Partial correlation analysis to determine the independent effect of standard PR2. The purpose of the partial correlation analysis was to test whether standard PR2 added unique predictive value to our model while controlling for standard EL5. We previously noted in our analysis that the standard PR2's high VIF score (5.94) indicated that it explained 83.2% of the variance shared with the other LASSO-selected standards (e.g., EL2, EL4, EL5). The variance percentage in the preceding sentence was calculated by converting the standard formula $VIF =$

$\frac{1}{1-R^2}$ to the form $R^2 = 1 - \frac{1}{VIF}$. Additionally, the correlation matrix indicated a strong bivariate correlation between standards PR2 and EL5 ($r = 0.795$, 63.2% shared variance; obtained by squaring r). In partial correlation analysis, a high correlation ($r > 0.5$) indicates that a standard adds unique predictive power to the model, even if it is highly correlated with another standard. In our case, the partial correlation analysis of standard PR2, while controlling for EL5, revealed a high and significant correlation value ($r = 0.598, p < 0.001$). We draw two conclusions from the partial correlation analysis. First, despite the high multicollinearity between PR2 and EL5, the partial correlation analysis confirmed that standard PR2 retains significant independent predictive value ($r = 0.598, p < 0.001$) after controlling for EL5. Second, we conjecture that the Ridge Ordinal Regression conclusion that standard PR2 is not a significant predictor for students' final grades ($p = 0.119$) is likely due to an overly large penalty applied by the analysis to standard PR2 based on its high VIF score, and is not indicative of an incompatibility with predicting final grades. These conclusions led us to estimate the practical effect on students' overall semester grade using an odds ratio based on their performance on four standards: PR2, EL2, EL4, and EL5.

Odds ratio and the relationship between predictor standards and final grade. The odds ratios that we calculated for standards PR2, EL2, EL4, and EL5 estimate a multiplicative increase in the odds that moving up one level on the standard mastery (e.g., moving from a "partially met" to a "fully met" on standard PR2) will increase the students' final grade measure (e.g., moving from a "B" grade to an "A" grade). We note that the odds ratio does not distinguish between starting mastery and starting grade levels and only measures the odds that, given a one-unit increase in mastery, the student's current grade level will also increase.

The following table, Table 4, shows the odds ratios for standards PR2, EL2, EL4, and EL5. For instance, the odds ratio for EL5 indicates that students who improve by one mastery performance level during the semester are 4.41 times more likely to achieve the next higher letter grade category, holding all other standards—including PR2—constant. We make two notes about the odds ratios. First, the high odds ratios for PR2, EL2, EL4, and EL5 reinforce the predictive power of these standards for students' final grades based on current mastery. Second, the overarching topical ideas connecting these four standards, which the odds ratios imply corresponded with an increased final grade in our sample of College Algebra students, included interpreting and solving exponential and logarithmic equations (EL2, EL4, EL5) and modeling real-world phenomena with functions and using these functions to make inferences about quantities and their values (PR2, EL5).

Table 4: Odds Ratio of Select Standards in Relation to Final Grade Improvement

Standard	PR2	EL5	EL2	El4
Odds Ratio	2.73	4.41	3.69	3.16

Discussion and Conclusion

The aim of this paper was to address two ideas related to students' performance in College Algebra coursework: retention of specific topics within the course (RQ1) and the topics whose mastery appeared to have the strongest predictive power for students' final grades (RQ2). Through our analysis, we determined that students' semester-long mastery of topics related to logarithmic functions (EL2: graphing; EL4: algebraic solving), exponential functions (EL4: algebraic solving; EL5: modeling), and quadratic functions (PR2: optimization) had the greatest

predictive power for their final grades. We further determined that students exhibited little relative retention loss on some standards (EL2, EL4) and large retention loss on others (PR2, EL5) on the final exam. Taken together, these results indicate that, for our sample, the most central standards related to retention loss and final grade predictability were PR2 and EL5.

While we do not claim generalizability of our results due to our small sample size, our findings both reinforce and extend prior research on students' thinking about precalculus topics. For instance, our finding that students' lowest relative retention of mastery ability is associated with modeling reinforces Thompson and Carlson's (2017) theoretical discussion of the importance of reasoning about quantities. We extend their results by providing empirical evidence that students may struggle to maintain their ability to quantitatively model real-world scenarios using algebraic rules over time. Additionally, our identification of College Algebra students' mastery of topics related to exponential and logarithmic functions as central to models predicting their final grades reinforces the importance of Ellis et al.'s (2016) and Kuper and Carlson's (2020) work on students' thinking about these topics. Our results extend these findings by indicating that mastering exponential and logarithmic functions is not only important for developing mathematical acumen but may also be more strongly related to students' final grades in precalculus coursework than other topics.

Our results may also have practical implications for teaching College Algebra or precalculus courses. For instance, our findings suggest a potential need for instructors to be intentional when planning instruction on exponential functions, logarithmic functions, and modeling problems. Additionally, our results indicate that students may find it easier to retain the ability to perform basic algebraic or graphing tasks related to exponential and logarithmic functions than to construct (and draw inferences from) quadratic and exponential models for real-world scenarios. Taken together, our results suggest that instructors might consider reflecting on the structure and pacing of precalculus courses, and on revisiting ideas related to modeling, exponential functions, and logarithmic functions.

While our study identifies important potential foci for improving precalculus coursework, it has practical limitations that could be addressed in future research. For example, our sample consisted of 39 students from a single College Algebra section. Consequently, we cannot claim generalizability of our results, and further work is needed to verify and extend the ideas presented in this paper. Additionally, this paper does not provide empirical evidence on how to modify precalculus curricula to improve students' retention of ideas related to modeling, exponential functions, or logarithmic functions. Instead, we highlight the need for further work to identify practical ways to support students' mastery of these topics, particularly at the curricular level. Finally, we collected our data from a course that used AG methods, suggesting the need to verify our results in a traditionally graded course, though this process may be more difficult due to the lack of clearly defined standards. We welcome future research in these areas.

In this case study, we examine the challenges faced by a strong multivariable calculus student when working on semi-structured interview tasks in differential calculus of functions of two and three variables. We use the notion of types of relations between schema components of the Action-Process-Object-Schema (APOS) theory to illustrate specific relations that even proficient students often fail to develop. Results reveal different aspects of directional derivatives, the gradient vector, and their relationship, that were particularly difficult for this student and can thus be expected to challenge most students.

Keywords: Advanced Mathematical Thinking, Calculus, Cognition

Introduction and Literature Review

Multivariable calculus is crucial for modeling a wide range of phenomena. Therefore, it is important to learn how to best support students' understanding of this subject. Here, we are primarily concerned with multivariable differential calculus, which is used for modeling change. Starting with the early work of Tall (1992) and Yerushalmy (1997), a growing body of research has emerged on the teaching and learning of multivariable differential calculus. This includes partial and directional derivatives (Borji et al., 2024, 2025; Martínez-Planell et al., 2015, 2017; Weber, 2015), gradient vectors (Moreno-Arotzena et al., 2020), slopes in three dimensions (McGee & Moore-Russo, 2015), total differentials (Trigueros et al., 2018; Lankeit & Biehler, 2024), and other topics in the multivariable differential calculus (Harel, 2021), including schema construction (Trigueros et al., 2025). While these studies provide information about students' understanding of differential multivariable calculus, much remains to be understood about how students relate the different types of derivatives.

Multivariable calculus introduces new challenges for students transitioning from two to higher dimensions. Part of the difficulty stems from the extra information that must be imagined with the increase in dimension, transforming drawings that would be "close" representations in a two-dimensional (2D) setting into "distant" ones in a three-dimensional (3D) context (Parzysz, 1988). For example, the graphical representation of secant lines to the graph of a one-variable function at a point and how they may approach a tangent line is straightforward on a 2D figure, but it is challenging to visualize, draw, and relate to the symbolic representation in the 3D case of a partial derivative of a two-variable function. This increased cognitive demand can hinder students' visual thinking (Eisenberg & Dreyfus, 1991), which is essential in calculus.

As dimensions increase, the possible interpretations of equations and the cognitive demand to understand their meanings both increase. For example, the equation $x = 1$ can represent a point on the number line, a line in 2D, or a plane in 3D space. The interpretation depends on the dimensions of the geometric context. Another illustration is when students who instinctively think of the equation $x^2 + y^2 = 1$ as a circle on a plane must interpret it as a right circular cylinder in 3D space. In general, students accustomed to performing procedural actions on symbolic expressions often find it challenging to have their mathematical activity depend on a

geometric context that they must now anticipate and imagine. In the case of two-variable functions, the simplest operation a student can perform is to substitute a number for a single variable in an expression of the form $z = f(x, y)$. However, frequently students do not understand the geometric meaning of the result (e.g., Trigueros & Martínez-Planell, 2007, 2010). These researchers also report that students struggle to represent the domain of two-variable functions in 3D space, where students must represent an ordered pair (x, y) as a triple $(x, y, 0)$. The interpretation gap between 2D and 3D also occurs in the differential calculus of two-variable functions. For example, a direction vector of a directional derivative is a vector with two components, while the function itself is represented by a surface in 3D space. Hence, to represent the direction vector of a directional derivative together with the function, the student must interpret the direction vector $\langle d_1, d_2 \rangle$ as $\langle d_1, d_2, 0 \rangle$. This is not obvious to beginning students. Rather, since the surface is a 3D object, students expect a direction vector to be a vector in 3D, possibly with a non-zero z component. Our study underscores situations where students need to bridge the gap between 2D and 3D representations. The following research question guided this study: What can we learn about the 2D and 3D representation gap in the differential multivariable calculus from the case study of one student?

Theoretical Framework

A schema, as understood in APOS theory (Arnon et al., 2014), is a coherent collection of actions, processes, objects, and other schemas dealing with a specific mathematical concept where the components of the collection are interrelated in such a way that an individual can tell when a problem situation falls within the scope of the schema. Schemas are in a constant state of evolution as individuals encounter new tasks and learn more mathematics. To work with schemas, a person may model them as a collection of components and different relations between them. For example, some of the components of multivariable differential calculus are function, slope, tangent plane, directional derivative, partial derivative, total differential, and gradient. Trigueros (2019) introduced three types of relations that group two or more components. These are useful for describing the evolution of a schema. A *correspondence relation* is one established out of habit or repetition, where the individual cannot explain the relation or needs help to establish it. A *transformation relation* involves some explanation or justification for how changes in one component are related to changes in another, but this might not be consistent across different problem situations. A *conservation relation* is fluidly and consistently established across different problem situations. It occurs when students show that related structures can be used interchangeably.

Methodology

This is part of a larger study examining students' understanding of the differential calculus of functions of two variables, which involves 59 students in two sections taught by the same instructor (the second author). Ten students agreed to participate in two, one-hour, semi-structured interviews (conducted by the lead author) about their understanding of multivariable differential calculus. We focus only on Jackson. He earned a course grade of A, was considered to be among the top students in the course, and performed much better in the interview than the other participants. The case study assumes that mathematical situations in which Jackson struggled are likely to challenge other students, as was indeed the case, and so it concentrates on examining these situations. Jackson's class used the digital resource CalcPlot3D (Seeburger, 2016) and 3D-printed surfaces for multiple collaborative, investigative activities. The instructor used a "locally linear approach" (Borji et al., 2024). To follow this approach, she included

explicit discussions of slopes in three dimensions (3D), leading to an exploration of vertical change on a plane symbolized by $\Delta z = \Delta z_x + \Delta z_y = m_x \Delta x + m_y \Delta y$. Then she used vertical change on a plane to discuss the point-slopes equation of a plane, $z - c = m_x(x - a) + m_y(y - b)$, the tangent plane at a point, $z - f(a,b) = f_x(a,b)(x - a) + f_y(a,b)(y - b)$, and directional derivatives, viewed as $D_{\langle u,v\rangle} f(a,b) = \frac{\text{vertical change}}{\text{horizontal change}} = \frac{f_x(a,b)u + f_y(a,b)v}{\|\langle u,v\rangle\|}$.

An interview instrument consisting of nine multi-part tasks was used. For the sake of this case study, we consider and renumber portions of four of these tasks.

Suppose the graph of $z = f(x,y)$ is as follows (Figure 1, top left):

a) State the sign (positive, negative, zero) of $D_{\langle -2,0.5\rangle} f(4,0)$. Justify your answer.
b) Represent the direction vector $\langle -2,0.5\rangle$ in the drawing.
c) If $H(t) = D_{\langle 1,2\rangle} f(t,0)$, draw how the graph of H may look for $2 \le t \le 4$.

The plane in Figure 1 (top right) is tangent to the graph of a differentiable function $z = f(x,y)$ at the point $(1,2,0)$.

d) Use the graph of the given tangent plane to find $D_{\langle 1,1\rangle} f(1,2)$.
e) Can you relate the computation you did in the previous part (a) to Figure 1 (bottom left)?

(For f as in Figure 1, bottom right) Approximately in which direction $\vec{v}$ does $D_{\vec{v}} f(2.5,1.5)$ appear to attain its largest possible value? (Give the answer as an approximate direction vector $\vec{v}$ in algebraic form.) Its smallest possible value?

(For f as in Figure 1, bottom right) Suppose H is defined by $H(x,y,z) = z - f(x,y)$. Let P be the darkened point on the surface, that is, P has coordinates $\big(2.5,1.5,f(2.5,1.5)\big)$. Approximately in which direction does the gradient vector $\nabla H(P)$ point? Explain.

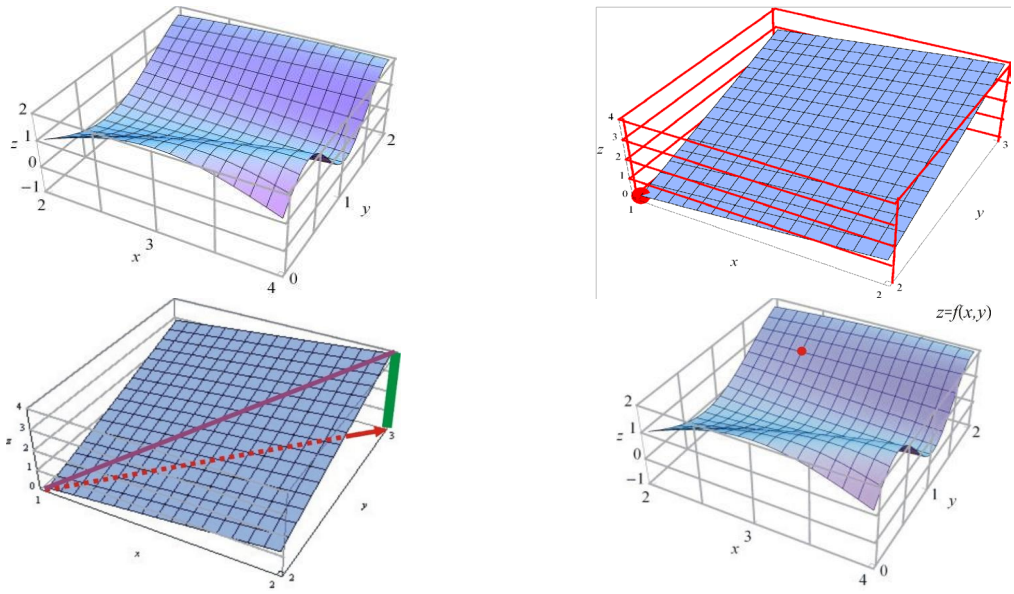

Figure 1: Figures for Task 1, 2, 3, and 4

The tasks were designed to provide insight into students' understanding of different components of the differential multivariable calculus and the relations students established between them. Task 1 was designed to provide opportunities to demonstrate a relation between the components of Function (F) and Directional Derivative (DD), possibly mediated by the Slope (S) component. Task 2 allowed consideration of the relation between the components of tangent plane (TP) and DD, while perhaps including the components of S and Gradient (G). Task 3 allowed further exploration of the relation between the components of DD, F, and G. Task 4 provided an opportunity for the student to relate F and G.

The analysis identified the components students related, which may have differed from researchers' expectations, as well as the type of relation established for each task. The analysis was done independently by two researchers then discussed by all until a consensus was reached.

Results and Discussion

In Task 1a, Jackson was given the graph in Figure 1 (top left) and asked to state the sign of $D_{\langle -2,0.5\rangle} f(4,0)$. He used an available 3D-printed surface corresponding to the one in the figure, rather than using the given graph. He easily determined the sign and justified it by pointing and using gestures on the 3D-printed surface:

> Jackson: I say it's positive … because from where I've got my finger at four, zero, if I were to move to the left in the *x* direction and up in the *y* direction, I'm moving uphill, almost, on this surface. So, I see the directional derivative is positive.

So, in this task, Jackson showed a transformation relation (because of his justification) between the components F and DD. Then, in Task 1b, he was asked to represent the direction vector $\langle -2,0.5\rangle$. Instead of drawing on the given graph, he again used the 3D printed surface.

> Jackson: Okay. So let me get this, alright, right here, and I draw it [did not draw; he physically represented the vector with a pencil] like $-2,0.5$. Something like this [placed the pencil tangent to the surface at the point corresponding to $(4,0,f(4,0))$].
>
> Interviewer: Is that vector pointing up? [since the represented vector had a positive *z* component]
>
> Jackson: Yeah, in the positive *y* direction.
>
> Interviewer: Is the direction vector a vector in two dimensions or three dimensions?
>
> Jackson: Two dimensions. So, okay, so on the surface. So, right here is a vector in two dimensions, where it's pointing up in the positive *y* direction and left negative 2 units [placed the pencil horizontally below the 3D-printed surface in the $\langle -2,0.5\rangle$ direction on what would be the *xy* plane].

Initially, Jackson placed the pencil tangent to the surface with a positive *z* component. Seeing this, the interviewer asked whether the vector was "pointing up." Jackson seemed to have interpreted "up" to mean in the *y* direction, and thus answered "yeah, in the positive *y* direction." However, with further questioning, Jackson realized the nature of the problem with his physical representation ("two dimensions, so okay, so on the surface …") and placed the pencil horizontally, as expected. The relation shown in this task between the components of F and DD was labelled as a correspondence relation because the initial representation of the direction vector as tangent to the surface seemed to be motivated by habit or repetition.

Martínez-Planell et al. (2015) observed that even high-performing students struggle with the geometric interpretation of the direction vector in a directional derivative. Jackson also experienced some difficulty. This suggests that geometrically representing a direction vector in the context of a directional derivative is not trivial for students. Directional derivative at a point was discussed in class in terms of the slope of a tangent line in 3D. This could possibly lead students to confuse the direction vector with the tangent line. From the other interviews in the larger study, it was noted that students often think of directional derivative as a direction or tangent vector.

Using the same surface, in Task 1c, Jackson was asked to describe how $D_{\langle 1,2\rangle}f(t,0)$ would change over the interval $2 \leq t \leq 4$. He ran his index finger pointing in the direction $\langle 1,2\rangle$ over the edge of the 3D-printed surface corresponding to $y = 0$ and was able to solve the task:

> Jackson: (2,0) to (4,0), direction $\langle 1,2\rangle$, going to the right.… It seems like it's gonna be changing sign, almost, yeah, from 2 to 3 changing sign, because when I am at (2,0), for instance, it seems like it's pointing towards negative z values, and by the time I make it to (4,0), it's pointing towards positive z values.

Jackson also drew (an approximation of) the graph of $H(t) = D_{\langle 1,2\rangle}f(t,0)$ correctly (Figure 2). When Jackson says, "it's pointing towards negative z values" and later "it's pointing towards positive z values", he seems to be referring to the tangent line and attending to whether the line points up or down. His argument seemed to be guided by the tactile determination of the change in inclination (from downwards to upwards) in the surface as he moved his finger from the point corresponding to (2,0) to that of (4,0). Jackson related the Function and Directional Derivative components (F-DD) and justified the relation with his argument. This was labelled as a transformation relation. Although one may think that the component Slope (S) is also part of this relation, as we will later see, Jackson seemed to be thinking of directional derivative as a measure of inclination without being aware of the slope of a tangent line as a rate of change.

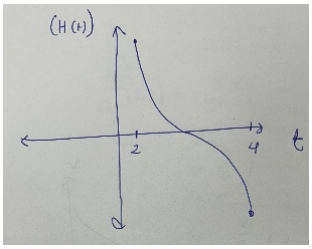

Figure 2: Jackson's work on Task 1c

In Task 2a, Jackson was given the graph of a tangent plane to a function at a point (1,2,0) (see Figure 1, top-right) and asked for the directional derivative of the function in the $\langle 1,1\rangle$ direction. He readily computed the directional derivative using the dot product formula. After computing the slopes of the plane in the x and y directions as $m_x = 1$ and $m_y = 3$, respectively, and finding a unit vector in the direction of the given direction vector $\langle 1,1\rangle$ he solved the task.

However, in Task 2b (discussed below), when asked to interpret his work geometrically, he did not interpret the directional derivative as the slope of a line in the tangent plane. Jackson did not think of the directional derivative as a slope for this task, contrary to what appeared to have happened when he used the printed 3D surface in Task 1c.

Jackson: [Reading the task] Can you relate the computation you did in the previous part to the figure below? (Figure 1, bottom-left) … the purple line represents our gradient, and the red line, the unit [sic] vector $\langle 1,1 \rangle$ maybe, and there's a green bar between the two.

Interviewer: You said the purple line represented the gradient, but the gradient only has two components.

Jackson: Hmm, okay. So, is the red line in the *xy* plane? Yeah, okay, … so that should be the gradient … but the direction also had two components as well. So, what's the purple line?

Interviewer: Well, it's in the tangent plane. That's a hint.

Jackson: It's in the tangent plane. It's not the gradient … So, if there's a change in z…

Interviewer: The tangent plane is made up of tangent lines.

Jackson: … Okay, so that's a tangent line. Alright. So, I'd say, I assume the red line is the gradient, and the purple line is the tangent line.

Jackson did not realize that the "red line" represented the direction vector $\langle 1,1 \rangle$. This showed once more that recognizing the geometric representation of a direction vector was a challenge for him. That is, the relation F-DD he constructed did not include the geometric representation of the direction vector. Furthermore, Jackson was unable to move from knowing that the purple line is a tangent line to thinking about the slope of the tangent line. He seemed not to think of directional derivative as a slope, with vertical change represented by the length of the green segment (vertical change) and horizontal change as the length of the red line segment (magnitude of the direction vector $\langle 1,1 \rangle$). Indeed, he never used the term "slope." That is, the component S was not leveraged as a mediator. So, recognizing that the directional derivative is a measure of inclination, as Jackson did by passing his finger over the edge of a 3D-printed surface in Task 1c, did not immediately translate into him recognizing that it is a quotient of vertical change over horizontal change, as he was expected to observe in the triangular diagram of Task 2b.

In Task 3, given the graph of a function, Jackson was asked to approximate the direction $\vec{v}$ in which the directional derivative $D_{\vec{v}}f(2.5,1.5)$ appears to attain its largest possible value.

Jackson: … So, for its maximum largest value, the $\vec{v}$ would be in the same direction as the gradient. So, at the point on this surface [pointing to $(2.5,1.5)$ on the graph], the gradient, … will be pointing up from that point. Hmm! Now, I'm gonna switch over to the surface to see … right here. Yep, I believe this is where the gradient is pointing, and that direction … would have an *x* and *y* coordinate. So that direction is … $x = 0$ and $y = 1$. Also, put me in the $\hat{\jmath}$ direction or $\langle 0,1 \rangle$ direction, I guess.

Observe that in this situation, Jackson had no trouble going from the graphical representation of a two-variable function to the graphical and symbolic representations of its 2D gradient vector $\langle 0,1 \rangle$. He had previously (in Task 1b) shown some difficulty physically representing the 2D direction vector on a 3D-printed surface, and (in Task 2b) initially represented the gradient as a vector tangent to a given surface (the tangent plane).

Interviewer: Okay, how about the smallest possible value?

Jackson: [The] smallest possible value would be perpendicular to the gradient. So, then I'd say $\langle 1,1,0 \rangle$, maybe at that point.

Interviewer: Why should it be perpendicular to the gradient?

Jackson: Because, I guess, for the directional derivative, it's the gradient dotted with the direction we're moving in, and to obtain the largest value possible for the directional derivative, Del *f* [the gradient] and U [a unit direction vector] would be in the same direction, since we're using the dot operator. And for it to be the smallest value 0, or no! The smallest value would be -1. So, it should be the opposite direction, not perpendicular. Sorry. So, if I said $\langle 0,1 \rangle$ before, it should be $\langle 0,-1 \rangle$ ...

Jackson started by relating the function (F), directional derivative (DD), and gradient (G) components and justified the relation by arguing, "to obtain the largest value possible for the directional derivative, Del *f* and U would be in the same direction, since we're using the dot operator." So, in this task, the relation F-G-DD is established as a transformation relation.

However, note that he initially gave a 3D vector ("then I'd say $\langle 1,1,0 \rangle$") as the direction vector in which the directional derivative is the smallest possible value. This shows an inconsistency in how he represented direction vectors, since he did not use three components in his previous response. He then argued that the smallest possible value occurred when a dot product is 0, before recognizing that the dot product could be -1. His argument to discuss the largest and smallest directional derivatives, as well as his justification of the relation F-DD-G, resulted from an algebraic consideration of directional derivative as a dot product. This suggests that, in this task, Jackson did not relate the component of Slope (S) with the other components in F-DD-G. He seemed to primarily think of directional derivative as a dot product rather than as a slope. In the student's mind, the algebraic consideration took precedence over the geometric interpretation of directional derivative as the slope of a tangent line.

In Task 4, Jackson was given a three-variable function $H(x,y,z) = z - f(x,y)$ and a point P on the surface $z = f(x,y)$ (see Figure 1, bottom-right). He was asked to approximate the direction in which the gradient vector $\nabla H(P)$ points.

Jackson: … Oh, okay. So that if I'm evaluating *H* at *P*, I assume that would mean the *z* [sic] value is just equal to 0, then and $\nabla H(P)$ should point in the same direction [referring to the direction $\langle 0,1 \rangle$ of Task 3] …

Since *P* is on the surface, then $z = f(x,y)$ and so, $H(P) = 0$. However, Jackson confused *H* with the two-variable function *f* and said, "that would mean the *z* value is just equal to 0." In order to stress the difference between *H* and *f*, the interviewer asked:

Interviewer: So, *H* is a function of how many variables?
Jackson: Hmm, okay, sorry. *H* is a function of 3 variables. So, its gradient would have three components. Then, alright. What would that third component be then, hmm? At the point … *z* is equal to 0 [still confusing *H* with *f*]. So, I'm gonna try plotting the point on the graph as best as I can. So, 2.5, 1.5, and the *z* value for *H*, I believe, is 0. [Looking at the graph of $z = f(x,y)$] Hmm, oh, no! [realizing his mistake] First thing I can think of, I feel like the *z* component should be positive [from looking at the graph]. I'm gonna first start by writing ∇H equals, at the point *P*, the first component is 0, *y* component is one, and *z* is what I'm left with to figure out.

When Jackson said, "the first component is 0, *y* component is one," he was still confusing *f* with *H*, as he was using the values previously obtained in Task 3 for f_x and f_y as if they were H_x and H_y. In order to lead him to reconsider, the interviewer asked:

Interviewer:	So, how do you compute a gradient vector?
Jackson:	You take the partial of each component with respect to x, y, z, respectively.
Interviewer:	Okay. Could you compute the partials of H?
Jackson:	Let's see, so H_x should equal $0 - f_x$. So, $-f_x$. H_y should equal $0 - f_y$ … H_z should equal one. Okay. [I'm] just making sure I did that right … I believe ∇H would be $-f_x$, $-f_y$, 1 as its components. So, at the point $(2.5,1.5)$ [it] should be $\langle 0,-1,1\rangle$.

Jackson was eventually able to find the gradient at P ($\nabla H(P) = \langle 0,-1,1\rangle$), but he required scaffolding to distinguish between the gradients of f and H, probably due to the habit of working with two-variable functions. So, we concluded that he was able to establish a correspondence relation between components of functions of two or three variables and gradient. In another interview task, which we do not discuss in this report, Jackson was able to draw the gradient of a two-variable function at a point, given the contour diagram of the tangent plane at the point. At that moment, the interviewer asked:

Interviewer:	… You said that the gradient of *f* was perpendicular to a contour line. Can that help you in the previous problem where you had the function of 3 variables?
Jackson:	… Okay, yeah, so since this is a function of three variables. I guess, instead of level curves, it'd be level surfaces, and the gradient will be perpendicular to the surface. So, at that point, I could try drawing a line directly normal to that point on the surface.

The fact that the interviewer's intervention was needed to help Jackson recall the relation between three-variable functions (and their level surfaces) and the gradient vector suggests that a correspondence relation was established between these two components.

Conclusions

Exploring issues that challenge strong students in multivariable differential calculus can highlight areas where most students need support. Depending on the course and student population, these aspects should be explicitly addressed during instruction. Underscoring some of these challenges is a contribution of this study.

Jackson found challenges with the directional derivative of a two-variable function: representing the 2D direction vector in a 2D rendering of the 3D graph or a 3D physical representation of the graph, interpreting the directional derivative as a slope, and relating the dot product representation of a directional derivative with its geometric representation as a slope.

Jackson encountered challenges with the gradient of a two-variable function: representing the 2D gradient graphically in 3D and recognizing the similarities and differences between 2D contour curves and 3D level surfaces of two- and three-variable functions, as well as their corresponding gradient vectors. This is another contribution of the study, and more so since there is not much written about directional derivative and gradient moving across dimensions.

The interplay between 2D and 3D objects and their representations is key to understanding student challenges. The challenge in representing 2D vectors in a 3D figure or physical manipulative, or of 3D vectors on a 2D rendering of a two-variable function graph, was anticipated by Parzysz (1988). The case of the difficulty in the (3D) graphical representation of a (2D) direction vector was also observed by Martínez-Planell et al. (2015). Similarly, the

graphical representation of a 3D gradient vector relative to a level surface represented in 2D was also a source of difficulty. This needs to be further studied. Relating the symbolic representation of directional derivative as a dot product with its geometrical representation as the slope of a tangent line in a given direction is also not easy for students. The dot product characterization hides the geometric interpretation of directional derivative as a slope. These observations extend the findings of Borji et al. (2025).

A limitation of this study is that we are considering only one student. Our future work will analyze interview responses of other student participants; preliminary analyses suggest that the challenges that Jackson experienced were common to other students. We assumed, although we could have verified, that what was challenging for Jackson was also challenging for most other students. Further studies are needed to corroborate this. Further, there are other aspects that perhaps most students need help with that were not encountered in this case study.

DIDACTICAL REORIENTATION FOR THE DESIGN OF VARIATIONAL TASKS: THE CASE OF CONTINUOUS EXPONENTIAL COVARIATION

REORIENTACIÓN DIDÁCTICA PARA EL DISEÑO DE TAREAS VARIACIONALES: EL CASO DE LA COVARIACIÓN EXPONENCIAL CONTINUA

Luis Miguel Amador Silva
University of Sonora
luis.amador@unison.mx

José Ramón Jiménez Rodríguez
University of Sonora
joseramon.jimenez@unison.mx

A didactic reorientation is proposed for the design of variational tasks in Calculus courses for engineers, centered on continuous exponential covariation. In contrast to the traditional approach, dominated by the formal treatment of numerical functions, this proposal seeks to recover the dynamic, continuous, and quantitative nature of change. Grounded in Harel's DNR model and in a historical-epistemological analysis, the study introduces Variational Ways of Understanding and Thinking as operational constructs to guide the pre-design, design, and analysis of tasks. Variational and non-variational ways of understanding continuous exponential covariation are distinguished, establishing criteria to promote covariational reasoning. The proposal provides theoretical and methodological foundations to reorient the teaching of Calculus toward a perspective consistent with the dynamic nature of varying quantities.

Keywords: Calculus, Cognition, Curriculum, Undergraduate Education

In university Calculus courses, particularly those aimed at engineering students, the study of variation and change is usually approached through a formal and static treatment centered on real numbers, numerical functions, limits, derivatives, and integrals of numerical functions. This didactic orientation, inherited from Mathematical Analysis, tends to privilege symbolic manipulation over the analysis of the processes of change underlying real phenomena, thereby limiting the development of mathematical thinking for interpreting and modeling situations from the physical and technological world.

In the case of exponential behavior phenomena, previous research has shown that their teaching is commonly structured around formal definitions, prototypical examples, and finally application exercises (Khanh et al., 2020). This instructional pattern represents a break with the historical-epistemological development of Calculus, whose origins lie in the need to understand and quantify continuous change processes, such as non-uniform motion and other variations dependent on time or space (Crosby, 1998; Kleiner, 2001; Jiménez, 2025).

This issue becomes especially relevant in engineering education. Calculus, historically conceived as the mathematics of variation and change, constitutes a fundamental tool for modeling and analyzing physical and technological phenomena. However, pre-university and university teaching of Calculus often follows a formal approach characteristic of Mathematical Analysis, one that is poorly aligned with the practical needs of these students. This discrepancy between curricular objectives and professional demands results in difficulties in understanding, low motivation, and a limited use of mathematical knowledge in applied contexts.

From a historical perspective, the study of variation and change emerged in response to the need to quantitatively understand real processes, such as non-uniform motion, through the analysis of variable quantities and their continuous behavior (Crosby, 1998; Kleiner, 2001). Calculus thus arose as a mathematics oriented toward modeling dynamic phenomena and coordinating covariational relationships between quantities. Nevertheless, this dynamic character

has been diluted in contemporary didactic practices. Variational thinking is frequently reduced to the manipulation of formulas, static definitions of functions, or the construction of graphs through point-plotting procedures, which hinders covariational reasoning and contradicts the continuous nature of change (Jiménez et al., 2022; Vasco, 2003). The dominant curricular conception anchors the study of variation to the treatment of numerical functions, excluding the temporality and dynamicity inherent to phenomena (Jiménez, 2025). From our perspective, this orientation does not foster the genuine development of variational thinking, understood as reasoning about variable quantities within phenomenological contexts.

Several authors have pointed out that the difficulties in developing this type of thinking cannot be attributed solely to individual cognitive factors of students, but are also closely linked to curricular design and prevailing didactic practices (Ímaz & Moreno, 2010). Within this framework, we argue for the need for a didactic reorientation in the design of variational tasks, conceived as a reconsideration of the criteria that organize learning experiences in order to privilege the analysis of variable quantities and their relationships of continuous covariation. In particular, this study focuses on continuous exponential covariation, whose teaching is often constrained by formal and static approaches that fail to reflect the inherent dynamics of the phenomenon (Foti, 2020).

Drawing on Harel's (2008a) conception of mathematical thinking, theoretical constructs are introduced to characterize and promote variational ways of understanding and thinking, with the purpose of providing conceptual and methodological tools to guide the design of learning tasks. The aim of this work is to contribute to the construction of operational criteria for the design of variational tasks on continuous exponential covariation, recovering the dynamic, continuous, and quantitative nature of change. Thus, the research question guiding this study is: What ways of understanding can be characterized as variational, and which correspond to non-variational ways, in the context of continuous exponential covariation?

Theoretical and Explanatory Framework

Harel (2008a, 2008b) states that the primary goal of Mathematics Education is to develop students' mathematical thinking, which consists of a set of mathematical ways of understanding and mathematical ways of thinking. The author defines ways of understanding as the particular cognitive product of a mental act carried out by a person, and ways of thinking as the cognitive characteristics of a mental act performed by a person, revealed through the recurrent actions of their ways of understanding.

This profound reflection developed by Harel regarding the characterization of mathematical knowledge and the fundamental purpose of mathematics teaching, and actively promoted by him in recent years (Harel, 2021), led him to formulate a methodological framework to achieve such a purpose. He called this framework "DNR-based instruction." The acronym derives from the three fundamental principles on which the framework is based: the Duality principle (D), the Necessity principle (N), and the Repeated Reasoning principle (R). Of particular interest here is the principle of Duality.

The Duality principle states that students develop ways of thinking only through the construction of ways of understanding, and the ways of understanding they produce are determined by the ways of thinking they already possess (Harel, 2008a, p. 19). This principle asserts that ways of understanding (concepts and skills) and ways of thinking (practices, dispositions, and beliefs) are interdependent; that is, a bidirectional relationship exists between them.

The theoretical constructs presented in Guershon Harel's view of mathematical thinking provide an operational pathway for promoting mathematical thinking. This perspective has motivated us to define and characterize two new theoretical constructs necessarily related to variational mathematical thinking. These constructs are *Variational Ways of Understanding (VWU)* and *Variational Ways of Thinking (VWT)*, a point that we will revisit later.

Variational Thinking Approach

The approach adopted in this study is distinguished by emphasizing a dynamic way of reasoning about the fundamental ideas that gave rise to Calculus. Among these ideas are the notions of continuous quantity, the understanding of variable quantity, and the treatment of the infinitely small. From this perspective, promoting a type of mathematical thinking linked to variation and change requires clearly specifying its object of study: variable quantities.

The Object of Study of Variational Thinking: Variable Quantities

In various natural and social phenomena, quantities arise that vary over time or space. By their nature, these quantities reflect the inherent dynamism of real-world processes and therefore constitute the central object of variational thinking. Examples of such quantities include time, temperature, pressure, and velocity, among others, all of which can be measured or quantified using the corresponding unit or standard and measuring instrument; that is, variable quantities possess units of measurement (Jiménez et al., 2022).

Variational thinking is concerned with understanding and mathematizing the behavior of these quantities by analyzing how they change, how they relate to one another, and what patterns emerge from their evolution. In this regard, Jiménez et al. (2022) identify four essential characteristics of variable quantities:

- The symbol representing them refers, in the first instance, to the quantifiable quality (temperature, pressure, time, density, etc.).
- This symbol also represents each and every numerical value that the quantity may assume within the phenomenon.
- These numerical values do not change randomly; rather, they follow a coherent temporal or spatial sequence.
- Such a sequence of numerical values may be continuous or discrete, although variational thinking focuses particularly on the continuity of change.

However, mathematical work centered on numerical functions is characterized by an abstract and static treatment. By its nature, a real-valued function of a real variable is conceived as a correspondence relation between two numerical sets, without necessarily requiring reference to real phenomena. Larson and Edwards (2016) express this as follows:

> Let X and Y be sets of real numbers. A real-valued function f of a real variable x from X to Y is a correspondence rule that assigns to each number x in X exactly one number y in Y. The domain of f is the set X. The number y is the image of x under f and is denoted by $f(x)$, which is called the value of f at x. The range of f is defined as the subset of Y consisting of all images of numbers in X. (p. 19)

This definition highlights the purely abstract, numerical, atemporal, dimensionless, and static character of numerical functions. The numerical variables involved merely represent elements of sets, without necessarily being linked to measurements or to the quantification of real-world phenomena. In contrast, the numerical values associated with variable quantities preserve an

intrinsic connection to the phenomenon from which they originate and are inseparably tied to a temporal dimension. Numerical variable values, on the other hand, are selected arbitrarily and lack a meaningful temporal relationship, since within numerical sets the order in which elements are taken is of little importance.

Dynamic Nature of Variational Thinking

Based on a critical analysis of the specialized literature on the subject, we have come to conceive variational thinking as requiring a dynamic way of thinking (Vasco, 2003), one that is directly related to the study of variable quantities. We conceive variable quantities as those perceptible and quantifiable properties or qualities present in real-world phenomena and processes that are intrinsically dynamic by nature. Variable quantities truly vary. They are ubiquitous in the so-called phenomena or processes of variation and change.

Within variational thinking, the leading role is played by variable quantities, which are mathematical objects of a nature essentially different from that of functions. Functions appear only as secondary actors, as one of the emergent tools for the mathematization of variable quantities and of the processes in which they are involved (Jiménez et al., 2022).

In the studies presented by Thompson and Carlson (2017), as well as by Jiménez et al. (2022), the authors conceive variational thinking as consisting of two components: variational reasoning and covariational reasoning, both related to the mathematical conceptualization of variable quantities. In the first case, reasoning and mathematical work are carried out on a single variable quantity along the number line, whereas in the second, simultaneous reasoning and mathematical work are carried out on two variable quantities within the Cartesian plane.

Theoretical Proposal: An Operational Structure for the Development of Variational Thinking

Based on the variational thinking approach and Harel's (2008a) conception of mathematical thinking, we propose that, in order to develop students' variational thinking, learning strategies must be designed to enable them to generate *Variational Ways of Understanding (VWU)* and *Variational Ways of Thinking (VWT)*. We define Variational Ways of Understanding as the particular cognitive product of the mental act of producing dynamic images related to the essential characteristics or properties of variable quantities present in ongoing phenomena of variation and change. Variational Ways of Thinking, in turn, are described as the cognitive characteristics of the mental act of producing dynamic images carried out by the student, revealed through the recurrent actions of their variational ways of understanding.

For example, if a student formulates an interpretation, similar or equivalent to the statement that "the numerical values assumed by the literal representing a variable quantity are associated with a unit of measurement," the student is exhibiting a Variational Way of Understanding, since this constitutes a particular cognitive product of the mental act of interpreting an important characteristic of variable quantities. Furthermore, if the student sustains more than one Variational Way of Understanding, it is likely that they also possess the Variational Way of Thinking that "variable quantities progressively assume numerical values that can be divided into three groups: the current value, previous values, and subsequent values."

For the organization, design, and analysis of instructional strategies or didactic activities, an operational structure of methodological-didactic implications is established, based on three essential stages. This structure has been adapted from Harel's DNR model (2008b).

Stage 1: Predesign

The purpose of this stage is to define the *Variational Ways of Understanding* expected to be promoted in students and to establish the conceptual and cognitive elements that guide the design

of the activities. To identify and characterize the *VWU* to be promoted in students, the following process must be carried out:

- First, the type of covariation to be addressed (linear, quadratic, exponential, etc.) must be characterized, as well as the application contexts in which such covariation manifests itself (physical, biological, economic, technological, among others). This makes it possible to establish the connection between variable quantities and their phenomenological meaning. In other words, the VWU characterize the dynamic development of the process.
- Second, a historical-epistemological analysis must be conducted in order to examine the development of the mathematical concept over time and how it is structured within disciplinary knowledge. This analysis provides a deeper understanding of the ways of reasoning and representing variation that have been significant throughout the history of mathematics.
- Finally, the VWU are formulated as specific configurations of thought expressed through variational language. These VWU are not formulated as formal definitions or declarative knowledge, but rather as more or less precise statements about the quantitative properties of variable quantities. Their function is to represent ways of mentally organizing the quantitative characteristics of the variable quantities involved in situations of change.

In this sense, *VWU* operate as normative orientations for task design, since they guide the selection and elaboration of didactic activities that foster in students a type of mathematical thinking coherent with the continuous, dynamic, quantitative, and relational nature of phenomena of variation.

Stage 2: Design

At this stage, the guidelines that direct the development of didactic activities intended to promote the previously formulated *VWU* are specified. Two fundamental components are defined here: principles for the design of mathematical tasks and principles for the design of technological tasks.

Principles for the Design of Mathematical Tasks

The design of mathematical tasks is guided through the outline of the cognitively logical sequence by which cognitive products involving students' mental acts are obtained, thereby favoring the progressive construction and analysis of the *VWU*. This structuring begins with the identification of the desirable and expected mental acts in students and is translated into statements and actions that guide task development.

Principles for the Design of Technological Tasks

The principles for the design of technological tasks are guidelines focused on coherently integrating digital resources such as GeoGebra, simulators, video clips, among others, in ways that establish a connection between the physical world and the abstract world of mathematics. Technology should facilitate cognitive experiences that not only present information dynamically but also enhance reasoning about the continuous variation of quantities (Swidan et al., 2019).

This approach encourages students to develop the intellectual need to actively interact with dynamic representations, visualizing and manipulating variable quantities in real time, thereby strengthening the construction of variational images coherent with processes of change. In this way, technology becomes a means of fostering the development of variational thinking and modeling phenomena from a visually dynamic perspective.

Once the instructional strategies or didactic activities have been defined, the implementation of the activities with students begins.

Stage 3: Analysis

The purpose of this stage is to evaluate the extent to which the designed and implemented activities succeed, or fail, in promoting the development of *Variational Ways of Thinking* in students within the specific context of study.

The analysis focuses on the mental productions expressed by students in their verbal or written statements, justifications, and arguments. Following Harel (2008a, 2008b), these productions allow the teacher to indirectly infer the common cognitive characteristics that emerge from the mental acts carried out during the development of the activities.

The analysis seeks to obtain solid evidence that students are capable of identifying and formulating the essential quantitative characteristics of the covariation being addressed, based on the joint and simultaneous coordination among the numerical values of the variable quantities involved in the analyzed phenomena.

In this way, the theoretical proposal presented constitutes a new approach to the design of variational tasks, distinct from what has been reported in the literature and inspired by Guershon Harel's pragmatic-pedagogical view of mathematical thinking. Its distinctive character lies in the operationalization of *Variational Ways of Understanding* and *Variational Ways of Thinking*, employed as articulating constructs for the processes of predesign, design, and analysis of tasks aimed at promoting students' variational thinking.

Results

The Predesign Stage as a Methodological Foundation for Identifying Variational Ways of Understanding

In order to address the research question guiding this study, the Predesign stage established within the methodological-didactic implications for the development of variational thinking was carried out. This stage made it possible to construct a solid conceptual and cognitive pathway for identifying, characterizing, and formulating the *Variational Ways of Understanding (VWU)* associated with continuous exponential covariation.

The Predesign stage was developed through three interconnected moments:

1. Characterization of the type of covariation and its phenomenological contexts: the mathematical topic under study, continuous exponential covariation, was defined, and its possible manifestations in physical, biological, and technological contexts were analyzed. This analysis made it possible to establish the connection between variable quantities and their phenomenological meaning, recognizing that the VWU must describe the dynamic, continuous, and quantitative development of the variation process.
2. Historical-epistemological analysis: a study was conducted on the historical development of the concept of exponential variation and of the ideas that structured continuous covariational reasoning. This analysis made it possible to identify ways of reasoning that have historically been relevant for understanding proportional dependence, relative rate of change, and exponential dynamics as a continuous phenomenon. These findings were fundamental for establishing conceptual distinctions between variational and non-variational ways of understanding.
3. Formulation of the VWU as specific configurations of thought: based on the two previous analyses, the VWU were formulated not as formal definitions, but as statements describing quantitative properties of variable quantities in situations of exponential

change. These configurations express how a student might mentally organize the dynamic behavior of a quantity that changes continuously and exponentially. Their normative function is to guide the design of tasks that promote reasoning coherent with the quantitative and continuous nature of variation phenomena.

Variational Ways of Understanding vs. Non-Variational Ways of Understanding Continuous Exponential Covariation

The results of the historical-epistemological analysis led to the identification of a set of Variational Ways of Understanding that may guide the design of variational tasks aimed at enabling students to reason about phenomena exhibiting exponential behavior.

The following distinctions are proposed:

- A Variational Way of Understanding is any form of reasoning centered on variable quantities, their quantitative dependence, and the continuous structure of change.
- A Non-Variational Way of Understanding is any form of reasoning that departs from this criterion by privileging numerical functions or relationships between numerical variables without explicit reference to the quantities involved in the phenomenon.
- Although some non-variational ways of understanding may be mathematically correct, they do not foster variational or covariational reasoning because they do not necessarily capture the continuous dynamics or the quantitative relationships among the quantities involved (see Table 1).

Table 1: Non-Variational vs. Variational Ways of Understanding Continuous Exponential Covariation

Non-Variational	Variational
• Equal arithmetic increments in the independent variable of an exponential function lead to equal proportional changes in the variable y.	• A covarying quantity with exponential behavior, undergoing equal arithmetic variations in the independent variable quantity, leads to equal proportional changes in the dependent variable quantity.
• In an exponential function, if h is the change in the independent variable, then $a^h - 1$ is the proportional change in the dependent variable.	• A covarying quantity with exponential behavior $N(\Delta h)$ undergoing equal arithmetic variations in the independent variable quantity, leads to proportional changes in the dependent variable quantity of the form $N(a^{\Delta h} - 1)$.
• The exponential function is a continuous function whose relative rate of increase depends specifically on the increment produced from any given value of x. Knowing this rate makes it possible to determine the base of the exponential function	• The average relative rate of change of a covarying quantity with exponential behavior, for equal increments in the independent variable quantity, is equal to a nonzero numerical constant.
• Exponential function as a differentiable function satisfying the differential equation $y' = ky$	• A covarying quantity whose instantaneous rate of change is directly proportional to the current value of that variable quantity, $\frac{dy}{dx} = ky$.

Conclusions

The characterization obtained provides a foundation for designing tasks aimed at promoting variational thinking regarding continuous exponential covariation. The identified Variational Ways of Understanding make explicit: the essential quantitative properties of the phenomenon, the continuous structure of exponential change, and the dynamic interdependence between quantities.

In contrast, non-variational ways of understanding reveal forms of reasoning detached from the dynamicity required by variational thinking (Jiménez et al., 2022). That is, they are mathematical ways of understanding centered on the properties of numerical functions and abstract variables; therefore, they are not characterized as variational.

From these distinctions, three implications for task design emerge: (1) prioritizing the analysis of real phenomena that allow the identification of variable quantities whose variation is observable and quantifiable; (2) promoting the construction of meanings grounded in intellectual necessity, in coherence with the Necessity principle of the DNR model; and (3) incorporating dynamic representations and technological tools that support the continuous visualization of covariational behavior.

Taken together, the results show that the Predesign stage not only made it possible to answer the guiding research question, but also provided a methodological framework for translating formal conceptual distinctions between variational and non-variational ways of understanding into operational criteria for the design of tasks on continuous exponential covariation.

A PATTERN-BASED APPROACH: IDENTIFYING AND LEVERAGING THE PRESENCE AND PREVALENCE OF LEARNERS' WAYS OF THINKING

Corey Brady
Southern Methodist University
corey.brady@smu.edu

Walter Stroup
University of Massachusetts, Dartmouth
wstroup@umassd.edu

Anthony Petrosino
Southern Methodist University
apetrosino@smu.edu

A key dimension of classroom teaching is attending to the shared needs of groups of learners—deciding how to use time and resources to support collective learning. It is vital, then, to identify approaches that actually leverage the group nature of classrooms—surfacing patterns in the ways-of-thinking students bring to instruction, which can be used to structure rich reflective discussions and guide classroom activity. This theoretical paper situates and introduces a pattern-based approach*, which comprises a range of classroom activity types—from open-ended* generative activities *to closed-form* pattern-based questions (PBQs)*. We compare the pattern-based approach to Peer Instruction (PI), an instructional innovation that also leverages group-centered design. We then describe a use of the pattern-based approach in Calculus I, showing how instructors can use PBQs to elicit students' ways-of-thinking as resources for instruction.*

Keywords: Assessment, Calculus, Classroom Discourse, Instructional Activities and Practices

Perhaps the most salient feature of classroom learning is that it occurs in a group. However, many educational innovations treat the size and diversity of classroom groups as a *liability* to be overcome, while others see it as an *asset* to be leveraged. Here, we introduce a *pattern-based approach* to integrating group-centered assessment and instruction—which takes the latter view—and we illustrate its application in Calculus I. From the pattern-based perspective, the diversity of thinking in a classroom group offers a rich ecology of ideas, in which robust, multi-faceted ways of thinking can be identified (Stroup et al., 2023). Discussion and responsive instruction that put these ideas in conversation can then allow all learners to develop more robust understandings. Our goal in this paper is to illustrate how the pattern-based approach can complement other "assessment for learning" (Black et al., 2004) methods. To situate our approach, we first review literature on formative assessment and active learning, including work that has directly supported Calculus reform.

Literature Review: Formative Assessment and Instructional Practices

Assessment for learning is now well established. Atasoy and Kaya (2022) note that in recent years "the assessment process has evolved from evaluating students' understanding by comparing their achievement with others to organizing instructional practices to improve teaching or learning in classrooms" (p. 1). This trend follows Cowie & Bell's (1999) proposal to define formative assessment as "the process used by teachers and students to recognize and respond to student learning in order to enhance that learning, during the learning" (p. 32).

Integrating with the Course's Success Metrics, Culture, and Instructional Activities

Still, Hansen (2020) notes how important it is for instructors to be explicit about their intentions with formative assessment practices, including both their place in course grading and in classroom culture. On the culture front, research suggests that assessment practices focusing on *ideas* rather than exposing or embarrassing students are more effective: "For students to feel confident and safe in their classrooms, their contributions (e.g., their responses, ideas, and explanations) should be carefully considered to avoid embarrassment (Chin, 2004; Hodgson,

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

2010)" (qtd in Ruiz-Primo, 2011, p. 20). Similarly, Wiliam (2011) finds that classroom feedback is less effective when it "cue[s] attention beyond the task (for example on the self)." (p. 6). Ruiz-Primo (2011) outlined criteria for "effective assessment conversations." Such discussions are "supportive tools of social participation and social cognition" (Ruiz-Primo, 2011, p. 18). Similarly, "in assessment conversations, it is important to focus not only on the 'cognitive' feedback but also on the 'affective' feedback" that students take away from the interaction (Ruiz-Primo, 2011, p. 21). These and other attributes support classroom assessment cultures where students attend to and build upon ideas of others (Sadler, 1989).

Formative assessment activities can be particularly effective when they connect closely to the instruction of the day, leveraging students' elicited "ways of thinking" as resources for instructional interaction. This aligns with key findings from Black & Wiliam (1998) that for formative assessment to be effective, it had to be integrated with classroom instructional practices (Wiliam & Thompson, 2008). In particular, according to Black & Wiliam (2009) well-designed formative assessment offers teachers the opportunity to "creat[e] and capitaliz[e] upon, 'moments of contingency' in instruction for the purpose of the regulation of learning processes" (Black & Wiliam, 2009, p. 12; and cf. Wiliam & Leahy, 2007). In this way "dialogic formative assessment interactions," are "characterized by the conscious discovery of novel information about student understanding" (Ruiz-Primo, 2011, p. 16), for the purpose of using that information to guide teaching and learning.

Active Learning and the Calculus Context

Aligned with assessment for learning, in the literature on Calculus Reform, there are widespread recommendations to integrate *active learning* approaches (Freeman et al., 2014; Hsu et al, 2008; Laursen & Rasmussen, 2019; Laursen et al., 2014; Saxe & Braddy, 2015; Smith et al., 2021; Theobald et al., 2020). Ström et al. (2021) present active learning as a broad term encompassing a range of interventions that foster "teaching methods and classroom norms that engage students in sense-making activities." (p. 147). More specifically, active learning practices aim to promote: (1) students' deep engagement in mathematical thinking, (2) peer-to-peer interaction, (3) instructors' interest in and use of student thinking, and (4) instructors' attention to equitable and inclusive practices. (Laursen et al, 2014; Laursen & Rasmussen, 2019; Rasmussen & Kwon, 2007). It is evident, then, that active learning intersects with formative assessment (items 2 and 3) as well as classroom culture (items 1 and 4).

As Calculus instructors implement active learning approaches, they can encounter barriers in integrating these techniques with the assessment practice of the course (Ehrenfeld & Mark, 2024; Uhing et al., 2021) and with broader instructional patterns (Reinholz, 2015; 2016). Nevertheless, Miller et al. (2006) suggest that even a modest inclusion of good questions and peer discussion can improve Calculus I outcomes, and Cronhjort et al. (2013) present an experimental study showing that active learning can be effective in this context.

A Historical Point of Comparison: Peer Instruction (PI)

Our pattern-based approach supports the four principles above defining active learning, and it does so by adopting a particular focus on the classroom group. This is consistent with, though not necessarily entailed in active learning, and in formative assessment or assessment-for-learning more broadly. We do, however, recognize a focal attention to group-centered learning and teaching (cf. Shepard, 2020) in Peer Instruction (Mazur, 1997), a specific active-learning approach that has had substantial impact. Comparing our approach to PI reveals both similarities and differences, each of which highlights essential features of our pattern-based approach.

Peer instruction was developed in response to a problem of practice that emerged in physics

education in the 1980s and 1990s. Accomplished professors at leading universities administered the Force Concept Inventory, or FCI (Hestenes et al., 1992)—a multiple-choice instrument designed to test for Newtonian understandings of physics—and they were surprised to find that their instruction did not generally alter their students' "common sense beliefs" (Halloun & Hestenes, 1985, p. 1043). Instead, results showed that their students retained ways of thinking consistent with once-dominant paradigms (e.g., Aristotelian perspectives) at odds with normative scientific explanations central to today's physics instruction. Following a notion that such "misconceptions" need to be "corrected early" in instruction, Peer Instruction, or PI (Lasry et al., 2008; Mazur, 1997) was developed as a pedagogical approach that accommodated the constraints of teaching in large-lecture-hall settings common in introductory STEM courses.

Schematic Overview of a Peer Instruction Episode

PI has been implemented widely, with a wide range of fidelity (Vickrey et al., 2015), largely at the postsecondary level, but in a wide range of settings (Crouch et al, 2007; Fakoya et al., 2023; Lasry et al., 2008; Yildirim & Canpolat, 2019; Zendrato et al, 2025) and with various extensions or embeddings into instructional sequences (e.g., Freeman et al., 2014; Michinov et al., 2015). Here, we provide an image of the activity structure of the core innovation, along with the rationale for its components.

A PI instructor poses conceptual questions to the class, at key moments in a lecture (Crouch & Mazur, 2001). These could be the original "ConcepTests" (Mazur, 1997) or other conceptually focused multiple-choice questions. PI questions are designed to provoke a diversity of responses; often, the correct answer does not receive even a plurality of "votes." A publicly displayed bar graph of responses demonstrates to the students that there is no consensus; and the next ("peer") phase of the activity leverages this fact. Students are asked to "discuss their answers" with "someone in the class with a different answer" (Mazur, 2009, p. 51). After the discussion period, the question is repeated, and the new distribution of responses is shown. The instructor may then also choose to engage directly with "misconceptions" associated with incorrect responses. There are several design features of PI that we find notable (and laudable):

Treating students' thinking as significant. PI elicits and engages with the diversity in students' ways of thinking, as a resource to drive instruction. Its questions are designed to evoke diversity, and peer interaction then leverages that diversity. Students are viewed as capable agents with reasonable viewpoints that they can articulate and argue for.

Using aggregate responses as a public artifact to motivate discussion and action. A key feature is the public but anonymous display—which then motivates the instructional sequence. For students, seeing the bar graph creates not only a sense of problem (we do not all think in the same way), but also a sense of community (whether or not I am correct, I am not alone).

Presenting attractors, versus distractors. In the original design, multiple-choice response options are not designed as "distractors" to trick students into answering incorrectly. Rather, like FCI items, they are created as "attractors," appealing to students' stable ways of thinking about phenomena. Thus, in responding, students are identifying with coherent or reasonable conceptualizations. The discussion and debate among alternatives engages with substantive conceptual issues, rather than the "test taking skills" associated with learning to avoid distractors.

The Pattern-Based Approach

This paper presents another group-centered approach to integrating assessment and instruction: the pattern-based approach. This activity structure is tailored for smaller, discussion-oriented classrooms, where it offers strategies to blend what Cowie & Bell (1999) describe as "planned" and "interactive" modes of formative assessment. A key objective is to use

questioning to elicit instructionally relevant patterns among students' ways-of-thinking (cf. Carpenter et al.,1996; Lesh et al., 2013). Below, we describe how this has been achieved with standardized Pattern-Based Questions, or PBQs. Although the pattern-based approach is certainly not restricted to using closed-form questions, a comparison with Peer Instruction's multiple-choice questions helps to illuminate the distinctive nature and potential of PBQs.

What are Pattern-Based Questions (PBQs)?

On its surface, a PBQ is very similar to a multiple-choice, multi-select ("choose all that apply") item. However, PBQs use this format to elicit more information, and more useful information, about groups of learners. Given a question with four options—A, B, C, and D—both multiple-choice, multi-select items and PBQs allow students to select more than one option (e.g., "A and C" or "B, C, and D") permitting 15 combinations (or 16 if "no response" is permitted). Thus, in theory, an optimally designed PBQ could present students with a prompt to classify themselves into one of 16 instructionally relevant patterns in ways of thinking about a topic.

Now, the goal of a *traditional* item is to determine whether or not students are thinking about a topic in the normatively correct manner. Thus, for traditional design, the response-option space contains a single correct pattern (whether a single response-option or an option-combination). In contrast, PBQs aim to make greater use of the combinatorial space of possible responses. They aim to capture the variety of different ways that students are currently thinking about the topic being assessed, in order to put these ways-of-thinking into conversation. In this regard, the design of PBQs have some features in common with Diagnostic Classification Models (Rupp & Templin, 2008; Sessoms & Henson, 2018; Williamson, 2023) and the related Cognitive Diagnostic Assessments (Sun & Suzuki, 2013), which also aim to interpret the response-option space in terms of ways-of-thinking. Importantly, for a given response option in the context of the set of four response options, a student's decision *not* to select that option is potentially as informative as their decision to select it. Thus, every student who responds is contributing four interrelated informative components about their way of thinking (that is, the shorthand "A and C" actually consists of "A, and not-B, and C, and not-D," and the question designer can make use of this combinatorial space to reveal meaningful patterns in the group.

Leveraging the Public Display of Responses

A PBQ invites students to identify ways of thinking that they resonate with, or find compelling, among the response options. The appropriate public display for PBQ responses is thus a bar graph of all possible response combinations of response options (see Figure 1). The 15-bar display depicts the presence and prevalence of ways-of-thinking in the responding group, providing valuable information for both teachers and students. Students see there are others in the class who think the way they did (cf., Minstrell, 2000; Minstrell & Stimpson, 1996). The display also concretely manifests the diversity of thinking present, spurring reflection and discussion. In particular, we have found that students are often interested in the "other bars"—different from their own—and are enthusiastic to conjecture "how someone might be thinking" who selected a given combination of options.

Schematic Overview of a PBQ Discussion

Comparing the pattern-based approach with Peer Instruction reveals both connections and contrasts along the "Features of PI" that we highlighted above.

Treating students' thinking as significant, *but* replacing a misconceptions approach with an asset-based perspective. Like PI, PBQs take students' ways of thinking seriously, evoking diversity in order to encourage students to articulate their thinking and viewing this as a

rich opportunity for learning and identity development. However, PI takes a misconceptions approach, engaging student ideas in order to problematize and ultimately root them out. In contrast, PBQs take an asset-oriented perspective to the diversity of students' ways of thinking, viewing their current conceptions as resources and connecting new concepts to prior thinking.

Using aggregate responses as a public artifact to motivate discussion and action, *but* exploring connections between ideas, rather than casting them as oppositional. The public display of student responses in a PI episode "calls out" persistent misconceptions, and the approach does not highlight how these misconceptions might be hybridized or connected (Smith et al, 1994). This is by design; built into the nature of the questions and the practice of engaging in oppositional debate is the idea that misconceptions must be confronted to be open to change. In contrast, PBQs are designed to enlist students in identifying connections between responses and among the different ways-of-thinking that appear in the class. We describe these patterns and connections with a musical metaphor: conceptual chords.

Presenting attractors, versus distractors, *but* encouraging students to conceptualize connections as routes for growth. PI divides students' perspectives into distinct "buckets"—the options of the multiple-choice question. A Kuhnian (1970) view of incommensurable scientific paradigms underlies this design, paired with a pedagogical theory of conceptual change that holds students' thinking can shift dramatically when confronted with contradictions in their conceptual systems (Strike & Posner, 1982; Longfield, 2009). Polarizing the class's thinking into categories prepares them for debate as a confrontation between paradigms. In contrast, we construct PBQs under a view that learners build new ways of thinking by reorganizing aspects of their prior conceptions into new structures (Piaget, 1972; Vygotsky, 1978). Thus, we view different patterns as milestones in pathways of conceptual growth. The pattern-based approach evokes diverse ways of thinking in order to create opportunities to put students in positions of agency, articulating connections that they see among this diversity.

Instructional Vignettes from Calculus I

In this section, we describe several instructional sequences responsive to student answers to PBQs. These occurred in a Calculus I course taught by the first author (C. B.) in Fall 2025. We focus on examples where students' response patterns revealed different ways of looking at mathematical objects, and on how this diversity could support and structure interactive discussions of patterns of thinking.

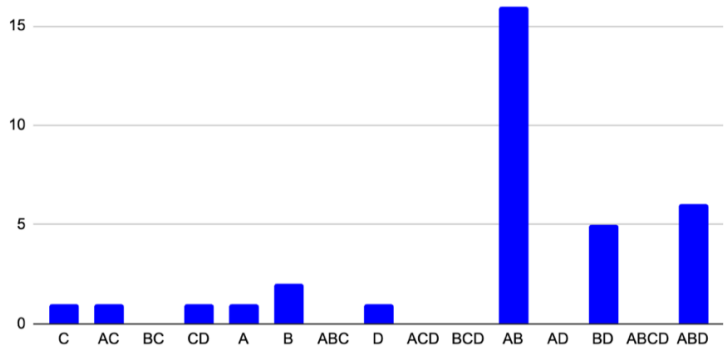

Figure 1: Response Display for a Four-Option PBQ

Note. The target combination, "ABD," is at far right, with other combinations ordered by greater or lesser distance from the target.

For example, given the response display in Figure 1, Author 1 focused first on option "B," shared by all of the four most common combinations (see Figure 2 for the PBQ). The discussion of this bar surfaced two compatible but distinct perspectives on "ending further forward than they started"—an "integral" one, based in accumulating distance, and a "compensation" oriented one, viewing the positive and negative parts of the graph as canceling each other out, with the positive in excess. This distinction helped to reveal the different ways of thinking behind "AB" and "BD." "AB" attends to the meaning of points on the graph as giving readings of velocity at particular times, while "BD" attends to accumulated distance as the signed area between the curve and the horizontal axis, which can be calculated using triangle formulas from geometry. Both are valued perspectives, and though the one associated with "BD" was a focus for the lesson of the day, the discussion helped to stabilize some of the multiple interpretations that can be derived from a velocity graph. One note about the response display is that only one response out of 34 (i.e., "C" only) lacks any correct option. Moreover, discussion of "C" revealed that it operated not *just* as a "distractor"—it included an ambiguity of language, in which "returns to where they started" could be seen to mean, turning around to head back to the starting line.

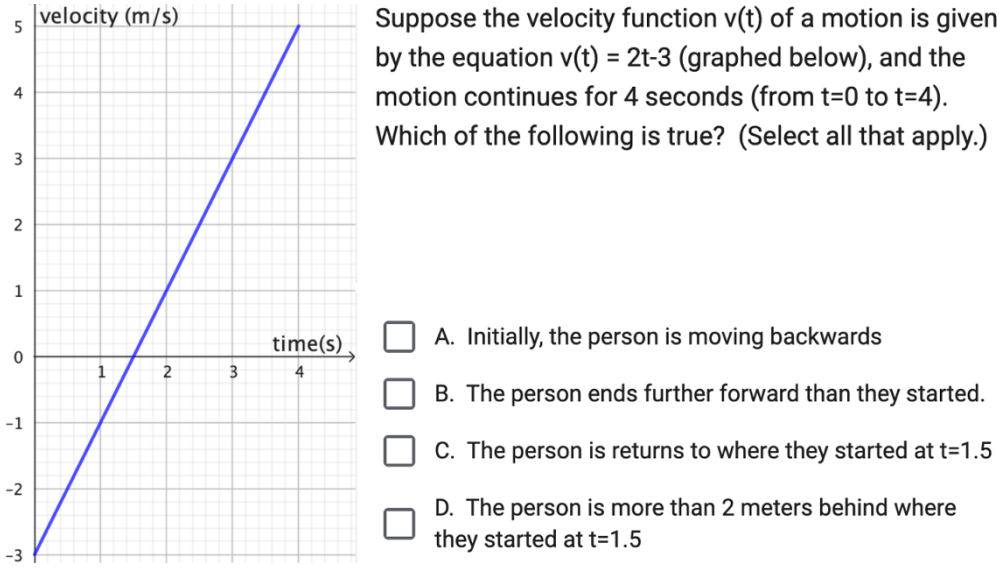

Figure 2: PBQ Producing the Responses in Figure 1

Another facilitation approach we have observed highlights a "popular" response combination that pairs one correct option with one that is incorrect. This was an appropriate strategy for orchestrating discussion of the PBQ responses shown in Figure 3, below (see Figure 4 for the PBQ). Noting that "quite a few of us" chose this combination, the instructor can ask about the reasoning. Any student can respond, either describing their own thinking or speculating what someone who chose this option "might have been thinking." Later, the teacher might solicit connections between this "bar" and another one. Through such discussions, students are invited to express their thinking in relation to others' thinking, as reflected in the display. The discussion is valuable both for students who are struggling with the focal topic, and also for those who have mastered it, who then have opportunities to articulate their current thinking and connect it with

prior ways of thinking. We often use PBQs at the start of an instructional session, since these discussions set the stage for later activities.

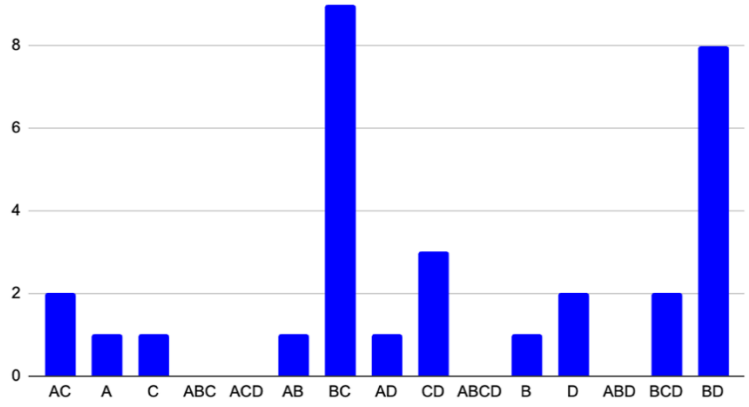

Figure 3: Responses to the PBQ of Figure 4

In the case of this PBQ, the "BC" combination suggests that students were attending to the behavior of the denominator and not of the numerator at x=1. The class had recently covered L'Hôpital's Rule and one student mentioned this as an approach, leading them to select A. Though incorrect, this response reflected noticing something important, and it also gave an opportunity to distinguish between the *value* of the function and its *limit* as x approaches 1. Finally, discussion of option D allowed an opportunity for students to recall the behavior of the logarithm, building on the initial discussion of the numerator's behavior at x=1. In this case, the focus was much *less* on the correct answer and much more on the kinds of thinking needed to detect and describe indeterminate limits and removable discontinuities.

Consider the function f(x) below. Which of the following are true? (Select all that apply.)

$$f(x) = \frac{\ln(|x|)}{x-1}$$

- ☐ A. f(1) = 1
- ☐ B. f(1) is not defined
- ☐ C. f(x) has a vertical asymptote at x=1
- ☐ D. f(-1) = 0

Figure 4: PBQ Producing the Responses in Figure 3

A third discussion approach can leverage situations where the majority of students are finding correct responses, but few are attentive to *all* of them. In Figure 5, below, all of the singleton correct answers have representation, as do the doubletons (see Figure 6 for the PBQ). In this setting, the discussion can work to support students in recognizing and "trying on" multiple different ways of looking at the mathematical object. Often, problem statements can frame mathematical thinking so that one way of looking appears to be the only correct or productive one. Yet having multiple ways at one's disposal can be a powerful problem-solving and sense-making resource. In this case, Author 1 was surprised to see that the bounds on the value of $f(x)$ were the least salient or accessible of the features involved, while even-odd-ness was more salient (especially given the exponentiation involved). Yet this offered opportunities

for students to express how they thought about properties of *products* of functions, across all these features (parity, periodicity, and value).

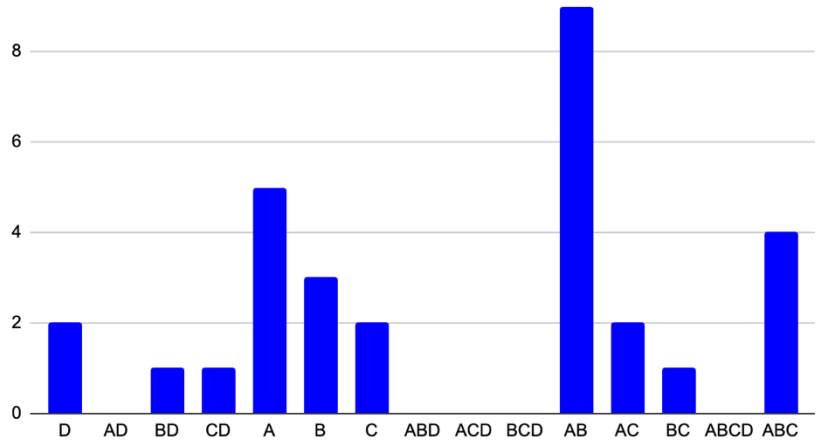

Figure 5: Response Display for the PBQ in Figure 6 (the target response is "ABC")

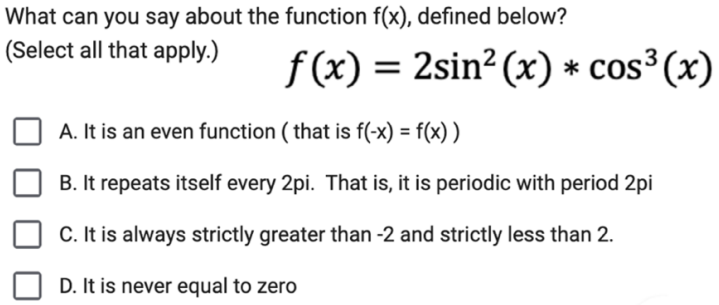

Figure 6: PBQ Producing the Responses in Figure 5

Connection to the Lesson and to Other Pattern-Based Activities

In this Calculus I class, PBQs were the opening activity of each instructional day, so that the "lectures" of the course could often be seen as unpacking and elaborating on the ideas raised in these discussions. Moreover, the PBQs paved the way for more open-ended pattern-based activities, called *generative activities* (Stroup et al., 2005), in which students construct mathematical objects that express given behaviors or features. In the case of the three PBQs above, these were: "Create a velocity graph so that the person ends up exactly where they started;" "Create a function that has a removable discontinuity at x= -3;" and "Create an even function that is the product of two functions that are not even." These generative activities show some of the "power" of the ideas explored in the PBQs, as the target properties are exemplified in entire families of objects, all created by the students.

Discussion and Conclusions

The pattern-based approach operates at the level of *groups*, exploring the presence and prevalence of distinctive patterns of thinking, and orchestrating a dialogue among them. As a result, it builds upon seasoned educators' knowledge and experience of the texture of students'

thinking as they develop increasingly sophisticated understandings. Because PBQ responses reflect *how* students think, rather than only *how correctly* they think, PBQs promise to elicit and convey more information than traditional closed-form assessment tools, as well as information that could be more useful for guiding instruction (cf. Shephard, 2016). The patterns of thought that appear in a group can be directly engaged in discussion, involving students in meaning-making around their own learning and encouraging them to connect their own ways of thinking with those of others in the group. These discussions can give opportunities for more voices to contribute; and animating key conceptual ideas can help to personalize the process of learning.

The research reported here seeks to make contributions to precalculus education by developing the curricular and pedagogical components of an enactive educational ecosystem that enables the emergence of a graphical understanding of the polar coordinate system (PCS). Students in a doctoral-level course in mathematics education are wayfaring from inquiries to insights about the qualities and behaviors of polar graphing as they reason through pole-based choreographies of movement and material interactions with conventional and invented graphing tools. In this Brief Research Report, we share preliminary findings from analyses of their wayfaring paths which reveal the shape of polar graphing problem solving and suggest configurations of tools, tasks, and practices that enable the emergence of its understanding. These findings have implications for the design of enactive approaches to teaching for emergent learning.

Keywords: Cognition, Curriculum, Design Experiments, Learning Theory, Precalculus

The polar coordinate system (PCS) is typically introduced in Precalculus, where it provides a foundation for undergraduate coursework in mathematics, physics, engineering, and other STEM fields. Regrettably, students' engagement with it is often limited to procedural tasks, such as plotting points, rote memorization of the relationship between the shapes of graphs and the parameters of their polar equations, and converting these equations between Cartesian and polar forms. And too little attention is paid to how radius and angle measure co-vary in the graphs of polar equations (e.g., Moore et al., 2014; Paoletti et al., 2013). This project seeks to remedy the anemia of this conventional approach by developing an enactive (Thompson, 2007; Varela et al., 1991) educational ecosystem for emergent learning that enables learners to graph and reason within the PCS. Prior research affirms the viability of this approach (Greenstein et al., 2024a, 2024b; Olson et al., 2024).

As we conceive of it, a graphical understanding of the PCS (or "polar graphing") entails an understanding of how radius, r, and angle measure, θ, covary to trace out polar curves, as well as a familiarity with polar families and the relation of their parameters to qualitative features of their graphs. The theory of change at work here is as follows: Conceptual knowledge (i.e., know-what; Varela, 1992) of polar graphing can emerge for the learner in fields of promoted sensorimotor interactions (Abrahamson & Sánchez-García, 2016; Abrahamson & Trninic, 2014) with the physical tools that afford embodied doing (i.e., know-how) associated with target concepts. Thus, our objective is to assume an enactive and materially agential approach to knowing in order to determine just what those tools and interactions look like. Through experimental, exploratory, and emergent inquiry, we are testing the conjecture that it is possible to teach polar graphing through an *embodied choreomathematics* that develops one's dynamic understanding of angular motion, rotation, and spatial curvature. The question framing the

inquiry shared here is as follows: *What are the elements of an enactive educational ecosystem that enables the emergence of a graphical understanding of the polar coordinate system?*

Theoretical Framing

The enactive theory of cognition (Maturana & Varela, 1987; Varela et al., 1991; Thompson, 2007) and the theory of inclusive materialism (de Freitas & Sinclair, 2014) frame our investigation of mathematical thinking as a complex and emergent phenomenon constituted in embodied and material engagement (Malafouris, 2013), and in the affect and aesthetics of relational interactions between learners and their environments. These theories reject Cartesian dualisms of mind and body, and take inspiration from phenomenology (Husserl, 1977; Merleau-Ponty, 1962) for its attention to the essence of lived experience. Affirming the compatibility of their epistemological commitments, the enactive approach we are taking is known as "4EA Cognition." 4EA cognition proposes that thinking is inherently *Embodied* (emerging from embodied interactions), *Embedded* (in social, cultural, and contextual situations), *Extended* (beyond bodies into tools, practices, and habits), *Enactive* (in that knowing is a worldly doing of sense-making from which meaning emerges), and *Affective* (driven by an emotional attunement that valences stimuli in terms of meaningful salience; Colombetti, 2013).

From an enactive perspective, knowing is an emergent phenomenon of interactions that arises, is contingent upon, and is shaped through the experiential structures that learners have constructed through histories of environmental interactions. What is critical for discerning the tools, tasks, and practices that lead to PCS understanding when framed from this perspective is that cognition ("thinking") is a distributed and emergent process that draws upon environmental affordances (Gibson, 1986) and the determining structures (Maturana & Varela, 1987) of each learner's embodied being as an active agent. These distributed processes are non-linear and unfolding events where "meanings build on one another, combine, [and] shape and get shaped through interactions" (Proulx, 2019, p. 5) in an emergent logic that is irreducible to any one component, process, or pedagogical practice. In short, if thinking is a distributed ecological phenomenon, then so is polar graphing.

Methods

This project is taking a design-based approach (Brown, 1992; Collins, 1992; DBRC, 2003) to discerning the curricular configurations of tasks, tools, and practices that can engage and develop learners' graphical understanding of the PCS. The exploratory case (Yin, 2014) presented here is of research undertaken in a doctoral-level applied theory course in mathematics education called *Choreomathematics of the Polar Coordinate System*. Students in the course are investigating mathematics as an embodied and aesthetic practice by designing, performing, and analyzing pole-based choreography within polar and cylindrical coordinate systems to develop a dynamic understanding of angular motion, rotation, and spatial curvature. The nine students enrolled in the class are participants in the research. Two (the second and third authors) are participant-researchers on the project, as is the course instructor (first author). In addition to photos and video recordings of students' activity and researchers' field notes (Van Maanen, 1988) about the mediators and phenomenologies of their activity, collected data includes students' journal entries and "line reflections." Journal entries are narratives of students' inquiries (what did you seek to learn?), insights (what did you learn?), and 4EA reflections (what conceptual, social, and material interactions shaped the learning and affect/phenomenology of your inquiry?). Their purpose is for students to draw from their mathematical experiences to cultivate an appreciation

for the embodied and extended interactions that constitute our diverse ways of knowing and learning mathematics.

Line reflections are depictions that students draw of their "path laid down in walking," a poetic phrase that Varela (1987) borrowed to convey the emergent behavior of enactive cognition. Using symbols such as loops, braids, knots, and forks, students' lines are meant to depict the unfolding paths of learning they take in each class as they aim to make sense of the graph of some new polar equation. Their purpose is to elucidate paths of learning that reveal how the dynamic, contingent, and structure-determined interactions of meaningful learning emerge more like entangled trails of wayfaring (Ingold, 2007) than point-to-point transport along a learning trajectory.

We are engaged in thematic analysis (Braun & Clarke, 2006) of the unfolding paths of "PCS knowing" that emerge in evolving assemblages of each group's embodied and extended interactions. The objective of the analysis is to assess and articulate the efficacy of curricular configurations from which PCS understanding can emerge and the pedagogical scaffolds that support them. At the same time, we are attending to students' in-the-moment thinking through phenomenological inquiry using micro-phenomenological methods (Petitmengin et al., 2019) that elicit the embodied, affective, and relational dimensions that often go unnoticed yet are consequential to their learning. What makes the collected data ideal is that learning involves enacted doing, and doing makes thinking visible and open to micro-phenomenological analysis.

Preliminary Findings

In this section, we share excerpts from the journal entries of two students who participate in different groups. Both entries will make reference to Figure 1. The common point of inquiry for the entries is the endeavor to make sense of the polar graph of $r = \theta$. Looking across the entries, we will see mathematical thinking about polar graphing happening across assemblages (de Freitas & Sinclair, 2014) of bodies, tools, diagrams, and discourses. Any insights that students achieve through these mediated interactions lend credence to claims of their efficacy and are thus suggestive of the very tools, tasks, and practices that constitute an effective, enactive educational ecosystem for learning the PCS.

Figure 1: Students Enact the Graph of $r = \theta$ Using a Dance Pole and HDMI Cord (Left), and a Cardboard Disk and Retractable Tape Measure (Right).

Group 1. We did our work at the pole. We wondered how r and θ covary and whether we could *feel* their respective rates of change simultaneously. One of us grabbed an HDMI cord to embody the changing radius, tied it around the pole, walked it out to its full length, which we designated 2π, and marked that point on the floor. We then folded it in half and in half again to locate $\pi/2$, π, and $3\pi/2$. Next, we used tape to make those same markings as θ-values on the floor. Tethered to our *radius*, our goal was to circulate the pole at a constant speed by focusing on *feeling* the constant change in the radius length and arriving at the 2π floor marker at the very same time that we reached 2π on the rope (see Figure 1, left). We each took turn after turn, but no one came close. Looking back and forth between the corresponding markings on the floor and on the rope, I eventually experienced an aha! moment of clarity when I suddenly *feelized* that our step *size* was the missing link! Constant changes in arc length must be reflected in continual increases in step size! This was a *pivotal moment* in our sense-making! We came up with dance steps of increasing size for each quadrant: *baby steps, short steps, normal steps,* and *mega steps*.

Group 2. We did our work on a 6-foot diameter disk that we took to be the polar plane. I began by intuiting that since r and θ were equal, the radius and angle measure would be equal, so then the graph of $r = \theta$ must be a circle. When a group member graphed it in Desmos, I was so confused about why it was a spiral! When a second group member was unable to explain it to me, he proceeded to find a way to embody the relationship using a retractable tape measure. While I held the tape measure at the origin of our polar plane, he extended it outward at familiar increments ($r = 0, \pi/6$, and $\pi/4$) while simultaneously rotating around the disk at arc lengths equal to those same increments (see Figure 1, right). I conceptualized this know-how as "you walk out that much, you turn that much," enacted this concept through my own trace around the disk, and formalized the experience as coordinated increases in distance *from* the origin (r) and rotation (θ) *about* the origin.

What these journal entries reveal are embodied and materially engaged interactions that lead to sense-making. These include forms of movement (e.g., walking, circling, stepping, and rotating) that embody polar equations as dynamic mathematical objects; people-material couplings that enact changing radii and angle measure (via a dance pole, HDMI cord, and floor markings) in addition to polar coordinates and spiral growth (via a large disk, retractable tape measure, and Desmos graph); and conceptual-material entanglements that make the abstract into the actual (as in the "aha!/feelized" and "you walk out that much, you turn that much" moments). There are other affective ("so confused"), discursive (step sizes), and perceptual ("looking back and forth") interactions in there, as well.

Conclusion

The objective of this work is to discern the elements of an enactive educational ecosystem that supports the emergence of a graphical understanding of the polar coordinate system. Preliminary findings of students' wayfaring along pole-based choreographies show how specific choreomathematical configurations foster insights into the qualities and behaviors of polar curves. These findings have theoretical implications relative to how enactive cognition and inclusive materialism can be applied in precalculus through embodied and materially agentive curricular interactions. They also have practical implications that move precalculus curricula beyond procedural PCS instruction toward emergent and embodied learning of polar graphing. As this work continues, we will refine these configurations of tools, tasks, and practices, and supplement these findings with phenomenologies of students' experiences of wayfaring along these emergent paths.

OBSERVING THE EMERGENCE OF CRYSTALLINE CONCEPTS THROUGH GENERATIVE STRUCTURAL REASONING

Michael D. Hicks
Middle Tennessee State University
mdhicks@mtsu.edu

In this brief report, I present an analysis of two students' generative structural reasoning as they worked to analogically develop the quotient ring concept based upon their previous knowledge of group theory. I observed key differences in their reasoning and subsequent creations. Although both students engaged productively with the task, one student began to establish a clearer articulation of what he would need to successfully design the quotient ring concept by appealing to general qualities of quotient objects, thus suggesting that his understanding of the underlying structure was progressing toward a crystalline conception of quotient objects. Implications of this study suggest one mechanism through which students might transition from possessing an instantiated conception of structure toward an emergent a crystalline conception through generative structural reasoning as opposed to analogical transfer alone.

Keywords: Advanced Mathematical Thinking, Reasoning and Proof, Undergraduate Education

In this paper, I present further empirical evidence sharpening previously documented theoretical claims (Hicks et al., 2023) that a student can recreate analogical concepts through processes of comparative and inductive analogy. The specific aim of this report is to delineate the ways in which two students come to observe the rich mathematical structure that underlies the concept of quotient objects in advanced mathematics. This qualitative study seeks to answer the following research questions: *How do two students reason about the underlying formal mathematical structure associated with the quotient ring concept? In what ways does their structural reasoning differ?*

Theoretical Background

This paper takes as its premise that knowledge construction is rarely linear. The development of a rich understanding of a particular concept can take place over time and across a series of (possibly unrelated) episodes that result in a refined understanding of a particular concept. The math education community has documented several cases in which prior knowledge influences new knowledge construction, or vice versa (e.g., diSessa, 1993; Ellis et al., 2022; McGowen & Tall, 2010). The context I describe here involves *generative structural reasoning* through analogy as a contrast to analogical transfer alone. By generative structural reasoning, I refer to reasoning that not only observes and reasons with formal mathematical structure, but also creates formal mathematical structure.

Crystalline and Amorphous Concepts

In a previous report, a colleague and I developed the concept of an *abstracted domain* (see Figure 1) as a theoretical contribution to observing students' structural reasoning through analogy (Hicks et al., 2023). In contrast to a source domain (typically an already known concept) and target domain (typically a new concept being explored), the abstracted domain represents the domain in which the underlying formal mathematical structure of the concepts is formed. Similar to Tall's notion of a concept becoming thinkable, we posited that this domain may not necessarily be recognized by the thinker in the moment of establishing the domain. In this report, I connect our contribution with Tall's notion of a *crystalline concept* to better describe the

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

development of the abstracted domain, and how it might leveraged for analogical concept creation.

A crystalline concept is one that "develops an increasingly sophisticated structure as we compress knowledge and link ideas together." (pg. 3–4) Tall's use of the word "crystalline" purposefully invokes a metaphor stemming from the study of solids possessing highly organized and uniform internal structure. Building on this metaphor, I borrow the term "amorphous" from the study of crystalline solids to introduce the term *amorphous concept*. A solid is called amorphous when it lacks the organizational structure of a crystal, meaning that its internal structure may appear disorganized despite forming a cohesive, observable shape. In the context of mathematics education, I use amorphous concept to refer to formal structures that continue to remain in a stage of development in which connections are yet to be made to become crystalline.

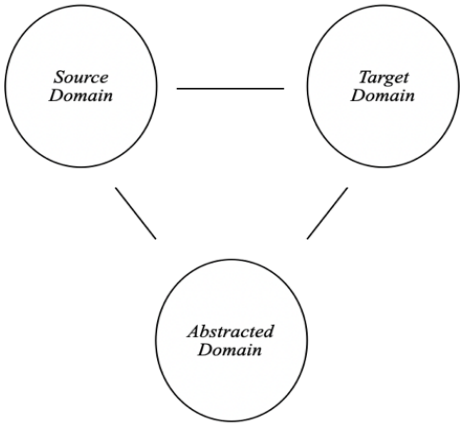

Figure 1: The Abstracted Domain in Relation to the Source and Target

Comparative and Inductive Analogy

Based upon both empirical evidence and theorizing about the nature of the abstracted domain, two forms of generative structural reasoning were identified: comparative analogy, and inductive analogy. Using the relationship displayed in Figure 1 as a template, these forms of reasoning are identified by considering the different activities that might lead to the development of the abstracted domain. In the case of comparative analogy, the abstracted domain is formed by recognizing the underlying structure that exists between two concepts that are compared between the source and target. Inductive analogy, on the other hand, involves identifying the abstracted domain from a single example which is then applied to the target domain to generate new concepts within that domain. Figure 2 displays these relationships using the sub-structure concept as an example.

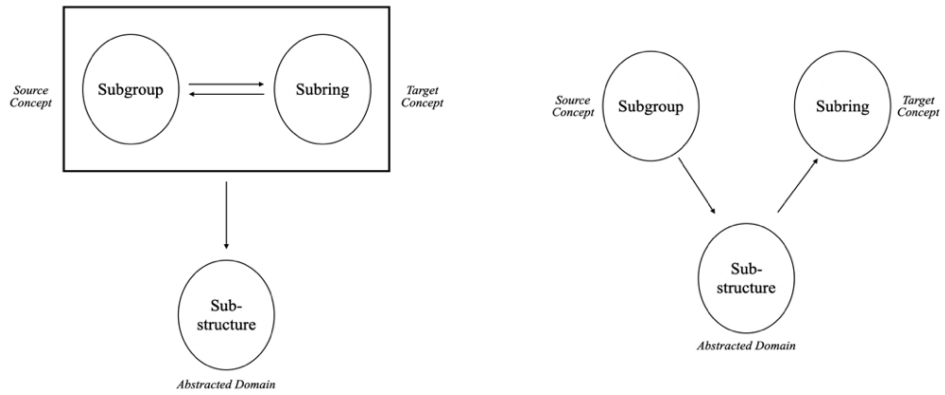

Figure 2: Comparative Analogy (left) and Inductive Analogy (right)

Methods

The data for this study is part of a larger study that was focused on investigating how students reasoned analogically to create structures in abstract algebra. Four students were recruited to participate in a series of five task-based interviews designed to elicit their approaches to constructing several ring-theoretic structures by analogy with what they knew from group theory. Each interview was video- and audio-recorded and subsequently transcribed. The data for this particular study is focused upon just two of the students, and upon just one interview from each student wherein they were asked to construct a structure in ring theory that was analogous to quotient groups in group theory. These students were chosen for this analysis because they exhibited fruitful reasoning associated with developing the quotient ring concept while serving as contrasting cases.

To describe Brandon and Andrew's generative structural reasoning about the quotient ring concept, I scrutinized all relevant events in their interviews in which progress was being made toward developing a formal mathematical structure, including cases of their defining activity, their creation of and checking of examples, and the revision of their ideas based on further exploration and investigation. Profiles of their reasoning were created and then compared with the goal of documenting how and in what ways their reasoning differed significantly. For this brief report, a subset of these results are described below.

Results

As hypothesized at the outset of the study, Brandon and Andrew displayed key differences in their generative structural reasoning. My overarching claim is that Andrew had developed an abstracted domain relevant to quotient objects and displayed evidence of transitioning from an amorphous conception toward a crystalline conception of quotient objects, whereas Brandon's conception remained as an instantiation of a concrete domain, never quite reaching the amorphous state by establishing an abstracted domain.

Variation in Domain Use and Selection

Analogical concept creation requires an established source domain to begin the development of the new concept in the target. In Brandon's case, the selection of source domain was immediately chosen as the quotient group concept, as encouraged by the task design. Afterward, the source domain remained largely static and unchanging throughout the course of the interview. Andrew, however, displayed variation in his selection of source domains. Although Andrew began in the expected manner by attending to the source domain as the quotient group,

he also explored other possibilities to draw upon his construction of the quotient ring concept. In particular, he drew upon the quotient space concept from topology, stating:

> The way I think of it, and this is probably from topology because I took topology first, and there's a thing called a quotient space. And the way we do that is we take points from space and we glue certain points together. That's the way my professor explained it. But I think of it as a quotient group in a similar way. This entire set equals 0, so we're taking all of these numbers and gluing them together to equal some representative number.

Here, not only is Andrew drawing upon another domain, but he is also reasoning conceptually across those domains by adapting ideas in one domain (e.g., "glue certain points" in topology) into the other (e.g., "gluing [numbers] together").

Another case of source domain selection arose in the form of example-based reasoning. I describe this special case here. As suggested by Duit (1991) in the science education community, examples are in and of themselves types of analogies. In fact, each of Brandon and Andrew drew upon the same example to support their reasoning through constructing the quotient ring concept. Despite this, I claim that the nuance in which each of Brandon and Andrew drew upon their examples further reveals differences in their attention to their formation of the abstracted domain and progression toward a crystalline concept.

Brandon's use of examples occurred in two phases. First, as Brandon continued his construction, he began to consider what he could recall about the quotient group $\mathbb{Z}/2\mathbb{Z}$. Almost as soon as he wrote down the example, he scratched it out, stating: "Oh, I'm trying to think about it in groups." The fact that Brandon discarded the investigation of the quotient group example based on the premise that it was related to groups and not rings suggests further evidence that he was not aware, nor becoming aware, of the underlying structure between the quotient group and quotient ring concepts themselves. Furthermore, although Brandon had previously recognized that all rings are examples of groups with a multiplicative operation, he did not leverage that connection here. Upon discarding the example, he returned to his investigation of the quotient ring concept and continued to push the equivalence relation idea further. The second phase of Brandon's use of examples occurred later after finalizing his quotient ring concept, and then being asked to consider the example $\mathbb{Z}/n\mathbb{Z}$ as part of a follow up task. He first considered the meaning of an equivalence class in this context, and chose to investigate the set $\mathbb{Z}_6$. Brandon's inquiry into the nature of the example did not progress from there.

Andrew also investigated the quotient group $\mathbb{Z}/n\mathbb{Z}$ to assist him with his construction. However, Andrew's attention and purpose for using the example was quite different in form and function. First, Andrew attended to the example $\mathbb{Z}/3\mathbb{Z}$ as a quotient group. In doing so, he enriched his recall of key properties of quotient group that he had been struggling to make sense of when working with the general definition, stating: "I always just go back to an example like this [writes $\mathbb{Z}/3\mathbb{Z}$.] So how would I form this? Let's test my definition." Andrew then worked with the specifics of the example to help of the general definition, and in doing so, recalled key properties such as coset, the notion of partitioning, and representative elements. In doing so, Andrew launched his creation of the quotient ring concept by exploring how these recalled properties could be adapted to the ring context. This further evidences the claim that Andrew was successfully coming to establish an understanding of the quotient object structure underlying each of quotient group and quotient ring.

Discussion

This in-depth analysis of Brandon and Andrew's generative structural reasoning further builds upon the ways in which comparative and inductive analogical reasoning might be displayed within students' thinking. In particular, this account of the students' reasoning revealed that, although each student engaged with productive mathematical thinking, Brandon attended only to concrete, instantiated concepts, while Andrew displayed evidence of forming an amorphous conception of the underlying structure of the concept and subsequently progressing toward a crystalline conception of the quotient object concept. A hypothetical categorization thus becomes visible: (a) concrete comparative reasoning in which only the source and target concepts are recognized and separated during the construction of a new concept, (b) emergent inductive reasoning transitioning from comparative reasoning in which an amorphous conception of an abstract domain becomes evident and useful for building new concepts, and (c) fully inductive reasoning in which the abstract domain is realized and leveraged to establish a new concept.

FROM REPRESENTATIONS TO CONCEPTUAL LAYERS: AN ANALYSIS OF LEARNING OPPORTUNITIES FOR THE DERIVATIVE

Dae S. Hong

Samantha Chediak
University of Iowa
samantha-warren@uiowa.edu

This study examined the learning opportunities provided in a Calculus I class, with a specific focus on lessons related to derivatives. The investigation analyzed a mathematician's classroom instruction and the accompanying textbook to understand the nature of the learning experiences offered to students. We paid particular attention to whether students were given opportunities to explore multiple aspects of the derivative concept. The findings suggest that, based on the lessons and textbook used, students were more likely to have limited opportunities to engage in multiple aspects of the derivative.

Keywords: Calculus, Class Practices, Derivative, Textbooks

Introduction

Calculus is a foundational course for most disciplines in science and engineering, not only in the United States but also worldwide. Due to its importance in undergraduate education, numerous studies have investigated how students learn calculus topics (Hong, 2024; Hong & Choi, 2019; Larsen et al., 2016). Despite the significance of calculus in undergraduate education, across the United States, 28% of students enrolled in Calculus 1 either fail or withdraw from the course (Bressoud et al., 2013). In the United States, three main topics in Calculus 1 are limits, derivatives, and integrals. Of these, the concept of the derivative has been studied frequently (Cooley et al., 2007; Haciomeroglu et al., 2010; Hong & Lee, 2024; Litteck et al., 2024). Many experts in teaching Calculus 1 considered understanding of the derivative as a central concept or a central skill that is fundamental to Calculus 1 (Sofronas et al., 2011). One key finding from these studies is students' inability to flexibly move among different representations of derivatives (symbolic, graphical, and verbal) (Cooley et al., 2007; Haciomeroglu et al., 2010). To better understand the reasons behind students' struggles, two critical areas to explore are classroom instruction and curriculum, which have not been examined often (Larsen et al., 2016). This study is not motivated merely by a lack of prior work, but by the need of deepening our understanding of how opportunities for students to explore different representations are presented in two crucial areas of student experience: the mathematics classroom and the textbook. By situating our analysis within curriculum materials and class practices, the study may contribute to ongoing discussions about how to design learning environments for students to explore multiple representations of derivative. Here are two research questions that guided us.

1. How did the instructional tasks afford opportunities for students to engage with multiple representations and layers of the derivative?
2. How did the tasks in widely used textbook afford opportunities for students to engage with multiple representations and layers of the derivative?

Related Literature

Theoretical Considerations

Duval's theory of semiotic representations (Duval, 2006) states that mathematical objects can only be accessed through semiotic representations. Duval's "registers" refer to systems of semiotic representations, include symbolic, graphical, and verbal forms. Duval distinguishes between two types of transformations involving representations: treatments, which are

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

transformations within the same register, and conversions, which involve changing from one register to another without altering the mathematical object itself (Duval, 2006). For example, expanding $(x+3)^2$ to x^2+6x+9 can be a treatment while expressing a quadratic function with an equation, $f(x) = (x+3)^2$, and then graphing it can be a conversion. To build a deeper conceptual understanding, students need opportunities to explore how the derivative can be represented and interpreted across different semiotic registers.

Conceptualizing Layers of the Derivative

In the context of derivatives, students can view the derivative as different layers such as the slope of the tangent at a single point, the ratios, limits, functions (Zandieh, 2000). With the ratio, students can see the derivative as dividing one quantity by another one. When each ratio converges to a single value, you can see the derivative as limit. Finally, when students consider such limits at every point on the interval, the derivative can be viewed as a function. Using this framework, Zandieh (2000) described that many students displayed what she termed "pseudostructural understanding" of derivatives, meaning that students were not able to see derivative as these layers. For example, consider differentiating the function $f(x) = x^3$ twice. When the equation is given, students can compute the first and second derivatives and use them to sketch the corresponding graphs. However, when the problem is presented without the equation, only the graph of the second derivative is provided, they need to interpret the values of the second derivative and relate them to the slopes of the tangent lines of the first derivative, considering how these slopes represent rates of change over an interval. This process allows students to see how limit, ratio and function are related in the context of derivative. Zandieh's framework can be tied to Duval's theory of representations as Duval's theory explains the need of representational conversions in mathematics general, while Zandieh's framework specifies the conceptual structures of the derivative that such conversions need to support.

Method

Data Sources, Setting and Analysis

This study took place at a Midwestern research university in the United States, focusing on the teaching practices of Dr. T, an experienced calculus instructor with a PhD in mathematics. Dr. T had taught Calculus 1 multiple times, and the study aimed to observe her class practices without external influence. There were 25 students in Dr. T's class and each class session was 50 minutes long. Data collection involved video and audio recordings of all 33 calculus lessons she taught. For this study, the analysis concentrated on three lessons about derivative concepts including the derivative as a function, the first and second derivative test and sketching graphs, as other lessons on derivative were dedicated primarily to different differentiation rules such as the chain rule and quotient rule. We were particularly interested in how Dr. T presented graphs of a function and its first and second derivatives. Dr. T is positioned as a critical case (Flyvbjerg, 2006). By situating this analysis within a "critical case"—an experienced mathematician teaching with the most widely adopted calculus textbook in the United States—this study highlights how normative instructional structures may shape derivative learning. The study does not claim that this professor's practices represent all calculus instructors; rather, the aim is to demonstrate pedagogy and challenges that can inform practice in teaching derivative. Dr. T used Calculus 7E (7th Edition) by Stewart (2010), the most widely used calculus textbook in the U.S. (Bressoud, 2011). This study examined two sections called "Derivative as a function" and "What Derivatives Tell Us about the Shape of a Graph." In all, we examined eight implemented tasks from Dr. T's lessons, 27 pages, 15 worked examples and 205 exercise problems from Stewart Calculus (SC). Our analysis involved breaking down each segment—defined as the discussion of one task—and we analyzed worked examples and exercise problems from the sections of

derivative. There are other sections on derivatives, but they are about various differentiation rules, so they were excluded from this study. Each unit of analysis included one worked example, and one exercise problem. In total, we examined eight tasks from Dr. T's class, 220 worked examples and exercise problems from SC. To ensure the reliability of our findings, a fellow mathematics education researcher who is familiar with teaching calculus reviewed the discussions of the eight tasks and 220 textbook tasks for inter-rater reliability. Our initial rating achieved 96.5% agreement (197 out of 204). After further discussion, we reached 100% agreement.

Example of Analysis

Table 1 shows analytic framework that we used and examples of each code. We coded each derivative task using Duval's representations and transformations, and Zandieh's three layers. With these codes, when we coded each task, we examined students' opportunities if they were able to solve them correctly.

Table 1: Analytic Framework and Coding Examples

Task	Presentations/Transformations	Layers
1. Find the derivative of the function using the definition of derivative. $(x) = 3x - 8$	Symbolic (Treatment)	Ratio/Limit/Function
2. If $f(x) = x + \frac{1}{x}$, find of $f'(x)$.	Symbolic (Treatment)	Function
3. Match the graph of each function in (a) – (d) with the graph of its derivative in I–IV. Give reasons for your choices.	Graphical → Verbal (Conversion)	Ratio/Function
4. Let $f'(x) = \sqrt[3]{x}$. If $a \neq 0$, Use Equation 2.7.5 to find $f'(a)$.	Symbolic (Treatment)	Ratio/Limit
5. Sketch the graph of a function that satisfies all of the given conditions. Vertical asymptote $x = 0$, $f'(x) > 0$ if $x < -2$, $f'(x) < 0$ if $x > -2$ $(x \neq 0)$, $f''(x) < 0$ if $x < 0$, $f''(x) > 0$ if $x > 0$	Symbolic → Graphical (Conversion)	Ratio/Function
6. Make a careful sketch of the graph of f and below it sketch the graph of f'. $f(x) = Sinx$	Symbolic → Graphical (Conversion)	Function
7. Find where the function $f(x) = 2x^3 - 15x^2 + 24x - 5$ is increasing and where it is decreasing.	Symbolic → Verbal (Conversion)	Function

The first and second tasks in Table 1 engage students primarily in using symbolic representations, and other representations may not be necessary to solve them. However, when solving the first task using the definition of the derivative, students will have opportunity to view the derivative as both a ratio and a limit, whereas the second task can be solved symbolically without explicitly considering these layers. The third task provides opportunities for students to use graphical representations of derivatives. In Task 3, when matching graphs of a function and its derivative, students need to reason about rates of change—that is, where the function is increasing or decreasing—and recognize and consider that infinitely many of these rates over entire interval form a new function. Students would

only implicitly encounter the idea of a limit as they considered rates of change over an entire interval. The fifth task invites students to use both symbolic and graphical representations. To graph the function, they must reason about rates of change (ratios) to describe and visualize its behavior. This is one example of a task that allows students to consider multiple conditions and intervals to think about derivative (Cooley et al., 2007). The sixth example allows students to work with both symbolic and graphical representations, integrating multiple perspectives on the derivative. Although this task involves a symbolic-to-graphical conversion similar to the fifth task, unlike that task, students may not need to consider rate of change when finding the derivative of sin$x$. As a result, these tasks require different types of knowledge. The fourth task primarily involves symbolic representation, and because students were asked to use the definition of the derivative (Equation 2.7.5), they again engage with the ideas of ratio and limit, but it is unlikely for them to consider rate of change over entire interval. Finally, the seventh example requires verbally identifying intervals. Students will need to consider signs of the function to identify the interval without necessarily considering ratio.

Results

Dr. T's First Lesson

Dr. T's first lesson was on derivative as a function. She began the lesson with one problem that students were asked to find the derivative of a function ($f(t) = t^{-1} - t$) and find the value of $f'(5)$—coded as Symbolic treatment and ratio/limit/function layer. This problem was solved using the equation and the definition of the derivative. Then, she pointed out that value of derivative at one point is instantaneous rate of change and that would be the slope of tangent line. Then, she had a task about sketching the graph of the derivative when the graph of a function is given (Figure 1).

Figure 1: One Task from Dr. T's Lesson

She was trying to let her students think about what it means to have instantaneous rate of change.

> At every point there's a tangent. So, at every point there is a slope. So, if this is the graph of x, I should be able to draw the graph of the derivative of the F by figuring out what the different slopes are.

From how she explained this task, we can see that Dr. T was trying to point out how graphs of a function and its derivative are related. Her students had opportunities to think about how instantaneous rate of change can be used and interpreted to sketch the graph of the derivative. Then, she did two more similar problems. In solving both tasks, Dr. T continuously mentioned how the signs of the given function can be used to sketch the graph of its derivative. For example, the third problem was about sketch the derivative of the following function—coded as Graphical to verbal conversion and function/ratio layer.

Figure 2: One Task from Dr. T's Lesson

> So, when you have a corner, the derivative is not defined. So, when we draw a derivative, it should not be defined as zero. Alright? Over here, what's the derivative positive or negative? It's negative because the thing decreasing and over here it's actually very close to zero negative and then it gets steeper and steeper.

Again, Dr. T mentioned how slopes can be used to understand the behavior of the derivative.

Dr. T's Second Lesson

Dr. T's second lesson was on the first derivative test. She drew a graph and stated the following—coded as Graphical to verbal conversion and function/ratio layer.

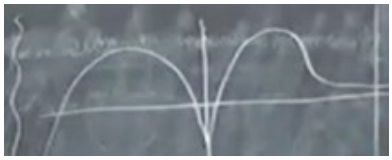

Figure 3: One Task from Dr. T's Lesson

> Here's a function and what we're going to do is design the sign of the derivative, the first, the second derivative everywhere. So, the first thing I would like to do is look at this function graph and decide where the first and or second derivative are either zero or undefined.

Once she gave her students time to work on this, she created a table to check how signs change at each interval and pointed out how the slopes of the function can be used to think about the graphs of its derivatives. After discussion of this task, she solved two more problems where equations are given to them. These problems were solved by differentiating the equation and creating a table.

Dr. T's Third Lesson

She continued with graphing functions and again, students were given equation (Figure 4) coded as Symbolic to graphical conversion and function layer. After discussing this task, she moved on to the next topic, L'Hospital's rule.

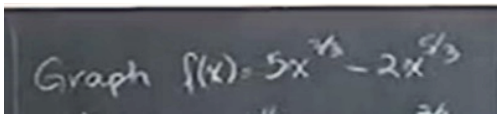

Figure 4: One Task from Dr. T's Lesson

In all, equations were given to students for four out of eight tasks and the graphs of functions were given for other four tasks. When graphs were used, she consistently pointed out how the values of function (the slopes) can be interpreted to find the graphs of derivatives. However, there were no tasks that asked students to consider several conditions and intervals to think about function and its derivatives (fifth example in Table 1) or ones that used by Cooley and colleagues.

Learning Opportunities in Stewart's Calculus

In two sections, there were 15 worked examples. Among them, 13 of them were presented with symbolic representation. For example, Figure 5 shows one worked example from Section 2.8—coded as symbolic to verbal conversion and function layer. Students may consider rate of change but the task does not ask students to consider rate of change explicitly.

> Find where the function $\boldsymbol{f(x) = 3x^4 - 4x^3 - 12x^2 + 5x}$ is increasing and where it is decreasing.

Figure 5: One Worked Example from SC (p. 297)

The solution shows the function can be differentiated and factored to find intervals where it increases. Unlike task in Figure 5, solution of worked example in Figure 6 shows that the graph of function was examined to see how instantaneous rate of change at each point can be translated to the graph of its derivative—coded as conversion—graphical to verbal and function/ratio layer.

> The graph of a function *f* is given in Figure 1. Use it to sketch the graph of the derivative $\boldsymbol{f'}$.

Figure 6: One Worked Example from SC (p. 153)

Figure 7 shows another worked example that does not include equations—coded as symbolic to graphical conversion and ratio/function layer. Solution shows that students need to consider and interpret each condition to see how the function behaves.

> Sketch a possible graph of a function f that satisfies the following conditions:
>
> $$\boldsymbol{f'(x) > 0 \text{ on } (-\infty.1),\ f'(x) < 0 \text{ on } (1,\infty)}$$
> $$\boldsymbol{f''(x) > 0\ (-\infty.-2) \text{ and } (2,\infty)\ f''(x) < 0 \text{ on } (-2,2)}$$
> $$\boldsymbol{\lim_{x\to-\infty} f(x) = -2, \lim_{x\to\infty} f(x) = 0}$$

Figure 7: One Worked Example from SC (p. 301)

Exercise Problems

Table 2 shows that about 60 % of tasks in this section allow students to use symbolic representation and 50% of tasks are about symbolic treatment.

Table 2: Exercise Problems in the First Section

Representation	Layer	Frequency	Percent
Symbolic (Treatment)	Function	2	2.6%
Symbolic (Treatment)	Ratio/function	18	23.6%
Graphical to Verbal (Conversion)	Ratio/function	30	39.5%
Symbolic (Treatment)	Ratio/limit	20	26.3%
Symbolic to Graphical (Conversion)	Ratio/Function	6	7.9%
Total		76	

Figure 8 shows one exercise problem from SC. It provides an equation to estimate the values of derivative at a few points, and students were asked to use these values to guess the formula for $f'(x)$—coded as Symbolic to graphical conversion and Ratio/function layer.

Let $f(x) = x^2$
Estimate the values of $f'(0), f'\left(\frac{1}{2}\right), f'(1)$ and $f'(2)$ by zooming in on the graph of f.

Figure 8: One Exercise Problem from SC (p. 163)

On the other hand, task in Figure 9 shows that students are asked to understand function and its derivative without equations. Without an equation, students need to consider how rate of change over time is related to the graphs of derivatives—opportunities to see conversion between graphical and verbal representations.

The figure shows the graphs of three functions. One is the position function of a car, one is the velocity of the car, and one is its acceleration. Identify each curve and explain your choices.

Figure 9: One Exercise Problem from SC (p. 165)

Table 3 shows distribution of exercise problems in the second section. For this section, about 67% of tasks provided equations to solve derivative tasks. The most frequent task in this section is coded as "Symbolic to verbal conversion and function layer" (Figure 10).

Table 3: Exercise Problems in the Second Section

Representation	Layer	Frequency	Percent
Symbolic to Verbal (Conversion)	Function	54	41.8
Symbolic to Graphical (Conversion)	Ratio/function	34	26.3
Graphical to Verbal (Conversion)	Ratio/function	41	31.8
Total		129	

(a) Find the intervals on which f is increasing or decreasing.
(b) Find the local maximum and minimum values of f.
(c) Find the intervals of concavity and the inflection points.

$$\boldsymbol{f(x) = \frac{x}{x^2 + 1}}$$

Figure 10: One Exercise Problem from SC (p. 306)

In contrast, examples in Figure 11 requires for students to consider various conditions of a function to sketch or identify the graph without using equations—coded as symbolic to graphical conversion and ratio/function layer.

Sketch the graph of a function that satisfies all of the given conditions.

$$f'(5) = 0,\ f'(x) < 0 \text{ when } x < 5$$
$$f'(x) > 0 \text{ when } x > 5,\ f''(2) = 0,\ f''(8) = 0$$
$$f''(x) < 0 \text{ when } x < 2 \text{ or } x > 8$$
$$f''(x) > 0 \text{ when } 2 < x < 8$$
$$\lim_{x \to -\infty} f(x) = 3\ ,\ \lim_{x \to \infty} f(x) = 3$$

Figure 11: One Exercise Problem from SC (p. 306)

Discussion and Conclusion

This study examined how opportunities to learn the concept of derivative were structured across enacted instruction and a widely used calculus textbook. Instead of focusing on students' challenges directly, we investigated the representational and conceptual affordances embedded in instructional tasks. Using Duval's theory of semiotic representations and Zandieh's layers, we analyzed how tasks positioned students to engage with representations and derivative layers. Our findings suggest that the structure of instructional tasks may systematically constrains sustained engagement with the derivative across multiple representational registers and conceptual layers as instructional tasks afford limited opportunities for students to explore multiple representations and layers. While symbolic fluency is essential in calculus, the issue is not just the prevalence of symbolic work, but the nature of representational activity students were expected to perform. Opportunities for conversion between registers—particularly those requiring students to coordinate graphical, verbal, and symbolic representations—were comparatively limited and often episodic. Similarly, when examined through Zandieh's framework, there were limited tasks that positioned students to engage simultaneously with the derivative as ratio, limit, and function. We were able to observe that students may consider ratio or limit implicitly for some tasks. Thus, it can enhance students' learning opportunities if they are asked to consider those layers explicitly. Our findings suggest that such fragmented understandings may not arise solely from cognitive difficulty, but also from the organization of learning opportunities themselves. When tasks privilege symbolic treatments and provide limited occasions for representational conversion and layered coordination, students may have few sustained opportunities to build structurally integrated conceptions of derivative. In conclusion, this study reframes difficulties with derivative not solely as issues of student cognition, but as consequences of how instructional tasks structure representational and conceptual activity. By analyzing opportunities to learn through complementary theoretical lenses, we contribute to ongoing discussions about how calculus instruction might better support deep and integrated understanding of fundamental concepts.

Keywords: Undergraduate Education, Professional Development, Instructional Activities and Practices

This brief report examines the development and early outcomes of a Community of Practice (CoP) designed to support mathematics faculty in exploring pedagogical approaches that promote student empowerment. Seventeen participants, representing a range of instructional roles and course contexts, engaged in bi-weekly discussions on topics such as balancing procedural and conceptual understanding, assessment practices, productive failure, technology use, and student engagement. Data were collected through session surveys, monthly reflections, informal gatherings, and an end-of-semester questionnaire. Initial findings indicate that faculty highly valued having a dedicated space for pedagogical dialogue and appreciated learning from colleagues' experiences across diverse teaching environments.

Objectives and Purpose of Study

Mathematicians and mathematics educators both have teaching goals that include empowering students to successfully make sense of mathematics. As faculty members, it is imperative to have opportunities to discuss mathematics pedagogy with others who may be facing similar situations, and we have seen such groups form regionally (e.g., Johnson et al., 2021), but our goal was to start within our department. Therefore, a group of five faculty members came together to create a Community of Practice (CoP) for a mathematics department where participants could explore various pedagogical theories and strategies together through a theme of student empowerment. While studies have considered mathematical CoP's relationship among the members and with administration (e.g., Sack et al., 2016), our CoP's initial goals were to encourage pedagogical discussions among the department. The research questions we developed to examine this CoP include: How do mathematics faculty engage with the pedagogical aspects of teaching mathematics? What aspects of faculty professional development, in the form of a CoP, do participants find helpful? Note that, for this paper, we use the term *faculty* to include any person who could serve as the instructor of record for a mathematics course, which includes tenure-track faculty, clinical faculty, lecturers, and graduate students.

Background and Theoretical Perspective

We entered this work aware that traditional lectures have been the dominant mode of instruction for in mathematics and other STEM courses across many institutions (Stains et al., 2018). While the sole use of traditional lecturing has been questioned for years (e.g., Gibbs, 1982), we also find literature suggesting that it may not be the lecture that is the issue, but the way the lecture is structured (e.g., Kohn, 2017). We were also aware that in our mathematics department, faculty taught or coordinated courses with enrollments ranging from 15 to 3000

students with sections that varied in size. This meant that our colleagues face differing challenges and use a variety of strategies, depending on the type of class they teach. Thus, our intentions were to offer mathematicians opportunities to discuss new and current practices that support empowering students in mathematics and how they might apply to courses with various sizes and settings.

Using Wenger-Trayner and colleagues' (2023) *Communities of practice within and across organizations: A guidebook* as a baseline structure, we considered the key characteristics of a CoP of *domain*, *community*, and *practice*. Within our department, our *domain*, or shared goals and passions, were our love of mathematics and empowering students through the teaching and learning of mathematics. We built *community* through regular formal meetings and opportunities to gather informally and discuss challenges and successes in our teaching experiences as well as to consider other research-based strategies. *Practice* was integrated as the organizers of the CoP led discussions about theories and strategies that could be helpful in addressing the shared challenges with empowering students that we discussed. At times, we included guests from other departments on campus (e.g., Teaching and Technologies and the Center for Instructional Excellence) to share with the community or asked members of the CoP to share specific experiences from their teaching practices (e.g., implementing standard-based grading).

We used the concept of student empowerment as common ground in our CoP for mathematics professors. Empowerment served as a shared goal that resonated with faculty members' inherent desires to see students succeed in mathematics. A focus on empowerment also helped us shift the content of CoP sessions from purely theoretical pedagogical ideas to tangible, student-centered outcomes (Christian et al., 2020). We considered three dimensions of empowerment in mathematics learning: self-empowerment, cognitive empowerment, and social empowerment (Hassi & Laurson, 2015) and the roles these dimensions serve in mathematics teaching and learning.

Methods

To create space for sustained, faculty-driven dialogue around approaches to teaching mathematics, a group of five faculty members (three clinical mathematics faculty, one tenure-track mathematics/mathematics education faculty, and one University Alliance Fellow) met regularly over the course of four months to design a six-session, bi-weekly CoP under the theme of student empowerment (Christian et al., 2020; Hassi & Laursen, 2015). A Math Welcome Luncheon, hosted by the Provost's Office for Teaching and Learning, served as the primary venue for introducing the CoP and initiating recruitment, while engaging the department in dialogue around math engagement and shared challenges related to admissions, instruction, student support, and mathematics placement. Faculty were also invited to participate through targeted email communications. We developed six CoP session topics inspired by our perceptions of the needs of the faculty in our own department. The topics stemmed from discussions of our development teams' own experiences and concerns with math teaching, particularly in entry-level math courses at the university (e.g., Pre-calculus and Calculus I and II). For each session topic, we reviewed research articles to support session development or to share with participants to read before the session. The session titles were: (1) Mathematical Empowerment: Reframing our Instructional Impact (Christian et al., 2020; Hassi & Laursen, 2015); (2) Balancing Procedural and Conceptual Understanding (Khoule et al., 2017); (3) Developing Assessments that Foster Empowerment and Reduce Anxiety (Lewis, 2023; Nilson et al., 2023); (4) Teaching Math through Failure and Disorientation (Dibbs, 2019); (5) Technology

as Pedagogical Leverage; and (6) Empowering Students through Engagement (Lugosi & Uribe, 2022).

We collected data from the CoP using end of session surveys, end of month surveys, informal meetings and discussions with participants, and end of semester questionnaire. At the end of each session, participants scanned a QR code and completed a short survey including questions like: "What is one idea, insight, or resource from today's session that you found thought-provoking or useful? To what extent did today's session feel relevant to your current teaching practice or course design?" At the end of each month, participants received an email with a link to a survey regarding the sessions of that month, including questions like: "What, if anything, have you applied—or considered applying—from recent CoP sessions in your own teaching or course planning?" At the end of the six sessions, participants received an end of semester survey with questions like: "Which aspect(s) of the CoP were most impactful for you (e.g., session discussions, shared tools, facilitation structure, peer collaboration)? Why?" Additionally, participants were invited to an informal luncheon for fellowship and to hear about the next steps for the CoP. At the luncheon, they were able to give input through a virtual platform (i.e., Mentimeter) on their takeaways and ideas for the future.

Seventeen faculty members committed to the CoP with a mixture of tenure-track and clinical faculty, lecturers, and graduate students with a variety of teaching roles (e.g., coordinating a calculus course for 3000 students; teaching three sections of 30 students). Because of the various opportunities for feedback, every participant gave written feedback at some point throughout the semester. We are still in the process of analyzing all collected data, but we share some interesting initial findings below and look forward to sharing these in more detail in the future.

Initial Results and Discussion

Participants revealed various insights through the end-of-session surveys. For example, session two, regarding balancing procedural and conceptual understanding, included participants bringing and sharing mathematics problems that they deemed procedural and items deemed conceptual. The discussion revealed that faculty held varied understandings of these constructs, as evidenced by the collaborative analysis of whether "Compute $\cos^{-1}\left(\cos\left(\frac{6\pi}{5}\right)\right)$" was a procedural or conceptual mathematics question. After the session, one participant wrote: "It was interesting to hear how we all think of procedural vs conceptual a bit differently … and not just our definitions but whether or not questions have to be one or the other or can be both." This finding highlights the importance of professional development addressing the procedural-conceptual distinction, which Khoule et al. (2017) demonstrated significantly impacts student anxiety and performance. When faculty develop shared understanding of these constructs through collaborative dialogue, they are better positioned to design instruction and assessments that intentionally allow students to develop both types of knowledge.

Participants had more time to reflect on what value the CoP was bringing to their practice before completing the surveys at the end of the month. Several participants shared the value of simply having this space to discuss teaching with other faculty, as this is not something that had been regularly prioritized in the department. For example, one participant shared, "The discussion has been most valuable … I like hearing about what others are experiencing and implementing in their classrooms, even if it isn't practical for my classes."

Our end-of-semester survey data showed that faculty found the CoP highly valuable, with average ratings of 4.2 out of 5 for worthwhileness and 4.3 out of 5 for likelihood to recommend to colleagues. The space for discussions continued to be most important to CoP members. In the

end-of-semester survey, we asked "Which aspect(s) of the CoP were most valuable to you?", and 87.5% of the respondents who answered that question indicated that discussions were the most valuable. The high value participants placed on discussions aligns with research demonstrating that communities of practice support faculty innovation through shared knowledge and resources (Johnson et al., 2021; Sack et al., 2016).

Conclusion

These CoP sessions with a group of university mathematics faculty allowed for meaningful discourse and revealed current practices that some faculty have tried for empowering students in mathematical thinking in both large lecture calculus and small section courses. Faculty attending these sessions learned about strategies their colleagues were using and, at times, shared their own successful strategies

Our initial analysis shows that participants clearly valued having a formal space for discussing pedagogy with colleagues and appreciated having a theme focused on student empowerment, likely due to the presence of *domain*, *community*, and p*ractice*, key characteristics of a CoP (Wenger-Trayner et al., 2023). In the future, participants recommended more time for practical implementation planning, collaborative development of course policy pilots, and continued focus on topics like assessment practices, mastery-based approaches.

TEACHING AND LEARNING ASSISTANTS' PERSPECTIVES ON ACTIVE LEARNING IN CALCULUS AND PRECALCULUS RECITATIONS

Orly Buchbinder
University of New Hampshire
orly.buchbinder@unh.edu

Rose Benson
University of New Hampshire
anhhong.benson@unh.edu

Keywords: Calculus, Precalculus, Undergraduate Education, Learning Assistants, Teaching Assistants

Institutions of higher education in the United States have been making significant efforts to reform introductory calculus courses to improve student retention and learning quality (Reinholz et al., 2021; Talanquer, 2014; Wu et al., 2018). Reform efforts such as active learning strategies, Teaching Assistants' (TAs) training, and the integration of Learning Assistants (LAs) have been shown to positively affect student learning, retention, and confidence (Clements, 2025; Williams & Fowler, 2014; Wilson & Varma-Nelson, 2016). However, little is known about LAs' and TAs' perspectives on these changes. To address this gap, we explore the research question: *How do LAs and TAs perceive the efficiency of the active learning recitations?*

This study took place at a mid-sized public university in the Northeastern U.S., focusing on recitation sections in Precalculus, Calculus I, and Calculus II. Each recitation was led by one TA, who divided students into small groups to work on problems provided by the course instructor, with one LA, who assisted students with problem-solving. Data were collected during group meetings with all LAs and TAs, held twice per semester across four semesters. The data included written feedback and group discussion summaries on aspects of the recitations that TAs and LAs found most helpful for students' learning, effective support strategies, and students' study skills. We used qualitative content analysis to identify key themes in the data (Mayring, 2021).

The results suggest that LAs and TAs perceived problem-solving in small groups as one of the most helpful aspects of the recitations. They felt students valued collaborating in a low-stakes, low-pressure, and judgment-free environment. TAs and LAs also observed that students appreciated having a brief review of the main mathematical ideas before group work. Among suggestions for efficiently facilitating group work, LAs and TAs mentioned using randomized grouping, sitting at students' eye level, knowing students' names, and allowing themselves to be vulnerable by admitting they did not know all the answers and using that as an opportunity to model problem-solving. At the same time, LAs and TAs noted that limited algebra skills and reliance on memorization negatively affected student confidence and decreased engagement.

These outcomes suggest that LAs and TAs view the active learning aspects of recitations positively and have developed effective strategies to support student learning before and during group work. LAs and TAs also perceived that students' challenges stemmed from insufficient prior knowledge and limited self-regulation skills, rather than resistance to active learning (Theobald, 2021; Tolman & Kremling, 2023). These results are significant because TAs and LAs are on the frontline of educational support in Calculus courses. Their perspectives can help unify instructional efforts to create cohesive learning environments.

INVESTIGATING THE LIMITS OF NOTHING: CALCULUS STUDENTS' CONCEPTIONS OF ZERO

Carlos Alejandro de Alba
San Diego State University & University of California, San Diego
cdealba3923@sdsu.edu

Keywords: Calculus, Mathematical Representation, Number Concepts and Operations

Zero's deceptive simplicity and importance in mathematics affords it the benefit of being useful across all levels of mathematics. It may not be bold to assert that students engage with zero in some way everyday they enter a classroom. Research on zero is rather limited, but it has emerged as a topic of interest in research on parity (Levenson et al., 2007), integer division (Grouws & Reys, 1975; Tsamir, 1996), and algebraic reasoning (Carpenter & Levi, 2000). Many of these studies found that students conceptualize zero as nothing but that this conception may be more nuanced than previously believed (Seidelmann, 2004; Vest & Alibali, 2024). Still, the existing body of research suggests that students' and teachers' understanding of zero is limited or incomplete (Inhelder & Piaget, 1969; Tsamir et al., 2000; Seidelmann, 2004). These studies have classified understanding and conceptions of zero, but they have yet to consider how a student's conception of zero may be a fragmented combination of the different conceptions previously proposed. Reframing previous frameworks on conceptions of zero into an overlapping scheme may allow for a greater understanding of the nuanced conceptions that previous studies have suggested.

This report and the associated poster concern work related to two research questions: *in what ways do calculus students conceptualize the concept of zero and its many roles in mathematics?* and *in what ways do calculus students employ varying conceptions of zero to navigate tasks and mathematical situations?* Zero's central role in calculus and the likelihood that students have encountered many mathematical contexts by the time they reach a calculus class has informed my decision to study calculus students. Furthermore, exploring calculus students' conceptions presents the opportunity to witness the negotiations that take place when a students' traditional conception of zero does not align with their understanding of algebra and calculus. For this study, 50 high school students and 84 undergraduates responded to a digital survey meant to uncover how they conceptualize zero as an isolated object and in the context of mathematical problem solving. The survey responses were analyzed using a Braun & Clarke (2006) thematic analysis, through the lens of the Nature of Zero (NZ) and a second time through the lens of the Uses of Zero (UZ). The analyses uncovered a diverse set of perspectives from students and while the most common responses were associated with the idea of nothing, students' descriptions of zero and its use uncovered further beliefs about what it means to be nothing and the complicated relationship nothing has with existence, especially in real-world examples.

A subset of 12 students, six from each sample, were invited to participate in follow-up interviews to further explore their conceptions of zero. These interviews have yet to be fully analyzed but initial findings suggest that students are comfortable using zero in mathematical situations but may not have a strong understanding of why zero behaves as it does. When some students describe zero, they find that their conception does not align with how they use zero to operate in domains such as multiplication, division, and limit calculations. Furthermore, many students report a belief that zero is simply an abstract representation of nothing, but this belief brings into question zero's existence, its nature, and its behavior in mathematics.

EXPLICATING TWO DIFFERENT USES OF PROXY QUANTITIES

Kevin C. Moore
University of Georgia
kevin.moore@uga.edu

Keywords: Cognition, Mathematical Representations, Modeling

Quantitative reasoning—constructing measurable attributes and reasoning about relationships between those attributes (Thompson, 2011)—has emerged as a critical way of thinking for STEM concepts across all grade levels (Czocher et al., 2022; Ellis et al., 2015; Johnson, 2015; Jones & Ely, 2023; Karagöz Akar et al., 2022; Kularajan et al., 2024; Rodriguez et al., 2019; Steffe & Olive, 2010). Because quantities range in their complexity, the mental operations an individual can enact for one quantity as compared to another vary. For instance, with respect to length, an individual can physically construct a unit-length, disembed that unit-length from a whole, and iterate it end-to-end to measure a whole (Steffe & Olive, 2010). With pressure, however, physically constructing a unit, disembedding that unit, and iterating it is not possible.

One way in which differences among quantities is handled is using *proxy* quantities. Defined generally, a proxy is an agent that represents or stands for something else (Floridi, 2015). In the context of quantitative reasoning, a proxy involves using a quantity in place of another quantity. In this poster, I distinguish between two forms of proxy quantity use. Both forms are for the purpose of moving from complicated quantities to those more familiar or convenient (e.g., from pressure to length) to better understand or explore some quantitatively complex situation. Yet, the two forms are distinct in their cognitive activity.

In one form, a proxy quantity is introduced because it is in a relationship with another quantity with respect to the context under consideration. An example of this includes substituting time in for a distance quantity, often when they are in a proportional relationship (Olsho et al., 2022; Zimmerman et al., 2024). More generally, if someone understands a relationship between quantities A and B, they might use that as a starting point when exploring A and C—adapting it based on how B and C are connected. Quantity B's relationship with A and simultaneous role as an intermediary makes it a proxy for C. This form of proxy use is common in science practice (Guttinger & Love, 2025; Olsho et al., 2022), and it occurs *within* a context.

A form of proxy use left somewhat implicit in educational research and teaching is that which involves using alternative quantities to represent quantities from some other context for the purpose of affording quantitative reasoning. For instance, mercury thermometers use the proxy quantity of length to represent temperature, thus allowing an individual to reason with length in place of temperature. More generally, this form of proxy use underpins a quantitative use of coordinate systems to represent covarying quantities from a context (Lee et al., 2020; Moore, 2021). For instance, an individual could use an instrument to collect the pressure and temperature of a sealed container full of gas and represent that data in a Cartesian coordinate system. Using the Cartesian representation, they could conclude that as the temperature increases, the pressure increases linearly. In drawing this conclusion, their enacted quantitative reasoning entails lengths along the coordinate axes acting as proxy quantities for pressure and temperature in the context.

As illustrated in this poster, these two forms of proxy use have important differences with respect to students' enactment of quantitative reasoning and thus provide a possible clarifying orientation for future explorations of students' meanings across STEM concepts.

EXPERTISE OF PROSPECTIVE TEACHER NOTICING BASED ON MODELS OF STUDENTS' THINKING

Julie M. Amador
University of Idaho
jamador@uidaho.edu

Alison Castro Superfine
University of Illinois Chicago
amcastro@uic.edu

John Bragelman
University of North Georgia
john.bragelman@ung.edu

Garrett Barnes
University of Illinois Chicago
jbarne45@uic.edu

Andrew M. Tyminski
Clemson University
amt23@clemson.edu

We focused on the degree to which prospective teachers demonstrated expertise in distinguishing between concrete and abstract aspects of students' thinking when noticing, as well as in individual versus pattern-focused noticing, both while generating models of students' thinking. Data were collected through simulations as part of a longitudinal study of 18 prospective teachers enrolled in three postsecondary mathematics content courses. Overall, most prospective teachers demonstrated less expert-like characteristics in their simulation interview responses, providing mostly a description of the simulated students' strategies and with limited connections to broader aspects of problem-solving strategies or mathematical thinking. Analysis shows that noticing of students' mathematical thinking occurs while model building, yet there is a significant difference in the interpretation of the students' mathematical thinking.

Keywords: Model Building, Noticing, Representations, Simulations, Students' Thinking

Researchers have emphasized the importance for teachers to attend to and interpret students' mathematical thinking (Jacobs et al., 2010; König et al., 2024; van Es & Sherin, 2008). This focus has been emphasized internationally in recent decades, with an astounding number of research papers on noticing (see König et al., 2017), including entire edited volumes exclusively on the topic (e.g., Dindyal et al., 2021; van Es & Amador, 2025; Weyers et al., 2024). At the same time, researchers have long studied key tenets of noticing (i.e., reasoning about students' thinking) and have focused on developing models of students' mathematical thinking (e.g., Norton, 2018; Steffe & Thompson, 2000; von Glasersfeld, 1981). Although in vernacular, these two foci (i.e., noticing, model building) within the mathematics education literature differ, we argue that the honing on students' mathematical thinking that is required to build a conceptual model of how a student thinks is parallel (in many ways) and complementary to the *specificity* (van Es & Sherin, 2021) needed to notice students' thinking at more extended levels (van Es, 2011). We contend that for a teacher to truly reach an extended level (i.e., van Es, 2011) of noticing in which they can attend to relationships between entities, including students' mathematical thinking, and demonstrate expertise of noticing (i.e., Bragelman et al., 2024), they must also be able to create a mental model of a particular student's mathematical thinking.

To better understand how prospective teachers notice and model students' mathematical thinking, we immersed 18 prospective teachers in a series of teaching simulations, characterized as malleable representations of practice (Amador et al., 2026), and asked them what they noticed as they interacted with a simulated student. We examined how prospective teachers demonstrated characteristics of expertise in two dimensions and answered the following research questions: When asked about how a student solved a problem, to what extent were prospective teacher responses (a) *concrete* versus *abstract,* or (b) *individual* versus *pattern-focused* with respect to noticing?

Theoretical Framing

Researchers have studied the expertise of teaching and teacher education (e.g., Berliner, 1988), with an often unintended comparison and analysis of the skills those more expert-like exhibit versus those more novice (Borko & Livingston, 1989; Carter et al., 1988; Sabers et al., 1991). In such efforts to describe teaching expertise, the lack of skills of those more novice stands in stark contrast to those with expertise (Bastian et al., 2022; Huang & Li, 2012; Jacobs et al., 2010; Stahnke & Blömeke, 2021; Wolff et al., 2016; Wolff et al., 2017); however, we work to intentionally describe expertise without assuming a deficit view of those without such skills. Teaching expertise is a central yet distinct consideration for noticing expertise. Lachner et al. (2016) note that the notion of teacher expertise may be a precursor to understanding that serves as a backdrop for a more refined focus on the expertise of noticing. As teachers demonstrate expertise in noticing, it is essential to capture the nuance of what it means to be expert-like, as the skills required for noticing expertise are more refined than skills regularly referenced for teaching expertise. Due to the refinement of noticing as a part of teaching, the expertise of noticing should be studied to articulate the granularity of knowing how to attend to and interpret students' mathematical thinking (i.e., Jacobs et al., 2010; van Es & Sherin, 2008; van Es, 2011). We employ a framework (i.e., Bragelman et al., 2024) that examines prospective teachers' ability to distinguish between *concrete* and *abstract* aspects of students' thinking, as well as *individual* versus *pattern-focused* noticing.

Related Literature

Noticing and Expertise

Jacobs and Spangler (2017) well document the importance of noticing and responding to students' mathematical thinking. In fact, they claim that mathematics teachers "need noticing expertise" to attend to and interpret instructionally important features in the classroom (p. 771). They contend that noticing is a core practice for teaching, and noticing expertise has been linked to other positive outcomes (e.g., task modification, see Choppin, 2011). Additionally, Jacobs and Spangler claim that noticing expertise—and they deliberately use the term "expertise"—can enable teacher learning and is a learnable skill for prospective teachers (e.g., Fernández et al., 2012; Schack et al., 2013). Although Jacobs and Spangler (2017) describe noticing as conceptualized through attention, interpretation, and decisions about the next instructional steps, they fall short of clarifying the specific dimensions of the expertise concept they invoke, which raises questions about specific components of noticing, such as model building and expertise.

Model Building and Expertise

Even though noticing and model building have traditionally been treated as distinct areas within mathematics education literature—in this paper they are theoretically linked—the precision required to construct conceptual models of student thinking parallels and complements the specificity necessary for extended noticing (van Es & Sherin, 2021), particularly for noticing where teachers attend to relationships between students' mathematical thinking and instructional strategies (van Es, 2011). Building models of students' mathematical thinking—which involves attending to and interpreting student reasoning to inform instructional decisions as outlined in seminal noticing research (Jacobs et al., 2010)—demands a level of expertise that remains understudied (e.g., Bragelman et al., 2024; Copur-Gencturk & Tolar, 2022; Bastian et al., 2022, 2024; Jacobs et al., 2024; Lee, 2018), particularly regarding prospective teachers. Given that noticing represents an aspect of teaching where expertise can be demonstrated (Jacobs et al., 2024) and significantly impacts students' mathematical thinking, and considering model building's role as a necessary component of advanced noticing, further research is essential to

characterize noticing expertise among prospective teachers, specifically their capacity to develop models of students' mathematical thinking that are both explanatory and predictive.

Context and Method

In prior research (i.e., Amador et al., 2026; Castro-Superfine et al., 2025) we presented a framework for different representations of practice, categorizing a representation as either *static*, *dynamic,* or *malleable* (Castro Superfine et al., 2025). The affordances of simulations, a malleable representation, include providing a safe, risk-free environment in which prospective teachers can engage in repeated practice, practice emerging skills, and explore different instructional strategies (Howell & Mikeska, 2021; Shaughnessy & Boerst, 2018). Through their questioning, prospective teachers engage in iterative cycles of attending to and interpreting students' thinking, two central components of teacher noticing (van Es & Sherin, 2002), and the process by which we argue model building (i.e., Norton, 2018) can occur.

Data for this study were collected as part of a longitudinal study of a cohort of 18 prospective teachers across three mathematics content courses. Over the course of three semesters, prospective teachers engaged in five curricular units focused on attending to, interpreting, and deciding how to respond to students' thinking aligned with the mathematical topics covered in each course. Each unit concluded with a teaching simulation in which a prospective teacher played the role of a teacher, eliciting the mathematical reasoning of a student, played by a research team member, on a particular math task. Teaching simulations were conducted outside of class time on a voluntary basis, and participants were incentivized for their participation.

Prospective teachers had the opportunity to participate in five teaching simulations, each involving a nonstandard strategy for a routine mathematics task. The simulations took place over Zoom and were immediately followed by an interview in which prospective teachers shared their understanding of the simulated student's approach to the task. Before each simulation, prospective teachers completed the focal math task independently and studied a written sample of student work from the task. During the teaching simulation, prospective teachers were instructed to elicit the strategy and reasoning used by the simulated student, as played by a member of the research team. After the prospective teacher felt they had elicited sufficient information from the simulated student, another member of the research team asked them a series of questions about their understanding of the student's strategy. We used the transcripts of these interviews as the basis of our analysis. In this paper, we present results from two simulations, Column Addition and Constant Difference. In the Column Addition simulation, a child is asked to add three two-digit addends <29+36+18>. The child adds the tens column first as a single digit, next adds the ones column, notating in two digits. Finally, the child combines the two tens digits to arrive at the correct solution. In the Constant Difference simulation, the student correctly applies a process for solving a multi-digit subtraction problem <784 – 315> that is used in many European and South American countries by adding 10 to the top number in the ones place and 10 to the bottom number in the tens place.

Data Analysis

As we were interested in exploring the intersection of prospective teachers' expertise in noticing with their model building, we built from a prior analysis of data from these simulations in which we coded prospective teachers' models of student thinking for the extent to which they were explanatory, predictive, and generalizable, characteristics which are necessary for an effective model (Castro Superfine et al., 2025). Responses were coded as *explanatory* if they accurately reflected the standardized student's strategy, *predictive* if they could produce an expected result on a similar task, and *generalizable* if the prospective teacher could characterize

the cases in which the strategy would work. We limited our analysis of expertise to responses coded as explanatory and predictive to ensure that the dimensions of expertise in prospective teachers' noticing relate to the simulated student's thinking. Table 1 summarizes the number of prospective teachers who had explanatory and predictive models for the Column Addition and Constant Difference simulations. We do not include generalizable as a delimiter on this analysis because it was the most challenging dimension for prospective teachers, and while generalizability is a key dimension of a full model of student thinking, we contend that prospective teachers are able to demonstrate dimensions of expertise related to student thinking without a full grasp of the mathematical generalizability of that thinking.

Table 1: Number of Prospective Teachers with Explanatory and Predictive Models

Simulation	Explanatory	Predictive	Total
Column Addition	13 (72%)	12 (67%)	18
Constant Difference	8 (100%)	8 (100%)	8

The co-authors first analyzed a subset of the Column Addition simulation data for the Concrete vs. Abstract and Individual vs. Pattern Focus dimensions of noticing expertise from the Framework for the Expertise of Noticing (Bragelman et al., 2024). We then coded the interview responses for all prospective teachers with explanatory and predictive models for the Column Addition and Constant Difference simulations using the codes in Tables 2 and 3. Four members of the research team coded each response individually and discussed divergences until 100% agreement was met.

Table 2: Coding for Concrete vs. Abstract Characteristics of Noticing

Less Expert-like	Developing	More Expert-like
Concrete Knowledge Response includes a declarative or absolute interpretation (that the student is thinking, more evaluative).	Response includes an interpretation that may contain declarative or absolute statements, but begins to indicate some "adaptive process" OR connects to problem-solving principles specific to children's mathematical thinking.	**Conditionalized Knowledge** Response includes interpretation "indicative of an adaptative process" with functional abstractions; suggests more robust problem-solving principles specifically to children's mathematical thinking.

Table 3: Dimension of Expertise for Individual vs. Pattern Focus in Noticing

Less Expert-like	Developing	More Expert-like
Object Perspective Response includes moments of children's mathematical thinking as discrete examples	Response includes features and patterns of children's mathematical thinking and	**Pattern Perspective** Response includes features and patterns of children's mathematical thinking beyond

for one or multiple students; however, does not yet connect these moments across students or within a student's progression of children's mathematical thinking.	begins to connect these moments across students or within a student's learning progression, but the connection is not fully developed.	explicitly stated, either about the learning progression of one student OR across multiple students (e.g., multiple students are thinking similarly about X).

Results

Concrete Versus Abstract Noticing

The following addresses the first part of the research question, which focuses on the extent to which prospective teachers' responses were concrete versus abstract regarding noticing. Table 4 centers on the emergent expertise of participants as their concrete versus abstract noticing was characterized as less expert-like, developing, or more expert-like, across the two simulations.

Table 4: Emergent Expertise in Concrete Versus Abstract Characteristics of Noticing

Simulation	Less Expert-Like	Developing	More Expert-Like
Column Addition	7	5	0
Constant Difference	4	3	1

For the Column Addition simulation, five of the 18 prospective teachers (~28%) exhibited emergent expertise in Concrete vs. Abstract characteristics of noticing. For Constant Difference, four of the 8 prospective teachers (~50%) exhibited emergent expertise in noticing. Prospective teachers with less expert-like responses were able to elicit from the hypothetical student the full strategy employed and use it predictively with a similar problem; however, their responses were limited to descriptions of the strategy. The following response is indicative of this more descriptive approach to describing the hypothetical student's process:

> He said that he started with the ones place, and he knew that he couldn't subtract four from five. So he knew he had to borrow for the ones place, but he didn't exactly know how to tell me where he borrowed from. He just knew he needed more for the ones place for that four, and he just said that he came up with the ten, that he added [ten]. Then he said that in order to keep it equal, that he had to add to the top number and to the bottom number, so he added another ten to that bottom one which made it two. And he said that you have to do that to keep the difference. And then after he said he just subtracted normally.

At the time of the simulation, the prospective teachers had not yet learned the constant difference strategy for subtraction, so this experience with the strategy was entirely novel. In other words, prospective teachers with less expert-like responses were not contextualizing the novel strategy against other problem-solving strategies.

In contrast, for prospective teachers exhibiting emergent expertise, their responses included adaptations to more abstract problem-solving strategies. For example, the single prospective teacher who exhibited more expert-like characteristics of noticing offered the following response when asked how the student found the difference:

> Well, for me, I had to do a completely different problem. I had to write a problem similar to it and see if I could do it just like he did it. I realized that it's almost the same as borrowing, but instead of taking eight and turning into seven, he's taking one and adding another one to

it, making it two. Eight minus two is still six. If you took um, borrowed, took the eight away and turned it into seven, it'd still be seven minus one; it'd still get six. That digit does not change.

In this response, the prospective teacher compares the strategy employed to the traditional regrouping strategy, offering insight into the efficacy of the strategy. *What* was noticed changed significantly as this prospective teacher interpretation of the process includes comparing the novel process to one the prospective teacher understood and so also included evaluating the mathematical validity of the strategy.

Individual Versus Pattern Noticing

The following answers the second part of the research question, which focuses on the extent to which prospective teacher responses were individual versus pattern focused regarding noticing. Table 5 centers on the emergent expertise of participants as their concrete versus abstract noticing was characterized as less expert-like, developing, or more expert-like.

Table 5: Individual Versus Pattern Focused Characteristics of Noticing

Simulation	Less Expert-Like	Developing	More Expert-Like
Column Addition	5	7	0
Constant Difference	3	4	1

For the Column Addition simulation, seven of the 18 prospective teachers (~39%) exhibited emergent expertise in Concrete vs. Abstract characteristics of noticing. For Constant Difference, five of the 8 prospective teachers (~63%) exhibited emergent expertise in noticing. Prospective teachers with less expert-like responses were able to articulate mathematical ideas or concepts understood by the hypothetical student; however, their responses were limited to a single problem. The following response is indicative of this approach:

> All I really got is that he was talking about how he had to keep it pretty much equal for the top and bottom, and he had to keep the difference. So. I think that adding that one to make it five, that would be him keeping the difference. If I need to elaborate more, I don't feel like I got enough from the interaction from him to do so.

In contrast, for prospective teachers exhibiting emergent expertise, their responses included aspects of children's thinking beyond explicitly stated. This could include within-student learning progress, or across students, such as comparing or contrasting cases. For example, the single prospective teacher who exhibited more expert-like characteristics of noticing offered the following response when asked what mathematical concepts the student understands:

> He would understand that five is equal to fifty or five tens, so he has a pretty good understanding of place value. He just he just he has a difficult, it seems like he has a difficult time grasping the concept of borrowing. <What evidence from the interaction makes you think that?> Because he said he had to add ten ones to make the four into fourteen and then he had to add one ten to the one to make it into two, so he knew that both times he was adding a ten, the only difference being that he was adding one ten versus ten ones. Around this age hear "whatever you do to the top you do to the bottom" when discussing fractions and that that can be greatly misconstrued amongst students, when it comes to stuff like this.

The response compares two strategies, particularly colloquialisms common in mathematics teaching and learning, and suggests the prospective teacher holds skepticism about whether employing such colloquialisms as problem-solving strategies correlates to mathematical understanding. In other words, both examples show *that* noticing of students' mathematical thinking occurs while also showing a significant difference in *the* interpretation of the student's mathematical thinking.

Discussion

Our aim in this paper was to better understand the extent to which prospective teachers demonstrate noticing expertise. We analyzed data from two teaching simulations to understand the nature of prospective teachers' noticing expertise in relation to their ability to develop models of students' mathematical thinking, focusing on responses from prospective teachers who could create a model of students' mathematical thinking. We then focused on the degree to which those prospective teachers demonstrated expertise in distinguishing between *concrete* and *abstract* aspects of students' thinking, as well as in *individual* versus *pattern-focused* noticing, both key dimensions of noticing expertise (Bragelman et al., 2024). Overall, most prospective teachers in our study demonstrated less expert-like characteristics in their simulation interview responses, providing mostly a description of the simulated students' strategies and with limited connections to broader aspects of problem-solving strategies or mathematical thinking.

In relation to the concrete versus abstract dimension of noticing expertise, most prospective teachers provided less expert-like responses, with slightly fewer prospective teachers providing responses that evidenced characteristics of developing expertise. While most prospective teachers' responses were limited to descriptions of the students' strategies, others described the students' strategies and provided some, albeit superficial, connections to other problem-solving strategies. Indeed, noticing students' mathematical thinking is often challenging for prospective teachers, particularly for those in the early stages of their teacher preparation coursework (e.g., Tekin-Sitrava et al., 2022). Prospective teachers tend to focus on other aspects of classroom environments rather than students' thinking with much granularity (Kaiser et al., 2017). Only one prospective teacher in our study demonstrated more expert-like characteristics in their simulation responses. Thus, while prospective teachers were able to accurately describe a student's strategy and predict how the student would solve a different problem, prospective teachers generally did not demonstrate emergent expertise in connecting students' mathematical thinking to other problem-solving strategies or principles.

Similarly, in relation to the individual versus pattern-focused dimension of noticing experience, some prospective teachers provided less expert-like responses, whereas slightly more provided responses that evidenced characteristics of developing expertise. Prospective teachers could connect parts of students' strategies, or certain steps in students' problem-solving process, to a broader progression of students' mathematical thinking, albeit not in a robust way. Several prospective teachers mentioned conceptions such as place value in their responses but did not elaborate much beyond that. This finding is similar to that of Callejo and Zapatero (2017), who found that prospective teachers could describe many mathematical elements of students' thinking but could not connect those mathematical elements to students' current understanding. Given noticing depends on knowledge of teaching and learning (Stürmer et al., 2013), findings are unsurprising given prospective teachers' lack of opportunity for instructional interactions.

Taken together, these findings raise two broader questions about prospective teachers' development of noticing expertise. First, is it reasonable to expect prospective teachers, particularly those who are in the early stages of their teacher preparation, to develop and

demonstrate expertise in noticing? It is reasonable to expect prospective teachers to express moments of noticing expertise but perhaps not demonstrate such expertise with great frequency or regularity, at least initially in their preparation. We agree that prospective teachers need to understand students' mathematical thinking, begin to interpret what children's thinking implies for their current understanding, and learn to decide where children need to go next in order to advance their learning (Jacobs et al., 2010; van Zoest & Stockero, 2012). However, developing such skills takes time and can be challenging for prospective teachers, who often lack experience and knowledge gained through classroom interactions with students. Yet the prospective teachers' responses analyzed in our study were able to build accurate models of students' thinking and to predict how students would solve similar problems. Perhaps one's ability to build an accurate and predictive model of students' thinking is necessary, but not sufficient for developing expertise in noticing. Indeed, in our prior work involving prospective teacher noticing in simulations (Castro Superfine et al., 2025), we argued that prospective teachers need more support for asking questions in ways that elicit and shape (van Es & Sherin, 2021) relevant information during interactions with students to allow for attending and interpreting that is responsive. Teaching simulations position prospective teachers to influence what elements of students' mathematical thinking become visible in their interaction with the simulated student, similar to how a teacher might do so through questioning (Webb et al., 2014). With limited instructional knowledge from which to draw, prospective teachers likely need more support in learning how and what questions are most efficacious to elicit students' thinking.

These findings raise a second question for characterizing the noticing expertise of prospective teachers. How can researchers capture the moments of expertise prospective teachers express? When presented with the opportunity to interact with a simulated student using a novel mathematics strategy, prospective teachers who are able to develop explanatory and predictive models of the student's thinking also express moments of noticing expertise, even amidst the noise of a university classroom, years before the prospective teachers begin their practice. As the findings show, these moments of skill expression are inconsistent within and across teaching simulations. Yet moments of expert-like skill expression in teacher noticing occurred in our sample of prospective teachers. As such, characterization of prospective teacher skill expression in noticing requires a fine-grained instrument as opposed to instruments that characterize noticing behavior of practicing teachers (e.g., Jacobs & Empson, 2021). The Framework for the Expertise of Noticing (Bragelman et al., 2024) offers one way to capture and describe such moments of emergent expertise, where prospective teachers begin to consider a student's thinking in broader, more abstract contexts or against the patterns of students' development.

By offering a framing of prospective teachers as capable of emergent expertise in noticing, we move the mathematics education field towards a new framing of prospective teachers, one that does not position them as deficient in a variety of skills but elevates them as demonstrating moments of expertise. We contend that researchers and mathematics teacher educators more broadly consider how they frame prospective teachers by acknowledging the expertise prospective teachers bring to the teacher preparation programs.

ELEMENTARY PRESERVICE TEACHERS' ENDORSED INDIVIDUAL NORMS FOR DISCUSSION OF AN OPEN MATHEMATICS TASK

Amy Brass

emainzer@ycp.edu

While sociomathematical norms (Yackel & Cobb, 1996) understandably receive considerable attention in mathematics education research, social norms are also necessary for mathematical activity, including engagement in productive mathematical discourse. Here, we explore the social norms endorsed by 58 elementary preservice teachers (PSTs) through self-reporting after they engaged in discussion of an open, justification-oriented mathematics task in their mathematics methods course. We drew on Yackel et al.'s (1991) norms for individual activity as we analyzed PSTs' responses to survey questions focused on (1) what they deem important for discussing and justifying solutions and (2) their actual and anticipated reactions to disagreeing with others' solutions or justifications. Findings suggest patterns and complexities of PSTs' endorsed social norms that have implications for mathematics teacher educators.

Keywords: Classroom Discourse; Affect, Emotion, Beliefs, and Attitudes; Preservice Teacher Education

In recent decades, Yackel and colleagues' seminal works describing the largely unspoken yet taken-as-shared social norms (Cobb et al., 1989; Yackel et al., 1991) and sociomathematical norms (Yackel & Cobb, 1996) that regulate mathematical discourse in classrooms have been one of the most significant influences on the field's understanding of mathematical discourse (Herbel-Eisenmann et al., 2017). Much of that research has focused on sociomathematical norms rather than social norms (Herbel-Eisenmann et al., 2017). This focus is understandable given that sociomathematical norms—such as what counts as mathematical evidence or what constitutes a mathematically different strategy—are specific to mathematics classrooms. Social norms—which include expectations for activity such as collaboration and persistence—apply to any classroom context. While social norms that support productive classroom discourse in general do not guarantee productive mathematical discourse specifically (Kazemi & Stipek, 2001), social norms are necessary for and "inextricably related to mathematical activity" (Yackel et al., 1991, p. 397). Social norms also have direct implications for students' opportunities to learn (Yackel et al.).

In addition to a focus on sociomathematical norms over social norms, studies of norms in mathematics education typically describe norms based on teacher interviews and observations of class sessions and do not seek the perspective of students (Levenson et al., 2009). Asking students what norms they see as existing in the classroom (perceived norms) and what norms the students themselves value (endorsed norms) provides a more nuanced and holistic representation of norms than observing enacted norms alone.

Our study seeks to further emphasize the centrality of social norms and students' individually endorsed norms in mathematics contexts by examining the endorsed norms of a specific population: elementary preservice teachers (PSTs). Teacher preparation guidelines emphasize the need for PSTs to experience the types of mathematical discussion with which they will engage their future students (Association of Mathematics Teacher Educators [AMTE], 2017; Conference Board of Mathematical Sciences [CBMS], 2012). The importance of these experiences have been particularly emphasized for elementary PSTs, as this way of engaging with mathematics likely

contrasts with the opportunities they had in their own schooling (e.g., Ball, 1990). By investigating PSTs' endorsed norms within the context of a mathematical discussion of a task that requires justification of one's ideas, we ascertain critical information about what norms PSTs are and are not taking up. This information has implications for PSTs' own opportunities to learn as well as the opportunities they will provide for their future students.

Our research questions are:

1. What norms do individual PSTs report endorsing after a discussion of an open, justification-oriented mathematics task?
2. How do PSTs describe actual or anticipated reactions to disagreeing with others' solutions and justification?

Theoretical and Conceptual Framings

Work on social and sociomathematical norms is situated within the emergent perspective, which in turn is built on the tradition of symbolic interactionism (Herbel-Eisenmann et al., 2017). The emergent perspective coordinates psychological and social understandings of learning and focuses on the reflexive relationship of individual students and the learning community. Yackel and colleagues' work is largely representative of this perspective, as it is the most cited in terms of research on mathematical discourse in recent decades (Herbel-Eisenmann et al., 2017). Their foundational studies (e.g., Yackel et al., 1991; Yackel & Cobb, 1996) took place in the context of a second-grade classroom in which the teacher sought to teach in a manner consistent with inquiry-based instruction.

In Yackel et al.'s (1991) examination of social norms, the authors identified norms that guided mutual construction of ideas, including the importance of cooperation, persistence, meaningful activity, and coming to a consensus. These norms can apply in any classroom context, not just to mathematics classrooms. Yackel and Cobb (1996) built on the idea of social norms by describing sociomathematical norms, which are specific to mathematics classrooms. Sociomathematical norms include what "counts" as mathematically different, sophisticated, or efficient and what constitutes an acceptable mathematical explanation. In an earlier description of the study, Cobb et al. (1989) foreshadowed the naming of social and sociomathematical norms by describing students as having two problems: the "mathematical problems" (for which sociomathematical norms are relevant) and "the negotiation of a viable cooperative relationship that would make it possible for them to solve their mathematical problems" (social norms) (p. 129). In other words, productive sociomathematical norms are only possible in the context of established social norms conducive to that productivity.

In addition to social norms for collaborative work, Yackel et al. (1991) identified social norms for individual activity. Their three identified norms frame our work: (1) "children figure out solutions that are meaningful to them," (2) "explain their solution methods to their partner," and (3) "try to make sense of their partner's problem-solving attempts" (p. 398). While social norms for individual activity are inextricably intertwined with Yackel et al.'s (1991) norms for social cooperation, norms for individual activity focus on the individual's responsibility within the social context of the discussion.

Importantly, social norms—including those for individual activity—have direct implications for students' opportunities to learn. Yackel and Cobb (1996) described opportunities to learn, which include the opportunity to apply what is learned from others' solutions to one's own, reconceptualize a problem in the process of working through an incorrect solution method, and broaden one's own understanding in order to make sense of others' solutions. These

opportunities to learn are vital to consider in terms of individuals' endorsed norms, as the norms the individual endorses contribute to or inhibit the individual's opportunities to learn.

Methods

This study was part of a larger exploratory study focused on PSTs' engagement in open mathematics tasks in their elementary mathematics methods course at a large public university in the Mid-Atlantic United States. We report here on the norms for individual activity that PSTs in three sections of the course reported endorsing regarding their discussion of a Which One Doesn't Belong? (WODB; Danielson, 2016) task.

Context and Participants

WODB is an instructional activity in which learners are presented with four mathematically interesting images or mathematical objects and asked to choose which of the four does not belong and why. The task is designed so that each of the four objects can be justified and in multiple ways. As such, the necessity of justifying one's response is built into the task. Learners are reminded of this goal with the statement: As long as your claim is true, it is correct.

The task with which PSTs engaged in this study was chosen in collaboration with the course instructor to bring out key ideas related to addition and subtraction. The task presented PSTs with four addition expressions (see Figure 1). Common responses to the task included attention to even and odd addends (e.g., top left expression, all addends are even), sums and multiples (e.g., top right expression, only sum that is a multiple of ten), number of digits (e.g., bottom left expression has a double-digit addend), and number of addends (e.g., bottom right expression has four addends). While multiple responses and justifications were possible, disagreement could nevertheless take place when a PST found evidence that disputed another PST's claim.

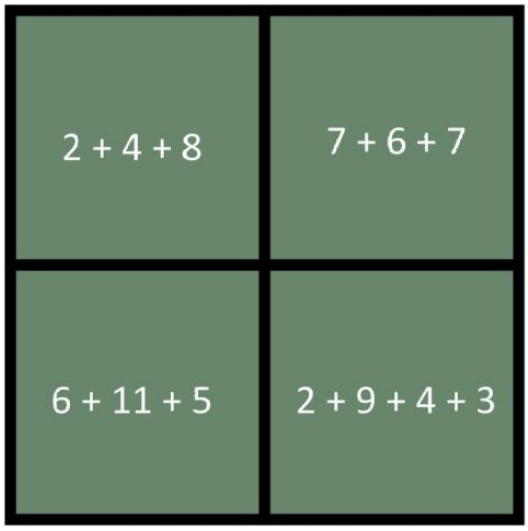

Figure 1: WODB Task (Heon, n.d.)

Across the three sections of the methods course, 58 PSTs participated in the study and were in attendance on the day of the WODB discussion ($n = 15$, $n = 21$, and $n = 22$). Of these PSTs, 54 PSTs presented as female and 4 PSTs presented as male. The discussion of the WODB task took place just before the midpoint of the semester. Participants had been introduced to the routine through a brief example, but had not previously engaged in a full discussion. After the

instructor introduced the task, PSTs had 2–3 minutes to record their thinking in writing. Then, the instructor invited PSTs to share their responses, encouraging them to connect with and build upon peers' responses rather than engaging in a parallel "show-and-tell" approach. To scaffold this conversational goal, the instructor supplied prompts for engaging with one another's thinking (see Figure 2). The discussions themselves ranged from approximately 10–20 minutes.

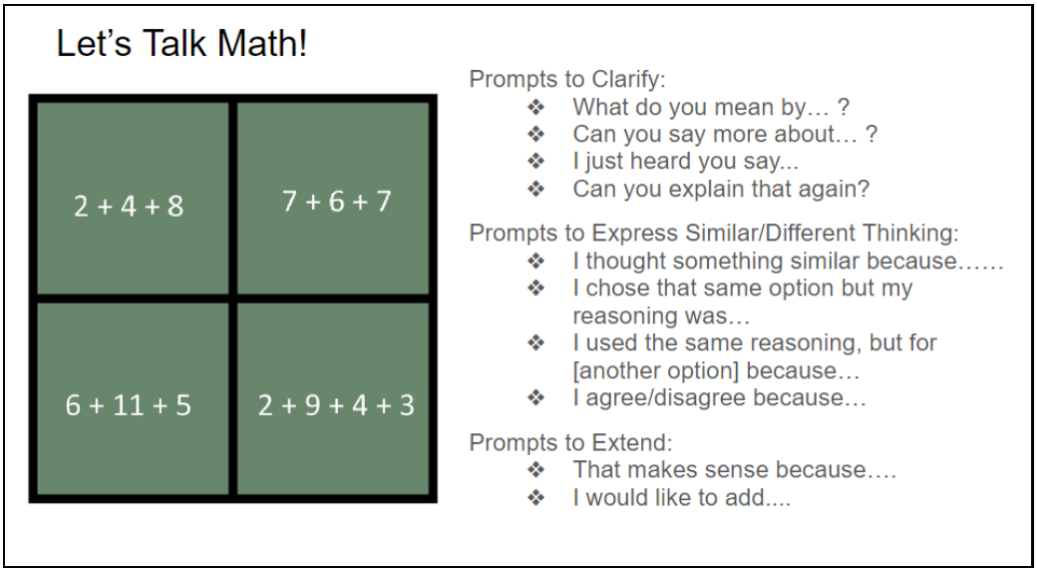

Figure 2: Prompts as Displayed During WODB Discussion

Data Collection and Analysis

Following the discussion, PSTs completed a brief open-response questionnaire that asked them about their engagement with the task and with one another's ideas. For the purposes of this report, we focused on participants' responses to survey prompts that asked about their views on discussion and disagreement: (a) Describe what you thought was important as you discussed and justified your solution and/or in others' discussions and justifications, and (b) What did you do (or what would you have done) if you disagreed with any of the solutions or justifications given during the discussion?

We engaged in a multi-step coding process that utilized both deductive and inductive coding (Miles et al., 2014) and analytic memos (Saldaña, 2021). Yackel et al.'s (1991) norms for individual activity served as *a priori* codes for deductive coding: generating meaningful solutions, explaining solution methods, and attempting to make sense of others' strategies and approaches. Additionally, inductive codes were developed according to patterns that emerged in the data. We used this strategy to collaboratively code one section of PST responses during a research meeting, which allowed us to discuss emerging inductive codes, develop a code book, and refine our coding strategy. Through this process, we noticed that only a small number of PSTs (n = 2, 3%) mentioned aspects of Yackel et al.'s norm related to figuring out a solution that is meaningful to the individual (p. 398). We speculated this was due to the wording of the survey question, which focused on discussing and justifying solutions, rather than the process of arriving at a solution and subsequently decided not to include this code in our analysis. We also noticed the need for an inductive code focused on factors external to individual norms that PSTs deemed important when explaining and justifying solutions and the need for an inductive code

related to reactions PSTs took or reported they would take when disagreeing with a solution or a justification (see Table 1 for a codebook excerpt). We individually coded the two remaining sections of participant responses. During research meetings, we compared codes to confirm agreement and to discuss any discrepancies until agreement was reached. Our analysis of the data illuminated patterns and complexities in PSTs' endorsed norms of mathematical discussions, which we share next.

Table 1: Codebook Excerpt

Code	Description	Example from PST Responses
Explaining	PST mentioned an aspect related to explaining their own solution method to their peers.	"I thought it was important to make sure your explanation worked for the option you chose" (Danielle, Section 2).
Attempting to Make Sense	PST mentioned an aspect related to making sense of their peers' solution methods.	"I felt that it was important keep an open mind as my classmates shared their thoughts" (Jenny, Section 1).
External Factors	PST mentioned an aspect important to them that was external to themselves or their peers (e.g., teacher, classroom environment).	"Having a safe classroom environment where discussion is welcomed is incredibly important, especially when discussing different opinions" (Hannah, Section 3).

Findings

Analysis of PSTs' survey responses revealed patterns and complexities surrounding the individual norms for mathematical discussions related to discussing and justifying solutions and disagreeing with others' solutions and justifications.

Patterns in Discussing and Justifying Solutions

PSTs' responses to the first question of interest on the survey focused on what they deemed important in discussing and justifying solutions. These classroom norms for individual activity (Yackel et al., 1991) were salient in PSTs' responses: explaining solutions to others and trying to make sense of others' problem-solving attempts (p. 398). PSTs placed a greater emphasis on explaining solutions (n = 32, 55%) than on making sense of others' approaches (n = 23, 40%). Table 2 displays the frequency of these norms in PSTs' responses.

Table 2: Aspects Important to Discussing and Justifying Solutions

Norms for Individual Activity	Number of PSTs			
	Section 1 n = 15	Section 2 n = 21	Section 3 n = 22	Total n = 58
Explaining Solutions to Others	8 (53%)	15 (71%)	9 (41%)	32 (55%)
Trying to Make Sense of Others' Attempts	7 (46%)	5 (24%)	11 (50%)	23 (40%)
External Factors	3 (20%)	5 (24%)	4 (18%)	12 (21%)

Note. Percentages do not equal 100%, as more than one norm was present in some responses.

Specific to explanations, PSTs mentioned the importance of being "able to back up how you got what you got and what you did" (Remy, all names are pseudonyms), "explaining your thought process fully and thoroughly" (Elsa), and having "an observable justification for my claim" (Aspen). There were also PSTs who stressed the importance of terminology and language within explanations. For example, Katherine mentioned that explanations should "walk the line between making sense to the larger group while still using appropriate terminology," and Susan noted that "use of vocabulary … [and] being clear in your reasoning" were important to explanations. These responses suggest that when endorsing the norm of explaining their solutions to others, PSTs place importance on supporting their solutions and using terminology and language they deem appropriate within their explanations.

PSTs' responses also mentioned aspects of attempting to make sense of their peers' strategies (n = 23, 40%). In doing so, PSTs mentioned the importance of being open to different perspectives. For example, Blair asserted, "It's important to look at it from the lens of your classmate. Think about how they solved it and look at it from that angle." Similarly, Lola noted, "I think it was important to take what others were saying and try to see that perspective. I think this is important so you can expand your thinking." There were also PSTs who made connections to their own work as they made sense of others' solution strategies. One of these PSTs remarked, "I tried to understand their thinking in a way that I could understand, relating their thinking to my thinking and solutions" (Serena). Marie also noted how the discussion "allowed us as students to extend on our own thinking and deepen our understanding." These responses suggest that PSTs saw their attempts to make sense of their peers' solution strategies as opportunities to extend their learning through seeing different approaches and making connections to their own thinking.

Interestingly, over 20% of PSTs (n = 12, 21%) mentioned external factors that they deemed important to discussion in their responses. These factors were often related to the teacher's role in the classroom, such as providing "a safe classroom environment" (Hannah) and providing "wait time" (Chris). Addy mentioned the importance of the instructor "reframing our thinking on the board" during the discussion, and William pointed out that providing reasoning in explanations "helped the teacher write your ideas down more clearly." As an additional external factor, there were two PSTs, both in Section 2, who valued external validation from their classmates. Hermione confided, "I'm not confident in math, so having others agree with differences I noticed was important," and Wendy thought it was important that "some other students used the same types of reasoning as me after I shared my thinking." The use of external factors suggests that some PSTs might not have seen themselves as active members of the discourse community.

Complexities When Disagreeing with Others' Solutions or Justifications

PSTs also indicated what they did or would do if they disagreed with any of the solutions or justifications provided during the discussion of the task. Similar to the norms they self-reported endorsing after the discussion, Yackel et al.'s (1991) norms of explaining solutions to others and trying to make sense of others' solution attempts (p. 398) were prevalent in PSTs' responses (see Table 3). Across PSTs, emphasis was placed on explaining their own solution versus attempting to make sense of others' solutions and justifications in response to disagreeing with others. That is, when disagreeing, PSTs emphasized their own solution strategy rather than trying to understand how others approached the problem.

Table 3: Norms Endorsed when Disagreeing with Others' Solutions or Justifications

Norms for Individual Activity	Number of PSTs			
	Section 1 $n = 15$	Section 2 $n = 21$	Section 3 $n = 22$	Total $n = 58$
Explaining Solutions to Others	6 (40%)	13 (62%)	10 (45%)	29 (50%)
Trying to Make Sense of Others' Attempts	6 (40%)	5 (24%)	10 (45%)	21 (36%)
Anti-norm	3 (20%)	6 (29%)	3 (14%)	12 (21%)

Note. Percentages do not equal 100%, as more than one norm was present in some responses.

Complexity in endorsed norms. When they disagreed with others' solutions or justifications, the PSTs who endorsed explaining their own solutions reported actions such as "contribut[ing] my opinions to the discussion" (Elsa) and "stat[ing] that I disagreed and explain[ing] why I disagreed" (Amelia). Similarly, Olivia mentioned, "I would have stated that I respectfully disagreed, as well as provided reasoning for why I disagreed that way they understood my point of view." These responses suggest a focus solely on their own solutions without trying to make sense of how others approached the problem. In contrast, there were PSTs who attempted to make sense of others' solutions and justifications during disagreements. These PSTs reported actions such as "try[ing] to consider another perspective" (Molly) and "open[ing] it up for a discussion to try to understand my classmate's thinking" (Ann). When Lola disagreed with her classmates' perspectives, she noted, "I just tried to look at it in a different perspective and see where they were coming from." Similarly, Jenny reported, "I feel that I would question it. I would want to try to understand that person's way of thinking about the task." These responses illustrate how PSTs also endorsed Yackel et al.'s (1991) norm of trying to make sense of others' approaches.

Although an equal number of PSTs endorsed norms related to explaining their own solution and attempting to make sense of others' solutions during disagreements in Section 1 and Section 3, explaining their own solution when disagreeing with others' solution approaches was most prevalent in Section 2. Additionally, in Section 2, almost 30% of PSTs ($n = 6$, 29%) reported reactions to disagreeing with colleagues that could be described as anti-norm reactions, actions that conflict with Yackel et al.'s (1991) norms. Anti-norms were present in each section and reflected PSTs' impassiveness when disagreeing with others. Examples of anti-norm statements about disagreeing include PSTs who "probably wouldn't have said anything" (Wendy) and who would have "just kinda brushed it off" (Laura). Anti-norm reactions might have been the results of PSTs not feeling "comfortable directly saying one of my classmate's answers was wrong" (Kelly) or not feeling confident enough to disagree. As Lily confided, "I would not say anything about disagreeing because everybody thinks differently and it probably would have made sense to other people even if it did not make sense to me."

Complexity in reactions. The different norms that were endorsed by PSTs connected to various actual and anticipated reactions to disagreeing with others' solutions and justifications. These reactions were active and public ($n = 34$, 57%), active and internal ($n = 10$, 17%), and passive ($n = 12$, 21%). When reactions were active and public, PSTs vocalized aspects of their disagreement by stating their disagreement, sharing their way of solving the problem, and asking questions to explore others' perspective, as previously discussed. PSTs also "used the prompts that were given [for discussion]" (Maria) as they vocalized aspects of their disagreement.

Approximately 10% of PSTs ($n = 6$) explicitly referenced using the provided discussion prompts (see Figure 2) in their reactions to disagreements. There were also PSTs who actively disagreed through internal grappling with others' perspectives, such as Hannah, who "listened to the other justifications and tried to understand the reasoning behind them." Similarly, Susan mentioned, "I just let it sink in and tried to understand where they were coming from," and Mae noted, "I just listened and tried the problem out in my head." These responses suggest that even when no public action was taken, some PSTs were actively engaged in attempting to understand others' solutions and justifications. In contrast, there were also PSTs who reported passive reactions to disagreeing with their classmates. These reactions were the anti-norm reactions to disagreeing with others, which included "remain[ing] quiet" (Calleigh) and doing "nothing" (Lynn).

Discussion and Future Directions

In addressing our first research question, related to the norms that individual PSTs endorsed through self-reporting after a discussion of a justification-oriented mathematics task, responses suggest that PSTs endorsed the norm related to explaining their own solutions with a greater frequency than the norm related to attempting to make sense of others' solutions and justifications. This pattern was present in PSTs' responses to both questions of interest on the survey. This suggests that as mathematics teacher educators prepare elementary PSTs to engage school students in meaningful mathematical discussions (AMTE, 2017; National Council of Teachers of Mathematics [NCTM], 2014), emphasizing the critique of others' reasoning is necessary as PSTs develop their skills "to engage all students in mathematical discussions involving explanation *and* critique as well as encourage the belief that each student can make valued contributions" (AMTE, 2017, p. 86, emphasis added). The development of this social norm has the potential to increase learning opportunities for PSTs and the elementary school students with whom they work as both PSTs and their students attempt to make sense of others' reasoning (Yackel et al., 1991).

As we addressed our second research question, we noticed complexities in PSTs' descriptions of their actual and anticipated reactions to disagreeing with others' solutions or justifications. These complexities include the presence of internal grappling while disagreeing with others in ways that might not outwardly signal engagement as well as the presence of anti-norm and passive behaviors. This suggests that as mathematics teacher educators position PSTs as active members of the discourse community (e.g., NCTM, 2014), intentionality must be used to help PSTs make their thinking public. We see the use of discussion prompts (see Figure 2), which 10% of PSTs ($n = 6$) explicitly referenced, as one strategy for encouraging the development of Yackel et al.'s (1991) social norms.

The patterns and complexities related to social norms we report here reflect PSTs' perspectives after engaging in a Which One Doesn't Belong task. In exploring the norms endorsed by elementary PSTs, future work could investigate whether and how these norms continue to develop as PSTs experience additional open-justification-oriented mathematics tasks. Additional future work could also explore the impact of different types of open tasks (e.g., How Many? [Danielson, 2018], Notice and Wonder [Fetter, 2013]) on the PSTs' endorsed norms as well as what instructional strategies (e.g., discussion prompts) impact PSTs' endorsed norms. It will also be important to compare and identify the relationship between PSTs' endorsed norms and enacted norms within the context of the discussion as well as the extent to which enacted norms (and anti-norms) afford or constrain PSTs' opportunities to learn. This study provides a necessary foundation in terms of endorsed social norms for individual activity on which future work will build.

TRAJECTORY-BASED ANALYSIS OF INSTRUCTIONAL BELIEF CHANGE IN PRE-SERVICE MATHEMATICS TEACHERS

This study examines how pre-service elementary mathematics teachers' instructional beliefs change over time during a course discussing constructivism. Adopting a longitudinal perspective, the study captures heterogeneous and nonlinear belief trajectories using data from 80 participants collected at four time points over a 15-week semester and analyzed through distance-based longitudinal clustering. Four distinct trajectories emerged, differing in initial levels, timing, and stabilization, with teacher-centered beliefs playing a more decisive role than student-centered beliefs. Most participants showed substantial shifts during the early phase of the course, suggesting a critical window for change, after which trajectories stabilized. These findings demonstrate that mean-level analyses obscure key dynamics in teacher learning and underscore the value of trajectory-based approaches in mathematics teacher education.

Keywords: Teacher Belief, Elementary Teacher Education, Longitudinal Clustering Method

Introduction

Research on pre-service teachers' instructional beliefs has long emphasized the importance of shifting from teacher-centered to student-centered approaches in mathematics classrooms. Within this body of work, belief change is often conceptualized as a desirable outcome of teacher education programs grounded in constructivist perspectives (Cobb & Yackel, 1996). Consequently, many empirical studies have examined whether instructional beliefs change before and after an intervention, typically reporting mean-level differences between pre- and post-measurements. While such findings provide valuable evidence regarding overall program effectiveness, they rest on an implicit assumption that belief change unfolds in a linear and homogeneous manner across individuals.

However, growing research suggests that teacher learning processes are rarely uniform or linear. Pre-service teachers enter teacher education programs with well-established instructional beliefs shaped by years of prior schooling, and exposure to constructivist ideas does not necessarily lead to coherent or consistent belief change. Instead, new instructional ideas often coexist with prior beliefs, resulting in tension, partial adoption, or selective reinterpretation. From this perspective, focusing solely on mean-level change risks obscuring important differences in how instructional beliefs evolve over time.

To address this limitation, the present study adopts a longitudinal perspective on instructional belief change among pre-service mathematics teachers participating in a semester-long course discussing constructivism. Rather than focusing on overall gains in student-centered beliefs, the study foregrounds individual trajectories of change, examining how different patterns of belief change emerge, when major shifts are most likely to occur, and which belief dimensions play a central role in differentiating these patterns. Using a distance-based longitudinal clustering method applied to repeated measures collected at four time points, the study aims to provide a more nuanced account of instructional belief change that moves beyond traditional pre–post designs.

Theoretical Framework

Instructional Beliefs in Mathematics Teacher Education

Instructional beliefs refer to teachers' conceptions about the nature of teaching and learning, including the roles of teachers and students in classroom activity. In mathematics education, these beliefs are often discussed along a continuum between teacher-centered and student-centered orientations (Pajares, 1992; Fang, 1996). Teacher-centered beliefs emphasize explanation, control, and the efficient transmission of mathematical knowledge by the teacher, whereas student-centered beliefs highlight students' active participation, exploration, and meaning construction.

Research has consistently shown that instructional beliefs are deeply rooted in teachers' prior learning experiences and cultural contexts (Pajares, 1992). Pre-service teachers, in particular, enter teacher education programs with relatively stable beliefs shaped through years of observing traditional classroom instruction, a process commonly described as the "apprenticeship of observation" (Lortie, 1975, as discussed in Pang, 2003). These beliefs function not merely as abstract preferences but as practical frameworks that guide how teachers interpret instructional situations and make pedagogical decisions (Fang, 1996).

Coexistence and Tension Between Teacher-Centered and Student-Centered Beliefs

Rather than forming a simple dichotomy, teacher-centered and student-centered beliefs often coexist and interact in complex ways. Previous studies have shown that teachers may endorse student-centered principles at a normative level while continuing to rely on teacher-centered practices in actual classroom settings (Pang, 2003; Fives & Buehl, 2016). This gap between adoption and enactment suggests that instructional beliefs are not unified or internally consistent but are structured across multiple levels, including normative beliefs about what ought to be done and practical beliefs about what is feasible in real classrooms.

In the Korean mathematics education context, this tension has been repeatedly documented. Pang (2003) demonstrated that many elementary mathematics teachers expressed strong support for student-centered instruction while maintaining explanation-driven, teacher-led practices. Such findings indicate that belief change cannot be understood solely as the acquisition of new student-centered ideas but must also account for the persistence and reorganization of existing teacher-centered beliefs.

Beyond Linear Models of Instructional Belief Change

Despite recognition of the complexity of instructional beliefs, much empirical research has conceptualized belief change using linear or stage-based models, often relying on pre–post comparisons. While these approaches provide useful information about overall trends, they implicitly assume that belief change progresses in a uniform direction and at a similar pace across individuals.

Recent studies on teacher learning challenge this assumption by emphasizing the nonlinear and dynamic nature of change. Drawing on professional development research, Bae and colleagues (2022) argued that changes in teachers' instructional orientations are better understood as generative processes involving disruption, reorganization, and stabilization rather than gradual accumulation. Similarly, Clarke and Hollingsworth's (2002) interconnected model conceptualizes teacher change as an interactive process among beliefs, practices, outcomes, and reflection, highlighting the possibility of uneven and recursive change pathways. These models collectively suggest that belief trajectories are not reducible to a single developmental arc; rather, distinct patterns of disruption and stabilization may emerge depending on the interaction between individual belief configurations and instructional experiences. The present study operationalizes

this perspective by applying trajectory-based analysis to capture such differentiated pathways empirically.

A Trajectory-Based Perspective on Instructional Beliefs

Building on these perspectives, this study adopts a trajectory-based framework for understanding instructional belief change. From this viewpoint, belief change is not evaluated solely by its direction (e.g., toward student-centered instruction) but by the patterns through which change unfolds over time. This framework foregrounds three key dimensions: initial belief configurations, the timing of major shifts, and subsequent stabilization processes.

First, initial configurations matter because pre-service teachers begin teacher education with differing degrees of teacher-centered and student-centered beliefs, shaped by their prior schooling experiences (Pajares, 1992; Pang, 2003). Second, the timing of change is critical. Research suggests that belief change may concentrate in particular periods when existing beliefs are challenged by instructional experiences that cannot be easily assimilated (Bae et al., 2022). Third, stabilization refers to how beliefs settle into relatively coherent patterns after periods of disruption, potentially leading to qualitatively different outcomes across individuals (Franke et al., 2001).

Research Questions

The purpose of this study is to examine how pre-service mathematics teachers' instructional beliefs change over time within a shared constructivist-oriented course context. Rather than treating belief change as a uniform or linear process, the study adopts a longitudinal perspective to explore whether qualitatively different patterns of change emerge across individuals.

Guided by this perspective, the study addresses the following research questions:

1. What distinct trajectories of instructional belief change emerge over time among pre-service mathematics teachers?
2. How do these trajectories differ in terms of the timing and magnitude of change across the course?
3. Which dimensions of instructional beliefs contribute most strongly to differentiating these trajectories?

Methods

Participants and Context

Participants were pre-service elementary mathematics teachers enrolled in a semester-long constructivist-oriented mathematics education course at a university in South Korea. The course was designed not to train specific instructional techniques but to encourage critical reflection on participants' existing instructional beliefs through readings, discussions, and writing activities centered on constructivist perspectives on mathematics teaching and learning.

Instructional belief data were collected from 132 participants across four measurement points (Weeks 1, 6, 9, and 12). To ensure the reliability of longitudinal trajectory analysis, only participants who provided valid responses at three or more time points were included in the analysis. This resulted in a final analytic sample of 80 pre-service teachers.

Measures

Instructional beliefs were measured using a previously validated scale (Hwang et al., 2022) that distinguishes between teacher-centered beliefs (TC) and student-centered beliefs (SC). Teacher-centered beliefs reflect emphasis on explanation, control, and efficient knowledge transmission by the teacher, whereas student-centered beliefs emphasize students' active

engagement, exploration, and meaning construction. All items were rated on a five-point Likert scale. Internal consistency reliability was satisfactory to high (Cronbach's $\alpha = .761–.943$) across all measurement points for both belief dimensions.

Analytic Approach

To examine heterogeneous patterns of instructional belief change over time, the study employed a distance-based longitudinal clustering method using the SFclust algorithm implemented in the FKmL package. Unlike variable-centered approaches that focus on average change, SFclust is designed to identify groups of individuals who share similar trajectories across multiple time points.

SFclust was selected for three main reasons. First, the method does not impose a priori assumptions about the functional form of change (e.g., linear or quadratic), making it well suited for capturing nonlinear belief trajectories. Second, it allows multiple belief dimensions to jointly contribute to cluster formation, enabling an integrated examination of teacher-centered and student-centered beliefs over time. Third, the method is particularly appropriate for relatively small samples with repeated measurements, as it emphasizes pattern similarity rather than parameter estimation.

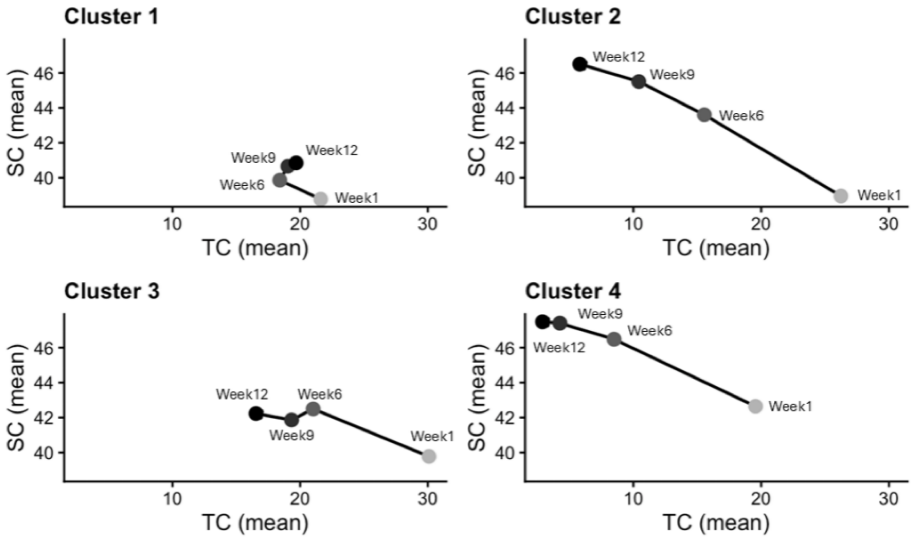
Prior to clustering, longitudinal data were organized in long format, with time represented as a numeric variable. Partial missing data were addressed using linear interpolation to preserve the continuity of individual trajectories. To prevent scale differences from disproportionately influencing distance calculations, belief variables were standardized using their respective standard deviations. An L1 constraint was applied during clustering to regulate variable contributions and enhance interpretability of cluster structures.

Determination of the Number of Clusters

The number of clusters was determined by considering both cluster stability and interpretability. Solutions with two to six clusters were evaluated through repeated analyses with different initial seeds. Cluster stability was assessed using the Adjusted Rand Index (ARI), and the minimum cluster size was examined to ensure that each cluster remained interpretable. Based on these criteria in Table 1, a four-cluster solution was selected as providing the best balance between stability and meaningful differentiation of belief trajectories.

Table 1: Cluster Stability Indices Across Different Numbers of Clusters

Number of Clusters	Mean ARI	SD of ARI	Minimum ARI	Maximum ARI	Minimum Cluster Size (Median)	Minimum Cluster Size (Minimum)
2	0.713	0.211	0.484	1.000	36.5	31
3	0.573	0.192	0.374	1.000	22.5	13
4	0.501	0.187	0.267	1.000	15.0	10
5	0.466	0.168	0.247	1.000	10.0	4
6	0.471	0.167	0.218	0.860	7.0	2



Results

The SFclust-based longitudinal clustering analysis identified four distinct trajectories of instructional belief change among pre-service mathematics teachers. These trajectories differed not only in the direction and magnitude of change but also in their initial belief configurations and temporal patterns of disruption and stabilization. Importantly, these differences were not

visible in mean-level analyses, which suggested a general decrease in teacher-centered beliefs and an increase in student-centered beliefs across the cohort.

Across the four trajectories, teacher-centered beliefs (TC) played a more decisive role than student-centered beliefs (SC) in differentiating clusters. Variable weight estimates indicated that TC contributed substantially more to cluster formation than SC, suggesting that patterns of weakening, persistence, or reorganization of teacher-centered beliefs were central to understanding heterogeneous belief trajectories.

Analysis of longitudinal trajectories revealed four qualitatively distinct patterns of change in instructional beliefs over time (Figure 1). These trajectories differed not only in the direction and magnitude of change but also in their initial belief levels and temporal dynamics. In particular, variation across clusters was more pronounced for TC than for SC, indicating that patterns of weakening or persistence of TC played a central role in differentiating trajectories.

Cluster (n)	Teacher-Centered Beliefs: Change Pattern	Student-Centered Beliefs: Change Pattern	Trajectory Type
Cluster 1 (13)	Initial decrease followed by stable maintenance	Gradual increase	Stable Maintenance
Cluster 2 (20)	Sharp decrease following a high initial level	Sustained and pronounced increase	High-Start Rapid-Shift
Cluster 3 (22)	Highest initial level with gradual decrease	Slight increase followed by stabilization	Gradual Transition
Cluster 4 (25)	Low initial level followed by a drop to the minimum	Continuous increase from a high level	Low-Start Consolidation/ Transition

Figure 1: Characteristics of Instructional Belief Change Across Clusters

With respect to teacher-centered beliefs, clusters exhibited markedly different change patterns. One trajectory was characterized by a modest initial decline followed by relative stability, indicating limited reorganization beyond the early phase of the course. In contrast,

another trajectory showed a steep and sustained decline from a high initial level, reflecting substantial weakening of teacher-centered beliefs across the semester. A third trajectory began with the highest initial TC levels and demonstrated a gradual but consistent decrease, suggesting a slower and more incremental adjustment process. The final trajectory was marked by relatively low initial TC levels and a rapid early drop to minimal levels, followed by sustained stability, indicating an early and decisive shift away from teacher-centered beliefs. Taken together, these findings demonstrate that teacher-centered beliefs did not decline uniformly across participants; rather, the timing and intensity of TC change varied substantially, resulting in distinct patterns of belief reorganization.

In contrast, student-centered beliefs showed more homogeneous patterns of change across clusters. All trajectories were characterized by either gradual increases or consistently high levels of SC over time. Differences across clusters were primarily reflected in the rate and timing of increase rather than in overall direction. Some clusters exhibited modest growth in SC that paralleled relatively stable TC trajectories, whereas others showed sharp and sustained increases in SC following early declines in TC. In one trajectory, SC increased slightly and then stabilized, while in another, SC remained high from the outset and continued to increase steadily throughout the course. These patterns indicate that increases in student-centered beliefs alone were insufficient to differentiate belief trajectories.

Across clusters, the most substantial changes in instructional beliefs occurred during the early phase of the course, particularly between Weeks 1 and 6. During this period, pronounced declines in teacher-centered beliefs were observed in several trajectories, whereas one trajectory exhibited only modest early change followed by stabilization. After the initial phase, belief trajectories tended to stabilize along divergent paths. For some clusters, teacher-centered beliefs converged toward relatively stable end states, while others continued to show gradual change. This temporal pattern suggests that early instructional experiences played a critical role in shaping subsequent belief trajectories, with later phases of the course serving primarily to consolidate rather than fundamentally reshape instructional beliefs.

To further examine how teacher-centered and student-centered beliefs interacted over time, trajectories were visualized in a two-dimensional belief space (Figure 1). The resulting patterns revealed distinct movement paths across clusters. Some trajectories showed limited overall movement, characterized by modest growth in student-centered beliefs without substantial disruption of teacher-centered beliefs. In contrast, other trajectories exhibited pronounced shifts marked by rapid declines in teacher-centered beliefs accompanied by strong growth in student-centered beliefs. Still others followed more gradual transition paths involving moderate TC decline and relatively stable SC levels. These joint trajectories underscore that instructional belief change cannot be reduced to a single dimension or directional shift; rather, qualitatively distinct patterns emerged through different configurations and interactions of teacher-centered and student-centered beliefs over time, even within a shared instructional context.

Discussion

The present study examined instructional belief change among pre-service mathematics teachers using a longitudinal, trajectory-based approach. Guided by three research questions, the discussion focuses on (a) the identification of distinct trajectories of change, (b) differences in the timing and magnitude of change across trajectories, and (c) the belief dimensions that most strongly differentiated these trajectories. Together, the findings underscore that instructional belief change is best understood as a heterogeneous and dynamic process rather than a uniform shift toward student-centered instruction.

Distinct Trajectories of Instructional Belief Change

Addressing the first research question, the analysis identified four qualitatively distinct trajectories of instructional belief change within a shared course context. These trajectories revealed substantial heterogeneity in how pre-service teachers' beliefs evolved over time, despite exposure to the same constructivist-oriented instructional experiences. This finding challenges assumptions implicit in mean-level analyses that belief change follows a single developmental pathway and instead highlights the coexistence of multiple patterns of reorganization.

Importantly, the identified trajectories differed not only in direction but also in their initial belief status and overall shapes. Some trajectories reflected early and decisive shifts away from teacher-centered beliefs, whereas others showed more gradual adjustment or relative stability after an initial change. These results suggest that instructional belief change involves qualitatively different developmental processes across individuals, rather than varying degrees of the same process.

Timing and Magnitude of Change

The second research question concerned how trajectories differed in the timing and magnitude of change. Across most trajectories, the most substantial changes occurred during the early phase of the course, particularly between Weeks 1 and 6. During this period, several clusters exhibited pronounced declines in teacher-centered beliefs, indicating that early instructional experiences played a critical role in disrupting existing belief structures.

Following this early phase, belief trajectories tended to stabilize along divergent paths. For some pre-service teachers, early disruption led to sustained reorganization, whereas for others, beliefs stabilized with only modest change. The existence of a trajectory characterized by limited early change followed by stability further illustrates that exposure to the same instructional context does not guarantee comparable belief transformation. These findings highlight the importance of attending to temporal dynamics in teacher education research and practice, suggesting that when change occurs may be as consequential as whether change occurs.

Central Role of Teacher-Centered Beliefs

The third research question examined which belief dimensions contributed most strongly to differentiating trajectories. The findings indicate that teacher-centered beliefs played a more decisive role than student-centered beliefs in shaping distinct patterns of change. While student-centered beliefs generally increased or remained high across all trajectories, they were insufficient on their own to distinguish among patterns of belief development.

Instead, trajectories were primarily differentiated by how teacher-centered beliefs weakened, persisted, or were reorganized over time. This finding suggests that instructional belief change cannot be adequately conceptualized as the accumulation of student-centered beliefs. Rather, meaningful change appears to involve varying degrees of destabilization and reconfiguration of existing teacher-centered beliefs, which often remain deeply rooted in pre-service teachers' prior schooling experiences and cultural norms.

Conclusion

Taken together, these findings have important implications for mathematics teacher education. First, they suggest that programs should attend explicitly to pre-service teachers' existing teacher-centered beliefs, particularly during the early stages of coursework. Simply promoting student-centered instructional principles may be insufficient if entrenched beliefs about teaching, authority, and knowledge transmission remain unexamined. Early instructional activities that surface, challenge, and problematize these beliefs may be especially influential in shaping longer-term belief trajectories.

Second, the presence of multiple trajectories within the same instructional context points to the need for differentiated support. Pre-service teachers enter teacher education with varying initial belief configurations, and these starting points appear to condition how individuals respond to instructional experiences. Recognizing this heterogeneity may help teacher educators design learning environments that are more responsive to different patterns of resistance, adjustment, and stabilization.

Methodologically, this study demonstrates the value of trajectory-based analytic approaches for investigating instructional belief change. By identifying heterogeneous and nonlinear patterns of change, distance-based longitudinal clustering offers insights that remain hidden in traditional pre–post designs. Future research could extend this work by incorporating qualitative analyses to examine how pre-service teachers interpret instructional experiences at key transition points, or by linking identified belief trajectories to subsequent instructional practices during teaching practica or early career teaching. Applying trajectory-based approaches to larger and more diverse samples would further clarify how instructional belief change unfolds across contexts. It should also be noted that distance-based clustering results may be sensitive to the choice of clustering parameters and initial seeds; while multiple runs and ARI-based stability checks were used to mitigate this concern, replication with independent samples remains an important direction for validating the identified trajectory structure.

In conclusion, this study advances understanding of instructional belief change in mathematics teacher education by aligning belief development with multiple trajectories rather than a single linear pathway. By directly addressing the research questions, the findings highlight the existence of distinct belief trajectories, the critical role of early phases of change, and the central importance of teacher-centered beliefs in differentiating patterns of development. Adopting a trajectory-based perspective offers a more nuanced account of teacher learning and provides a foundation for designing teacher education programs that more effectively support meaningful and sustained instructional belief change.

USING TUTORING TO SUPPORT ELEMENTARY TEACHER CANDIDATE CONFIDENCE

Kristy Litster
Valdosta State University
klitster@valdosta.edu

Jodi Cronin
Valdosta State University
jcronin@valdosta.edu

This study explored changes in 48 senior elementary teacher candidates' confidence relating to planning and adjusting mathematics lessons, assessing student understanding, supporting critical thinking, motivating low-interest students, establishing routines, and working with families after completing a tutoring project as part of their math methods course. Paired sample t-tests of survey data measuring confidence before and after the tutoring showed significant gains in all areas. Qualitative results indicated tutoring activities supported candidate confidence in pedagogical knowledge for breaking up standards, creating and implementing organized yet flexible lessons, assessing student understanding beyond correct answers using activities and questioning, and finding or adapting appropriate resources. One significant theme across all data was the improved confidence for working with parents and families.

Keywords: Elementary School Education, Preservice Teacher Education

Litster, Ramirez, and Terry (2025) note that in order to maintain quality in elementary content and methods courses over time, there must be a process of ongoing review and refinement of courses that keeps in mind the needs of the teacher candidates and their professors. Active learning tasks should be one of those considerations. Mathematics teacher educators (MTEs) have a variety of pressures in the content and processes they include in their methods course designs. Litster et al. (2000) warn that "active learning does not mean adding content to an already limited schedule" (p. 635). Instead, they note that MTEs must carefully choose which types of tasks or projects the TCs will engage with that best support mathematics teaching and learning expectations through active learning experiences.

We advocate that a tutoring project is one such active learning experience that provides multiple benefits to TCs' confidence in teaching and learning mathematics as well as their pedagogical content knowledge (PCK). Thus, the purpose of this study was to explore how refining a mathematics content course to exchange simulated teaching experience projects with a tutoring project influenced changes in teacher candidates' (TCs') confidence for teaching and learning mathematics.

Theoretical Framework

This study is grounded in Situated Learning Theory (Lave & Wenger, 1991). This theory posits that learning cannot be acquired solely in isolation; rather, teacher candidates must engage in socially authentic contexts that are real, low-risk, and include active rather than passive involvement. Darling-Hammond et al. (2002) stated that TCs' "sense of preparedness is by far the strongest predictor of teaching efficacy" (p. 294). They noted that programs in their study that helped TCs feel better prepared were those that interwove practicum experiences with coursework. Experiential learning helps teacher candidates connect with communities, apply practical knowledge, and apply theory to practice (Williams & Sembiante, 2022).

Multiple research studies have confirmed that real contexts, such as early field experiences that interweave experiences and coursework, can provide low-stress practice that supports TCs' self-efficacy and identity as a teacher. For example, Iwai (2025) found that early field

experiences helped students improve their self-confidence in instructional strategies, student engagement, and classroom management. The only area in which students did not increase in confidence was family engagement, due to a lack of experience in this area during the early field experience.

Litster et al. (2025) found that the implementation phase of an interview project, where TCs worked directly with a child, showed the highest percentage of evidence across multiple institutions for specialized content knowledge and pedagogical content knowledge. Abbott et al. (2026) showed improved confidence, identity and classroom readiness from site-based methods courses. These improvements were primarily based on positive perceptions of "real" settings, opportunities for curricular development, and development of TCs' roles as teachers.

While students can learn from simulated experiences such as peer demonstrations or computer-based classroom simulations, the level of realism matters (Theelen et al., 2019). When preservice teachers (PTs) perceive the simulated or peer behavior as unrealistic or exaggerated, engagement decreases and confidence gains are limited. While Artificial Intelligence (AI) and technology continue to improve realism, working directly with a K-5 student allows TCs to elicit and use evidence of student thinking (National Council of Teachers of Mathematics [NCTM], 2014), practice noticing skills (Jacobs et al., 2010), and develop pedagogical content knowledge (Ball et al., 2008).

Methods

This study used a convergent-parallel mixed methods design (Creswell & Plano Clark, 2011), gathering quantitative and qualitative data concurrently and merging them using complementary techniques (Teddlie & Tashakkori, 2006) to answer the research question: How did teacher candidates' confidence for teaching mathematics change after participating in a tutoring project?

Participants were 48 teacher candidates in their third of four professional semesters, enrolled in the only mathematics methods course in their program. During this course, students engaged in a tutoring project where they conducted a pre-assessment, designed and implemented 25-minute math lessons with one or two tutoring students twice a week for approximately eight sessions based on tutoring data, and met with parents to share student outcomes as well as recommend resources.

K-5 students were recruited from districts and private schools near the university. Parents or family members brought the students to the university twice a week for free hour-long tutoring sessions in math and literacy (25 min each).

Quantitative data included a self-efficacy survey measuring candidates' confidence in nine areas of mathematics teaching before and after participating in the tutoring project. The survey was adapted from Tschannen-Moran & Woolfolk Hoy's (2001) teacher efficacy survey. Teacher candidates rated themselves on a scale of 1–9 in each area. Paired samples *t*-tests were computed using SPSS to identify significant changes in TCs' confidence before and after the tutoring project.

Qualitative data included four open-response questions evaluating change in confidence related to (1) identifying and breaking up elements of a math standard, (2) assessing student thinking, reasoning, and understanding, (3) lesson planning and teaching, and (4) finding and using math resources. An additional question asked candidates to reflect on their overall impressions of the tutoring project. Descriptive and pattern coding were used to analyze TC responses for patterns and themes (Saldaña, 2015).

Results

We first present the quantitative paired samples *t*-test statistics and results (see Table 1). Second, we present qualitative themes from the open-ended responses.

Table 1: Paired Sample *t*-Test for Teacher Candidate Self-Efficacy Survey

	Statistics		Paired Differences

Plan and Meet with Parents	2.38	4.04	–1.660	1.128	.165	–1.991	–1.328	–10.084	46	<.001

As shown in Table 1, all areas of the self-efficacy survey demonstrated statistically significant gains at the p <.001 level for change in teacher candidates' confidence after engaging in the tutoring program. The lowest areas of student confidence before (MB) starting the tutoring program were planning and meeting with parents, assisting families for home support, and planning and adjusting math lessons.

Teacher candidates showed a growth (M) in confidence of approximately 1.7 points in establishing routines/transitions and meeting with parents, and approximately 2 more points in the other areas. The greatest gains were in planning and adjusting lessons (2.4) and assisting families for home support (2.5). The highest areas of confidence after tutoring (MA) were gauging student comprehension and motivating low-interest students (7.7).

Qualitative results revealed multiple themes across five categories: (1) finding and breaking up standards; (2) planning and teaching; (3) assessment of student thinking, reasoning, and understanding; (4) finding and identifying resources; and (5) overall impressions of the tutoring project.

Two common themes relating to teacher candidate's confidence in finding and breaking up standards were (1) improvements in TCs' ability to align lessons to the standards and (2) breaking up elements of a standard into more time-appropriate or manageable chunks. One TC's reflection best illustrates the first theme relating to alignment.

> At the beginning of the tutoring project, I honestly felt unsure about breaking down a math standard because the wording sometimes felt confusing and overwhelming. After receiving feedback, I realized how important it was to stay aligned to the exact standard instead of adding extra components. This helped me better understand how standards guide instruction. By the end of the tutoring sessions, I felt much more comfortable analyzing standards and designing lessons directly from them.

Other TCs echoed these statements, citing the use of state resources to clarify alignment (I used websites like Georgia Inspire to clarify what the student needed to know.) and being intentional about activities and resource (Over time, I learned to break the standard into clearer parts. This shift helped me design more intentional activities; Overall, I feel more confident now in

choosing resources that actually match the learning goal instead of just picking whatever looks good.).

Breaking standards into smaller chunks also helped TCs manage time. As two TCs reflected, "At the beginning, looking at a full math standard felt overwhelming because there was so much packed into just one sentence. As I started planning lessons, I learned how to break the standard into smaller, manageable skills." and "Breaking it down helped me feel more confident making lessons that build understanding step by step." Breaking down the skills also supported student comprehension. Other TCs noted, "breaking the skill into smaller chunks made it easier for [student] to master each step and helped build his confidence;" "I noticed that when I slowed down and focused on one element at a time, the student understood the content better;" and "This experience showed me that breaking standards into smaller parts makes instruction more effective and less overwhelming for both students and myself."

Three common themes relating to planning and teaching were (1) structured organization to improve pacing and time management; (2) importance of flexibility during implementation; and (3) finding the right balance between fun, efficient, and rigorous. In regards to organization, students often noticed that the timing for their activities did not always match their original planning (I learned that what I planned on paper did not always match how long activities actually took or how engaged the students would be.). However, over time they were able to provide clearer organization to improve their pacing and time management. For example, one TC reflected, "My first few lessons were not as structured, and transitions felt rushed. Over time, I began organizing sessions into clear segments. This structure helped the sessions run more smoothly and increased my confidence." In another example, "Lesson planning and teaching required a lot of time and organizing instructions into clear, manageable steps to build upon the prior knowledge of what she already knew."

Teacher candidates often reflected on how the project reinforced the importance of flexibility and helped build this skill. One TC's reflection illustrates this theme:

> At first, lesson planning felt stressful because I worried about choosing the right activities and making sure everything made sense. However, teaching the lessons helped me realize that flexibility is just as important as planning. For instance, during the measurement lessons, I had to adjust pacing when we ran out of time measuring with paper clips. Each session made me feel more comfortable leading instruction and making decisions in the moment. By the end of tutoring, I felt much more confident in both planning and teaching.

The importance of flexibility was echoed by other TCs, such as these three examples: "These adjustments helped me feel more prepared and flexible as a tutor, rather than feeling stuck to a rigid plan." "In the beginning, I tried to plan every minute of the session, but I discovered that being responsive to [student's] energy and engagement made the lessons more effective." "I noticed that my teaching does not always follow the lesson plan exactly. At first, this made me feel unprepared, but I began to realize that this flexibility is actually responsive teaching."

Many TCs gained confidence in finding the right balance of fun, efficiency, and rigor. Some students noticed they started having fun, but not necessarily learning—"At the beginning of tutoring I wanted her strictly to have fun, but I noticed I was more focused on the activities rather than the learning goals. Once I realized my fault I made corrections to make it fun but also efficient." Other TCs had the opposite problem, but were still able to find balance—"From day one, my lessons included too much content, but I began to make the tutoring session change from just paperwork to more movement and engaging." Many TCs came to enjoy seeing students grow while also having fun (My favorite lesson was our answer and match puzzle. Both my

students were very engaged during these lessons and were showing great progress in their subtraction work.).

Three common themes relating to assessment of student thinking, reasoning, and understanding were: (1) difference between being correct and understanding; (2) identifying and responding to misconceptions; and (3) using probing questions. At least half of TCs reflected that when they started assessing students, they focused on being correct (At first, I mainly paid attention to whether the answer was correct; At first, I mainly looked for correct answers as evidence of understanding; At the beginning, I focused on whether they got the question right or wrong). However, over time this changed from "correct" to "understanding" (Over time, I realized that understanding how she got the answer mattered much more.). As TCs' focus changed, so did their assessment practices. For example, some TCs started using hands-on tasks as assessments, "instead of just asking for answers, I began asking him to show me with base ten blocks and explain what he was doing." Other TCs used conceptual questions (This showed me the importance of asking follow-up questions like, "How do you know?" or "Can you show me another way?" I began incorporating think-alouds to better assess conceptual understanding.) These changes increased TCs confidence in understanding students (I became more confident in using questioning, observation, and modeling to truly understand his thinking; I felt more confident analyzing student responses and adjusting instruction based on their reasoning rather than just accuracy; Working with [student] taught me that effective teaching starts with understanding how students think.).

Student were able to gain confidence in using their assessment strategies to identify misconceptions and respond with appropriate adjustments. These four examples illustrate this theme: "Observing how she positioned the hour and minute hands helped me identify misconceptions about half-hour concepts. These instances allowed me to change instruction immediately through modeling and guiding questions." "Hearing their explanations made it easier to catch misconceptions and adjust instruction in the moment." "I would have my students explain the reasoning behind their answers. This would eventually help them with changing their own mistakes the more I did it." "Asking questions allowed me to adjust my instruction and provide immediate support when misunderstandings occurred."

While conceptual questions allowed TCs to assess student understanding, probing questions helped prompt discourse and elicit student responses. Many TCs noted that at the beginning of the project, students did not talk a lot (e.g., "Especially with Kindergarten, kids do not always verbalize their misconceptions, struggles, thoughts, etc." "Initially, I found it challenging to effectively assess how well students understood the material, as they would sometimes provide incomplete or unclear responses."). However, questioning prompted the discourse (e.g., I learned to ask probing questions like, "What does your equation represent?"; I learned to ask probing questions and give students the opportunity to explain their reasoning.). These opportunities directly impacted TCs' confidence (My level of confidence increased in assessing student thinking, reasoning, and understanding because I became more comfortable asking guiding questions during lessons.)

Three common themes relating to finding and identifying resources were: (1) appreciation for accessible recourses, (2) shift from worksheets to hands-on activities, and (3) modifying resources to align with standard objectives. TCs appreciated having access to resources such as physical manipulatives from a nearby supply closet (I was able to get any physical resources I needed from the math room, which was very helpful.) or collaborative colleagues (Most of my activities were figured out through consultation with my classmates and professors). On day one

of the semester, the professor had TCs explore the resources in the supply closet to document pros and cons of similar manipulatives. TCs used these resources in almost every lesson (I chose to use fraction tiles, fraction circles, white boards, erasers, paper, and dry erase markers. I used these materials throughout all my lessons.), especially after seeing the benefits such as this TC, "The first day, the student would not really want to share with me how she did it. It wasn't until the second day when we used the manipulatives that the student was able to explain to me how she got her answers and show me many different ways to solve the problem." On the first day, TCs worked in groups to identify potential grade-specific activities. Some TCs continued this practice through the tutoring whereas others called on their colleagues as needed "At the start of the tutoring project, I relied heavily on activities I witnessed in my practicum field experience last semester. These did not always work for my student's needs so I asked my professor for help and ideas."

Many students started with worksheets, which is what they have experienced themselves and seen in the classroom ("At first, I relied mainly on worksheets;" "At the start of this project, I wasn't sure what types of resources would best support multiplication beyond worksheets."). However, by the end of the project, most students gained confidence in moving beyond worksheets based on their experiences with students. For example, one TC reflected:

> At first, I relied mostly on basic worksheets, but I realized that [Student A] and [Student B] learned better with interactive tools like counters, number lines, ten-frames, and simple subtraction games. I also learned to adapt resources rather than using them as-is, such as turning a worksheet into a game. This helped me feel more confident in choosing resources that matched both the standard and the learning needs of my students.

These additional examples also illustrate this shift: "I soon discovered that hands-on and interactive materials made the lessons more meaningful for [Student]." "I definitely got more creative during tutoring. I found myself being more resourceful with my teaching tools and this allowed for more creative lessons." "Later, I intentionally chose concrete models, interactive challenges, and even a scavenger hunt to make learning more meaningful."

The final theme brings together ideas prior themes relating to standard alignment and intentionality of resources as TCs reflected on their increased confidence in adapting resources to meet their needs. Two TC stated:

> Finding and using math resources was one of the areas in which I grew most confident. Because I clearly understood the purpose of each activity, modifying or designing resources felt more focused and intentional. This process strengthened my confidence in choosing materials that align with both the math standard and the student's need.

> I learned to evaluate resources more critically, ensuring they aligned directly with the math standard and learning goal. By the end of the project, I felt more confident locating high-quality math materials and adapting them to meet the specific needs of my student.

Although we cautioned students from paying for any resources during this course, several TC did find them useful, with adaptations: "Not everyone's favorite, but I love finding ideas on Pinterest and teachers pay teachers. I know these aren't 'educational' sites, but if you review them and tweak them, they can give you some great ideas." "Resources can be tailored to specific learning goals."

Three common themes stemming from TCs' overall impressions of the tutoring project were appreciation for: (1) the ability to practice planning and implementing creative mathematics

tasks, (2) opportunities to work and talk with parents, and (3) better understanding of how to be flexible and adaptive.

One TC reflected, "I got to see how effective my lessons were and self reflect on my teaching abilities. I also got to be creative and find ways to engage my students. I enjoyed seeing my students grow by the end of the sessions." Many students used creativity by incorporating student interests ("I got out of it was to find out what students like and really implement that into your lesson."), integrating real world contexts ("Finding different ways get the kids engaged and actually putting what they learn to real life"), and making it fun ("I think I was able to grow as an individual as well as a future educator because I got to learn how to plan for *one* student and how to make it a fun but educational time." "Instead of using a number line to explain a math concept on the table, I had them get up and "hop" when using the number line on the whiteboard.").

Another TC reflected, "I think what I got most from this experience was learning how to prepare for talking with parents. It was something we don't talk a lot about in our classes, so it was nice to get experience in a big aspect of teaching." This sentiment was echoed by at least half the TCs. For example: "I was nervous about the parent conferences but I feel like those outlines really helped a lot!" "I think the parent conference really boosted my confidence in talking to a child's parent." "One positive I got from this is to talk to parents and plan for conferences." "I have more confidence to meet with parents."

Many students reflected on improvements to flexibility and adaptability. For example: "The ability to be flexible and to account for different learners' strengths and weaknesses more fluidly." "I learned how to tweak and plan for personalized instruction based off a students' strengths and weakness and how to better support/scaffold within areas of struggle." "I really enjoyed getting to give assessments and base my teaching based off of the data. I was scared of my ability to do this." "I feel like I really felt what it is like as a teacher for your plans to never go the way you want them to. I felt the real feeling of defeat when you think that you aren't doing a good job but then realizing that things aren't nearly as bad as I thought. If this is going well, I can change it right now."

A few other reoccurring themes related to enjoying seeing the positive effects on student learning ("I really enjoyed watching my student grow educationally."), increased confidence to apply strategies to larger classroom settings ("Working with a student one-on-one and figuring out their learning needs. This could help me get an idea on where to start with each student in my classroom."), and better organization of resources ("It showed me that organization is *super* important when setting up lessons and unit plans.") and time ("Time management!") when working with students.

Discussion

The results support literature that active experiential learning opportunities through early field experiences that combine authentic contexts with coursework can support teacher candidate confidence (e.g., Abbott et al., 2026; Williams & Sembiante, 2022). Many early field experiences are classroom-based and do not provide TCs with opportunities to engage with parents and families, despite this being an important aspect of teaching (Iwai, 2025). This may explain why supporting and working with families were the two lowest areas of TCs' confidence in this study before the tutoring project.

A significant convergent result from this study demonstrated that an after-school tutoring project, in which TCs engage directly with parents or families, can increase confidence in planning and meeting with parents as well as assisting families with home support. Although meeting parents had the lowest post-score overall (improving from 2.38 to 4.04), assisting with

home support showed the largest gain (4.81 to 7.29).

Results also indicated improvements to TCs' confidence in applying pedagogical content knowledge (Ball et al., 2008), specifically relating to planning and adjusting lessons. TCs reported increased confidence in identifying and breaking up standards into time-appropriate and developmentally appropriate components as they sequenced their lessons across specific units of instruction for their students. They also improved their ability to organize activities, materials, and transitions to directly align with those standards and their students' needs. Finally, practice adapting lessons during and between tutoring sessions supported an increase in confidence for flexibility when planning and teaching mathematics.

TCs indicated an improved confidence in using noticing skills to identify and use evidence of student thinking (Jacobs et al., 2010; NCTM, 2014). This included confidence in gauging comprehension beyond correct answers by using probing questions to encourage critical thinking, identify misconceptions, and verify understanding of the "why" behind the "how". In addition to confidence in the content and pedagogy, TCs demonstrated increased confidence in their ability to motivate and engage students. By the end of tutoring, many shifted from relying primarily on worksheets to incorporating hands-on conceptual explorations, real-world connections and story problems, and engaging practice games or activities.

In conclusion, community tutoring is a structure that differs from traditional field experiences. As one student said, "Lesson planning for tutoring looked a little different, as it was a lot more focused within the time allotted for the specific subjects, with certain areas being focused on such as representing learning in multiple ways, prompting student questioning and higher-order thinking, and the implementation of literacy into math, all working together to not only assess the student, but to build instruction around their strengths and weaknesses and support them in acquiring the skills and knowledge necessary to improve." Similar to Darling-Hammond et al. (2002), the interweaving of experiential learning and coursework allowed for structured application with specific ongoing support from the professors. We highly recommend that teacher education programs consider incorporating early community-based field experiences, such as tutoring clinics within their methods courses to support teacher candidate confidence in teaching mathematics.

COGNITIVE SHIFTS IN PRE-SERVICE SECONDARY TEACHERS' CONCEPTUAL AND PROCEDURAL COORDINATION ABOUT ASYMPTOTIC BEHAVIOR

Luan Nguyen
Oklahoma State University
luan.nguyen10@okstate.edu

Michael Tallman
Oklahoma State University
michael.tallman@okstate.edu

We present the results of a qualitative study that investigated the cognitive mechanisms through which pre-service secondary mathematics teachers (PSMTs) coordinate their conceptual and procedural knowledge about the asymptotic behavior of rational functions. While literature establishes that PSMTs often favor procedural proficiency over conceptual depth, the internal reorganization of these knowledge forms remains underexplored. Grounded in Piaget's theory of reflecting and reflected abstraction, we analyzed how participants' schemes evolved during task-based clinical interviews. Findings reveal that disrupting routine procedures with anomalous function behaviors triggers reflected abstraction, leading participants to integrate structural explanations with procedural execution. These results suggest that teacher education should engender cognitive conflict to foster specialized content knowledge in PSMTs.

Keywords: Preservice Teacher Education, Cognition, Learning Theory, Undergraduate Education

Shulman (1986) proposed that effective teaching goes beyond procedural competence, requiring teachers to understand the concepts and principles of a discipline (*substantive structures*) and comprehend the means by which they are established (*syntactic structures*). Building on this perspective, Tallman (2021, 2023) argued that teachers' subject-matter content knowledge is most effective when their mathematical schemes are coherent and coordinated. Tallman further proposed that a teacher's awareness of the mental actions and conceptual operations organized within these schemes is crucial to developing content knowledge with the potential to inform effective pedagogical action.

Star and Stylianides (2013) demonstrated that teachers' application of conceptual and procedural knowledge profoundly influences how they assess and respond to students' work, underscoring the practical significance of understanding how teachers might be supported in integrating their procedural and conceptual knowledge structures. Empirical findings further suggest that pre-service secondary mathematics teachers often perform procedures successfully while demonstrating limited conceptual justification (Tchoshanov & Monarrez, 2024). However, less is known about the cognitive processes through which procedural action schemes are destabilized and reconstructed into structurally grounded explanations.

This gap is particularly salient in the context of teachers' knowledge about the asymptotic behavior of rational functions, where teachers' fluent application of common procedures—such as comparing degrees or identifying zeros of the denominator—often dissuade the need for conceptual justifications that connect limiting behavior with the algebraic structure of rational expressions. Drawing on Piaget's notions of *action schemes*, *reflecting abstraction*, and *reflected abstraction*, this study examines how procedural schemes are enacted, disrupted, and reorganized to develop deeper conceptual understanding. Specifically, this study was guided by the research question: *How do pre-service secondary teachers' mathematical schemes shift as they coordinate procedural and conceptual knowledge of asymptotic behavior in rational functions throughout their participation in task-based clinical interviews*?

Procedural and Conceptual Knowledge of Asymptotic Behavior

Yerushalmy (1997) proposed that asymptotes can be understood in a meaningful way or at a surface level, which depends heavily on recall of declarative knowledge. For instance, a vertical asymptote was meaningfully understood by participants of Yerushalmy's study as "a vertical line that exists only at points where the function is not defined and the function's values approach negative or positive infinity" (Yerushalmy, 1997, p. 8). Participants conceptualized a horizontal asymptote as "a horizontal line, parallel to the *x*-axis, that comes closer to the curve at infinity" (Yerushalmy, p. 12), and oblique asymptotes were characterized by the function's linear end behavior without being limited to finite values (Yerushalmy, p. 8). Building on these meanings, we outline the basic procedural and conceptual knowledge of the horizontal, vertical, and slant asymptotes of rational functions in Table 1.

Table 1: Basic Procedural and Conceptual Knowledge of Asymptotes

	Procedural Knowledge	Conceptual Knowledge
Horizontal Asymptote	A horizontal line found by comparing the degrees of numerator and denominator of a rational expression.	A horizontal line represents the limit of a function's values as $x \to \pm\infty$; the function may cross its horizontal asymptote. The student understands that the difference between the function's values and the value of the limit can be made as small as desired by increasing *x* beyond a threshold defined in terms of the desired error bound.
Vertical Asymptote	A vertical line found by setting the denominator of a rational expression equal to zero and solving for the independent variable.	A vertical line that a graph of a rational function approaches but never touches, indicating where the function is undefined. The student understands that the function's values tend to $\pm\infty$ because the denominator of a function defined as a quotient approaches zero while the numerator approaches a non-zero value, making the quotient approach $\pm\infty$. Such as: $\lim_{x\to a^-} f(x) \to \pm\infty$, and $\lim_{x\to a^+} f(x) \to \pm\infty$.
Slant (oblique) Asymptote	A slanted line found by performing polynomial long division and discarding the remainder.	Describes the function's linear end behavior as $x \to \pm\infty$ but does not restrict finite values. The student understands that the end behavior of a rational expression behaves linearly. More specifically, the student understands that as *x* increases or decreases without bound, the function's value $f(x)$ varies at essentially a constant rate with respect to *x*.

The conceptual characterizations of asymptotes expressed in this table also allow participants to reason about how input and output quantities change together. In this sense, the forms of reasoning we classify as conceptual knowledge align with descriptions of *quantitative reasoning* (Thompson, 1990, 1994, 2011) and *covariational reasoning* (Carlson et al., 2002; Thompson & Carlson, 2017) reported in the literature. Quantitative reasoning refers to the mental actions involved in conceptualizing situations in terms of quantities and quantitative relationships

(Thompson, 2011; Tallman, 2021). Covariational reasoning refers more specifically to reasoning about how two quantities change together, such as how changes in x correspond to changes in $f(x)$ simultaneously (Carlson et al., 2002). In this study, we applied the theoretical frameworks of quantitative and covariational reasoning to supplement our broader perspectives of Piagetian abstraction and radical constructivism to analyze participants' conceptual knowledge and the transition from procedural to conceptual reasoning.

Theoretical Perspective

We leveraged Piaget's notions of reflecting and reflected abstraction as analytical constructs to describe participants' integration of procedural and conceptual knowledge structures (Piaget, 2001; Tallman, 2021; Tallman & Uscanga, 2020; Tallman & O'Bryan, 2024). Reflecting abstraction involves three phases: (1) *differentiation*: the individual dissociates an action or coordinated sequence of actions from the outcomes they produce; (2) *projection*: the individual constructs an internalized representation of the actions, and (3) *reorganization*: the individual integrates these internalized actions into coherent mental structures that can be applied to a generalized class of objects. Once these actions are internalized and reorganized, the abstraction becomes reflected through the subject's retroactive operation on these actions at the level of thought, where the internalized actions constructed through reflecting abstraction are organized within cognitive schemes (Tallman, 2021, p. 4). This retroactive operation leads to a higher level of awareness of and coherence in an individual's mathematical conceptions, which enables the individual to strategically apply their meanings in a range of novel contexts.

We also applied Piaget's notion of an action scheme in our analysis. An action scheme is a cognitive structure that enables an individual to carry out a goal-directed sequence of actions in response to a situation perceived as paradigmatic (Tallman et al., 2021). Such schemes often support efficient performance but remain tied to the limited contexts that reflect the recognition criteria of the scheme. In this study, the enactment of action schemes characterizes procedural knowledge, particularly when participants fluently apply rules for determining asymptotes without fully articulating structural justifications. Cognitive shifts are therefore identified as moments when these procedural schemes are disrupted, examined, and reorganized into structurally grounded explanations of asymptotes, marking the coordination of procedural actions with conceptual understanding.

Methods

Participants

The participants in this study were two pre-service secondary teachers, Mia and Kathy (pseudonyms), both in their fourth year of a secondary education program with a concentration in mathematics at a large Midwestern R1 university. Mia served as a learning assistant in an entry-level mathematics course, tutored courses through Calculus III for three semesters, and completed her student teaching in an 8th-grade Pre-Algebra class. Kathy served as a learning assistant for Calculus I for three semesters and completed her student teaching at a high school where she taught Precalculus, Trigonometry, Geometry, and AP Calculus AB.

Setting and Tasks Interview

We designed this research as an exploratory case study (Yin, 2009) and structured it around a three-part data collection process to elicit participants' reasoning and support their reflection.

Introductory interview (25 minutes). During the introductory interview, we focused on each participant's experiences and beliefs about teaching rational functions, particularly focusing on how they envisioned explaining the concept of asymptotes to their future students.

Task-based clinical interview (75 minutes). We conducted the task-based clinical interview (TBCI) with each student immediately after their introductory interview. The structure of the clinical interview and our analysis of the data followed the experimental and analytical approaches, respectively, as described by Goldin (1997, 2000) and Clement (2000). The tasks focused on provoking participants' reasoning about the asymptotic behavior of rational functions and were designed to investigate how they coordinated their procedural and conceptual knowledge (Table 2).

Final interview (20 minutes). Two days after the TBCI, we conducted a follow-up interview to examine each participant's reflections on their prior reasoning. Participants revisited their earlier work and described how their thinking had shifted and how they coordinated their procedural and conceptual knowledge across tasks. In total, participants' time commitment for the study was approximately two hours.

Table 2: Three Interview Tasks with Rationale and Analytical Focus

Tasks	Rationale and Analytical Focus
Task 1: Find the domain of each function and identify any horizontal and vertical asymptotes: a. $\frac{1-5x}{1+2x}$ b. $\frac{2x^2}{x+1}$ c. $\frac{3x+1}{x^2+x+9}$	This task is primarily procedural. Although it invited procedural enactment, we prompted participants to explain the meaning of asymptotes as they worked. Our analysis focused on whether participants' action schemes were conceptually grounded or merely enacted as isolated rules and procedures.
Task 2: Define a rational function with domain $(-\infty, k)\cup(k, 5)\cup(5, \infty)$ with $k < 5$ such that the function has only one vertical asymptote at $x = 5$.	Following Task 1, we designed this task to disrupt the action scheme of setting denominators equal to zero to identify vertical asymptotes. Our analysis focused on how participants' mathematical schemes had shifted.
Task 3: Define $f(x) = \frac{p(x)}{q(x)}$ where p and q are polynomials. Define p and q such that $y = 2x + 1$ is an oblique asymptote.	We designed this task to disrupt routine procedural approaches. For this task, reliance on procedures alone is likely insufficient, prompting participants to coordinate a procedural and a conceptual approach. Our analysis focused on how participants reasoned when their action schemes become unstable, which allowed us to document the extent to which participants integrated their procedural and conceptual knowledge structures, and the extent to which these structures were enriched through this integration.

Data Analysis

During the interviews, we engaged in iterative cycles of *responsive and intuitive interaction* and *analytical interaction* with each research participant. These forms of interaction are essential to the teaching experiment methodology (Steffe & Thompson, 2000) but are appropriate in the

context of task-based clinical interviews for constructing a viable second-order model of the students' mathematical understandings and ways of reasoning.

After completing data collection, we transcribed and analyzed all interviews using Braun and Clarke's (2006) thematic analysis approach to identify patterns of meaning across tasks. The coding process was theoretically informed by our Piagetian perspective. We characterized procedural knowledge by the enactment of action schemes, particularly when participants relied on memorized rules and fixed sequences of steps in familiar contexts without being able to provide conceptual justifications. We identified participants' application of conceptual knowledge through evidence of reflecting abstraction, such as when participants examined their prior procedures, articulated why those procedures worked, and extended their reasoning beyond rule-based enactment. We then identified participants' cognitive shifts through behavioral indications of reflected abstraction, marked by moments in which previously enacted procedures were disrupted or overgeneralized, and participants reorganized their schemes into more stable and conceptually grounded structures. In these instances, procedural and conceptual knowledge were coordinated, and their coherence became part of participants' awareness.

Results

Due to space limitations, we present and discuss only Mia's case, as her expressed reasoning more compellingly demonstrated a shift from procedural enactment to conceptual reorganization. Mia's trajectory also provided a clearer illustration of the cognitive shifts identified in our analysis.

Mia's Conceptions of Asymptotic Behavior in the Introductory Interview

Mia identified asymptotic behavior as the central idea of rational functions and emphasized the importance of teaching this concept by building on students' prior knowledge, stating, "It starts with breakdown, kind of, what they do know foundationally." She believed teaching vertical asymptotes effectively entails linking new ideas to students' understanding of "undefined slopes" and "exploring how graphs approach but never touch the vertical boundaries." For horizontal and slant asymptotes, Mia supposed that letting students compare the degrees of the numerator and denominators would be easier for them to start exploring these concepts. Then, Mia suggested framing rational functions as "top heavy," "bottom heavy," or "balanced" to convey the criteria by which horizontal asymptotes exist. When explaining slant asymptotes, Mia was only able to associate a characteristic of the symbolic representation of a rational function with the existence of a slant asymptote, as she stated, "the numerator is one higher than the denominator." Mia struggled to articulate a conceptual justification for this condition during the interview.

During the introductory interview, Mia articulated an intention to connect instruction on rational functions to students' prior knowledge and expressed a desire to teach the asymptotes conceptually. However, her explanations provided limited insight into her own personal meanings for asymptotic behavior and into how those meanings related to the procedures she described to determine horizontal, vertical, and oblique asymptotes. The central focus of the TBCIs that followed the introductory interview was to elicit observable products of Mia's meanings for asymptotes so that we might construct and refine a viable model of her mathematical schemes.

Mia Enacted Stable Procedural Schemes with Limited Conceptual Justification

When engaged in Task 1, Mia effectively applied action schemes but demonstrated little inclination to move beyond uncritical enactment toward meaningful conceptual understanding. She accurately identified the vertical asymptote of each function by setting the denominator

equal to zero and solving for the independent variable. Describing her solution to Part (b), Mia stated, "It's *x* equals negative one, because I put *x* plus one equals zero. And so that's my vertical asymptote." After she explained her solution, we asked Mia to elaborate on the meaning of the vertical asymptote she had obtained. Mia connected her answer with visual intuition, saying, "If you're thinking visually left to right, like what would be impeding that, that would be a vertical asymptote." We interpret Mia's comment to indicate her conception of vertical asymptotes as impediments to the generation of a continuous curve representing the correspondence of a function's input and output values. Mia's remark suggests that she might have envisioned the action of sketching a function's graph, moving from left to right, and approaching a vertical asymptote, which acts like a kind of barrier that forces the curve to approach positive or negative infinity. This interpretation reflects Mia's conceptual understanding of vertical asymptotes; however, there is little evidence that this interpretation was meaningfully connected to the procedure she applied to determine the location of the vertical asymptotes for each function in Task 1, nor to the algebraic structure of a rational expression. Specifically, Mia did not articulate how the function changes as *x* varies near the function's undefined value.

Mia used a degree comparison method to identify the horizontal asymptotes in Task 1: "First, you need to look at your polynomial on the numerator and denominator. Identify the polynomial of highest degree […] I would call this balance." While responding to Part (a), she circled the leading terms "$-5x$" and "$2x$" in the numerator and denominator of the rational function $y = \frac{1-5x}{1+2x}$, and labeled the case as "balanced," indicating that the degrees of the numerator and denominator are equal. She then correctly concluded that the horizontal asymptote is determined by the ratio of the leading coefficients and obtained $y = -5/2$ as the solution.

Mia used metaphors such as "top-heavy" and "bottom-heavy" to describe different cases while responding to Parts (b) and (c). We interpreted her use of these metaphors as a possible indication of reasoning quantitatively about the behavior of a rational function, as she seemed to compare the relative sizes of some amount represented in the numerator and denominator. However, Mia did not fully explain why the ratio of leading coefficients determines the horizontal asymptote of a rational function when the degrees of its numerator and denominator are equal, or how changes in *x* simultaneously affect the ratios of leading terms in the numerator and denominator. In particular, Mia did not express her intuitive understanding that a horizontal asymptote is the constant function $y = k$ such that the values of the rational function *f* can be made as close to *k* as desired by making $|x|$ sufficiently large. Mia's work on Task 1 established her procedural fluency, showing that her rule-based enactments functioned as her dominant mathematical schemes.

Task 2 prompted Mia to define a rational function with a domain restriction satisfying only one vertical asymptote (see Table 2). Aware that neither *k* nor 5 are in the domain of the function, Mia acknowledged, "I know that I have funky things going on here with my domain." She considered how the function should behave within intervals of its domain, rather than plug in values of *x* to get a sense of the graphical behavior of the function. Mia then attended to the distinction between holes and vertical asymptotes, noting: "I want the vertical asymptote at five, I need the hole to be somewhere else, if the hole's somewhere else, then I have to have something that cancels in the numerator and the denominator." Mia's expressed reasoning demonstrates her familiarity with the procedure for identifying a hole, with some evidence of conceptual understanding of the distinction between removable and infinite discontinuities. About Mia's answer ($\frac{(x-2)(x-1)}{(x-5)(x-1)}$), we asked: "Where did the two [in the numerator] come from?" She responded: "I just put in a different number than five because I didn't want a hole at five, so

two is whatever k is. A hole is not a vertical asymptote." Mia's explanation provides further support for her understanding that a common linear factor in the numerator and denominator of a rational expression corresponds to a removable discontinuity, and that a hole is distinct from a vertical asymptote.

Task 2 disrupted Mia's zero-denominator action scheme by requiring her to construct a rational function that satisfied both a domain restriction and the condition of having only one vertical asymptote. Unlike in Task 1, where she identified vertical asymptotes by applying memorized rules, while completing Task 2 Mia coordinated factorization, domain restriction, and discontinuity type to define a function that satisfied a domain restriction with one vertical asymptote. Mia's expressed reasoning on Task 2 suggests emerging reflecting abstraction, as previously enacted procedures were reorganized into a more structurally coherent scheme.

Reflected Abstraction Through the Structural Reorganization of Action Schemes

Task 3 prompted Mia to construct a rational function with a slant asymptote of $y = 2x + 1$. She initially relied on a familiar rule, explaining that "p is one degree higher than q's highest degree," reflecting her knowledge of the condition for the existence of a slant asymptote. Mia then defined a function satisfying this condition such that the quotient was equal to the slant asymptote, producing $f(x) = (2x^3 + x^2)/x^2$ (Figure 1, left). Although this function met the degree condition, that it simplifies to $f(x) = 2x + 1$ (for $x \neq 0$) yields a linear function with a hole, rather than an irreducible rational function *approaching* a slant asymptote. This initial solution for f revealed a limitation in Mia's conceptual understanding as she correctly applied the structural condition for the existence of a slant asymptote but did not initially recognize that a slant asymptote describes the approximately linear end behavior of a non-linear rational function.

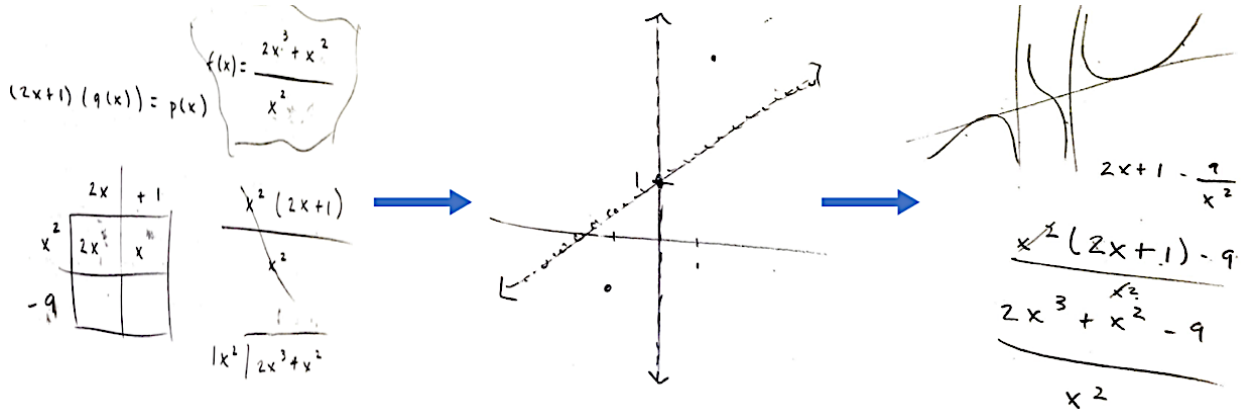

Figure 1: Mia's Reasoning Shifted, Refining Her Initial Solution in Task 3

When asked to graph the function she had constructed, Mia appeared uncertain and identified the line $x = 0$ as a vertical asymptote, marking it with a dotted line on her graph (Figure 1, middle), without recognizing that the function actually has a hole at $x = 0$. To sketch the graph, she evaluated specific values of x (e.g., $x = 1$ and $x = -1$). Although this strategy reflects an effort to understand the function's behavior, all computed points lie on the line $y = 2x + 1$. Notably, Mia did not initially recognize that the graph of the function she defined was linear, with domain R\ {0}, even though she appeared to define f to simplify to $2x + 1$.

After completing the sketch of her graph, we asked Mia to identify the slant asymptote on the graph. At that moment, a critical shift occurred: Mia factored x^2 in the numerator of $\frac{2x^3+x^2}{x^2}$ and

cancelled with the x^2 in the denominator. Noticing that the expression in the denominator cancels with a factor in the numerator, and recognizing that all values of a rational function's input for which its denominator equals zero are excluded from the domain, Mia questioned, "Did I make that a hole instead of a vertical?" This question marked a transition from procedural enactment to reflective examination of her prior actions. By recognizing the removable discontinuity and acknowledging that f simplified to a linear form, Mia began to think more conceptually about how to construct a different example. We asked her to explain how a slant asymptote affects the graph of a rational function. Mia's response demonstrates her attention to the global behavior of a rational function, explaining that as one considers values from negative infinity to positive infinity, the term of highest-power in a rational expression dominates while additional terms become insignificant as the input increases or decreases without bound. She refined her example to $f(x) = 2x + 1 - 9/x^2$ (Figure 1, right), explaining that the term "$-9/x^2$ becomes negligible as $x \to \pm\infty$." This explanation reflects Mia's coordination of algebraic structure with limit-based reasoning about a rational function's end behavior, indicating reorganization of her prior action schemes into a more conceptually grounded and structurally coherent understanding. Mia not only revised her prior solution but explained why $2x + 1 - 9/x^2$ approaches $2x + 1$ as $x \to \pm\infty$. Mia's previously enacted procedural schemes were reorganized and integrated into a single structurally coherent scheme linking algebraic form and end behavior.

Mia's Reflection on the TBCI During her Final Interview

Mia acknowledged that in comparison to Task 1 from the TBCI, Task 2 was more challenging because Task 1 could be "completed procedurally." Although she successfully solved Task 2, Mia reflected that she often relied on a "plug-and-chug" procedural approach and recognized that Task 2 disrupted her uncritical application of these procedures. She expressed more excitement when reflecting on Task 3, emphasizing that its novelty helped her reason about why slant asymptotes occur.

Discussion

Mia's comments in the introductory interview anticipated her reasoning in the task-based clinical interview. She demonstrated stable enactment of action schemes while working through Task 1. Procedural approaches dominated her mathematical thinking as she relied on rule-based identification of asymptotes while offering limited structural justification in terms of limits and end behavior. This result supports Tallman's (2021) claim that procedural accuracy does not guarantee conceptual clarity. When Mia's application of routine procedures was disrupted in Tasks 2 and 3, she began to reorganize her scheme. She demonstrated a shift toward coordinating algebraic form with asymptotic behavior, suggesting the emergence of structural coherence and development of her conceptual understanding of asymptotes.

Cognitive shifts like the one Mia demonstrated are not just personal psychological developments. When they become a repeated experience of pre-service secondary teachers, these shifts have the potential to challenge the procedural status quo in secondary mathematics classrooms. We argue that mathematics teacher education programs should involve disrupting PSMTs' procedural action schemes and supporting them in becoming teachers who prioritize conceptual depth over rote memorization.

Our results suggest that mathematics teacher education curricula and instruction should explicitly include anomalous tasks (like Tasks 2 and 3) as a standard pedagogical tool to elicit PSMTs' cognitive conflict and engender the reorganization and refinement of their mathematical schemes.

We examined how middle school and elementary preservice teachers' (PSTs') visual and contextual representations evidenced their fraction multiplicative reasoning prior to instruction. The contextual representations showed PSTs successfully constructed contexts that represented the multiplicand in relation to a clearly defined whole, but connecting both fractions to the original whole was challenging. PSTs' visual models demonstrated an emerging understanding that the multiplier should operate within the multiplicand. When additional partitioning of the referent unit was required, some PSTs relied on familiar procedures (e.g., creating common denominators), reflecting non-multiplicative or algorithmic reasoning. Building on PSTs' demonstrated strengths and areas for growth, we offer instructional recommendations for mathematics teacher educators (MTEs) to support multiplicative reasoning with fractions.

Keywords: Mathematical Representations, Preservice Teacher Education, Rational Numbers

Background and Study Purpose

The National Council of Teachers of Mathematics (NCTM, 2014) has identified that effective mathematics teaching should offer opportunities for students to connect multiple mathematical representations, use those representations to problem-solve, and develop procedural fluency grounded in conceptual understanding. Using and connecting representations supports learners in unpacking and relating different constructs. Visual representations in particular support the development of foundational fraction concepts because "the area model is more convenient for part–whole meanings of fractions" (Toluk-Uçar, 2009, p. 174). In addition to supporting concept development, representations demonstrate learners' mathematical reasoning. For example, preservice teachers' (PSTs') written contextual problems for given symbolic expressions reveal the meanings they attach to those expressions (Toluk-Uçar, 2009), such as establishing relationships between the multiplier and multiplicand (i.e., referent unit) in fraction multiplication. Thus, engaging PSTs in representing fraction multiplication visually and contextually potentially reveals how they transfer meanings across representations.

Research has suggested PSTs find some representations more accessible than others. PSTs were more successful at converting symbolic expressions into word problems than at transforming word problems into appropriate visual representations (Toluk-Uçar, 2009). Moreover, engaging with multiple representations, including word problems, helped PSTs to construct meaning from contextual scenarios (Sosa-Martín et al., 2024) and enhanced their conceptualization of abstract mathematical ideas. Thus, creating visual models for contextual problems and posing story problems for given representations arguably supports PSTs' understanding of partitioning and units, ideas that are often abstract in fraction multiplication (Mack, 2001). Unpacking PSTs' representations and abstractions also informs Mathematics Teacher Educators' (MTEs') instruction related to fraction multiplication.

Building on the research summarized above, we investigated how PSTs' contextual story problems and visual models reveal their conceptions of multiplicative reasoning and partitioning, an area that warrants further investigation. We highlight patterns of how PSTs drew upon previously learned concepts of fractions, fraction addition, partitioning, referent units, and multiplicative reasoning to construct contextual and visual models for fraction multiplication.

Theoretical Considerations: Representations for Fraction Multiplication

Both mathematicians and mathematics educators have identified the flexible use of multiple representations as a key mathematical practice (NCTM, 2014; Wasserman, 2023), underscoring how mathematical knowledge is learned and discovered by establishing relationships between multiple representations. Fluency with representations reflects teachers' pedagogical content knowledge (Ball et al., 2008), evidenced in "the ways of representing and formulating the subject that make it comprehensible to others" (Shulman, 1986, p. 9).

Barmby and colleagues (2009) proposed the *Representational-Reasoning* model to highlight how connections between representations reflect learners' mathematical understanding. Within this model, understanding is framed as a network of internal representations connected through explicit reasoning and expressed through external representations (i.e., physical, symbolic, verbal, contextual, visual [NCTM, 2014]). When learners engage with multiple external representations, they can build and strengthen connections among their mental (internal) representations, which are "abstractions of mathematical ideas or cognitive schemata that are developed by a learner through experience" (Pape & Tchoshanov, 2001, p. 119). Because learners' internal representations cannot be assessed directly, researchers rely on external ones to infer potential connections learners established between underlying ideas. Moreover, because internal representations may stem from memorized algorithms or real-life experiences linked to mathematical concepts (Barmby et al., 2009), using this model to examine PSTs' contextual and visual representations may reveal the types of internal reasoning they may be drawing on. This, in turn, allows MTEs to better support PSTs in constructing coherent connections between multiple representations and developing a holistic understanding of fraction multiplication.

Conceptual understanding of fraction multiplication involves multiple concepts, including the meaning of a fraction and multiplicative reasoning. Multiplicative reasoning occurs through understanding the concept of unitizing, which involves "operating with singleton units to coordinate composite units" (Singh, 2000, p. 273). There are potential obstacles in learning unitizing as students typically learn fraction addition and whole number multiplication prior to fraction multiplication (Common Core, 2010). Similarly, PSTs bring experience with fraction addition, whole number multiplication, and even tendencies to rely on recalled procedures (Lovin et al., 2018). This may mean students and PSTs rely on understanding multiplication as repeated addition by interpreting 3×4 as $4 + 4 + 4$, and these interpretations are not the same as interpreting 3 times 4 as "3 fours" (Götze & Baiker, 2021, p. 263). Interpreting multiplication as repeated addition of the same-sized groups does not readily translate to fraction-by-fraction multiplication (Thompson & Saldanha, 2003), which requires learners to identify the distinct roles of the multiplicand and the multiplier. Moreover, PSTs who are familiar with the multiplication algorithm may attempt to map the algorithm directly onto a representation (Kang et al., 2025), demonstrating basic but not advanced reasoning connections (Barmby et al., 2009).

To address these challenges of multiplicative reasoning, we explored PSTs' potential internal representations externalized in their contextual and visual models. This exploration revealed the networks of reasoning among internal representations and their sources, and highlighted implications for framing instruction to support PSTs' representational reasoning in fraction

multiplication. We asked PSTs to construct visual and contextual representations (with explanations) for given symbolic and contextual problems, which enabled us to investigate how they coordinated internal and external representations in reasoning about fraction multiplication (Barmby et al., 2009). We asked the following research question: What did PSTs' contextual and visual representations reveal about their fraction multiplication reasoning prior to instruction?

Methods

Context and Participants

This study is part of a larger project conducted across four U.S. universities—three Midwestern and one Southeastern. The four authors taught math content and methods courses at their respective institutions. The larger project aims to develop, implement, and study assessment tasks that reveal nuances in PSTs' conceptions of fraction multiplication and to design instructional sequences to strengthen it. For this manuscript, we selected 31 PSTs (6 middle school and 25 elementary) from four institutions, representing 50% of the PSTs enrolled in their respective courses. PSTs at each institution varied in the number of mathematics content courses they had taken. We implemented a sequence of activities focused on fraction multiplication: (1) whole number × fraction, (2) fraction × whole number, (3) unit × non-unit fraction, (4) unit × unit fraction, (5) non-unit × non-unit fractions, and (6) fractions greater than 1 × non-unit fraction. Across these tasks, we emphasized using area models and creating contextual problems.

Assessment, Data, and Analytic Methods

We invited PSTs to construct (1) visual models for two given fraction multiplication story problems and (2) a contextual story problem for a given fraction multiplication statement (see Table 1). For this study, we used only the pretest data, as we aimed to understand what types of representations PSTs demonstrate for fraction multiplication prior to instruction. All the PSTs' contextual and visual representations for these tasks were the data for this study.

Table 1: Assessment Tasks to Collect PSTs' Visual and Contextual Representations

Solve the Following
Use a visual model and symbolic notations to solve tasks 1 and 2 and provide a brief narrative explanation that will help the reader understand how you solved the problem. 1. Alex is working on designing a garden. He wants to plant 3/5 of the garden with tomatoes and 2/3 of the tomatoes will be cherry tomatoes. How much of the garden will be planted with cherry tomatoes? 2. Tegan is also working on designing a garden. He wants to plant 4/5 of the garden with potatoes and 2/3 of the potatoes will be red potatoes. How much of the garden will be planted with red potatoes? 3. Create a fraction multiplication story problem that requires students to find 1/2 of 3/4.

In the first round of data analysis, we used open and axial coding (Saldaña, 2021) to identify the types of representations PSTs used, which helped us develop separate codebooks to analyze PSTs' multiplicative reasoning with fractions demonstrated through their visual and contextual representations. Both the codebooks had common codes related to: (a) mathematical operations represented; (b) whether a clearly defined referent unit was present and operated on; and (c) computations used and mathematical correctness. In addition, the codebook for contextual problems captured the relationships between the given fractions and the whole; whether the context involved discrete (counts) or continuous (e.g., area, volume) representations; and how

the unknown was framed (Table 2). The codebook for visual representations categorized how models were drawn, labeled, and described (Table 3). In the second round of analysis, we categorized PSTs' contextual and visual representations into five categories of multiplicative reasoning: Integrated, Partially Integrated, Transitional, Foundational, and Uninterpretable. Each category is described differently for visual and contextual representations (see Tables 2 and 3 for descriptors). In both rounds, two coders independently coded the data and resolved discrepancies through discussion.

Findings

We describe evidence of PSTs' understanding of fraction multiplicative reasoning first with contextual representations and then with visual representations.

Fraction Multiplication Reasoning Evidenced in PSTs' Contextual Representations

About one-third (29%) of PSTs' story problems were Integrated representations (Table 2). They demonstrated evidence of correct use of multiplicative reasoning and the referent unit. Thus, their representations reflected an interpretation of the given fraction statement as ½ of ¾ (i.e., ½ × ¾). As such, they wrote story problems that appropriately represented ½ × ¾ as *a half of three-fourths of a single whole*. For example, Elena wrote the following story problem: "Audrey is painting a wall. She want[s] to cover ¾ of the wall with a mural, but she want[s] ½ of the mural to be in black and white. How much of the wall will be in black and white?"

Table 2: Integration of Contextual Representations Across PSTs

Integration of Representations	Descriptors	Participants *n* (%)
Integrated	• Context represents multiplicative reasoning • Mathematically correct stories depict the given symbolic statement • Multiplicand is interpreted as the referent unit • Clear and correct referent whole • The unknown in the story clearly asks for fraction multiplication	9 (29%)
Partially Integrated	• Context represents multiplicative reasoning • Mathematically correct stories, but the context switches the multiplicand and multiplier in the given symbolic statement • Multiplier is interpreted as the referent unit • Clear and correct referent whole • The unknown in the story clearly asks for fraction multiplication	2 (7%)
Transitional	• Context does not consistently represent multiplicative reasoning (e.g., subtraction, addition, and/or division are represented) • Mathematically correct stories, but they do not represent the given symbolic statements • Referent units are not correctly used (e.g., counts used) • Clear and correct referent whole	5 (16%)
Foundational	• Context does not represent multiplicative reasoning • Stories are mathematically incorrect and/or require clarification because one or more of the following occur: operations are unclear or mixed, wholes are not specified, referent units are misused, or the unknown in the story problem is not clearly defined	15 (48%)
Uninterpretable	• Did not write a story problem	0 (0%)

About 7% of the PSTs' contextual problems showed evidence of their multiplicative reasoning; however, they flipped the order of the multiplier and multiplicand (i.e., ½ as the referent unit) as seen in Jimena's story that belonged to the Partially Integrated category:

> Lori wanted to bake a cake for the birthday party coming up, so she decided to do 2 flavors. Lori wanted ½ of the cake with vanilla and ¾ of the vanilla to be with strawberry filling. How much of the cake will be with strawberry filling?

About 16% story problems were themselves mathematically correct but did not consistently represent multiplicative reasoning (Transitional Integration). Instead, they represented additive reasoning or mixed representations. Karl wrote a fraction addition problem for ½ of ¾: "Bob ate ½ [of] a pizza. Jim ate ¾ of another pizza. How [much] did the[y] eat all together?" This story reflected Karl's additive reasoning, though they did not specify if the pizzas were the same size.

About half (48%) of the PSTs' representations were Foundational. These stories were mathematically incorrect or required clarification because they either used multiple operations (e.g., starting with multiplication and shifting to division), used multiple units (e.g., beginning with fractions and switching to counts without specifying the total), or treated fractions as separate wholes rather than composite units. Emma used subtraction ("leaving her 3 slices left"), multiplication ("½ of the remaining 3 slices"), and treated the numerator and denominator of ¾ as separate wholes: "Katie had 4 slices of pizza. She ate 1 slice, leaving her 3 slices left. What is ½ of the remaining 3 slices?" Another PST Kylie wrote: "There were bins of marbles, one was ½ full and the other was ¾ full. How many bins were there to fit all the marbles?" We marked this representation as Foundational because they asked "how many" without providing a total count.

Fraction Multiplication Reasoning Evidenced in PSTs' Visual Representations

We utilized the same five categories for PSTs' visual representations (Table 3) to unpack their visual models for the contextual problems ⅔ × ⅗ and ⅔ × ⅘ holistically.

Table 3: Integration of Visual Representations Across PSTs

Integration of Representations	Descriptions	Participants *n* (%)
Integrated	• Models represent multiplicative reasoning for both tasks • Models demonstrate correct products • Multiplicand identified as the referent unit for both tasks • Operation within the identified referent unit for both tasks • Product relates back to the original whole	1 (3%)
Partially Integrated	• Models represent multiplicative reasoning for both tasks • Models demonstrate correct products • Multiplier identified as the referent unit for at least one task • Operation within the identified referent unit for both tasks • Product relates back to the original whole	2 (7%)
Transitional	• Models represent multiplicative reasoning • One of the factors identified as the referent unit for each task • Began to operate within identified referent units, but could not complete because either the referent units were represented separately or not partitioned correctly for at least one task	14 (45%)
Foundational	• Models do not represent multiplication for either of the tasks • Use of referent units not shown in both tasks	9 (29%)
Uninterpretable	• No models or models are uninterpretable for both tasks	5 (16%)

In the top panel of Figure 1, Cristino's description indicates that they first operated within the referent unit and then extended the lines to determine the size of the newly formed units relative to the whole. In contrast, Charlotte's model on the bottom panel of Figure 1 shows that they did not necessarily operate within the referent unit when partitioning. Although these models appear similar, we classified them as Integrated and Partially Integrated based on their visual representations and/or explanations concerning the principle that the multiplier should operate exclusively within the referent unit representing the multiplicand.

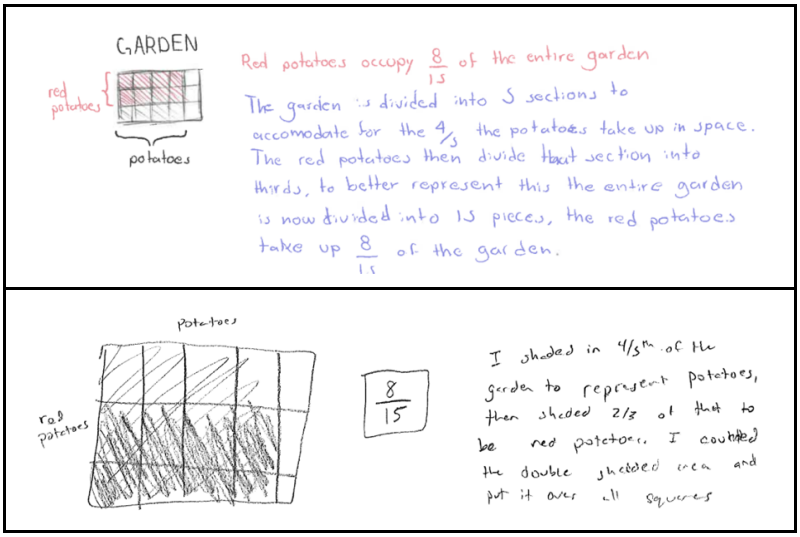

Figure 1: Visual Representations for ⅔ × ⅘ by Cristino (top) and Charlotte (bottom)

About a half (45%) of the PSTs exhibited some understanding of the referent unit (Transitional Integration). However, their models did not show the evidence of the concept related to (a) partitioning the referent unit to represent the multiplier or (b) how partitioning the referent unit relates to the whole to make sense of the newly formed unit fractions. As a result, PSTs often represented the first story problem meaningfully, as it did not require additional partitioning, whereas the second task was more challenging because additional partitioning was needed to represent the multiplier. In Figure 2, Amelia's visual representations illustrate that she correctly identified the referent unit and operated (or attempted to operate) in both cases but had difficulty representing ⅔ within ⅘ for the second task, as it required additional partitioning.

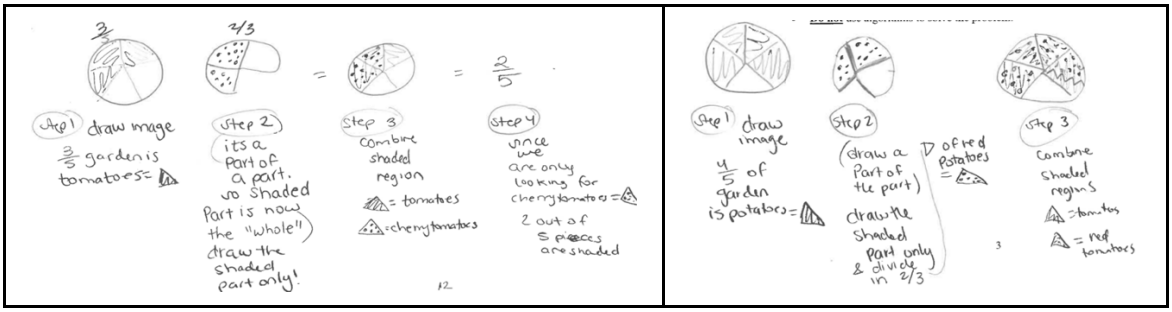

Figure 2: Amelia's Visual Representations for ⅔ × ⅗ (left) and ⅔ × ⅘ (right)

Kylie was able to operate within the referent unit (Transitional Integration) but created a single rectangular model for each problem. Similar to Amelia, they successfully represented Task 1, wherein no additional partitioning of the referent was required (Figure 3, left), and grappled with additional partitioning and did not complete Task 2 (Figure 3, right).

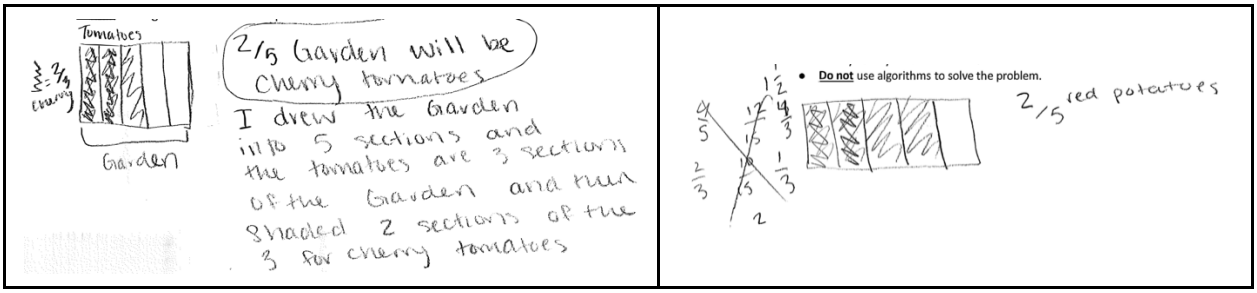

Figure 3: Kylie's Visual Representations for ⅔×⅗ (left) and ⅔×⅘ (right)

About one-third (29%) of the PSTs' representations fell into the Foundational Integration category, indicating that fraction multiplication was not represented in their models and/or models did not show the concept of the referent unit. In Figure 4, the left model illustrates that Liana attempted to use subtraction, created a common denominator, and tried to depict the fractions visually. In the final category, labeled Uninterpretable Integration, PSTs' models could not be meaningfully interpreted, as they provided no clear indication of which fractions or operations were represented, nor how the referent units were identified, as shown in Taylor's model (Figure 4, right).

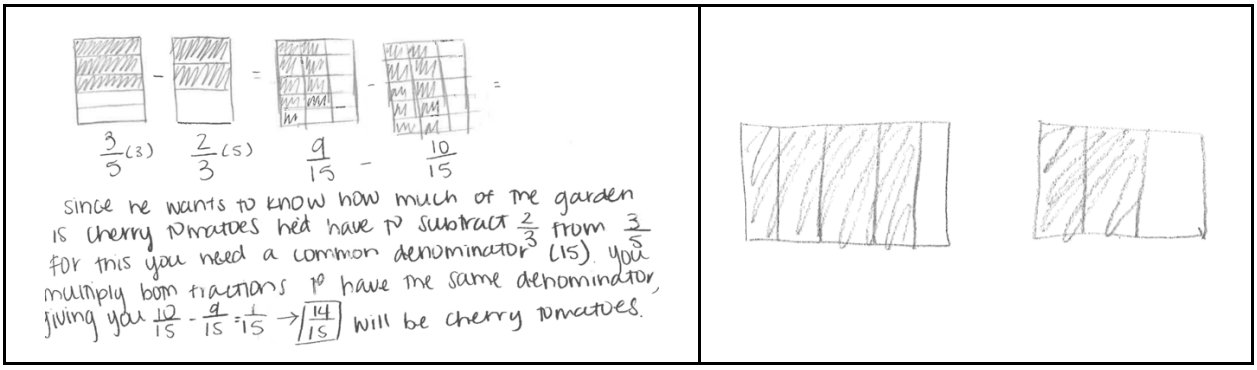

Figure 4: Visual Representations by Liana (⅔ × ⅗; left) and Taylor (⅔ × ⅘; right)

Discussion and Implications

Overall, our findings indicate that, prior to instruction, many elementary and middle school PSTs demonstrated a fundamental use of multiplicative reasoning, referent units, and fraction concepts, and they expressed these ideas through both contextual and visual representations. For example, more than half of the PSTs demonstrated an understanding that the multiplier must be operated within the model constructed for the multiplicand. We were encouraged by the depth of reasoning exhibited prior to explicit instruction. Meanwhile, our findings showed areas where PSTs' existing understandings need strengthening. We frame these areas not as shortcomings of

PSTs, but as productive starting points that can guide MTEs in designing targeted instruction to create opportunities for PSTs to refine and extend their reasoning, so they are better prepared to teach fraction multiplication to K-12 students.

Although many PSTs visually represented referent units for both tasks, the implied connections of their mental models of partitioning within the referent unit seemed comparatively underdeveloped. This was evident in the second task in our study, where they needed to partition the referent unit. As PSTs grappled with partitioning to represent the multiplier within the referent unit, many attempted to create common denominators or relied on algorithms. This suggests that when their reasoning about partitioning was not fully developed, they drew on other internal models, such as fraction addition rules (i.e., making common denominators) or memorized algorithms (i.e., creating equivalent fractions, keep-change-flip, etc.) to construct external representations. They seemingly believed that creating the same denominator would help them partition correctly. This aligns with Barmby and colleagues' (2009) idea that basic reasoning among internal representations may limit the construction of external representations that reflect conceptual understanding. Also, PSTs' prior understanding about partitioning was potentially informal and did not support the conceptual complexities needed (Mack, 2001). Accordingly, we suggest that MTEs should highlight the concept of partitioning within a fraction of the whole and support PSTs in examining how the size of newly formed unit fractions change in relation to the original whole when beginning instruction on fraction multiplication.

PSTs' contextual and visual representations also suggested that PSTs may need more opportunities to understand multiplication as operating on single units and that the composition of multiple units can form a new single unit (Singh, 2000). Prior studies have shown that using the concept of repeated addition may not automatically transfer to the development of multiplicative reasoning, which is closely associated with unitizing (Götze & Baiker, 2021), and we see similar evidence among our participants. We found PSTs using additive reasoning to create contextual or visual representations or not treating the multiplicand as a single unit. For example, some PSTs interpreted ¾ as three separate pieces rather than a single unit to be operated on multiplicatively. This again suggests that MTEs should be intentional about how PSTs use multiplicative reasoning, and that using precise language—such as "3 fours" for 3×4 instead of repeated addition (Götze & Baiker, 2021, p. 263).

Insights from PSTs' written story problems also provide helpful guidelines for MTEs. The participants who found it challenging to write coherent stories tended to grapple with two representational connections: (a) maintaining a clear relationship between the two fractions and the original whole, and (b) consistently using the same unit within a single story. For instance, some stories began with one whole (e.g., a garden area) and then shifted to another context without a clear whole (e.g., the number of flowers). Other stories shifted between units within a single story, such as volume and surface area. This pattern suggests that, alongside operating within a referent unit, PSTs would benefit from explicit attention to preserving the original whole and consistently using the same unit throughout a problem context.

Our study portrays PSTs as already having meaningful and generative ideas about fraction multiplication. To follow, we will look at how these reasonings shift after instruction and how they vary with the number of mathematics courses PSTs completed. By building on these ideas and intentionally supporting connections among referent units, partitioning, unit consistency, and unitizing, MTEs can help PSTs develop robust understandings of fraction multiplication.

ELEMENTARY PRESERVICE TEACHERS' JUDGMENTS IN AI-MEDIATED DATA SCIENCE LESSONS

Gianna Shields
San José State University
gianna.shields@sjsu.edu

This exploratory study investigates how elementary preservice teachers (n=8) enrolled in elementary math methods at a public university designed AI-mediated data science lessons and how their confidence and instructional judgment developed through this process. Guided by an AI-Mediated Teaching Framework, they engaged in collaborative lesson planning supported by AI tools. Data sources included pre- and post-surveys, lesson plans, AI decision logs, peer evaluations, collaborative transcripts, and reflections. Results indicated increased confidence across all framework constructs, with the largest gains in ethical reasoning and equity-centered design. Qualitative findings showed that PSTs used AI as a design partner by accepting low-stakes suggestions, adapting outputs for developmental appropriateness and coherence, and rejecting ideas that lacked data science alignment.

Keywords: Preservice Teacher Education, Technology, Learning Environment Design, Statistics, Probability, Data Science

In mathematics education, Artificial Intelligence (AI) has been positioned as something that can be helpful for generating tasks, differentiating instruction, and significantly reducing planning time (Trust et al., 2023; Berryhill et al., 2024). Current research suggests that AI-generated instructional materials can vary significantly in quality and almost always require careful human judgement to protect rigor, conceptual coherence and alignment with instructional goals (Sapkota & Bondurant, 2024; Gattupalli et al., 2023). These concerns are particularly prevalent among preservice teachers (PSTs) who may be vulnerable to accepting AI-generated materials at face value, or unsure about how to integrate AI into the instructional planning process (Guan et al., 2025; Abualrob, 2025). Data science has also become an area of focus for elementary mathematics across the United States (Institute of Education Sciences, 2025), especially in California (California Department of Education, 2023). Research supports that when data science is integrated into early mathematics, it can support students' sensemaking, reasoning, and engagement with real world contexts (Institute of Education Sciences, 2025). Currently there is little empirical evidence at how PSTs design and evaluate data science lessons, specifically when AI tools are used in the planning process (Shin et al., 2021; Rosenberg & Jones, 2024). However, less is known about the instructional choices that help PSTs move beyond using AI for idea generation toward using AI with professional judgment. In particular, research has not yet examined how PSTs evaluate, adapt, and reject AI-generated suggestions while designing elementary data science lessons.

This exploratory study examined how elementary PSTs engaged with AI while designing a data science mathematics lesson. AI was positioned as a pedagogical thought partner whose input must be evaluated, revised, and aligned with instructional goals (Luckin, 2018; UNESCO, 2024). This study addressed the following research questions: (1) How do elementary preservice teachers design an AI-mediated data science lesson plan in mathematics when supported by an AI-Mediated Mathematics Teaching Framework? (2) In what ways do their confidence and instructional judgment related to AI-mediated data science lesson planning change before and

after engaging in framework-guided lesson planning? (3) How do they evaluate, adapt, and reject AI-generated instructional ideas during collaborative lesson planning?

AI-Mediated Teaching Framework

The AI-Mediated Teaching Framework (Figure 1) builds from mathematics teacher education, technology integration, and AI literacy scholarship. It foregrounds teachers' responsibility to evaluate mathematical accuracy, cognitive demand, equity, authorship, bias, and alignment with learning goals. The framework extends prior work by making AI-specific planning practices explicit, including prompt design and decisions to accept, adapt, or reject AI-generated suggestions.

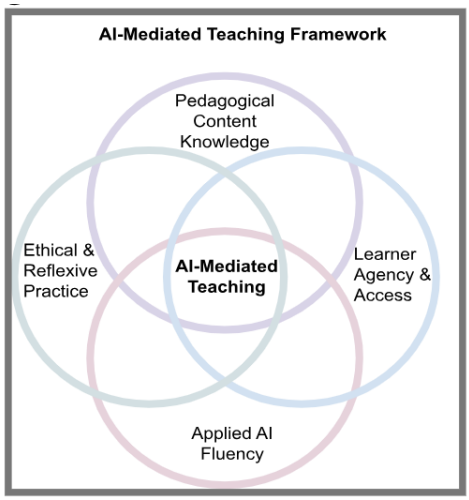

Figure 1: The AI-Mediated Teaching Framework (Shields, 2026)

Pedagogical Content Knowledge (PCK). AI is positioned as a provisional design partner whose suggestions are evaluated through the lens of PCK. PSTs are encouraged to use AI to generate examples, representations, or task ideas while using their own judgement to assess accuracy, cognitive demand and alignment with learning goals.

Learner agency and access. This component draws on Universal Design for Learning (CAST, 2018), Multi-Tiered Systems of Support (McIntosh & Goodman, 2016), Culturally Sustaining Pedagogy (Paris & Alim, 2017), Multilingual and English Language learner supports to design tasks that offer multiple entry points, honor students' funds of knowledge, promote inquiry and encourage collaboration. The framework positions AI-generated materials as starting points that need refinement to ensure inclusive and student-centered learning experiences.

Applied AI fluency. This component involves the practical knowledge and skills needed to use AI tools responsibly and effectively during lesson planning. This includes understanding AI affordances and limitations, crafting intentional prompts, and iteratively refining outputs (Luckin, 2018; Holmes et al., 2021). Research suggests that while PSTs may express confidence in using AI, they often lack structured opportunities to evaluate AI-generated content (Abualrob, 2025). Within the framework applied fluency is developed through collaborative prompting, documentation of AI interactions, and explicit evaluation of outputs.

Ethical and reflexive practice. This component grounds the considerations of bias, data privacy, authorship, transparency in alignment with AI literacy frameworks (Stanford Commons,

n.d.; UNESCO, 2023, 2024). PSTs are prompted to reflect on how AI shapes their instructional decisions, whose perspectives are centered in lesson contexts, and how AI-generated materials may reinforce or challenge inequities. Reflection is not used as an add on, but a core part of professional judgment in AI-Mediated Teaching.

Operationalizing the Framework Through a Rubric

The AI-Mediated Teaching Framework was used through a lesson-planning rubric that structured PSTs' engagement with AI during data science lesson design. The rubric scored the four constructs of the framework while anchoring content specific criteria in the California Mathematics Framework (CMF) and youcubed data science progression (California Department of Education, 2023; Boaler, 2021). PSTs used a 1–4 rubric to evaluate AI suggestions and make explicit accept, adapt, or reject decisions based on alignment with learning goals, student needs, and ethical considerations. The rubric also functioned as a peer-evaluation tool. Table 1 shows a concise version of the rubric.

Table 1: Concise Rubric for AI-Mediated Teaching Framework (Shields, Under Review)

Construct	Rubric Criteria
PCK	(1) Learning target and question are unclear or not grade-appropriate. Activities don't really match the target. Misconceptions and success criteria are missing or very superficial. (4) Learning target and statistical investigative question are clear, grade-appropriate, and rooted in a meaningful context (school/community). Activities build logically from data collection to representation to analysis. Anticipated misconceptions and success criteria are specific and realistic.
Learner Agency & Access	(1) Lesson is mostly one-size-fits-all, with few chances for students to make decisions or share their perspectives. Little or no attention to language supports, scaffolds, or cultural relevance. (4) Lesson offers meaningful student choice and voice (e.g., input on data context, representations, or discussion ideas). Multiple representations (tables, graphs, verbal/written explanations) are built in. Clear ELL/MLL supports, MTSS scaffolds, and culturally sustaining connections to students' communities and languages.
Applied AI Fluency	(1) Little or no evidence of intentional AI use. Accept/Adapt/Reject is missing or not explained. The lesson seems copied from AI or, conversely, AI is barely used despite the assignment. (4) AI prompts are purposeful (different prompts for tasks, data sets, questions, etc.). The AI Decision Log clearly shows Accept / Adapt / Reject choices with strong rationales tied to PCK, agency/access, or ethics. The pair improves the lesson by revising AI output rather than copying it.
Ethical & Reflexive Practice	(1) Little or no sign that AI outputs were checked for accuracy, bias, or privacy. Harmful or misleading content may still be present. AI's role in the lesson is not explained or is presented as "always correct. (4) The pair clearly checks and corrects AI's math, data, and claims. They avoid or edit out biased, sensitive, or PII-related content. They explicitly name how

	they will explain AI's role to students (authorship, bias, privacy) and make visible who created what. Reflection shows honest critique of AI limits.
Overall Rigor & Coherence	(1) Lesson feels fragmented; rigor is mostly procedural with little reasoning or evidence-based discussion. (4) Lesson feels coherent from warm-up to cool-down. Activities, representations, and questions all support the learning target and investigative question. Students are asked to reason, justify, and use evidence, not just compute.

Methods

This study combined quantitative survey data with qualitative analysis of lesson artifacts, AI decision logs, peer evaluations, collaborative transcripts, and written reflections.

Participants and Context

Participants were eight multiple subject PSTs enrolled in an elementary math methods course at a public university that the author taught. All participants had limited prior experience designing data science lessons or using AI tools for instructional planning. The lesson planning activity was embedded in the regular course instruction and aligned with course learning objectives related to data science integration, equity, and instructional design.

Instructional Sequence and Task Directions

The lesson-planning task was implemented as a structured instructional sequence within the elementary mathematics methods course. PSTs first discussed the role of data science in elementary mathematics, with attention to statistical investigative questions, data collection, representation, and interpretation. They were then introduced to the AI-Mediated Teaching Framework and the accompanying rubric. The instructor modeled how AI-generated instructional suggestions could be evaluated for mathematical accuracy, developmental appropriateness, equity/access, and ethical considerations. PSTs then worked in pairs to design a grade-level data science lesson using one generative AI tool of their choice. Rather than being given a fixed prompt, pairs were asked to develop and revise their own prompts, document AI outputs, and record whether they accepted, adapted, or rejected each suggestion. The final lesson plan, AI decision log, peer evaluation, collaborative transcript, and individual reflection served as study artifacts.

AI-Mediated Lesson Planning Task

The participants worked in collaborative pairs to design a data science lesson plan that engaged students in a statistical investigation appropriate for their grade level. They chose from three generative AI tools (i.e., ChatGPT, Gemini, Magic School) as a planning support to generate lesson ideas, task contexts, questions, and representations. Rather than assigning prompts, the activity emphasized iterative prompting and evaluation. They developed, refined, and revised their own prompts in alignment with instructional goals and documented their interactions with AI throughout the planning process. The documentation process indicates how they accepted, adapted, or rejected the AI suggestions during lesson development.

Data Sources

Pre/post survey. A 12-item Likert scale survey (*1 = strongly disagree, 4 = strongly agree*) evaluated PSTs' confidence and understanding across the four framework components. Survey items were grouped as follows: (1) Applied AI Fluency (Q1–Q3): Ex. "I can create prompts for AI tools that generate lesson ideas aligned with my instructional goals." (2) Ethical & Reflective Practice (Q4–Q6): Ex. "I can identify and address potential bias in AI-generated instructional materials." (3) Pedagogical Content Knowledge (Q7–Q10): Ex. "I know how to align lesson

content with the PK–5 California Common Core Math Standards and California Mathematics Framework." (4) Learner Agency & Access (Q11–Q12): Ex. "I know how to adapt lesson content to meet the diverse learning needs of all students."

Peer evaluation. Each PST individually evaluated a lesson plan produced by another pair. Because each lesson was evaluated by two different PSTs, evaluation scores provide an external validity check on lesson quality. The rubric was used to evaluate the four constructs (PCK, Learner Agency & Access, Applied AI Fluency, and Ethical & Reflective Practice) on a Likert scale from 1–4.

Qualitative data. The qualitative sources included: (1) collaborative planning transcripts: Audio transcripts captured PSTs' real-time collaborative planning conversations, providing insight into how instructional decisions were negotiated. (2) AI decision logs: The log documented how AI outputs were evaluated and revised. (3) Lesson plans: A complete K–8 data science lesson plan (learning goals, task description, representations, discussion prompts, and scaffolds) focused on asking statistical investigative questions. (4) Individual post-collaboration reflections: Post-collaboration reflections captured PSTs' perceptions of their learning, confidence, and remaining questions.

Data Analysis

Pre–post survey data were analyzed descriptively to examine changes in preservice teachers' self-reported confidence across the four framework constructs. Paired-sample effect sizes were calculated using Hedges' g^z to account for the small sample size.

Qualitative data including: lesson plans, AI decision logs, collaborative transcripts, and written reflections, were analyzed by mapping evidence to the four constructs of the AI-Mediated Teaching Framework. Additional inductive coding was conducted to capture patterns in preservice teachers' interactions with AI, including common rationales for adaptation, acceptance, or rejection of AI-generated suggestions. Peer-evaluation data were analyzed using both descriptive statistics and interrater reliability measures. Because each lesson was independently evaluated by two preservice teachers, percent agreement and quadratic weighted Cohen's kappa were calculated for each construct to assess consistency across raters.

Results

Survey Results

Table 2 shows pre-post mean and standard deviation scores for PSTs' (n=8) self-reported confidence, which shows growth in each of the constructs after the collaborative lesson planning process. The largest gains were seen in the ethical and reflexive practice ($g^z = 1.05$) and learner agency & access ($g^z = 1.27$), both showing large effect sizes. These results show growth in PSTs' self-reported confidence with ethical reasoning about AI use and designing equitable, learner centered instruction. Moderate gains were seen in PCK ($g^z = 0.84$) showing that teachers reported increased confidence in designing data science math lessons. Applied AI fluency showed positive improvement ($g^z = 0.65$) indicating that PSTs' self-reported confidence using AI tools and professional judgment increased. Across all framework constructs, standard deviations decreased from pre to post surveys, suggesting increased convergence in PSTs' confidence following the instructional sequence.

Table 2: Pre/Post Mean Survey Scores

Construct	Pre M (SD)	Post M (SD)	Mean Diff	Hedges' g^z
PCK	2.84 (0.63)	3.38 (0.35)	0.53	0.84
Learner Agency & Access	2.88 (0.58)	3.50 (0.46)	0.63	1.27
Applied AI Fluency	2.63 (0.77)	3.17 (0.53)	0.54	0.65
Ethical & Reflexive Practice	2.79 (1.01)	3.75 (0.39)	0.96	1.05

Qualitative Results

Qualitative analysis of lesson plans, AI decision plans, peer evaluations, collaborative transcripts, and reflections showed how the PSTs used instructional judgment while lesson planning with AI. Findings are organized by themes associated with the four framework constructs. Table 3 summarizes how PSTs used instructional judgment across the four components of the framework while planning data science lessons. Across artifacts, decision logs, and peer evaluations, PSTs consistently evaluated and revised AI generated outputs. AI was used as a thought partner that PSTs decided whether to refine or simplify outputs that did not fit the instructional goals. Lessons in which AI outputs were explicitly revised were rated most highly in peer evaluations, reinforcing the importance of refinement in AI-mediated planning.

Table 3: Preservice Teacher Reflection Quotes

Framework Construct	PST Reflection
PCK	*"Data science feels less like an add-on and more like a lens I can build into what I already do in math." (PST reflection)*
Learner Agency & Access	*"When students see the purpose, they're more willing to talk about their thinking and explain their ideas."*
Applied AI Fluency	*"AI gave us a lot of ideas, but we still had to decide what actually worked for our students."*
Ethical & Reflexive Practice	*"Just because AI suggests something doesn't mean it's right. I felt responsible for checking the math and thinking about how it would affect the students."*

Accept, Adapt, Reject Decision Patterns

In the analysis of the AI decision logs, adapting the AI outputs was the most common response. Table 4 shows a representation of AI output decisions that teachers did during their lesson planning activity. The table shows evidence that PSTs used critical thinking through evaluation, adaptation, and justification in refining their prompts while planning their data science lessons.

Table 4: PST AI Output Decision Percentages

Decision	% of Decision Made
Adapt	61.1%
Accept	22.2%
Reject	16.7%

Table 5 highlights excerpts from collaborative planning conversations that illustrate PSTs' accept, adapt, and reject decisions when evaluating AI-generated instructional ideas. Across data sources, PSTs positioned AI as a design partner. AI generated outputs were most often adapted, and in some cases, rejected when they were not aligned with instructional goals. Direct acceptance of AI outputs was limited and generally restricted to low stakes components such as wording or brainstorming.

Table 5: PST Collaboration Quotes Paired with Decisions

Decision	Instructional Move	Quote from Collaboration Transcript
Reject	Identifying misalignment with data science goals	*"Wait, this feels kind of Physical Education-focused. Where's the data science in this?"*
Adapt	Refining investigative question for sense-making	*"We can keep the context, but we need to change the question so students are actually analyzing the data."*
Adapt	Simplifying AI-generated supports for usability	*"This is way too much for one lesson. Let's cut this down so students can focus on reasoning, not steps."*
Accept	Using AI for low-stakes idea generation	*"This part works as a starting point, we can keep the wording and build from there."*

Table 6 shows peer evaluation mean scores across design pairs on five constructs aligned with the study framework. Three pairs (Pairs #2, #3, and #4) received consistently high ratings (M = 3.5–4.0) with little to no variability (SD = 0.00 in most cases), indicating strong inter-rater agreement and perceived instructional coherence. In contrast, Pair #1 received comparatively lower ratings (M = 2.5–3.5) with moderate variability (SD = 0.71), suggesting more mixed peer perceptions. Applied AI Fluency showed the greatest differentiation across groups, particularly for Pair #3 (M = 2.00), highlighting variability in the depth of AI integration despite otherwise strong pedagogical and ethical design elements. Peer evaluations reflected high levels of rigor and coherence, with applied AI use emerging as the primary area of distinction among groups.

Table 6: Peer Evaluation Scores

Lesson	Rater	PCK	Agency & Access	AI Fluency	Ethical & Reflexive	Overall Coherence
1	PST 1 / 3	4 / 4	4 / 3	3 / 4	4 / 4	4 / 4
2	PST 5 / 7	3 / 2	2 / 3	4 / 3	4 / 3	4 / 3
3	PST 2 / 6	4 / 4	4 / 4	4 / 4	4 / 4	4 / 4
4	PST 4 / 8	4 / 4	3 / 3	2 / 2	4 / 4	4 / 4

Interrater reliability shown in Table 7 was calculated from the peer evaluation scores shown in Table 6. Because each lesson plan was independently evaluated by two preservice teachers using the same rubric, percent agreement and quadratic weighted Cohen's kappa were calculated for each construct across the four collaboratively developed lesson plans. Quadratic weighting was used due to the ordinal nature of the 1–4 rubric scale. Percent agreement ranged from 50%

to 100%. Weighted kappa values indicated substantial agreement for Pedagogical Content Knowledge (κ = .75) and Applied AI Fluency (κ = .64), moderate agreement for Learner Agency & Access (κ = .43), and perfect agreement for Overall Coherence (κ = 1.00). Ethical & Reflexive Practice showed high raw agreement (75%), though kappa was reduced due to restricted variance across raters, a known statistical limitation when most scores cluster within a narrow range. The lower agreement observed for Learner Agency & Access appears to reflect differences in how raters interpreted the specificity and depth of equity-oriented supports within the lesson plans.

Table 7: Interrater Reliability Results of Peer Evaluation

Construct	Percent Agreement	Weighted Kappa (κ)	Agreement
PCK	75%	0.75	Substantial
Learner Agency & Access	50%	0.43	Moderate
Applied AI Fluency	50%	0.64	Substantial
Ethical & Reflexive Practice	75%	0.00*	Restricted Variance
Overall Rigor & Coherence	100%	1.00	Perfect

Shown in Table 8 are PSTs' reflective comments illustrating how the AI-Mediated Teaching Framework shaped their instructional decision-making during AI-mediated data science lesson planning.

Table 8: PST Reflection on AI-Mediated Teaching Framework

PST Reflection on AI-Mediated Teaching Framework
"Before this, I saw AI as either a complete replacement for planning (which felt unethical) or a tool I shouldn't use at all (which felt naïve given where education is heading). The framework gave us a middle path—using AI as a collaborative partner while maintaining our professional judgment and commitment to students."
"One way the framework improved rigor and coherence was through the use of pedagogical content knowledge (PCK), which allowed me to focus the lesson on a specific teaching framework with clearly defined learning objectives. This ensured that the lesson generated from AI would actually follow those objectives."
"The framework helped me realize that just because AI suggests something doesn't mean it's correct or appropriate. I felt more responsible for checking the math and thinking about how it would affect students… One of the hardest parts was realizing how specific you have to be with AI. The framework helped me understand what to ask for and what to push back on when the output didn't match what we needed."
"The collaboration part of this assignment was extremely helpful. Having another future educator working through the framework with me made the process of using AI much smoother and more thoughtful."

Limitations and Next Steps

Several limitations should be addressed when interpreting these findings. This exploratory study involved a small sample size within a single course context using self-reported confidence ratings, limiting generalizability. In addition, the analysis focused on lesson planning and design artifacts rather than enacted classroom instruction. Future research should examine how AI-

mediated planning translates into classroom practice and how students engage with these lessons using a much larger sample size to better assess for scalability. Further work is also needed to explore how PSTs' AI fluency and professional judgement develop over time with repeated opportunities for AI mediated planning and reflection. Building on these findings, the instructional sequence and AI-Mediated Teaching Framework will be refined and implemented in PK-5 math methods courses in two different sites this spring semester, which will allow for the examination of the framework across several PST classrooms and instructional contexts.

Acknowledgments

I gratefully acknowledge Ferdie Rivera for his guidance, feedback, and support throughout the development of this study.

The purpose of this qualitative study was to explore prospective elementary teachers' (PTs') understanding of why we multiply by the reciprocal when dividing by a rational number. We analyzed a sample of 44 PTs' written responses on pre- and post-unit assessments, class homework, end-of-semester exam questions that involved division by rational numbers, and task-based interviews. We coded data deductively and inductively to investigate PTs' conceptual and procedural understanding, and their misconceptions about rational number ideas. We found that PTs showed (a) continued reliance on procedures across the semester, (b) growth in conceptual understanding, and (c) a decrease in misconceptions about rational number division. We also discuss the implications of this research in mathematics teaching and mathematics teacher education programs.

Keywords: Conceptual Understanding, Procedural Reliance, Prospective Teachers, Rational Numbers, Problem Solving

Rational number operations remain one of the most persistently challenging areas in elementary mathematics, for both students and the teachers who teach them (Lamon, 2007, 2020; Newton, 2008; Siegler & Pyke, 2013). This challenge is crucial because rational number reasoning is one of the gateways to algebraic thinking that make up a large portion of the mathematics that students take in middle and secondary school (Empson & Levi, 2011; Wu, 2011). PTs, therefore, are tasked with preparing their future students to be competent in rational number thinking so that the students can adapt to algebraic thinking in middle and secondary school. To achieve this task, PTs need to develop the necessary mathematical knowledge for teaching rooted in both procedural and conceptual knowledge about rational numbers. Most PTs, however, enter teacher preparation programs with deep procedural knowledge of rational number operations and with less conceptual knowledge, and if not well prepared, they risk reproducing the same knowledge patterns in their own students (Ball, 1990; Tirosh, 2000). There is a need, therefore, for PT preparation programs adopting teaching methods that prepare PTs to teach effectively. One instructional approach that holds theoretical promise for closing this gap is teaching through problem solving. While teaching through problem solving is among NCTM's (2000) recommendations for effective mathematics instruction, empirical evidence directly examining how this approach shapes PTs' conceptual understanding of specific rational number procedures, such as fraction division, remains limited. This study addresses that gap. We have two aims for this study: to investigate how teaching through problem solving can support PTs'

conceptual understanding of division and multiplication involving rational numbers, and to examine whether and how PTs' conceptual understanding, procedural fluency, and misconceptions change over the course of such instruction. We hope that findings from this study will include arguments of how procedural and conceptual knowledge development occurred in a problem-solving set-up, and how misconceptions tied to both forms of knowledge can be addressed.

Theoretical Framework

Our study is conceptually grounded in three areas of literature: (a) Mathematical Knowledge for Teaching (MKT), (b) teaching through problem solving, and (c) rational number learning.

Mathematical Knowledge for Teaching

Ball and colleagues (2008) introduced the MKT framework and defined it as the knowledge required by teachers to teach mathematics effectively. They adopted Shulman's (1986) subject matter knowledge as a category of MKT and divided it into three categories: (a) common content knowledge (CCK), which is the mathematical knowledge known by both mathematicians and non-mathematicians, such as the ability to perform procedures; (b) specialized content knowledge (SCK), which is the deep mathematics content knowledge required specifically by mathematics teachers; and (c) horizon content knowledge, which is the knowledge of how different mathematics topics are related. They also adopted pedagogical content knowledge from Shulman (1986). Our study is grounded in the MKT framing, specifically two forms of subject matter knowledge: CCK and SCK.

Procedural and Conceptual Knowledge as MKT

Procedural knowledge is the ability to perform procedures efficiently, and as such, this knowledge may be known by both mathematicians and non-mathematicians, as it may at times involve memorizing and reproducing procedures. On the other hand, conceptual knowledge is the ability to comprehend and understand underlying mathematical principles and relationships. Researchers such as Hiebert and Lefevre (1986), Hurrell (2021), and Salifu (2021) argued that both procedural and conceptual knowledge are important for mathematics teachers to teach effectively. Procedural knowledge can be considered a form of CCK, whereas conceptual knowledge can be considered a form of SCK (Ball et al., 2008; Newton et al., 2022). Research has shown that most PTs join teacher preparation programs with prior knowledge rooted in procedural fluency with limited conceptual understanding (Ball, 1990; Li & Kulm, 2008; Ma, 2010; Tirosh, 2000), which raises the need for teacher preparation programs to develop the PTs' conceptual knowledge while at the same time attending to their procedural knowledge. One teaching approach that we have used to achieve this goal is teaching through problem solving (Masingila et al., 2025).

Teaching Via Problem Solving: Procedural and Conceptual Understanding

Teaching via problem solving involves engaging students in tasks without predefined solutions to help them develop reasoning and adaptability (Lesh & Zawojewski, 2007). In previous studies, we found that teaching through problem solving can support students' understanding of why mathematical procedures are useful (Caviness & Masingila, 2023; Masingila & Wambua, 2015; Xie & Masingila, 2017). Such findings are consistent with Hiebert and Lefevre's (1986) definition of conceptual understanding. We contend that teaching via problem solving can enhance students' understanding of procedures and the rationale behind such procedures, that is, procedural and conceptual knowledge, respectively, as we have found in earlier studies (Caviness & Masingila, 2023; Masingila & Wambua, 2015).

Division Involving Rational Numbers

One key area of mathematics that researchers have shown interest in is the study of conceptual versus procedural knowledge in operations involving rational numbers. The NCTM (2000) defined rational numbers as numbers that can be expressed as the quotient of two integers, with the denominator nonzero. Rational numbers can be expressed in various forms, such as fractions, decimals, and percentages (Van de Walle et al., 2013). Researchers like Perry (2023) and Herreros-Torres et al. (2026) argued that fraction understanding remains the most challenging for PTs. Using Hiebert and Lefevre (1986) and Salifu's (2021) call, we assert that students need both procedural and conceptual knowledge about rational number operations.

One fraction operation that has proved challenging for most PTs is fraction division (Copur-Gencturk, 2021). Petit et al. (2015) defined fraction division as the process of determining how many times a fraction fits into another. Siegler and Pyke (2013) and Olanoff et al. (2016) noted that when dividing fractions, most students use the invert and multiply algorithm, a procedural shortcut where the divisor is inverted and multiplied by the dividend. Researchers have consistently shown that while PTs may use the algorithm correctly, they are not able to justify its rationale (Kang, 2022; Nillas, 2010). The conceptual knowledge attached to the invert and multiply procedure is that inverting the divisor shows how many quantities of the divisor fit in one unit, and multiplying therefore means taking the number of divisors in one unit and multiplying that by the dividend (Masingila, 2022b), which is similar to finding how many of the divisors fit into the dividend (Petit et al., 2015).

Across the studies reviewed, it is evident that most PTs have procedural knowledge of fraction division, most of which is rooted mainly in the use of the invert and multiply rule, with less conceptual understanding, which makes it hard for them to transfer their knowledge to other fraction representations. Sahin and colleagues (2020) showed that PTs can develop conceptual understanding when involved in small and whole-class discussions, which is a promising finding that builds on in our study. Consequently, the imbalance between procedural and conceptual knowledge has been proven to cause misconceptions about fraction division.

A misconception refers to a student's conception that produces a systematic pattern of errors (Smith et al., 1993). The conceptions may be tied to students' past or current knowledge that is incomplete to fully account for either procedural or conceptual knowledge. Smith and colleagues argued that mathematics education research should "document misconceptions in as many subject-matter domains as possible" (p. 123). Therefore, there is a need to, in the process of discussing procedural and conceptual knowledge, also address PTs' conceptions that lead to errors with respect to the two forms of knowledge.

Research Questions

In our review of the literature, we found that most PTs hold more procedural knowledge and less conceptual knowledge on fraction division, and that they also hold some misconceptions that need to be addressed. While teaching through problem solving has been shown to be promising in addressing this gap, we did not find evidence on how teaching through problem solving impacts PTs' development of both procedural and conceptual knowledge, and whether or not it affects the misconceptions they hold about fraction division in particular. We anticipate that answering this question will help address some of the unpreparedness or under preparedness faced by mathematics teachers in the area of rational numbers. In particular, our study aims to answer this research question: What appears to be the impact of teaching and learning via problem solving on PTs' procedural and conceptual understanding of why we multiply by the

reciprocal when dividing by a rational number, and what misconceptions resurface and get addressed in the process?

Methods

Our research design was a basic qualitative inquiry (Merriam & Tisdell, 2016). We chose a basic qualitative design because our goal was to understand how PTs make meaning of fraction division in the context of teaching and learning via problem solving, without constraining ourselves to a named qualitative tradition.

Participants and Context

The participants in this study were 44 PTs enrolled in the second course of a mathematics content course taught through problem solving at a university in the northeastern United States during the Spring 2025 semester. The course emphasized topics such as rational numbers, geometry, and measurement. During the study period, instruction focused on rational numbers and operations with rational numbers. Classes met twice a week for 80 minutes and centered on small-group problem solving rather than lectures. Four mathematics education graduate students served as interns in the course. They supported PTs' learning via problem solving.

Data Collection and Analysis

We used multiple data sources to explore PTs' understanding of rational numbers: (a) a pre-unit assessment consisting of three items administered before instruction on rational numbers, with each item having two parts; (b) group classwork from the two problem-solving class sessions each week focused on rational number reasoning; (c) PT's weekly written homework; (d) the end-of-semester course examination that included rational number items; (f) a post-unit assessment parallel to the pre-unit assessment administered after three weeks of instruction; and (g) end-of-unit interviews with five participants designed to probe procedural and conceptual reasoning and to assess how PTs' understanding of rational number ideas had changed. The data were collected over a span of six weeks. Overall, all the data artifacts used in this study were designed to help us answer our research question in line with our theoretical framework of MKT.

We began analysis with a deductive, theory-driven thematic approach (Boyatzis, 1998) by drawing initial codes from prior research on prospective teachers' rational-number understanding. Our initial codes included procedural reliance and conceptual understanding, extracted from Desai (2025). We then applied inductive coding to capture additional codes emerging from the data, such as misconceptions about rational number ideas. We coded in two stages. In Stage 1, each researcher independently coded the pre-unit assessments, and then we discussed the coded data segments as a group to refine code definitions and ensure consistency. In Stage 2, we coded the remaining data, followed by regular weekly team meetings to resolve differences and reach consensus on final codes.

Findings

Our aim in this study was to explore the impact of teaching and learning via problem solving on PTs' understanding of why we multiply by the reciprocal when dividing fractions. In our findings, we use the pseudonyms PT 1 to PT 44 to refer to the 44 PTs. Of the 44 PTs: (a) 33 completed the pre-unit assessment, with five PTs leaving the questions unanswered, (b) 28 PTs handed in their classwork to be used as data, (c) 40 PTs completed the post-unit assessment, with one PT leaving the questions unanswered, and (d) all 44 PTs completed the final exam. We present here our findings under three different themes: conceptual understanding, procedural reliance, and misconceptions in rational number understanding across different data sets.

Conceptual Understanding

Pre-unit assessment. In the pre-unit assessment, two PTs, PT 3 and PT 25, demonstrated conceptual understanding. PT 3 drew a number line and marked 12 one-fourth segments to visualize $3 \times 4 = 12$, illustrating the reciprocal as counting groups of the fraction that fit into one whole. The PT's work shows that each group of one whole would have four one-fourths, hence 12 one-fourths in three whole units.

Classwork and homework. When solving ongoing class homework, six PTs demonstrated conceptual understanding in tasks requiring division by a rational number. In responding to one of the homework questions, "Why do we multiply by the reciprocal when dividing fractions?," PT 6, stated that "*Dividing by a number is the same as multiplying by its reciprocal [since] you're asking how many of that fraction fit into the first one.*" The PT's reasoning demonstrated conceptual understanding because inverting a fraction tells how many of those fractions fit into one whole. Five other PTs also reasoned like PT 6 in solving homework tasks.

Post-unit assessment. In the post-unit assessment completed at the end of the rational number unit, one PT, PT 3, demonstrated conceptual understanding. In explaining $5 \div \frac{1}{3}$, the PT drew a rectangular strip and divided it into five sections, each representing a value of three one-thirds. The strip had a total of 15 one-thirds. The PT's conceptual understanding stems from seeing the three one-thirds as one whole and then drawing five one-wholes.

Final exam. On the final exam completed at the end of the semester, 18 PTs demonstrated conceptual understanding when responding to a question asking why dividing a number by $\frac{4}{13}$ is the same as multiplying the number by $\frac{13}{4}$. PT 10 explained that *"… when you multiply by a reciprocal, it tells how many times that fraction fits into the number. Multiplying by the reciprocal flips the division into multiplication, which gives the same value."* The PTs' reasoning aligns with our definition of conceptual understanding of why the invert and multiply rule works.

Interviews. In task-based interviews we conducted with five PTs at the end of the course, three PTs (PT 36, PT 13, and PT 35) demonstrated that they had developed conceptual knowledge of fraction division. We share below their explanations.

PT 36 noted that dividing $\frac{3}{2}$ by $\frac{1}{4}$ requires switching the division to multiplication and inverting $\frac{1}{4}$ to $\frac{4}{1}$. She applied this procedure to have $\frac{3}{2} \times \frac{4}{1} = \frac{12}{2} = 6$. When we probed to explain why this procedure works, she said:

> Because in order to divide, you have to change it to multiplication because you're trying to see how many one-fourths go into three halves, so you have to multiply. And in order to multiply a division problem, you have to switch it over to four over one because one over four times four over one equals one whole. So that means four over one, there's four whole pieces and one fourth pieces, so that gives you one. So, if you have one fourth and four over one, when you multiply those together, that gives you one. So that's why you have to flip 'em [them] over and then you multiply across and simplify. (PT 36, Interview)

Her reasoning about $\frac{3}{2} \div \frac{4}{1}$ meaning how many groups of one-fourths are in three halves, and that $\frac{1}{4}$ multiplied by $\frac{4}{1}$ equals one whole shows that PT 36 had developed partial conceptual understanding as she was moving towards recognizing that $\frac{4}{1}$ shows how many groups of $\frac{1}{4}$ are in one whole; hence the need to multiply to get the number of one-fourths in $\frac{3}{2}$. Her explanation satisfies our definition of conceptual understanding.

Growth in conceptual understanding. In summary, the above findings across our data sets show that the number of PTs who demonstrated conceptual understanding in the pre- and post-

unit assessments was low (1 or 2). However, the larger number of PTs who demonstrated conceptual understanding on the final exam (18) shows that PT growth in reasoning beyond why procedures work increased gradually across the course. The interviews with five PTs also allowed PTs to give more justifications of why the invert and multiply procedure is a valid method, with three of the five PTs interviewed demonstrating conceptual knowledge. Also important to note is that the three PTs who demonstrated conceptual understanding in the interviews had started the unit relying solely on procedures.

Procedural Reliance

Pre-unit assessment. In the pre-unit assessment, 23 PTs demonstrated procedural reliance. Twenty-two of the PTs inverted the divisor and switched division to multiplication, noting that they used the "keep, change, flip" method, as that is the way they have memorized the "invert and multiply" rule. They attributed the procedure to what they were taught in elementary school: keep the first number, change the division sign to multiplication, and flip the fraction.

Classwork and homework. In completing class homework, 21 PTs demonstrated procedural reliance in their work. Most PTs simply noted that the invert and multiply rule works because dividing by a number is the same as multiplying by its reciprocal. Other PTs reasoned that since division is the inverse of multiplication, changing division to multiplication implies inverting the second fraction. PT 1, for instance, wrote, "*It [dividing by a rational number] is the same as multiplying by its reciprocal [because] doing the opposite procedure on the opposite number yields the same product*." Whereas most PTs reasoned this way, their reasoning did not justify why the invert and multiply rule works.

Post-unit assessment. In the post-unit assessment administered towards the end of the course, a total of 34 PTs demonstrated procedural reliance in their work. As in the pre-unit assessment, all the 34 PTs used the invert and multiply rule without a clear justification as to why the rule works. PT 28, like 32 other PTs, wrote, "*I did keep change flip*." PT 29 similarly wrote, "*When dividing fractions, it's multiplying by the reciprocal*." Other PTs just write *"KCF"* to denote "keep change flip," while others wrote *"reciprocal"* to illustrate multiplying by the inverse.

Final exam. On the final exam done at the end of the semester, 22 PTs showed procedural reliance in solving a question on division by a rational number. Similar to findings from the pre- and post-unit assessment, most PTs stated that it is possible to invert and multiply because of the "*keep-change-flip [rule]*." PT 7 wrote, "*Because multiplication and division are opposites, when reversing the fraction, the operation is also getting reversed*." Apart from stating "*keep change flip*" as the reason why the invert and multiply rule works, other PTs reasoned like PT 7 on the final exam.

Interviews. In the interviews, two of the five PTs interviewed appeared to rely solely on the invert and multiply procedure, and when probed to justify why the procedure was valid, their responses appeared to restate the procedure rather than to justify why they used it. The two PTs both solved the question as $\frac{3}{2} \times \frac{4}{1} = \frac{12}{2} = 6$. PT 10 explained her reasoning as follows:

> I kept three halves. I changed the divisions and multiplication, and then I flipped the numerator and the denominator. So I got three halves times four over one, and then I just multiplied it across. So, three times four is 12, two times one is two, and then divided the 12 by the two and got six. (PT 10, Interview)

PT 38 reasoned in a similar way to PT 10. Both PT 10 and PT 38's explanations relied primarily on procedural descriptions of the invert and multiply rule, with limited explicit reference to the conceptual meaning of fraction division.

Continued reliance on procedures across the unit. In summary, the above findings demonstrate that from the pre-unit assessment through to the post-unit assessment, the final exam, and the interviews, procedural reliance remained dominant across all data sources. Initially, 22 PTs relied on procedures like keep-change-flip without explaining their rationale. This trend persisted throughout the semester, as seen in classwork (22 PTs), final exam (22 PTs), post-unit assessments (34 PTs), and interviews (two of five PTs).

Misconception

Misconceptions were evident in how the PTs did the work procedurally and in their explanation of why such procedures work. As a result, some misconceptions were tied to procedural knowledge, while some were tied to conceptual knowledge.

Pre-unit assessment. At the start of the unit, four PTs showed misconceptions in their work. PT 5 used multiplication for division and wrote "$3 \times \frac{1}{4} = 0.75$." We interpreted this as the PT using the invert and multiply rule without inverting the fraction. PT 44 solved the question as "$3\times \frac{4}{1} = 12$," but referred to this process as cross multiplication instead of the invert and multiply process. This showed a misconception in the PTs' view of division as cross multiplication. PT 3 and PT 38 made an error similar to PT 5 by performing multiplication without inverting. All the misconceptions in the pre-unit assessment can be attributed to the PTs' developing procedural knowledge about fraction division.

Post-unit assessment. We observed four cases of misconceptions about division by rational numbers in the post-unit assessments. For example, PT 5 multiplied five by $\frac{1}{3}$ instead of dividing, meaning the PT probably used multiplication for division or was using the invert and multiply rule, but did not invert the fraction. PT 16 inverted $\frac{1}{3}$, but instead of multiplying, she added the numerators. The PT seems to have misconceived multiplication for addition. The two other PTs solved the question correctly but noted that they used cross multiplication. We interpreted that the PTs confused the invert and multiply rule for cross multiplication. Similar to the pre-unit assessment and the classwork, the misconceptions observed in this case can all be attributed to the four PTs' reliance on procedural knowledge.

Final exam. On the end-of-the-semester exam, three PTs showed misconceptions when explaining whether division is the same as multiplying by the reciprocal. PT 41 wrote, "*Dividing by the reciprocal is the same as asking how many times the whole fraction goes into the denominator of the other fraction*." This was a misconception that can be attributed to conceptual knowledge of fraction division. To be correct, she would have stated that the reciprocal of a fraction shows the number of fractions that fit in one whole, which changes the division to multiplication. Although her answer was not clear, she appeared to think of division as asking how many times a fraction goes into another.

Persistence in misconceptions about division involving rational numbers. The findings above show that instances of misconceptions were evident across all stages of data collection but remained low. Overall, misconceptions involved confusing division for multiplication, using the invert and multiply rule but failing to invert the divisor, or inverting the divisor and performing addition instead of multiplication.

Discussion

Our goal was to investigate the effect of teaching and learning via problem solving on PTs' understanding of why, when dividing a number by a fraction, we change division to multiplication and invert the divisor. In general, we found that at the start of the study, most PTs had deep procedural knowledge of fraction division and could apply the invert and multiply rule well but could not justify the reasoning behind the procedure. Additionally, a few PTs showed conceptual knowledge about fraction division, while some also had misconceptions tied mainly to their reliance on procedural knowledge. These initial findings compare with what other researchers like Kang (2022), Kang and Breiten (2024), Ma (1999), Morano and Riccomini (2020), and Tirosh (2000) found: most PTs can perform the standard invert and multiply rule but may have challenges justifying why the rule works. As the study progressed, the number of PTs who developed conceptual knowledge kept fluctuating, while at the same time, the number of those who exhibited procedural knowledge remained high. A notable change was towards the end of the study when the number of PTs demonstrating both procedural and conceptual knowledge of fraction division was almost equal, at 22 and 18, respectively. The interviews also allowed us to deeply assess some PTs' learning, and we found that three of the five PTs had developed conceptual knowledge, while two had developed procedural knowledge of fraction division. Our findings indicate that from the start to the end of the study, the course helped the PTs develop both procedural and conceptual knowledge. Our findings respond to Hiebert and Lefevre (1986), Hurrel (2021), and Salifu's (2021) recommendations that both procedural and conceptual knowledge are needed to prepare effective mathematics teachers.

In the process of developing procedural and conceptual knowledge, we noted cases of incomplete conceptions that produced errors, which we termed as misconceptions. All the misconceptions observed at the start and during the progress of the study were attributed to procedural knowledge, whereas two of the three misconceptions realized at the end of the study were attributed to conceptual knowledge. In total, we had 10 procedural misconceptions and one conceptual misconception. Examples of procedural misconceptions involved: (a) inverting the divisor and then performing addition instead of multiplication (such as PT 16 in the post-unit assessment), (b) changing division to multiplication without inverting the divisor (such as PT 5 in the pre-unit assessment), (c) applying the procedure correctly but then stating that the procedure is called cross multiplication (such as PT 44 in the pre-unit assessment), and (d) using whole-number reasoning to claim that dividing a number by a fraction increases/decreases the number (such as PT 15 in classwork). The misconceptions identified in this study reflect knowledge and instructional gaps shown by earlier studies (Alghazo & Alghazo, 2017; Powell & Nelson, 2020). We found one misconception linked to conceptual knowledge, which involved PT 41 reasoning that dividing fractions means finding how many groups of the divisor go into the dividend. This finding illustrates how promoting conceptual knowledge can be useful in PT learning, given that PTs' learning to justify mathematical procedures reduces the number of misconceptions they may hold about fraction division.

Based on our findings, we recommend that mathematics teacher preparation programs design activities that require PTs to reason, discuss, and defend their mathematical thinking rather than simply memorizing and practicing procedures. For sample activities that can be used in teaching and learning via problem solving, see Masingila et al. (2022a, 2022b). We also suggest that teacher education programs embrace teaching and learning via problem solving to promote both conceptual understanding and procedural accuracy. For more details on how a teaching and learning via problem solving course can be designed and enacted, see Caviness and Masingila

(2023), Masingila and Wambua (2015), and Xie and Masingila (2017). Finally, we recommend targeted instruction that addresses specific procedural and conceptual misconceptions that PTs have about fraction division, which is also a future direction for our study.

ELEMENTARY PRESERVICE TEACHERS' SPATIAL VISUALIZATION THINKING AND APPLICATION TOWARDS EXPLAINING ASTRONOMICAL PHENOMENA

Jennifer Wilhelm
University of Kentucky
jennifer.wilhelm@uky.edu

Rebecca Krall
University of Kentucky
rebecca.krall@uky.edu

This sequential explanatory mixed-methods study builds upon research examining in what ways preservice teachers (PSTs) visualized astronomical concepts they are expected to teach. We utilized a Spatial Visualization theoretical framework to investigate: (a) What do PSTs scores on a lunar phases and seasons assessment show about their spatial awareness regarding astronomical phenomena? (b) In what ways do PSTs utilize their spatial thinking towards applying to real life phenomena? Quantitative data consisted of students completing a content survey assessing cause of phases, cause of seasons, and visualization of Earth/Moon/Sun scale. Qualitative data involved interviews concerning 2D/3D Earth/Moon/Sun modeling of lunar phases and Earth/Sun modeling of seasons. In comparing Earth-based and Space-based spatial perspectives, PSTs tended to perform better on Earth-based items concerning cause of seasons.

Keywords: Preservice Teacher Education, Geometry and Spatial Reasoning

Objectives

This study builds upon prior research examining how elementary preservice teachers (PSTs) visualize and conceptualize astronomical phenomena they are expected to teach. Sixty PSTs from an elementary methods class were assessed on their understanding of cause of lunar phases and seasons as well as understanding the scale of the Earth/Moon/Sun system. This research investigated how elementary PSTs navigated Earth/Moon/Sun geometric configurations, motions, and scale. Specific spatial domains measured were periodicity, geometric spatial visualization (a Space-based perspective), cardinal directions, and spatial projection (an Earth-based perspective).

Spatial Visualization Theoretical Framework

In terms of astronomy, spatial visualization of celestial bodies (i.e., the Moon, planets, stars) and their heavenly motions are more complex than most people realize; it is inherently abstract. The necessary spatial skills vary by astronomy topic, but spatial ability contributes to understanding astronomical topics such as cause of lunar phases and cause of seasons. Learners are introduced to such ideas in the form of 3D physical models as well as 2D representations with the idea that these ways of understanding will translate to mental visuo-spatial abilities where they mentally manipulate the scale, orbit, and geometric orientation of the celestial bodies at play (Miragliotta & Baccaglini-Frank, 2018; Makamure & Jojo, 2021).

The Next Generation Science Standards (NGSS lead states, 2013) and Common Core State Standards-Mathematics (National Governors Association, 2010) discuss the importance of student understandings related to spatial-scientific learning (i.e., scale, patterns, and modeling). Research literature has connected increased spatial reasoning ability, including Earth-based and Space-based visualizations, with an increased understanding of concepts such as lunar phases and seasons (Cole et al., 2018; Plummer et al., 2014; Wilhelm et al., 2018). The NGSS state that students should learn "patterns of apparent motion of the Sun, the Moon, and stars in the sky… and [can be] explained with models" and "Earth's spin axis is fixed in direction over the short-term but tilted relative to its orbit around the Sun. The seasons are a result of that tilt…"

Predominant misconceptions that students hold to explain cause of the Moon's phases include Earth's shadow, Sun's shadow, and object blocking notions (Wilhelm et al., 2018). In addition to this, students often are not aware that the Moon orbits the Earth and if they do, they do not know the orbital time period (Trundle et al., 2002). Similarly, students who display incomplete understanding about the cause of seasons tend to hold some of the following perceptions: (1) the Earth is closer to the Sun in summer, (2) the direction of the Earth's axis during orbit around the Sun changes throughout the orbit, (3) incorrect time duration of one Earth rotation on its axis, and (4) visualizing the Sun revolves around the Earth (Atwood & Atwood, 1996; Bakas & Mikropoulos, 2003; Trumper, 2006; Wild & Trundle, 2010).

Research Questions and Participants

The purpose of this research was to examine how well PSTs understand astronomical concepts (requiring spatial visualization) that they are expected to teach. Specifically, we examined PSTs' spatial awareness of astronomical phenomena from both Earth-based and Space-based perspectives. Research questions included: (a) What do PSTs scores on a lunar phases and seasons assessment show about their spatial awareness regarding astronomical phenomena? (b) In what ways do PSTs utilize their spatial thinking towards applying to real life phenomena. These questions were explored with 60 undergraduate preservice teachers from one south-central university in the United States. The participants in this study were PSTs enrolled in an elementary science methods and mathematics methods course taken during their senior year. The participants completed two courses in mathematics and one course in physics designed for elementary and middle school PSTs during either their sophomore or junior year. Of the 60, 57 PSTs were female (1 Hispanic American, 1 Asian American, 4 African American, and 51 White) and 3 were male (1 Native American, 2 Decline to answer).

Methods

For this sequential explanatory mixed methods study, data collection involved administering the Astronomical Assessment, a combined inventory of the Lunar Phases Concept Inventory (LPCI; Lindell & Olsen, 2002), Earth/Moon/Sun scaling questions, and a Seasons Concept Inventory (SCI; Krall et al., 2023). The LPCI is a 20-item multiple choice instrument that assesses eight science domains and four spatial domains (see Table 1). Four scaling questions were added to the lunar phases portion of the Astronomical Assessment to gauge PSTs' conceptions of the relative size and distance between the Earth, Moon, and Sun. The SCI was constructed using 14 questions from previously published concept inventories (Bakas & Mikropoulos, 2003; Roald & Mikalsen, 2001; Trumper, 2006; Wild & Trundle, 2010). Questions were selected to address four domains presented in Wild & Trundle (2010). The domains included: (1) Earth's axis is tilted, (2) Earth orbits Sun, (3) Tilt of Earth's axis and its orbit around Sun causes variable amounts of sunlight hitting different Earthly regions, and (4) day and night are caused by Earth's rotation on its axis.

The lunar phases questions were coded as Earth-based or Space-based. In addition, each question was spatially coded as Periodic Patterns (PP), Geometric Spatial Visualization (GSV), Cardinal Direction (CD), Spatial-Projection (SP), or SC (Scale). Table 1 outlines the definition of each code. The Seasons questions were also coded as Earth-based or Space-based. In addition, each Seasons question was coded as: Domain 1: Axis tilt, Domain 2: Earth Orbits Sun; Domain 3: Variable Sunlight, Domain 4: Rotates on Axis, and Domain 5: Cumulation of Domains 1–3.

The sequential process for data collection occurred in two phases. In Phase 1, PSTs volunteered to take the assessment in their elementary methods course, taking students

approximately 29 minutes to complete. Phase 2 was conducted within two weeks of taking the Astronomy Assessment where five students volunteered to be interviewed regarding their understanding of cause of lunar phases and seasons. These interviews were semi-structured and designed to probe deeply into the PST volunteers' thinking. Protocol questions included requests to illustrate both 2D and 3D explanations for why we see lunar phases and what causes seasons. The average interview time was approximately 25 minutes.

Table 1: Lunar Phases Concept Inventory Spatially Coded

LPCI Scientific Domains	Spatial Domains
A- Period of Moon's orbit around Earth B – Period of Moon's cycle of phases	**Periodic Patterns - PP** (*regular intervals of time and/or space*)
C – Direction of the Moon's orbit around Earth E – Phase due to Sun/Earth/Moon Positions G – Cause of lunar phases	**Geometric Spatial Visualization - GSV** (*visualizing the geometric spatial features of a given system as it appears in space*)
D – Moon motion from Earthly perspective F – Phase-location in sky-time of observation	**Cardinal Directions - CD** (*object's vector direction in space as a function of time from a given position*)
H – Effect of lunar phase with change in Earthly location	**Spatial Projection - SP** *(projecting oneself into a different location, confined to the surface of Earth, and visualizing from that global perspective*)
I – Relative size of and distances between Earth/Moon/Sun	**Scaling - SC** (*relative sizes and distances between objects*)

Results

Lunar Phases Survey Findings

Of the 60 PSTs who took the assessment, 27.4% had a scientific explanation of the cause of lunar phases, that is, phases are caused by the changing geometric positions of the Earth/Moon/Sun, which affect how much of the Moon's illuminated surface is visible to a viewer on Earth. Other PSTs held common misconceptions with more than half (53.2%) holding the Earth-shadow explanation and 19.4% holding a Sun-shadow explanation. The lunar phases questions that were coded as Earth-based perspective questions showed PSTs scoring 32.3% correct while the coded Space-based perspective questions showed PSTs scoring 31.3% correct. Figure 1 shows PSTs scoring best on those questions addressing Earth/Moon/Sun scale (SC; 44.2% correct), periodicity of lunar phases and orbit (PP; 40.7% correct), and viewing phases from various Earthly locations (SP; 40% correct). Questions that dealt with cardinal direction of the Moon for phases at different times showed the least understanding.

Seasons Survey Findings

Of the 60 PSTs, nearly half (47.6%) scored correctly on those Seasons questions coded as Earth-based perspective. However, only 28.1% of the PSTs scored correctly on the Seasons questions coded as Space-based perspective. Figure 2 shows PSTs scoring best on those questions that focused on the effects of Variable Sunlight on Earth (48.3% correct). For questions regarding the concept that Earth rotates on its axis, PSTs scored 38.3% correct. The questions with the least understanding concern the concept that Earth orbits the Sun and the effect of Earth's tilted axis.

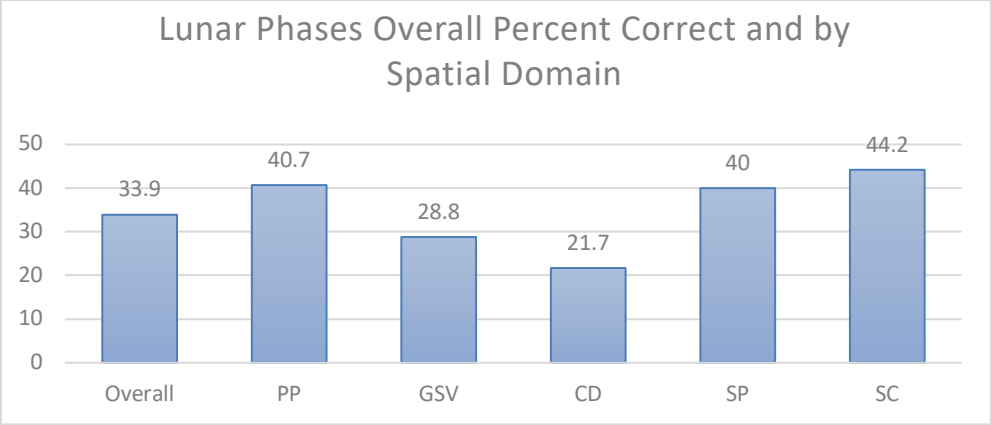

Figure 1: Lunar Phases Survey Overall Results and by Spatial Domain

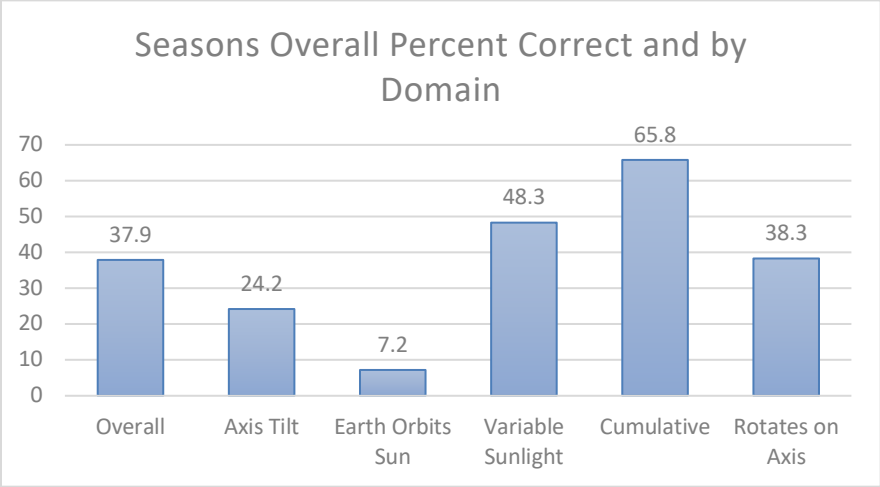

Figure 2: Seasons Survey Overall Results and by Domain

Interview Findings

We highlight two of the five interviews that display the lunar phases and season's understandings and visualizations of the PSTs. These two examples are representative of the five interviews. The two interviewees highlighted were Phoebe and Fiona (pseudonyms).

Phoebe. Phoebe stated that she rarely looked at the Moon. When asked to sketch any way she might have seen the Moon, she drew sketches of the Moon during a full Moon phase and crescent phase (3 similar crescent shapes) as shown in Figure 3.

Researcher:	[after having drawn a full Moon] Would you mind drawing the other ways that the Moon can be perceived? [She drew three crescent shapes.] With your drawings, can you explain a little why they appear differently?
Phoebe:	So, this would be a full Moon [pointed to circle of full Moon], then the crests and, like, throughout the month they will appear differently.
Researcher:	Why does the Moon look different (at different times)?
Phoebe:	I guess it's just how the Sun is hitting it, we portray it different [sic] on Earth.

Researcher: And do you know a little bit more about why this happens?
Phoebe: I'd say it has to do with something the way the Earth is on its, like, tilt and it rotates. We just see it differently.

Phoebe seemed to understand that perspective from Earth might be a reason we see the Moon differently at different times when she claimed, "it's just how the Sun is hitting it, we portray it different on Earth." However, Phoebe incorrectly followed up with the statement that it has something to do with the Earth's tilt.

For the Seasons questions, Phoebe sketched a drawing of the Sun and the Earth positioned at different locations around the Sun in what appeared to be an elliptical orbit (see Figure 3). Phoebe described this orbit in terms of how the Earth "rotates" around the Sun. She stated, "So, here's the Sun. Here's the way that Earth rotates around the Sun. So, then summer would be here [position where Earth is closest to the Sun] because we're closer and then winter would be here because it's farther away." Phoebe held the misconception that the Earth is closer to the Sun in the summer and concluded that would be the reason why it is warmer in the summer.

Fiona. When Fiona sketched Moon phases she recollected observing, she drew a full, a crescent, and a gibbous Moon, although she did not name them as such (see Figure 3).

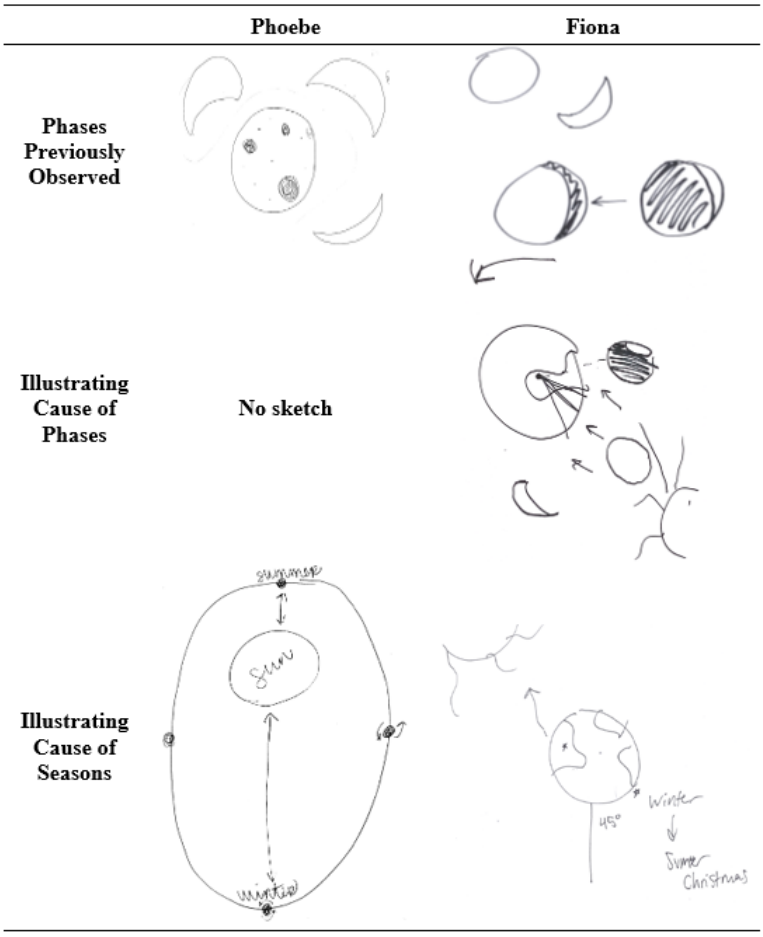

Figure 3: PSTs' Spatial Sketches of Cause of Lunar Phases and Seasons

Below is an excerpt of Fiona explaining why the Moon looks different at different times:

Fiona:	So, if I was right here, and I was looking up at the Moon, like I said, I always assume it's going to be right up here. [Stating Moon is always found in the same location.] Now this is the part that it could be wrong, but I think it's okay if I'm wrong. I think the Sun is going to be like here. … And then depending on where I am, and how much Sun is coming through, is what I would see. But I don't know exactly like what Moon phase I would see.
Researcher:	When you say the Sun is coming through, what do you mean?
Fiona:	From the Sun and the energy, I guess, but specifically the light.
Researcher:	But when you say "through," you mean?
Fiona:	Around and probably, yeah, around.
Researcher:	Okay. So, but you're saying for this one [pointing at the Moon Fiona drew between the Sun and the Earth in her cause of Moon phase sketch in Figure 3], you're not sure, what Moon phase?
Fiona:	I think it'd be a full Moon in the picture I drew but it could be wrong.
Researcher:	If say that were a full Moon, where would the Moon be for us to see something that looks like that [pointing to her crescent Moon phase she had sketched].
Fiona:	Here, and then for the flipped version, but I don't even know if that's actually a thing, it would be here and then that would be covered. Does that make sense?
Researcher:	Okay, so how would that be covered? Like covered with what?
Fiona:	That's a good point. I don't know. I guess it would not. It would be covered but I'm not sure what is covering it. But that's like what I would see from that point.

In Figure 3, under Fiona's sketch of Earth/Moon/Sun geometric positions that would result in viewing a full Moon or a crescent Moon from an Earthly perspective, Fiona first sketched the Earth (farthest left circular figure) and the Sun (bottom right figure with Sun's rays shown with squiggle lines). She sketched the Moon between the Earth and Sun. When asked what Moon phase we would observe with the Moon in that position, Fiona stated that she was not sure, but it was probably a full Moon. She was then asked to show where the Moon would be located for us to observe a crescent Moon, and she drew a crescent Moon on the lower left side and then she said the flipped version would be on the other side (the Moon that is shaded except for a small patch facing away from the Sun). She indicated that the Moon was covered except for the small patch. When asked what the Moon was covered by, Fiona indicated that she did not know. Fiona did not seem to be aware that the illuminated side of the Moon should be facing the Sun.

For the Seasons portion of the interview, Fiona was asked why it was warmer in summer and colder in winter in Lexington. She replied:

Fiona:	Because of our axis, and like how we are, not rotated, but positioned, I guess. And where we are in relativity to the Sun…

Fiona's initial answer suggested that she believed the position of Earth relative to the Sun and Earth's axis has something to do with it. She was asked to draw a sketch to illustrate her meaning. She drew the Earth and explained that it was tilted on its axis at 45°. She then drew a

half circle to illustrate the Sun, explaining that Earth "rotated" around the Sun [gesturing with her hands an orbital movement]. She elaborated further.

Fiona: And it is our summer when we are directly in front of it [Sun], and our rotation is closest to the Sun. And that is why Australia would have winter at that time. [Drawing stars to show that Australia was located on the opposite side of Earth from Lexington.] But, if you flipped it [shows rotation with her hands], then they [Australia] would have summer, and we [Lexington] would have winter at Christmas [and Australia would have Christmas during their summer].

Fiona believed that Earth's rotation on its axis caused the seasons rather than the combination of Earth's tilt on its axis and its orbit around the Sun.

Later in the interview, the researcher asked questions to clarify Fiona's thinking about the causes of seasons and the motion of Earth and the Sun.

Researcher: Okay, so does anything move? Like, does the Sun move, or does the Earth move, or both?

Fiona: Okay, well, I don't know about the Sun. I know the Earth moves. It rotates like this [demonstrates motion of rotation on an axis], as well as like this [demonstrates orbiting around the Sun]. I know our Moon moves around us, but I don't think the Sun moves, but I could be wrong. And then yeah, we rotate around the Sun… [uses the 3D models to show Earth orbiting Sun].

Researcher: So, you said that the Earth moves around the Sun. How long does it take to go around this?

Fiona: It's a month? I don't know. I think a month.

Researcher: And does that affect anything about the seasons?

Fiona: Oh, my immediate reaction says yes, but I don't think so.

Fiona believed that Lexington is warmer in summer because of the closer proximity of Earth to the Sun due to its rotation (Earth's rotation on its axis) toward the Sun. As the Earth rotates away from the Sun in the fall it becomes cooler until Lexington experiences winter when that side of Earth has rotated to be directly opposite the side facing the Sun. It is interesting that Fiona understood that Earth orbits the Sun, but she did not believe this movement affected the seasons experienced on Earth. Further, she believed the path Earth follows around the Sun would take about a month to complete. Although she did not mention a time frame for the complete Earth rotation on its axis, her answer suggests the rotation would take one year to complete. The three interviews not highlighted showed interviewees with the same way of spatially thinking regarding the cause of seasons, that is, claiming Earth's rotation on its axis caused the change of seasons where the side facing the Sun would be summer. Visualizing seasons in this manner also illustrates PSTs' lack of understanding the cause of day and night.

Discussion and Conclusion

This study examined PSTs' spatial awareness of astronomical phenomena from both Earth-based and Space-based perspectives. Regarding RQ1, performance patterns suggest that PSTs' spatial reasoning is fragile across perspectives and particularly vulnerable when tasks require mental transformation into a Space-based frame of reference. On the lunar phases assessment, approximately one-third of PSTs answered correctly for both Earth-based (32.3%) and Space-

based (31.3%) items. The similarity in performance indicates that even when questions are grounded in the more familiar Earth-based viewpoint, PSTs struggle to accurately coordinate Earth/Moon/Sun relationships.

In contrast, results for seasons revealed a clearer divergence. PSTs performed better on Earth-based items (47.6% correct) than on Space-based items (27% correct). This pattern supports the interpretation that Earth-based questions may allow PSTs to draw upon experiential or phenomenological reasoning (e.g., temperature changes, daylight length), whereas space-based questions require coordinated spatial transformations—mentally visualizing axial tilt, orbital motion, and the angle of solar incidence. The substantially lower performance on Space-based items suggests limited facility with perspective-taking and dynamic spatial reasoning.

Findings from RQ2 further illustrate the nature of PSTs' spatial thinking. Interview data revealed that participants such as Phoebe and Fiona could sketch recognizable lunar phases, demonstrating some competence with static 2D representations. However, their explanations exposed incomplete or incorrect causal reasoning. Fiona's explanation that phases occur because of "how much Sun is coming through" similarly suggests a partial but unintegrated understanding of illumination. These responses indicate that PSTs may possess emerging representational skills (e.g., drawing phases) without fully developed mental models capable of supporting accurate causal explanations. Taken together, the quantitative and qualitative findings suggest that PSTs' spatial reasoning is often compartmentalized: they may reproduce familiar images yet struggle to mentally manipulate celestial bodies in 3D space across time. This disconnect aligns with prior research showing that misconceptions in astronomy persist even when learners can produce correct diagrams (Sağdıç & Şahin, 2023; Galperin & Raviolo, 2019). The results highlight the importance of explicitly addressing perspective-taking, dynamic modeling, and the coordination of multiple frames of reference within teacher preparation.

Overall survey scores of 40% or below, coupled with interview evidence of persistent misconceptions, underscore the need for more intentional development of spatial reasoning within elementary teacher preparation. In particular, findings point to the importance of incorporating sustained space-based interventions that require PSTs to shift perspectives, physically model Earth/Moon/Sun systems, and engage in iterative mental simulations. While misconceptions may persist even after instruction, as noted by Tsai and Chang (2005), deeper engagement with spatial representations can move learners toward more sophisticated, though still evolving, understandings.

Recent practice-based and modeling-focused interventions (e.g., Türk & Kalkan, 2018; Galano & Testa, 2025) reinforce that strengthening foundational astronomical knowledge must occur alongside the development of spatial visualization skills. Echoing physicist Wolfgang Pauli's reflection that deeper understanding often involves "misunderstanding at a deeper level," this study identifies a critical starting point rather than an endpoint. The goal is not merely correct answers, but increasingly coherent mental models that integrate geometry, motion, and perspective. Developing PSTs' ability to mentally rotate, transform, and coordinate celestial bodies in both Earth-based and Space-based frames is essential if they are to teach these concepts with clarity and conceptual integrity. Future research should examine longitudinal impacts of explicit spatial interventions and investigate how improvements in spatial visualization translate into classroom practice and student learning outcomes.

DECOMPOSING LEARNING OBJECTIVES TO SUPPORT PRESERVICE TEACHERS

Comfort Aje
Purdue University
caje@purdue.edu

This theoretical paper introduces a framework that uses decomposition of practice to support preservice teachers in developing and refining learning objectives within lesson design tasks. The framework focuses on learning objective construction as a central component of planning that can be separated, examined, and intentionally developed. By unpacking the parts of a learning objective, the framework makes the instructional decisions embedded in objective design visible. The aim is to bring greater clarity and coherence to lesson planning and to strengthen preservice teachers' ability to design learning objectives that are clearly focused, well-aligned with tasks, and grounded in meaningful mathematical understanding.

Keywords: Instructional Activities and Practices, Preservice Teacher Education

Relevance of Lesson Planning in Instruction Practices

Instructional practices in mathematics classrooms involve far more than delivering content; they require teachers to skillfully lead discussions, elicit student thinking, and guide learners toward deeper conceptual understanding (Lampert & Graziani, 2009). Mathematics teacher education has directed increased attention to helping preservice teachers (PTs) engage in structured opportunities to rehearse and analyze complex instructional routines. Kazemi et al.'s (2009) exemplifies this with four instructional activities designed to assist preservice elementary teachers' instruction delivery. One of the instructional activities includes a strategy-sharing routine in which the teacher poses a computational problem, helps with different solution strategies, and facilitates a mathematical discussion that highlights connections among solution paths. The work of Kazemi et al. (2009) shows that instructional practice is not something teachers simply implement; rather, it is developed through active engagement in carefully designed teaching activities. The instructional activities from their work help PTs understand how instructional goals shape and connect to the mathematical discussions that occur in the classroom.

Research suggests PTs develop more robust instructional practices when they engage in cycles of participation, analysis, practice, and implementation (Fitriati et al. 2023). In the instructional activities developed by Kazemi et al. (2009), preservice elementary teachers first experienced the activity as mathematics learners, then collaboratively analyzed the work of teaching using a teacher-educator guide as a tool for noticing key instructional moves. The preservice elementary teachers subsequently wrote a lesson plan, practiced the activity with targeted feedback, and finally implemented their plans in classrooms. The findings from this design highlighted a strong link between practice and classroom implementation, demonstrating that structured opportunities for instructional practice enable PTs to analyze how learning objectives influence the depth and richness of classroom discussions.

The emphasis on learning through implementation in practice aligns with broader research on PTs' development, including work on problem posing (Crespo, 2003), leading mathematical discussions (Ghousseini, 2009), and responsive questioning (Nicol, 1998). Across these studies, instructional practices are made learnable by breaking them into smaller, more manageable components that can be examined, rehearsed, and refined. This emphasis is further reinforced by

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

research on rehearsals in teaching (Lampert et al., 2013) and on core practices within practice-based teacher education (Forzani, 2014). which collectively emphasizes the importance of structured practice in developing pedagogical competence.

In delivering instruction in the classroom, different planning and decision-making processes are necessary for effective student learning (Fitriati et al., 2023). Lesson planning has been seen as a complex, goal-oriented professional practice that shapes the structure and content of classroom instruction (Cevikbas et al., 2024). To plan lessons, teachers consider students' interests, instructional objectives, resources and materials, and assessment methods, highlighting the importance of teachers developing their own learning objectives, activities, and goals. Building on this foundational view, Superfine (2009) conceptualizes lesson planning as a dynamic problem-solving activity in which teachers navigate multiple interacting elements, including curricular demands, pedagogical beliefs, prior experiences, and reform-oriented approaches to teaching and learning. Within this process, learning objectives serve as a critical anchor, shaping how teachers interpret curriculum materials, select tasks, and anticipate student thinking. The model proposed in the work of Superfine (2009) highlights that teachers often encounter challenges in aligning learning objectives with instructional activities and student understanding, revealing lesson planning as a cognitively demanding practice that involves coordinating multiple components in relation to clearly defined learning goals. These perspectives position lesson planning not as a linear procedural task, but as an integrative process in which the development and refinement of learning objectives are central to effective instructional design.

Research further emphasizes the vital role of lesson planning in developing teacher skills and ensuring instructional quality (Cevikbas et al., 2024). Lesson planning is widely recognized as essential for effective teaching across subject areas and as a foundational component of initial teacher education (Cevikbas et al., 2024; König et al., 2021; Munthe & Conway, 2017). However, as Morris and Hiebert (2017) demonstrate, planning skills do not automatically transfer from teacher education coursework into classroom practice, pointing to a persistent gap between learning about teaching and implementing it. This gap reveals the need for more intentional and structured support that helps PTs not only understand the components of lesson planning but also apply them in meaningful ways. In this sense, strengthening how PTs learn to develop and use learning objectives becomes particularly significant, as it can support the alignment, clarity, and effectiveness of their instructional decisions in practice.

Role of Learning Objectives in Task Design

In mathematics education, tasks are considered the main drivers of learning, with students spending most of their learning time involved in structured activities guided by clearly defined objectives (Hammer & Ufer, 2023; NCTM, 2014). Coletta and Norris-Bauer (2017) describe objectives as clear statements of student learning outcomes that direct task design and align instruction. They emphasize structured objective writing based on cognitive taxonomies such as Bloom’s Taxonomy and ongoing alignment between objectives and activities. The work of Coletta and Norris-Bauer (2017) positions lesson planning as a crucial area where PTs must learn to turn broad curriculum goals into clear learning objectives and well-organized instructional tasks. This makes lesson planning an important area for supporting the development of learning objectives in teacher training. It also emphasizes the need for structured approaches that help PTs connect learning objectives directly to instructional tasks and student thinking, ensuring greater coherence in lesson design.

Learning objectives serve as the central element of lesson planning, guiding task selection, instructional strategies, and assessment decisions (Cevikbas et al., 2024). As noted in Cevikbas et al. (2024), "…a lesson plan can be designed to effectively engage learners and meet desired learning outcomes" (p. 108). PTs often struggle to create learning objectives that are clear, measurable, instructionally meaningful, and well-integrated into lesson planning (Abadi & Ekawati, 2018). Objectives are frequently written as vague content statements or activity descriptions rather than precise descriptions of intended student learning, which limits their effectiveness in guiding instruction and assessment and contributes to their struggle to integrate task design in the lesson plan (Gonzalez et al., 2020). This issue highlights the broader, limited structured support for translating curricular goals into pedagogically coherent and actionable learning objectives within teacher preparation programs. As a result, although clearly defined learning objectives can strengthen coherence and alignment across planning components (Chen & Zhang, 2019). But there remains a gap in understanding how a focus on objectives can be balanced with attention to students' thinking as it unfolds during instruction. This study addresses that gap by introducing a decomposition-based framework that makes this process visible and teachable.

This study responds to the identified gap in the literature by positioning the development of learning objectives as a specific aspect of teaching practice that requires explicit and structured support. Drawing on the concept of decomposition of practice, the study introduces a framework that breaks down the process of writing learning objectives into smaller, learnable components that can be examined, practiced, and refined. This approach is significant because it moves beyond treating objectives as routine statements and instead makes the instructional reasoning behind them visible, supporting PTs in developing clearer, more aligned, and instructionally meaningful lesson plans. The central argument of this study is that learning objectives, when treated as a decomposable element of practice, can be more effectively taught and learned, thereby improving PTs' competence in constructing objectives that guide coherent instruction while remaining responsive to students' thinking. Guided by this argument, the theoretical paper investigates the extent to which decomposing learning objectives supports PTs in writing clear, measurable, and meaningful learning objectives.

Existing Theoretical Framework

Decomposing Learning Objectives as a Form of Pedagogical Practices

Decomposition of practice offers a theoretical approach that breaks teaching into essential, learnable components, making key elements visible so PTs can study, practice, and refine them before integrating them into full instruction (Grossman et al., 2009; Resnick & Kazemi, 2019). It includes developing learning objectives and organizing lesson plans, before integrating them into coherent instruction (Tyminski et al., 2014). Prior research shows this approach has been used to break down practices like leading discussions and managing classroom interactions into components that can be rehearsed (Ghousseini & Herbst, 2016). Extending this idea, writing learning objectives can be treated as a specific, learnable part of lesson planning that requires clear thinking about what students should learn. When this clarity is missing, the resulting lesson is often less coherent and less effectively organized (Gonzalez et al., 2020).

In the decomposition of practice framework, a learning objective means identifying and studying its essential parts before asking PTs to design a full lesson. A learning objective can be broken into at least three components: (1) the specific content or concept students are to learn, (2) the cognitive action students are expected to perform (e.g., explain, justify, compare), and (3) the level of understanding or quality of reasoning that demonstrates success (Anderson &

Krathwohl, 2001). PTs may also need to examine how the objective connects to tasks and evidence of learning. To support this work, teacher educators could engage PTs in analyzing sample objectives, revising vague objectives into clearer ones, distinguishing between activities and learning goals, and aligning objectives (Sztajn et al., 2020).

Research shows that decomposition of practice supports PTs' learning by breaking complex instructional work into clear, manageable parts and organizing learning around those elements. For instance, Cheng (2014) structured lesson study so PTs focused on key planning tasks, such as selecting topics, setting learning goals, and designing instruction, one at a time, which helped deepen their understanding of lesson design. Similarly, Achinstein and Fogo (2015) demonstrated that separating teaching into idea-focused and action-focused components supported the development of pedagogical content knowledge. In mathematics education, decomposition has also been applied to practices like leading discussions, interpreting student thinking, and selecting tasks (Ghousseini & Herbst, 2016; van Es, 2011; Stein et al., 2009). Across these studies, a common pattern emerges: identifying key components, studying them in focused ways, and providing PTs opportunities for practice before integrating them into full classroom instruction.

Building on this understanding of decomposition, this study applies the approach specifically to learning objective writing by positioning it as a distinct and learnable component of lesson planning that requires focused attention. Rather than assuming PTs already inherently know how to write clear objectives, the framework guides them in examining key elements, what students are expected to learn, how learning is demonstrated, the level of understanding required, and how it will be assessed. It can often begin with analyzing examples to distinguish meaningful learning statements from simple activity descriptions. PTs are also supported in connecting objectives to student thinking and instructional tasks, similar to how Cheng (2014) helped clarify lesson focus. By breaking objectives into clear components for study and practice, this approach highlights their role in shaping coherent and aligned lesson design. The theoretical approach positions decomposition as a key tool for PTs to develop the professional skills needed to create meaningful, coherent, and aligned learning objectives (Sztajn et al., 2020).

Decomposing Learning Objectives to Support Preservice Teachers

The reviewed literature consistently positions learning objectives as a central component of lesson planning that shapes instructional decisions, task selection, sequencing, and attention to student thinking (Chen & Zhang, 2019; Fitriati et al., 2023; González et al., 2020). However, studies also show that PTs often struggle to write objectives that are clear, measurable, and meaningfully connected to instruction and assessment (Lim et al., 2018). Effective objectives typically include identifiable elements such as content, observable student actions, expected levels of understanding, and evidence of learning, as well as assessment (Anderson & Krathwohl, 2001; Orr et al., 2022; Rodriguez & Albano, 2017). These elements directly influence the coherence and quality of lesson design. This supports the argument that decomposing practice offers a productive framework for making these elements visible and learnable. Drawing on these findings, this study contributes to the ongoing discussion by arguing that learning objectives should be understood as a decomposable component of teaching practice that benefits from focused analysis and structured support. By breaking objectives into key elements, PTs can better understand how objectives guide instructional decisions, shape learning, and support coherent, mathematically meaningful lesson development.

This design-based research study reports how preservice teachers (PSTs) perceived the authenticity of AI conversational agents simulating children with mathematical misconceptions. We designed and implemented a chatbot within mathematics methods courses to provide PSTs with structured opportunities to practice questioning strategies aimed at eliciting and building on students' ideas in a low-stakes, practice-based environment. The chatbot simulated one-on-one teacher-student interactions and served dual roles: an elementary student with misconceptions generating child-like mathematical responses and a mentor providing feedback on PSTs' questioning. Two iterations were conducted using traditional and generative AI models We compare PSTs' perception of authenticity across two iterations. Results inform the design of AI-mediated practice tools to support the development of pedagogical responsiveness of PSTs.

Keywords: Preservice Teacher Education, Teacher Noticing, Technology

Purpose and Theoretical Framework

Responsive teaching requires teachers to attend to the substance of students' mathematical thinking and to use that thinking productively in the moment (Robertson et al., 2016). Central to this practice is strategic questioning not only to elicit students' ideas, but to interpret and build on those ideas to advance conceptual understanding. Developing this form of responsiveness is challenging because it depends on engagement with students' often unpredictable reasoning and explanations.

Practice-based teacher education has sought to address this challenge through approximations of practice that provide structured, low-stakes opportunities for rehearsal (Grossman et al., 2009, Lampert et al., 2013). Recent advances in conversational AI extend these approximations by enabling student-emulating agents capable of generating child-like mathematical responses, including common misconceptions (Lee, et al., 2025). Such AI-mediated simulations allow PSTs to repeatedly practice formulating questions, interpreting responses, and determining instructional next moves in real time (Cao et al., 2023).

On the other hand, emerging scholarship raises concerns about authenticity and contingency in AI-generated interactions (Lee, et al., 2025; Zheng et al., 2025). If student responses appear scripted, overly polished, or insufficiently responsive to teacher questioning, the simulation may fail to approximate the complexity of classroom discourse or sustain participants' suspension of disbelief.

This brief research report examines the authenticity of AI-generated student responses across two iterations of chatbot development. By comparing iterations, we identify design trade-offs that inform the development of AI-based approximations of practice in mathematics teacher education.

Method

Research Design

This study used a design-based research approach to examine how preservice teachers' (PSTs') perceptions of the authenticity changed as an AI-based student-emulating agent developed through two iterations—first with traditional AI and second with generative AI. PSTs engaged in a simulated one-on-one interaction with a virtual student named *Noah* through a fraction comparison task. The chatbot was designed to serve dual roles: the virtual student who responded to PSTs' questions with child-like reasoning about fractions and the mentor who provided instant feedback on the PSTs' questioning. In each iteration, PSTs first watched a video of Noah solving a fraction problem and explaining his thinking. They then interacted with the AI-based student-emulating agent in a simulated dialogue. Following the interaction, PSTs completed a survey to report their perceptions of the chatbot's responses and the perceived authenticity of their experiences. Data were collected across the two iterations of the chatbot intervention implemented in different semesters with different groups of PSTs. The purpose of comparing iterations was to examine how changes in the chatbot training approach influenced PSTs' perceptions of authenticity.

Context and Participants

Participants were preservice elementary teachers enrolled in an undergraduate teacher education program at a four-year public university in the Midwestern United States. The chatbot simulation was embedded within a mathematics methods course. The program included a sequence of two mathematics methods courses.

The first iteration of the study was conducted in Spring 2025 in the second method course across included five course sections, with 97 PSTs volunteering to participate. The second iteration was conducted in Fall 2025 across the first method course in a course sequence, with 54 PSTs completed the survey. Participation was voluntary and survey responses were collected following PSTs' completion of the simulation.

Chatbot Development

The chatbots were developed across two iterations using different AI chatbot platforms. The first iteration used IBM Watsonx Assistant, a rule-based AI platform that relied on predefined responses that the system would select based on an interpretation of the user's intent, utilizing technologies such as Natural Language Processing, Deep Learning, and Machine Learning. This allowed controlled dialogue grounded in specific misconceptions, while the chatbot's flexibility in responding to diverse questions. The second iteration was redesigned using OpenAI's GPT-4o, a generative AI model. This iteration used prompt-based instructions to produce student-like responses in real time, enabling more fluid and context-sensitive dialogues. Across both iterations, the chatbots were designed to serve dual roles: virtual student with fraction misconceptions and virtual mentor with appropriate feedback on PSTs' questioning.

Data Sources: Survey Instrument

The data presented here represent a subset of a larger dataset that includes PSTs' conversations with the chatbots as well as analysis of responsive teaching practices before and after their experiences with the chatbot. This brief report focuses specifically on PSTs' perceptions of authenticity.

Survey data were collected immediately after PSTs interacted with the virtual student Noah. The survey included Likert-scale and open-ended items designed to capture perceptions of the chatbot's authenticity and pedagogical usefulness. This brief report focuses specifically on authenticity. PSTs responded to the Likert item, "*The responses from the virtual student were*

authentic," and to the open-ended prompt, "*Please explain why the virtual student's responses were authentic or not*." These items elicited perceptions of whether Noah's reasoning appeared realistic, conversational, and responsive to their questioning.

Data Analysis

Likert-scale responses were analyzed using descriptive statistics to compare response distributions across iterations. Percentages were calculated for each category (Strongly Agree to Strongly Disagree) to examine shifts in perceived authenticity following revisions to the chatbot training approach (Table 1).

Open-ended survey responses were analyzed using an inductive coding process. First, responses were reviewed to identify recurring patterns related to authenticity. Codes were iteratively refined through comparison across responses, resulting in a final codebook representing themes aligned with three dimensions of authenticity: linguistic authenticity (e.g., conversational tone, repetitiveness), cognitive authenticity (e.g., student-like reasoning, misconception errors), and interactional authenticity (e.g., responsiveness, inflexibility). Codes were then applied to all responses, and frequencies were calculated to compare the prevalence of themes across iterations. The analysis focused on identifying relative differences in PST-reported perceptions of authenticity across the two chatbot training approaches.

Results

As shown in Table 1, perceptions of authenticity improved modestly in Iteration 2. Agreement (Strongly Agree + Agree) increased from 51.55% in Iteration 1 to 61.12% in Iteration 2, while disagreement decreased from 23.71% to 18.52%. Neutral responses also declined slightly. Overall, these descriptive trends suggest a positive shift in perceived authenticity following revisions to the chatbot training approach.

Table 1: Likert Scale Responses to the Item "The responses from the virtual student were authentic"

	Iteration 1	Iteration 2
Strongly agree	7.22%	5.56%
Agree	44.33%	55.56%
Neither agree nor disagree	24.74%	20.37%
Disagree	23.71%	16.67%
Strongly Disagree	0.00%	1.85%
N	97	54

Qualitative findings provide a more nuanced view of these shifts (Table 2). From Iteration 1 to Iteration 2, both linguistic authenticity and interactional contingency improved. In Iteration 1, participants frequently noted repetitiveness (19.6%) and unnatural tone (15.5%). In Iteration 2, both concerns declined substantially (3.7% and 7.4%, respectively), suggesting improved conversational flow and a less programmed or scripted feel.

Interactional breakdowns also decreased. In Iteration 1, unresponsiveness (29.9%) and inflexibility (11.3%) were commonly described, such as, "the student has a limited number of possible responses, and the student tends to repeat verbatim the same answers he has given previously to vastly different questions. The bot also doesn't understand context and only replies based on language that is overly precise, rather than context based like a child." Inflexibility

referred to instances in which responses were unrelated to the users' questions or the intent was misread. In Iteration 2, unresponsiveness dropped to zero and inflexibility declined (7.4%), indicating stronger contingency and responsiveness to PST questioning.

In contrast, cognitive authenticity showed regression. In Iteration 1, many PSTs described student-like reasoning (28.9%) and realistic misconceptions (6.2%), noting that "Noah's responses felt authentic because he explained his thinking the way a real student might," with few references to non-student-like responses (2.1%). In Iteration 2, although student-like reasoning remained present (25.9%), references to non-student-like responses increased substantially (25.9%). Participants described the chatbot as having "stronger understanding … then the Noah in the video," or being "smarter than the video," raising concerns about the plausibility of the mathematical thinking demonstrated by the chatbot.

Table 2: Comparison of Authenticity Dimensions Across Two Chatbot Training Iterations

Dimensions	Key Indicators (Codes)	Iteration 1 ($N = 97$) (f, %)	Iteration 2 ($N = 54$) (f, %)
Linguistic Authenticity	Natural tone	26 (26.8)	13 (24.1)
	Unnatural tone	15 (15.5)	4 (7.4)
	Repetitiveness	19 (19.6)	2 (3.7)
Cognitive / Mathematical Authenticity	Student-like reasoning	28 (28.9)	14 (25.9)
	Non-student-like responses	2 (2.1)	14 (25.9)
	Misconception-like errors	6 (6.2)	2 (3.7)
	"I don't know"	8 (8.2)	0 (0)
	Nonsensical responses	9 (9.3)	1 (0)
Interactional Authenticity (Contingency)	Responsive	20 (20.6)	14 (25.9)
	Unresponsive	29 (29.9)	0 (0)
	Inflexibility	11 (11.3)	4 (7.4)
	Forgetfulness	1 (1.0)	0 (0)
	Reset	1 (1.0)	1 (1.9)

Overall, Iteration 1 was characterized by stronger cognitive authenticity but frequent interactional breakdowns, whereas Iteration 2 demonstrated improved contingency and conversational stability but reduced perceptions of student-like reasoning. This suggests that different models for AI-based chatbots have different affordances; future research should account for different dimensions of authenticity and could explore how authenticity might be improved across these dimensions to create a more robust approximation of practice for PSTs.

MATHEMATICS TEACHER EDUCATORS' ORIENTATIONS TOWARD AI USAGE FOR INSTRUCTIONAL PLANNING WITH A COMMON MATHEMATICAL TASK

Terrie M. Galanti
University of North Florida

This study begins to identify distinctions in mathematics teacher educator's (MTE's) orientations toward generative AI as a critical friend in instructional planning. As four MTEs from different universities, we individually interacted with AI to plan our usage of a common mathematical task in content and methods courses for prospective teachers. The Orange Juice proportional reasoning task provided a backdrop of "sameness" against which we could perceive differences in our decisions and actions. We identified two primary orientations: AI as a "thought partner" for pedagogical dialogue and AI as a "helping hand" for instructional resource generation. Implications for use of AI as a critical friend in collective MTE inquiry are offered.

Keywords: Teacher Educators, Preservice Teacher Education, Professional Development

Mathematics teacher educators (MTEs) design and facilitate courses to support prospective teachers in enacting task-based, student-centered instruction; developing an understanding of the mathematics they will encounter in their classroom; and recognizing how students' thinking might progress in relation to specific mathematical ideas (Zaslavsky & Leikin, 2004). In our prior work, we collaboratively developed and studied a collective MTE inquiry routine (Kochmanski et al., 2025) with the goal of structuring our own professional learning. This routine consists of consists of five elements: (a) the selection of a common mathematics task, (b) one-on-one planning conversations between each participating MTE and a critical friend, (c) the implementation of the common task, (d) one-on-one debriefing conversations between each participating MTE and a critical friend, and (e) a collective debriefing. The one-on-one planning and debriefing conversations can be challenging to schedule due to the significant demands on MTE time. In this study, we explore how MTEs might use generative AI technologies in a coaching or critical friend capacity during the second element of the collective MTE inquiry routine. This exploration examines distinctions in MTEs' orientations toward generative AI during instructional planning. If AI can serve as a critical friend in MTE instructional planning, then it may prove useful for making structured forms of collective inquiry more accessible to the broader MTE community.

Theoretical Background

As mathematics educators grapple with rapid advancements in AI and the place it should have in teaching and learning, the majority of research has focused on the capabilities and limitations of generative AI in doing mathematics (Zhuang et al., 2025). There are also a growing number of empirical studies by MTEs related to their own prospective teachers' use of AI as a lesson planning assistant (Gurl et al., 2024; Yanar & Ergene, 2025) and a problem solving assistant (Yilmaz at al., 2025). Frambaugh-Kritzer and Stolle (2025) examined the

affordances and limitations of AI as a critical friend within self-study, reporting that AI asked probing questions and provided meaningful feedback. Nishide and colleagues (2025) noted the importance of prompt engineering and the difficulty of building a flow within their communications with AI about teaching practice. They further argued that while ChatGPT as a critical friend could serve as a catalyst for deeper inquiry, it could not replace the situated, relational qualities of dialoguing with a human.

Collective MTE Inquiry Routine

The collective MTE inquiry routine integrates evidence-based aspects of self-study (Brandenburg, 2008), artifact-enhanced collegial inquiry (Van Zoest & Levin, 2021), lesson study and coaching (Gibbons & Cobb, 2017). Participants take an action research stance (Gellert et al., 2012), as they investigate the efficacy of their instruction. This routine is designed to be inclusive of the many different institutional contexts and types of courses that MTEs might teach. In this study, we examine the purposeful use of generative AI as a critical friend in the second of the five elements of MTE inquiry. This element emphasizes a one-on-one planning conversation between each MTE and a peer MTE. We position AI in the role of peer MTE in this element. The following question guided our investigation: How do MTEs use generative AI technologies as they plan to implement a common mathematics task with mathematics teachers?

Methods

We chose the Orange Juice task (Lappan et al., 2009) from Illustrative Mathematics as our common task because it elicits a range of representations of proportional reasoning strategies (See Figure 1). It is appropriate in both elementary and secondary teacher education contexts, allowing for a wide range of MTE learning goals related to teachers' content knowledge, interpretations of student thinking, and effective pedagogies. Each of the four MTEs had a conversation with a generative AI tool of their choice about their implementation of the common mathematics task in a course for pre-service teachers. The uniqueness of the contexts contributed to the richness of the conversations between the MTEs and AI in varied uses of the task.

Terrie planned to use the Orange Juice Task in her STEM teaching methods course for prospective secondary math and science teachers. Her goal for conversation with ChatGPT 5.2 was to generate ideas for modeling and reflecting on posing purposeful questions as an effective teaching practice (National Council of Teachers of Mathematics, 2014), She sought ideas for emphasizing the importance of proportional reasoning and tying together questioning frameworks from both disciplines (Cartier et al., 2013; Smith et al., 2018). The product of their conversation was a crosswalk of questioning strategies and sets of transcripts of student work with varied questioning approaches for pre-service teacher analysis.

Alee planned to use the task in a methods course for preservice secondary mathematics teachers. She engaged with Gemini to support her in figuring out how to integrate the task into a lesson focused on development of and alignment between unit goals and the unit assessment. During the conversation, Alee queried Gemini about ways to use the Orange Juice task that connected to the unit they taught from, while also leveraging the task as a learning opportunity. After back-and-forth dialogue about different pedagogical structures for the lesson, she decided on using the task to surface multiple different representations for solving with the purpose of informally assessing the problem for connections to unit goals.

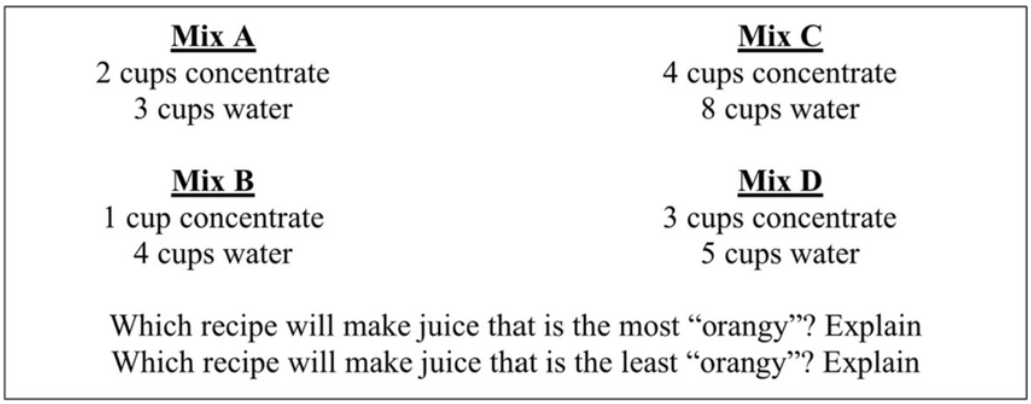

Figure 1: Orange Juice Task (Lappan et al., 2009)

Jonathan teaches two content courses (one undergraduate and graduate) that explore concepts related to proportional reasoning. He planned to use the task in both classes to support his students in the areas of anticipating student solution strategies and analyzing student thinking. Given these goals, he asked Google Gemini 3 to generate a list of potential student solution strategies. Jonathan was familiar with the many common strategies, but he was interested to see if Gemini would generate any additional plausible strategies. Additionally, he asked Gemini to create student solution strategies that involve common errors or misconceptions, such as using additive reasoning. Jonathan knows several common errors/misconceptions, but he was interested to see if Gemini would produce any "novel" ones. For both requests, Gemini provided five potential solution strategies, and after prompting, it generated several additional strategies.

Nick planned to implement the task in a content course for middle grades mathematics teachers that primarily focused on essential understandings related to ratios and proportions. His goal for his conversation with ChatGPT 5.2 was to produce a set of students' work that he could use in the class, as well as produce evidence of pedagogical reasoning that students might make sense of and critique. Nick used ChatGPT 5.2 to first produce five ways in which students might solve the Orange Juice Task. He then asked ChatGPT 5.2 to select three of the five strategies to feature in a discussion and put them in a sequence, explaining why the AI made the decisions it did. In the class, Nick first asked the mathematics teachers to solve the Orange Juice Task on their own. Then, having discussed their strategies, he shared ChatGPT's work with the teachers in his class. He asked the teachers to look for similarities and differences in the strategies the class produced as compared to ChatGPT. He also asked the class to critique the AI's decisions related to selecting and sequencing strategies for a discussion.

We engaged in remote, collaborative qualitative analysis (Sauder et al., 2023) of screenshots of the human–AI dialogues and transcripts of our Zoom conversations. Each MTE first conducted an open coding of their own AI interaction, attending to how AI was taken up in instructional planning and the purposes guiding each prompt. We then met synchronously to share initial coding and identify recurring patterns across cases. Through iterative discussion and constant comparison, we developed and refined two overarching categories that captured qualitatively different ways of engaging with AI during planning. Disagreements were resolved through dialogue, with attention to grounding inferences in specific excerpts from the data.

Findings

We identified two broad orientations for the use of AI in instructional planning. Terrie and Alee treated AI as a "thought partner" who could surface alternative ideas and support pedagogical sensemaking. Jonathan and Nick treated AI as a "helping hand" who could generate student strategies and streamline lesson planning. Below, we provide two representative examples of these different approaches.

Alee started her conversation with AI by prompting, "I would like you to brainstorm with me for a lesson plan." She provided her purpose, a picture of the task, and course objectives related to assessment. Subsequent interactions resembled the exchange of ideas between two human MTEs. In one such interaction, AI responded with a set of "Conceptual Learning Goals" and offered to "brainstorm 2–3 specific Check for Understanding questions." Alee clarified that "learning goals do not start with 'I can,'" highlighting that learning goals are written for teachers. She positioned AI as a "thought partner" that she could challenge and redirect.

In contrast, Jonathan and Nick treated generative AI in a "helping hands" manner, asking it to produce work to increase the efficiency of their lesson planning. Jonathan uploaded the task to AI and prompted, "Please solve this problem using as many different strategies as you can. Identify the strategies that you use". Each of the subsequent prompts by Jonathan elicited a deeper explanation or an elaboration on an AI response, most often taking the form of another question. Prompts included, "What are some other possible student solution strategies that involve common errors or misconceptions?" and "What would be a logical follow-up question to this task?" AI offered to create a practice quiz and demonstrate how to use a ratio table to help students to visualize errors. These patterns of asking questions and reviewing answers along with MTE acceptance of AIs offers to create resources were consistent with a "helping hands" orientation toward use of AI.

Discussion and Conclusions

These two orientations towards AI reflect different perceptions of the potential role of AI in instructional planning. Terrie and Alee elicited pedagogical dialogue in their interactions with AI as a "thought-partner," while Jonathan and Nick looked to obtain resources by positioning AI as a "helping-hand." In both cases, MTE expertise shaped the productivity of the interactions, and all MTEs acknowledged that these orientations could shift depending on instructional goals.

Our findings suggest that AI can support the one-on-one planning phase of the collective inquiry routine, but the depth of this support depends less on the tool itself and more on how MTEs engage with it. Positioning AI as a "thought partner" more closely aligns with the peer coaching element of the inquiry routine because MTEs actively challenge and refine AI responses. By contrast, using AI as a "helping hand" offers fewer visible opportunities for deeper pedagogical inquiry than conversations with a critical friend might offer.

As research on how MTEs study their own practices, contexts, and development in their work to support prospective teachers' learning continues to gain traction (e.g., Castro Superfine & Pitvorec, 2021; Medová et al., 2020), the usefulness of AI as a support for professional learning needs further exploration. While this study focused on how AI might support an MTEs' instructional planning, we also noted that each of us gained new insights into how we might purposefully use AI with our own students. As AI becomes increasingly integrated within mathematics teaching and teacher education, understanding how MTEs deliberately and reflectively engage with AI will strengthen our readiness to meet the needs of tomorrow's teachers.

EXPLORING THE ASSOCIATION BETWEEN AI INTERACTION LEVELS AND MATHEMATICAL MODELING PERFORMANCE IN PRESERVICE SECONDARY TEACHERS

Yasemin Gunpinar
University of Texas at Tyler
ygunpinar@uttyler.edu

Nirmala Naresh
University of North Texas
nirmala.naresh@unt.edu

This study examines how preservice secondary teachers interact with a conversational Artificial Intelligence (AI) tool during a mathematical modeling task and how interaction relates to performance. Nineteen participants first completed a shipping box design problem independently and then revisited the task using Khanmigo. AI interactions were classified as foundational, constructive, or creative, reflecting the depth of reasoning and questioning. Analysis focused on changes in modeling performance and patterns of AI use. Results indicate that overall performance improved after AI engagement, with higher scores associated with constructive interaction. No students demonstrated creative engagement. These preliminary findings suggest that structured AI interactions can enhance mathematical modeling performance and highlight opportunities to cultivate reflective AI literacy in teacher preparation.

Keywords: Modeling, Preservice Teacher Education, Technology

In the field of mathematics education, advances in generative artificial intelligence (AI) have fueled interest in how new tools can support students' reasoning (e.g., Joung & Kim, 2026; Yoon et al., 2024), teachers' decision-making (e.g., Yilmaz et al., 2026), and programmatic goals in teacher education (U.S. Department of Education [USDOE], 2023). The National Council of Teachers of Mathematics (NCTM) argues that AI has legitimate potential to personalize tasks to students' interests, surface partial understanding, and assist teachers in assessment and planning (NCTM, 2024). At the same time, it is critical that teacher agency and autonomy remain central, and that AI use is guided by transparency, ethical awareness, and attention to bias in outputs (Dykema, 2023). In this way, AI can amplify both students' thinking and teachers' professional judgment while supporting equity, privacy, and instructional integrity.

In teacher education, emerging studies call for developing AI literacy to help preservice mathematics teachers (PMTs) interrogate AI outputs and design learning environments where AI augments, rather than automates, mathematical reasoning (Yilmaz et al., 2026). Mathematics teacher educators (MTEs) are exploring ways to integrate AI tools into PMT coursework, shaping not only what mathematics is learned but how PMTs reason, reflect, and position themselves as future teachers (Aqazade et al., 2026; Joung & Kim, 2026). Structured engagement with AI-supported modeling tasks, coupled with rubric-guided reflections, has been shown to allow PMTs to experience AI as a thought partner (Kim et al., 2026; Naresh & Gunpinar, in press; Sawyer, 2024). Building on this work, the current study reports preliminary findings from one semester of a larger, multi-semester research program examining how structured interactions with a conversational AI tool, Khanmigo, influence PMTs' mathematical reasoning and engagement. This study addresses the research question: To what extent is the level of AI interaction associated with mathematical modeling performance among preservice secondary teachers?

Theoretical Lens

AI tools used in mathematics education range from answer-oriented utilities, such as camera calculators and symbolic solvers, to adaptive platforms and intelligent tutoring systems that support guided dialogue (Vaerenbergh & Pérez-Suay, 2022). Generative AI tools add a conversational layer, explaining procedures, responding to questions, and engaging in interactive problem solving (AI for Education, n.d.). Investigating the role of AI in mathematical problem-solving raises questions about how learners position AI within their activity.

The Instrumental Genesis perspective (Sinclair et al., 2023) describes how digital tools become integrated into mathematical practice. The distinction between a tool as an artifact and as an instrument emphasizes how learners develop schemes of use through purposeful activity. As learners appropriate the tool, it organizes both action and understanding, highlighting the role of teachers in coordinating tools, tasks, and interactions to support conceptual understanding. This lens draws attention to how design features and AI affordances invite particular representations and actions and underscores the interplay between performing techniques and articulating mathematical ideas (Trouche, 2020).

Analytical Frameworks

Two conceptual frameworks guided analysis. The first, from the Maryland Comprehensive Assessment Program (MCAP), conceptualizes mathematical modeling as integrated acts of sense making, including framing the situation, selecting and coordinating information, and articulating reasoning that can be tested and refined (Maryland State Department of Education, 2023). The second framework describes PMTs' engagement with AI along three levels: foundational engagement treats AI as a source of recall and procedural guidance, constructive engagement treats AI as a partner for explanation and strategy development, and creative engagement treats AI as a collaborator for exploration and novel generalizations (Naresh et al., 2024a). These frameworks allow examination of both the depth of mathematical reasoning and the quality of AI interaction.

Methods

The overall study employed a mixed methods research design and the data reported in this paper were analyzed descriptively. The study was conducted in a university mathematics content course for undergraduates pursuing secondary teacher certification. This course was taught by the second author. Twenty-two PMTs were enrolled, and analyses reported here include the 19 participants who consented to research use of their work under institutional review protocols. The authors have been engaging PMTs in their respective classroom contexts in the use of AI tools for mathematical problem solving. Based on lessons learned from prior semesters (Naresh & Gunpinar, in press; Naresh et al., 2025), a key pedagogical decision in the semester under study was to implement a planned intervention that structured how PMTs engaged with AI tools. This intervention was designed to support more intentional mathematical learning by having PMTs work purposefully with a generative AI (Khanmigo) tool during mathematical modeling activities during class time rather than using it only as a supplemental tool for out-of-class projects (Naresh et al., 2024b).

Data were collected across three phases: pre-intervention, intervention, and post-intervention. In this paper, we report on a part of data collected during the pre-intervention phase. At the start of the semester, PMTs completed a candy container package design task independently during class time. This task involved designing a rectangular box to hold 16 identical cylindrical candy containers while minimizing cardboard use (Virginia Department of Education, n.d.). The task

was selected because it (a) elicited decisions about container arrangement and packing efficiency, (b) required attention to dimensional constraints, and (c) encouraged comparison of layouts using surface area as a measure. Additionally, the task provided opportunities for PMTs to frame, refine, and validate solution paths. PMTs were asked to state and justify assumptions, provide diagrams, and include calculations supporting their proposed dimensions. After submitting their independent solutions, PMTs then solved the same problem using Khanmigo. The primary data sources included PMTs' independent and AI-supported solutions, transcripts of their interactions with AI, and follow-up reflections on their interactions with Khanmigo.

Data analysis focused on both changes in PMTs' mathematical modeling performance and patterns of AI engagement. Scores were assigned according to the MCAP four-point rubric, and AI interactions were categorized as foundational, constructive, or creative. Performance on the box design task was compared between the first independent attempt and the second AI-supported attempt. Patterns of PMT-AI engagement were then examined in relation to performance scores to identify whether more sophisticated engagement was associated with higher mathematical modeling outcomes. Additionally, illustrative excerpts from selected PMT-AI interactions were analyzed to characterize the nature of foundational and constructive engagement.

Findings

Among the 19 participants, mathematical modeling performance improved substantially following AI interaction. Initially, only 16% of students achieved the highest score of three points, while 42% scored one point, 37% scored two points, and one student scored zero (Table 1). On the second attempt, no students scored zero or one point, 53% earned two points, and 47% earned three points. Overall, the data show that all students either improved or maintained their performance, with nearly half achieving the highest performance level after AI-supported engagement.

Table 1: Math Modeling Performance Change from First Attempt to Second Attempt with Khanmigo (*n* = 19)

Math Modeling Performance	First Attempt	Second Attempt
0 point	1 (5%)	0
1 point	8 (42%)	0
2 points	7 (37%)	10 (53%)
3 points	3 (16%)	9 (47%)

In Table 2, a clear pattern emerged between AI engagement and performance. Students with foundational AI interaction predominantly earned two points, responding briefly and following AI prompts without extending reasoning. Students with constructive engagement showed stronger performance overall, with 37% achieving three points, using AI to explain, justify, and refine their solutions. No students reached the creative engagement level, indicating that novel exploration was not observed in this phase.

Table 2: The Relationship between AI Interaction and Mathematical Modeling Performance (*n* = 19)

Redo with Khanmigo	Foundational	Constructive	Creative
2 points	9 (47%)	1 (5%)	0
3 points	2 (11%)	7 (37%)	0

Illustrative examples further highlight these patterns. One student with foundational engagement responded to AI prompts with short statements such as "two rows of eight" or "6," following Khanmigo's guidance without elaboration. In contrast, a student demonstrating constructive engagement proposed detailed arrangements, pressed the AI for clarification about efficiency, and questioned the reasoning behind alternative layouts, reflecting more sophisticated mathematical reasoning.

Discussion and Conclusions

These preliminary findings suggest that structured engagement with conversational AI can enhance mathematical modeling performance among preservice secondary teachers. Constructive engagement, characterized by active reasoning, iterative questioning, and explanation, was associated with the highest performance levels, while foundational engagement supported moderate improvement. The absence of creative engagement suggests that additional scaffolding or task design may be needed to elicit novel problem-solving strategies with AI. Overall, these findings underscore the potential of conversational AI as a tool to support mathematical reasoning and highlight opportunities to cultivate reflective and critical AI literacy in teacher preparation. As part of a larger, ongoing study, these results provide initial insights into the interplay between AI engagement and student performance.

In our ongoing analysis we intend to examine patterns of engagement across a larger sample and additional modeling tasks, including fine-grained coding and qualitative analyses of interaction sequences and specific prompting moves. We will also draw on the instrumental genesis perspective (Sinclair, 2023; Trouche, 2020) to examine how PMTs appropriate conversational AI within their mathematical activity and how patterns of engagement reflect emerging schemes of use. These analyses will also strengthen interpretations of the relationship between PMTs' AI use in mathematics modeling in the current study and inform future iterations of AI-supported modeling tasks in teacher education.

CROSSING THE DIVIDE: A DISSERTATION STUDY OF COMPUTING INTEGRATION IN MATHEMATICS TEACHER EDUCATION

Rebekah Hanak
University of Missouri, Columbia
rrhd2b@missouri.edu

This study examines how mathematics teacher educators (MTEs) with computing-related expertise conceptualize and situate computing within mathematics teacher education programs. As computing becomes more visible in K–12 policy, standards, and professional discourse, teacher preparation programs are beginning to integrate computing in varied ways. This qualitative multi-case study draws on semi-structured interviews with six MTEs across institutions in the U. S. as well as associated curricular artifacts from their teacher education courses. Guided by Schoenfeld's (2011) goal-oriented decision-making framework, preliminary cross-case analyses reveal substantial variation in MTEs' goals, orientations, and resource landscapes—including varied policy contexts—and differences in how computing is represented, positioned, and integrated within mathematics teacher education programs.

Keywords: Teacher Educators, Preservice Teacher Education, Computing and Coding, Computational Thinking

Introduction

Mathematics and science are becoming increasingly computational, with computational thinking (CT) gaining prominence in professional practice and national standards (ACM Education Policy Committee, 2014; NGSS Lead States, 2013). Research has shown that computing-integrated tasks can support mathematical reasoning, modeling, and problem solving when designed in mutually supportive ways (Bih Fofang et al., 2020; Weintrop et al., 2016). Integration, however, does not automatically yield such mutual support; computational activities can also drift into disconnected coexistence with mathematical goals rather than deepening disciplinary understanding.

Preparing teachers to navigate this complexity remains an open challenge. Preservice teachers often enter methods courses with emerging but underdeveloped understandings of computing and CT, and relatively little is known about how best to support their development in these areas (Moon et al., 2023; Yadav et al., 2014). Although innovative modules and embedded coursework have begun to address this need, less attention has been paid to how MTEs themselves conceptualize and situate computing within teacher preparation programs.

This study examines computing integration in mathematics teacher education from the perspective of MTEs and the curriculum materials they design and provide. Guided by Schoenfeld's (2011) goal-oriented decision-making framework, the study addresses (RQ1) how MTEs with computing-related expertise from different universities across the United States (a) envision the integration of computing within mathematics teacher preparation programs and (b) interpret and evaluate existing approaches for integration, and (RQ2) how computing is represented, positioned, and integrated within the curriculum materials associated with those programs. By attending to how MTEs conceptualize and situate computing within mathematics teacher preparation programs, this study illuminates emerging models of integration and the structural and pedagogical conditions shaping this work.

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

Conceptual Framework

This study draws on Schoenfeld's (2011) goal-oriented decision-making framework to examine how MTEs conceptualize and situate computing within teacher preparation. Schoenfeld argued that instructional decisions can be understood through three interrelated constructs: goals, resources, and orientations. These constructs interact in particular ways as individuals interpret a situation, draw on available resources, and act in ways aligned with their goals and beliefs.

Applied to mathematics teacher education, this framework provides a lens for examining how MTEs' approaches to computing integration are shaped by the goals they hold for preservice teachers (e.g., disciplinary depth, innovation, equity, policy alignment), the resources available to them (e.g., curricular materials, institutional structures, time, technological infrastructure), and their orientations toward computing (e.g., enrichment, core disciplinary practice, pathway to access). Importantly, state and institutional policy contexts are conceptualized as part of the resource landscape that enables or constrains integration, influencing how MTEs interpret what is possible or necessary within their programs. This framework guides analysis of interview data (RQ1) by foregrounding the rationales underlying MTEs' visions alongside their interpretations and evaluations of existing approaches.

To examine how computing is situated in the MTEs' teacher education practice (RQ2), curriculum artifacts were analyzed along three dimensions. First, the analysis attended to how computing is represented—that is, the scope of activities or practices treated as computational (e.g., programming, robotics, algorithmic reasoning, or unplugged activities). Second, the analysis considered where computing is positioned within program structures (e.g., embedded in teaching methods courses, located in educational technology courses, or offered as stand-alone computer science (CS) courses). Third, the analysis examined how computing is integrated relative to mathematics—whether it is framed primarily as a tool for mathematical exploration or as disciplinary content in its own right. Together, these dimensions provide a structured lens for understanding variation in how computing integration takes shape, or is situated, across institutional contexts.

Method

Research Design

This study employed a qualitative multi-case design to examine how MTEs conceptualize and situate computing integration within mathematics teacher education programs. The study focuses on two primary data sources: semi-structured interviews with MTEs (RQ1) and associated curricular artifacts (RQ2). The design allows for examination of individual institutional contexts while supporting cross-case comparison of integration models.

Participants, Context, and Data Sources

Participants include six MTEs with computing-related expertise from large public universities across the United States. Institutions were selected to encompass variation in how computing is integrated within mathematics teacher preparation, including programs that embed computing within methods or educational technology courses and programs that offer stand-alone computer science coursework. While all participants have experience engaging with computing in some capacity, the extent and structure of integration vary across sites. All participant names used herein are pseudonyms.

Data consist of (a) two semi-structured interviews with each MTE (45–60 minutes); and (b) curricular artifacts provided by participants, including syllabi, assignments, and instructional materials from courses that entailed computing. Interview questions probed participants' goals, orientations, and resources related to computing integration in mathematics teacher education

with attention to varied state and institutional policy contexts. Curriculum artifacts provided evidence of how computing is represented, positioned, and integrated within coursework.

Data Analysis

Interview transcripts were analyzed using thematic analysis (Braun & Clarke, 2006) through an inductive–deductive approach. Initial open coding identified emergent themes, followed by focused coding informed by Schoenfeld's (2011) constructs of goals, orientations, and resources. Institutional and policy contexts were examined as part of the resource landscape shaping decision-making. Analytic memos were developed to support cross-case comparisons and theory building with analysis remaining iterative as patterns were refined across cases.

Curriculum artifacts were analyzed through document analysis guided by three dimensions: (a) representations of computing, (b) how computing is positioned within program structures, and (c) how computing is integrated relative to mathematics. Cross-case comparisons were conducted to identify patterns and variation in integration models across institutional contexts. Findings reported here reflect preliminary analyses.

Findings

Guided by Schoenfeld's (2011) framework, this section is organized around key findings in relation to variation in MTEs' goals, orientations, and resource landscapes (RQ1), and the implications of this variation for how computing is represented, positioned, and integrated within curriculum artifacts (RQ2). Preliminary cross-case analysis reveals distinct models of computing integration emerging from the interaction of these constructs.

Finding 1 (RQ1a)

MTEs articulate distinct goals for computing integration in teacher preparation. Across cases, MTEs articulated distinct primary goals for computing integration in mathematics teacher education. These goals functioned as organizing logics for instructional and programmatic decisions. One participant emphasized preparation for future learning, arguing that PSTs should leave with a flexible conceptual framework that allows them to incorporate emerging tools, without computing being a barrier. Another MTE had a goal of computing being an epistemic extension of mathematical practice, insisting that integration must deepen mathematical reasoning rather than function as a technological demonstration. A third framed computing as preparation for disciplinary evolution toward data science, emphasizing modeling practices, workforce relevance, and teacher self-efficacy in CS. A fourth described computing as a means of making mathematical reasoning explicit and testable, while attending to affective safety and broadening participation.

These distinct goals shaped how participants evaluated the purposes, depth, and necessity of computing within their programs.

Finding 2 (RQ1a + RQ2)

MTEs' orientations toward computing shape what counts as integration and how it appears in coursework. Participants differed in how they conceptualized computing, reflecting distinct orientations toward the role of technology in mathematical practice. For some, computing encompassed a broad spectrum of tools used to make mathematical processes visible. For others, computing was defined more narrowly as interaction with technological systems that function as representational media for exploring, generalizing, and modeling. Another orientation centered computing on data analysis and iterative modeling as core disciplinary practice. Still another emphasized computing as abstraction and communicative precision, requiring learners to formalize procedures in ways that make reasoning explicit and testable.

Despite this variation, a shared throughline was that computing becomes valuable when it makes mathematical structure visible, revisable, and accountable. For example, when preservice teachers programmed regrouping logic in a non-base-ten system, errors in their code immediately revealed misconceptions about place value, requiring them to revise their reasoning rather than rely on informal explanation.

These orientations have direct implications for RQ2. Preliminary artifact analysis suggests that differences in definition of computing correspond to differences in representation (e.g., robotics modules, coding-based representational tasks, data-modeling sequences), positioning (embedded in methods, located in educational technology courses, or structured as standalone CS pathways), and integration (computing framed as an exploratory tool, disciplinary practice, or parallel content area).

Finding 3 (RQ1b)

Resource landscapes mediate feasibility, sustainability, and programmatic placement. Participants consistently described integration as shaped by resource conditions, including funding, institutional structures, credit-hour constraints, disciplinary expertise, and policy context. Statewide infrastructure, grant funding, and collaborative networks enabled sustained integration in some contexts, while shrinking coursework, overloaded methods classes, enrollment pressures, and accountability systems constrained depth in others. Legislative pathways and endorsement structures influenced whether computing could be embedded, required, or offered as standalone coursework. Several participants noted that reliance on local "champions" can both enable innovation and produce inequitable distribution of opportunities. As one MTE reflected, "Right now it works because I'm here and pushing it. But I don't know if it would survive without someone advocating for it." This comment underscores how integration is often sustained through individual initiative rather than structural guarantees.

In Schoenfeld's terms, these resource landscapes shape how MTEs interpret what is possible and necessary within their programs. Decisions about where computing is positioned (embedded vs standalone), whether it is required or elective, and how extensively it is integrated reflect not only pedagogical commitments but structural feasibility.

Cross-Case Synthesis

Integration models emerge from the interaction of goals, orientations, and resources. Taken together, these findings suggest that computing integration in mathematics teacher education is best understood not as a single reform effort, but as a set of contextually mediated models shaped by interacting goals, orientations, and resource landscapes. Attending to these interactions provides a framework for understanding why integration takes different forms across programs—and what structural and pedagogical conditions may support more coherent and equitable approaches moving forward.

Acknowledgments

This brief report is based on a dissertation study under the advisement of Samuel Otten and the guidance of Corey Webel, Tiffany LaCroix, Laura Ridenour, and Jeremy Zelkowski. I thank all the participating MTEs for sharing their time and expertise.

PROSPECTIVE TEACHERS' USAGE OF GENERATIVE ARTIFICIAL INTELLIGENCE TO CREATE IMAGES FOR MATHEMATICAL STORY PROBLEMS

Hamilton L. Hardison
Texas State University
Hhardison@txstate.edu

Dai Duong Le
Texas State University
ppa25@txstate.edu

We discuss our first-time implementation of Adobe Firefly into a mathematics content course for prospective elementary and middle grades teachers (PTs). Our intention was to respond to calls from professional organizations and support PTs in learning one new way to integrate generative artificial intelligence in the mathematics classroom. Throughout the course, PTs occasionally engineered images to accompany mathematical story problems. On the final examination, they designed multiple images to accompany a single problem, and they discussed visual features that offered elements of challenge or support for solving the problem. We analyzed the features PTs identified and found that they attended to a variety of visual elements when considering levels of support and challenge for the images they created.

Keywords: Number Concepts and Operations, Technology, Artificial Intelligence, Imagery

Artificial intelligence (AI) is in vogue, and professional organizations like the National Council of Teachers of Mathematics (Dykema, 2023) have tasked mathematics educators with determining how to integrate it into our profession; at this time, exactly how this should be accomplished remains largely an open question. Presently, we characterize our field as being in a state of exploration regarding the possibilities permitted by AI—mathematics educators are examining what these tools can do and how to use them in educational spaces.

Walkington (2025) synthesized four main uses of GenAI in the field: (a) mathematics problem-solving, (b) mathematics tutoring and feedback, (c) adapting mathematical tasks to learner needs, and (d) supporting mathematics teachers in planning. When reading about the work that researchers are currently doing, we noticed that some researchers are examining how AI can do the present work of teaching more efficiently. We certainly find importance in this work as teachers' time is valuable and maximizing the impact of that time is critical. We also think it is important to examine new pedagogical possibilities afforded by AI regardless of their time-saving status, which is the focus of our present work. In other words, we are interested in new ways to support learning that would not be possible or practical without AI (Hardison & Goméz-Marchant, 2025). For example, in this report, we focus on how prospective elementary and middle grades teachers designed images to accompany mathematical story problems and the features they considered in assessing the levels of support and challenge offered by the images they designed. We address the research question: What visual features do prospective teachers consider when designing AI-generated images to accompany division story problems?

Background

We link our project to the work of Steven Greenstein and Pat Thompson. From Greenstein and colleagues (2023), we draw on a perspective that positions prospective teachers as agents of curricular change. In this view, teachers are framed as designers of classroom artifacts. For example, Greenstein et al. (2023) supported prospective teachers as they designed and 3D-printed fraction manipulatives to use in mathematically pedagogical interactions with children. Here, rather than focus on 3D-printed manipulatives, we focus on images PTs designed using Adobe Firefly, which is a GenAI that takes natural language inputs for generating imagistic

outputs. Drawing on Thompson (2002), we are particularly interested in artifacts that teachers design as didactic objects, which are simply artifacts intended to support reflective mathematical discourse. Thompson notes that objects become didactic when they are mentally coupled with anticipations of discussing particular mathematical ideas. We consider these images to be didactic objects precisely because prospective teachers considered factors that might support or challenge students mathematical thinking as they solved the accompanying story problem. We discuss our methods below.

Methods

The project focused on our first-time implementation of Adobe Firefly into two sections of an undergraduate course for prospective teachers (PTs). The course focused on number and operations in the elementary and middle grades and included, for example, types of story problems (Carpenter et al., 1999) for supporting children's reasoning about the four basic operations. Throughout the course, PTs occasionally used Adobe Firefly to generate images to accompany mathematical contexts.

For the present report, we focus on data from 23 PTs who were enrolled in one section. Specifically, we report on final exam responses wherein PTs were asked to (a) author a story problem for the division $6 \div 4 = \square$, (b) engineer three accompanying images offering varying levels of support and challenge, and (c) to discuss the visual features accounting for these levels.

Data analyzed include the problem PTs wrote, the prompts PTs submitted (three prompts per PT), and the rationales indicating features impacting the relative support or challenge within each image. Here, we focus exclusively on analyzing the rationales PTs provided. To analyze this data, we engaged in open coding. We began by independently analyzing PTs responses individually in descriptive terms. Then, we came together to discuss our analyses and worked to collapse our descriptive terms into broader features that were reflective of responses across PTs. Eventually, the codes reached a point of stability wherein no further changes occurred

Results

We begin by presenting an example to elaborate our current categories and corresponding features that PTs identified as impacting levels of support and challenge (Table 1).

Table 1: An Example of Problem, Prompts, and Images produced by PT1

Problem: There are six chocolate chip cookies to be split among four kids. How many cookies will each kid get?		
Low Support, High Challenge Prompt: Many chocolate chip cookies of different sizes with a jar of cookies in the background	**Medium Support, Medium Challenge Prompt:** 6 separate chocolate chip cookies on a plate	**High Support, Low Challenge Prompt:** In the middle of the picture, have 6 chocolate chip cookies all on top of one plate; on the edges of the picture, have four empty plates; five plates total in entire picture
		

The block quotation below presents a partial rationale offered by this prospective teacher:

> I consider a picture to offer low support if the quantity does not match what is specified in the problem. There are six cookies grouped more so together in the middle, but there are a few beside them and in jars in the background. These cookies being stacked it would be more challenging to picture splitting them each up from the picture alone. I liked how there is a bit of support with one cookie facing mostly forwards to show the circular shape which is a nice shape to be able to divide.
>
> The medium level support picture is more straightforward and connects well with the problem to offer good support. There are exactly six cookies each spaced apart from one another to be distinct. The view from above helps to show all of their circular shapes clearly. There are many ways students can interact with the picture itself to solve the problem. This is in the medium level because there aren't the four children in the problem accounted for.
>
> The high-level support expands off the adequate second picture to account for not just the quantity of cookies from an above view but also the four children for them to be split amongst. For higher optional support, there are four different colored empty plates surrounding the six cookies that students can think of distributing how they choose onto each plate to solve the problem. I edited them to be different colors to help for thinking of each of the four kids. I liked their placements making them similar still by them all surrounding the middle filled plate.

We note PT1 attended to several features as they designed these three images to offer varying levels of support and challenge. For example, PT1 indicates purposefully designed images with considerations of whether image dividend and divisor match the story problem. PT1 explained in their rationales that "the quantity does not match what is specified in the problem" in the first image and "there aren't the four children" in the second image. PT1 also attended to the background and whether items are easy to see and share in the generated images. For the second image, PT1 claimed that "There are exactly six cookies each spaced apart from one another to be distinct. The view from above helps to show all of their circular shapes clearly."

We abstracted 9 different features PTs attended to when considering images' levels of support and challenge (Table 2). We retroactively organized these features into two categories: (a) features that account for individuals' initial interpretation of the problem and (b) features that account for individuals' partitioning and sharing actions. For example, 61% of PTs attended to whether and how items were partitioned in the image, which is important for the given number choices since a fair share will necessarily involve a fractional part of the dividend quantity. Some PTs (39%) described that representations of the quotient in the image impacted the level of support and challenge for the image. Most PTs (52%) considered whether the dividend quantity represented in the image matched the numerosity specified in the problem and nearly half of PTs (48%) similarly considered whether the divisor quantity was appropriately represented. Finally, some PTs used labels (9%) to indicate partitioning or to assign shares of the dividend quantity.

PTs also attended to items related to individuals' initial interpretation of the problem—attending to the qualities of the background (4%) or attending to whether items were easy to see (17%). We were intrigued that so many prospective teachers (26%) considered whether the dividend quantities were homogeneous or heterogeneous. In other words, this code was assigned when prospective teachers considered whether the dividend quantity items were equivalent (cookies of the same shape) or distinguishable (e.g., cookies of different shapes). Shape was one of several features PTs considered with respect to homo- and heterogeneity. For example, some

prospective teachers distinguished items along lines of size or color. Finally, some PTs (9%) also attended to whether some shapes might be more difficult to think about sharing in the first place (e.g., triangular shapes might be more challenging to share than circular shapes).

Table 2: PT-Indicated Features Impacting Level of Support and Challenge

Category	Feature	Number of PTs (%)
Interpretation of the Problem	Background	1 (4%)
	Obscured or easy-to-see items	4 (17%)
	Homogeneous vs heterogeneous dividend quantity	6 (26%)
	Some shapes easier to share than others	2 (9%)
	Partitions	14 (61%)
Partitioning and Sharing Action	Quotient represented	9 (39%)
	Whether image dividend quantity matches problem	12 (52%)
	Whether image divisor quantity matches problem	11 (48%)
	Measurements or labels	2 (9%)

Discussion and Conclusion

In this report, we discussed aspects of our first-time implementation of Adobe Firefly into a course for prospective elementary and middle grades teachers. In the above sections, we have presented an accounting of the features that PTs identified as impacting levels of support and challenge offered by images accompanying mathematical story problems. The rationales offered by the PT reflect their considerations of visual features salient in the didactic objects they created.

We noted in our study that many prospective teachers attended to aspects of the image that we associate with the partitioning and allocation process. In other words, they did not view these images as simply decorative pictures. Future research may more closely investigate how prospective teachers can use image GenAI to produce illustrations that align with models of students' thinking from extant research.

We also note that in this report we focused on static imagery. Generative AI models are now capable of generating video from natural language input. Therefore, future research might also investigate how prospective teachers can generate their own dynamic videos to illustrate mathematical concepts or otherwise support students' mathematical thinking.

We wish to close with some words of caution. First, we encourage educators and researchers alike to critically analyze the images produced since biases in training data may yield biases in imagery (Goméz-Marchant & Hardison, 2024). We also emphasize that we are exploring pedagogical possibilities with AI. Questions remain regarding the pros and cons of actually incorporating these AI-generated images into mathematics instruction.

DESIGNING AND RECOGNIZING FORMATIVE ASSESSMENT IN DIGITAL LEARNING ENVIRONMENTS

Suzanne R. Harper
Miami University

Dana C. Cox
Miami University
Dana.Cox@MiamiOH.edu

This qualitative study investigates how prospective secondary mathematics teachers (PSMTs) design and recognize formative assessment in Amplify Activity Builder. Analyzing 16 designs and 50 peer reviews, we found a critical disconnect: PSMTs prioritized explicit, teacher-mediated feedback (e.g., text inputs) but largely overlooked the "epistemological feedback" inherent in dynamic tools (e.g., sliders). Results suggest PSMTs view digital tools as media substitution. We argue teacher education must explicitly train PSMTs to recognize how dynamic technological consequences function as immediate feedback.

Keywords: Formative Assessment, Preservice Teacher Education, Technology

Despite widespread recognition that formative assessment practices significantly improve student mathematical learning (Lee et al., 2020) and are essential components of effective instruction (Black & Wiliam, 2009), teacher preparation programs face persistent challenges in developing these competencies in prospective teachers (Cevikbas et al., 2024). These challenges intensify when integrating digital technologies, where the affordances and constraints of the medium fundamentally reshape how teachers can elicit, interpret, and respond to student thinking. As mathematics classrooms increasingly incorporate technology-enhanced learning environments, understanding how prospective teachers learn to design and recognize formative assessment opportunities within these contexts becomes critical for teacher education.

This study addresses this gap by examining how prospective secondary mathematics teachers (PSMTs) incorporate and recognize formative assessment practices when designing interactive mathematics activities using Amplify Activity Builder (AAB), a dynamic digital platform that combines graphing calculators, dynamic geometry tools, and real-time student response systems. Specifically, we investigate: (RQ1) What opportunities for feedback that moves learners forward do PSMTs incorporate in Activity Builder designs? and (RQ2) What opportunities do PSMTs recognize when reviewing their peers' designs?

Related Literature

Formative assessment (FA) occurs when teachers use evidence of student learning to make informed instructional decisions that move learning forward (Black & Wiliam, 2009). Research links effective FA to improved learning outcomes, engagement, and self-regulation (Lee et al., 2020; Leenknecht et al., 2021; Brookhart & Chen, 2015), making it to effective mathematics instruction and teacher education (Association of Mathematics Teacher Educators [AMTE], 2017; Conference Board of the Mathematical Sciences [CBMS], 2012). However, effective FA is not simply discrete techniques; it is a continuous, multi-step cycle requiring teachers to simultaneously gather evidence of student thinking, interpret this evidence, provide feedback, and make real-time instructional adjustments (National Council of Teachers of Mathematics [NCTM], 2014). For prospective teachers still developing pedagogical expertise, orchestrating these interconnected processes represents a significant challenge, particularly in unfamiliar technological environments.

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

Digital learning environments like AAB offer both affordances and constraints for FA. AAB incorporates Desmos Graphing Calculator technology with dynamic geometry tools and virtual manipulatives, providing real-time, interactive feedback mechanisms for both students and teachers. When combined with well-designed tasks, AAB can help teachers engineer high-quality class discussions built on student thinking and create opportunities for meaningful feedback, seminal FA strategies (Wiliam & Thompson, 2008) that benefit from auditable trails of mathematical thinking (Harper & Cox, 2018).

Yet designing effective AAB lessons is not as simple as translating existing curriculum into a digital format. Effective digital design requires pedagogical transformation, not merely media substitution (Puentedura, 2013). While research documents formative assessment's importance and implementation challenges, less is known about how prospective teachers learn to design and recognize formative assessment opportunities within specific digital tools. Understanding what PSMTs recognize and overlook when designing and reviewing technology-enhanced activities can inform how teacher educators support the development of these critical competencies.

Theoretical Framework

This study draws on Wiliam and Thompson's (2008) theory of formative assessment to guide our analysis of how teachers design tasks in AAB that support FA practices. Black and Wiliam (2009) conceptualized FA not as discrete techniques, but as a coherent pedagogical approach centered on creating and capitalizing on "moments of contingency" in instruction to regulate learning processes. Specifically, FA occurs when evidence about student achievement is elicited, interpreted, and used by teachers, learners, or peers to make instructional decisions that are likely to be better, or better founded, than decisions made without such evidence.

Both versions operationalize this theory through five key aspects that operate across three agents (teacher, peer, and learner) and address three essential processes: establishing where learners are in their learning, clarifying where they are going, and determining how to bridge that gap. The five aspects are:

1. Clarifying learning intentions and criteria for success
2. Engineering effective classroom discussions and other learning tasks that elicit evidence of student understanding
3. Providing feedback that moves learners forward
4. Activating students as instructional resources for one another
5. Activating students as the owners of their own learning

Among the five strategies, we focus specifically on aspect 3: "Providing feedback that moves learners forward." Within digital environments like AAB, feedback can take multiple forms. It may be automated and delivered directly to students through the technology, or it may be teacher-mediated, where the platform provides information to the teacher who then decides how to respond. Understanding how PSMTs design these different types of feedback opportunities, and whether they can recognize them in peers' work, provides insight into their developing pedagogical reasoning about FA in technology-enhanced environments.

Methodology

This qualitative study involved 17 PSMTs in their first or second year of a secondary mathematics certification program at a Midwestern university, enrolled in a course on mathematical problem solving with technology taught by the first author. The initial AAB

designs (n = 16; one PSMT did not complete the assignment) were collected after PSMTs explored the technological features of AAB through pre-designed activities and prior to any formal instruction on teaching methods. Importantly, the assignment emphasized technological features and mathematical content without explicitly mentioning FA, allowing us to observe what assessment practices emerged organically.

Each PSMT reviewed approximately three randomly assigned peer AAB designs using a rubric with eight criteria tied to Wiliam and Thompson's (2008) framework, generating 50 peer reviews total. This study focuses on one criterion: "Providing Feedback that Moves Learners Forward," with four performance levels: (a) activity offers specific prompts/feedback to advance student thinking; (b) activity supports teacher feedback moments; (c) feedback opportunities lacking or unlikely to move learning forward; (d) no feedback mentioned.

Analysis proceeded in two phases. In phase one, two researchers independently coded all 16 designs for feedback opportunities. The coding process was iterative: we began with a priori categories distinguishing automated from teach-mediated feedback, then defined these through constant comparison into eight distinct types (Table 1). Initial inter-rater agreement was 82%, with disagreements resolved through consensus discussion. Primary disagreements concerned whether certain features truly created opportunities for advancing thinking versus simply confirming correctness, a distinction central to FA theory. In phase two, we systematically compared identified feedback opportunities with peer-assigned performance levels, noting where PSMTs recognized strong, weak and missing opportunities.

Table 1: Counts of Formative Assessment Practices in PSMTs' AAB

Observed Formative Assessment Practices	# of authors who used it	Recognized by reviewer as Strong	Recognized by reviewer as Weak	Recognized by reviewer as Missing	Total # of Reviews
Teacher Feedback	16	28	18	4	50
Entering Equations	5	5	5	5	15
Answers Provided	3	4	0	3	7
Draggable points	1	2	0	1	3
Slider Observations	1	1	0	2	3
Modifying Equations	4	0	1	11	12
Tested Prediction	1	0	0	3	3
Revisit and Revise	1	0	0	3	3
Peer Feedback	1	0	0	3	3

Findings

While PSMTs included various approaches (Table 1, column 1), only four were used by more than one student: Teacher Feedback, Entering Equations, Answers Provided to posed questions, and Modifying Equations. Every author included at least one opportunity for students to enter a response into a textbox for teachers to review, though the decision to offer feedback (or not) was left to the teacher in the moment. Most of these, along with all of those that provided answers, were oriented towards establishing the correctness of responses rather than allowing students to determine this for themselves.

Regarding recognition (RQ2), columns 2–4 reveal that not all opportunities were visible to PSMTs. Reviewers rated opportunities as "weak" when they recognized feedback existed but judged it unlikely to advance learning. Four types of opportunities were not visible at all: asking students to *modify equations* and examine the result on a graph, asking students to *revisit and revise* early thinking, asking students to *test predictions,* and *peer feedback* were not recognized by reviewers as opportunities for feedback to move learners forward. Though, when the author allowed students to enter their own equations before observing graphical behavior, it became more recognizable than simply modifying equations. Five authors utilized *entering equations* as a tool by which students could engage with the mathematics. Two of those went unnoticed, while three were highlighted by reviewers as a form of feedback that would move learners forward.

Other opportunities were more recognizable, including opportunities for direct teacher feedback and incorporating dynamic measurement and *draggable points*. One additional finding that we hope to touch on in the presentation that is not represented in Table 1 is that though PSMTs did not recognize many opportunities for FA outside of direct teacher feedback, they certainly recognized the lack thereof (72%).

Implications and Conclusion

Our findings reveal that PSMTs conceptualize feedback narrowly as verbal or written comments from humans, not recognizing mathematical consequences (e.g., a line shifting when a slope changes) as legitimate feedback that moves learners forward. This gap in professional vision has critical implications for teacher education.

Without explicit intervention, novice teachers default to digitizing traditional worksheets over transforming pedagogy. While PSMTs frequently included text boxes for teacher review, designs prioritized correctness over leveraging technology to prompt reflection or support conjecture testing. We introduce the term *epistemological feedback* to describe how dynamic technology provides immediate mathematical consequences that serve as feedback (e.g., a graph shifting when parameters change). Unlike correctness feedback, epistemological feedback reveals mathematical relationships, allowing learners to test conjectures and observe consequences. The invisibility of epistemological feedback in peer reviews suggests PSMTs need explicit support recognizing how dynamic environments create moments of contingency.

We recommend three pedagogical moves for teacher education. First, explicitly name and model epistemological feedback during technology explorations, consistently asking "What mathematical feedback does the tool itself provide?" Second, engage PSMTs in analyzing contrasting cases, such as comparing "digitized" worksheets with transformed tasks that leverage epistemological feedback. Third, implement design cycles where PSMTs receive guidance on whether their tasks create opportunities for students to learn from mathematical consequences.

Future research should investigate whether explicit instruction in epistemological feedback shifts PSMTs' design patterns. This limited study advances understanding of how prospective teachers develop pedagogical reasoning about technology, highlighting a critical dimension of technological pedagogical content knowledge requiring explicit attention in teacher preparation.

ORCHESTRATING MATHEMATICAL DISCOURSE IN INTERMEDIATE CLASSROOMS: TEACHER MOVES AND STUDENT ENGAGEMENT

David Hung
Faculty of Education, University of Ottawa
david.hung@uottawa.ca

Mathematical discourse improves student achievement, yet intermediate teachers face implementation challenges. This qualitative multiple case study examined how four Grade 7–8 expert teachers orchestrated discourse across diverse schools in a large urban district. Data included interviews, observations, and field notes. Findings revealed teachers employed strategic questioning, established explicit norms, and used varied grouping. Teachers with strong mathematical knowledge and experience navigated challenges more effectively (Ball et al., 2008). Participants acknowledged certain concepts resist discourse approaches, suggesting curriculum-specific considerations. This study contributes to how expert teachers adapt discourse moves to the development realities of teenagers, extending talk-moves and MKT frameworks in the intermediate grades. Findings illuminate complex teacher decision-making underlying successful discourse implementation and offer practical implications for professional development.

Keywords: Classroom Discourse, Instructional Activities and Practices, Middle School Education, Teacher Knowledge

Objectives and Research Question

Reform documents advocate for mathematics classrooms where students construct understanding through collaborative discourse (NCTM, 2014; Ontario Ministry of Education, 2020). Research demonstrates that discourse-based instruction significantly improves student achievement, particularly for students from low-income backgrounds (Chapin et al., 2003; Boaler & Staples, 2008). However, productive mathematical discourse is not easy to implement and facilitate (Ball & Forzani, 2011; Webb et al., 2019), and many teachers struggle with orchestrating meaningful student-to-student mathematical conversations (Stein et al., 2008; Leatham et al., 2015). The intermediate grades (ages 12-14) present unique challenges for discourse implementation. Adolescent learners exhibit heightened self-consciousness, increased peer influence, and developing abstract reasoning capacities (Eccles et al., 1991), making mathematical sharing in public particularly vulnerable (Marks Krpan, 2013). At this stage the social risk of being seen as wrong can outweigh the reward of contributing, so willingness to reason publicly must be deliberately cultivated through norm-setting, grouping, and questioning calibrated to emerging abstract reasoning. Despite these challenges, research on discourse practices specifically in Grade 7 and 8 mathematics classrooms remains limited (Walshaw & Anthony, 2008). This study addresses that gap by documenting how teachers recognized as expert at these grade levels adapt discourse practices to the developmental characteristics of early adolescents. It investigates: *How do experienced Grade 7 and 8 mathematics teachers orchestrate discourse to promote student learning across diverse classroom contexts?* Three sub-questions guided the inquiry: (1) What teacher moves do expert intermediate teachers employ during mathematical discourse? (2) What strategies do they use to establish learning environments conducive to discourse? (3) How does teacher knowledge shape the way they facilitate discourse?

Theoretical Framework

This study draws on social constructivist perspectives that position learning as socially mediated through language and interaction (Vygotsky, 1978; Lave & Wenger, 1991). Mathematical understanding develops through participation in communities where ideas are shared, challenged, and refined (Sfard, 2008; Cobb & Yackel, 1996). Discourse serves as the mechanism through which students externalize thinking, engage with others' reasoning, and collectively construct mathematical meaning (Lampert, 1990; Michaels & O'Connor, 2015).

The study employs Ball, Thames, and Phelps' (2008) framework of Mathematical Knowledge for Teaching (MKT), which distinguishes specialized content knowledge required for teaching from common content knowledge. This framework helps explain variation in teachers' discourse facilitation, as teachers must flexibly interpret student contributions, recognize mathematical validity in unconventional solutions, and select productive student ideas to advance collective understanding (Sleep, 2012; Stockero & Van Zoest, 2013).

Additionally, the study draws on Chapin, O'Connor, and Anderson's (2009) talk moves framework, which identifies specific teacher moves that scaffold productive discourse: wait time, revoicing, repeating, reasoning, and adding on. Another extension by O'Connor, Michaels, and Chapin (2015) emphasizes how these moves distribute cognitive authority from teacher to students while maintaining mathematical rigor. The study also draws on Liljedahl's (2020) Building Thinking Classrooms, particularly visibly random grouping and thinking tasks, which create the conditions for discourse to emerge. Talk moves and MKT then explain how teachers facilitate and sustain that discourse.

Methods

Participants and Context

Four expert intermediate mathematics teachers participated in this multiple case study, purposefully selected for their expertise with discourse-based instruction. Expertise was determined through three criteria: those with at least five years teaching mathematics in intermediate grades; those who were identified by school administrators as effective math leaders; and those who were well-versed with using discourse confirmed through pre-screening. All participants taught Grade 7 and/or 8 mathematics in a large urban district. Three held mathematics specialist additional qualifications, and all four had held school mathematics leadership roles such as lead teacher or coach. The schools they were at, served linguistically diverse communities where more than 50% of students spoke a language other than English at home. Languages include Mandarin, Cantonese, Russian, Persian, Spanish, Arabic, and Korean, among others.

Data Collection

Data collection followed case study protocols (Merriam, 2009; Stake, 1995) and included: (1) two semi-structured interviews per teacher, conducted before and after classroom observations; (2) two 45-minute classroom observation sessions per teacher, audio-recorded to capture discourse patterns; (3) researcher field notes documenting classroom environment, student interactions, and teacher moves; and (4) demographic data from school websites and publicly available statistics. Interview protocols explored teachers' beliefs about discourse, implementation strategies, challenges encountered, and decision-making processes. Observations captured naturally occurring discourse during mathematics instruction.

Data Analysis

Analysis followed Merriam's (2009) two-stage process for multiple case studies. Each case was first analyzed individually using Kvale's (2007) meaning condensation procedure, with

transcripts coded into emergent categories in NVivo. Then cross-case analysis was conducted to identify commonalities and variations across the four cases (Stake, 1995). Trustworthiness was established through triangulation across interviews, observations, and field notes, and through member checking of transcripts.

Results

Analysis revealed five major themes characterizing effective discourse orchestration in intermediate mathematics classrooms. Across the eight observed lessons, the recorded discourse was predominantly teacher-to-student and student-to-student, with teachers intervening through talk moves, asking guiding questions, and responding to student questions with another question rather than giving definitive answers. The themes below draw on both interview and observation data.

Theme 1: Establishing Foundations Before Discourse

All four teachers emphasized deliberate preparation before implementing discourse. As one teacher explained, "At the beginning of the year, I prepared the students" by explicitly teaching collaborative norms and practicing group work skills. Teachers allocated 1-2 weeks at school year's start for students to learn discourse expectations through low-stakes mathematical tasks. This preparation included modeling respectful disagreement and practicing accountable talk moves (Marks Krpan, 2013; Resnick et al., 2010). Teachers viewed this investment as essential, with another teacher noting, "It all begins with the first day, the first month of the school year and it is all in the classroom management."

Theme 2: Strategic Questioning to Advance Thinking

Teachers employed purposeful questioning beyond traditional Initiate-Response-Evaluate patterns (Sinclair & Coulthard, 1975). Questions focused on eliciting reasoning rather than answers, consistent with Stein et al.'s (2008) high-level cognitive demand framework. Teachers planned prompting questions strategically, with one explaining: "Some of my anticipated questions are going to be a lot higher level thinking; and so that would go towards some of my kids that could handle it. Some of my questions might be a little bit simpler depending on who I am working with." Teachers used wait time strategically (Ingram & Elliott, 2016), allowing students processing time before requiring responses. They revoiced student contributions to amplify ideas across the classroom and pressed students to clarify, elaborate, or justify mathematical claims (Franke et al., 2009). In one observed lesson, during the consolidation phase, a teacher avoided confirming or rejecting a student's answer. Instead, she restated it as a question and asked the group to decide whether it was correct. This moment illustrates how a single teacher move can maintain the mathematical challenge of the task while encouraging students to take ownership of the reasoning.

Theme 3: Responsive Grouping Strategies

Teachers utilized flexible grouping approaches adapted to instructional goals and student needs. Random grouping predominated for most tasks, implemented through playing cards or other randomization methods to ensure students worked with diverse peers. These practices align with Liljedahl's (2020) visibly random groupings. Teachers noted that regularly changing group compositions helped reduce the social anxiety, which is typical of early adolescence. However, teachers made strategic modifications for English language learners. One teacher explained, "even if it is random grouping, I will consider putting two people of the same language together, especially in grade 8 because the content is there". This decision reflected asset-based thinking (Civil, 2007), positioning home language as a resource for mathematical thinking rather than a deficit.

Theme 4: Mathematical Knowledge Enables Flexibility

Cross-case analysis revealed that teachers with deeper mathematical content knowledge navigated discourse more fluidly. These teachers recognized mathematical validity in unconventional student approaches, asked probing follow-up questions that advanced thinking, and connected student ideas to mathematical big ideas. One teacher demonstrated comfort admitting uncertainty, explaining: "you know what; I do not know the answer to that. Let us see if we can figure that out together; let us grab a textbook; let us get your phone; I will grab my computer; let us see if we can find an answer." This intellectual humility paradoxically strengthened discourse by positioning students as mathematical authorities (Engle & Conant, 2002).

Theme 5: Acknowledging Discourse Limitations

All participants agreed that discourse is not the only strategy to use to teach mathematics. While it may be very effective, it may come after some direct instruction. One participant shared during their interview that “if they [students] have had no exposure at all to those kinds of geometric constructions, I think that there has to be some direct instruction before they can just kind of talk." This reflects the view that foundational knowledge must precede discourse for certain content. These teachers also expressed that highly procedural topics like standard algorithms might be better taught using non-discourse approaches. Teachers drew on their content knowledge, teaching experience, and pedagogical expertise to decide when discourse would be the best approach to use (Hiebert & Grouws, 2007).

Discussion and Implications

This study illuminates the orchestration work underlying successful mathematical discourse in intermediate classrooms. The study's contribution is threefold. First, it foregrounds the intermediate grades, showing that effective discourse requires managing the social vulnerability of early adolescence, in addition to developing discourse-based facilitation skills. Second, it links frameworks usually treated separately, demonstrating how MKT (Ball et al., 2008), talk moves (Chapin et al., 2009), and task and grouping structures (Liljedahl, 2020) operate together in expert practice. Third, it adds nuance to our understanding of which concepts may be best taught using non-discourse-based approaches. The deliberate preparation phase echoes Boaler's (2015) "relational equity" and disrupts deficit narratives about adolescents (Esmonde, 2009). Teachers' strategic questioning moves extend Chapin et al.'s (2009) framework by showing that expert teachers deploy talk moves responsively rather than formulaically, and the link between MKT and discourse success (Ball et al., 2008) implies that professional development should target both pedagogical moves and mathematical content. The acknowledgment that certain content is not best taught through discourse initially resonates with Hiebert and Grouws' (2007) argument that posits that no single method is universally effective. Teachers' judgment about when discourse serves learning is itself sophisticated professional expertise (Sherin et al., 2011).

For professional development, findings suggest three priorities: (1) providing teachers with extensive practice facilitating discourse with adolescents; (2) strengthening teachers’ Mathematical Knowledge for Teaching, especially specialized content knowledge; and (3) developing teachers’ judgment about when discourse is the appropriate approach. Video analysis of discourse can support teachers in building adaptive expertise (Hatano & Inagaki, 1986; Marks Krpan, 2018).

Mathematics autobiographies of preservice elementary teachers are examined and compared with an administration of the Mathematics Teacher Efficacy Belief Instrument, in order to determine patterns between a preservice teacher's relationship with mathematics and their efficacy in teaching mathematics. Implications for teacher education are also considered.

Keywords: Preservice Teacher Education; Teacher Beliefs; Affect, Emotion, Beliefs, and Attitudes

The Problem

Since the publication of the seminal text "Adding it Up" (National Research Council, 2001), productive disposition toward mathematics was named as one of five strands of mathematical proficiency. In addition, the Association of Mathematics Teacher Educators (AMTE) named having "positive and productive dispositions toward teaching mathematics" (2017, p.6) as one of the primary responsibilities for mathematics teacher educators in preparing teachers of mathematics. But, what if a student's relationship with mathematics cannot be described as productive? What if the relationship is influenced by instances of shame experienced with mathematics? Going further, what happens when those same students arrive in an elementary mathematics methods course, positioned as future teachers of mathematics? And how does one's disposition toward mathematics influence one's efficacy in the teaching of mathematics?

The question driving this project is "What is the nature of the relationship between elementary preservice teachers' stories with mathematics and measures of those same students' beliefs about mathematics teaching efficacy?" In an attempt to approach the answer to the question, mathematics autobiographies (referred to as MatHistories) of students are examined and compared with an administration of the Mathematics Teacher Efficacy Belief Instrument (MTEBI) (Enochs et al., 2000), in order to determine patterns between a preservice teacher's relationship with mathematics and their efficacy in teaching mathematics. The goal of this examination is to identify pathways for repairing relationships with mathematics for the benefit of the students in the preservice teachers' future classrooms. What follows is an explanation of the literature that frames this study, the mode of inquiry, the findings, and a discussion of the implications of this work.

The Theoretical Framework

For the purpose of this brief report, the learning of mathematics is equated with developing a desired relationship with mathematics (Lampert, 2001) or moving more central within a community of practice/community of doers of mathematics (Lave & Wenger, 1991). When intention is not being focused on developing the relationship with mathematics, and instead the emphasis is on rote memorization of facts and the mindless execution of algorithms, an

undesired relationship with mathematics is formed. Instead of a productive relationship between mathematics and students, there is a negative relationship that is characterized by shame and anxiety.

When asked to do mathematics, many claim negative feelings of dislike and anxiety (Novak & Tassell, 2017). The formation of these feelings has been linked to several different factors (Harper & Daane, 1998). Students cite experiences with teachers as one of the major causes of negative attitudes and anxiety towards mathematics. Individuals who have experienced shame in the context of mathematics learning may avoid and/or withdraw from future activities associated with mathematics (Ashcraft, 2002). Further, these shame experiences with mathematics can lead to poor student performance as well as lasting mathematics anxiety (Wilson, 2018).

Self-efficacy as it relates to mathematics has been the subject of numerous studies over the past few decades. Scholars have looked at how it is affected by factors such as mathematics anxiety (Unlu et al., 2017), gender (Szczygiel, 2020), education level (Brady & Bowd, 2005), and mindset (Tassell et al., 2020). Mathematical teaching self-efficacy is defined as one's perceived belief in their ability to understand and teach mathematics. Recent studies have established links between teachers' mathematics self-efficacy, anxiety, and student performance (Unlu et al., 2017; Ramirez et al., 2018). One link shows that teachers with high mathematics anxiety have low self-efficacy, and vice versa (Unlu et al., 2017). Also, the higher a teacher's anxiety level around teaching mathematics, the lower the achievement of their students (Ramirez et al., 2018). Thus, relationships that preservice teachers have with mathematics are significantly associated with their mathematics teaching self-efficacy (Briley, 2012) and the need to help influence their relationship towards the positive.

The Mode of Inquiry

In this study, set in a large, remote public university in the midsouth, 51 preservice teachers from two sections of an elementary mathematics methods course provided a written account of their history with mathematics (i.e. MatHistory), as well as their responses to the MTEBI (Enochs et al., 2000).

Responses for the mathematics autobiography went through several cycles of coding (Saldaña, 2013). Holistic coding (Saldaña, 2013) was used to categorize histories by the overriding relationship with mathematics (e.g. positive, negative, and variations in between). Next, provisional coding (Saldaña, 2013) was used to identify emotions that were named in each history, as either triggers (i.e. events that led to the emotion), or pathways (i.e. outcomes related to the emotion). Next, the researchers engaged in open coding (Saldaña, 2013) of the triggers and pathways in order to categorize the mathematical experiences that led to the emotions and students' responses. Finally, stories, which contained a full set of trigger, emotion, pathway were categorized given positive or negative nature of each element with a focus on stories that turned toward a positive pathway.

In addition to the coding, the MTEBI subscores (Enochs et al., 2000), mathematics teaching outcome expectancy (MTOE), and personal mathematics teaching efficacy (PMTE) were calculated. MTOE is a measure of expectation that the teaching of mathematics can influence a student's relationship with mathematics, and PMTE is a measure of belief in one's ability to enact teaching of mathematics that can influence a student's relationship with mathematics. Finally, each preservice teacher's MTEBI scores were compared to the holistic coding of their histories with mathematics.

The Findings

The largest category from the holistic coding of histories with mathematics was "negative relationship." "Negative relationship" was defined as an overall negative history with mathematics, whereas a "repaired relationship" was defined as an overall negative history with mathematics that concluded with a positive disposition toward mathematics. When comparing these categories of stories with their respective subscores from the MTEBI, there was a noticeable difference in the PMTE subscores between the two groups. The major qualitative difference in the histories of mathematics between these two groups was a significant positive moment in the latter part of their history with mathematics for those in the "repaired relationship" category. This led to further questions and analysis about the context for the repair, and the resiliency of the repair given future struggles with mathematics or the teaching of mathematics. Preliminary investigations have shown that experiences in elementary

Analysis continues on this project to investigate questions as they emerge from previous analysis. What has emerged is the significance of the moment of repair for the histories with mathematics in the "repaired relationship" category and what it might look like to design and enact such experiences. Other studies have investigated the effects that methods courses can have on preservice teachers' mathematics teaching anxiety and self-efficacy. Vinson (2001) found that the majority of preservice teachers lowered their mathematics learning and teaching anxiety as well as boosted their mathematics teaching self-efficacy after being enrolled in a mathematics methods course that focused on instructing the preservice teachers on the best strategies for teaching their future students. A study conducted by Harper and Daane (1998) had similar findings, but also determined that preservice teachers need to be made aware of their mathematics anxiety and negative feelings toward mathematics, in order for them to develop a more positive relationship with mathematics and not transmit those same feelings onto their students.

Conclusion

The goal of this work is to continue to seek pathways for reconciling preservice teachers' relationships with mathematics given evidence that reconciliation is possible. By better understanding the perspectives that PSTs bring to the elementary mathematics methods classroom, through their mathematical narratives and their efficacy toward the teaching of mathematics, mathematics teacher educators can be better prepared to provide reconciling relationships with mathematics/mathematics teaching that can be implemented within their classroom and/or programs to support the high quality preparation of teachers of mathematics.

ITERATIVE GOAL SETTING AS A CATALYST FOR PRESERVICE ELEMENTARY MATHEMATICS TEACHER DEVELOPMENT

Paula Jakopovic
University of Nebraska at Omaha
paulajakopovic@unomaha.edu

This case study explores the role that iterative goal setting across a semester-long mathematics methods course plays in supporting the development of elementary preservice teachers' mathematics identities and professional vision for teaching. Using narrative analysis framed around identity positioning and goal orientation, this report presents preliminary findings by offering an intrinsic case of one preservice teacher whose goal orientations and vision for mathematics teaching shifted over time. Implications from this study seek to inform work around elementary preservice teachers' mathematics identity and self-efficacy development by identifying specific reflective practices and structures that can help them grapple with the tensions of transitioning from mathematics learner to teacher.

Keywords: Preservice Teacher Education, Elementary School Education, Identity and Agency

Elementary preservice teachers (PSTs) often have negative experiences as mathematics learners that lead to challenges negotiating their future identity as teachers (Brown & McNamara, 2011; Kaasila et al., 2012). This directly impacts student learning opportunities, as PSTs may default to procedural instructional approaches rather than engaging students in active learning that promotes conceptual understanding and problem solving—limiting students' access to high quality instruction (Boaler, 2002a; Boaler & Staples, 2008; Hill et al., 2005). Teachers with low mathematics teacher self-efficacy are more likely to transmit feelings of math anxiety to students (Beilock et al., 2010; Smith & Fotou, 2023), leading to lower academic achievement (Aguirre et al., 2024; Boaler, 2002b). In order to change this paradigm, mathematics teacher educators are tasked with helping PSTs learn to navigate their past experiences and leverage them to inform future visions of becoming effective mathematics teachers. Reflection and goal setting in disciplinary methods courses can help PSTs reinterpret their understanding of mathematical learning and construct new narratives for themselves as mathematics teachers (Sfard & Prusak, 2005). In this preliminary report, I present an instrumental case study of one PST, selected from a larger qualitative study, to explore her progression of mathematics identity development. This study seeks to answer the question: How does iterative goal setting and reflection in an elementary mathematics methods course elucidate shifts in preservice teachers' identity development?

Theoretical Framing

Sfard and Prusak (2005) explain identity as a communicational practice where individuals define themselves through narratives that are "reifying, endorsable, and significant" (p. 16). Identity can position learners as either central or marginal figures in classroom spaces in ways that either affirm or challenge their self-concept (Aguirre et al., 2024; Anderson, 2007; Darragh, 2014; Harre et al., 2009). Similarly, teacher identity requires the ongoing negotiation of values and experiences, where individuals must navigate actual versus "expected" narratives that are or can potentially become part of one's identity (Sfard & Prusak, 2005). Elementary PSTs often enter their teacher preparation programs with negative self-concepts about their ability to learn and effectively teach mathematics (Brown & McNamara, 2011; Kaasila et al., 2012). As such,

mathematics teacher educators are often tasked with helping PSTs navigate tensions between their past mathematics identities as learners and future identities as mathematics teachers.

"Professional practice" refers to intentional, reflective approaches that cultivate teachers' instructional effectiveness, equity-minded dispositions, and professional identities (Darling-Hammond & Bransford, 2005; Grossman et al., 2009). It empowers teachers to advocate for learners, embrace multicultural perspectives, and enact transformative practices (Darling-Hammond & Oakes, 2021; Grossman et al., 2009; Gay, 2018; Zeichner, 2012). Reflection and goal setting are well documented professional practices to support PSTs' growth (Camp, 2017). Offering PSTs structured, iterative opportunities to reflect allows them to examine their beliefs, experiences, and aspirations—aiding them in connecting their past experiences to future teaching goals (Schutz et al., 2018). Articulating these aspirations supports PSTs in exploring pathways to shifting their mathematics identities as both learners and teachers. Research supports the role that effective goal setting requires participants to be aware of their progress (e.g., Latham et al., 1978), and that goals focused on learning versus performance are more likely to help individuals develop tools for problem solving and increase self-efficacy (e.g., Latham & Brown, 2006).

Methods

This study took place at a midsized, urban university in the Midwest. Participants included 22 elementary PSTs enrolled in a 15-week mathematics methods course in Spring 2024. At the beginning of the semester, participants wrote mathographies (Drake, 2006), reflecting on past mathematical events—including high, low, and turning points in their stories—before setting goals for themselves as learners and future teachers of math. PSTs engaged in class activities and teaching rehearsals paired with reflective opportunities to iteratively review and refine their goals in light of new experiences at four stages of the semester, tying goals to mathematics teaching practices (NCTM, 2014) and the InTASC teaching standards (CCSSO, 2013). This paper presents the experiences of one PST, "Abbi," as an instrumental case (Stake, 1995) selected from the larger data set to provide an in-depth illustration of how shifts in goal setting and attainment influenced Abbi's sense of confidence as a math teacher. Narrative analysis (Connelly & Clandinin, 2006; Polkinghorne, 1995) guided the examination of her mathography and three subsequent reflection assignments where she reviewed previous goals, reflected on teaching rehearsals, and revised/extended goals based on her progress. Rather than fragmenting the data into decontextualized codes for this case, the participant's narrative was analyzed holistically to preserve the coherence of her story while identifying key shifts in her thinking over time.

Findings

Past Learning Experiences Influence Future Aspirations

Abbi was selected as a PST whose relationship with math was neither completely negative or positive, rather it was experienced as a self-described roller coaster. As a young learner, Abbi found herself excelling in math and being positioned as a central figure in the classroom. She noted,

> I was always in the higher math group and I felt smart when it came to math. I specifically remember a time in fifth grade when my teacher commented on my work for long division in front of the class and it made me feel really good.

As she shifted into middle school, however, her experiences began to change. She found herself in a classroom setting where content was being modeled strictly through lecture and individual practice, and she did not feel comfortable asking the teacher for help. Abbi shared how this

experience impacted her identity, saying, “I remember having lots of tears in class because I just felt so behind and honestly dumb because I couldn’t keep up with my classmates. I was too embarrassed to ask for help.” Abbi found her positioning in the math classroom had flipped—instead of being a central figure she now found herself on the periphery and her identity in flux. In high school, Abbi explained that she finally had a mathematics teacher who was able to help her regain some of her lost confidence. She reflected,

> [My teacher] explained everything in a way I could understand. She actually took the time to help fill in the gaps in my math understanding that had been holding me back for so long. I wish I had a teacher who would’ve done that for me sooner.

Despite having a somewhat tumultuous experience with math as a learner, as Abbi set a number of learning focused goals for herself at the start of the semester. These goals focused on building a strong foundation for herself as a math teacher, as well as becoming comfortable asking questions in class, regardless of how this positioned her among her peers. She explained, “My experience with math has made me want to focus on embracing asking the ‘dumb questions’ as a math learner because it’s better to ask what feels like a dumb question than to go on confused.” In addition to setting goals for herself as a learner in class, she also wrote a similar goal to “create a safe and comfortable environment for my students to ask any question,” indicating her desire to provide for her students supports she did not always have herself as a learner. Abbi saw a direct connection between the experiences she wanted to build for herself as a learner in her methods course with the ones she wanted her future students to have in her own classroom.

Midsemester Shifts in Identity and Goal Articulation

In the first five weeks of the semester, PSTs engaged with course activities where they learned about effective mathematics teaching practices (e.g., National Council of Teachers of Mathematics, 2014; 2020), as well as the core teaching practices outlined by the Interstate Teacher Assessment and Support Consortium (InTASC, 2013). Part of this work included enacting a number of teaching rehearsals, where PSTs engaged in scaffolded, collaborative planning and received structured feedback to support their attainment of these practices, before transitioning to a field-based practicum in Week 6. As they shifted into classrooms, Abbi reflected on her progress towards her initial teaching goal. She described a continued desire for students to feel comfortable sharing their thinking with her and asking questions and maintained this as a target goal moving forward. She said, “I want to make sure I am continuing to engage students with questions and checks for understanding.” Abbi further tied this goal back to the mathematics teaching practice of “eliciting evidence of student thinking” (NCTM, 2013) as a way to help her make informed instructional decisions to support their growth as learners.

Approximately two to three weeks into the field experience, Abbi came back to her goals again, this time aligning them to the InTASC practices. She identified three target InTASC standards that she wanted to focus on: 1) using knowledge of students to make instructional decisions, 2) using knowledge of students’ diverse backgrounds to create inclusive learning environments, and 3) using relevant, evidence-based instructional strategies that allow students to apply content area concepts (InTASC, 2013). Here, Abbi continued to focus on creating an inclusive and supportive learning environment, however she also extended her goals by identifying core practices that could help her make actionable progress toward this goal. She began to recognize that gathering evidence of student thinking not only helped students to feel heard and supported, it also gave her important data she could use to tailor instruction in ways that met the needs of all learners. Further, Abbi began to transition from considering effective, evidence-based teaching practices from a theoretical set of ideas to clearly identifiable teaching

moves she could integrate into lessons to further support building a supportive learning environment. When asked why she opted to adjust her goals she explained, "I knew I was already doing it, and I wanted to get more specific with how I went about helping students."

"Becoming a Math Teacher:" End of Semester Growth and Ongoing Aspirations

At the end of the semester, Abbi returned to her original goals to reflect on progress, revisions, and adaptations she wanted to make based on new pedagogical learning and experiences. She began my sharing a desire to maintain one of her original goals, stating, "I still want to create a safe environment for my students to make mistakes… comfortable with being unsure to get where we finally understand by not being afraid to ask questions." Abbi's continued focus on ensuring her future students had what she sometimes felt she did not as a student—a safe space for asking questions when confused or uncertain—as integral to the type of teacher she wanted to become. In addition to this broader goal that supported creating an inclusive classroom environment, Abbi added a new goal based on her reflections. She shared,

> My new, maybe more important goal, is to make sure my students understand the algorithms they use and why they work. I feel I have the ability to explain math well using math language and vocabulary in a way that students can understand. I really like the idea of being a teacher who can lay a strong foundation in the conceptual understanding of math and the why behind it, allowing my students to hopefully be super successful in their math careers.

This illustrates how Abbi saw a path forward in designing instruction that supported the classroom environment she wanted to create by making content meaningful and accessible to students. She explained that the opportunities to "take stock of" her progress at different points in the semester helped to increase her own confidence and competence engaging in effective mathematics teaching in wants that added a new inflection point to her previous math narrative.

Discussion and Conclusion

Abbi began the semester as a PST whose goals were at odds with many of her experiences as a mathematics student. The preliminary findings from analysis of her experiences in her methods course suggest that her engagement in activities that included targeted reflection and iterative goal setting helped to reshape her views not only of what mathematics teaching looks like, but also her beliefs in her ability to become an effective mathematics teacher. These experiences reinforced her desire to ask questions in class, initially a goal about her own participation that eventually transitioned to her supporting students in the classroom. In her final reflection she explained that the evidence-based teaching practices she learned about through coursework helped her set and achieve actionable goals that become more targeted over time. This case study thus offers insights into the role that goal setting can play as a generative practice for supporting PSTs' mathematics teacher identity development by offering space for them to make note of incremental growth identify places where goal achievement supported their math identity development. Providing PSTs with structured, ongoing opportunities to reflect on pedagogical knowledge and teaching beliefs and how they evolve over time can support PSTs in navigating the tensions between their past experience as mathematics learners and their aspirations as future teachers. This work contributes to ongoing conversations about how teacher preparation programs can most intentionally support PST identity development to inform their future professional visions.

PRESERVICE TEACHERS' AI-ASSISTED DIFFERENTIATION OF A MATHEMATICS TASK

Hea-Jin Lee
The Ohio State University at Lima
lee.1129@osu.edu

This study examines the theory-practice gap in elementary preservice teachers' (PSTs) AI-assisted differentiation of a volume-measurement task. This paper analyzed artifacts from thirteen PSTs who consented to research use. Qualitative artifact analysis focused on cognitive demand, scaffolding quality, learner assumptions, and indicators of AI assistance. Findings show that PSTs often reduced task quantity, simplified reflection, and increased teacher control for students with mathematical learning difficulties, while extending independence or complexity for advanced learners. Artifacts with stronger AI-likelihood indicators used sophisticated pedagogical language but enacted conventional simplifications that limited opportunities for mathematical reasoning. These findings suggest a declarative-procedural gap in AI-assisted mathematics lesson design and differentiated instruction.

Keywords: Preservice Teacher Education, Measurement, Instructional Activities and Practices, Technology, Special Education

Introduction

Differentiation is often framed as a means of expanding equitable access to learning, yet it can reproduce inequity when teachers lower the cognitive demand of mathematical tasks for students with learning difficulties. This concern is important in preservice teacher education, where PSTs learn to adapt tasks while developing beliefs about who is capable of mathematical reasoning. Effective differentiation should vary routes of access while preserving meaningful engagement with important mathematical ideas (Tomlinson, 2001). Similarly, maintaining cognitive demand is central because students need opportunities to reason, justify, and make connections, rather than simply complete simplified procedures (Smith & Stein, 1998).

Generative AI adds a new layer to this teacher education challenge. AI tools can provide research-based language about scaffolding, learner variability, and cognitive load, but such language may not translate into task designs that preserve rigorous mathematical activity (Kasneci et al., 2023; National Council of Teachers of Mathematics [NCTM], 2024). This study examines PSTs' written adaptations of a volume-measurement task for students with mathematical learning difficulties and for mathematically advanced or gifted students. The study asks: (1) How do PSTs modify a mathematics task when differentiating for different learner profiles? (2) To what extent do these modifications maintain or reduce cognitive demand? (3) How do AI-likelihood indicators relate to the enacted quality of PSTs' designs?

Theoretical Framework

This study draws on two theoretical perspectives to examine PSTs' differentiation practices. First, we apply Smith and Stein's (1998) framework of cognitive demand in mathematical tasks, which distinguishes between maintaining rigorous learning objectives while varying pathways to access (Tomlinson, 2001) and reducing expectations for students with learning difficulties. Research consistently shows that teachers struggle to implement high-quality differentiation, often lowering cognitive demand rather than providing strategic scaffolding (Boaler, 2015; Charalambous & Pitta-Pantazi, 2016)—a challenge particularly acute for PSTs, who may hold

deficit-based beliefs about student capability (Aguirre et al., 2013; Turner et al., 2012). In this study, cognitive demand refers to whether PSTs preserved opportunities for students to predict, measure, compare, reason about units, and explain errors in a volume-measurement task.

Second, we employ the declarative-procedural knowledge distinction to theorize AI's role in teacher learning. AI tools may provide declarative knowledge, such as knowing that differentiation should maintain cognitive demand, without supporting procedural knowledge development, or knowing how to design such tasks. This theory-practice gap (Thurm & Barzel, 2022) helps explain why AI assistance might produce research-based language without transforming instructional design decisions, as PSTs articulate principles they cannot yet enact. This perspective also helps explain why the emergence of generative AI tools presents both opportunities and concerns for teacher education (NCTM, 2024; Villegas-Ch et al., 2025).

Methods

Nineteen PSTs enrolled in a mathematics methods course completed a differentiation task. PSTs were asked to modify a volume-measurement activity (Lee & Link, 2012) for students with mathematical learning difficulties and for mathematically advanced or gifted students. The assignment required modifications across four dimensions of differentiation: content, process, product, and environment. PSTs also provided written justifications for their instructional choices. AI tools were available as optional supports. The dataset consisted of differentiated handouts or directions and accompanying written justifications from the 13 consenting PSTs.

This study used qualitative artifact analysis in two phases. First, open coding identified recurrent design moves and rationales across the paired adaptations. Second, the codes were organized into four analytic dimensions aligned with the theoretical framework: cognitive demand, scaffolding quality, learner assumptions, and AI-likelihood indicators. *Cognitive demand* captured whether adaptations preserved the core mathematical work of prediction, measurement, comparison, unit reasoning, and error analysis. *Scaffolding quality* captured whether supports increased access without removing opportunities for student reasoning. *Learner assumptions* captured how PSTs positioned students with mathematical learning difficulties and mathematically advanced or gifted students in relation to mathematical capability, independence, and rigor. *AI-likelihood* captured textual and design features suggesting possible AI assistance, such as dense theoretical terminology, generic research claims, parallel structure, and limited connection to the specific volume task.

Findings

Analysis revealed four patterns in PSTs' differentiated task adaptations: task-level separation, scaffolding as teacher control, unequal access to reflection, and a declarative-procedural gap in artifacts with stronger AI-likelihood indicators.

Differentiation as Task-Level Separation

The dominant pattern was differentiating by amount, difficulty, and autonomy rather than preserving a common mathematical goal with varied access. Ten of the 13 artifacts reduced the number of containers for students with mathematical learning difficulties. One PST justified this reduction by noting that students might experience "cognitive overload," suggesting that support was often interpreted as reducing task quantity. In contrast, adaptations for mathematically advanced or gifted students typically maintained or increased the number, irregularity, or complexity of containers.

This pattern was not only about quantity. In several artifacts, PSTs changed the mathematical work expected of each learner group. Students with mathematical learning difficulties were

sometimes asked only to identify which container held “the most” or “the least,” whereas advanced students were asked to predict numerical volume, compute differences, convert units, graph results, or explain discrepancies between predicted and actual measurements. Thus, some students with mathematical learning difficulties were assigned different mathematical work altogether: qualitative comparison instead of numerical prediction, observation of teacher modeling instead of active problem solving, or simplified recording instead of explanation. These adaptations changed who had access to estimation, unit reasoning, and mathematical explanation.

Scaffolding as Teacher Control

A second pattern involved different assumptions about learner independence. Eleven of the 13 artifacts positioned students with mathematical learning difficulties in teacher-led groups with modeling, step-by-step directions, or close adult guidance. In contrast, advanced students were often given independent work, peer collaboration, open-ended exploration, or additional mathematical extensions. This pattern suggests that PSTs frequently associated support with teacher control and advanced learning with autonomy. One rationale explained that a teacher-led group would help because “the teacher can lead students step by step,” illustrating how support was often framed as procedural direction rather than structured access to reasoning.

Some teacher support was productive when it directed attention to mathematical structure. One PST proposed asking, “What do you notice about the height of the bottle?” “What do you notice about the width?” and “How does this affect its volume?” These prompts maintained the task’s reasoning goals while making relevant features more visible. However, many teacher-directed adaptations did not include such mathematically focused prompts; in those cases, scaffolding functioned more as procedural management than access to reasoning.

Unequal Access to Reflection and Error Analysis

A third pattern was the removal or simplification of reflection for students with mathematical learning difficulties. Nine of the 13 artifacts removed or weakened the original prompt, “What might account for any errors in your predictions?” Some replaced it with “How did you do?” emoji self-assessments, or multiple-choice explanations. One PST stated that students with learning difficulties did not need to reflect because they were not predicting actual numbers.

This change matters because error analysis was one of the richest mathematical opportunities in the original task. Explaining inaccurate predictions can support reasoning about height, width, shape, container thickness, measurement precision, and units. When this prompt was removed, students with mathematical learning difficulties had fewer opportunities to engage in metacognitive and explanatory reasoning.

AI-Likelihood and the Declarative-Procedural Gap

Artifacts with stronger AI-likelihood indicators often included sophisticated pedagogical language, referencing cognitive load, concrete-to-abstract progression, working memory, learner variability, and research-based scaffolding. However, the corresponding adaptations were often conventional: reducing quantity, simplifying vocabulary, adding familiar reference objects, or limiting open-ended explanation. This pattern reflects a declarative-procedural gap: some PSTs could state principles of effective differentiation but did not consistently translate them into designs that maintained cognitive demand.

The relationship between AI-likelihood and quality was not straightforward. Some artifacts with moderate AI-likelihood indicators showed stronger differentiation because general pedagogical ideas were adapted to the specific mathematics of volume estimation. In contrast, artifacts with stronger AI-likelihood indicators sometimes read as polished but generic, with

limited connection to prediction, measurement, comparison, and error analysis. Because AI use was not self-reported or verified, this finding should be interpreted cautiously. The central issue is not whether PSTs used AI, but whether they critically transformed available suggestions into mathematically sound designs.

Several artifacts demonstrated more productive differentiation by maintaining the core mathematical work while varying tools, prompts, participation structures, or extensions. Productive moves included using familiar benchmarks to support estimation, asking focused questions about height and width, modeling one example before releasing responsibility, and requiring students to justify predictions or identify sources of error. Together, these patterns suggest that stronger AI-likelihood was not associated with uniformly higher design quality; polished pedagogical language did not necessarily correspond to adaptations that preserved cognitive demand.

Table 1: Examples of Access-Oriented Differentiation That Preserved Cognitive Demand

Productive Move	How it Maintained Mathematical Access
Reference tools	Familiar benchmarks supported estimation while students still predicted, measured, ordered, and compared volume.
Focused prompts	Questions about height, width, shape, and container properties directed attention to relevant structure without supplying answers.
Graduated participation	Modeling one example, completing one collaboratively, and then releasing students preserved the task while reducing uncertainty.
Metacognitive extensions	Advanced students developed estimation strategies, compared measurement methods, explained discrepancies, or created guides.
Process documentation	Students justified predictions and identified sources of error, making reasoning visible.

Discussion and Implications

Findings suggest that PSTs' central challenge was designing adaptations that preserved rigorous mathematical activity while expanding access for different learners. Across artifacts, students with mathematical learning difficulties were often given fewer containers, more teacher control, and less access to numerical estimation, error analysis, and independent reasoning. In contrast, mathematically advanced or gifted students were more likely to receive extensions involving additional quantities, conversions, graphs, or open-ended exploration. Thus, differentiation sometimes functioned as task-level separation rather than varied access to shared mathematical goals, raising equity concerns about who is positioned to engage in mathematical reasoning (Aguirre et al., 2013; Turner et al., 2012).

The AI-likelihood findings sharpen this concern. Artifacts with stronger AI-likelihood indicators often used sophisticated language about scaffolding, cognitive load, and learner variability, yet the enacted designs frequently simplified the mathematical work. For mathematics teacher educators, these findings suggest that AI-integrated assignments should foreground critique and redesign rather than task generation alone (Kasneci et al., 2023; NCTM, 2024). PSTs should evaluate whether adaptations preserve the mathematical goal, identify where cognitive demand is reduced, and revise supports to increase access without removing reasoning. One routine is to have PSTs annotate each modification by naming the mathematical goal preserved, the barrier addressed, and the reasoning opportunity maintained, consistent with calls

to support productive struggle and use evidence of student thinking in mathematics instruction (NCTM, 2014).

CREATING A POSITIVE LEARNING ENVIRONMENT IN A MATH COURSE FOR PRESERVICE TEACHERS

Kien H. Lim
University of Texas at El Paso
kienlim@utep.edu

Hilda Y. Sotelo
University of Texas at El Paso
hysotelo2@utep.edu

This study examines how a mathematics instructor cultivated a positive learning environment in a synchronous online course for 23 preservice teachers. Guided by self-determination theory, growth mindset, and mathematical caring, the course integrated high-cognitive-demand tasks, collaborative problem solving, flexible policies, and motivational supports. Data sources included reflection logs (Likert-scale items and open-ended responses) and a focus group; the instructor's reflexive self-study informed result interpretation. Wilcoxon signed-rank tests indicated significant gains in students' sense of inclusion and trust, though some instructor-related ratings declined late in the semester. Qualitative findings emphasized students' appreciation for flexibility, encouragement, and growth-oriented feedback. Despite time and technological pressures, participants described the environment as supportive and motivating.

Keywords: Preservice Teacher Education

In the context of higher education, creating a positive learning environment is critical for student success and well-being. In mathematics education, especially for preservice teachers, creating a positive learning environment is foundational to student learning and well-being. The disruptions caused by the COVID-19 pandemic have further amplified ongoing challenges related to engagement, motivation, and mental health. In response to these realities, the first author made a conscious effort to foster a classroom culture that supports students both intellectually and emotionally. This study examines the specific actions he took to build that environment, the challenges he encountered, and how students perceived these efforts. By reflecting on these experiences, we aim to contribute to the broader conversation on how teacher educators can create spaces where students feel safe to take risks, persist through challenges, and grow in their mathematical thinking.

Literature Review

In mathematics education, national standards emphasize not only content knowledge but also mathematical thinking, such as NCTM's five process standards and the CCSSI's eight standards for mathematical practice. Yet, many preservice teachers continue to approach mathematics passively, often viewing it as a set of rules and procedures (Lampert, 1990; Lim, 2012). While high-cognitive-demand tasks are essential for developing conceptual understanding, their effectiveness depends on thoughtful implementation (Stein et al., 2009). The five practices for orchestrating mathematical discussions (Smith et al., 2009) offer a framework for helping students make meaningful connections among strategies and ideas.

Attending to both cognitive and affective domains is critical. Challenging tasks can lead to frustration, especially when students lack the support to persist. Self-determination theory (Ryan & Deci, 2000) highlights the importance of competence, autonomy, and relatedness in fostering intrinsic motivation. Teachers who support autonomy tend to promote greater engagement, while controlling approaches can have the opposite effect.

Caring relationships also play a central role in student learning. For Noddings (1984), caring requires one to "step out of their own personal frame of reference into the other's" (p. 24). In

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

mathematics education, Hackenberg (2005) extends this idea through the concept of mathematical caring, which balances cognitive and emotional support during problem-solving. Maloney and Matthews (2020) further describe caring in terms of empathetic, transactional, and blended typologies. In this study, the first author aimed to practice empathetic care by modeling a growth mindset and a commitment to self-improvement.

Dweck (2006) distinguishes between fixed and growth mindsets. Students with a growth mindset believe that intelligence can be developed, embrace challenges, and persist through setbacks. Research on brain plasticity supports the idea that all students can learn mathematics when given the right opportunities and strategies (Boaler, 2013). Growth mindset interventions have been shown to improve academic outcomes (Blackwell et al., 2007). In this course, the first author incorporated activities and resources from youcubed.org to help students develop a "mathematical mindset" (Boaler, 2019).

Together, these frameworks—NCTM's five process standards, self-determination theory, growth mindset, and mathematical caring—guided the instructional decisions in this study. They informed the strategies used to support student engagement, persistence, and well-being in a mathematics course for preservice teachers.

Background

This study was conducted at a public university in the southwestern United States, where over 80% of the student population identifies as Hispanic. In Spring 2021, during the COVID-19 lockdown, 24 preservice middle school teachers enrolled in a capstone mathematics course participated in the study. One student's data was excluded because he joined only the first three classes via Zoom, resulting in a final sample of 23 participants.

The course was taught synchronously online, with students attending 80-minute Zoom sessions on Tuesdays and Thursdays. Weekly homework was submitted via OneNote Class Notebook by Sunday, and quizzes were completed on Blackboard using Respondus Lockdown Browser before the next class. High-cognitive-demand tasks (see Lim, 2014, 2016) were integrated into class sessions to foster mathematical thinking and conceptual understanding, often through collaborative problem-solving in breakout rooms. The course text, *Developing Essential Understanding of Expressions, Equations & Functions* (Lloyd & Herbel-Eisenmann, 2011), supported students in connecting foundational algebraic concepts to strategies discussed in class for solving novel problems.

Methods

This practitioner study drew on multiple data sources—quantitative Likert-scale items, qualitative open-ended responses, and a post-course focus group—to examine the instructor's actions, the challenges encountered, and students' perceptions of the learning environment.

Course Design and Instructional Approach

The first author designed the course to balance cognitive rigor with affective support. Core features included:

- **High-cognitive-demand tasks:** Novel problems requiring reasoning and multiple representations; discussion-oriented debriefs connected strategies to key algebraic ideas.
- **Collaborative structures:** Guided small-group work in Zoom breakout rooms, rotating roles, and public sharing of strategies to normalize partial solutions and revision.

- **Growth mindset language and routines:** Explicit reframing of errors as data for learning; reflection prompts on persistence and strategy; resources from *youcubed.org* (Boaler, 2019).
- **Relational pedagogy and care:** Consistent modeling of respect and trust, flexible office hours, and attention to students' well-being during a period of heightened stress.

Data Collection

Over the 15-week semester, students completed ten reflection logs on: growth mindset (Weeks 2, 8, and 15), problem-solving (Weeks 3 and 12), the learning environment (Weeks 4 and 11), their perceptions of the instructor (Weeks 5 and 14), and mathematics learning (Week 6). Each log began with several Likert-scale items (1 = disagree a lot to 6 = agree a lot), followed by a few open-ended questions.

For this study, we analyzed the logs on the *learning environment* and the *instructor*. In addition, five students participated in a Zoom focus group in mid-June (about one month after the course). The session, facilitated by the second author (not involved in the course), addressed:

- How did students perceive the instructor or the learning environment?
- What actions contributed to establishing a positive learning environment?
- What challenges were encountered and addressed?

Analytic Approach

Quantitative analysis. We conducted Wilcoxon signed-rank tests to compare ratings from Week 4 to Week 11 (learning environment) and from Week 5 to Week 14 (instructor).

Qualitative analysis. We used thematic analysis to identify and organize recurring ideas in responses to two open-ended prompts:

- How would you describe the learning environment of the synchronous classes so far? (Weeks 4, 11)
- The teacher says he wants to create a positive learning environment. Has he been successful? Why or why not? (Weeks 5, 14)

Themes were compared across time points and triangulated with focus group data to enhance trustworthiness.

Instructor Reflexivity

Given the practitioner-researcher role, the first author conducted a reflexive self-study (Lim, 2026) to surface beliefs, predispositions, and rationales underlying instructional decisions. This process included 50 personal journal entries and 16 Zoom-based dialogue sessions with a spiritual friend. The reflexive analysis informed interpretation of student data, particularly around trust-building, navigating tensions (breadth vs. depth; task demand vs. readiness; pacing), shifting perceptions of students (from deficit- to strength-based), and personal/professional growth.

Results – Student Reflection Logs

Table 1 shows the average student ratings (1 = disagree a lot to 6 = agree a lot) for three statements about the learning environment. Ratings increased for all items, with statistically significant gains in students' sense of respect and trust, and their feeling of inclusion.

Table 1: Comparison of Students' Ratings on the Learning Environment: Wilcoxon Signed-Rank Test (n = 22)

Item	Week 4	Week 11	W-Statistic	p-value	Significant? ($\alpha = 0.05$)
There is a high level of respect and trust in this class.	5.09	5.41	20.5	0.0254	Yes
I feel included within the learning environment.	5.05	5.36	10.0	0.0029	Yes
I feel comfortable making mistakes in this class.	4.36	4.68	24.0	0.1367	No

Written responses echoed these results. Nearly all students described the learning environment positively in Weeks 4 and 11, using words like *great*, *good*, and *comfortable*. While S14 and S19 had some reservations, both recognized the instructor's efforts. S14 appreciated that the instructor was "trying his best considering the circumstances," especially compared to previous asynchronous courses. S19 found the synchronous format "a little tough" but still noted that students had "a positive attitude and [were] willing to learn."

Between Weeks 4 and 11, students' focus shifted. In Week 4, ten students commented on structural features such as Zoom, iClickers, and breakout rooms, but only three did so in Week 11. Conversely, twelve students in Week 11 emphasized classroom atmosphere—describing it as comfortable, fun, or supportive—compared to five in Week 4. S21 wrote, "I enjoy coming to class and learn … the professor sometimes talks to us about life and gives me motivation to not give up." Three students in Week 11, up from one in Week 4, highlighted the sense of trust and respect. S7 noted, "I always say what it is I am thinking or am having trouble with."

Table 2 presents student ratings of the instructor across eight items. While most ratings stayed high, three showed statistically significant declines: creating a welcoming community, showing interest in students' thinking, and providing support. These declines may be attributed to the stress students experience near semester's end.

Table 2: Comparison of Students' Ratings about the Instructor: Wilcoxon Signed-Rank Test (n = 20)

Item	Week 5	Week 14	W-Statistic	p-value	Significant? ($\alpha = 0.05$)
The teacher creates a welcoming and inviting classroom community.	5.75	5.45	0.0	0.0143	Yes
The teacher challenges us intellectually.	5.65	5.70	6.0	0.6547	No
The teacher is interested in the way we think about math.	5.90	5.50	0.0	0.0047	Yes
The teacher understands our struggles in learning math.	5.15	4.85	34.5	0.2372	No

The teacher provides an appropriate level of support for us to overcome our struggles.	5.45	4.90	6.0	0.0045	Yes
The teacher uses growth mindset language to motivate us to remain persistent.	5.65	5.35	9.0	0.0833	No
The teacher accepts us for who we are.	5.60	5.55	6.0	0.6547	No
The teacher cares for our well-being.	5.60	5.55	6.0	0.6547	No
The teacher creates a welcoming and inviting classroom community.	5.75	5.45	0.0	0.0143	Yes

In open-ended responses, ten students in Week 5 and six in Week 14 emphasized the instructor's supportive, respectful, and student-centered approach. They appreciated the safe environment where they could ask questions, make mistakes, and stay engaged. S1 wrote that the instructor was "always open to all answers and questions," while S23 said, "he never puts us down" for mistakes. Two students in Week 5 and six in Week 14 mentioned the instructor's emphasis on kindness, citing examples like "show us a video or share a message to be kind" (S3) and "makes us feel cared for" (S6).

Interestingly, four students in Week 5—but none in Week 14—noted the instructor's focus on smiling. S5 wrote, "he is always encouraging us to smile," and S12 added, "he greets me with a smile and by my name." Finally, four students in Week 5 and six in Week 14 described how the class supported a growth mindset. Some reflected on their own development—like S3, who said, "I am being open to learn from my mistakes and not give up." Others appreciated the instructor's encouragement, as S7 shared: "even in situations where we didn't necessarily get the correct answer, he always encouraged us to see that this was still a learning experience."

Results – Focus Group

Students' Perceptions of the Instructor

Students consistently described the instructor as supportive, student-centered, and growth-oriented. They appreciated his encouragement and the way he pushed them to think deeply:

- "He motivated me to keep trying different ways … he would let us go over each other's thoughts" (S19)
- "Push you to make sure you understand it" (S16)

Several students found the instructor personally inspiring:

- "He kind of motivates me to be a teacher like him" (S16)
- "Inspired me to become a teacher" (S2)

His availability and flexibility were also frequently mentioned:

- "Every time I emailed him, he responded the same day" (S2)
- "Going to his office hours helped a lot, he was flexible with the timing" (S5)

- "He would change his office hours when needed, when they didn't work with my schedule" (S16)

Establishing a Positive Learning Environment

Students highlighted the instructor's emphasis on growth mindset as a key factor in shaping the classroom culture:

- "Making mistakes was seen as an opportunity to learn" (S19)
- "The teacher's emphasis on a growth mindset helped me think outside the box" (S16)

They also appreciated the encouragement to explore multiple problem-solving strategies: "He allowed us to explore new ideas and approaches. If we found a new way to solve a problem, he would explore that option and explain it to the class" (S3)

Collaborative learning was another positive feature. Students enjoyed working in groups and found it both engaging and effective:

- "I really like the group work that we did" (S19)
- "We did some really entertaining activities … especially when he put us in groups" (S3)

These group activities not only supported mathematical understanding but also fostered a sense of community. Tools like iClicker helped reduce anxiety around participation: "I like when he uses the clicker because it's anonymous" (S16)

Challenges Encountered and Addressed

Despite the overall positive environment, students noted several challenges. Maintaining focus during class was difficult at times due to personal stress:

- "You're in the class, but you're physically there while your mind is somewhere else" (S3)
- "Having a bad time … because of life in general" (S1)

To address this, the instructor incorporated motivational videos and maintained a consistently encouraging tone:

- "He would start with some videos … like to be kind" (S2)
- "He gave us a lot of positive reinforcement" (S16)

Students also found the original homework timeframes challenging: "The time frame for the homework was kind of hard" (S16). The instructor responded by adjusting deadlines and offering extensions.

Finally, students expressed mixed experiences with class time allocation. While some wanted more time for group work, others appreciated the instructor's efforts to prioritize it:

- "We don't have enough time for group work sometimes" (S19)
- "He wanted to give us extra time to work within our groups to really understand" (S16)

One student also described early frustrations with the LockDown Browser: "I honestly had a really bad relationship with the quizzes at the beginning" (S3). This concern was addressed when the instructor removed the LockDown Browser requirement for later assessments.

Discussion

Findings from the reflection logs and focus group point to the value of addressing students' cognitive and emotional needs in mathematics teacher education. Students generally described the instructor as supportive, responsive, and focused on helping them persist with challenging work. Although several instructor-related ratings decreased slightly toward the end of the semester—likely influenced by typical end-of-term stress—students' written comments continued to emphasize encouragement, flexibility, and care. The shift in student reflections from structural aspects of the course to classroom atmosphere suggests that the learning environment became increasingly relational over time.

The reflexive self-study (Lim, 2026) helps explain how these conditions were cultivated. First, the instructor's attention to *trust-building*—through authenticity, acknowledging mistakes, and modeling a growth mindset—aligned with students' descriptions of feeling safe to contribute and learn from errors. Second, the self-study documented *tensions in practice* (e.g., breadth vs. depth; cognitive demand vs. readiness; pacing within constraints). Decisions to prioritize depth, allow more time for group problem solving, and occasionally lower task demand to stay within students' zones of proximal development are consistent with students' appreciation for flexibility and the emphasis on understanding over speed. Third, the instructor's shifting perceptions of students—from a deficit to a strength-based lens—cohere with students' accounts of being encouraged, listened to, and supported. Finally, the self-study's theme of *personal and professional growth* (greater awareness of emotional responses and their impact) provides a plausible rationale for the steady use of kindness routines, flexible office hours, and motivational messages that students cited as helpful.

Taken together, the student data and self-study suggest that growth mindset messaging, opportunities for multiple problem-solving strategies, and collaborative routines contributed to a space where students felt more comfortable taking risks and learning from mistakes. Group work and tools such as iClicker supported participation and a sense of community, while flexible deadlines and adjustments to assessment procedures helped alleviate stress and technological challenges. The self-study adds context for these moves, indicating that they were not ad hoc but reflected ongoing reflection on trust, care, and the realities of student experience during the pandemic.

Overall, these converging sources suggest that relational and motivational teaching practices can play a meaningful role in supporting preservice teachers' engagement in mathematics, especially in online or hybrid contexts. By modeling empathy, responsiveness, and adaptability—practices the self-study framed as intentional and reflective—the instructor created conditions that supported students' mathematical engagement as well as their confidence as future educators.

Limitations

This study reflects the experiences of a single course taught by one instructor during an atypical period (the COVID-19 pandemic). The small sample size and reliance on self-report data limit generalizability. The focus group was conducted one month after the course, which may influence participants' recall. While the reflexive self-study (Lim, 2026) helps contextualize instructional choices, it is interpretive and situated; future work could triangulate instructor reflexivity with systematic classroom observations or peer debriefing.

Conclusion

This action study illustrates how intentional instructional design—emphasizing growth mindset, autonomy supports, collaborative problem solving, and relational care—can contribute to a positive learning environment for preservice teachers in mathematics. Students reported feeling increasingly included and trusted within the class and described the instructor as supportive, even when end-of-semester pressures affected some quantitative ratings. Humanizing practices in online settings, paired with high-cognitive-demand tasks, may help preservice teachers develop confidence, perseverance, and a broader sense of what it means to learn and teach mathematics. The reflexive self-study clarifies the reasoning behind these practices and underscores the ongoing work of balancing rigor with care.

A LONGITUDINAL STUDY OF PRESERVICE MATHEMATICS TEACHERS' IDENTITY DEVELOPMENT IN HONG KONG

Rui Liu
The University of Hong Kong
ruiliu@connect.hku.hk

Biyao Liang
The University of Hong Kong
biyao@hku.hk

This ongoing study examines preservice mathematics teachers' longitudinal identity development across prior mathematics learning, coursework in initial teacher education, and school-based practicum. It conceptualizes PSMTs' learning to teach as a process in which identities develop, and are projected, reconfigured, and negotiated across contexts. The study follows preservice mathematics teachers throughout a one-year teacher education program in Hong Kong, using a collective case study informed by narrative inquiry and ethnographic methods. Preliminary analysis of one case illustrates how earlier mathematics and student identities were projected into teacher education and practicum, and how these identities shaped the participant's emerging teacher identity. The case suggests that reform-oriented ideas were not simply rejected but were selectively taken up and reorganized across contexts.

Keywords: Identity and Agency, Preservice Teacher Education

Initial teacher education is expected to prepare preservice mathematics teachers (PSMTs) to enact reform-oriented teaching practices (Ma & Singer-Gabella, 2011; Nicol, 1998). However, many PSMTs still teach mathematics in traditional ways after beginning their careers, and the influence of teacher education is often "washed out" in schools (Zeichner & Tabachnick, 1981).

Accounting for this "wash out" effect requires tracing PSMTs' experiences from prior schooling through teacher education and into their teaching in schools. Before teacher education, an "apprenticeship of observation" during their schooling can produce durable images of teaching that favor existing practices and hinder engagement with reform-oriented alternatives (Lortie, 1975). Within teacher education, reform ideas may be understood only superficially when they conflict with PSMTs' prior beliefs (Frykholm, 1999) or remain disconnected from practice (Zeichner, 2010). During practicum and early employment, their enactment of reform-oriented teaching is further conditioned by mentors, colleagues, limited resources, or administrative expectations (Jong, 2016; Losano et al., 2018; Steele, 2001).

A growing body of evidence suggests that PSMTs' learning to teach is a complex, longitudinal process shaped by both prior and ongoing experiences, with implications for their future careers. Yet existing research has rarely adopted a holistic view that examines PSMTs' past and present experiences and the ways these experiences inform their learning to teach mathematics. The ongoing study aims to provide a comprehensive portrait of PSMTs' learning to teach over the long term. In this report, we present a preliminary analysis of the study on one case.

The study considers three contexts in which PSMTs develop as learners and teachers of mathematics: (a) prior mathematics learning contexts (i.e., schools and colleges), (b) courses within the teacher education program, and (c) school-based practicum placements. School-based practicum can approximate work contexts for PSMTs as teachers. Across these contexts, PSMTs participate in different activities, interact with different people, and position themselves and are positioned in different ways; accordingly, the identities they construct and enact may develop along distinct trajectories. Overall, this study addresses the following research question: *How do*

PSMTs' identities develop longitudinally across the contexts of prior mathematics learning, coursework in initial teacher education, and school-based practicum?

Theoretical Perspective

As this study examines PSMTs' learning to teach mathematics across contexts, identity provides a productive lens for linking individual learning and practice with the social contexts in which they are situated (Wenger, 1998, p. 145). We define identity as *socially situated ways of acting in a specific kind of practices* (Darragh, 2016; Darragh & Radovic, 2018). This definition draws from *communities of practice* (Lave & Wenger, 1991; Wenger, 1998), which delineates learning as participation and as being able, or unable, to act socially within a context (Bishop, 2012). Accordingly, we operationalize identity by examining observed actions, narrated actions, and participants' meanings, justifications, and reflections concerning these actions in relation to particular social practices (Darragh, 2016; Radovic et al., 2018; Skott, 2019).

To integrate identity development across contexts, this study focuses on PSMTs' longitudinal development of sub-identities related to learning to teach mathematics, namely, their *mathematics identity, student identity, and teacher identity* (Ma & Singer-Gabella, 2011). Each sub-identity is developed within particular social contexts, projected into other contexts, and continuously negotiated in relation to other sub-identities within those contexts.

Methodology

Three participants were recruited from a postgraduate teacher education program at a top university in Hong Kong with a stated commitment to preparing PSMTs to enact reform-oriented teaching practices. Each cohort of the program enrolls around twelve students. The PSMTs first took courses on the university campus from September to the following February and then participated in professional practicums in March and April in local schools.

We adopted a collective case study (Stake, 2000) informed by ethnographic methods (Creswell & Guetterman, 2019; Emerson et al., 2011; Spradley, 2016) and narrative inquiry (Connelly & Clandinin, 1990; Sfard & Prusak, 2005). The data collection was organized into three phases based on the structure of the teacher education program: at the early stage of the program, we interviewed the PSMTs about their past school experiences; during the coursework stage, we sat in on their teacher education classes, observed the classes, took fieldnotes without participating, and interviewed them about the classes; during practicum, we observed their teaching in practicum schools, took fieldnotes, and interviewed them about their teaching.

Preliminary data analysis in this report is grounded in qualitative content analysis, specifically deductive category assignment or structuring (Mayring, 2015). In this approach, theoretically informed categories are applied to empirical materials through a deductive, theory-guided coding process and revised through close engagement with the data. The initial category framework for this analysis was developed from the theoretical conceptualization of identity as a 3×3 matrix consisting of three contexts and three sub-identities (e.g., student identity in teacher education courses). Data segments were coded based on the operationalization of identity described above and categorized into the matrix for further interpretation.

Results

This section presents Bob's case to illustrate how the influence of teacher education was not simply washed out but filtered and reproduced through his identities. We organize the findings around Bob's sub-identities in the three contexts. These results illustrate how the current

conceptualization of identity can contribute to a fine-grained description of PSMTs' learning to teach mathematics.

Bob was a male PSMT in the program. He finished his schooling and obtained a Bachelor of Science in the Chinese Mainland. Before entering this teacher education program, he had taught for one year at an international secondary school in Hong Kong.

Prior Mathematics Learning

Bob described the mathematics instruction he experienced in school as a practice organized through "explain[ing] a concept," "show[ing] an example," and then doing "exercises and tests." At that stage, mathematics learning for him was "grounded in foundational skills," "mastered by extensive practice," "evidenced by long-term sustainment," and "regulated by the results." At university, although he tried to continue the high-school drilling model in tertiary mathematics courses initially, he found it infeasible because of the increased volume of content. To find a more effective way of doing exercises for learning mathematics, he turned to exam-oriented online courses and AI-facilitated self-study.

This emphasis on hard work and exercises reflects Bob's student identity, which is organized around the strategic allocation of effort toward what counts in the local accountability system. He strategically gave up learning arts subjects by not attending to teaching but doing his own work, judging them to be lower priority relative to his schooling goal of earning good grades in science subjects. However, his teachers tolerated him because he continued learning and did not disrupt the class. This practice continued in his university learning. In university courses, he usually learned by himself through online resources instead of attending in-person classes.

Teacher Education Courses

In teacher education courses, Bob did not simply reject the alternative ways of doing mathematics that he encountered. Rather, course ideas were filtered through his existing mathematics identity. When discussing teaching the perfect square formula with multiple representations (e.g., the sum of the areas of squares or the sum of the products of items in the table), he described it as interesting but said that he would not put it into his own mathematical system. He also said, "I would prefer my students to use algebraic thinking when dealing with algebraic problems." This suggests that alternative mathematical representations were recognized but not incorporated into what counted for him as legitimate mathematics.

Bob's participation in coursework continued to reflect his efficiency-oriented student identity. In the teacher education program, he prioritized obtaining the teaching certificate and did not engage much in classes. He sometimes looked up at the screen and took notes or photos of slides, especially when teachers introduced methods that seemed readily applicable, including flipped classroom approaches and assessment design. He explained that when he heard "an interesting idea" or "a useful website," he would "note it down." Although the participation form changed from high school to university, the efficiency-oriented practice logic was preserved.

Bob's teacher identity was largely informed by his mathematics identities at this stage. He rejected the use of calculators in his classrooms, saying, "there is no calculator… everything is calculated on paper." He believed that using calculators would undermine students' foundational skills. When asked about inquiry-based teaching, Bob positioned it as incompatible with exam-driven contexts, because he "will not have enough time to finish the lesson." He also claimed that finishing a lesson is not only a matter of going through the textbook but also of "cover[ing] all the type[s] of practice … there are so many types of necessary practice." He remained skeptical of "innovation in teaching," viewing it as a risk to instructional quality. He said that "many theories in the program cannot fit into the real classrooms" and explicitly stated that his

way of lecturing is "better than messing up during teaching." For him, lecturing could "guarantee teaching quality" and help students develop foundational mathematical competence.

School Practicum

In practicum, Bob's mathematics identity and teacher identity were simultaneously enacted through a procedural orientation to mathematics practices. He treated mathematics practices as something to be retained, recalled, and applied through correct procedures. He once framed a task as "testing your memory" and told students, "If you forget anything, check your notes." When solving an equation involving a square root with one unknown, he identified the keyword as "separate" and then demonstrated a standard solution procedure. In tutoring a student on this task, he said that "you put the root on one side" and "you need to square both sides." At the same time, this procedural orientation was not merely mechanical. He highlighted the different procedures for the equations that requires "separate" or not. His mathematics teacher identity was enacted as a focus on students' accurate replication and flexible adaptation of procedures; he asked students to remember procedures with notes, repair inaccurate algebraic manipulations, and adapt procedures to the structure of the equation.

Bob's practicum teaching was also shaped by his student identity as a practicum student accountable to mentors and university supervisors. During the practicum, he adjusted his lessons to make his teaching more visibly interactive for his mentor and university supervisors. After being reminded by his mentor, he asked students to solve questions on the board to create more interaction but found that this slowed his progress. When a university supervisor came to observe, he drew on an inquiry-oriented approach promoted in teacher education but transformed it into a highly structured task that could be easily monitored and time-controlled in his classroom. This suggests that reform-oriented practices were not absent in practicum, but were reconfigured into visible, controllable forms whose affordances for supporting student learning were limited as he reflected.

Discussion and Conclusion

This preliminary case suggests that Bob's identities developed longitudinally through the constitution, projection, reconfiguration, and negotiation of earlier identities across contexts. His mathematics identity authorized foundational fluency, sufficient practice, procedural accuracy, and question-type coverage as legitimate mathematical practices. This identity was projected from prior mathematics learning into teacher education courses and practicum, where it shaped how he interpreted course ideas and enacted teaching. His student identity also developed across contexts, from strategic effort allocation in schooling to selective engagement in teacher education and accountability to mentors and supervisors in practicum. His teacher identity then emerged through negotiating these mathematics and student identities during teaching.

This case also suggests an alternative framing of the metaphor of "wash out." In Bob's case, teacher education ideas did not simply go away. Rather, they were selectively taken up and transformed. Reform-oriented ideas appeared in his practicum teaching, but they were reorganized around clarity, time control, progress, procedural coverage, and external evaluation. Thus, the critical issue to consider in teacher education is not only whether it has an influence in PSMTs, but also how that influence is recontextualized through PSMTs' existing identities.

Therefore, teacher education should not only present reform-oriented ideas as a set of theories or strategies that PSMTs can later implement, but also engage PSMTs in examining and reconstructing their mathematics and student identities through which they interpret teaching and cultivate them through reform-oriented ways of doing mathematics and learning to teach mathematics in teacher education classrooms.

LEARNING TO SEE AND RESPOND: PRACTICE-BASED PREPARATION FOR EQUITABLE MATHEMATICS INTERVENTION

Kayce L. Mastrup
California State University Monterey Bay
kmastrup@csumb.edu

Jillian Talley
California State University Monterey Bay
jitalley@csumb.edu

Elementary students experiencing mathematics anxiety, emerging bilingual (EB) status, and/or specific learning disabilities (SLD) are frequently served through fragmented interventions. This pilot study examines a cross-disciplinary, practice-based learning sequence in which elementary mathematics preservice teachers (PSTs) and school psychology graduate students (SPSY) collaboratively design mathematics interventions in general education settings. Grounded in practice-based teacher education, MTSS and UDL, affective perspectives, and DisCrit, the study centers early number concepts, including fractions as numbers. Participants analyze case scenarios, design Tier 1 and Tier 2 supports, rehearse instructional and consultation moves, and engage in structured reflection. Analysis examines shifts in instructional coherence, integration of affective and linguistic supports, and equity-oriented reasoning.

Keywords: Equity, Inclusion, and Diversity; Number Concepts and Operations; Preservice Teacher Education; Students with Disabilities.

Introduction

Elementary students experiencing math anxiety, emerging bilingual (EB) status, and/or specific learning disabilities (SLD) are frequently served through fragmented or pull-out interventions that are disconnected from core mathematics instruction. These structures shape not only students' access to mathematical content but also their mathematical identities and classroom positioning. Within multi-tiered systems of support (MTSS), Tier 1 and Tier 2 instructional responses are intended to occur within the general education context. Yet novice teachers often report limited preparation for designing and enacting instructional responses that attend simultaneously to cognitive, affective, and linguistic dimensions of mathematics learning—particularly for students positioned at the intersection of EB status and SLD.

Research identifies early number concepts, including fractions as numbers, as critical leverage points for long-term mathematics development. However, preparation programs often emphasize identification and referral over instructional decision-making, leaving PSTs with limited experience interpreting assessment data and designing responsive instruction within core mathematics teaching.

School psychologists support teachers in interpreting assessment data, yet their work is often focused on special education processes rather than Tier 1 and Tier 2 consultation. Teachers report difficulty translating psychoeducational reports into actionable classroom practices (Burns et al., 2020). This creates an opportunity for interdisciplinary preparation that strengthens consultation and instructional coherence across roles.

This pilot study examines a cross-disciplinary, practice-based learning sequence in which PSTs and SPSY collaboratively analyze case scenarios and design mathematics interventions grounded in early number concepts within general education contexts.

Purpose of Study

The purpose of this study is to examine how participation in this structured, interdisciplinary learning sequence shapes preservice teachers' conceptualizations and enactment of mathematics

intervention in general education classrooms for students experiencing mathematics anxiety and/or specific learning disabilities, with attention to emerging bilingual learners. The study also investigates how engagement in case-based collaboration supports school psychology graduate students' development of consultation practices and instructional alignment. Finally, it explores how interdisciplinary collaboration surfaces instructional and assessment considerations that can inform the design of coursework in mathematics teacher education and school psychology preparation programs.

Research Questions

1. How do PSTs conceptualize mathematics intervention in general education context, for students with math anxiety, EB status, and/or SLD, before and after participation in a practice-based interdisciplinary learning sequence?
2. How do school psychology graduate students' reflections inform the identification of skill development needs to support teachers' implementation of math interventions in general education settings?
3. How does interdisciplinary case-based collaboration surface instructional and assessment considerations that can inform mathematics teacher education and school psychology preparation?

Theoretical Framework

This study integrates four complementary perspectives, each defined below.

Practice-Based Teacher Education

While student teaching provides authentic experience, it does not guarantee systematic engagement with specific instructional problems, particularly intervention design (Hammerness et al., 2005). Practice-based approaches position approximations of practice, rehearsals, and representations of practice as central to learning to teach (Grossman et al., 2009). Structured approximations allow candidates to engage in complex decision-making within supported contexts.

Multi-Tiered Systems of Support (MTSS) and Universal Design for Learning (UDL)

MTSS frames intervention as layered support within general education systems, while UDL emphasizes proactive design responsive to learner variability, including linguistic and affective dimensions (CAST, 2024; Center on Multi-Tiered Systems of Support, 2026). Together, these frameworks situate intervention as instructional design within tiered, inclusive systems.

Affective Dimensions of Mathematics Learning

While attitudes to mathematics, even negative attitudes, cannot be equated with mathematics anxiety alone, people who think they are "bad at mathematics" are more likely to experience anxiety when engaging in mathematical tasks (Hoffman, 2010). For the purposes of this study, we adopt Richardson and Suinn (1972) definition of mathematics anxiety as a "feeling of tension and anxiety that interferes with the manipulation of numbers and the solving of mathematical problems in…ordinary life and academic situations."

Research in mathematics anxiety demonstrates the impact of affect on working memory (Caviola et al., 2012), persistence and task avoidance (Ashcraft and Rudig, 2012), and the development of mathematical identity (Dowker et al., 2016). Anxiety can tax cognitive resources needed for strategy selection and flexible reasoning, particularly during tasks involving number sense and early quantitative relationships.

Importantly, mathematics anxiety should not be conceptualized solely as an intrapersonal deficit. Students' affective positioning in mathematics classrooms is shaped by instructional

histories, classroom discourse norms, and narratives about ability. Thus, affect operates within sociocultural and institutional contexts, not merely within the individual learner.

Addressing intervention without attention to affective positioning risks reinforcing deficit narratives and avoidance patterns. For example, interventions emphasizing speed, error correction, or isolated skill practice may unintentionally intensify anxiety and confirm students' beliefs that mathematical competence is fixed. In contrast, interventions that foreground conceptual understanding, strategy flexibility, and opportunities for sense-making may support both cognitive growth and more fluid mathematical identities.

Within teacher preparation, PSTs often receive limited support in recognizing the affective dimension of students' mathematical engagement or in designing responses that attend to both cognitive and emotional factors. Through the disciplinary collaboration of SPSY graduate students and elementary mathematics PSTs, this study positions affect as central to instructional decision making.

Sociocultural and Equity-Oriented Perspectives

From this perspective, EB status and dis/ability are not viewed solely as individual deficits but as positioned identities shaped within instructional systems. Attention to language, representation, and participation structures is central to equitable mathematics teaching. One lens that helps to push back on ableism and racism within education systems is DisCrit. DisCrit incorporates a dual analysis of race and ability by drawing on concepts from both Disability Studies and Critical Race Theory (Annamma et al., 2013). As noted by Annamma et al. (2013), "the legacy of historical beliefs about race and ability, which were clearly based on white supremacy, has become intertwined in complex ways that carry into the present day" (p. 2); this is true of all systems, including educational systems. DisCrit provides a lens for examining how race, language, and dis/ability are socially constructed within educational systems and shape students' positioning in mathematics (Annamma et al., 2013). Utilizing Sociocultural and equity-oriented perspectives with the DisCrit position intervention as instructional design work situated within equity-oriented general education practice.

School psychologists and teachers are in a unique position to cultivate opportunities for all students. Through holding this framework, we can encourage SPSY and PSTs to advocate for all students and disrupt systemic oppression. Additionally, by drawing on DisCrit, we examine how SPSY and PSTs reason about mathematics anxiety, EB, and SLD within MTSS structures. This framework allows us to analyze not only the interventions proposed but also how participants position students' competence, agency, and access to mathematics learning within tiered systems of support.

Together, these frameworks function in a complementary manner to guide both the design and analysis of this study. Practice-based teacher education provides the pedagogical structure for approximating intervention design; MTSS and UDL situate that work within tiered, inclusive systems; affective perspectives foreground the cognitive and identity-related consequences of intervention decisions; and DisCrit interrogates how race, language, and dis/ability shape students' positioning within those systems. In combination, these lenses allow us to examine not only what interventions candidates propose, but how they reason about access, competence, and equity within general education mathematics contexts.

Methodology

Design

This pilot study uses a qualitative-dominant mixed-method design. The intervention will be implemented in Spring 2026 across two courses: Elementary Math Methods (PSTs) and School

Psychology Practicum/Intervention (SPSY graduate students). Participants include elementary PSTs in a credential program and second-year SPSY graduate students enrolled at a public university in California.

Intervention: Practice-based Learning Sequence

The five-phase sequence includes foundational instruction on math anxiety, SLD, EB-responsive practices, and early number concepts; structured case analysis of students positioned at intersections of EB, SLD, and anxiety; collaborative design of Tier 1 and Tier 2 interventions; rehearsal of instructional and consultation moves; and structured reflection.

Data Sources and Analytic Approach

All data will be collected in Spring 2026, with analysis occurring in Summer 2026 and preliminary findings presented at PME-NA Fall 2026. Data sources include pre/post intervention plans, written case analyses, participant reflections, consultation artifacts, and rubric-based ratings of intervention quality.

Analysis will employ a qualitative-dominant approach using a hybrid deductive–inductive coding process. Initial codes will be informed by constructs from the theoretical framework (e.g., instructional coherence, integration of affective and linguistic supports, equity-oriented reasoning), while allowing for emergent themes across artifacts and interdisciplinary dialogue. Pre/post comparisons will examine shifts in how PSTs and SPSY candidates conceptualize intervention within general education contexts. Cross-case analysis will identify patterns in consultation language, alignment between assessment and instruction, and positioning of students' competence and agency. To enhance analytic trustworthiness, multiple researchers will code a subset of artifacts and engage in consensus discussions, supported by analytic memos documenting interpretive decisions.

Anticipated Contributions

This pilot study contributes to the PME-NA scholarship in four primary ways. First, it extends research on preparing PSTs to design and enact mathematics interventions within general education classrooms by foregrounding instructional responses rather than referral processes. The study examines how structured approximations of practice can support intervention reasoning grounded in core mathematical ideas.

Second, the study contributes to understanding how PSTs and SPSY graduate students reason about intersectionality in mathematics learning. By analyzing case-based decision making, the study illuminates how candidates attend to math anxiety, EB, and SLDs in relation to conceptual mathematical development.

Third, the project adds to the literature on practice-based approaches for supporting early number concepts by examining how interdisciplinary teams analyze student thinking and select evidence-based intervention strategies grounded in core mathematical ideas.

Finally, it contributes to equity-oriented teacher preparation research within PME-NA by investigating how cross-disciplinary collaboration can support more coherent, inclusive, and instructionally grounded approaches to Tier 1 and Tier 2 mathematics intervention.

As a pilot study, implementation will occur in Spring 2026. Findings from the initial implementation–including analyses of participant artifacts and interdisciplinary collaboration–will be presented at PME-NA to inform mathematics teacher educators and school psychology faculty interested in integration assessment, consultation, and instructional design within preparation programs.

USING CASES TO PREPARE FOR EQUITY-RELATED CLASSROOM ENCOUNTERS: CREATIVE INSUBORDINATION THEMES FROM PRESERVICE ELEMENTARY TEACHERS

Bailey Ondricek
University of Utah
bailey.ondricek@utah.edu

Preparing preservice teachers to respond to equity-related issues in their future classrooms can be a challenge for teacher educators (e.g., Chang-Bacon, 2022). Case-based scenarios, or cases, provide rich opportunities for preservice teachers to grapple with these issues. This research uses the lens of creative insubordination (Gutiérrez, 2016) to examine preservice teachers' responses to one such case, which illustrates inequitable time distribution for math and science across school districts. Written data from six semesters of elementary math methods courses were analyzed to illustrate how creative insubordination strategies emerged in preservice teachers' responses to the case. Findings from this analysis offer insights on which strategies preservice teachers considered more readily and invite discussion on how teacher educators may support preservice teachers in considering less frequently cited strategies.

Keywords: Preservice Teacher Education; Teacher Educators; Equity, Inclusion, and Diversity

Study Purpose

The National Council of Teachers of Mathematics (NCTM) has called for a mathematics education culture of equity and access, where math teachers enact culturally responsive and equity-focused pedagogy (NCTM, 2014). In response to this call, our team has worked with local teachers to develop case-based scenarios the depict authentic challenges they have encountered related to teaching math equitably. The cases are designed to be used in math methods classes to support preservice teachers (PSTs) to think through equity concerns prior to encountering them in their own classrooms. This study focuses on the Daily Schedule case (see Figure 1), considering the research question: How do themes of creative insubordination emerge in PST responses to the Daily Schedule case?

Perspectives

Cases have been used in teacher education to support PSTs in examining critical tensions (e.g., Arellano et al., 2001). Our cases follow the traditional narrative form with details that engage the PST reader in critically considering multiple interpretations (Shulman, 1992). Concerns of authenticity and deep reflection in case design (Bencze et al., 2001) were addressed in our cases by partnering with local teachers to ensure relevant scenarios, and an in-class implementation process that invites PSTs to first read and reflect on the case independently before engaging in small group discussions and a whole-group debrief of the case.

Authoring teachers were invited to consider one or more feature of culturally grounded pedagogy (CGP) in designing their case. CGP integrates the work of multiple equity-focused scholars (Aguirre et al, 2013; Banks, 2019; Gay, 2002; Ladson-Billings, 1995, 2014; Paris, 2012) and includes the following four features: 1) leverage students' multiple strengths and competencies, 2) honor students' lived experiences, 3) dismantle power and status hierarchies, 4) diversify curriculum and challenge dominant perspectives (Dobie et al., 2024). The teachers authoring the Daily Schedule designed the case with a focus on CGP feature 4.

The final prompt in the Daily Schedule case invites PSTs to consider strategies for advocating for their students, given inequities in time distribution of subject areas in their Title I school with a high multilingual population. This call to action solicited a range of strategies that align with the ideas of creative insubordination (CI) (Gutiérrez, 2016) which emerged from mathematics teachers' experiences addressing political situations. In the analysis that follows we matched PSTs' responses to the case with each of Gutiérrez's six strategies: press for explanation, counter with evidence, use the master's tools, seek allies, turn a rational issue into a moral one, and fly under the radar. This analysis offers insights into strategies that PSTs may be more comfortable implementing and strategies that may require additional support.

You are a first-grade teacher, newly hired to a Title 1 District with a high ELL population and a heavy focus on literacy. You've learned that about 60% of the students were below benchmark at the end of last year in literacy. The month before school begins you receive your daily schedule for the upcoming school year. You notice that you are only allotted 30 minutes for science twice a week, and 45 minutes a day for math. In comparison, there are 3 hours each day allotted for literacy (including phonics, intervention time, fluency, and reading comprehension). You're talking with a friend from your teacher prep program who got a job at a school in the neighboring district (non-Title 1, majority White, low ELL population), and they tell you that they are allotted an hour and a half of math and 1 hour of science per day.

After learning about this disparity between the two districts, you decide to ask someone about your schedule. Your instructional coach is your primary support for teaching and learning across all subject areas, so you approach them to ask why you don't have more time to teach math and science. Your coach says, "That's not what these kids need." When elaborating, they added that it would be nice to have more time for math and science, but last year's reading scores indicated a need to increase the focus on literacy.

Please discuss the following questions:

1. What do you notice happening in this scenario? What initial reactions and feelings come up for you?
2. What's the value in your coach's perspective in terms of supporting student learning and engagement? What are the drawbacks of that perspective for student learning and engagement?
3. What is your own personal perspective, and what experiences have you had or ideas have you encountered to support that perspective?
4. Given the circumstances, how do you think you can best advocate for your students' math and science learning moving forward?
    a. What information would you want to gather and what research might be helpful to know about to inform your advocacy? (e.g., I would want to learn more about… It would be helpful to know if researchers have studied…)

Figure 1: Daily Schedule Case

Methods

Written response data was collected from 107 PSTs across six semesters of elementary math methods classes between 2021–2025 in a university teacher education program in the mountain west. PSTs engaged with the case by a) individually reading the case and writing responses to case prompts, b) engaging in small group discussions, c) participating in a whole class discussion, and d) completing written exit tickets reflecting on experiences engaging with the case. This analysis focuses on PSTs' written responses to case prompts, which are referenced in full at the end of the case (see Figure 1). Written responses were chosen as the unit of analysis because they reflected PSTs' initial strategies prior to input from peers or the instructor.

The primary author read through the data set in its entirety and determined that responses to prompt 4 were most aligned with strategies for CI and selected these responses for coding. Two coders coded 10% of the data for the six CI strategies to calculate inter-coder agreement, finding a high level of agreement (Krippendorff's alpha = .82) The primary author coded the remainder of the data. Altogether, 168 strategies described in PST responses were coded.

Results

Analysis showed differing frequencies in the strategies described in response to this case. *Countering with evidence* and *using the master's tools* appeared with high levels of frequency, with *flying under the radar* and *pressing for explanation* occurring least often and *seeking allies* and *turning a rational issue to a moral one* having middling frequency. Highlighted below are additional details on these patterns, along with their potential significance for preparing PSTs to advocate for students.

Frequently Cited Strategies

High frequency in the countering with evidence strategy (n = 82) was unsurprising as our case prompt solicited gathering evidence: "What information would you want to gather… to inform your advocacy?" Included in this count were any responses wherein PSTs described sharing research or classroom data that proved reduced time for mathematics would not be an effective solution for improving literacy scores. Some responses acknowledged the importance of both classroom and external data, as one PST wrote, "Due to the fact that the data coming from my classroom would be pretty short-term as far as how long the research has been being done, I would want to present studies that support my point that have shown positive results coming from a study done over several months or years."

The other most commonly described strategy from our PSTs was using the master's tools (n = 53). This code was applied when PSTs justified doing what was in students' best interest using language that might be valued by administrators or stakeholders. Overwhelmingly, PST responses under this category involved using integration as a way of getting around the scheduling issue. One PST described this as a "loophole," writing, "I would try my hardest to integrate it into my literacy, that way there are still mathematical and scientific elements in everyday lessons. Sort of as a loophole to the system."

Infrequent Strategies

Given that a press for explanation is already built into the case ("you approach [your instructional coach] to ask why you don't have more time to teach math and science"), it was unsurprising to see a lower number of responses describing pressing for explanation (n = 6), which we defined as asking an authority figure to explain the time constraints in the daily schedule. The few responses that included an additional press for explanation typically involved a general statement about the types of questions a preservice teacher would be interested in

asking about the time distribution decisions, for example, "I would want to know if they had discussed alternative solutions and what those solutions were."

We expect that flying under the radar may have been less frequently described (n = 3) by our PSTs given to the extra supervision that new teachers receive. In our coding scheme, we defined this strategy as PSTs describing acting in opposition to the provided schedule without drawing attention. This is illustrated in one PST response which read, "I may fudge a couple things to incorporate more time for science and math, but if I get questioned I will share what literacy things I am doing [during] those times."

Strategies for Future Emphasis

PST responses that described discussing concerns with colleagues were coded under seeking allies (n = 9). This definition is not an exact match with Gutiérrez's (2016) description as PST responses did not differentiate allies from other colleagues. Thus, we expanded this code to include collaboration or discussion with any colleagues. For example, one PST wrote, "I can best advocate for math and science for my students by discussing their importance just as equally as literacy to other teachers, colleagues, coaches, the principal, etc." This grouping of all colleagues together when advocating or seeking support signals an opportunity to further discuss finding critical friends and seeking support from more experienced educators with PSTs (Lord, 1994).

A second strategy warrants further attention is turning a rational issue into a moral one (n = 15). While Gutiérrez (2016) characterizes this strategy as an appeal to the heroism of stakeholders, we broadened this definition to include any PST responses that included a moral claim, even if it did not extend to advocacy with an outside party. One PST explained, "I would talk to my principal and get in contact with the school board and district about the restriction this causes for students to achieve social mobility." Other responses in this category did not necessarily extend the moral accountability to a specific stakeholder which may suggest that not all PSTs not realize the ways in which they can publicly advocate for students.

Discussion

This research highlights the valuable role that cases can play in supporting PSTs to develop their understanding of CGP and developing advocacy strategies. Written responses to case prompts offer a window into the ways in which PSTs feel more comfortable engaging in creative insubordination, as well as strategies that might benefit from more attention in the future. Thus, PST educators can use cases targeted to local concerns as a formative tool to determine where PSTs may need support in understanding their options for advocacy. To encourage these efforts, our research team is working to develop design principles that researchers and teacher educators can use in developing their own cases that prompt rich discussion and grappling with relevant teaching concerns.

PATTERNS IN PROSPECTIVE TEACHERS' MATHEMATICAL CONTENT KNOWLEDGE WHILE CRITIQUING AI-GENERATED GEOMETRIC JUSTIFICATIONS

Ayse Ozturk
Old Dominion University
aozturk@odu.edu

Pavneet Kaur Bharaj
California State University, Long Beach
pavneetkaur.bharaj@csulb.edu

This paper reports preliminary findings related to prospective elementary teachers' (PTs) mathematical content knowledge from a larger qualitative study examining how PTs critique AI-generated geometric justifications. Twelve PTs participated in the study by submitting written critiques of five AI-generated geometric justifications. Through thematic analysis of the PTs' written critiques, we analyzed patterns in PTs' content-dependent reasoning, capturing instances in which PTs' evaluation accuracy was shaped by their understanding of geometric definitions, properties of two- and three-dimensional shapes, and the hierarchical relationships among figures. We identified three recurring patterns: conceptual gaps in distinguishing cones and pyramids, partial understanding of the relationship between kites and rhombi, and limited awareness of inclusive versus exclusive definitions.

Keywords: Elementary Prospective Teachers, Geometry, Justification, Content Knowledge

Recent advances in generative artificial intelligence (AI) have introduced new opportunities and challenges in mathematics teacher education (Son et al., 2024; Yoon et al., 2024). When AI-generated explanations are used as instructional objects, prospective teachers (PTs) are positioned not only as learners but also as evaluators of mathematical reasoning (Klawa et al., 2025; Uygun et al., 2025). This evaluative stance requires activating mathematical content knowledge, particularly in geometry, where definitions, classifications, and hierarchical relationships play a central role in justification. Building on the literature, this paper focuses answering the research question: *How does PTs' mathematical content knowledge influence their critiques of AI-generated geometric justifications?*

Conceptual Framework: Justification Rubric

In this study, we adopted Melhuish et al.'s (2020) definition of justification as using definitions or properties to support claims and explain why they hold. We specifically focused on PTs' critiques of geometric justifications where spatial thinking and logical argumentation intersect to support formal justification (Stylianides et al., 2016). We adapted Brunheira and Ponte's (2019) conceptual framework, which builds on the organization of levels of justifications (see Figure 1).

This framework describes a progression in the quality of geometric justification, focusing on how claims are supported and generalized. At the most robust level, justifications rely on established geometric ideas and explicitly connect those ideas to the claim in a way that explains why it holds beyond a single case. At intermediate levels, reasoning may draw on appropriate geometric properties but remains incomplete, either because key steps are missing or because the argument is tied to a specific example rather than extended to a broader class of figures. Less developed responses attempt to justify claims using inappropriate or loosely connected ideas, revealing breaks in logical coherence or dependence on intuition instead of warranted geometric reasoning. At the lowest level, explanations do not engage with geometric

reasoning at all, instead depending on measurements or calculations without making conceptual connections to underlying geometric structures.

Level	Description	Evidence Indicators	Points
Level 3	**Correct geometric justification**: Argument uses relevant, established geometric properties to explain *why* the claim is true. Applies to a general class of figures, often using a generic example.	- Correct use of definitions, theorems, or properties. - Clear logical sequence that works for all relevant cases. - Language indicates generality ("for all…", "whenever…").	3
Level 2	**Incomplete (Partially Correct) justification**: Uses some relevant properties but omits key steps or assumptions. Reasoning may be tied to a single figure even if it hints at generality.	- Some correct reasoning but missing one or more critical information. - May rely on a specific geometric figure or property without clarifying applicability to all cases.	2
Level 1	**Incorrect justification:** Uses irrelevant or unestablished properties to justify the claim. The conclusion may be correct by coincidence, but reasoning is flawed.	- Misuse of definitions or properties. - Logical gaps that make the justification invalid. - Relies on intuition rather than evidence or theorem.	1
Level 0	**No geometric justification**: Relies solely on measurement, numerical computation, figures without connecting to geometric properties.	- "It works because I measured it" / "the textbook says so." - No explicit geometric figures or properties mentioned or explained.	0

Figure 1: Levels of Geometric Justification (Adapted from Brunheira & Ponte, 2019)

As shown in the adapted framework, three fundamental elements of justification are emphasized when PTs used this rubric to evaluate AI-generated justifications: the use of definitions, the logical sequencing of claims, and the generalizability of the argument. The rubric guided PTs' evaluations of the AI-generated justifications and informed the initial data analysis and coding process by focusing on how PTs referenced these elements in their critiques, particularly in relation to their mathematical content knowledge.

Research Setting and Participants

This pilot study involved twelve PTs enrolled in a mathematics content course at a public university in the southeastern United States. The data come from a larger qualitative study examining how PTs critique AI-generated geometric justifications across two universities. Although 50 PTs returned signed consent forms from two institutions, this paper reports only on the pilot data from the twelve participants. All names used in this paper are pseudonyms.

Materials, Methods, Sample Task, and Data Collection

This exploratory qualitative study (Kalu & Bwalya, 2017) examined twelve PTs' written evaluations of AI-generated geometric justifications. Using the rubric (Figure 1), PTs assigned a Level 0–3 score to each AI-generated response and cited evidence to provide their evaluations by attending to definitions, geometric properties, logical sequencing, and the generalizability of the arguments presented in the AI responses. An example task is provided below (see Figure 2).

Statement: **A cone is a special type of pyramid.**

ChatGPT-generated response: Yes, a cone is like a pyramid because both have one base and come to a single point at the top, called the apex. For example, if you think about a square pyramid and a cone, they both narrow as you go up. The only difference is that a cone has a circular base instead of a polygon base. So, a cone can be seen as a pyramid with a round base.

Assigned Level:
Evidence to Assigned Level:
Suggested Improvements (if any):

Figure 2: Sample Task

In this sample task, the appropriate evaluation is a Level 1, as the AI-generated response is incorrect. A cone is not a polyhedron because it has a curved surface and a circular base, which is not a polygon. A cone does not satisfy the defining properties of a pyramid. The task design positioned PTs as critics, encouraging them to think critically, question automated reasoning, and develop confidence in explaining their ideas. Researchers/instructors of the geometry content courses developed a worksheet consisting of five such tasks, including the example shown in Figure 2. PTs completed the worksheet as a homework assignment and as part of the course requirements.

Data Analysis and Example Students' Written Critiques

The data set consisted of rubric-scored written critiques from twelve PTs, collected through a homework worksheet in which participants rated AI-generated justifications. Our analysis focused on how prospective teachers (PTs) engaged with geometric definitions, properties, and hierarchical relationships when critiquing AI-generated justifications. We conceptualized each AI-generated response and the corresponding PT critique as a *content-evaluation excerpt*, in which PTs were required to interpret the mathematical validity of a claim, assign a justification level using the rubric, and provide written evidence to support their evaluation (Figure 2). These excerpts served as analytic units for examining how PTs' mathematical content knowledge shaped their evaluative judgments. The criterion for selecting written excerpts was that they illustrated variation in how PTs attended to core geometric ideas when evaluating AI-generated reasoning.

Using a thematic analysis approach (Xu & Zammit, 2020), data analysis proceeded in four steps: (a) identifying evidence of content-dependent reasoning within PTs' written critiques, (b) using the justification rubric (Figure 1) to code how PTs referenced definitions, properties, and generalizability when evaluating AI responses, (c) comparing rubric scores with the mathematical accuracy of PTs' written justifications to identify content-related inconsistencies, and (d) inductively developing themes that captured recurring patterns in PTs' mathematical content knowledge across tasks. While additional analyses are ongoing to examine how PTs' critique practices develop over time and across instructional contexts, this paper focuses on illustrating one analytic theme from the data: emergent patterns in mathematical content knowledge as revealed through PTs' written critiques of AI-generated geometric justifications. To foreground this theme, we selected illustrative excerpts from different PTs that highlight variation in how content knowledge shaped evaluative decisions.

Emergent Content Knowledge Patterns Within PTs' Written Work

In this theme, we display initial patterns in PTs' mathematical content knowledge as evidenced through their written critiques of AI-generated geometric justifications. Our analysis focuses on how PTs engaged with core geometric ideas—such as definitions, properties, and

hierarchical relationships—when evaluating the validity of AI-produced reasoning. By examining where PTs accepted, partially rejected, or accurately critiqued AI explanations, this analysis reveals how their content knowledge shaped evaluative judgments. This theme encompasses patterns where PTs' accuracy depended on their understanding of geometric concepts. Errors stem from gaps in content knowledge rather than misinterpretation of rubric criteria. Three recurring patterns emerged within the theme: Conceptual gaps in distinguishing cones and pyramids, partial understanding of kite–rhombus relationships, and limited awareness of inclusive versus exclusive definitions of trapezoid. These patterns illuminate both developing aspects of PTs' geometric understanding (see Table 1).

Table 1: Patterns in Content Knowledge and PTs' Written Work

Patterns in Content Knowledge	Illustrative Written Work:
Conceptual Gaps in Cone-Pyramid Distinction. Reflecting PTs' difficulty distinguishing between cones and pyramids based on formal geometric definitions.	**Student 1:** *"ChatGPT's response correctly explains similarities between cones and pyramids and distinguishes the circular base as the only difference."* This excerpt illustrates a conceptual gap regarding the defining property of pyramids as polyhedral. In contrast, a PT with stronger content knowledge rejected the AI reasoning: **Student 11:** *"I would give level 1 because the response is wrong. My evidence is that a shape with a curve will never be a polygon. Since pyramids are made of flat polygonal faces, a cone cannot be a type of pyramid.*
Partial Understanding of Kite-Rhombus Relationship. Capturing variability in PTs' understanding of hierarchical relationships among quadrilaterals.	**Student 2:** *"Not every kite is a rhombus. Some only require two adjacent sides to be equal, while rhombuses require four."* Although directionally correct, this explanation omits that kites require two pairs of adjacent congruent sides. In contrast, a more precise critique stated: **Student 7:** *"ChatGPT's response level is 2, which is partially correct. Because a kite has two pairs of adjacent equal sides, while a rhombus has all four sides equal. Therefore, every rhombus is a kite, but not every kite is a rhombus."*
Limited Awareness of Inclusive vs Exclusive Definition of Trapezoid. Acknowledging the existence of inclusive versus exclusive definitions when critiquing an AI-generated statement about trapezoids.	**Student 6:** *"ChatGPT's response level is 2, which is partially correct. Looking over the definitions, I can say that the statement depends on the definition being used. For example, If trapezoids are defined as having at least one pair of parallel sides, then the claim is false because parallelograms are also trapezoids."* Only two PTs explicitly referenced definitional conventions—specifically, the inclusive and exclusive definitions of trapezoids—when critiquing the AI-generated response. All other PTs relied exclusively on the exclusive definition of a trapezoid and consequently assigned the AI response a Level 1 rating.

When critiquing AI-generated justifications involving three-dimensional figures, seven out of 12 PTs struggled to distinguish cones from pyramids using formal geometric definitions. In particular, some PTs accepted AI explanations that characterized cone as a type of pyramid with a circular base. These responses suggest reliance on surface level similarities such as the presence of a single apex in both shapes rather than attention to defining properties. PTs who demonstrated stronger content knowledge rejected this reasoning by invoking the defining characteristics of pyramids as polyhedral composed exclusively of flat polygonal faces.

Most PTs (nine out of 12) correctly noted that not all kites are rhombi; however, some explanations lacked precision in defining the requirement that kites contain two pairs of adjacent congruent sides. Students varied in their precision when articulating the hierarchical relationship

between kites and rhombi. The last pattern was rare but significant. Only two PTs explicitly acknowledged the existence of inclusive versus exclusive definitions when critiquing an AI-generated statement about trapezoids. The scarcity of this pattern suggests that most PTs treat definitions as fixed and limit their ability to critically evaluate AI responses.

Results and Conclusion

This study examined how PTs' content knowledge shaped their critiques of AI-generated geometric justifications. Analysis of written excerpts show that many PTs relied on surface-level similarities, leading to acceptance of incorrect claims, whereas those with stronger content knowledge used formal definitions and hierarchical relationships to reject flawed explanations. Overall, PTs showed emerging understanding of quadrilateral classifications. The findings suggest that AI critique tasks as a useful tool for revealing PTs' content knowledge and informing targeted instructional focus in teacher education, aligning with the previous studies (e.g., Yoon et al., 2024).

MATHEMATICS, ME, AND MY FUTURE STUDENTS: INCOMING ELEMENTARY PRESERVICE TEACHERS' BELIEFS

Sarvani Pemmaraju
Middle Tennessee State University
sdm4j@mtmail.mtsu.edu

PISA results for the U.S. have consistently declined in mathematics. The 2018 PISA study found students' beliefs about malleability of their intelligence positively impacted achievement, particularly when their teachers held positive beliefs about students' abilities. Yet preservice teachers (PSTs) held negative beliefs about mathematics. To inform interventions addressing these beliefs, this interpretivist study examined incoming PSTs' beliefs about mathematics and mathematical abilities, and how these align with beliefs about their hypothetical students' abilities. Data from two qualitative surveys given to elementary PSTs in an introductory content course were analyzed using open thematic analysis. Findings indicate PSTs held both positive and negative beliefs, with past teachers influencing both. PSTs held more positive beliefs about their students' abilities than their own. Implications for research and practice are discussed.

Keywords: Preservice Teacher Education; Teacher Beliefs; Affect, Emotions, Beliefs, and Attitudes

Introduction and Background Literature

The United States continues to face challenges with persistent underperformance and a declining interest in mathematics (Boaler, 2016; Gouëdard, 2021; Schleicher, 2019), which was evident in international assessments like the Programme for International Student Assessment (PISA). Between 2018 and 2022, average PISA results in mathematics declined for the U.S, reflecting not only a gap in mathematical skills, but also a problem related to beliefs and attitudes toward mathematics. Additionally, the 2018 PISA study revealed that students' beliefs in the malleability of their intelligence had significant positive associations with their test scores across seventy two countries, including the U.S. (Schleicher, 2019; Yeager & Dweck, 2020). Moreover, these associations were stronger when students were taught by teachers who held positive beliefs about their students' abilities (Gouëdard, 2021). These findings highlight the importance of beliefs, both about mathematics and mathematical abilities, in addition to mathematical skills.

However, research revealed that students, including preservice teachers (PSTs), often hold numerous non-availing beliefs about mathematics and the nature of mathematical knowledge (e.g., Celik et al., 2018; Muis, 2004). One common belief is that mathematical knowledge is unchanging and is simply received passively from a source, such as a teacher or textbook (Celik et al., 2018). PSTs also bring a range of beliefs and misconceptions into teacher education that inhibit their ability to benefit from instruction (Lloyd, 2017; Pajares, 1993). Although interventions and course experiences in teacher training promoted desired changes in these beliefs to some extent, research found that PSTs who entered teacher education with these deeply rooted mathematical beliefs often held on to them even after coursework in some cases (Auslander et al., 2019; Chamberlin, 2013). When looked closely, most of these interventions were implemented towards the later part of teacher education programs (e.g., Auslander et al., 2019). Less attention has been given to understanding what beliefs PSTs bring into teacher education, their prior experiences that framed these beliefs, and interventions targeting them. Addressing this gap, the current study aims to understand PSTs' beliefs in an introductory

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

mathematics content course to inform design of interventions that leverage PSTs' existing positive beliefs while intentionally addressing the negative ones.

Moreover, although prior studies examined mathematical beliefs of PSTs, no other study to the best of my knowledge examined PSTs' beliefs about their future students' mathematical abilities, especially in an introductory course. Understanding these beliefs is an important first step in designing interventions using PSTs' strengths to address their negative beliefs. As part of a bigger study aiming to design better interventions to foster positive beliefs of PSTs in an introductory content course, this current study sought to investigate the following questions.

RQ1: *What beliefs about mathematics and mathematical abilities do incoming elementary preservice teachers bring to their introductory mathematics content course?*

RQ2: *How do incoming elementary preservice teachers' beliefs about their own mathematical abilities align or misalign with their beliefs about mathematical abilities of their future students?*

In this study, I define beliefs as "psychologically held understandings, premises, or propositions about the world that are thought to be true" and can be seen as lenses that shape one's perspective or as dispositions that guide one's actions (Philipp, 2007, pg. 259).

Theoretical Framework

Interpretivism (Stinson & Walshaw, 2017) provided the lens to understand PST beliefs. Sun's (2015) beliefs about mathematics and mathematical abilities framework provided the central mechanism for data collection. Sun's (2015) beliefs about mathematics framework consisted of three constructs namely: identification with mathematics, nature of mathematics, and mastery-oriented beliefs (or beliefs about making mistakes). This study considered two additional constructs, namely experiences that affected these beliefs (Boaler et al., 2022), and beliefs about mathematical authority (Wilson & Lloyd, 2000). Beliefs about mathematical ability can be viewed as either malleable or fixed (Dweck, 2006), across two dimensions of one's own abilities and their future students' abilities. Beliefs across the dimension of hypothetical future students' abilities are specific to PSTs and are considered in this study building on Sun's work.

Data Collection, Analysis, and Methods

Participants were twelve elementary PSTs enrolled in an introductory mathematics content course on number and operation, at a public university in the southeastern U.S. Two data collection instruments namely 'Beliefs about Mathematics' and 'Beliefs about Mathematical Ability' surveys were adapted from Sun's (2015) validated Likert scale instrument. I adapted Sun's (2015) instrument by splitting it into two shorter surveys. I reworded items into open ended surveys to collect qualitative data and added a few items to collect data from participants treating them as future teachers rather than as students. For example, I added questions asking participants about their hypothetical students, which is suited for future teachers only. I open coded survey responses until saturation of codes. Coding was conducted in iterations by revisiting and refining to determine broader themes and to improve robustness of findings.

Findings

Research Question 1

Due to space restrictions, only participant beliefs about three out of five constructs are described here. Findings indicate PSTs held both positive and negative beliefs about mathematics. Surprisingly, the theme "past teachers" was related to both positive and negative beliefs. Table 1 below highlights other themes in each category.

Table 1: Themes Related to Positive and Negative Experiences with Mathematics

Overall Positive Experiences ~ 45%	Overall Negative Experiences ~ 55%
Past teachers ~ 10%	Past teachers ~ 25%
Advanced course work ~ 40%	Pandemic during high school ~ 17%
Love for mathematics ~ 10%	Harder concepts ~ 41%
Job related to mathematics ~ 20%	Geometry ~ 17%
Good experiences with math ~ 20%	

The most concerning response was from a participant Zara, who described their previous experiences with mathematics as follows.

> Zara: I always liked math. It made me feel smart, but sometime in high school the math problems started getting harder and teachers started teaching less. Not only was this during the Covid-19 pandemic so we were in and out of school but my teachers were tired and burnt out. It became more and more difficult to grasp the concepts and I had just accepted that I was bad at math.

This participant who previously felt good at math had changed their beliefs about their mathematical abilities due to various negative experiences they had, such as harder concepts in high school, pandemic, and teachers during pandemic. Understanding such past experiences of PSTs helps design better interventions to foster their positive beliefs about mathematical abilities, which can have an impact on the next generation of students.

To dig deeper into the construct of *Identification with Math*, I asked my participants to use four to five words to describe mathematics and use pictures from the internet to describe their feelings about mathematics. The most frequently used words were "challenging" and "rewarding." These words when looked together with the pictures participants used indicated that the participants associated mathematics with persistence, effort, and making mistakes which result in the rewards. They recognized that their effort in mathematics is rewarding, which means they have the potential to emphasize the value of effort, persistence and making mistakes in their future mathematics classrooms.

Regarding participant beliefs about *Making mistakes* in mathematics, findings show that while most PSTs understand mistakes support learning, many still experience frustration, embarrassment, or discouragement about making mistakes. This was evident from participant responses, one of which is highlighted below.

> Sam: In all things, including math, mistakes help you learn. In most learning environments, it is important to avoid mistakes because it will affect your grade. Many teachers don't give students the opportunity to learn and grow, they just care if the student is right or wrong. It is important to let students make mistakes without punishment as they will learn from them.

Research Question 2

To answer RQ2, participants were first asked to describe their own mathematical abilities by asking them "*How comfortable are you with mathematics on a scale of 1–10? Describe any prior experiences that shaped these beliefs?*" Then, they were asked to describe their thoughts about a hypothetical situation, where they are teaching in a classroom, see some kids struggle with content, and when this concern was shared with a fellow teacher, they respond "*Some kids*

can never do well in math, no matter how hard they try." Participant Anna's responses are presented.

> Anna (about own abilities): I don't see myself as a math person. On a scale from 1 to 10 I'll say I'm about a 6. I've never understood math well so it takes me a lot of work to understand it. I think I have a harder time when it comes to math that deals with graphs.
>
> Anna (about hypothetical students' abilities): I would think that the fellow teacher is really ignorant because they are assuming that some kids never do well when it is very possible for all kids to do well. You just need to understand that all kids learn differently.

Similar to Anna's response highlighted above, almost all participants disagreed with the hypothetical fellow teacher's response, while only one participant agreed. This indicates PSTs held more positive beliefs about their students' abilities than their own abilities. Two sample participant responses where PSTs valued their mission as future teachers are highlighted below.

> Ava: it's our job as educators to help them [students] believe in their ability to learn.
>
> Felix: This mindset is how kids end up never doing well in math, because nobody else believed in them improving, so they could not believe in themselves.

These PSTs demonstrated strong motivation to become effective teachers, potentially inspired by their own negative mathematical experiences to intentionally avoid those for their students.

Discussion and Conclusion

Building on prior research, these findings add to the literature PSTs' beliefs about their hypothetical students, which moves the field forward in designing better interventions that build on PSTs' strengths to address their negative beliefs. As Kagan (1992) asserted, PSTs' preexisting beliefs must be made explicit and challenged for them to meaningfully examine and integrate new ideas into their belief systems. Such integration requires PSTs to reexperience mathematics in research-based ways as learners of mathematics rather than as teachers (Mizell & Cates, 2004). This is possible only when PSTs' beliefs are revealed early in teacher education.

Findings that PSTs held both positive and negative beliefs about mathematics carry implications for both research and practice. For research, this underscores the need for designing effective interventions that can help PSTs overcome academic challenges in mathematics, thus fostering their positive beliefs about mathematics during their teacher education (Young & Dyess, 2021). For practice, tension between participants recognizing mistakes as opportunities for learning yet discouraging, suggests that teacher preparation programs must intentionally foster environments that normalize productive struggle and help students experience struggle as a natural and valuable part of mathematical thinking (Young & Dyess, 2021). It is important to provide PSTs with opportunities to reexperience mathematics in a mastery-oriented way by valuing mistakes, encouraging productive struggle, and positioning learners as the mathematical authority. PSTs holding more positive beliefs about their students' abilities than their own indicate they hold high values for their job as future educators. Teacher preparation programs should build on this strength by nurturing PSTs' mathematical proficiency and encouraging them to see their own growth as essential for enabling their future students' success.

REVEALING PRESERVICE TEACHERS' STANCES TOWARD STUDENT THINKING IN AI-SIMULATED CONFERENCES

Jessica L. Postma
Western Michigan University
jessica.l.postma@wmich.edu

Responding to student thinking in the moment is a challenging instructional practice that requires genuine curiosity. This study examines how elementary preservice teachers' (PSTs') stances toward student thinking were revealed through their responses during an AI-simulated mathematics conference. Transcripts from eight PSTs were analyzed to examine the moves they enacted and the stances those moves revealed. PSTs often began by eliciting student thinking, reflecting a curiosity stance. However, when incorrect thinking surfaced, many shifted toward fix-it or completion stances, using moves such as funneling, retelling as restart, and selective probing. Although PSTs may learn how to structure a mathematics conference, sustaining a curiosity stance remains challenging. These findings show how AI-simulations can make PSTs' stances toward student thinking visible.

Keywords: Preservice Teacher Education

Introduction

In the mathematics classroom, some of the most impactful instructional decisions happen while students are at work. As teachers engage with individuals or small groups of students, they must decide how to respond to student thinking in the moment. Doing this well requires drawing out and making sense of partial or incorrect thinking and responding in ways that support students' thinking without taking it over. Munson (2018) argues that such work cannot be productive unless teachers orient themselves as genuinely curious about student thinking.

Responding to student thinking productively is challenging for teachers in general and even more so for preservice teachers (PSTs). Research shows that PSTs often make assumptions about student thinking rather than questioning it, lead students toward a specific solution path, and miss opportunities to investigate student thinking (Shaughnessy & Boerst, 2018). Additionally, they tend to focus on the procedural steps taken instead of the reasoning that supports those steps (Jacobs et al., 2010; Kilic, 2018). These challenges become even more apparent when students have incorrect thinking. In these situations, PSTs have been found to avoid engaging with incorrect thinking altogether (Sherman, 2020; Shaughnessy et al., 2021) or shift into trying to fix it (Shaughnessy & Boerst, 2018).

These tendencies are concerning because engaging with incorrect thinking has been shown to have benefits for students and teachers. Students who view incorrect thinking as opportunities for learning are more open to adjusting solution pathways and persisting through challenges (Tulis et al., 2018) and have greater motivation in the mathematics classroom (Grassinger & Dresel, 2017). For teachers, engaging with students' incorrect thinking can uncover gaps and misconceptions that can inform instructional decisions (Bray, 2013). With these benefits in mind, teacher education must better support PSTs in developing and sustaining a curiosity stance toward correct and incorrect student thinking.

Practice-based approaches to teacher education have been used to support PSTs in learning to enact complex instructional practices such as responding to student thinking (Grossman et al., 2009). Within these approaches, approximations of practice provide opportunities for PSTs to

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

rehearse instructional decision-making with less risk. Approximations such as scripting, rehearsals, and simulations have been shown to support PSTs in learning to respond to student thinking more productively (e.g., Campbell & Baldinger, 2022; Webel & Conner, 2017). More recently, AI-simulations have gained attention as a promising form of approximation for developing PSTs' responsiveness to student thinking (Ke et al., 2020; Lee et al., 2025). Unlike many other approximations, AI-simulations allow PSTs to engage with student thinking as it unfolds in real time. Additionally, they create opportunities for PSTs to respond to unpredictable and incorrect student thinking practice, more closely approximating interacting with real K-5 students. Since PSTs must make instructional decisions in the moment, AI-simulations may provide a context in which PSTs' stances toward student thinking become visible.

This study examines how elementary PSTs respond to student thinking during an AI-simulated small-group, in the moment interaction while students are at work. Throughout this paper, this interaction is referred to as a mathematics conference. Specifically, this work intends to answer the following research question: How are PSTs' stances toward student thinking revealed through their responses in an AI-simulated mathematics conference?

Theoretical Frameworks

This study is grounded in two related frameworks: the Eliciting-Interpreting-Advancing (EIA) practice and Munson's (2018) conceptualization of stance.

Eliciting-Interpreting-Advancing Student Thinking

The first framework is the high-leverage teaching practice of eliciting and interpreting student thinking as conceptualized by TeachingWorks (2018). The goal of this responsive practice is to draw out students' ideas and make sense of their reasoning to ultimately inform instructional decisions. However, in the context of a mathematics conference, responding requires more than eliciting and interpreting. Teachers must also decide how and when to advance student thinking in real time.

Drawing on Munson's (2018) framework for conferring in mathematics, this work is conceptualized as three connected components: Eliciting, Interpreting, and Advancing (EIA) student thinking. Eliciting refers to uncovering what students have done and how they are making sense of the task. Interpreting involves making sense of students' thinking to determine what they understand and where they might be struggling. Advancing includes responding to students' thinking in ways that support continued sense-making. Figure 1 illustrates this conceptualization of the EIA practice as a dynamic cycle.

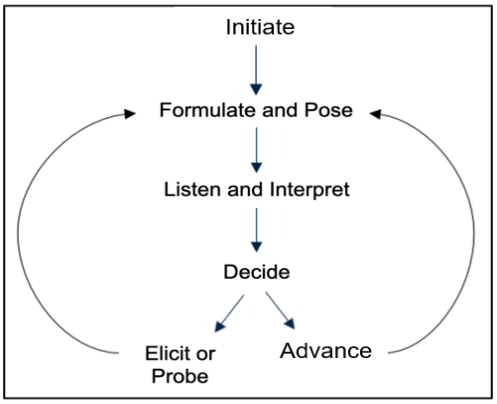

Figure 1: EIA Practice

Within this framework, teacher responses are called moves. Initiating the conversation, eliciting or probing, and advancing student thinking, each have their own set of observable moves, taken from Munson (2018). For example, initiating the conversation may involve a general eliciting move that creates space for students to share their thinking (e.g., What have you tried so far?). Eliciting further may include general or targeted follow-up moves that clarify or press on specific aspects of revealed student thinking. Advancing includes moves such as retelling, orienting students to one another, or positioning students as competent.

In this study, moves were considered productive when they supported understanding, interpreting, or advancing student thinking. Moves were considered less productive when they redirected attention away from understanding or using student thinking and toward correcting student thinking or guiding students to an answer. Therefore, in addition to Munson's (2018) moves, several less productive moves identified in prior research were included in the analysis. One example is funneling (Wood, 1998), where a teacher narrows student thinking through a series of questions that guide students toward a particular answer.

Analyzing moves alone does not fully explain how student thinking is treated during a conference. So, a second framework is used to interpret the stance reflected in those moves.

Stance

Munson's (2018) conceptualization of stance refers to a teacher's orientation toward student thinking and shapes how students' ideas are treated during a mathematics conference. Munson identifies four stances that a teacher can take during a math conference:

- Curiosity: treating student thinking as an object of inquiry
- Fix-it: treating thinking as something to correct
- Completion: orienting toward finishing the task
- Management: prioritizing behavior over thinking

Since the purpose of the EIA practice is to understand and build on student thinking, a curiosity stance supports teachers in treating this thinking as something to learn about instead of something to evaluate or correct. In contrast, fix-it, completion, and management stances focus on correcting errors, finishing tasks, and managing behavior. Considering stance alongside teacher moves helps reveal how PSTs approach and respond to student thinking during a mathematics conference.

Methods

Participants

Participants were eight graduate-level elementary PSTs enrolled in a synchronous, online mathematics methods course at a public university. All participants were working toward initial elementary teacher certification.

AI-Simulation as an Approximation of Practice

The AI-simulation was used as an approximation of practice for a small-group mathematics conference and was a required out-of-class assignment embedded within a multi-week instructional sequence focusing on the EIA practice. Prior to completing the simulation, PSTs read Munson (2018), participated in class discussions, and completed two scripting approximations focusing on the EIA practice.

The AI-simulation was conducted using a custom GPT developed through OpenAI's ChatGPT. The GPT was programmed to act like two second-grade students who were solving the following problem: *Aubree has 7 balloons. She has 5 fewer than Blair. How many balloons*

did Blair have? One AI-student (Maya) had been programmed to reason correctly about the relational structure of the problem, whereas the other AI-student (Jordan) displayed the common misconception that "5 fewer" requires subtracting 5 from 7. The GPT was instructed to maintain each student's thinking and not reveal which student was correct or incorrect. The AI-students also could reference and describe their written representations when responding.

PSTs interacted with the AI-students through a text-based chat interface and were instructed to interact with the students like they would during a small-group mathematics conference. The goal of the conference was to elicit, interpret, and advance student thinking rather than tell students how to solve the problem correctly. This was the first time that PSTs were asked to enact the EIA practice in its entirety and respond to student thinking in real time. Since PSTs could not anticipate how students would respond and were responsible for continuing the interaction through their written moves, this approximation required in the moment instructional decision making like that of a mathematics conference with actual K-5 students.

Data Analysis

The primary data source was full transcripts of each PST's interaction with the AI-simulated students. These transcripts captured PSTs' real time instructional decisions as they elicited, interpreted, and advanced student thinking while students were at work.

Data analysis occurred in three stages. First, transcripts were deductively coded using the EIA practice move codes drawn from Munson (2018) and other literature. Each teacher turn served as a unit of analysis and was coded according to the primary move enacted (e.g., general eliciting, targeted follow-up, retelling, funneling). This stage identified how PSTs responded to student thinking throughout the conference. Second, analytic memos were written for each PST's conference, examining how patterns of moves across the interaction and responses to student thinking reflected different stances toward student thinking and moments when those stances appeared to shift. Third, a cross-case analysis was completed to identify patterns in how stance was revealed and how it shifted across the eight PSTs. Themes were refined through ongoing comparisons of conferences and stance patterns across PSTs.

Results: Stances Revealed Through PSTs' Responses

This section describes how PSTs' stances toward student thinking were revealed through in the moment responses during the AI-simulated mathematics conference. Although PSTs enacted a range of teacher moves, patterns in those moves and responses to student thinking provided evidence of different stances throughout the conference.

A Curious Start

Simulations typically began with PSTs making a general eliciting move intended to learn about how students were approaching the problem. For example, Anna opened with, "What have you done so far?" Such initiations positioned students as contributors and signaled an initial curiosity stance.

These early general eliciting moves quickly surfaced the students' contrasting interpretations of the story problem, as seen in Jenna's conference:

Jenna:	Can you explain what you have drawn on your paper so far?
Maya:	Yeah! So, I drew Aubree right here, and I counted them—one, two, three, four, five, six, seven. Then I drew Blair over here, and I gave her more balloons, because it says Aubree has five less than Blair. So, I counted—seven, eight, nine, ten, eleven, twelve. Blair has twelve balloons.

Jordan: Um… I drew Aubree too with seven balloons. And then it says she has five less, so I took away five. So, um… I just put two balloons for Blair.

There were slight variations in how this curiosity was enacted. For example, Hannah entered the conversation with the AI-students by asking, "What are you guys working on?" While this question initiated the conversation, it led to Maya restating the story problem in her own words and then Jordan describing where they were in making sense of the problem. Therefore, this move does not directly help Hannah understand how each of the students was thinking. Even so, across cases, PSTs demonstrated an initial willingness to hear from students. Thus, conferences commonly began with moves that indicated a curiosity stance.

Moves that Sustained a Curiosity Stance

A few PSTs were able to sustain a curiosity stance through follow-up moves that pressed for clarification or further explanation.

General follow-up. Katie aimed to try to better understand Jordan's thinking after he said that he "started with seven and then took away five, "'cause it says five less than." She asked, "Jordan, can you show me what you did on your paper?" By doing this, Katie attempts to understand multiple aspects of Jordan's thinking, including his representation. This general follow-up move helps Katie remain curious and offered Jordan the opportunity to further explain his work and thinking.

Targeted follow-up. PSTs also sustained curiosity by questioning the AI-students about specific aspects of their explanations or representations. One example comes from Jenna, who responded to Jordan's explanation with the question, "Who has five less, Jordan?" In his initial response, Jordan used the phrase "she has five less," where the referent was left somewhat ambiguous. By asking for clarification, Jenna demonstrates close attention to Jordan's language and attempted to interpret his reasoning more precisely. In this moment, she maintains a curiosity stance by attempting to understand how Jordan was understanding the relationship between the quantities.

Grace also used a targeted follow-up move.

Maya: I think I know! I drew it right here. Aubree has seven little circles for balloons. See, Aubree has seven, and Blair has more. So, I think Blair's number has to change from that.

Jordan: I did mine different. I took seven and then did 7 – 5 = 2. So, I wrote two for Blair. But then Maya said it should. Be more, so I'm kinda confused.

Grace: Sure, that's okay, Jordan. Let's see why Maya feels like it should be more. Maya, what makes you think Blair has more?

Grace acknowledged Jordan's confusion and then asked Maya to explain her thinking. Since her question is built directly on the students' language and ideas, it reflects an effort to make sense of how each student was interpreting the problem. In this example, the targeted follow-up move was associated with a sustained curiosity stance.

Moves Associated with a Shift in Stance

Although conferences began with curiosity, PSTs tended to shift stances once Jordan's incorrect or uncertain thinking surfaced. At that point, PSTs did not press students to explain their thinking. Instead, they moved from eliciting toward advancing moves such as retelling or funneling. This pattern demonstrates a shift away from a curiosity stance to a fix-it stance where the goal is to repair incorrect thinking or a completion stance where the goal is to guide the

students through the problem toward a shared correct answer. In both cases, the goal becomes getting the right answer instead of understanding student thinking.

Limited and selective probing. Probing could have allowed PSTs to explore how Jordan was making sense of the phrase "five less." While probing did occur, it was often directed toward the student with correct thinking. One example of this occurred in Anna's conference:

Anna:	What have you done so far?
Maya:	Um, we were talking about the balloon problem. I drew two circles—one for Aubree and one for Blair—and I wrote a seven in Aubree's circle because she has seven balloons. Then I said Blair should have more than Aubree since Aubree has less. So, I was trying to figure out how many more.
Jordan:	Yeah… I wrote "7 minus 5 equals 2," 'cause it said Aubree has five less. So, I thought maybe that means Blair has two. But I'm not sure if that's right.
Anna:	Maya, I like how you drew two circles. That helps me see your thinking. So, you think Blair should have more, why?

While Anna's initial question signaled curiosity, the direction of her follow-up showed that this curiosity was selective. Instead of pressing Jordan to unpack why subtraction made sense to him, Anna directed her probing question to Maya, whose reasoning aligned with the correct interpretation of the relationship in the problem. Throughout the rest of the simulation, Jordan's thinking remained unexplored. Similar patterns were seen in other PSTs' simulated conferences.

Retelling as a restart. Another common indicator of a stance shift was retelling. If enacted productively, retelling can support student sense-making by asking to restate the problem in their own words. However, it often functioned as a reread or restart. For example, after Jordan responded to Jenna's question about who had five less, Jenna said, "[Jordan], can you read me the question again and let's start from the beginning. Maya, please don't help Jordan just yet." Here, Jenna shifted from being curious about Jordan's thinking to correcting it. She did not attempt to understand how Jordan was making sense of the problem. Instead, she used this opportunity to restart the problem. Thus, Jenna stepped out of the curiosity stance and into a fix-it stance that focused on getting the correct solution.

Additionally, by instructing Maya not to help, Jenna positioned one student as correct and the other as incorrect. At this point, the students could infer which was which. By having Jordan reread the problem, his thinking was framed as something that needed to be fixed. This shift toward a fix-it stance through rereading or restarting was seen frequently across simulations.

Funneling toward completion. Funneling moves also showed this shift. These moves essentially work to lead students to the correct solution through a series of questions. The goal then becomes different than trying to make sense of and use student thinking. Hannah, for example, asked multiple funneling questions:

- "Ok so how many fewer balloons does Aubree have than Blair?";
- "The problem says that Aubree has five less balloons than Blair. So, who has more balloons?"; and
- "Well Jordan, if the number of balloons that Aubree has is 5 less than Blair, and you said Blair has more balloons. Then how many more balloons does Blair have than Aubree?"

These questions gradually clarified the relationships between the quantities in the problem. Rather than examining how Jordan initially interpreted "five less," the funneling questions lead him toward the comparison structure of the problem, reflecting a fix-it stance being taken.

Another example comes from Anna:

Anna:	Jordan, you wrote numbers on your paper, but can you read the story to me again to tell me first how many balloons Aubrey has?
Jordan:	Um… it says Aubree has seven balloons. So, she's the one with seven.
Anna:	Yes, so let's say Aubrey is turning seven years old, so she has a bunch of balloons with helium in them all tied together with string. Can you show me what that might look like on your paper?

Anna makes two funneling moves in a row, both of which direct Jordan toward a specific solution path. The questions structure how he should proceed. This leaves Jordan little opportunity to generate or test his own reasoning. Instead of investigating Jordan's interpretation of the problem, Anna guides him toward the intended understanding through closed questioning. This pattern of guiding students to the correct answer and toward completing the problem was common across PSTs. In doing so, the conference shifts away from centering student thinking and instead guides students down a predetermined solution path.

Discussion and Conclusion

This study examined how PSTs' stances toward student thinking were revealed through their in the moment responses during an AI-simulated mathematics conference. Across simulations, PSTs frequently began with a general eliciting move that signaled curiosity and a willingness to learn about students' thinking. However, once incorrect student thinking surfaced, that curiosity was often not sustained. In these moments, PSTs tended to shift toward fix-it or completion stances, which were evident through their use of selective probing, retelling as restart, and funneling.

One interpretation of these findings is that incorrect thinking changed the nature of the interaction for PSTs. At the beginning of the conference, PSTs could focus on learning about students' thinking through general eliciting moves. However, once Jordan revealed an incorrect interpretation of "five fewer," PSTs were required to make sense of that thinking and decide how to respond in the moment. Instead of continuing to explore how Jordan was making sense of the relationship described in the problem, many PSTs moved toward helping him revise his thinking. Prior research has found that PSTs often struggle to engage with incorrect thinking (Sherman, 2020; Shaughnessy et al., 2021). The present study extends this work by showing how those challenges became visible during a real time interaction. Incorrect thinking was not ignored. Instead, it often marked the point at which PSTs shifted from trying to understand student thinking to trying to correct it. A possible explanation for this shift is that PSTs may view the role of the teacher as helping students arrive to the correct solution. When Jordan revealed incorrect thinking, many PSTs treated that thinking as something that needed to be fixed rather than investigated. This aligns with Shaughnessy and Boerst's (2018) findings that PSTs often move quickly into helping students instead of learning more about their thinking. From this perspective, the use of retelling as restart, selective probing, and funneling may not reflect a lack of attention to student thinking. Instead, these moves may stem from a belief that effective teaching means helping students get back on the correct path. If PSTs enter teacher education with experiences that position teaching as explaining, correcting, and guiding students toward solutions, then sustaining a curiosity stance when incorrect thinking is shared may be particularly challenging.

This interpretation is further supported by how PSTs distributed their attention across students. Probing was disproportionately directed toward Maya, whose thinking aligned with the intended mathematics. Jordan's thinking, on the other hand, was often left unexplored. Bray (2011) reported similar patterns, suggesting that teachers are more likely to engage with student thinking they perceive as mathematically correct. One possible explanation is that Maya's reasoning was easier for PSTs to recognize and interpret because it aligned with their own understanding of the problem. By contrast, Jordan's thinking required PSTs to make sense of reasoning that conflicted with that understanding. Thus, PSTs may have been more comfortable probing Maya's thinking than continuing to investigate Jordan's. Sustaining a curiosity stance, therefore, may require learning view to incorrect thinking as something to understand.

The findings may suggest that PSTs were learning the structure of a mathematics conference before learning to enact it productively. Most PSTs began their conferences with a general eliciting move, indicating that they recognized the importance of first learning about students' thinking. The challenge came later, when PSTs had to decide how to respond to unexpected or incorrect reasoning. Sustaining a curiosity stance requires more than knowing which move to enact next. It requires viewing student thinking as the object of focus throughout the interaction. The common use of retelling as restart and funneling suggests that many PSTs were still developing this aspect of the EIA practice. Similar patterns have been documented in prior research, where responding to students' emerging thinking is often more difficult than initiating an interaction (Jacobs et al., 2010; Kilic, 2018).

For mathematics teacher education, supporting PSTs in learning the EIA practice may require more than teaching its structure and the moves within it. Sustaining a curiosity stance appears to require learning how to engage with incorrect thinking in ways that prioritize understanding over correction. That said, teacher educators may need to create opportunities for PSTs to investigate incorrect thinking, consider possible interpretations, and practice responding. AI-simulations may provide a useful context for this work because they create opportunities for PSTs to engage with student thinking in the moment while also making their stances visible for reflection. Additionally, they allow PSTs to practice responding to incorrect thinking prior to enacting the practice with real elementary students. Future research should investigate how PSTs' stances develop across multiple approximations of practice and whether repeated opportunities to engage with incorrect student thinking support a more sustained curiosity stance.

LA METACOGNICIÓN EN FUTUROS DOCENTES DE MATEMÁTICAS: UN ESTUDIO DE INVESTIGACIÓN-ACCIÓN Y BTC

METACOGNITION IN FUTURE MATHEMATICS TEACHERS: AN ACTION-RESEARCH AND BTC STUDY

Perla Ramírez Escobar
Escuela Normal de San Felipe del Progreso
perlaramirezescobar@normalsanfelipe.edu.mx

Este estudio examina el desarrollo de la metacognición en docentes en formación de la Licenciatura en Enseñanza y aprendizaje de las matemáticas a partir de la implementación del enfoque Building Thinking Classrooms (BTC) en sus cursos de geometría. Se adoptó una metodología de investigación-acción para la aplicación de la propuesta de investigación. Los datos analizados para los resultados incluyeron observaciones de aula, producciones matemáticas en pizarras verticales no permanentes, narrativas reflexivas y un cuestionario de conciencia metacognitiva aplicado antes y después de la intervención. Los resultados sugieren que el BTC genera condiciones estructurales que favorecen la visibilización y regulación del pensamiento matemático en la formación inicial docente.

Palabras clave: Geometría, conocimiento matemática para la enseñanza, metacognición

Introducción

La formación inicial de docentes de matemáticas enfrenta el desafío de superar prácticas centradas en la memorización de procedimientos y promover experiencias que favorezcan el desarrollo de un pensamiento matemático profundo. En el caso de la geometría—ya sea plana, del espacio o analítica—la enseñanza tradicional suele privilegiar el uso mecánico de fórmulas, lo que limita la comprensión conceptual y la reflexión sobre los propios procesos de aprendizaje.

Desde la Psicología de la Educación Matemática, la metacognición se reconoce como un elemento clave para comprender cómo los estudiantes planifican, monitorean y evalúan sus procesos cognitivos, favoreciendo el desarrollo de la autonomía intelectual. Asimismo, el modelo de niveles de Van Hiele ofrece un marco teórico pertinente para analizar el desarrollo del razonamiento geométrico, al describir una progresión en la comprensión de los conceptos y relaciones espaciales.

En este contexto, el enfoque Building Thinking Classrooms (BTC) propone reorganizar las dinámicas de aula para promover el pensamiento colectivo mediante la resolución de problemas, el trabajo colaborativo y la participación activa de los estudiantes. Sin embargo, aún es limitado el conocimiento sobre cómo este tipo de entornos favorece específicamente el desarrollo de la conciencia metacognitiva en la formación inicial docente.

El presente estudio articula tres experiencias previas desarrolladas en cursos de geometría plana y del espacio, geometría analítica y formación docente, integradas bajo el enfoque BTC. El objetivo es analizar cómo el BTC favorece el desarrollo de la conciencia metacognitiva en futuros docentes de matemáticas, en relación con su razonamiento geométrico.

Revisión de la literatura

La geometría puede entenderse, en términos generales, como el estudio de las propiedades, relaciones y medidas de las figuras en el plano y en el espacio (Real Academia Española, 2001). En el ámbito educativo, constituye una rama fundamental de las matemáticas orientada al

análisis de las estructuras, características y transformaciones de los objetos geométricos (Cordero, 2021). Más allá de su dimensión descriptiva, la geometría involucra procesos de visualización, argumentación y construcción de relaciones, lo que la convierte en un campo privilegiado para el desarrollo del razonamiento matemático.

No obstante, su enseñanza enfrenta desafíos importantes, como la alta abstracción de sus conceptos y la escasa vinculación con contextos significativos para los estudiantes, lo que suele derivar en aprendizajes fragmentados y predominantemente procedimentales (Cordero, 2021). En este sentido, diversos autores coinciden en la necesidad de diseñar tareas accesibles pero intelectualmente demandantes que favorezcan la exploración, la formulación de conjeturas y la argumentación matemática (García y López, 2008). Asimismo, el uso de herramientas tecnológicas como GeoGebra ha sido señalado como un recurso que potencia la visualización dinámica y la comprensión conceptual.

Desde una perspectiva cognitiva, el modelo de razonamiento geométrico de Van Hiele (1986) ofrece un referente central para comprender cómo los estudiantes construyen conocimiento en este dominio. Este modelo plantea una progresión de cinco niveles—visualización, análisis, clasificación, deducción y rigor—que describen formas cualitativamente distintas de interpretar los objetos geométricos. El tránsito entre niveles no depende exclusivamente de la edad, sino de las experiencias de aprendizaje diseñadas en el aula. En consecuencia, la enseñanza de la geometría requiere propuestas didácticas alineadas con el nivel de razonamiento de los estudiantes, con el fin de favorecer avances hacia formas más complejas de pensamiento geométrico.

En el presente estudio, el modelo de Van Hiele se utiliza como referente analítico para interpretar las transiciones en el razonamiento geométrico observadas durante la intervención, particularmente en relación con el paso de niveles de visualización hacia formas de análisis y razonamiento informal deductivo.

Por otra parte, la metacognición, entendida como el conocimiento y la regulación de los propios procesos cognitivos (Flavell, 1979), constituye un elemento clave en el aprendizaje matemático. Este constructo se organiza en tres procesos fundamentales: planificación, monitoreo y evaluación, los cuales intervienen directamente en la resolución de problemas y en la toma de decisiones estratégicas (Schoenfeld, 1985).

Investigaciones recientes han señalado que la metacognición no se desarrolla de manera aislada, sino que emerge en interacción con tareas matemáticas cognitivamente demandantes que implican la explicitación de estrategias, la revisión de procedimientos y la reestructuración del pensamiento (Mevarech & Kramarski, 2014; Schoenfeld, 2016). En particular, la resolución de problemas no rutinarios y la argumentación favorecen procesos de autorregulación, ya que los estudiantes deben justificar sus decisiones, identificar errores y ajustar sus estrategias (Kramarski & Heaysman, 2021).

En el contexto de la formación inicial docente, la metacognición adquiere una doble dimensión: los futuros docentes no solo regulan su propio aprendizaje matemático, sino que comienzan a desarrollar conciencia sobre cómo promover estos procesos en sus estudiantes. De este modo, la metacognición se concibe como un proceso situado, mediado por el diseño de tareas y las dinámicas de interacción en el aula.

En esta línea, el enfoque Building Thinking Classrooms (BTC), propuesto por Liljedahl (2021), plantea la creación de entornos de aprendizaje intencionalmente diseñados para promover el pensamiento matemático a través del trabajo colaborativo, la resolución de problemas no rutinarios y la participación activa de los estudiantes. Este enfoque desplaza la

enseñanza centrada en la transmisión de procedimientos hacia prácticas que favorecen la construcción colectiva del conocimiento y el desarrollo de la autonomía intelectual.

Diversas investigaciones han documentado efectos positivos asociados con la implementación del BTC, incluyendo mejoras en el rendimiento académico, el pensamiento crítico y la motivación hacia el aprendizaje de las matemáticas (Ramírez y Soto, 2025; Muir, 2025). Asimismo, este enfoque contribuye a redefinir el rol del docente como mediador del aprendizaje y diseñador de experiencias matemáticas significativas.

En el presente estudio, el BTC se asume como marco de intervención didáctica, particularmente en lo que respecta al diseño de tareas colaborativas, la organización del aula y la promoción de dinámicas que favorecen la explicitación de procesos metacognitivos. De este modo, se establece una articulación entre el desarrollo del razonamiento geométrico (Van Hiele), la regulación del aprendizaje (metacognición) y las condiciones de aula que lo posibilitan (BTC).

Metodología

El presente estudio se sustenta en el supuesto de que la metacognición se construye en interacción con tareas matemáticas cognitivamente demandantes, más que mediante la instrucción explícita de estrategias aisladas de autorregulación. Asimismo, se asume que el diseño estructural del aula influye en la emergencia de procesos metacognitivos, en la medida en que organiza las oportunidades de participación, interacción y explicitación del pensamiento. En este marco, el enfoque *Building Thinking Classrooms* (BTC) se adopta como referencia para el diseño de la intervención, al generar condiciones que favorecen el desarrollo del pensamiento matemático y metacognitivo a través de tareas no rutinarias, el trabajo colaborativo y la visibilización de los procesos de razonamiento.

La población del estudio estuvo conformada por 52 estudiantes de la Licenciatura en Enseñanza y Aprendizaje de las Matemáticas (LEAM), pertenecientes a una escuela normal pública del centro de México. Los participantes cursaban asignaturas de Geometría Plana y del Espacio y Geometría Analítica en los primeros semestres de su formación inicial docente.

La investigación se enmarca en un enfoque cualitativo con diseño de investigación-acción, orientado a comprender e interpretar los procesos de pensamiento, las interacciones en el aula y las transformaciones conceptuales que emergen durante la intervención. En este enfoque, el docente asume simultáneamente el rol de investigador, lo que implica diseñar e implementar una propuesta didáctica intencional, analizar sus efectos y reflexionar de manera sistemática sobre su propia práctica. El estudio tiene un carácter exploratorio-interpretativo, ya que busca identificar cómo se desarrollan los procesos metacognitivos en un contexto auténtico de formación inicial docente.

El proceso de investigación se desarrolló a través de ciclos de planificación, acción, observación y reflexión. En una primera fase, se realizó un diagnóstico inicial mediante la aplicación de un cuestionario de conciencia metacognitiva (pretest) y el análisis de producciones iniciales de los estudiantes, con el propósito de identificar sus formas de razonamiento geométrico, tomando como referencia el modelo de Van Hiele.

Posteriormente, se diseñó una intervención basada en tareas geométricas no rutinarias, alineadas con los principios del enfoque BTC. Estas tareas estuvieron orientadas a promover la exploración, la formulación de conjeturas, la argumentación y la reflexión sobre los propios procesos de pensamiento. De manera intencional, se incorporaron preguntas metacognitivas dirigidas a fomentar procesos de planificación, monitoreo y evaluación, tales como la selección de estrategias, la verificación de procedimientos y la valoración de resultados.

La implementación de la intervención se llevó a cabo mediante dinámicas características del

BTC, incluyendo la organización de los estudiantes en equipos de trabajo conformados de manera aleatoria, el uso de pizarras verticales para la resolución de problemas y la discusión colectiva de estrategias y soluciones. Durante este proceso, el docente promovió la explicitación del pensamiento matemático a través de preguntas abiertas y retroalimentación orientada a la reflexión, con el fin de favorecer la verbalización de procesos metacognitivos.

El análisis de la información se realizó mediante la triangulación de diversas fuentes de datos, entre las que se incluyen las producciones matemáticas elaboradas en pizarras verticales, narrativas reflexivas de los estudiantes, los resultados del cuestionario de conciencia metacognitiva aplicado en modalidad pre y post, así como observaciones y notas de campo. Para el análisis cualitativo se establecieron categorías basadas en los procesos metacognitivos de planificación, monitoreo y evaluación. De manera complementaria, el modelo de Van Hiele se utilizó como referente analítico para interpretar las transformaciones en el razonamiento geométrico observadas durante la intervención.

En cuanto a los criterios de validez, el estudio se sustentó en la credibilidad, la coherencia interna y la triangulación de datos. La inclusión de evidencias textuales provenientes de narrativas y producciones matemáticas permitió fundamentar las interpretaciones en datos empíricos. Asimismo, se reconoció el posible sesgo derivado del doble rol docente-investigador, el cual fue atendido mediante el registro sistemático de observaciones y la reflexión continua sobre el proceso de intervención.

Resultados

La implementación del enfoque Building Thinking Classrooms (BTC) en el curso de Geometría plana y del espacio permitió identificar transformaciones tanto en el razonamiento geométrico como en los procesos metacognitivos de los estudiantes. El análisis se realizó a partir del modelo de niveles de Van Hiele y de las categorías de metacognición: planificación, monitoreo y evaluación.

En una primera fase, las tareas de tipo low floor, como la identificación de figuras geométricas en el entorno y su modelación en GeoGebra 3D, favorecieron el nivel de visualización. Sin embargo, además del reconocimiento de formas, se observaron manifestaciones iniciales de conciencia metacognitiva. Por ejemplo, cuando un estudiante expresa: “Me di cuenta de que muchas construcciones en el pueblo usan cuerpos geométricos modificados”, se evidencia un proceso de monitoreo cognitivo, al reflexionar sobre cómo interpreta su entorno a partir del conocimiento matemático. En este proceso, el uso de GeoGebra funcionó como un mediador que permitió contrastar representaciones empíricas con modelos formales, favoreciendo el tránsito hacia niveles de análisis.

En tareas de mayor demanda cognitiva (high ceiling y open middle), se identificó un avance hacia el nivel de ordenación (deducción informal) en aproximadamente el 80% de los estudiantes. En la actividad sobre el baricentro, la afirmación: “El baricentro es como el punto de equilibrio porque siempre queda dentro del triángulo” muestra no solo comprensión conceptual, sino procesos de evaluación metacognitiva, al reconocer una propiedad invariante y justificarla a partir de la experiencia y la modelación.

De manera similar, en la generalización de la fórmula de la distancia, los estudiantes dejaron de aplicar procedimientos de forma mecánica y comenzaron a reconstruir su origen. Este proceso implicó planificación estratégica—al decidir cómo trasladar el razonamiento de la recta numérica al plano cartesiano—y monitoreo continuo, al verificar sus resultados ante diversas condiciones.

El análisis diagnóstico y final permitió identificar que el 100% de los estudiantes se mantuvo en el nivel de visualización (nivel 0) y evidenció dominio del nivel de análisis (nivel 1), mientras

que el 80% alcanzó el nivel de ordenación (nivel 2), construyendo generalizaciones y justificando relaciones. No se observaron evidencias correspondientes a los niveles superiores (deducción formal y rigor), lo cual resulta consistente con el momento formativo de los participantes.

Desde una perspectiva metacognitiva, el tránsito del nivel 1 al nivel 2 no solo implicó mayor complejidad conceptual, sino una transformación en la regulación del pensamiento: los estudiantes comenzaron a explicar el "por qué" de los procedimientos, y no únicamente el "cómo".

En relación con las condiciones estructurales del aula, características del enfoque BTC—como la organización aleatoria de equipos, el uso de pizarras verticales y la restricción de un solo marcador por equipo—generaron dinámicas que favorecieron la metacognición colectiva. Antes de registrar sus respuestas, los estudiantes debían consensuar estrategias, lo que promovió procesos de planificación compartida, monitoreo grupal de errores y evaluación conjunta de las soluciones.

Asimismo, las intervenciones docentes, basadas en preguntas abiertas como "*¿Funciona con números negativos?*" o "*¿puedes demostrarlo en otros casos?*," propiciaron una forma de metacognición guiada, en la que el cuestionamiento intencional sostuvo la reflexión sin anular la autonomía de los estudiantes.

Las entrevistas semiestructuradas permitieron identificar niveles más complejos de reflexión metacognitiva. Por ejemplo, la afirmación "Aprendí a construir mis propias generalizaciones utilizando mis conocimientos previos" evidencia conciencia sobre el propio proceso de aprendizaje, mientras que expresiones como "Ahora recuerdo cómo calcular la distancia porque comprendo su origen" reflejan procesos de evaluación retrospectiva. De igual forma, el reconocimiento de que "El proceso es tan importante como el resultado final" sugiere una dimensión metacognitiva asociada a la valoración del aprendizaje.

En conjunto, los resultados muestran que la metacognición no se desarrolló como un contenido explícitamente enseñado, sino como un proceso emergente derivado de las condiciones didácticas generadas por el enfoque BTC. Particularmente, el tiempo de reflexión individual favoreció la planificación inicial, mientras que el trabajo colaborativo promovió el monitoreo y la evaluación a través de la interacción y la confrontación de ideas. El uso de pizarras verticales contribuyó a hacer visible el pensamiento matemático, facilitando la revisión constante de estrategias y la construcción colectiva del conocimiento.

En síntesis, los resultados sugieren que la implementación del BTC no solo favoreció el avance en los niveles de razonamiento geométrico, sino que también promovió el desarrollo de una conciencia metacognitiva situada, vinculada tanto al aprendizaje como a la futura práctica docente.

Discusión y conclusiones

Los resultados obtenidos sugieren que la metacognición puede emerger como consecuencia del diseño estructural del aula, más que como resultado exclusivo de la instrucción explícita sobre estrategias de autorregulación. En concordancia con Schoenfeld (1985, 2016), los procesos de planificación, monitoreo y evaluación se activan cuando las tareas matemáticas exigen toma de decisiones, validación de procedimientos y argumentación, tal como se evidenció en las actividades desarrolladas durante la intervención.

En este sentido, el enfoque Building Thinking Classrooms (Liljedahl, 2021) no enseña la metacognición de forma directa; más bien, genera condiciones organizativas y normativas que favorecen la explicitación y regulación del pensamiento matemático. Elementos como la

resolución de problemas no rutinarios, la discusión colectiva y la validación de ideas contribuyen a normalizar el aprendizaje a partir del error y a desplazar la atención de la respuesta correcta hacia el proceso de razonamiento.

Desde una perspectiva sociocultural (Vygotsky, 1978), los hallazgos pueden interpretarse en términos de una regulación cognitiva que se construye inicialmente en el plano interpsicológico para posteriormente interiorizarse. Las prácticas propias del BTC—como el trabajo en grupos aleatorios, el uso de superficies verticales no permanentes y la interacción constante—favorecieron esta regulación compartida. Este resultado coincide con los planteamientos de Mevarech y Kramarski (2014), quienes destacan el carácter social de la metacognición en el aprendizaje matemático. En consecuencia, la metacognición observada en este estudio puede entenderse como un fenómeno situado, mediado por la interacción y las normas de participación en el aula.

Por otro lado, el tránsito entre los niveles de Van Hiele (1986) estuvo acompañado por el desarrollo progresivo de procesos metacognitivos. En particular, el paso del nivel de análisis al de ordenación implicó no solo una mayor complejidad conceptual, sino también cambios en la forma en que los estudiantes justifican, evalúan y validan relaciones geométricas. Este hallazgo es consistente con lo planteado por Clements y Battista (1992), quienes sostienen que el avance en el razonamiento geométrico requiere experiencias que promuevan la reflexión sobre las propiedades y sus interrelaciones.

Asimismo, se identificó una transición desde una concepción algorítmica de la geometría hacia una comprensión más relacional y reflexiva, en términos de Skemp (1976). La reconstrucción de fórmulas a partir de su significado, como ocurrió con la fórmula de la distancia, sugiere que los estudiantes comenzaron a privilegiar la comprensión conceptual sobre la aplicación mecánica de procedimientos.

Desde la perspectiva de la formación inicial docente, los resultados indican que la experiencia no solo impactó el aprendizaje matemático, sino también la forma en que los estudiantes conciben la enseñanza. Esto dialoga con la noción de conocimiento especializado del profesor de matemáticas (Ball et al., 2008), particularmente en su dimensión pedagógica, al evidenciar que comprender la estructura conceptual de los contenidos fortalece la capacidad para enseñarlos. En este sentido, la intervención contribuyó a la construcción de una identidad docente reflexiva, en línea con lo planteado por Zeichner (2010).

No obstante, es importante reconocer algunas limitaciones del estudio. En primer lugar, la duración de la intervención pudo haber sido insuficiente para favorecer el desarrollo de niveles más avanzados de razonamiento geométrico, lo que explicaría la ausencia de evidencias en los niveles de deducción formal y rigor. Asimismo, el doble rol del docente como investigador puede haber influido en la interpretación de los datos, a pesar de los esfuerzos por garantizar la triangulación y la sistematicidad del análisis. Finalmente, el carácter exploratorio del estudio y el contexto específico de formación inicial docente limitan la generalización de los resultados.

En conjunto, los hallazgos permiten afirmar que el diseño de entornos de aprendizaje orientados al pensamiento, como los propuestos por el BTC, no solo favorece el desarrollo del razonamiento geométrico, sino también la emergencia de procesos metacognitivos y la construcción de una perspectiva docente centrada en la comprensión y la reflexión.

CONSTRUCTING PRESERVICE TEACHER AGENCY WHEN ANALYZING TASKS: A SELF-STUDY

Kate Raymond

Through self-study, this research focuses on the challenges and tensions we faced as we implemented a semester-long project to support preservice teachers in selecting and analyzing high-quality math tasks. While several frameworks exist to analyze high-quality tasks, we observed that pre-service teachers continued to struggle. Grounded in social constructivism, we engaged our students in co-constructing rubric criteria for selecting a mathematics task based on their learning in our methods courses. Through four cycles of practice, reflection, and questioning, we implemented and revised our semester-long project while analyzing student work. Through this iterative process, we realized that some preservice teachers' focus was limited to a single, often superficial meaning of the written task, prompting rubric changes to include "teacher edits." Our findings point to tensions related to ambiguity, professional authority, and contextual decision-making.

Keywords: Instructional Activities and Practices, Preservice Teacher Education, Teacher Educators

Our interest in pre-service teachers' (PSTs') analysis of tasks began to take shape early in our mathematics teacher educator careers when the three authors participated in AMTE's STaR Fellowship. As we discussed our teaching, we noticed our PSTs experienced similar struggles when asked to identify high-quality mathematical tasks. As we engaged PSTs in activities aligned with best mathematics teaching practices outlined in NCTM's *Principles to Action* (2014), and the Mathematics Teaching Framework's (Smith & Stein, 1998) levels of cognitive demand, our PSTs still did not consistently grasp the concept of identifying high-quality mathematics tasks. Recognizing these common struggles among our PSTs, we embarked on an in-depth collaborative self-study. Using self-study, we engaged with two research questions as we analyzed student work samples and our own documented experiences: (a) What challenges and tensions do we face when fostering PSTs' ability to choose high-quality mathematics tasks? (b) How can we develop methods to address the challenges and tensions we identify?

Literature Review

High-quality mathematical tasks are central to quality mathematics teaching that supports the development of reasoning skills, effective mathematical discourse, and conceptual understanding (NCTM, 2014; Smith & Stein, 1998). Task selection is critical since "no other decision that teachers make has a greater impact on students' opportunity to learn" (Lappan & Friel, 1993, p. 524). Students who regularly engage with high-quality tasks demonstrate greater learning gains than those who work primarily with low-level tasks (Boaler & Staples, 2008; Stein & Lane, 1996; Tarr et al., 2008). Consequently, developing PSTs' capacity to distinguish and select high-quality tasks is a key goal of mathematics methods courses, as emphasized in the *Standards for Preparing Teachers of Mathematics* (AMTE, 2017). In addition, PST's need to develop professional agency, the capacity to make informed, intentional pedagogical decisions within and beyond curricular structures (AMTE, 2017), which requires a willingness to adapt tasks.

Despite this emphasis, research consistently documents PSTs struggle to identify or select high-quality tasks. Studies report mixed results when PSTs use established frameworks to evaluate tasks (Lee et al., 2023; Osana et al., 2006). Similar challenges appear when PSTs use the Worthwhile Task Evaluation Guide (Kartal et al., 2020) or lists of task characteristics (Nicol & Crespo, 2006). We observed challenges in our methods classes, motivating our collaborative self-study. Self-study is widely recognized as a powerful methodology for examining and questioning the complexities of teacher education practice, surfacing tensions, and refining instructional approaches (Hauge, 2021; LaBoskey, 2004; Loughran, 2004; Zeichner, 1999). Engaging colleagues introduces multiple lenses for analyzing problems, helps to reframe practices, and allows for transparent examination of problems of practice that deepen understanding and enhance pedagogy in ways that extend beyond individual reflection, as thoughts are challenged and transformed by others (Hauge, 2021; Pithouse-Morgan, 2022).

Methods

This research used a collaborative self-study methodology, centered on cycles of practice, reflection, and questioning, to interrogate our teaching practices of fostering PSTs' ability to select and to analyze high-quality mathematics tasks. Through sustained questioning and reflection, our practices intentionally evolved to better align with constructivist theories and improve students' task selection. As practitioner researchers, we systematically examined our practices throughout this self-study (Shaw & Lunt, 2018). We chose to conduct a self-study because our inquiry aligned with Vanassche and Kelchtermans' (2015) themes of exploring pedagogical impacts, articulating practice philosophy, and analyzing belief-practice gaps.

While recommended data collection and analysis approaches exist (Loughran & Northfield, 1998), self-study allows flexibility (Loughran, 2004). Data sources included PST-constructed rubrics, task analysis completed by PSTs throughout the courses, our reflections on instructional decisions, and notes from our collaborative reflective meetings. These constitute the base for our interpretations, consistent with the need for authentic artifacts and reflective practices in self-study (LaBoskey, 2004; Pinnegar & Hamilton, 2009). Data was collected across two large public research universities and a large public teaching university. Demographics, expectations, and structures varied across sites. As such, attending to these differences while identifying similarities was essential for interpreting PSTs responses (Vanassche & Kelchtermans, 2015). Our inquiry cycle had four phases: (1) reflecting on student work to identify challenges and alignment with constructivist theories; (2) revising strategies to address misalignments; (3) implementing new methods; and (4) collecting data used for reflection in the first phase of the next cycle. Within these cycles, data was analyzed through descriptive coding, dialogic interpretation, and reflective analysis (Saldaña, 2016; Nolan, 2010; Schuck & Russell, 2005; Tzur, 2001). Consistent with self-study's call for openness and vulnerability (LaBoskey, 2004; Mason, 2007), tensions emerged inductively from analysis.

Across these cycles of collaborative self-study, we identified tensions between research and practice, confidence and uncertainty, and autonomy and agency, which are common themes in teaching self-studies (Berry, 2004). These tensions helped us acknowledge complexities and evolve our practices, thereby enhancing our professional growth. The cyclic nature of this process allowed us to develop and test ideas to improve our practice for students' benefit (LaBoskey, 2004). This led to our adoption of broader perspectives and, ultimately, improved pedagogy (Loughran, 2004). Rather than generalizability, our goal, consistent with self-study, was working hypotheses about our practices (Lincoln & Guba, 1986).

Results

We began the first cycle of collaborative self-study inquiry shortly after we discovered our shared interest in PSTs' task selection. Starting with a reflection phase, we questioned each other about how we developed our PSTs' understandings of what makes a high-quality task and how to select one. We recognized our PSTs often favored traditional methods of teaching mathematics they experienced in their K-12 schools. Our PSTs often felt overwhelmed as they attempted to consider the multiple facets of mathematics tasks. One of our shared practices was to provide our students with tools for task selection, primarily Smith and Stein's (1998) Mathematics Task Framework (MTF) and Van de Walle et al.'s (2023) Worthwhile Task Evaluation Guide. We noticed our PSTs were uncomfortable and unsure when tasks met some of the criteria in the framework but not others. Additionally, as classroom authority figures, our PSTs were hesitant to make anything but positive judgments on tasks we provided.

In considering criteria for high-quality tasks, we recognized that Smith and Stein's (1998) framework focused solely on the cognitive demand of the task and did not allow for a holistic analysis. Conversely, Van de Walle et al.'s framework descriptions are often broad and integrate multiple concepts that may be new to developing PSTs within a single category, leaving PSTs feeling overwhelmed when using it. As we questioned the alignment of our practices with social constructivism, we began to contemplate what it might look like for PSTs to develop their own analytical strategies that fostered autonomy and stronger feelings of professional agency over the curriculum. Attempting to meet these goals, we each agreed to integrate a semester-long project during which PSTs would collaboratively construct a tool to analyze the quality of mathematics tasks (Long et al., 2025). That tool would take the form of a rubric, and our PSTs would be asked to reflect on their learning throughout our methods classes to collaboratively construct criteria and evidence for the rubric. We also decided to have our PSTs use the rubric to evaluate tasks they and their peers found online, to avoid presuming quality.

In our second round of reflections, as students were co-constructing rubrics to analyze the quality of tasks in each of our classes, a second challenge emerged: our PSTs sometimes responded to tasks in ways that demonstrated a perceived lack of autonomy and of our authority over them. Many PSTs did not consider how a teacher might implement a task beyond the written words. For example, one PST stated that students could not use tally marks to complete a place value task because the task did not explicitly state that paper and pencil were to be supplied. Thus, PSTs demonstrated their belief that teachers have little agency over curriculum and therefore did not consider the deeper potential of tasks. These beliefs may stem from PSTs' experiences with heavily scripted curricula in their own education, which can position teachers as implementers rather than designers of curricula (Aguirre et al., 2013).

As this pattern emerged, we drew on transactional theory (Raymond, 2021; Rosenblatt, 1978), used within the literature discipline, which posits the meaning created while reading depends on the stance of the reader. Readers may adopt an aesthetic stance, in which they read to create multiple possible interpretations of written text, or an efferent stance, in which the focus is limited to a single, often superficial meaning. As we became aware our students might adopt efferent stances, we began to consider ways to encourage a more aesthetic stance among PSTs. In response, we revised the initial framework from traditional categories of "exceeds expectations," "meets expectations," or the like, to adopt categories representing *teacher edits*. Namely, when analyzing a mathematics task against PST co-created criteria, the pre-service teachers decided if the task "meets as written," "requires teacher edits," or the task was "unable

to meet with teacher edits." This shifted PSTs' perspective as they analyzed tasks, prompting them to consider how they might meet expectations for high-quality tasks.

After implementing the revised framework, we engaged in a third round of reflections and observed growing PST confidence and ability. However, we also noticed PSTs often did not connect task decisions to the context in which the task would be used. When we asked PSTs to analyze a task, we provided context such as grade level, class description, a mathematics standard, and when the standard was developed (e.g., "you want to develop students' fluency with…"). Yet PSTs rarely considered these descriptions or adjusted their criteria based on the context. For example, some tasks support new conceptual understanding, while others foster procedural fluency, yet PSTs' analyses often favored criteria that valued one type over the other.

Discussion

We uncovered multiple tensions in our work with PSTs around task analysis. The first tension we came to recognize was our desire to develop clear expectations for what constitutes a high-quality task, while also recognizing the inherent ambiguity in teaching that PSTs must learn to navigate. This tension persists as we recognize a single tool may not capture the nuances needed to analyze the use of a task for a particular purpose or context, even when it is constructed by PSTs themselves. The second tension we uncovered related to PSTs' perceptions of themselves as novices, as we engaged them in the work of a professional educator. We asked our PSTs to analyze products we presented to them, which are typically created by an unknown person whom they presume has more experience and knowledge. As a result, our PSTs hesitated to alter or enhance tasks. By incorporating the idea of *teacher edits* to task analysis, we reframed alterations not as questioning the authority of their instructors or curriculum writers, but as a professional expectation of teachers. This change supported our PSTs as autonomous professionals capable of making curricular decisions. The final tension we uncovered was the need to recognize that while there are common criteria used to assess the quality of a mathematical task, the weight given to each criterion may depend on the purpose of the task. Each tension uncovered related to PSTs' abilities to assert agency over the tasks they were analyzing. As we became aware of each of these tensions, we were purposeful in constructing strategies for addressing these tensions that were aligned with social constructivism to better model constructivist pedagogies and to foster our PSTs' feelings of autonomy. Thus, uncovering these tensions allowed us to improve our practices and frame our PSTs as emerging educators.

Conclusion

Through collaborative self-study, we identified tensions related to ambiguity in defining task quality, PSTs' developing professional agency, and the contextual weighting of task criteria that required us not only to revise our semester-long project but also to reconsider how our practices positioned PSTs in relation to curriculum and professional decision-making. Encouraging a more aesthetic stance toward tasks (Raymond, 2021; Rosenblatt, 1978) supported PSTs in viewing curriculum as adaptable rather than fixed. This shift strengthened their confidence and more fully aligned our own instructional practices with social constructivism. Our findings suggest that evaluating high-quality tasks cannot be separated from considerations of instructional purpose, timing, and context. Although PSTs demonstrated growth in selecting and revising tasks, they continued to struggle with determining when and for what purposes particular tasks were most appropriate. Future research should further explore how teacher education can explicitly support PSTs in weighing task criteria differently depending on instructional goals and classroom contexts. Ultimately, fostering PSTs' capacity to select and analyze high-quality mathematics

tasks involves cultivating professional agency, comfort with ambiguity, and the ability to situate curricular decisions within purposeful instructional contexts.

STUDENT RESPONSES TO QUESTIONS REFERENCING PEERS' CONTRIBUTIONS IN NUMBER TALKS

kribs@uta.edu

Research on mathematics classroom discourse has emphasized both students' participation in discussion and the cognitive demand of their mathematical talk, yet these dimensions are often examined separately. Building on prior analyses of teacher question types, and our tracing of how these questions are used to provide opportunities for students to engage with each other's thinking, we integrate social network analysis with a cognitive-level discourse framework to trace students' responses to teacher questions that position them to engage with peers' mathematical contributions during Number Talks. Findings illustrate that teacher questions referencing peers' mathematical contributions can position students in distinct participation–reasoning roles, shaping both how students engage with peers' thinking and the cognitive level of discourse that emerges from those interactions.

Keywords: Classroom Discourse, Instructional Activities and Practices

Classroom discourse is widely recognized as central to students' opportunities to develop mathematical understanding, particularly when students attend to and respond to one another's mathematical thinking (Chapin et al., 2003; Lampert & Cobb, 2003; Webb et al., 2014). Research has further shown that teacher questioning plays a critical role in shaping these opportunities by structuring who participates in discussion and whose contributions become the focus of collective sense-making (Boaler & Brodie, 2004; Franke et al., 2009; Smith & Stein, 2011). Thus, learning opportunities in mathematics classrooms are not evenly distributed, but are mediated through patterns of questioning, response, and uptake during classroom interaction.

Our prior work examined teacher question types (Joswick et al., 2025a) and the peer-referencing discourse structures (Joswick et al., 2026), revealing patterns of who discusses whose mathematical contributions during Number Talks. Together, these studies described how teacher questioning structures opportunities for participation, but they did not examine students' responses within those opportunities. Thus, although this work clarifies how questioning shapes participation and whose ideas become the focus of discussion, it leaves unresolved the nature of students' reasoning in these positioned moments—and the learning such participation affords.

The present study centers students' responses within teacher-structured opportunities to respond in relation to peers' mathematical contributions and examines the cognitive level of the discourse (Weaver et al., 2005) those responses produce. By integrating attention to participation structure with analysis of cognitive demand, this work aims to more fully characterize the learning opportunities afforded through classroom discourse during Number Talks. Guided by this purpose, we ask: *How are teacher-structured opportunities to engage with peers' mathematical contributions taken up by students, and what cognitive levels of discourse emerge from those interactions?*

Methodology

Data Collection

Our data come from 17 teachers enrolled in an online master's course designed to support adoption of classroom Number Talk practice, often new to participants. We used a tailored teacher learning cycle (Joswick et al., 2020) grounded in *Teacher Education by Design* (2014), involving cycles of learning, planning, implementation, reflection, and peer feedback. Teachers submitted three videos of successive Number Talk enactments using problems drawn from Number Talk literature (e.g., Humphreys & Parker, 2015; Parrish, 2010). We analyze the third, culminating video transcribed from these small-group Number Talks (3–5 students).

Data Coding

To trace how students interact with one another and each other's ideas during Number Talks, we coded the data to identify dialogic ties—opportunities for students to respond or build on peers' solutions, strategies and ideas—using our four-phase discourse analysis coding, illustrated in Figure 1. At Phase 1, we identified the question type (e.g., *Orient*) a teacher asked using our established framework (Joswick et al., 2025a). For Phase 2, we further analyzed each question to find those specifically asking students to consider their *peers' thinking* (specifically around their problem *solutions*, *strategies* used to solve, and mathematical *ideas*). Phase 3 allowed us to track directionality—who the teacher invited to answer, who responded, and whose thinking was discussed. The final phase of coding analyzed student responses, their cognitive level of discourse, using the cognitive-demand framework of Weaver et al. (2005), operationalized in our prior work to characterize the depth and complexity of students' mathematical reasoning within discourse (Joswick et al., 2025b). The research team coded independently before reconciling discrepancies to reach 100% agreement (Halpin, 2024).

Phase 1	**Phase 2**	**Phase 3**			**Phase 4**
Teacher question type	Whose/what thinking is asked about	Who was invited to answer	Who answered	Whose thinking was discussed	Student cognitive level of discourse

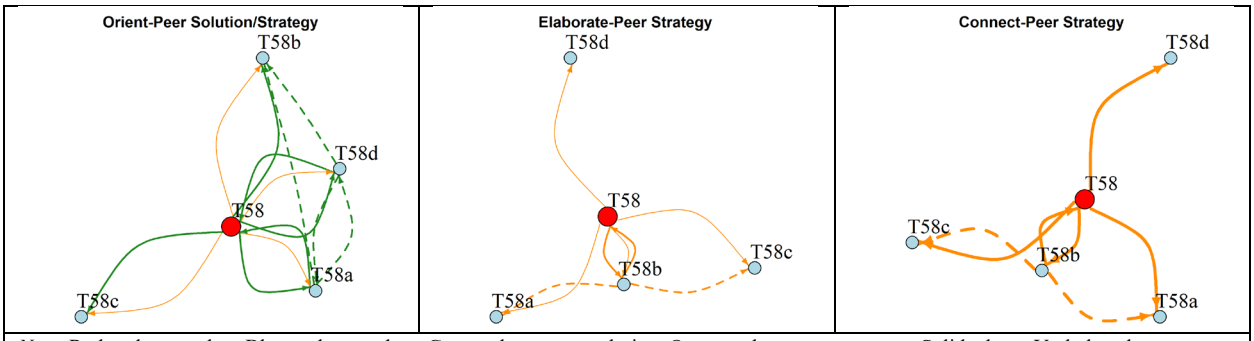
Figure 1: Four-Phase Discourse Coding, Illustrated by Teacher 58 and Four Students

Data Analysis



To analyze the data via Social Network Analysis (SNA) (Borgatti et al., 2022), we transformed the data into frequency matrices (i.e., layers by phase 1, 2, and 4 codes) to create a multiplex network (Magnani et al., 2021). This captures layers of student participation and cognitive discourse level with each other's thinking with directional ties (i.e., phase 3 coding), leveraging our prior SNA of student participation in collaboration networks (Sanders et al., 2025). Using R, we visualized each network with the teacher as the ego and students as alters (Perry et al., 2018). We then calculated network descriptives to examine network cohesion and teacher (i.e., ego) influence (Borgatti et al., 2022) as well as alter level descriptives—normalized eigenvector centrality (i.e., how well-connected a Number Talk participant is to other well-

connected participants).

Selected Findings

For this brief report, we highlight selected findings using illustrations from 4th year teacher, T58, and their grade 4 group of four students: T58a, T58b, T58c, and T58d. Prior to the graduate course T58 was enrolled in, they had limited experience with Number Talks. In their Number Talk, the following problems were posed successively: *2x3x8, 4x2x6,* and *6x8.* T58 was selected as an illustrative case because the Number Talk contained multiple instances of peer-referencing *Orient, Elaborate*, and *Connect* questions.

To foreground the student perspective, we present findings organized around how individual students encountered teacher-structured opportunities to engage with peer thinking embedded in *Orient*, *Elaborate*, and *Connect* questions (Joswick et al., 2025a) and the cognitive levels of discourse (Weaver et al., 2005) evident in their responses. These particular question types are analytically salient because they move classroom discourse beyond the sharing and clarification of strategies toward opportunities for students to collectively reason about numbers and build conceptual connections. Examining these moments through a four-phase analytic structure (see Figure 1) allows us to trace how positioned opportunities to engage with peers' mathematical thinking were taken up in qualitatively different ways (see Figure 2). From a student-level perspective, the analysis revealed three distinct participation–reasoning profiles: a central explanatory contributor (T58b), students positioned as idea sources without response authority (T58a, T58c), and a peripheral participant limited to agreement-level discourse (T58d).

Note. Red node = teacher, Blue node = student, Green edge = peer solution, Orange edge = peer strategy, Solid edge = Verbal exchange, Dashed edge = Connection to peer thinking, No bold = *no answer*, bold = *answering*, Moderate bold = *emerging explaining*, Heavy bold = *relating*

Figure 2. Network Visualization Across Selected Question Types

Student T58b: Central Explanatory Contributor

Student T58b emerged as the most active and oftentimes most central student across the *Orient*, *Elaborate*, and *Connect* questions regarding peer thinking. For instance, T58b had normalized eigenvector centralities of 1.00 (*Orient*), 1.00 (*Elaborate*), and 0.71 (*Connect*) indicating that T58b was well-connected to other well-connected participants (i.e., teacher and students) in the Number Talk, more well-connected than the teacher except for connect questions. The cognitive level of discourse of T58b's responses and engagement with *peers' thinking* varied systematically.

T58b solely engaged in the *emerging explaining* cognitive level of discourse (i.e., partially explaining a mathematical idea in direct response by stating a description of what the student

did) for *Elaborate* questions. When T58 then shifted to another *peer's strategy* ("Ok, what did he split?" referring to T58a), T58b again supplied the explanation, "The 2 and the 8. And then he got 16 and multiplied it by 3 then." In contrast, for *Connect* questions, T58b responded with a *relating* cognitive level of discourse (i.e., describing a connection or relationship to prior knowledge or experience). T58b's *relating* cognitive discourse response indicates how T58a's and T58b's strategies are related: "[T58a] also, uh did, um splitting it. But he split it in a different way." Despite not answering an *Orient* question, T58b's solutions were positioned centrally demonstrating influence through ideas.

Students T58a and T58c: Influence Through Ideas

In contrast to T58d (peripheral participant with *peer thinking*) and T58b (central contributor to *peer thinking*), students T58a and T58c were positioned by T58's questions as influential students through centering their solutions and strategies. In *Connect* questions, T58a had moderate normalized eigenvector centrality (0.64), indicating that despite not answering teacher questions, their *strategies* were positioned as valuable to the discussion by both T58 and T58b through questions such as, "Okay, what about [T58a]? How is [T58a]'s different or similar [from T58c]?" This particular question represents an opportunity where T58b was able to engage with T58a's strategy at a *relating* cognitive level of discourse. Similarly, in an *Elaborate* question ("Which numbers did [T58c] break?"), T58 offered up T58c's strategy for further explanation by T58b, amplifying T58c's thinking and increasing their normalized eigenvector centrality to 0.60.

Student T58d: Peripheral Participant Limited to Agreement-Level Discourse

T58d represents a student that was mostly on the periphery of the Number Talk participation. T58d is a unique case in that their only response to T58's questions centering peer thinking was for *Orient* where T58d responded to T58a's solution using the Number Talk, non-verbal hand signal for "me too" (Okay, [T58a] says 48. If you agree with [T58a], do "me too", from T58). T58d's response represents am *answering* cognitive level of discourse (i.e., short answer to a direct question from the teacher). T58d achieved their highest network position in the *Orient* network with a normalized eigenvector centrality of 0.77 while across the *Elaborate* and *Connect* questions, T58d only had connections to T58 through directed questions, but T58d did not respond to these questions or have their thinking taken up by other students.

Discussion & Conclusion

This study contributes to research on mathematics classroom discourse by integrating attention to participation structure with analysis of the cognitive level of student responses within teacher-structured opportunities to engage with peers' mathematical thinking. Our findings demonstrate how students are positioned within the group to respond to *peers' thinking*, based on their participation. As illustrated by T58, the findings highlight that students participate with *peers' thinking* in different ways and that not all students are either given or take up opportunities to engage with peers thinking in a manner that ensures higher cognitive levels of discourse. Rather, students' uptake of these positioned opportunities varies, producing differentiated access to explanation, comparison, and agreement within the same Number Talk. These patterns suggest that engagement with peers' mathematical thinking is not a uniform experience, as students occupied different participation–reasoning roles associated with different levels of cognitive discourse. Methodologically, integrating our four-phase discourse coding with multiplex social network analysis provides a sensitive lens for tracing how cognitive discourse connects through participation structures. This work adds nuance to whose ideas are being discussed, what type of questions are being asked to whom, and how different question types contribute to different cognitive levels of discourse. This approach extends prior discourse

research (e.g., Joswick et al., 2025a, 2025b) by making visible the relationship between positioned opportunity and cognitive uptake.

ELEMENTARY TEACHERS' PERCEPTION AND INTERPRETATION OF LEARNING THEORIES IN MATHEMATICS TEACHING AND LEARNING

Boran Yu
University of North Carolina at Chapel Hill
boranyu@unc.edu

Dionne Cross Francis
University of North Carolina at Chapel Hill
dicross@unc.edu

Despite the significant impact of learning theories on instructional design and implementation, they remain subject to practitioners' direct examination. This study explored how elementary pre-service teachers (PSTs) interpret learning theories in the context of mathematics education. Nineteen PSTs from a graduate-level mathematics methods course selected one learning theory (among behaviorism, cognitivism, constructivism, sociocultural learning, and experiential learning) that best aligned with their experience with mathematics teaching and learning and explained their choice. Experiential learning was most aligned with PSTs' experience, and behaviorism was prioritized for designing learning environments. PSTs' selections of theories appeared to balance acknowledgment of the theories with the practicality of implementing them, foregrounding their competence and value as examiners of learning theories.

Keywords: Learning Theory, Teacher Beliefs, Teacher Knowledge, Preservice Teacher Education

Background

As education developed as a rigorous social science subject, theory and research evidence about teaching and learning have played an increasingly important role in educational decision-making (Darling-Hammond et al., 2020). Specifically, learning theories, which reveal how learning actually happens, have informed and shaped the design and implementation of instructional practices (Ertmer & Newby, 2013). Within the field of mathematics, constructivism has guided a set of reform-based practices towards student-centered instruction focused on conceptual understanding (National Council of Teachers of Mathematics [NCTM], 2014). Prior studies highlighted the positive effects of integrating theories into mathematics teacher education to deepen their understanding of how students learn specific concepts (Ivars et al., 2020), thereby further developing their professional knowledge and beliefs (Cross Francis et al., 2025; Oonk et al., 2015).

However, achieving synergy between theory and practice may be hindered by the generalized knowledge valued by the researcher community versus the practical knowledge valued by the teacher community (Buchmann, 1984). Teachers' interpretation and understanding of theory are critical for addressing the tension between theory and practice, and maintaining the fidelity of, and their enthusiasm for, designing and implementing theory-driven instruction (Allen & Wright, 2014; Lendínez Muñoz et al., 2023). Pre-service teachers (PSTs) tend to face more tensions since they are enrolled in programs with theory-heavy courses and are often simultaneously involved in field experiences (Cheng et al., 2012; Oonk et al., 2020). Therefore, it is important to understand how PSTs interpret theory and envision integrating them into their instruction.

This study explores how elementary mathematics PSTs perceive and interpret five learning theories in relation to mathematics teaching and learning. We focus on answering two research questions: (1) What learning theories do elementary PSTs perceive as most aligned with their experience of learning and teaching mathematics? (2) What experiences did PSTs draw on to support their choices and interpretation of the learning theories?

Learning Theories Associated with Mathematics Teaching and Learning

Behaviorism is a theory of learning that foregrounds the use of positive and negative reinforcement to condition certain behaviors. In mathematics teaching and learning, this explains that students need to be conditioned to respond to specific mathematical procedures through repeated practices (Byrnes, 1992; DeLay, 1996). Later reform movements in mathematics led to a shift from behaviorism towards an emphasis on constructivism and other learning theories (e.g., cognitivism and sociocultural learning theory) (Anderson et al., 1999; NCTM, 2014). Cognitivism, deviating from behaviorism's notions of learning as a change in behavior, highlighted the importance of cognitive information processing and the role of prior knowledge and deep thinking in learning math. Constructivist-based teaching shifts the focus of learning from rote memorization of mathematical facts, as implied by behaviorism, and encourages active learning grounded in prior experiences and the student's interaction with the environment. (Bada & Olusegun, 2015). Socio-cultural learning theory argues for mathematics learning through social interactions, emphasizing scaffolding by more knowledgeable others to reach zone of proximal development (ZDP) (Walshaw, 2017). More recently, scholars have argued for the use of experiential learning, which foregrounds learning through engaging in and reflecting on experience (e.g., learning a biological concept through field experience) (Kolb et al., 2014). Experiential Learning implied building early mathematics experience by letting students use manipulatives to explore mathematical ideas (Simon, 2022).

Methods

Participants and Context

Nineteen PSTs enrolled in a graduate-level elementary mathematics method course participated in the study, and most of them are white females. The methods course is grounded in constructivist-oriented mathematics teaching practices while also exposing PSTs to other learning theories to facilitate a deep understanding of students' learning of mathematics. Meanwhile, PSTs are also engaged in field experiences and an experiential learning week within the graduate teacher education program.

Data Collection

The data source for this study included PSTs' written reflections on five learning theories (behaviorism, cognitivism, constructivism, sociocultural theory, and experiential learning) related to mathematics teaching and learning. These theories were not considered exclusive, as they overlap in ideas and may be situated at different scopes. Data were collected during the fifth week of a 15-week course. At this point, PSTs have engaged in their one-week experiential learning set of activities, read about behaviorism and socio-cultural theory, and read and discussed constructivism as a part of their coursework in the methods class. PSTs were asked to select the theory most aligned with their mathematics teaching and learning following these two prompts: (1) how mathematics learning occurs and what role the mathematics teacher plays according to this theory, and (2) the reasons they selected the theory.

Data Analysis

For research question 1, we determined the frequency with which each learning theory was mentioned by PSTs. For research question 2, we summarized the teaching and learning experiences they described as reasons for selecting each learning theory.

Findings

Research Question 1: Choice of Learning Theories

Table 1 shows the number of PSTs who thought each theory most closely echoed their

experiences or reflected high-quality mathematics teaching and learning. It is worth noting that the sum of the percentages is not 100%, as some PSTs may select multiple theories.

Table 1: Frequency of PSTs' Selection of Learning Theories

	Behaviorism	Cognitivism	Constructivism	Socio-cultural Theory	Experiential Learning
Counts (Percentage)	4 (21%)	3 (16%)	2 (11%)	1 (5%)	10 (53%)

Research Question 2: Interpretations and Reasons for Learning Theories

Behaviorism. Four PSTs indicated that they related most to behaviorism, based on their own experiences of learning and math teaching, while their interpretations presented different orientations. Emma and Jackson, interpreted behaviorism as an approach to build a positive environment in which certain behaviors (i.e., trying to solve problems rather than feeling afraid to make mistakes) were reinforced. Emma described in her reflection:

> This theory (behaviorism) argues that the likelihood of a behavior increases based on positive or negative reinforcement … Behaviorism is a way to support students' motivation and attitudes towards math, boost engagement and create consistent routines that really work for students.

By contrast, the other two PSTs chose to stick to behaviorism in their future teaching as a compromise with real-world challenges. Eleanor interpreted behaviorism as a rational choice of teachers due to the heavy workload of teachers. Evelyn described the positive results from her learning experience within the behaviorism paradigm, which encouraged her to believe that behaviorist approaches are suitable for teaching mathematics:

> I learned many of the basic principles of math through repetitive practice. We did not use base ten blocks or were rarely taught the "why" behind everything but I was still strong in math throughout school. … The (mathematical) foundations should start to just come naturally instead of taking a long time to process and decode. I believe behaviorism is the best way to achieve this.

Cognitivism. Three PSTs, Aria, Mandy, and Mia, related most to cognitivism and agreed on the importance of students' cognitive engagement when learning mathematics. Mandy and Aria framed cognitivism in a student-centered way, highlighting the role of teachers in engaging students cognitively based on their prior knowledge. However, Mia's framing was more teacher-centered, foregrounding the role of teachers in presenting the information clearly to students and managing their learning process. They all chose cognitivism based on their observations of the value of understanding students' thinking during instruction and of building cognitive connections among mathematical concepts. Mandy described her positive experience of being taught using cognitive approaches, which made her believe in the value of cognitivism:

> I had math taught to me in ways that research suggests is helpful to the learning brain. I remember being instructed to do fill-in-the-blank notes, and taking hand-written notes is supposed to put things into your memory better … As a teacher, I will try to take cognitive approaches.

Constructivism. Two PSTs, Charlotte and Amelia, chose constructivism as the closest to their learning and teaching math. These two PSTs emphasized connecting prior and current knowledge. Charlotte described constructivism as the best way for her to learn mathematics and a valuable way to build students' confidence and enjoyment in learning math through connecting with their background knowledge.

Sociocultural theory. Nora is the only PST echo the most with sociocultural theory. She appreciated the idea of the zone of proximal development and emphasized the role of teachers in providing scaffolding for students. Such appreciation derived from her early learning experiences, where her mother scaffolded her to navigate through the memorization-based mathematics teaching she struggled with.

Experiential learning. Experiential Learning was selected by ten PSTs as the most aligned with their experience of teaching and learning mathematics. They shared the belief that hands-on activities help them build their own knowledge by making mistakes and reflecting on them. Half of them referred to their own experiences of learning math and thought the best way is to "physically do something" (Abigail), "make inquiries and discoveries" (Olivia, against rote memorization), "apply them" (Lucas), and "reflect on the mistakes" (Sophia). Seven PSTs referred to their observations of the benefits of using hands-on or inquiry-based instruction, including "letting students know they are doing great, and mistakes are welcome as opportunities of learning" (Amelia), "building confidence and problem-solving skills" (Jamie), "more engaged when they can manipulate with materials and solve problems with peers" (Chole), and "students' critical thinking skills" (Ava).

Discussion and Conclusion

This study explored how elementary mathematics PSTs perceive and interpret learning theories and led to two major findings. First, this study revealed the complexity of practitioners' interpretations of learning theories and their connection to instruction, aligning with prior studies (Cheng et al., 2012). PSTs' interpretation of theory and why they foregrounded a specific theory is a thoughtful process if they balance their learning experiences, observation of teaching, and their visions for teaching mathematics. For instance, despite recognizing the drawbacks of behaviorist approaches, Eleanor still believes them to be the optimal approach with the heavy workload. These findings are more nuanced than prior studies, which only focused on PSTs' accurate interpretation and use of theory in their teaching (Oonk et al., 2015; Van Katwijk et al., 2019). These findings highlight the importance of providing PSTs with more scaffolds to unpack and reason about theory-based mathematical teaching approaches and navigate the tensions with practical situations (Lendínez Muñoz et al., 2023).

Second, this study challenged the deficit-oriented perspective of attributing the theory-practice gap to practitioners' inability to understand and apply learning science concepts (e.g., McAfee et al., 2021). PSTs were able to draw on learning theories to critically examine their learning experiences and determine which would be most applicable in a specific context. Rather than serving as the golden principle for practice, learning theories could serve as a powerful prompt for PSTs to reflect on their experiences as learners and teachers and how to address tensions between theory and practice (Cochran-Smith & Lytle, 1999). Addressing these tensions is the central task for PSTs, as it involves developing their beliefs and visions for future classroom practice (Feiman-Nemser, 2001; Oonk et al., 2020).

Implications from this study can be twofold. Research-wise, more effort should be made to incorporate practitioners' perspectives into how learning theories are explored and taught in mathematics education. Further investigation into a broader range of practitioners' perspectives

is needed, as context-wise this study is limited within a methods course. Within teacher education, the value of learning theory lies not only as the cornerstone for high-quality practice but also as a resource to build PSTs' instructional vision and to examine their own practice.

MODELACIÓN POR FUTUROS PROFESORES EN UN CONTEXTO DE PROPORCIONALIDAD INVERSA Y ESTRÉS HÍDRICO

MODELING BY PRE-SERVICE TEACHERS IN A CONTEXT OF INVERSE PROPORTIONALITY AND WATER STRESS

Oscar Ivan Zambrano-Montero
Universidad de Guadalajara
oscar.zambrano5231@alumnos.udg.mx

Verónica Vargas-Alejo
Universidad de Guadalajara
veronica.vargas@academicos.udg.mx

Se presentan los resultados de un estudio cualitativo cuyo objetivo fue analizar cómo futuros profesores se enfrentaron a un problema cercano a la realidad relacionado con el estrés hídrico. El estudio se sustentó en la perspectiva de modelos y modelación y contó con la participación de tres futuros docentes. Se utilizó una actividad en la que subyacía la proporcionalidad inversa, la actividad solicitaba la elaboración de una carta donde los participantes debían describir un procedimiento para estimar la cantidad de agua disponible por persona en los próximos años ante el crecimiento poblacional. Los resultados evidencian el desarrollo de dos tipos de modelos: un modelo recursivo y un modelo funcional. Durante el proceso de modelación se identificó una preocupación por el estrés hídrico, asociada a la percepción de una disponibilidad de agua cada vez más limitada.

Palabras clave: Modelación, Proporcionalidad inversa

Introducción

La proporcionalidad inversa es un tema de gran relevancia porque muchos problemas de la vida real se pueden resolver a través de ella (Ramírez & Hernández, 2017). Sin embargo, de acuerdo con varias investigaciones (Godino & Batanero, 2002; Ramírez & Hernández, 2017), la comprensión de la proporcionalidad inversa suele presentar dificultades para los estudiantes debido a que cuando se enseña este concepto frecuentemente suele limitarse a un método algorítmico y mecánico y a una manipulación de números de manera aleatoria y descontextualizada. Además, es común que se argumente que dos cantidades x e y son inversamente proporcionales porque "una cantidad aumenta, y la otra disminuye," omitiendo la condición de la constante k de proporcionalidad inversa: $x * y = k$ (Herrera-García et al., 2023).

Dado que la proporcionalidad inversa es un concepto útil para resolver problemas de la vida real, y existen dificultades de comprensión, es necesario cambiar la forma mecánica de enseñarla. Una forma es a través del uso de problemáticas cercanas a la vida real, como las denominadas MEAs (por sus siglas en inglés, Model Eliciting Activity, traducida al español como Actividad Provocadora de Modelos, de acuerdo con Vargas-Alejo et al., 2016), tal como lo propone la perspectiva de modelos y modelación (MMP, por sus siglas en inglés). Ello implica que los profesores las conozcan y aprendan a utilizarlas en el aula.

El propósito de este trabajo es presentar parte del análisis de los resultados de una investigación desarrollada con futuros profesores, basada en la MMP, la cual implica fomentar que ellos conozcan las MEAs, experimenten su resolución y reflexionen sobre el potencial de las mismas para propiciar aprendizaje. La pregunta de investigación es ¿qué modelos construyen futuros profesores al enfrentarse a una actividad sobre el estrés hídrico de su localidad en la que la proporcionalidad inversa está implícitamente involucrada?

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

Marco teórico

El marco teórico que sustenta este estudio es la perspectiva de modelos y modelación (Lesh, 2010). La MMP promueve el aprendizaje matemático a través de tareas llamadas Model Eliciting Activities (MEA). Las MEAs "son similares a muchas situaciones de la vida real en las que las matemáticas son útiles" (Lesh & Doerr, 2003, p. 4). Bajo esta perspectiva, de acuerdo con Lesh y Doerr (2003), una MEA requiere la creación de modelos que pasan por procesos de prueba, revisión y refinamiento. El desarrollo de modelos implica ciclos iterativos, donde las ideas se expresan, prueban y ajustan de forma continua a través de las interacciones entre estudiantes y el docente al resolver un problema (Lesh, 2010).

El diseño de una MEA se da con base en seis principios (Lesh et al., 2000; Lesh & Doerr, 2003): principio de la realidad, principio de construcción del modelo, principio de la autoevaluación, principio de documentación del modelo, principio de prototipo simple y principio de generalización del modelo.

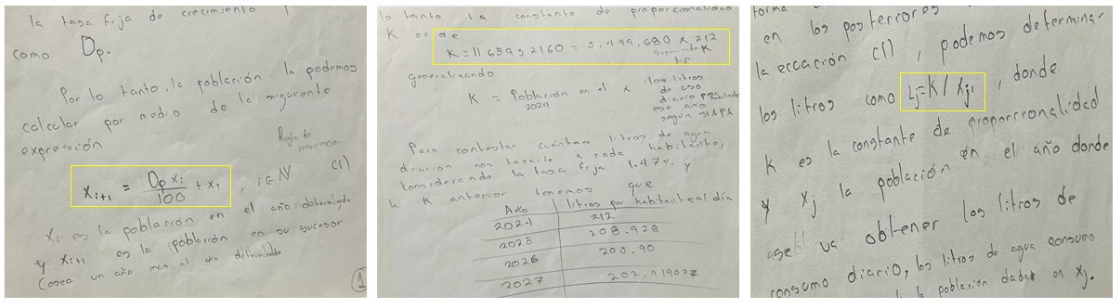
Metodología

La investigación fue cualitativa, tipo estudio de caso múltiple (Ponce, 2018) ya que permite analizar los patrones similares y diferenciales entre los individuos ante una misma situación problema, lo cual contribuye a contrastar los diferentes procesos de modelación que emergieron. Participaron tres futuros profesores (A1, A2 y A3) quienes se encontraban estudiando una maestría en enseñanza de las matemáticas. Los futuros profesores tenían estudios universitarios en matemáticas y estaban interesados en ser profesores del nivel medio superior y superior.

La MEA "El estrés hídrico en la ZMG" se construyó con base en los seis principios de diseño. Esta actividad está compuesta por tres partes: a) una nota periodística en la que se describe el estrés hídrico en la Zona Metropolitana de Guadalajara (ZMG), b) preguntas relacionadas con el contexto de la nota periodística que contribuyen a reflexionar sobre la problemática descrita, y c) una situación problema donde se solicita a los futuros profesores la elaboración de una carta en la que se describa un procedimiento para explicar cómo cambiaría la cantidad de agua disponible por persona si la población de la ZMG, la cual era de 5,499,680 en el año 2024, sigue aumentando. El concepto de la proporcionalidad inversa está implícitamente involucrado porque se requiere para analizar cómo en la medida que aumente la población, podría disminuir la cantidad de agua disponible ante la situación actual del estrés hídrico.

La implementación de la MEA tuvo una duración de 90 minutos (como sugiere la MMP) y consistió en las siguientes tres fases. Los futuros profesores resolvieron la MEA de manera individual, enseguida la discutieron de forma grupal y finalmente, comentaron la actividad.

Los instrumentos de recolección de datos fueron grabaciones de audio y las cartas solicitadas en la MEA. Se usaron para analizar los modelos construidos al resolver la situación problema.



Resultados

Primera fase

Se lograron identificar dos tipos de modelos para resolver la MEA.

Modelo recursivo de proporcionalidad inversa. A partir de la tasa de crecimiento anual y la población inicial, el futuro profesor A1 propuso un procedimiento recursivo (Figura 1) de la siguiente forma: $x_{i+1} = \frac{D_p x_i}{100} + x_i$, donde D_p es la tasa de crecimiento anual, x_i es la población inicial y x_{i+1} es la población al año siguiente. Enseguida, para obtener la población de la ZMG del periodo de 2024–2038, usó fórmulas recursivas en Excel de la forma: $= (G10 * 1.47)/100 + G10$. Además, calculó la constante k de proporcionalidad inversa al multiplicar la población inicial (año 2024) por el dato de los 212 litros diarios de agua que gasta una persona en la ZMG.

Finalmente, en lápiz y papel, escribió la expresión de proporcionalidad inversa siguiente: $L_j = \frac{k}{x_j}$, donde x_j es la población anual y L_j son la cantidad de litros de agua que gasta una persona de la ZMG a lo largo de los años. Con ello predijo la cantidad de agua que le tocaría a cada persona en los siguientes años.

A B C

Figura 1: Modelo recursivo propuesto por A1

Modelos recursivo y exponencial. El futuro profesor A2 creó un modelo recursivo en el cual se observa cómo calculó la cantidad total de habitantes para el periodo 2024-2026, la cantidad de litros que le tocaría a cada habitante de la ZMG y el total de agua que se gastó en el 2024 (Figura 2). Enseguida, propuso un modelo exponencial. Finalmente, en su carta incorporó ambos y propuso al SIAPA la siguiente función para predecir la población en los siguientes años: $P(t) = 5499680(0.0147)^t + 5499680$. Sin embargo, esta expresión no concuerda con los resultados previamente obtenidos de manera recursiva.

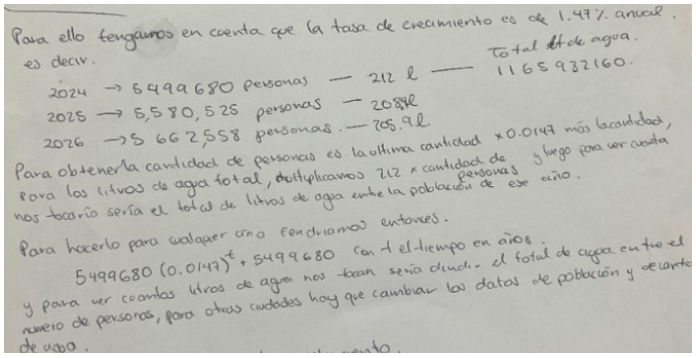


Figura 2: Modelo recursivo y exponencial propuesto por A2

Segunda fase de discusión grupal

Durante esta fase los futuros profesores explicaron sus modelos. A3, quien no construyó un modelo debido a que asumió que faltaba información, estuvo de acuerdo con el modelo creado por A1. Por su parte, A1 señaló que también era importante rescatar elementos del modelo de A2 por su aportación al entendimiento matemático del problema con base en el uso de una función exponencial.

Tercera fase

Durante esta fase, los futuros profesores describieron el uso de la proporcionalidad inversa en sus modelos. A1 indicó que el modelo recursivo (Figura 1A) lo desarrolló, primero en lápiz y papel y se apoyó en Excel para automatizar la proyección poblacional (Figura 1B). Con estos datos tabulados, regresó al lápiz y papel para calcular la constante k de proporcionalidad inversa y estructurar la fórmula de proporcionalidad inversa (Figura 1C). Ambos procedimientos le permitieron escribir su carta. A2, por su parte, señaló que no había identificado a la proporcionalidad inversa como un tema matemático subyacente en la situación problema. Ella solo se había enfocado en resolverla. Sin embargo, la había usado.

Finalmente, todos manifestaron que fue interesante resolver esta MEA por incluir, además de un conocimiento matemático, una problemática actual y, por tanto, les parecía importante llevarla al aula.

Reflexiones finales

Los resultados muestran que la proporcionalidad inversa fue utilizada en los dos tipos de modelos construidos. Ambas interpretaciones permitieron a los futuros profesores predecir el comportamiento de la distribución del agua en la ZMG, lo cual valoraron como preocupante y pertinente para su discusión en el aula con sus futuros estudiantes. Tal como lo señala Méndez et al. (2023) en investigaciones con estudiantes, se concluye que las MEAs favorecen procesos de matematización acordes con la interpretación del problema y promueven la reflexión sobre el contexto de la situación planteada. De manera particular, este estudio aporta evidencia de que los futuros docentes no solo desarrollan modelos matemáticos, sino que también reconocen el potencial interdisciplinar formativo y de impacto social del posible uso de las actividades en el aula ante los resultados obtenidos.

LEARNING TO TEACH: PREPARING PRESERVICE TEACHERS TO FACILITATE MATHEMATICAL DISCOURSE

Weichen Zhao
San Diego State University Imperial Valley
wzhao5@sdsu.edu

Huan Qin
San Diego State University Imperial Valley
hqin@sdsu.edu

Mathematical discourse is central to students' mathematical sense-making, yet preservice teachers often struggle to facilitate it effectively. This pilot study examines a three-phase discourse session embedded in a mathematics methods course, grounded in Universal Design for Learning and Mathematical Knowledge for Teaching. The session supported preservice teachers in developing discourse-focused pedagogical strategies. Pre- and post-survey results showed consistent growth, with the largest gains in revoicing, professional noticing, and supporting students' reasoning. Qualitative findings revealed shifts toward student-centered perspectives and increased awareness of discourse moves. Together, results suggest that structured engagement and practices can support preservice teachers' developing competence in facilitating meaningful mathematical discourse.

Keywords: Mathematical Discourse, Preservice Teacher Education, Universal Design for Learning, Mathematical Knowledge for Teaching

Mathematical discourse (MD) plays a vital role in supporting students' development of deeper mathematical proficiency across mathematical topics (Legesse et al., 2020; Demirci & Baki, 2023). MD is commonly conceptualized as purposeful communication among students and teachers that involves explaining reasoning, justifying solutions, and debating mathematical ideas, practices that are central to students' sense-making and conceptual development in mathematics learning. Research further indicates that classrooms characterized by sustained routines of mathematical discourse are associated with improved mathematics achievement and support students' autonomy, motivation, self-regulation, and strategic learning behaviors (Turner et al., 2003).

The National Council of Teachers of Mathematics (2014) emphasized that "effective mathematics teaching engages students in discourse to advance the mathematical learning of the whole class" (p. 29), positioning MD as central to promoting thinking in mathematics classrooms. However, research suggests that enacting this vision in practice remains challenging, particularly for preservice teachers who often struggle to identify specific teacher moves that effectively support productive MD (Lee et al., 2013; Ducharme et al., 2022; Aduko & Akayuure, 2025). This brief report describes the design and implementation of a session, situated in a mathematics methods course, aimed at supporting preservice teachers' (PSTs) understanding of their roles in promoting mathematical discourse. The report presents the design rationale, instructional activities, and initial findings related to PSTs developing competencies and growing awareness of their roles in facilitating MD.

Theoretical Framework

This study is conceptualized through the lenses of Universal Design for Learning (UDL; CAST, 2018) and Mathematical Knowledge for Teaching (MKT; Ball et al., 2008). UDL provides an equity-oriented framework for designing learning environments that offer all students multiple opportunities for equitable math learning through multiple means of engagement, representation, and action and expression. MKT further foregrounds PSTs'

developing competencies in rigorous mathematics instruction, including their ability to facilitate MD. In particular, MKT highlights the pedagogical content knowledge required to interpret, respond to, and build on students' diverse mathematical and linguistic contributions within classroom discourse. Together, these frameworks support the instructional design and teacher knowledge to shape PSTs' understandings of how to create inclusive MD spaces that value diverse ways of communicating mathematical ideas.

Methodology

Study Context and Participants

The pilot study is situated in a mathematics methods course within a satellite campus of a research university in the Southwestern U.S. By the borderland region, the campus serves the majority of the student population who self-identified as Hispanic or Latinx. Many PSTs enrolled are bilingual or bicultural, with many who were binational. The program is a post-bachelor, certificate-based program, and PSTs who are preparing to obtain teaching credentials at early grades must attend this mathematics course over the first year of coursework. Sixteen PSTs participated and granted permission to use their survey results for the purpose of the study.

Mathematical Discourse Session Design

The MD session was designed as an ongoing instructional experience intended to support PSTs' developing beliefs and pedagogical competencies related to facilitating MD. Accordingly, the design of the session was guided by three essential design principles grounded in the study's theoretical framework.

Design Principles

Promoting engaging in learning to facilitate mathematics discourse. Guided by the UDL engagement principle, the researcher designed the MD session to actively engage PSTs through a range of activities intended to promote motivation and interest. These activities included multiple ways of presenting mathematical ideas, such as the use of manipulatives and technological tools, as well as collaborative learning opportunities.

Infuse preservice teachers' mathematical knowledge for teaching. The session was designed drawing on Ball et al.'s (2008) framework of MKT, which emphasizes the mathematical knowledge, skills, and sensibilities required to enact effective mathematics instruction. Guided by this framework, the session was organized around the question: What does a PST need to know in order to support students' learning of mathematics, particularly through facilitating mathematical discourse?

Space for practice and reflection. The session was intentionally designed to provide PSTs with structured opportunities for both practice and reflection. PSTs were encouraged to reflect on their learning experiences and examine how the session influenced their beliefs and perceptions of their roles as facilitators of mathematical discourse. Such intentional structured support is critical, as research suggests that without guided opportunities to practice ambitious instructional routines, PSTs often struggle to implement them effectively in classroom settings (Bennett, 2010).

Session Implementation

The MD session was designed as an enriching instructional experience within a mathematics methods course to support PSTs' developing understanding of the importance of MD, their knowledge of pedagogical strategies, and their ability to design discourse-rich instructional activities. The implementation was organized into the following three phases.

Phase one: Establishing rationale for facilitating mathematical discourse. The first phase of the session focused on helping PSTs understand why MD is essential in elementary

mathematics classrooms. PSTs were invited to reflect on their own experiences with MD through structured prompts, positioning discourse as a pedagogical tool for reducing anxiety, increasing participation, and supporting students in expressing mathematical thinking.

Phase two: Engaging pedagogies that support mathematical discourse. The second phase represented the core of the session, during which PSTs engaged as learners in a range of pedagogical strategies designed to support meaningful MD. Multiple examples were presented and discussed across grade levels and content domains.

After engaging with pedagogical strategies for engaging students in MD, PSTs were asked to shift their attention to their roles as facilitators. This portion of the session foregrounded professional noticing of students' mathematical thinking (Jacobs et al., 2010), the use of discourse moves to interpret, and respond to student ideas (Chapin et al., 2009; Herbel-Eisenmann et al., 2013), and emphasizing on teachers' roles (Walshaw & Anthony, 2008).

After session phase: Practicing and designing mathematical discourse activities. The following phase provided PSTs with structured opportunities to design and practice facilitating their own discourse-focused instructional activities. These practice-based experiences supported PSTs in developing deeper insights into how to design and facilitate meaningful MD activities.

Instruments

The researchers developed pre- and post-survey instruments, informed by the MKT framework (Ball et al., 2008). The pre-survey consisted of 23 Likert-scale items designed to measure PSTs' competency and confidence related to facilitating mathematical discourse (e.g., revoicing, pressing for justification, anticipating student strategies, and responding to student thinking). Demographic items and questions related to prior experience were also included to provide contextual background for interpreting results. Additionally, the instrument drew on studies related to professional noticing (Jacobs et al., 2010) and research on discourse moves in mathematics classrooms (Chapin et al., 2009; Herbel- Eisenmann et al., 2013) and teachers' role (Walshaw & Anthony, 2008).

The post-survey consisted of 18 items, of which 16 multiple-choices items mirrored the pre-survey structure with two additional open-ended questions designed to gather PSTs' reflections on their experiences in the session and their evolving beliefs about their roles as teachers during discourse-oriented mathematical interactions.

The pre-survey was administered prior to implementation of the session, and the post-survey was administered following completion of the three-phase instructional session to examine shifts in PSTs' perceived competencies and beliefs. Among the 16 collected surveys, fifteen surveys were valid in supporting the initial findings presented in this study.

Data Analysis

Data sources for this pilot study included pre- and post-survey responses and PSTs' curriculum artifacts (i.e., designed mathematical discourse activities). The present study focuses on initial findings from the survey data, supplemented by descriptive narrative from artifacts and feedback of the session.

Survey data were analyzed using descriptive statistics to examine shifts in PSTs' self-reported competencies related to facilitating MD. Likert-scale responses were converted to numerical values, and item-level and overall means were calculated for both pre- and post-survey responses. Mean differences were computed to identify areas of growth across discourse-related competencies. Given the exploratory nature of this pilot implementation and the small sample size, the analysis emphasizes descriptive trends rather than inferential statistical claims. In addition to the quantitative analysis, responses to the two open-ended questions were reviewed

and analyzed using thematic analysis (Braun & Clarke, 2006). The research team generated themes capturing how PSTs articulated their understanding of discourse practices and how they considered the session shaped their emerging identities as facilitators of MD.

Initial Findings

The research team analyzed 15 valid survey results. Descriptive analysis of pre- and post-survey data revealed consistent growth across all discourse-related competencies. The overall mean increased from 3.40 to 4.27 on a five-point Likert scale, indicating a substantial shift toward agreement with statements describing competence in facilitating mathematical discourse. The largest increases were observed in items related to revoicing student ideas (+1.15), noticing mathematical thinking during discussion (+1.09), supporting students in revising their reasoning (+1.08), and facilitating peer restating (+1.08). These competencies align closely with professional noticing (Jacobs et al., 2010), implementing discourse moves (Herbel-Eisenmann et al., 2013) and core components of MKT (Ball et al., 2008), particularly teachers' ability to interpret and respond to students' thinking. While findings are exploratory due to the small sample size, the consistent upward trends suggest that structured engagement and reflection within the session may support PSTs' developing competence in facilitating meaningful MD.

Qualitative analysis revealed three emerging themes. First, PSTs described moving from viewing mathematical discourse as teacher-led explanation to understanding it as a student-centered sense-making routine. Many articulated a clearer conception of their role as facilitators who elicit, connect, and build on students' strategies. As one PST, Grace (pseudonym), noted, "Mathematical discourse isn't about getting students to talk more, it's about getting them to reveal the structures, assumptions, and strategies behind their thinking. When students articulate how they know, not just what they know." Second, responses reflected increased awareness of specific discourse moves, such as 3Rs (rephrasing, restating, and reasoning), suggesting that PSTs began to conceptualize discourse facilitation as intentional, skill-based pedagogical practice. Third, several PSTs emphasized the importance of anticipating multiple student strategies and responding productively to unexpected thinking. Together, these qualitative themes complement the quantitative findings and indicate conceptual growth in how PSTs understand and enact discourse-oriented mathematics instruction.

Discussion and Implications

The findings from this pilot study suggest that structured engagement with MD can support PSTs' developing pedagogical competencies and overall understanding of their roles as facilitators of MD. The consistent quantitative growth across all survey items indicates that discourse facilitation can be decomposed, practiced, and meaningfully developed within mathematics methods courses. The qualitative findings further suggest that growth extended beyond increased confidence to include shifts in how PSTs conceptualized MD.

For mathematics teacher educators, this study highlights the value of explicitly integrating discourse-focused design principles into mathematics methods coursework. Rather than assuming PSTs will "pick up" discourse practices through observation alone, the coherence between quantitative trends and qualitative themes provides preliminary evidence that discourse facilitation is a developable aspect of PSTs preparation. Future iterations of this work will further examine how these developing competencies translate into enacted classroom practice and how sustained engagement with discourse-oriented instruction shapes PSTs' professional identities over time.

FROM PROCEDURES TO RELATIONAL UNDERSTANDING: SHIFTS IN PRESERVICE TEACHERS' CONCEPTUALIZATIONS OF FRACTION DIVISION

Stacey C. Zimmerman
Western Carolina University
szimmerman@wcu.edu

Bima Sapkota
University of Kentucky
bsapkota@uky.edu

Preservice Teachers (PSTs) need more opportunities to develop a conceptual understanding of fraction division. This exploratory study examined shifts in PSTs' fraction division definitions and contextual representations following sequenced instructions designed to support conceptual understanding. Eighteen PSTs completed pre- and post-assessments requiring written definitions and constructed word problems. We found movement from procedural and partitive descriptions toward relational, measurement-oriented definitions. However, conceptual shifts did not always translate into PSTs' word problems as they negotiated units and relationships for non-unit fractions. These findings suggest conceptual growth and representational fluency may develop unevenly and underscore the importance of intentional task sequencing and attention to multiple meanings of division in mathematics teacher education.

Keywords: Rational Numbers, Mathematical Representations, Preservice Teacher Education

Framework, Objectives, and Research Questions

Prior research has documented challenges in conceptualizing fraction division (Bowen, 2021; Copur-Gencturk, 2021), highlighting difficulties in representing fraction division through clear verbal descriptions (Lo & Luo, 2012). One area of challenge for preservice teachers (PSTs) is the concept of unitizing (i.e., considering a set of singleton units as a new unit) (Lo & Luo, 2012). Similarly, Copur-Gencturk (2021) found that even in-service teachers struggle to explain how visuals and real-world examples connect to the concept of fraction division. To address these challenges, researchers have explored how pictorial representations and hands-on activities support Preservice Teachers (PSTs) in developing conceptual understanding. For instance, Sahin et al. (2020) reported that instruction emphasizing pictorial modeling strategies positively influenced PSTs' understanding, specifically improving both accuracy and labeling. Arnal-Bailera and Arnal-Palacián (2023) found that PSTs often relied on manipulatives solely for visual support without creating meaningful contexts. They also noted that PSTs need more opportunities to learn how to appropriately select and interpret manipulatives.

Collectively, these studies highlight the potential of visual representations and the need to extend instructional time for fraction division. However, given the already rigorous and tightly structured nature of teacher preparation programs, it may not be practical to require PSTs to take additional mathematics content courses (Garner et al., 2024). Given this context, we became interested in exploring whether one intentionally designed day of instruction involving hands-on activities and contextual tasks could make a meaningful difference in supporting PSTs' understanding of fraction division. We contribute to the body of work on fraction division by exploring how specific instructional design choices can help to shift PSTs' use of algorithmic procedures toward conceptual fluency. We asked the following three research questions: (1) How did PSTs' definitions of fraction division shift after instruction? (2) How did PSTs' word problems reflect alignment with the intended symbolic division structure? (3) How did numeric complexity (unit vs. non-unit fraction divisors) influence representational coherence?

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

Methods

This exploratory study involved 18 elementary and middle grades PSTs enrolled in a mathematics content course emphasizing sense-making through number theory, operations, fractions, and proportional reasoning at a southeastern regional public university. As part of the study, PSTs engaged in contextual, hands-on tasks focused on fraction division. We collected data from the pre- and post-assessments that we administered prior to and after the instruction. In those tests, we asked PSTs to explain the meaning of fraction division, write story problems for given fraction division statements, and create visual representations for given problems. In this study, we used only their definitions of fraction division and story problems as data.

We first used an inductive coding method (Saldaña, 2016), identifying patterns across all PSTs' fraction division definitions and story problems. Based on those patterns and the memos created during inductive coding, we developed separate rubrics for coding fraction definitions and story problems (Table 1). Each researcher used the rubric to code the data and then met to resolve discrepancies. Afterward, we examined differences between the pre- and post-tests to identify any shifts in PSTs' definitions and story problems, reported in the findings section.

Table 1: Coding Rubrics

Fraction Definitions	Fraction Story Problems
Missing / Irrelevant: Response is missing or does not address the task	**Not Interpretable:** Missing, incomplete, or cannot be mapped to any clear operation
Partitioning / Non-Operational: Fractions are described as "split," "cut," or "broken." Focus on parts, not division as an operation. No relationship between the two fractions	**Non-Division Context:** Fractions present, but models a different operation (e.g., addition, subtraction, multiplication, or sharing the wrong quantity)
Procedural / Operation-Aware: References division rules or algorithms (e.g., "divide," "keep-change-flip"). Shows awareness of a process. Limited connection to units or meaning	**Ambiguous Division:** Division suggested, but divisor/dividend roles unclear, units confused, or the structure does not accurately represent the problem
Conceptual / Measurement. Describes division as "how many times one fraction fits into another." Uses unit iteration, grouping, or comparison. Relational reasoning connects the dividend and the divisor.	**Explicit Fraction Division:** Clearly and coherently models the problem (measurement or partitive interpretation)

Findings

Findings are organized by the three research questions. We first report shifts in PSTs' definitions of fraction division, followed by analysis of their constructed word problems and how numeric complexity impacted their ability to generate coherent problem context.

RQ1: How did PSTs' Definitions of Fraction Division Shift After Instruction?

To examine shifts in PSTs' conceptualizations of fraction division, we categorized written definitions into four themes: Missing/Irrelevant, Partitioning/Non-Operational,

Procedural/Operation-Aware, and Conceptual/Measurement (Relational). These categories reflect increasing alignment with a measurement interpretation of division. Table 2 displays the distribution of responses across categories for pre- and post-assessments. Pre-assessment definitions frequently reflected partitioning or procedural interpretations of fraction division. Many participants described fractions as being "cut" or "split" without attending to the relational structure of division or referenced algorithms (e.g., "keep-change-flip"). Following the instructional session, a clear shift toward relational and measurement-based definitions was observed. For example, one participant initially defined fraction division as "involves keeping the first one the same, changing the sign to multiplication and flipping the second fraction," but later described it as "how many times one fraction can fit into the other," explicitly framing division as measurement. Post-assessment responses more frequently described fraction division as determining "how many times one fraction fits into another," emphasizing unit iteration, grouping, or comparison (see Table 2).

Table 2: Distribution of PST Definitions of Fraction Division (Pre/Post)

Definition Category	Pre (%)	Post (%)
Missing/Irrelevant	0%	0%
Partitioning/Non-Operational	50%	27%
Procedural/Operation-Aware	33%	17%
Conceptual/Measurement (Relational)	17%	56%
(n = 18 PSTs)		

Participants increasingly coordinated the dividend and divisor as quantities rather than relying solely on procedural language. While not all participants demonstrated fully relational reasoning, the overall distribution of responses reflected meaningful movement away from algorithmic descriptions and toward measurement interpretations. These findings suggest that the instructional sequence supported growth in conceptualizing fraction division.

RQ 2: How did PSTs' Word Problems Reflect Alignment with the Intended Symbolic Division Structure?

Although conceptual definitions shifted toward measurement interpretations, word-problem construction revealed greater variability. Pre-assessment word problems frequently modeled operations other than division despite including examples. For example, one PST wrote, "Malory has 3/4 of her book left while Caleb has 2/3. who is further along?", framing the situation as a comparison rather than a division structure. Similarly, another pre-word problem asked "I ate 3/4 of my pizza. Later I ate 2/3 of what was left. How much of the total pizza did I eat?," modeling sequential subtraction/multiplication rather than division. In some cases, division was implied but roles of the dividend and divisor were unclear, or units were not coherently coordinated.

Post-assessment responses demonstrated improved alignment for the simpler division expression (e.g., ⅓ ÷⅙). Many participants constructed measurement-based contexts that explicitly asked how many fractional units fit into a given quantity. For instance, one PST wrote, "Emma has 1/3 of a candy bar. She breaks it into small pieces. Each piece is 1/6 of a candy bar. How many small pieces did Emma make?," clearly modeling division as unit iteration. Another asked, "Joe has 1/3 yard of string. How many 1/6 yard pieces can he cut?," maintaining consistent units and coordinating the dividend and divisor appropriately.

However, alignment was less consistent when PSTs modeled division involving non-unit

fractions (¾ ÷ ⅔). These responses often reflected ambiguity in coordinating units or reverted to subtraction or comparison contexts. For example, one post-word problem asked, "We have 3/4 of a cake and Lizze wants 2/3 how much cake is left?," shifting the task toward subtraction. Another wrote, "Lily has 3/4 of chocolate and she wants to share with her friends. She gives them 2/3 each," without clarifying the referent unit or how the quantities relate structurally.

These results indicate that while participants' conceptual definitions improved, translating that understanding into coherent contextual representations required additional coordination of quantities and units. Specifically, representational coherence weakened when both the dividend and divisor were non-unit fractions, making it more difficult for students to maintain a clear problem context. To examine this pattern more closely, we compared participants' representations across the two division tasks, which differed in numeric complexity.

RQ3: How Did Numeric Complexity Influence Representational Coherence?

Taken together, these findings suggest that conceptual growth and representational fluency may develop unevenly, particularly as the symbolic demands of fraction division increase. To examine this pattern more closely, we compared participants' representations across the two division tasks, which differed in numeric complexity. A comparison suggests that increased numeric complexity amplified representational challenges. When the divisor was a unit fraction (e.g., ⅓ ÷ ⅙), participants more readily constructed measurement-based word problems that aligned with the symbolic expression. In contrast, when both the dividend and divisor were non-unit fractions (e.g., ¾ ÷ ⅔), responses displayed greater variability and misalignment.

This pattern suggests that coordinating two non-unit fractional quantities requires more sophisticated unit reasoning. Participants appeared to struggle with maintaining consistent referent units and clarifying which quantity was being measured by which. For example, one PST wrote, "She gives them 2/3 each," without specifying the referent unit or how the 3/4 quantity structured the situation, illustrating ambiguity in coordinating dividend and divisor roles. Even when relational definitions were articulated elsewhere in the assessment, representational coherence was less stable under increased numeric complexity.

Discussion and Implications

The shifts observed in PSTs' fraction definitions and visual representations suggest that how instructional tasks are sequenced and connected can influence PSTs' understanding of fraction division, even within a single, intentionally designed day of instruction. Further, our findings reinforce prior research indicating that brief interventions are insufficient for addressing some challenges associated with fraction division (Bowen, 2021; Copur-Gencturk, 2021). In our study, PSTs did not always translate conceptual definitions of fraction division into word problems, particularly in non-unit by non-unit fractions. When both fractions were non-unit, PSTs frequently attended to the numerator and denominator as separate numbers rather than reasoning about the relational structure of the division situation. PSTs' challenges with word-problem construction were also tied to interpreting the divisor in terms of the number of groups rather than the size of the unit (i.e., treating 2/3 as a count of people). Consistent with prior studies (e.g., Lo & Luo, 2012), these findings highlight the central role of unit and unitizing in fraction division and suggest that instructional approaches in teacher preparation should foreground these ideas. Moreover, these findings point to several implications for mathematics teacher education. Explicit attention to multiple meanings of division, including measurement and partitive interpretations, potentially supports PSTs' conceptual development. In addition, our results suggest that the fractions used in instructional tasks matter, and that intentional sequencing—from unit-by-unit to non-unit by non-unit fraction division—may support PSTs' ability to

coordinate units and relationships. Finally, facing these challenges firsthand offers PSTs a valuable learning opportunity, fostering intentionality and empathy in teaching fractions.

AGENCY, AUTONOMY, AND ADAPTABILITY: TENSIONS IN THE TRANSITION TO NOVICE TEACHER

Meredith Beggs
Univ. of Central Missouri
mbeggs@ucmo.edu

Michael Lawson
Kansas State University
mlawson1@ksu.edu

Sherri L. Martinie
Kansas State University
martinie@ksu.edu

Keywords: Identity and Agency; Cognition; Affect, Emotion, Beliefs, and Attitudes

Adaptability is a foundational professional disposition in math teaching. Teachers interpret situations (cognitive), regulate emotions (affective), and enact instructional decisions (behavioral) in real time and across personal, student, curricular, and contextual factors. Although frequently cited as a desirable (Collie & Martin, 2017), adaptability is often described as "flexibility" rather than coordinated cognitive, affective, and behavioral functioning. The *Tripartite Model of Adaptability* (Martin et al., 2013; Collie & Martin, 2016) conceptualizes adaptability as the integration of these domains, providing a lens for examining how teachers navigate professional challenges. Special attention must be paid to the transition from school-to-career (e.g., Akkermans et al., 2013; Savickas, 2005) which represents a time when adaptability becomes consequential. For novices, this transition is not merely about managing workload but about learning to act professionally within instructional constraints. In this transition, questions of autonomy (i.e., perceived freedom to act) and agency (i.e., intentional action within constraints) become central to how adaptability is experienced and enacted. Accordingly we ask: *How is adaptability described and experienced by novice secondary mathematics teachers?*

This qualitative study draws on semi-structured interviews from three novice secondary mathematics teachers following their first year of teaching. Participants, all NOYCE scholars, represented three early-career educators responding to the demands of new school settings and shifting role expectations. Analytic and reflexive memoing were also used as sources of data (Paulus et al., 2014). Analysis was iterative and theory-informed. Initial coding identified moments of cognitive, affective, and behavioral adaptability. Secondary coding examined how perceptions of autonomy and enactments of agency shaped these adaptive responses.

Findings indicate that increased autonomy in the first year does not automatically strengthen adaptability. When teachers were granted greater agency, tensions emerged: Affective tension in emotionally charged decision-making; Cognitive conflict in moral and professional dilemmas and behavioral risk-taking when considering deviations from department norms or mandated curriculum. Adaptability appeared uneven when autonomy and agency were misaligned. High autonomy paired with low confidence limited behavioral enactment of adaptability, while strong agency paired with a constrained environment heightened stress and an increased moral/ethical reasoning. When autonomy and agency were more aligned, greater coherence emerged across cognitive reframing, emotional regulation, and instructional action. The first year represents a critical, emotionally charged period in which autonomy and agency shape adaptability as decisions carry real consequences.

Induction programs must intentionally support PSTs to transition from student teaching to full professional responsibility. Support should focus on building agency in teachers through reflective decision making, addressing emotional and moral dilemmas that may emerge, and positioning the teacher as an authority of experience. Without this support, novice teachers may not exercise agency in an attempt to limit risk taking, emotional overload, or moral tensions, leading to less innovative teaching.

ENHANCING PRE-SERVICE TEACHERS' TPACK THROUGH DYNAMIC GEOMETRY INSTRUCTION: A QUASI-EXPERIMENTAL STUDY

Keywords: TPACK, Dynamic Geometry, GeoGebra, Preservice Teachers

Technology integration in mathematics education involves more than technology proficiency; it involves a well-integrated knowledge of content, pedagogy, and technology. In geometry, visualization and transformation-based reasoning play a crucial role. Although dynamic geometry environments provide many opportunities for exploring invariance and relational properties through manipulation, teacher preparation programs for pre-service teachers have often focused on technical skills rather than on integrated technological pedagogical content knowledge (TPACK).

The National Council of Teachers of Mathematics (NCTM, 2000) identifies technology as essential to the teaching and learning of mathematics, noting its influence on both the mathematics that is taught and how students develop understanding. Drew Polly (2014) emphasizes the integration of technology at the elementary level, noting its positive impact on teaching and learning by supporting students' exploration of tasks, enabling the construction of dynamic mathematical models, and facilitating the modelling of mathematical situations. Geometry is a fundamental component of mathematics education that supports the development of students' logical thinking, visual imagery, and spatial reasoning skills, as emphasized by Battista (2007).

This study is grounded in the Technological Pedagogical Content Knowledge (TPACK) framework (Mishra & Koehler, 2006). The framework conceptualizes teacher knowledge as an interaction among Technological Knowledge (TK), Technological Content Knowledge (TCK), Technological Pedagogical Knowledge (TPK), and Technological Pedagogical and Content Knowledge (TPACK). A quasi-experiment with a pretest and posttest design was employed to compare two classes of an elementary mathematics methods course, which were randomly assigned to treatment (GeoGebra-based teaching) and control (traditional teaching) groups. The data were collected through a modified TPACK survey (TPACK Survey; Schmidt et al., 2009), which was used to measure students' TK, TCK, TPK and TPACK. This tool was modified to fit the specific needs of this study in terms of teaching rotations and reflections with the use of GeoGebra software.

Data were gathered using the five-point Likert scale, and composite scores were generated for each domain. A total of 96 survey responses (25 control pre, 21 control post, 28 treatment pre, and 22 treatment post) were used in the TPACK analyses. The geometry assessment test was in the form of a researcher-made pre-test and post-test on conceptual and procedural knowledge regarding rotation and reflection on a coordinate plane. The two-way ANOVA analysis showed significant Group × Time interaction effects for all TPACK components.

Additionally, the results showed that there were significantly greater gains in geometry concept learning in the treatment group. The results also indicated that dynamic geometry instruction facilitates both integrated TPACK development and geometry achievement. The results imply that teacher educational institutions need to design learning activities where pre-service teachers will be able to utilize technology to support student learning and success.

Pennsylvania House Bill 1407 represents a significant shift in the Commonwealth's approach to teacher credentialing, moving away from specialized grade spans toward a broader, binary model. Currently, Pennsylvania's three-tier system (Pre-K–4, 4–8, and 7–12) aligns with the Association of Mathematics Teacher Educators (AMTE) position that middle-level learners possess unique developmental and academic needs requiring specialized educator preparation (Hale, 2020). HB1407 proposes a consolidation into two categories: "Primary" (Pre-K–6) and "Secondary" (7–12). While the bill's sponsors argue that this change will mitigate the teacher shortage by increasing "placement flexibility" for administrators (Nelson, 2025), this shift effectively reclassifies fifth and sixth grades as elementary, potentially disregarding the specialized pedagogical content knowledge historically required for these bridge years.

To investigate the potential unintended consequences of this legislation, our research team (composed primarily of pre-service elementary and middle-level educators) conducted a stakeholder perception study. We surveyed four distinct groups (n = 70): pre-service teachers, practicing in-service teachers, school administrators, and teacher educators. By capturing a cross-section of the educational community, we sought to determine how the proposed expansion of the "primary" certification span would influence instructional quality, teacher self-efficacy, and institutional operations.

The data revealed a stark divergence in priorities between those in the classroom and those in administrative roles. Respondents who opposed the bill—predominantly pre-service and in-service teachers—expressed recurring concerns regarding a deficit in deep content knowledge for upper-elementary grades. Conversely, administrators were less likely to focus on pedagogical specialization, prioritizing the logistical benefit of staffing flexibility. Notably, our study uncovered an unanticipated impact on the research team itself; pre-service teachers pursuing Pre-K–4 certification reported significant apprehension regarding their interest and readiness to teach fifth and sixth-grade mathematics curricula. The results suggests that while HB1407 may resolve the quantity of available teachers, it may inadvertently compromise the quality of instruction and teacher retention due to a lack of specialized preparation for the middle-level learner.

PRESERVICE TEACHERS' GROWTH THROUGH DEVELOPMENTALLY SEQUENCED MICROTEACHING

Jung Colen
Bellarmine University
jcolen@bellarmine.edu

Yong S. Colen
Indiana University of Pennsylvania
yscolen@iup.edu

Keywords: Elementary School Education, Instructional Activities and Practices, Learning Trajectories and Progressions, Preservice Teacher Education

This study examines the perceived self-growth of preservice teachers (PSTs) when experiencing two developmentally sequenced microteachings. While prior studies found the value of repeated microteaching opportunities to develop instructional skills and reflective practice (Amobi, 2005; Fernández, 2010; Remesh, 2013), our study addresses a gap by shifting the focus from the frequency of microteaching to the intentional, developmental, sequential experiences that conceptualize learning (Grossman et al., 2009; Zeichner, 2010).

The study's theoretical framework affirms that microteaching should be conceptualized as a developmentally scaffolded learning trajectory (Daro et al., 2011). This belief aligns with the developmental differences in elementary school mathematics instruction (Clements & Sarama, 2014; National Research Council, 2001; Van de Walle et al., 2019). We hypothesized that sequencing microteaching for developmental progression would support PSTs to gain a deeper understanding of teaching mathematics and to improve their confidence in teaching.

We employed a qualitative study with 12 elementary PSTs enrolled in a mathematics methods course at a midwest university. The new assignments involved two sequenced microteachings: a co-taught, concrete, K-3 mathematics lesson in mid-semester, followed by an independent, abstract, 3-6 mathematics lesson towards the end of the semester. We collected written reflective narratives from the PSTs and analyzed their preparation, facilitation, reflection, and perceived growth. In particular, we employed a thematic analysis in which we identified PSTs' perceived benefits to intentional, developmental, sequential experiences.

The key themes that emerged were: (1) developmental sequencing supported growth in confidence, (2) teaching across the grade bands deepened pedagogical content knowledge, (3) noticeable shifts occurred from procedural to conceptual instruction, (4) purposefully used manipulatives and hands-on activities, and (5) demonstrated collaboration and instructional ownership. The poster will display PSTs' in-depth reflections and excerpts on each theme.

The findings suggest developmental, sequential experiences enhanced PSTs' preparation for the complex elementary school mathematics teaching. Progressing from a co-taught, concrete lesson to an independent, abstract lesson functioned as a scaffolded professional learning experience that fostered instructional precision, conceptual growth, and professional identity development. Finally, rather than relying solely on observable teaching behaviors, our study highlights the importance of centering PSTs' reflection as a key measure of teacher growth.

Keywords: Teacher Beliefs, Preservice Teacher Education

Inquiry-based instruction has long been a cornerstone of science (Crawford, 2014) and mathematics education reform (Cribbs et al., 2020) because it improves student learning, retention, and engagement (Crippen & Archambault, 2012; Minner et al., 2010). By emphasizing exploration and problem solving over memorization, inquiry-based approaches foster deeper conceptual understanding (Chapman, 2011; Savelsbergh et al., 2016). However, implementation remains challenging due to limited teacher preparation, misconceptions about inquiry, and practical constraints such as time and testing demands (Chin & Lin, 2013; Welch et al., 1981).

Guided by conceptual change theory (Posner et al., 1982), this study examines how pre-service teachers' (PSTs) perceptions of inquiry-based instruction changed after completing the *Inquiry Approaches to Teaching* course. This study asked: How do PSTs' perceptions of inquiry-based learning change after completing the Inquiry Approaches to Teaching course?

Participants were 20 secondary PSTs enrolled in a one-credit introductory inquiry methods course within the UTeach teacher preparation program. The course introduced inquiry-based instruction through modeling, practice, and the implementation of three inquiry-based lessons. Data was collected over one semester through online discussion posts completed before and after field experiences. PSTs responded to two prompts comparing inquiry-based and traditional instruction and describing the benefits of inquiry-based teaching. Researchers conducted iterative in vivo coding (Saldaña, 2021) using MaxQDA, collaboratively refining codes into themes through consensus.

Three primary themes emerged when examining traditional and inquiry-based teaching: (1) *Role of the Teacher*. PSTs initially described traditional instruction as teacher-centered, lecture-based, and focused on knowledge transmission. Later, they characterized inquiry-based teaching as facilitative, with teachers guiding exploration, using questioning and formative assessment, and fostering student engagement. (2) *Role of the Student.* Traditional instruction was viewed as emphasizing passive learning, note-taking, and limited collaboration. In contrast, inquiry-based learning positioned students as active participants who explored ideas, collaborated with peers, solved problems, and assumed greater ownership of learning. (3) *Role of the Learning Environment.* PSTs described traditional classrooms as fast-paced, focused on memorization, and offering few opportunities for critical thinking. Inquiry-based environments, although perceived as requiring more time and planning, were viewed as promoting hands-on learning, productive use of errors, deeper conceptual understanding, and authentic problem solving.

The findings are significant for secondary mathematics and science teacher preparation, where positive attitudes toward inquiry have historically been less prevalent than among elementary educators (Marshall et al., 2009). Early exposure to inquiry-based teaching may strengthen PSTs' confidence and willingness to implement inquiry as practicing teachers. Additionally, because much of the existing literature focuses on science education (Chinn et al., 2013; Choi & Ramsey, 2009; Fitzgerald et al., 2019; Windschitl & Thompson, 2006), this study extends the evidence base by demonstrating similar benefits for mathematics PSTs.

Keywords: Preservice Teacher Education, Teacher Knowledge, Teacher Beliefs

For decades inquiry-based teaching has been well regarded in the mathematics education community because it has been found to enhance student learning, engagement, and retention (Crippen & Archambault, 2012; National Council of Teachers of Mathematics, 1991). Despite these benefits, few teachers implement inquiry-based teaching in their classrooms (Cribbs et al., 2020; Rönnebeck et al., 2016; Wang, 2020). One reason may be because preservice teachers (PSTs) frequently conflate inquiry-based instruction with other student-centered practices—such as active learning or collaborative work (Goldberg & Darwin, 2025). PSTs tend to ignore the epistemic and instructional features that distinguish inquiry from other pedagogical approaches (see also Kuster et al., 2019). Although researchers examined teachers' beliefs about and use of inquiry (Marshall et al., 2009) or assessed student preferences for either student- or teacher-centered instruction (Cooper et al., 2017), we still need to unpack how PSTs conceptualize inquiry-based instruction to understand if those understandings align or misalign from theoretically grounded definitions. Having a robust understanding of how PSTs conceptually understand inquiry-based instruction can enable teacher preparation programs to identify persistent misconceptions and design methods coursework that support inquiry-oriented instruction.

Considering this, our research team outlines the development of a survey designed to assess PSTs' understanding of inquiry-based instruction as guided based on a theoretically articulated framework, substantiated and refined through empirical evidence. We define inquiry-based teaching as "instruction [that] has *students* construct knowledge by discovering and interpreting information and findings for themselves" (Goldberg & Darwin, 2025, p. 4). Mathematical inquiry is further delineated as using logical reasoning, conjectures, evaluation, and exploration to determine the validity of mathematical concepts (Chinn & Clark, 2013).

In our prior work, we have published on how PSTs consider inquiry-based instruction in relation to other commonly invoked pedagogical approaches (Goldberg & Darwin, 2025). This framework allowed us to capture what literature talks about key instructional roles of involved stakeholders in the learning process, epistemic instructional goals, and classroom dynamics that characterize inquiry-based teaching. We are also leaning onto the empirical findings as informed by qualitative data drawn from seven cohorts of secondary PSTs enrolled in teacher preparation program. This study will examine data from PSTs in an introductory inquiry-based methods course (n = 155) on how they define and contextualize inquiry-based teaching after being exposed to inquiry-based instruction throughout the course. Having PSTs reflects on the idea of inquiry-based instruction highlights not only what PSTs emphasize when reasoning about inquiry, but also what is routinely absent from their explanations or how their thinking may be conflated with other pedagogical strategies.

By leveraging a theoretically articulated framework accompanied with rich empirical evidence of PST thinking, the larger goal of this project is to develop a survey instrument that

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

captures how PSTs understand inquiry-based instruction, rather than whether they simply endorse it. Such work will support research and teacher education efforts that attend to conceptual change in PSTs' understanding about inquiry. At the session, we will share the conceptual grounding, empirical motivation, and design logic guiding this survey development, and invite feedback from the community on advancing measurement work related to inquiry-based mathematics instruction.

Keywords: Equity, Inclusion, and Diversity; Preservice Teacher Education; Teacher Noticing

A central focus in mathematics teacher education is to support the varied needs of students and their communities and thoughtfully engage with issues of justice and equity (AMTE, 2017). Teacher preparation programs have an opportunity—and obligation—to prepare pre-service teachers (PSTs) to deeply consider such issues in their teaching even before they have their own classrooms. One approach we explore for doing so is the use of teaching cases, or written narratives that depict authentic, complex teaching dilemmas and require PSTs to think critically (Shulman, 1992). Such cases can support PST reflection and offer insight into PST beliefs (e.g., Abell et al., 1998; Grossman, 1992). In our research, in-service teachers design teaching cases based on their own experiences related to enacting culturally grounded pedagogy in mathematics (Dobie et al., 2024), conceptualized as (a) leveraging students' multiple competencies, (b) honoring students' lived experiences, (c) challenging status and power hierarchies, and (d) diversifying curriculum and challenging dominant perspectives (e.g., Aguirre et al., 2013; Ladson-Billings, 2014; Paris, 2012). We add the lens of teacher noticing (e.g., Sherin et al., 2011), with attention to noticing for equity (e.g., van Es et al. 2022), to investigate how cases can support PSTs to *notice* classroom, school, or societal inequities as well as student strengths; consider a range of *interpretations* for what they are noticing; and suggest possible *solutions*. In this study we ask, "How can teaching cases depicting issues related to enacting culturally grounded pedagogy in mathematics support PSTs' developing skills in noticing for equity?"

Seven cases (focused on issues such as inequitable group dynamics, assumptions about the abilities of multilingual students, and disparities in access to math between districts) were implemented 1–5 times each in math methods courses for future elementary teachers. Implementation entailed PSTs writing individual responses to case prompts, discussing the case in small groups and then as a whole class, and completing an exit ticket about their experience. Here we highlight the analysis of one case focused on inequitable group dynamics that was implemented three times. Data include written responses to three case prompts from 63 PSTs. A three-part coding scheme was designed inductively and deductively (Miles et al., 2014) to capture the details PSTs *noticed* from the case; the *interpretations* offered that aligned with the themes of culturally grounded pedagogy; and the *solutions* proposed to resolve the dilemma. Two coders coded all responses and resolved any disagreements. Findings highlight PSTs' attention to details about students and their actions; the potential for varied interpretations, alongside PSTs' tendency to consider the role of personality more than factors such as race, gender, and language; and the varied solutions offered when PSTs were prompted to consider several possible action steps. PST responses to cases offer insights into their noticing and space for teacher educators to further develop that noticing in a constrained situation on the path to building skills for noticing in more complex videos and classroom observations.

VARIATION IN MENTOR TEACHER–TEACHER CANDIDATE CO-NOTICING ACROSS PLANNING, HUDDLES, AND DEBRIEFS

Manqing Gao
Portland State University
manqgao@pdx.edu

Torrey Kulow
Portland State University
kulow@pdx.edu

Keywords: Instructional Activities and Practices, Preservice Teacher Education, Teacher Educators, Teacher Noticing

Purpose of the Study and Theoretical Framework

Professional noticing research has largely examined teachers' attention to students' mathematical thinking during instruction (Jacobs et al., 2010). Teacher education structures practice across planning, enactment, and debrief, yet we know little about how noticing reorganizes across the three phases or how temporal conditions shape attending, interpreting, and decision-making. This study examines variation in mentor teacher and teacher candidates' attending to, interpreting, and deciding about student participation when engaging in anticipatory noticing, in-the-moment noticing, and retrospective noticing (van Es & Sherin, 2008; 2010) within the Asset-Focused Co-Noticing Tool I (ACT I). Drawing on van Es and Sherin (2008; 2010), we conceptualize noticing as a phase-sensitive. Anticipatory noticing involves projecting possible student participation prior to instruction. In-the-moment noticing involves attending to and interpreting participation during enactment while making immediate instructional decisions. Retrospective noticing involves reflecting on participation and instructional moves to inform future action. The research question is: What differences emerge in how dyads attend, interpret and respond when engaging in anticipatory, in-the-moment, and retrospective noticing while using ACT I?

Methods

Participants were two MT–TC dyads in a secondary mathematics licensure program in the Pacific Northwest during Fall 2023. Data included video recordings of planning and debrief, audio recordings of huddles, and tool artifacts. we analyze their first and second uses of ACT I. We use Jacobs et al.'s (2010) AIR framework as the coding lens for all three phases. Transcripts were segmented by phase and coded with the AIR framework: attending codes captured which aspects of student participation and mathematical work were foregrounded; interpreting codes captured how participation was explained; and responding codes distinguished short-term and long-term decisions. Cross-phase comparisons examined how anticipatory noticing was confirmed or revised during in-the-moment noticing, and how retrospective noticing reframed participation and instructional decisions.

Findings and Implications

In anticipatory noticing, dyads attended to predicted participation guided by the equity prompt they selected, interpreted that participation tentatively (e.g., who might speak or remain silent), and framed decisions as provisional, revisable hypotheses to be tested during instruction. During in-the-moment noticing, attention shifted to enacted behaviors such as silence, talk, and partner dynamics. Interpretations became immediate and behavior-linked, and decision-making narrowed to short-term tactical adjustments made under time pressure. In retrospective noticing, dyads revisited specific noticed participation moments and expanded interpretations to include

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

interactional structure and task design. Decision-making shifted from tactical to strategic, articulating long-term instructional redesign for future lessons.

This study shows how mentor teacher–teacher candidate co-noticing differs across planning, enactment, and debrief. These differences can help teacher educators design planning, huddle, and debrief structures around what each phase supports.

Palabras clave: Formación inicial de profesores, desarrollo profesional, conocimiento del profesor, mirada profesional

Presentación

Esta investigación tiene como objetivo caracterizar las prácticas de profesores de matemáticas en formación inicial en relación con la mirada profesional sobre el pensamiento matemático del estudiante, al orquestar recursos pedagógicos en discusiones matemáticas.

En este trabajo es posible distinguir tres aproximaciones teóricas: la Mirada Profesional (Jacobs et al., 2010), las Oportunidades Pedagógicas con Significado Matemático para la Construcción del Pensamiento Matemático (MOST) (Leatham et al., 2015). Y la Orquestación Instrumental (Drijvers, 2012; Drijvers, et al., 2010; Trouche, 2004). La primera aproximación permite dar cuenta del análisis de la competencia profesional del profesor con base en cada una de las tres habilidades de la mirada profesional: *identificar, interpretar y responder*. La segunda permite analizar los momentos de enseñanza (MOST) que ponen de manifiesto el pensamiento matemático del estudiante y así mismo ser un instrumento de análisis para el desarrollo de las tres habilidades de la mirada profesional. Y la tercera, la articulación de las dos anteriores cuando se orquestan recursos pedagógicos en discusiones matemáticas.

Metodología

Esta investigación es de estilo cualitativo y se realizó como un estudio de casos múltiple.

Los instrumentos utilizados fueron las videograbaciones como fuente central de análisis y dos entrevistas semiestructuradas, de planificación y de reflexión. El análisis de los datos es de carácter inductivo y se realiza con base en la articulación local de tres aproximaciones teóricas ya mencionadas. El análisis se llevó a cabo en tres fases. La primera fase se ejecuta alrededor del análisis mediante la teoría fundamentada (Teppo, 2015) para dar cuenta de la mirada profesional. En la segunda fase, se identifican momentos MOST con base en el instrumento analítico de esta teoría, se comparan y se clasifican. Y en la tercera fase se establecen articulaciones entre los tipos de orquestación y las respuestas del profesor al pensamiento matemático del estudiante.

Resultados

En esta investigación se obtuvieron tres grupos de resultados: el primer grupo se relacionó con las habilidades de *interpretar* y *responder* a la comprensión de los estudiantes; y el bajo nivel de desarrollo de éstas en los estudios de caso de la investigación. El segundo resultado refiere a la identificación de un número reducido de momentos que cumplen con la estructura analítica MOST. Y el tercer resultado expuso que, como tendencia, el tipo de orquestación *guía y explicación* es el más frecuente en los casos de la investigación.

A THREE-STAGE TEACHING REHEARSAL ARC TO DEVELOP PEDAGOGICAL COMPETENCE IN PRESERVICE TEACHERS

Paula Jakopovic
University of Nebraska at Omaha
paulajakopovic@unomaha.edu

Keywords: Instructional Activities and Practices, Preservice Teacher Education

Elementary preservice teachers (PSTs) are often tasked with teaching mathematics using evidence-based pedagogical practices that are ambitious and include the use of high-quality mathematics tasks promoting discourse and that build conceptual understanding (Association of Mathematics Teacher Educators [AMTE], 2017; National Council of Teachers of Mathematics [NCTM], 2014). However, many elementary teacher preparation programs lack content-specific practica, particularly in mathematics, limiting PSTs' opportunities to rehearse high-leverage teaching practices (Polly et al., 2019). Without scaffolded approximations of practice, PSTs may experience a disconnect between theoretical learning and implementation in classrooms (e.g., Emerson et al., 2018). Providing coherent structures in content-focused methods courses that allow PSTs to engage in iterative planning and teaching rehearsals that are paired with targeted feedback can help them refine their implementation of these evidence-based practices.

This poster offers a framework grounded in practice-based teacher education (PBTE), which conceptualizes teacher learning through structured opportunities to engage in representations, decomposition, and approximations of practice (Grossman et al., 2009). The framework situates learning as iterative, scaffolded for PSTs to progressively assume responsibility for instructional decision making to integrates evidence-based practices in action (Figure 1).

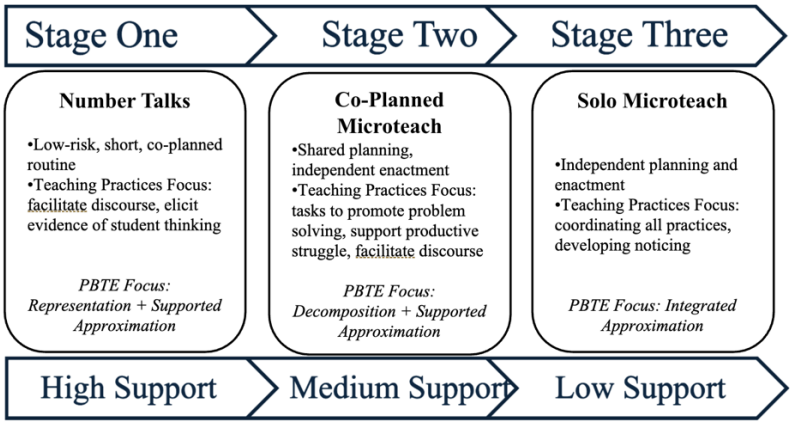

Figure 1: Three-Stage Teaching Rehearsal Arc

Implemented in an elementary math methods course at a Midwestern university, the framework was designed to address the absence of content-specific practica. Each stage of the arc focuses on high-leverage math teaching practices, gradually shifting the cognitive load of planning and implementation from shared practice to solo work. The framework offers a transferrable structure for methods courses where content-specific practica are not available. Embedding progressive rehearsal arcs in methods courses can provide PSTs with systematic opportunities to develop competence through supported approximations of practice.

PRESERVICE AND INSERVICE TEACHERS' VIEWS OF PLANNING ACTIVITIES FOR MATHEMATICS INSTRUCTION: A COMPARATIVE ANALYIS

Laura B. Kent
University of Arkansas
lkent@uark.edu

Keywords: Elementary School Education, Instructional Activities and Practices, Preservice Teacher Education, Professional Development

Preservice elementary teachers often enter mathematics methods course(s) with their identity tied to their experiences as mathematics students, collegiate level courses such as college algebra, and perhaps, one or two mathematics content courses for future elementary teachers (Moler, et al., 2025). The methods course is likely one of their first experiences in which the focus shifts from their own understandings of mathematics to how ideas develop for children and pedagogical content knowledge (PCK) (e.g. Vettriselvan, et al., 2022; Lily, et al., 2024). Prior research showed differences between preservice and inservice teachers in relation to beliefs about instructional approaches and best practices for student learning (e.g. Vesga-Bravo, et al., 2022; Brugar, et al., 2023). The purpose of this research was to compare preservice and inservice elementary mathematics teachers' preferences for instructional activities.

This study answers the following research questions:

1. What activities do preservice teachers (PSTs) prefer in the development of their mathematics pedagogical strategies?
2. How do their preferences compare to inservice teachers?

Data sources were part of larger surveys that were given to inservice teachers at the end of a mathematics professional development program and elementary mathematics methods course. Forty-two inservice teachers spanning grades five and six and 35 preservice elementary teachers were asked to rank ten professional development activities from 10 (most valuable) to 1 (least valuable). The ten activities were as follows: watching videos of students solving problems, predicting student solution strategies, observing in classrooms, interviewing individual students, sorting student work, planning with other teachers, learning about problem types, videos of classroom instruction, questioning techniques, and readings. The highest ranked activities for the preservice teachers were classroom observations and planning with other teachers. These activities were also ranked high for inservice teachers (Kent, 2020; Kent & Skelton, 2024). Two activities in which there were differences in rankings between preservice teachers and inservice teachers were in the areas of viewing videos. Preservice showed a higher preference for valuing videos of students solving mathematics problems and classroom instruction than inservice teachers. Inservice teachers showed a higher preference for learning about questioning strategies from observing peer teachers thank preservice teachers.

These results could indicate that mathematics PD activities centered around peer coaching and observations of lessons in real-time should be prioritized for inservice teachers rather than video-based seminar style PD programs. Conversely, preservice teachers indicated a preference for video-based activities to learn about teaching mathematics. Future research should consider if there are specific differences between what is gleaned from video-based activities and whether improvements can be made to types of videos used for both inservice and preservice teachers. Additional research should also continue to explore advantages of observations of mathematics

lessons and development of observation instruments that support teacher learning and adaptations of best instructional practices for teachers at all levels of experience.

Keywords: Preservice Teacher Education; Cognition; Affect, Emotion, Beliefs, and Attitudes

In mathematics classrooms, teachers must adapt (e.g., to student reasoning, contextual factors, and curricular pressures). This study examines how adaptability is defined and experienced during mathematics pre-service teacher (PST) education. While adaptability is frequently referenced as a desirable disposition in teacher preparation (Collie & Martin, 2017), it is often operationalized in practice as general flexibility rather than a coordinated process. As such, this study is grounded in the *Tripartite Model of Adaptability* (Martin et al., 2013; Collie & Martin, 2016), which conceptualizes adaptability as three coordinated domains: *cognitive* (i.e., interpretation, reframing, anticipatory reasoning)*, affective* (i.e., emotional regulation/ orientation)*, and behavioral* (i.e., observable instructional/relational adjustment). Our study asks: *How is adaptability described and experienced by secondary mathematics preservice teachers?*

This qualitative study draws on semi-structured interviews with three secondary mathematics PSTs following their student teaching, along with reflexive memos (Paulus et al., 2014) and field notes from NOYCE seminars that focused on adaptability. Analysis was iterative and theory-informed. Using open, *in vivo*, and axial coding (Saldaña, 2013), we generated a codebook and identified adaptability moments in personal and teaching contexts. Then we mapped these moments onto cognitive/affective/behavioral domains and conducted cross-case comparisons to examine patterns in definitions and experiences of adaptability

Table 1: PSTs' Adaptability Definitions and Personal/Classroom Experiences.

Adaptability	Dani	Erica	Shelley
Definition (emphasis)	"Shift gears" (behavioral)	"Liquid, moving with anything that comes" (cognitive)	"Stay calm and process" (affective)
Personal (familiar)	Moving from small town to large university	Responding to car failure on a road trip	Missing a train stop in another country
Classroom (unfamiliar)	Adjusting to a large high school for the first time	Weather causing change of lesson plans to move from outside to inside	Learning to manage stressful teaching moments from mentor

Findings indicate these PSTs entered preparation with domain-specific orientations toward adaptability and leveraged familiar personal experiences as interpretive anchors when navigating and adapting to unfamiliar teaching contexts. For example, behavioral orientations surfaced in proactive environmental adjustments, cognitive orientations appeared in reframing instructional disruptions, and affective orientations were evident in emotional regulation during stressful teaching moments. Importantly, PSTs described coordinating the interplay of cognitive, affective, and behavioral adaptability contributing to adaptive decision-making. These findings

suggest mathematics teacher preparation can help PSTs leverage initial strengths to cultivate cross-domain adaptability for professional decision-making.

In elementary grades, students grasp abstract mathematics and science concepts more effectively when they are taught with interdisciplinary approaches (Munier & Merle, 2009). However, interdisciplinary teaching is not an easy task for elementary teachers (Wieseman & Moscovici, 2003). More recent studies show that PSTs could be prepared better if they have opportunities to learn about interdisciplinary teaching approaches and develop necessary professional content and pedagogical knowledge during their pre-service years with attention to interdisciplinary instruction (Aslan-Tutak & Sezer, 2025; Beudels et al., 2021; Ribeirinha & Correia, 2025). Thus, the purpose of this study was to explore how PSTs across three institutions conceptualized, planned, and implemented interdisciplinary lessons.

Interdisciplinary mathematics education is defined as "conjunction of mathematics with other knowledge in problem solving and inquiry" (Williams & Roth, 2019, p. 14). Two theoretical models focus on the level of integration (Huntley, 1999) and organization of integration (Fogarty, 1991).

This study used a qualitative research design (Saldaña, 2015) to explore PSTs' initial ideas relating to interdisciplinary lesson planning. Participants were 47 pre-service teachers in four mathematics methods courses at three different universities. Responses from both the online discussions and lesson plans were collected and structurally coded using the Level of Integration and Organization of Integration frameworks (Saldaña, 2015). Implemented lessons were structurally coded during observations of implementation. Frequency tables were generated to identify pre-service teacher's initial conceptualization, integrated subjects, lesson planning, implementation, and relationships between conceptualization, lesson planning, and implementation.

Results indicated that while most PSTs conceptualized level of integration as combining both math and another subject, there were a variety of organization conceptualizations. The highest conceptualization was webbed (using theme, 28%), followed by sequential subject teaching (23%), shared content (19%), no integration (17%), and skills-only focus (13%).

Most students did not plan an integrated lesson that aligned with their initial conceptualizations, with approximately half of the lesson plans having no integrated subject. This may be due to an interpretation of story problems being an integration of literacy and mathematics. However, without a literacy focus it remains just math. For those that did integrate, art was the highest integrated subject (34%), followed by literacy (24%), social studies (21%), and science (14%), with one lesson each for PE and drama.

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

When implementing the planned lessons, about two-thirds of the lessons aligned with planning. Two issues that impacted alignment were teaching inaccurate mathematics due to the PSTs misconceptions on the topic or going off on an unrelated tangent.

AN EXPLORATORY ANALYSIS OF PROSPECTIVE ELEMENTARY TEACHERS' "TAKEAWAYS" FROM A MATHEMATICS WHOLE-CLASS DISCUSSION

Jane-Jane Lo
Western Michigan University
jane-jane.lo@wmich.edu

Nitchada Kamlue
Western Michigan University
nitchada.kamlue@wmich.edu

Keywords: Classroom Discourse, Preservice Teacher Education

The transition from a mathematics student to a mathematics teacher requires a shift in how one perceives classroom discourse—moving from a passive focus on arriving at correct answers to an active, diagnostic focus on interpreting student thinking and leveraging misconceptions for conceptual learning. While significant research focuses on the facilitation of discussions (e.g., Smith & Stein, 2018), studies on what remains in the prospective teacher's mind once the discussion has concluded is lacking. This poster reports an analysis of prospective elementary teachers' (PTs) written responses to the prompt "What do you want to remember from this conversation about comparing fractions to a larger benchmark?"

Data were collected from 24 PTs immediately after a whole-class discussion centered on an incorrect peer contribution: *6/7 is bigger than 7/8 because sevenths are bigger than eighths.* The discussion was facilitated by an experienced mathematics teacher educator enacting the *building* teaching practice (Stockero et al., 2026). Two researchers independently applied *in vivo* coding to the 24 open-ended responses (Creswell & Poth, 2018). Through iterative comparison, codes were clustered into three primary takeaway orientations: (a) affective (16.6%), (b) mathematical (50.0%), and (c) representational (33.3%). Sub-classifications for specific mathematical takeaways will be detailed on the poster.

Table 1: Example of Each Primary Focus

Type of Primary Focus	Example
Affective	To not get overwhelmed and just acknowledge I know what I am doing. Sometimes it can be overwhelming, but I just breathe then do what is asked and I understand the problem. (PT20)
Mathematical	I had the same idea as we talked about. Instead of thinking about the larger part, think about the smaller part that is left. So this case, look at the 1/7 and 1/8 that are left. and we know that 1/7 is larger than 1/8, so seeing that 1/7 is missing from the 6/7 we know that 6/7 is smaller than the 7/8. (PT9)
Representational	I want to remember the diagram and the thinking of how we got the answer. It was helpful to see it in action and not really guess the answer. (PT21)

This study reveals that the PTs derive varied insights from the same productive whole-class discussion. While focusing on affective or representational aspects is common, these findings underscore the need for mathematics teacher educators to more deliberately guide PTs toward primary mathematical objectives. Future research could investigate how different types of scaffolding might more effectively shift PTs' attention toward the underlying mathematics of PTs' contributions or the intended pedagogical goals of the instruction.

Research indicates that tracking worsens inequities by granting advanced opportunities to students in higher tracks while denying these benefits to those in lower tracks, thereby perpetuating existing educational disparities (Clandfield et al., 2014; James & Turner, 2017; Smaller, 2014). Several research studies reported that detracking leads to success for more students (Boaler, 2002, 2008; Boaler & Staples, 2014; Burris & Weiner, 2005; Strutchens et al., 2011). While the concept of detracking has been widely studied, a strong body of research suggests that equitable mathematics teaching practices in secondary schools requires further investigation as there is lack of or poor implementation overall (Berry & Berry, 2017; Boaler & Staples, 2008; Boston & Smith, 2009; Clandfield et al., 2014; Feiman-Newmser, 2012; Gresalfi et al., 2009; Gutierrez, 1996; Hand, 2012; Horn, 2005; Larnell et al., 2016; Leinward, 2015; NCTM, 2014; TDSB, 2018; Van Es & Sherin, 2002).

The purpose of this project was to investigate the current practices and teaching techniques of secondary school teachers that cater to a wide range of student abilities in their Grade 9 detracked mathematics course. Sixteen schools participated, with fourteen teachers interviewed from the largest school board in Canada. The interviews were transcribed and coded based on four categories: teacher beliefs, experiences in teaching the Grade 9 Mathematics course, best practices, and challenges.

Teachers reported meeting students' individual needs as a common teaching practice when teaching mixed-ability students. A key focus was assessing students' mathematical skills on an ongoing basis as well as hosting student-teacher conferences. Some teachers reported that using independent student working time was best suited to cater to the different needs in the classroom. Other teachers reported using open questions, introductory tasks that allow for multiple entry points, or low-middle-high entry level tasks in order to differentiate instruction for their students. The participants acknowledged that differentiated instruction is not a new concept, but that it has been placed at the forefront of the grade 9 mathematics course due to the restructuring of placing all (mixed ability) students in one classroom.

The classroom learning environment was also a common theme for teaching mixed-ability students in a grade 9 mathematics classroom. Teachers reported several different ways to form group work, such as naturally formed groups, working with senior-level students, hybrid groups (online and in-person mix), and the visibly random grouping approach. Teachers also spoke about the timing of introducing group work regularly at the start of the school year. Another key teaching practice is using vertical non-permanent surfaces (VNPSs), encouraging movement, openness, and collaboration throughout the classroom. The application of VNPSs was reported

by nearly all the participants in the study. Our study presents the teacher experience of detracking; however, there is a need to continue research into sustainable, equitable practices, targeting and bridging gaps of mixed abilities within the classroom.

ADAPTABILITY AS COORDINATED DOMAIN FUNCTION: INTRODUCING THE TRIPARTITE MODEL IN SECONDARY MATHEMATICS TEACHING

Sherri L. Martinie
Kansas State University
martinie@ksu.edu

Michael Lawson
Kansas State University
mlawson1@ksu.edu

Meredith Beggs

Keywords: Cognition; Affect, Emotion, Beliefs, and Attitudes; Preservice Teacher Education

This study applies the *Tripartite Model of Adaptability* (Martin et al., 2013; Collie & Martin, 2016) to better understand how secondary mathematics teachers respond to classroom contexts during student teaching and their first year in the classroom. Rather than reducing adaptability to flexible behavior, the model conceptualizes it as a coordinated function across cognitive, affective, and behavioral domains. Demonstrating its explanatory power, the tripartite model was used to interpret pre-service teachers' (PST) experience adapting during student teaching and their first year teaching. This study is guided by two questions: (1) How is adaptability enacted across cognitive, affective, and behavioral domains in preservice and novice mathematics teachers? (2) What influences shape adaptive responses in mathematics teachers?

The Tripartite Model conceptualizes adaptability as multidimensional. *Cognitive adaptability* involves interpretation, reframing, and anticipatory reasoning as PSTs and novices draw on prior knowledge to make sense of unfolding events. *Affective adaptability* refers to emotional orientation and regulation including managing frustration, uncertainty, stress, or defensiveness to maintain responsiveness. *Behavioral adaptability* consists of observable instructional or relational adjustments such as modify pacing, questioning, tone, or task structure. Contextual understanding serves as an illustrative case of domain integration, demonstrating how knowledge-informed interpretations, emotional regulation, and aligned action operate together.

This qualitative study draws on interviews with three secondary math teachers conducted after student teaching and again after their first year in the classroom and incorporates analytic and reflexive memoing (Paulus et al., 2014). Initial coding (Saldaña, 2013) identified instances of adaptive responses and contextual information that informed their thinking, feeling, and acting. Secondary coding mapped these instances onto the tripartite domains, distinguishing between influences (e.g. prior experiences, perspective taking) and enactments (cognitive, affective, and behavioral shifts evident in teachers' in-the-moment descriptions and actions).

Findings show that adaptability in mathematics teachers emerged through coordinated cognitive, affective, and behavioral processes that deepened over time. Participants described not only behavioral adjustments (e.g. shifting strategy or pacing), but also cognitive reframing and affective regulation that appeared to underlie those shifts. We distinguish between influences (e.g. prior experiences, teacher visioning, mentorship, autonomy) and enactments, such as reinterpreting student behavior through contextual knowledge (cognitive), regulating toward empathy rather than reactive (affective), and adjusting instruction (behavioral), with cognitive reappraisal often enabling affective and behavioral change.

The Tripartite Model positions adaptability as coordinated domain functioning rather than isolated behavioral flexibility. For teacher education, this suggests that programs must: (1) Develop contextual knowledge alongside emotional regulation skills, (2) Provide structured opportunities for developing these domains, and (3) Support reflective practices that strengthen cross-domain coherence. By conceptualizing adaptability as multidimensional and integrated, the

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

model offers a framework for designing teacher preparation experiences that better support PSTs and novices in adapting to current and future complex classroom environments.

Most teacher preparation programs in the U.S. prepare two levels of mathematics teachers: elementary and secondary. Professional organizations (e.g., Association of Mathematics Teacher Educators [AMTE], 2017; Conference Board of Mathematical Sciences [CBMS], 2001, 2012; National Council of Teachers of Mathematics, 1991, 2014) have published recommendations for the preparation of mathematics teachers at both levels. In addition, researchers have investigated many aspects of elementary and secondary mathematics teacher preparation programs (e.g., Greenberg & Walsh, 2008; Masingila et al., 2022; Max et al., 2017; Mintos et al., 2019; Newton et al., 2014; Ronau et al., 2020; Tatto et al., 2010; Walsh, 2022).

In 2017, AMTE released *Standards for Preparing Teachers of Mathematics* (*SPTM*), a national guide that articulates a vision for mathematics teacher preparation and supports the continuous improvement of teacher preparation programs (AMTE, 2017). *SPTM* sets forth what well-prepared beginning teachers of mathematics should know, be able to do, and the dispositions they should develop throughout their programs. While *SPTM* was created by a team of experts in mathematics and mathematics education and is grounded in theory, there is a need to know how current programs are aligned with these recommendations.

In this study, we utilize a national survey to investigate current characteristics and curriculum of mathematics teacher preparation programs by collecting information (e.g., syllabi, activities, readings) from instructors of mathematics content and pedagogy courses with the aim of describing the current nature and structure of these programs in the U.S. and examining their alignment to SPTM. We use the following guiding research question: *What are the characteristics and curricula of U.S. elementary and secondary mathematics teacher preparation programs?* to describe (a) program structure, (b) activities used to support pre-service teacher content and pedagogical development, and (c) program alignment with SPTM.

In addition to a descriptive reporting of current program characteristics (e.g., goals, courses, instructors), we use the four *SPTM* standards for preservice teacher knowledge, skills, and dispositions as a conceptual framework for the study: (1) Mathematics Concepts, Practices, and Curriculum; (2) Pedagogical Knowledge and Practices for Teaching Mathematics; (3) Students are Learners of Mathematics; and (4) Social Contexts of Mathematics Teaching and Learning. Each standard has three to six indicators, with 19 total indicators (e.g., know relevant mathematics content, plan for effective instruction, anticipate and attend to students' thinking about mathematics content, draw on students' mathematical strengths). We aim to determine how current mathematics teacher education programs are aligned with these indicators, not in an evaluative sense but rather to explore the broad landscape of mathematics teacher preparation.

This study explores how current elementary and secondary mathematics teacher preparation programs support and develop beginning teachers of mathematics. Findings from this study will provide evidence to stakeholders related to how teacher preparation programs are realizing an updated vision of mathematics teacher education and create a shared database of goals, courses, readings, and activities for the mathematics teacher education community.

EMOTIONAL REGULATION IN MATHEMATICS THROUGH EMOTIONAL COACHING FOR PRE-SERVICE TEACHERS

Brenda Ramírez-Gómez
Universidad Autónoma de Guerrero
bramirez@uagro.mx

María Del Socorro García-González
Universidad Autónoma de Guerrero
msgarcia@uagro.mx

Keywords: Preservice Teachers, Emotional Regulation, Mathematics, Emotional Coaching

Emotional regulation toward mathematics constitutes a fundamental aspect of initial teacher education, as the emotional experiences of future teachers influence their learning, professional development, and future educational practice (Rita & Pérez-Tyteca, 2017). Various studies have shown that mathematics often generates both positive and negative emotions, including anxiety, insecurity, and concern, which may affect academic performance and the willingness to teach this discipline.

In response to this issue, the present study aims to promote emotional regulation toward mathematics among pre-service teachers through the implementation of an emotional coaching process. Although previous studies have addressed emotional regulation in teacher education, such as those conducted by Caballero-Carrasco et al. (2021) and Garrido-Martos et al. (2019), further research is still needed on interventions specifically focused on emotions associated with the learning and teaching of mathematics.

The study is grounded in the Cognitive Structure of Emotions Theory (Ortony et al., 1996), as well as in the concepts of emotional knowledge, emotional regulation, and emotional coaching.

The research follows a qualitative approach through a case study involving three sixth-semester pre-service teachers enrolled in the Bachelor's Degree in Mathematics Teaching and Learning in Mexico. The methodology comprises five phases: identification of emotions and development of an emotional profile, enhancement of emotional knowledge, design of emotional regulation strategies, implementation of the strategies, and evaluation of the emotional changes achieved. Data are collected through questionnaires, semi-structured interviews, narratives, drawings, reflective journals, and emotional profiles.

The expected results aim to provide a methodology for regulating negative emotions toward mathematics among pre-service teachers and to explore the potential of emotional coaching as a strategy for strengthening their emotional and professional well-being.

PMENA-ENHANCING PRESERVICE TEACHERS' DEVELOPMENT OF WORTHWHILE TASK DESIGN THROUGH GENERATIVE AI ASSESSMENT

Holly B. Rougeaux
Indiana University of Pennsylvania
rougeaux@iup.edu

Keywords: Pre-Service Teacher Education, Artificial Intelligence, Assessment, Problem Solving

Introduction and the Problem

Development, selection, and implementation of worthwhile tasks are essential for student engagement and learning of mathematics. Worthwhile tasks are cognitively demanding, promote problem solving and critical thinking, and are characteristically open, providing a low-floor high-ceiling approach (Small, 2020; Smith & Stein, 1998; Van de Walle et al., 2023). Moreover, open questions and parallel tasks align to the Universal Design for Learning (UDL) framework providing for differentiation (Small, 2020) and emphasizing the "do" of UDL Math (Lambert, 2024). Despite the value of worthwhile tasks (Stein & Smith, 1998) pre-service teachers (PSTs) tend to resort to worksheets, procedural work, and Artificial Intelligence (AI) generated problems in lesson design and implementation (Arbaugh & Brown, 2005; Lee et al., 2026; Maiorca et al., 2024). Developing and accessing worthwhile tasks proves challenging. To aid educators, Smith and Stein (1998, 2018) developed a task analysis guide for levels of cognitive demand to identify and select these tasks. In addition, Artificial Intelligence (AI) adds a new layer to this process. The research questions are: RQ1. To what extent does the creation of AI-generated rubrics enhance PSTs' development of worthwhile tasks? RQ2. What are student perceptions of creating and using AI-generated rubrics to develop worthwhile task knowledge?

Design and Data Collection

A mixed-methods design will be employed with a convenience sample of PSTs (N=52) enrolled in two sections of the Fall 2026 methods course titled, MATH 335 Teaching Mathematics in Special Education. PSTs will complete a survey (pre-assessment) regarding their perceived knowledge of worthwhile tasks after instruction and prior to rubric design. PSTs will then create or select an initial worthwhile task (Sapkota, 2022). Aligned to Liljedahl et al.'s (2007) theoretical framework, PSTs will solve the task (predictive phase) and implement the task with a small group of PSTs (trial period) to determine mathematical and pedagogical affordances (Lee et al., 2024). PSTs will use generative AI to produce a rubric (reflective phase) aligned to Smith and Stein's Task Analysis Guide (Smith & Stein, 1998; Smith & Stein, 2018). Initial task scores will be generated by the PST and generative AI utilizing this rubric. PSTs will then develop a final task (refined initial task) based on knowledge from the rubric creation and the initial task assessment (adjustment phase). Final tasks will be self- and AI-assessed using the same rubric. Growth scores will be compared between the initial and final tasks. A post-survey will be administered to garner PSTs' perceived knowledge and to collect reflections.

Data Analysis & Results

Pre- and post-survey responses and rubric scores from initial and final worthwhile tasks will be analyzed using paired t-tests. In Vivo and Descriptive coding will be used to identify emerging trends from PST reflections (Mertler & Charles, 2011; Saldaña, 2021).

DESIGNING EQUITY-ORIENTED DATA TALKS IN ELEMENTARY PRESERVICE TEACHER EDUCATION

Gianna Shields
San José State University
gianna.shields@sjsu.edu

Keywords: Pre-Service Teacher Education; Statistics, Probability, and Data Science

Data science is increasingly recognized as a core strand of K–12 mathematics, engaging students in posing questions, interpreting variability, and making evidence-based decisions (Bargagliotti et al., 2020; California Department of Education, 2023; Lee & Wilkerson, 2018). Guided by an equity-oriented data science pedagogy lens, this study integrates statistical inquiry, mathematical discourse for multilingual learners, and students' lived experiences as central to justice-oriented mathematics learning (Aguirre et al., 2013; Gutstein, 2006; Moschkovich, 2010). The study asks: How do elementary preservice teachers incorporate community relevance, language supports, accessible representations, and action-oriented decision-making into Data Talk designs?

This exploratory study asks: How do elementary preservice teachers incorporate community relevance, language supports, accessible representations, and action-oriented decision-making into Data Talk designs? Qualitative analysis examines planning artifacts from a single three-hour class session in an elementary mathematics methods course at a public university. Grounded in research on K–12 data science and mathematical discourse, the session framed investigations as cycles of posing questions, collecting or curating data, representing and interpreting results, and drawing conclusions in context (Bargagliotti et al., 2020). PSTs were encouraged to embed structured sentence frames (Moschkovich, 2010) and to situate investigations in students' lived experiences (Gutstein, 2006).

Twenty-four PSTs working in grade-band groups (TK–K, K–2, 3–5, 6–8, and special education contexts) of 3–4 students, designed a "Data Talk" using a planning template organized in alignment with GAISE II as Wonder, Collect/Curate, Represent, Interpret, Act. The template required a clear investigative purpose, justified representation choices, discourse supports, anticipated misconceptions, and a decision-making or action component. Data sources included planning templates, presentation slides, and peer feedback. Artifacts were analyzed thematically with attention to community relevance, language scaffolds, representation accessibility, and action orientation. PSTs consistently selected contexts grounded in students' lived experiences (e.g., recess preferences, book genres, transportation access). Most investigations included decision-making components, positioning data science as participatory rather than procedural (Gutstein, 2006). All groups embedded sentence frames such as "I notice…" and "I claim ___ because…," foregrounding discourse as central to reasoning (Moschkovich, 2010). Several groups explicitly addressed sampling fairness, reflecting emerging data science awareness consistent with GAISE II (Bargagliotti et al., 2020).

Given the bounded nature of this single-session inquiry, findings are illustrative rather than generalizable. This artifact analysis suggests that structured planning supports preservice teachers in operationalizing equity-oriented data science practices in elementary mathematics. The poster will include the framework, Wonder–Collect/Curate–Represent–Interpret–Act progression, sample PST-designed Data Talks, thematic findings, and implications for mathematics teacher education.

INTEGRATING LITERACY AND EARLY DATA SCIENCE IN PK-3 PRESERVICE TEACHER EDUCATION

Gianna Shields
San José State University
gianna.shields@sjsu.edu

Keywords: Preservice Teacher Education; Statistics, Probability, and Data Science

Data science is emerging as a central strand of K–12 mathematics, beginning in the early grades with counting, sorting, classifying, and comparing quantities as foundations for later statistical reasoning (Bargagliotti et al., 2020; California Department of Education, 2023; Lee et al., 2021; National Governors Association Center for Best Practices & Council of Chief State School Officers, 2010). In early childhood settings, these practices build on children's developing competencies in counting and comparison (Clements & Sarama, 2009). Equity-centered mathematics education further emphasizes language and meaningful contexts in supporting young learners' sense-making (Aguirre et al., 2013). Preservice teachers (PSTs) may struggle to connect children's literature, early numeracy, and foundational data practices in developmentally appropriate ways. This study examines: How do preservice teachers design and revise literacy-based lessons that engage preschool (P), transitional kindergarten (TK), and kindergarten (K) learners in early data science?

The study was conducted in a PK–3 mathematics methods course at a public university. In one class session, PSTs worked in groups of four to select a children's book curated by the course instructor, focused on early numeracy and designed a standards-aligned lesson for P, TK, or K that incorporated counting collections, sorting or classifying, and comparing quantities. In the following session, PSTs engaged in structured peer feedback and revised their lessons. Data sources included initial plans, peer feedback, revised plans, and written reflections. Grounded in research on early mathematics and K–12 data science, the task framed early data practices as organizing, representing, and comparing quantities in context (Bargagliotti et al., 2020). Integrating literacy with mathematics situated these investigations in familiar, play-based environments while supporting discourse and reasoning (Aguirre et al., 2013). The design cycle emphasized standards alignment, purposeful questioning, and opportunities for justifying.

Artifacts were qualitatively analyzed thematically with attention to the depth of data practices, standards alignment, literacy and play integration, and revisions following feedback. Initial plans often emphasized counting but varied in explicit attention to data organization or comparison. After peer critique, many groups strengthened the data component by adding sorting structures, representations, and prompts encouraging children to compare quantities and explain their reasoning. Revisions showed clearer alignment and more intentional questioning. Reflections suggested that feedback helped PSTs distinguish between counting as a procedural activity and engaging children in data-informed comparison. Because this inquiry was limited to a two-session design cycle, findings are illustrative rather than generalizable. However, the analysis suggests that integrating children's literature with structured peer critique may support PSTs in developing more robust conceptions of early data science in PK–3 mathematics. The poster will include research grounding early childhood data science, the lesson design and feedback structure, examples of initial and revised lesson excerpts, and implications for PK–3 teacher education.

DEVELOPING PRE-SERVICE TEACHERS' FOUNDATIONS FOR FAMILY STEM

Amber Simpson
Binghamton University
asimpson@binghamton.edu

Lasse Eronen
University of Eastern Finland
lasse.eronen@uef.fi

Keywords: Integrated STEM / STEAM, Preservice Teacher Education

Research consistently shows that parent–child math interactions are crucial drivers of children's mathematical skills, motivation, and identity (Fiskerstrand, 2022; Pomerantz et al., 2025), and that the quality of these interactions matters as much as their frequency (Silinskas & Kikas, 2019). Despite this evidence, educators are rarely prepared to cultivate meaningful family engagement around mathematics. Research indicates that home–school cooperation remains underdeveloped in teacher education programs (Cabral et al., 2024), leaving pre-service teachers (PTs) feeling underprepared (Meehan & Meehan, 2018). Yet, programs that involve community-based and practice-based models (e.g., family math nights) demonstrate shifts in PTs' beliefs and skills (Bofferding et al., 2016; Suh & Calabrese, 2025). To build upon this research, we engaged pre-service teachers in designing family STEM escape rooms that foregrounded mathematical reasoning, problem solving, and collaborative sense-making among children and caregivers. Grounded in the practice-based teacher education (Grossman et al., 2009), we addressed the following: In what ways do pre-service teachers design take-home escape room kits to support family engagement in STEM-based problem solving? To answer the research question, we utilized a multiple instrumental case study (Stake, 1995). Participants were three groups of 3–4 secondary education PTs as part of a teacher education program at the University of Eastern Finland. They each developed an escape room kit for young children and their families to engage in STEM concepts and practices in their home environments in collaboration with a local school. The data sources included video recordings of their collaboration (approximately 3.5 hours of data for each group) and a 30-minute post-interview with each group informed by prior research and the video recordings. Data analysis was informed by thematic analysis (Braun & Clark, 2006), which involved iterative coding to identify patterns in PTs discourse.

First, many PTs reflected on the unique affordances of the home environment (e.g., safe place for failures to occur), recognizing it as a valuable and often overlooked space for meaningful STEM learning. This acknowledgement suggests an emerging understanding of families as active participants in children's learning and homes as sites rich with cultural and intellectual resources. Second, PTs designed the kits to position caregivers as facilitators and children as the primary investigator. By prioritizing communication over content mastery, they provided caregivers a pedagogical role supported by "hidden" information, such as safety manuals or background context. This design choice highlights an evolving awareness that family engagement is most effective when it is relational rather than instructional. Third, in the design process, PTs made a conscious effort to distance the activities from traditional classroom expectations. As such, they used escape room mechanics (e.g., trial and error loops) to shift family's perception of what mathematics and STEM more broadly can look like. Based on these initial results, the significance of this study contributes to how we might prepare PTs to not only engage families in ambitious and collaborative inquiry in their homes, but develop their foundational understanding of how to meaningfully engage caregivers in their child's learning.

Acknowledgments

This project was funded by the U.S. Department of State in collaboration with Fulbright Finland.

Keywords: Preservice Teacher Education, Early Childhood Education

Early mathematical knowledge is a strong predictor of later academic achievement (Claessens et al., 2009; Duncan et al., 2007), positioning early childhood as a critical period for mathematics learning. Accordingly, instruction should be active, discourse-rich, and responsive to children's emerging ideas (National Association for the Education of Young Children [NAEYC] & National Council of Teachers of Mathematics [NCTM], 2010; NCTM, 2014). Within this broader conversation, productive struggle has become a central instructional goal. Classrooms that foster productive struggle provide opportunities for students to grapple with ideas not immediately apparent (Hiebert & Grouws, 2007; Huinker & Bill, 2017). Such struggle may surface through informal language, partial representations, social negotiation, or apparent frustration, and is not always articulated through mathematics claims (Bjorklund et al., 2020). For pre-service teachers (PSTs), this raises questions about how to define, notice, and support productive struggle in young children's mathematics. Research suggests that PSTs often struggle to interpret students' mathematics thinking in real time and may intervene prematurely when students appear stuck (Jacobs et al., 2010; Lee & Ginsburg, 2009; Warshauer, 2015). Teacher preparation must, therefore, find ways to approximate practice, creating opportunities for PSTs to notice, interpret, and support productive struggle (Grossman et al., 2009; McDonald et al., 2013).

Drawing on video case analysis (Borko et al., 2008; Sherin & van Es, 2009), we designed a video case study for elementary PSTs focused on noticing and supporting productive struggle in a K-2 context. After completing the task and discussing anticipated points of struggle, PSTs were introduced to the video context and reviewed selected clips and transcripts. In small groups, PSTs responded to a series of open-ended prompts focused on identifying moments of productive struggle and considering how to support or extend students' thinking. From this data, we conducted a qualitative thematic analysis of PSTs' written responses (Braun & Clarke, 2006) around how they anticipated struggle, recognized productive struggle, interpreted the mathematics underlying students' difficulties, and proposed instructional responses.

Preliminary analysis shows that PSTs demonstrated strengths in noticing and valuing productive struggle. Many PSTs were able to anticipate aspects of the task that might create difficulty for children. PSTs also recognized that moments of confusion, disagreement, or hesitation could be mathematically productive, noting the importance of allowing time to grapple, ask questions, and test ideas. However, PSTs' noticing was not always math-specific. In some cases, PSTs cited students as "confused" or "stuck" without articulating the mathematical ideas underlying the particular struggle. Instead, they focused on affect or participation. This suggests that while PSTs may value productive struggle, they need scaffolded support to identify what students struggle with mathematically. This underscores the importance of structured

approximations of practice that help PSTs move beyond general commitments to productive struggle toward more precise mathematical noticing in early childhood settings.

AN EXPLORATORY STUDY ON OPEN PROBLEM SITUATIONS TO PROMOTE MODELING COMPETENCIES IN UNIVERSITY TEACHERS

UN ESTUDIO EXPLORATORIO SOBRE TAREAS PARA PROMOVER COMPETENCIAS DE MODELIZACIÓN EN PROFESORES UNIVERSITARIOS

Rafael Antonio Arana-Pedraza
Universidad de Sonora
rafael.arana.pedraza@gmail.com

Silvia Elena Ibarra Olmos
Universidad de Sonora
silvia.ibarra@unison.mx

This exploratory study analyzes the work of two university mathematics teachers as they engage with an open problem situation (open-ended mathematical modeling task) focused on systems of linear equations (SLE) in the context of engineering education. The theoretical framework arises from integrating Borromeo Ferri's mathematical modeling cycle with the modeling competencies proposed by Maaß. Based on a literature review, guidelines for task design are established and a pilot implementation with two teachers is conducted, revealing a partial realization of the mathematical modeling cycle. The pilot implementation highlights the potential of incorporating open problem situations and identifies possible refinements to the proposed task.

Keywords: Professional Development, Modeling, Algebra and Algebraic Thinking

Introduction

At both the national and international levels, there is a growing interest in the design, implementation, and analysis of initial and continuing teacher education initiatives, as reflected in proposals by international organizations and in research reports found in the specialized literature.

In Mexico, it has been reported that there is a wide diversity of initiatives in the initial preparation of in-service mathematics teachers, especially at the higher education level (Beneitone et al., 2007; Camarena, 2004; Dolores, 2014; Fonseca, 2011). For this reason, it is important to promote professional development opportunities that strengthen teachers' mathematical knowledge and, above all, their didactical knowledge through reflection on their teaching practice.

Purpose of the Study

This study analyzes the work carried out by university mathematics teachers as they solve an open problem situation (open-ended task) designed from a mathematical modeling perspective, focused on the development of models based on systems of linear equations (SLE). The results of this exploratory study provide empirical evidence of the strategies developed to solve the proposed open problem situation, as well as the possible difficulties encountered in doing so.

Theoretical Framework

Mathematical modeling is considered a process in which a problem from a real-world context is translated into the context of mathematics in such a way that it can be solved and then interpreted back in relation to reality. The literature has proposed different cycles that make it possible to characterize this process; for this work, the mathematical modeling cycle from a cognitive perspective proposed by Borromeo Ferri (2018) was selected.

This cycle (Figure 1), consisting of six cognitive processes, begins with a problem from reality, from which the individual generates a mental representation of the situation through task

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

understanding. Subsequently, simplification and structuring of the task make it possible to create a real model of the situation. Then, a mathematical model is constructed from the real model, on which mathematical work is carried out to obtain mathematical results. Based on the interpretation of these mathematical results, real-world results are obtained, which must be validated by comparing those results with the mental representation of the situation.

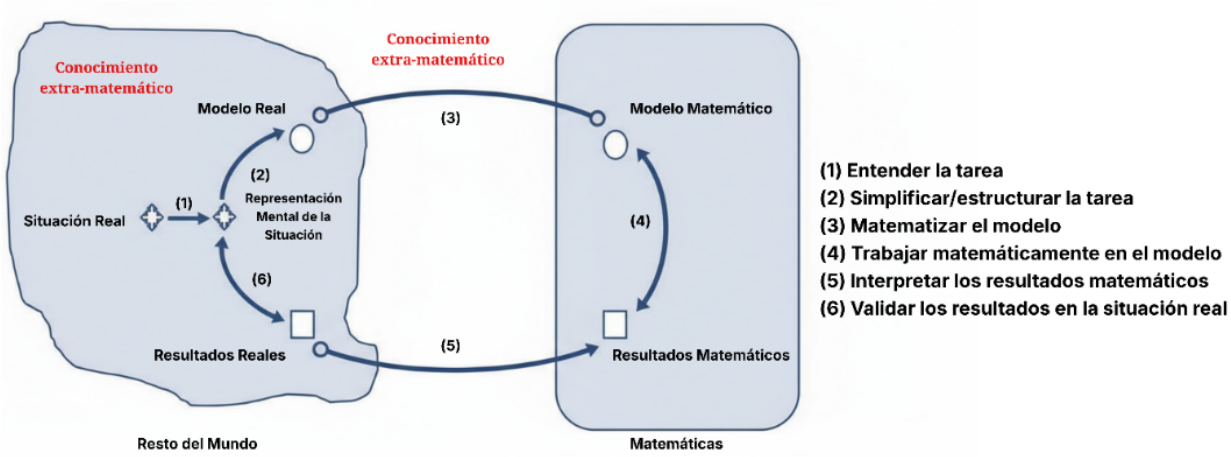

Figure 1: Mathematical Modeling Cycle from a Cognitive Perspective

The integration of the cognitive processes in the cycle presented by Borromeo Ferri (2018) with the modeling competencies proposed by Maaß (2006), as developed by Ramírez-Montes and collaborators (2021), is taken up in Table 1. Based on the authors' proposal, it is possible to delimit the types of practices or tasks that teachers should be able to develop in each of the cognitive processes of the cycle; therefore, these will form part of their didactic-mathematical knowledge and competencies.

Table 1: Alignment of Modeling Competences with the Cognitive Processes of the Mathematical Modeling Cycle

Modeling Competence	Competence to…	Cognitive Processes
Understand the real problem and develop a model based on reality	Make assumptions about the problem and simplify the situation; recognize the quantities that influence the situation, identify key variables; construct relationships among variables; search for available information and distinguish between relevant and irrelevant information.	(1) Understand the task (2) Simplify / Structure the task
Set up a mathematical model from the real model	Mathematize the relevant quantities and their relationships: simplify relevant quantities and their relationships if necessary and reduce their number and complexity; choose appropriate	(3) Mathematize the model

	mathematical notation and represent situations graphically.	
Solve mathematical questions within this mathematical model	Use heuristic strategies such as breaking the problem into subproblems, establishing relationships with similar or analogous problems, reformulating the problem, visualizing it in a different way, varying the quantities or available data, etc.; use mathematical knowledge to solve the problem.	(4) Work mathematically on the model
Interpret mathematical results in a real situation	Interpret mathematical results in extra-mathematical contexts; generalize solutions developed for a particular situation; communicate solutions using appropriate mathematical language and/or discuss them.	(5) Interpret mathematical results
Validate the solution	Critically review and reflect on the solutions found; revisit parts of the model or repeat the modeling process if the solutions do not fit the situation; consider other ways of solving the problem or developing alternative solutions; question the model as a whole.	(6) Validate the results in the real situation

Methodology

This study adopts an exploratory qualitative approach, consisting of a literature review and the design and piloting of an open problem situation based on the mathematical modeling cycle. These components are organized as follows:

1. For the literature review, a keyword-based search was conducted using search engines, with categories including: a) teacher professional development, b) mathematical modeling, c) engineering education, d) linear algebra, and e) systems of linear equations. Through this review, an overview of the current state of the central issues addressed in the study was established.
2. Based on the findings from the literature, it was determined which characteristics the proposed open problem situation should possess, as well as the selection of the context and the formulation of the open problem situation that would foster teachers' mathematical work in solving it.
3. Subsequently, the expected tasks to be carried out by teachers when solving the proposed open problem situation were identified, in connection with modeling competencies and the cognitive processes of Borromeo's mathematical modeling cycle. This specification of expected tasks provides a frame of reference for analyzing teachers' written work in the pilot study.
4. Then, an exploratory activity (pilot study) was conducted with two university-level mathematics teachers during two sessions of approximately 120 minutes each. Information was collected through an active observation process, in which the observer acted as facilitator of the activity using the technique of jointly guided work through appropriate questioning.

5. Finally, a descriptive analysis was carried out of the tasks performed by the teachers by contrasting them with the expected tasks, which made it possible to identify the strategies they adopted and the difficulties they faced while solving the open problem situations.

Results

The main findings for each of the aforementioned stages are presented below.

Literature Review

Regarding the difficulties in learning SLE, it has been found that, in school contexts, instruction tends to focus primarily on the study and solution of square systems with a unique solution, favoring an intramathematical approach and solution methods restricted to algebraic representations. This hinders learning by disconnecting algebraic meaning (equations) from geometric meaning (lines/planes), fostering misinterpretations of results and the perception of SLE solutions solely as a single intersection point (Oktaç, 2018; Trigueros et al., 2007).

Additionally, mathematical modeling has been identified as one of the prevailing trends in the literature of the discipline, both in the design of teaching proposals and in teacher education and professional development, especially with respect to mathematics education for future engineering professionals. With regard to the design of instructional proposals for mathematical training in engineering, several studies (Pizarro, 2020; Rodríguez-Gallegos & Quiroz-Rivera, 2016; Vázquez et al., 2016) agree that its incorporation, together with problems representative of students' future professional practice, fosters a deeper and more contextualized understanding of mathematical concepts. As part of professional development activities, emphasis is placed on its integration with authentic situations and appropriate contexts, the design of experiences that involve mathematical validation, and reflection on one's own learning processes (Cruz et al., 2020; Dede & Taşpinar, 2021; Ledezma et al., 2024).

The literature review carried out makes it possible to identify a scenario in which teaching strategies are undergoing transformation, driven by the incorporation of mathematical modeling as a suitable approach, particularly for the study of SLE in engineering programs. In this context, there is clear evidence of the need to update and diversify didactic knowledge and strategies through the integration of contextualized problems, the use of multiple representation registers, and the strengthening of competencies that connect real engineering contexts with disciplinary content in Linear Algebra, such as SLE.

Design of the Open Problem Situation

Drawing on the information collected during the literature review, a set of guidelines was proposed to inform decision-making in the design process, so that it would:

1. Promote the incorporation of authentic, open problem situations whose resolution requires the use of models involving various cases of SLE with real coefficients, primarily focusing on rectangular systems with infinitely many solutions.
2. Incorporate contexts suitable for engineering education that enable participants to move through each of the phases or cognitive processes of the mathematical modeling cycle, as well as to give meaning to and validate the solution of an SLE while solving the proposed problem situations.
3. Encourage the use of digital technology for the solution, validation, and interpretation of the proposed situations and the solutions obtained.

For the design of the open problem situation, the task proposed in Pochulu (2018) regarding the study of a one-liter milk container was adapted. In this case, the focus is on engaging a

modeling pathway in the context of redesigning the dimensions of a container based on SLE, formulated as follows:

> Tetra Pak® designs and produces carton packaging products for the food industry. One of its main products is the Tetra Brik®, made of layers of cardboard, polyethylene plastic, and aluminum in the shape of a parallelepiped. Considering the containers used for storing milk with a capacity of 1 liter, analyze and argue whether modifying the dimensions of the container, while keeping the amount of material and its shape fixed, changes its capacity. In addition, analyze the advantages and/or disadvantages of designing containers with different dimensions. Base your analysis and argumentation on a mathematical strategy.

For work with the open problem situation, participants are provided with real milk containers and a measuring tape. Based on the given situation and materials, it is expected that the planned tasks (Table 2) will be activated as participants follow a modeling pathway.

Table 2: Identification of Expected Tasks for Each Modeling Competence and the Associated Cognitive Processes of the Mathematical Modeling Cycle

Modeling Competence	Cognitive Processes	Expected Tasks
Understand the real problem and develop a model based on reality	(1) Understand the task (2) Simplify/ Structure the task	• Measure the real container provided as concrete material. • Construct a graphical representation (unfolded net of the material) of the real model using the actual dimensions of the container. • Analyze particular cases for different values of the container dimensions. • Identify quantities that vary (dimensions, volume) and those that remain invariant (area). • Identify the relationships among the different dimensions that make up the container. • Construct a graphical representation (unfolded net of the material) with a generalized description of the container dimensions.
Set up a mathematical model from the real model	(3) Mathematize the model	• Define unknowns (variables) that represent each of the container's dimensions. • Construct a mathematical model based on SLE, taking the measurements of the material as a constraint of the problem.
Solve mathematical questions within this mathematical model	(4) Work mathematically on the model	• Select an appropriate solution method for the proposed SLE. • Identify the solution set of the system.

Interpret mathematical results in a real situation	(5) Interpret mathematical results	• Identify constraints on the solution set based on the context of the problem. • Determine the range of admissible values for the free variable(s) in the solution set of the system.
Validate the solution	(6) Validate the results in the real situation	• Identify additional constraints for decision-making (minimum required volume, ergonomic or logistical conditions of the product). • Argue for the advantages and/or disadvantages of choosing different dimensions for the container.

Exploratory Activity (Pilot Study)

The exploratory activity was carried out over two working sessions with the participating teachers, who were guided through the use of questions that were carefully formulated on the basis of their contributions. In general terms, the participants engaged in a partial realization of the mathematical modeling cycle, developing tasks related to the first three cognitive processes in Borromeo Ferri's cycle, as shown in Table 3.

Table 3: Tasks Performed by the Teachers in the Pilot Study for Each Modeling Competence and the Associated Cognitive Processes in the Mathematical Modeling Cycle

Modeling Competence	Cognitive Processes	Tasks Performed
Understand the real problem and develop a model based on reality	(1) Understand the task (2) Simplify/ Structure the task	• Measure the real container provided as concrete material. • Construct a graphical representation (prism) of the real model using the actual dimensions of the container. • Calculate the volume of the container using the real measurements ($V = 1072.5\ cm^3$). • Analyze particular cases for different values of the container dimensions. • Identify quantities that vary (dimensions, volume) and those that remain invariant (area). • Identify the relationships among the different dimensions that make up the container. • Construct a graphical representation (prism) with a generalized description of the container dimensions.

Set up a mathematical model from the real model	(3) Mathematize the model	• Define unknowns (variables) that represent each of the container's dimensions. • Construct a mathematical model to calculate the volume of the container when one of its dimensions (height) changes and the other two remain constant. • Construct a mathematical model to calculate the surface area of the container when one of its dimensions (height) changes and the other two remain constant. • Construct a mathematical model to calculate the volume of the container when all of its dimensions change. • Construct a mathematical model to calculate the surface area of the container when all of its dimensions change.

During the first session, the teachers worked on tasks related to *understanding the problem* (the open problem situation) by constructing different particular cases in which the choice of dimensions was made arbitrarily, varying the measurements taken from the milk container that had been provided. This allowed them to formulate some initial ideas regarding the surface area and volume of the container. On this basis, they concluded that some of the proposed modifications would require a greater amount of material, which they deemed inappropriate for the company as it would entail a higher cost.

Subsequently, a case was posed in which two of the dimensions (width and length) remained constant, while the third (height) varied. Assigning a literal to the varying dimension led them to formulate two equations (one for surface area and another for volume), which allowed them, by the end of the first session, to conclude that they could not find a unique value that would keep both volume and surface area constant. In addition, by manipulating the concrete material provided, they reflected on inaccuracies in the calculation of area when folds required to form the container were not taken into account.

In the second session, the work from the previous meeting was reviewed. Through questions about the tasks they had performed, the teachers were prompted to reflect on the modification of the dimensions, taking into consideration issues related to material use and ergonomic and logistical aspects of the container redesign.

Building on these reflections, a case was proposed in which all of the container's dimensions could change, and equations were established to represent the volume (restricted to 1000 cm^3) and the total area (without a specific fixed value as a constraint). These final considerations enabled the participants to identify the area of the material sheet as one of the constraints that must remain unchanged in order to establish equations that support the construction of the mathematical model.

Final Remarks

The implementation of the exploratory activity reported here made it possible to confirm that the proposal promotes tasks that support participants' progression through several cognitive processes of the mathematical modeling cycle (Borromeo Ferri, 2018) and, consequently, the development of the associated modeling competencies (Maaß, 2006). Although a complete mathematical modeling cycle was not achieved in this exploratory phase, the use of appropriate questioning focused on participants' work can guide them in solving the open problem situation, fostering movement through each of the cognitive processes.

Additionally, the use of open problem situations such as the one proposed activates a variety of mathematical strategies, which makes it a mathematically rich situation and appropriate for a modeling-oriented approach.

Finally, the pilot implementation of the open problem situation made it possible to identify potential improvements in the formulation of the problem situation, as well as in the incorporation of additional resources to enrich the activity. In particular, the analysis of concrete cases supported participants in understanding the problem, formulating assumptions, and recognizing key relationships; therefore, integrating materials to construct physical models of these cases represents a feasible enhancement.

Este estudio exploratorio analiza el trabajo de dos profesores universitarios de matemáticas al realizar una situación-problema abierta basada en la modelización matemática, enfocada en sistemas de ecuaciones lineales para la formación de ingenieros. El soporte teórico de la propuesta resulta de la integración del ciclo de modelización matemática de Borromeo Ferri con competencias de modelización propuestas por Maaß. A partir de la revisión bibliográfica, se proponen pautas para el diseño de la situación-problema y se lleva a cabo el pilotaje con dos profesores, revelando un ciclo parcial. El pilotaje de la propuesta permite identificar el potencial de la incorporación de situaciones-problemas abiertas, así como mejoras en la misma.

Palabras clave: Desarrollo profesional, Modelización, Álgebra y pensamiento algebraico

Introducción

A nivel nacional e internacional se observa un creciente interés en el diseño, implementación y análisis de acciones de formación inicial y continua del profesorado, lo cual es visible tanto en las propuestas de organismos internacionales como en los reportes de investigación que se encuentran en la literatura especializada.

En México se ha reportado que existe una gran diversidad de iniciativas en la formación inicial de los profesores de matemáticas que se encuentran en servicio, especialmente en el nivel superior (Beneitone et al., 2007; Camarena, 2004; Dolores, 2014; Fonseca, 2011). Por lo anterior, es importante la promoción de espacios para el desarrollo profesional que potencialicen el conocimiento matemático de los profesores, pero sobre todo el conocimiento en la didáctica a partir de la reflexión sobre la práctica docente.

Propósito del estudio

Este estudio analiza el trabajo desarrollado por profesores universitarios de matemáticas al resolver una situación-problema abierta, diseñada bajo una perspectiva de modelización matemática, enfocada en el desarrollo de modelos basados en los sistemas de ecuaciones lineales (SEL). Los resultados de este estudio exploratorio proporcionan evidencia empírica sobre las estrategias desarrolladas para la resolución de la situación-problema propuesta, así como las posibles dificultades que enfrentan al resolverla.

Marco teórico

La modelización matemática se considera como un proceso en el que se traduce un problema de un contexto real, hacia el contexto de las matemáticas de tal manera que pueda ser resuelto y posteriormente regresado hacia la realidad. En la literatura se han propuesto diferentes ciclos que permiten caracterizar este proceso; para este trabajo se ha considerado utilizar el ciclo para la modelización matemática desde una perspectiva cognitiva propuesto por Borromeo Ferri (2018).

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

Este ciclo (Figura 1), conformado por seis procesos cognitivos, se inicia con un problema de la realidad sobre el cual el individuo genera una representación mental de la situación a partir del entendimiento de la tarea. Posteriormente, la simplificación y estructuración de la tarea, permite la creación de un modelo real de la situación. Después, se crea un modelo matemático del modelo real, sobre el cual se trabaja matemáticamente y se obtienen resultados matemáticos. Con base en la interpretación de los resultados matemáticos, se obtienen resultados reales que deberán ser validados a través de la comparación de dichos resultados reales y la representación mental de la situación.

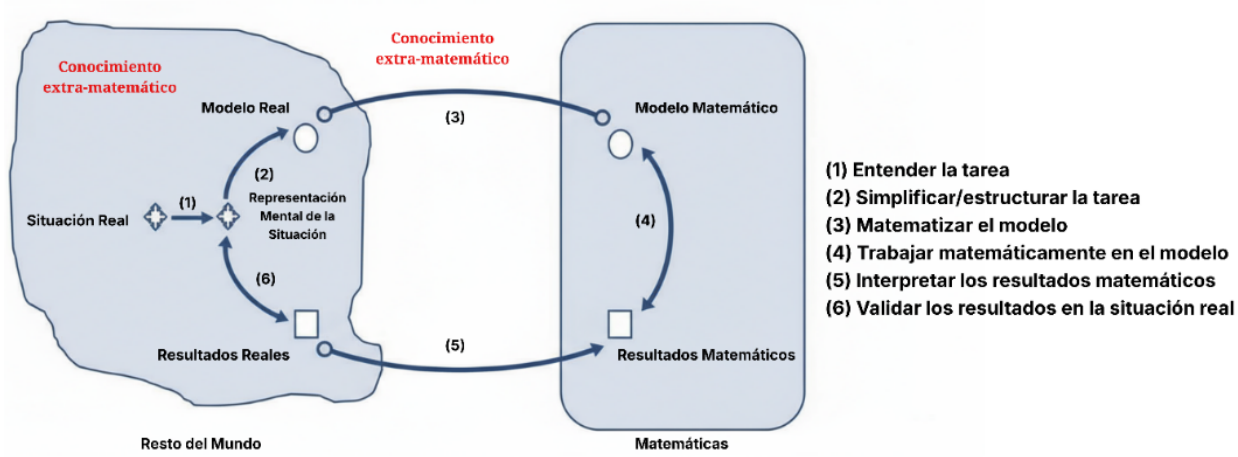

Figura 1: Ciclo de modelización desde una perspectiva cognitiva

Se retoma la integración de los procesos cognitivos del Ciclo presentado por Borromeo Ferri (2018) con las competencias de modelización que presenta Maaß (2006) realizada en el trabajo de Ramírez-Montes y colaboradores (2021) que se presenta en la Tabla 1. A partir de lo que presentan los autores, es posible delimitar el tipo de prácticas o tareas que los profesores deberán poder desarrollar en cada uno de los procesos cognitivos del ciclo, por ende, formarán parte de sus conocimientos y competencias didáctico-matemáticas.

Tabla 1: Articulación de las competencias de modelización con los procesos cognitivos del ciclo de modelización

Competencia de modelización	Competencia para…	Procesos cognitivos
Comprender el problema real y elaborar un modelo basado en la realidad	Hacer suposiciones sobre el problema y simplificar la situación; reconocer las cantidades que influyen en la situación, identificar variables clave; construir relaciones entre las variables; buscar información disponible y diferenciar entre información relevante e irrelevante	(1) Comprender la tarea (2) Simplificar/ Estructurar la tarea

Establecer un modelo matemático a partir del modelo real	Matematizar las cantidades relevantes y sus relaciones: simplificar cantidades relevantes y sus relaciones si es necesario y reducir su número y complejidad; elegir notaciones matemáticas apropiadas y representar gráficamente situaciones	(3) Matematizar el modelo
Resolver preguntas matemáticas dentro de este modelo matemático	Utilizar estrategias heurísticas como dividir el problema en subproblemas, establecer relaciones con problemas similares o análogos, reformular el problema, visualizarlo de forma diferente, variar las cantidades o los datos disponibles, etc.; emplear conocimientos matemáticos para resolver el problema	(4) Trabajar matemáticamente sobre el modelo
Interpretar resultados matemáticos en una situación real	Interpretar resultados matemáticos en contextos extramatemáticos; generalizar soluciones desarrolladas para una situación particular; comunicar soluciones usando lenguaje matemático apropiado y/o dialogar sobre ellas	(5) Interpretar resultados matemáticos
Validar la solución	Revisar críticamente y reflexionar sobre las soluciones encontradas; revisar partes del modelo o repetir el proceso de modelización si las soluciones no se ajustan a la situación; considerar otras formas de resolver el problema o desarrollar soluciones alternativas; cuestionar el modelo en general	(6) Validar los resultados en la situación real

Metodología

Se presenta un estudio cualitativo de tipo exploratorio conformado por una revisión de la literatura, así como el diseño y pilotaje de una situación-problema abierta basada en el ciclo de modelización matemática. Estas fases se organizaron de la siguiente manera:

1. Para la revisión de la literatura, se llevó a cabo una búsqueda por palabras clave en motores de búsqueda, en la que se incluyeron categorías como: a) desarrollo profesional docente, b) modelización matemática, c) formación de ingenieros, d) álgebra lineal y, e) sistemas de ecuaciones lineales. Mediante esta revisión, se ubica un panorama sobre la situación actual de las cuestiones nodales del estudio.
2. Derivado de los hallazgos en la literatura, se definieron las características que debían poseer las situaciones-problemas propuestas, así como la selección del contexto y el establecimiento de la situación que propiciara el trabajo matemático del profesorado para resolverla.
3. Posteriormente, se determinaron tareas esperadas que el profesorado desarrolle al resolver la situación-problema abierta que se propone, asociadas con las competencias de modelización y los procesos cognitivos del ciclo de modelización matemática de Borromeo. La definición de estas tareas esperadas proporciona un marco de referencia para el análisis de las producciones del profesorado en el pilotaje.

4. Luego, se llevó a cabo una actividad exploratoria (pilotaje) con dos profesores de matemáticas de nivel universitario durante dos sesiones de aproximadamente 120 minutos cada una. Se recolectó información mediante un proceso de observación activa, con la participación del observador como conductor de la actividad a través de una técnica de elaboración conjunta guiada por preguntas adecuadas.
5. Finalmente, se efectuó un análisis descriptivo de las tareas realizadas por el profesorado mediante el contraste con las tareas previstas, lo que permite establecer qué estrategias siguen y qué dificultades enfrentan durante la resolución de las situaciones-problemas abiertas.

Resultados

A continuación, se presentan los principales resultados de cada uno de los momentos descritos anteriormente.

Revisión de la literatura

Con respecto a las dificultades en el aprendizaje de los SEL, se ha encontrado que en el contexto escolar se promueve principalmente el estudio y solución de sistemas cuadrados con solución única, privilegiando un abordaje desde un contexto intramatemático y con métodos de solución que se restringen al trabajo con registros algebraicos. Esto dificulta su aprendizaje al desvincular el significado algebraico (ecuaciones) y el geométrico (líneas/planos), promover interpretaciones erróneas de los resultados y la percepción de la solución de los SEL únicamente como un punto de intersección único (Oktaç, 2018; Trigueros et al., 2007).

Adicionalmente, se ha ubicado a la modelización matemática como una de las tendencias en la literatura del campo disciplinar, tanto en el diseño de propuestas de enseñanza como respecto a la formación y desarrollo profesional de los profesores, en especial cuando se refiere a la educación matemática para futuros profesionales de la ingeniería. Con respecto al diseño de propuestas de enseñanza para la formación matemática en ingeniería, diversos estudios (Pizarro, 2020; Rodríguez-Gallegos & Quiroz-Rivera, 2016; Vázquez *et al.*, 2016) coinciden en que su incorporación, acompañada de problemas representativos del futuro quehacer profesional de los estudiantes, favorece una comprensión más profunda y contextualizada de los conceptos matemáticos. Como parte de las actividades de desarrollo profesional, se resalta su incorporación en conjunto con situaciones auténticas y contextos apropiados, el diseño de experiencias que involucren la validación matemática y la reflexión sobre los propios procesos de aprendizaje (Cruz et al., 2020; Dede y Taşpinar, 2021; Ledezma *et al.,* 2024).

La revisión de la literatura realizada permite identificar un escenario en el que las estrategias de enseñanza se encuentran en transformación, impulsadas por la incorporación de la modelización matemática como un enfoque idóneo, particularmente en el estudio de SEL dentro de los programas de formación de ingenieros. En este contexto, se evidencia la necesidad de actualizar y diversificar los conocimientos y estrategias didácticas, mediante la integración de problemas contextualizados, el uso de diversos registros de representación y el fortalecimiento de competencias que articulen contextos reales de la ingeniería con los contenidos disciplinares del Álgebra Lineal como los SEL.

Diseño de la situación-problema abierta

Mediante la información recolectada durante la revisión de la literatura, se proponen directrices que permiten la toma de decisiones para el diseño, de tal manera que este permita:

1. Promover la incorporación de situaciones-problemas auténticas y abiertas que requieran su resolución mediante modelos que consideren el uso de diversos casos de SEL $m \times n$

con coeficientes reales, atendiendo primordialmente aquellos sistemas de forma rectangular y con infinitas soluciones.
2. Incorporar contextos adecuados para la formación de ingenieros que permitan el tránsito de los participantes por cada una de las fases o procesos cognitivos del ciclo de modelización, además de la significación y validación de la solución de un SEL, al resolver las situaciones-problemas planteadas.
3. Fomentar el uso de tecnología digital para la resolución, validación e interpretación de las situaciones planteadas y las soluciones que se encuentran.

Para el diseño de la situación-problema abierta se adaptó la situación planteada en Pochulu (2018) con respecto al estudio del envase para leche con capacidad de un litro. En este caso, se enfoca en la movilización de una ruta de modelización en el contexto del rediseño de las dimensiones de un envase basada en los SEL, redactada como se muestra a continuación:

> La empresa TetraPak® diseña y produce productos de envasado de cartón para la industria alimentaria. Uno de sus principales productos es el *Tetra Brik* ® formado por capas de cartón, plástico polietileno y aluminio con forma de paralelepípedo. Considerando los envases para el almacenamiento de leche con capacidad de 1 litro, analice y argumente si al modificar las dimensiones del envase, pero manteniendo la cantidad de material y forma, se modifica su capacidad. Además, analice las ventajas y/o desventajas que tiene el diseño de envases con diferentes dimensiones. Base su análisis y argumentación en una estrategia matemática.

Para el trabajo con la situación-problema, se les proporciona a los participantes envases de leche reales y cinta métrica. A partir de la situación y el material que se les presenta, se espera que se movilicen las tareas previstas (Tabla 2) al recorrer una ruta de modelización.

Tabla 2: Determinación de tareas previstas para cada competencia de modelización y los procesos cognitivos asociados del ciclo de modelización

Competencia de modelización	Procesos cognitivos	Tareas previstas
Comprender el problema real y elaborar un modelo basado en la realidad	(1) Comprender la tarea (2) Simplificar/ Estructurar la tarea	• Medir el envase real proporcionado como material concreto. • Construir una representación gráfica (hoja de material extendida) del modelo real con las medidas concretas del envase. • Analizar casos particulares para diferentes valores de las dimensiones del envase. • Identificar cantidades que cambian (dimensiones, volumen) y aquellas que permanecen invariantes (área). • Identificar las relaciones entre las diferentes dimensiones que componen el envase. • Construir una representación gráfica (hoja de material extendida) con una generalización para las dimensiones del envase.

Establecer un modelo matemático a partir del modelo real	(3) Matematizar el modelo	• Definir incógnitas (literales) que representen cada una de las dimensiones del envase. • Construir un modelo matemático basado en los SEL, tomando en cuenta las medidas del material como restricción del problema.
Resolver preguntas matemáticas dentro de este modelo matemático	(4) Trabajar matemáticamente sobre el modelo	• Seleccionar un método de resolución adecuado para el SEL planteado. • Identificar el conjunto solución del sistema planteado.
Interpretar resultados matemáticos en una situación real	(5) Interpretar resultados matemáticos	• Identificar las restricciones del conjunto solución con base en el contexto del problema. • Determinar el rango de valores permitidos para la o las incógnitas libres en el conjunto solución del sistema.
Validar la solución	(6) Validar los resultados en la situación real	• Identificar restricciones adicionales para la toma de decisiones (volumen mínimo necesario, condiciones ergonómicas o logísticas del producto). • Argumentar ventajas y/o desventajas de la elección de diferentes dimensiones para el envase.

Actividad exploratoria (pilotaje)

La actividad exploratoria se llevó a cabo durante dos sesiones de trabajo con los profesores, guiándoles mediante el uso de preguntas convenientemente establecidas a partir de sus participaciones. De manera general, los participantes realizaron un ciclo de modelización parcial, desarrollando tareas relacionadas con los tres primeros procesos cognitivos del ciclo de Borromeo, como se muestra en la Tabla 3.

Tabla 3: Tareas realizadas por los profesores en el pilotaje para cada competencia de modelización y los procesos cognitivos asociados del ciclo de modelización

Competencia de modelización	Procesos cognitivos	Tareas realizadas
Comprender el problema real y elaborar un modelo basado en la realidad	(1) Comprender la tarea (2) Simplificar / Estructurar la tarea	• Medir el envase real proporcionado como material concreto. • Construir una representación gráfica (prisma) del modelo real con las medidas concretas del envase. • Calcular el volumen del envase considerando las medidas reales ($V = 1072.5\ cm^3$). • Analizar casos particulares para diferentes valores de las dimensiones del envase.

		• Identificar cantidades que cambian (dimensiones, volumen) y aquellas que permanecen invariantes (área). • Identificar las relaciones entre las diferentes dimensiones que componen el envase. • Construir una representación gráfica (prisma) con una generalización para las dimensiones del envase.
Establecer un modelo matemático a partir del modelo real	(3) Matematizar el modelo	• Definir incógnitas (literales) que representen cada una de las dimensiones del envase. • Construir un modelo matemático para el cálculo del volumen del envase cuando cambia una de sus dimensiones (alto) y dos permanecen constantes. • Construir un modelo matemático para el cálculo del área superficial del envase cuando cambia una de sus dimensiones (alto) y dos permanecen constantes. • Construir un modelo matemático para el cálculo del volumen del envase cuando cambian todas sus dimensiones. • Construir un modelo matemático para el cálculo del área superficial del envase cuando cambian todas sus dimensiones.

Durante la primera sesión, se realizaron tareas relacionadas con la comprensión del problema (situación-problema abierta) mediante la construcción de diferentes casos particulares en donde la elección de las dimensiones se dio de manera arbitraria, variando las medidas tomadas del envase de leche que se les proporcionó, permitiendo establecer algunas ideas con respecto al área superficial y el volumen del envase. A partir de lo anterior, se estableció que algunas de las modificaciones requerirían el uso de una cantidad mayor del material, lo cual no consideraban pertinente para la empresa al representar un mayor costo.

Posteriormente, se planteó un caso donde dos de las dimensiones (ancho y largo) permanecían constantes, mientras que otra variaba (alto). A partir de lo anterior, asignando una literal a la dimensión que varía se plantearon dos ecuaciones (una para el área superficial y otra para el volumen) lo que les permitió establecer, al final de la primera sesión, que no podían encontrar un valor único que permitiera que tanto el volumen como el área permanecieran constantes. Además, mediante la manipulación del material concreto proporcionado se reflexionó sobre imprecisiones en el cálculo del área al no considerar los dobleces que permitían formar el envase.

En la segunda sesión, se revisó el trabajo realizado en la sesión anterior. Mediante el uso de preguntas sobre las tareas realizadas se reflexionó con los profesores sobre la modificación de las dimensiones tomando en cuenta cuestiones sobre el uso del material, cuestiones ergonómicas y logísticas del rediseño del envase.

A partir de dichas reflexiones se propuso un caso en el que todas las dimensiones del envase podían cambiar, estableciendo ecuaciones que les permitían representar el volumen (restringido a 1000 cm^3) y el área total (sin encontrar un valor concreto al cual restringirse).

Estos últimos planteamientos permitieron a los participantes establecer el área de la hoja de material como una de las restricciones que debían permanecer sin cambios para el establecimiento de ecuaciones que les posibilitaran la construcción del modelo matemático.

Comentarios finales

La implementación de la actividad exploratoria reportada ha permitido constatar que la propuesta promueve tareas que facilitan el tránsito de los participantes por diversos procesos cognitivos del ciclo de modelización (Borromeo Ferri, 2018) y, por ende, el desarrollo de las competencias de modelización asociadas a ellos (Maaß, 2006). Aunque en esta exploración no se concretó un ciclo de modelización completo, el uso de preguntas adecuadas sobre el trabajo de los participantes puede guiarles en la resolución de la situación-problema abierta, propiciando el tránsito por cada uno de los procesos cognitivos.

Adicionalmente, el empleo de problemas abiertos, como el propuesto, moviliza diversas estrategias matemáticas, lo que lo convierte en una situación matemáticamente rica y adecuada para un enfoque de modelización.

Finalmente, el pilotaje de la situación-problema abierta ha permitido identificar posibles mejoras en la formulación de la situación problema, así como la incorporación de recursos adicionales para enriquecer la actividad. En particular, el análisis de los casos concretos facilitó a los participantes la comprensión del problema, la formulación de suposiciones y el reconocimiento de relaciones clave; por ello, integrar materiales para construir modelos físicos de dichos casos representa una mejora viable.

Agradecimientos

Se agradece a la Secretaría de Ciencia, Humanidades, Tecnología e Innovación (Secihti) por el apoyo que ha brindado con la beca número 4020264.

Teacher noticing activities are common in teachers' professional learning programs, and research is needed to understand what they afford. Teachers' annotations of representations of practice offer a useful data source for studying noticing, yet many analyses rely on frequency-based methods that treat noticing dimensions as independent categories. Such approaches have limited capacity to capture how different aspects of noticing are coordinated within a single lesson moment. This paper explores the use of frequency-based analysis and Epistemic Network Analysis (ENA) to investigate how dimensions of teacher noticing relate to each other in the annotations of storyboard-based lesson representations. We apply and compare both approaches to illustrate their complementary analytic affordances.

Keywords: Teacher Noticing, Research Methods, Professional Development, Instructional Activities and Practices

Introduction

Teacher noticing has emerged as a central construct in research on teacher education and professional development (König et al., 2022). Lesson annotations—written comments attached to specific moments in a lesson representation—constitute a tractable data source for investigating teacher noticing, as they provide linguistically externalized and event-attached representations of what teachers attend to and their interpretations of it (Brown et al., 2024). Annotations do not capture the moment-by-moment process of noticing; rather, they represent the state of noticing at a particular instructional moment.

Noticing is widely theorized as multidimensional, with its dimensions understood to be interrelated (Rotem & Ayalon, 2022; Scheiner, 2016; van Es & Sherin, 2025). Researchers have developed analytic frameworks intended to capture its multiple facets. For example, Rotem and Ayalon (2022) distinguished cognitive, affective, and social dimensions of teacher noticing. However, conceptualizing noticing as multidimensional and interrelated has not been matched by analyzing it as such. Many studies code these dimensions separately, offering limited insights into how the dimensions of noticing are linked and coordinated. In fact, recent work suggests that how these dimensions are connected, not just how often each appears, can distinguish the noticing profiles of different professional communities. For instance, Stahnke and Gegenfurtner (2025) found that expert teachers' noticing tightly linked decision-making to student behavior and learning, whereas novices' centered on perceiving and orienting themselves within the scene. Examining this kind of relational structure, however, remains uncommon—a gap that is partly methodological: Many noticing-related studies use frequency-count approaches as independent categories, which limits the capacity to examine how they interact (Csanadi et al., 2018).

Together, these considerations raise a methodological question: How can analytic methods be aligned with conceptualizations of noticing as a multidimensional construct involving

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

coordinated patterns? Addressing it requires tools that model relationships among dimensions rather than their frequencies alone. In this paper, we compare Epistemic Network Analysis (ENA) with frequency-based analysis to demonstrate how ENA can offer complementary insight into teachers' noticing through their annotations of representations of practice.

Literature Review

Methods of Analyzing Teacher Noticing

Teacher noticing research often relies on frequency-based analyses (Stahnke & Gegenfurtner, 2025). In these studies, noticing is coded into predefined categories, and shifts in category frequencies serve as primary indicators of teacher growth. For example, van Es and Sherin (2008) interpreted teachers' increased frequency of references to student mathematical thinking as evidence of growth in learning to notice. Similarly, research comparing novice and expert teachers frequently draws on counts of coded events, statements, or linguistic features to characterize their differences in noticing. For instance, Wolff et al. (2016) analyzed frequencies of teachers' eye movements and their use of mental and perceptual words to infer the cognitive richness of expert and novice teachers' perceptions of problematic classroom management. Although frequency-based analysis can describe distributions across noticing dimensions, it captures these dimensions in isolation and offers limited insight into how teachers coordinate them within a single interpretive moment (Csanadi et al., 2018).

Recent studies have attempted to address the multidimensional nature of noticing, yet most remain grounded in additive or aggregative logics. Researchers have addressed interactions among dimensions by either sacrificing analytic nuance or introducing increasingly complex categorical structures. For instance, Stahnke and Blömeke (2021) developed a nuanced framework capturing multiple subcategories of teachers' perception, interpretation, and decision-making (PID) in their focus of analysis. Although cross-coding was used to capture interactions among dimensions, the framework was ultimately collapsed into broader categories in the interest of analytic feasibility. As a result, relationships among finer-grained dimensions were examined primarily through aggregated category frequencies rather than through explicit modeling of their coordination. Other studies have sought to preserve multidimensionality by constructing combinations or composite categories to represent patterns of co-occurrence. For instance, Rotem and Ayalon (2022) coded teachers' written reflective reports across multiple cognitive, affective, and social dimensions of noticing and analyzed patterns of co-occurrence with 11 possible dimensional combinations. Similarly, to capture teachers' coordination among different aspects of noticing, Amador et al. (2025) included a dimension termed *specificity*, which was designed to reflect how teachers connected their comments to particular individuals or instructional elements, such as student thinking. While these approaches allow for some degree of interaction among dimensions, they do by multiplying categories or constructing partial combinations—increasing coding burden while capturing only a limited subset of possible relational configurations.

The Application of Epistemic Network Analysis

Epistemic Network Analysis (ENA) was originally developed to model learning as changes in the relational structure among elements of thinking and practice (Shaffer et al., 2016). It is grounded in epistemic frame theory, which holds that members of a community of practice develop shared patterns of knowledge, skills, values, and ways of reasoning that shape their participation in professional activity (Shaffer, 2006). In teacher education, ENA has been used to study changes in teachers' cognitive structures by modeling shifts in the relational organization of discourse across different stages of professional development. For example, Zhang and Hsu

(2025) applied ENA to analyze in-service teachers' coordination of epistemic frame elements across four community activities. By constructing and comparing network representations at successive time points, they traced how connections among these elements evolved as teachers engaged in collaborative reflection and lesson design. Zhang et al. (2022) similarly applied ENA to compare student teachers' negotiation processes during collaborative problem solving before and after different online learning tasks. By coding discourse into four collaborative problem-solving dimensions and modeling their co-occurrence patterns, the authors examined how relational structures differed across student groups and over time. Together, these studies suggest that ENA is well-suited for investigating and tracing the state of noticing as reflected in co-occurrence patterns among noticing dimensions—offering a relational perspective that extends beyond distributional summaries.

A handful of studies exist that apply ENA to explore the concepts related to teacher noticing, and most of them analyze teacher talk. Farrell et al. (2022) used ENA to examine how student teachers connect noticed events to pedagogical knowledge, showing differences between novices and others who exhibited more sophisticated reasoning patterns. Similarly, Stahnke and Gegenfurtner (2025) demonstrated that going beyond showing the extent to which expert and novice teachers attend to specific components, ENA can reveal expert-novice differences in their mental models of classroom management representations. Unlike synchronous talk turns, asynchronous annotations are produced without the time pressures of live interaction, freeing teachers from immediate interactional demands and potentially enabling more layered and comprehensive articulation of what they notice. These characteristics suggest that teacher noticing as exhibited in annotations is well-suited for relational analysis—that is, uncovering how noticing dimensions co-occur—rather than being treated as a set of independent, countable dimensions.

Analytic Framework

Aligned with the view that noticing should be studied multidimensionally, this paper draws on two complementary dimensions: the content teachers notice and the stance they adopt toward what they notice (van Es & Sherin, 2008, 2021). Research on representations of practice assumes that teachers can situate themselves within the instructional activity being depicted (Chieu et al., 2015). Here, stance serves as an indicator of presence—reflecting the degree of participants' involvement in the depicted experience (Tamborini & Skalski, 2012). When annotating representations of practice, participants may position themselves as active participants or as more detached observers of it (Herbst & Chazan, 2006; Schwarts et al., 2025). Building on Chieu et al.'s (2015) use of evaluation, alternativity, and reflection to capture stance, we applied and adapted this framework to our example annotations. Specifically, *evaluation* characterizes instances in which teachers position themselves outside the depicted activity to appraise the lesson as an object (e.g., *"A good approach by the teacher to collect similar ideas," T104*), *reflection* captures moments where teachers position themselves between participation and observation by interpreting underlying instructional logic or expressing uncertainty (e.g., *"I'm wondering what are the other students doing while the teacher is having these discussions with the pairs […], T101)*, and *alternativity* refers to teachers' positioning within the lesson to propose plausible alternative actions (e.g., *"Again the teacher could ask 'Are [you] sure that the triangles are congruent? Can you prove it?'," T106)*.

Our content coding framework draws on several existing frameworks (e.g., Star & Strickland, 2008; Amador et al., 2025) and is organized around the instructional triangle (Cohen et al., 2003). Accordingly, annotations tend to reflect teachers' attention to exchanges among

teachers, students, and content. In this paper, the content-related codes that have been used are *instructional practice*, *communication*, *mathematical content,* and *student learning*. We take them to mean, respectively, teachers' attention to instructional design and teachers' pedagogical moves (e.g., *"isn't the task first individual and then partnering up? I find the instruction a bit confusing," T101*), to classroom discourse and interactional features such as wording of questions/responses (e.g., *"Student 1: Since it's a competition, I guess everyone should have an equal chance to win the prize; right? Teacher: Yes, that's correct […]," T103*), to mathematical problems, representations or ideas (e.g., *"Why is C a circle center and of what circle? This is exactly what needs to be proven?", T104*), and to students' engagement, progress, and development (e.g., *"[...]I'm also wondering if students made the connection between their task and the theorem," consensual annotation*).

Methods

Description of the Example Data

The data are drawn from a professional development program called Story*Circles*. In Story*Circles*, teachers collaboratively composed and annotated a mathematics lesson in storyboard format within a multimedia environment (Herbst & Milewski, 2018). Storyboards, defined as structured visual representations of classroom events, offer a balance between the symbolic economy of written cases and the rich but potentially unwieldy detail of video (Herbst et al., 2014). Storyboards reduce incidental detail and foreground key instructional actions and discourse, making the underlying organization of classroom events more perceptible.

Our analysis draws on two lesson commentaries produced by a group of six teachers: an Individual Lesson Commentary (ILC) and a Consensual Lesson Commentary (CLC), developed while reviewing the same storyboard of the *Midpoint of the Hypotenuse* lesson created by another group. Over three weeks, teachers engaged in asynchronous individual work and weekly synchronous meetings. Asynchronous work involved individual annotation of the storyboard, while synchronous meetings provided opportunities to review annotations, discuss them collectively, and interact with peers and the facilitator. By the end of the three weeks, teachers were expected to reach consensus on the annotations to be shared with the group that had created the storyboard. The ILC was completed prior to the second synchronous meeting, with teachers independently annotating the storyboard. Annotations unrelated to stance or content (e.g., "Left a blue pin") were excluded, yielding a final dataset of 47 ILC annotations across 35 frames. The CLC was derived from ideas agreed upon during the final two synchronous meetings and represents the group's shared feedback. Across the same 35 frames, the group produced 22 consensual annotations. All annotations were done on Anotemos, an online, social, and multimodal media annotation software application (www.anotemos.com).

Coding

Each annotation was coded for stance and content using binary indicators (1 = present, 0 = absent). Because a single annotation could express more than one idea, multiple stance codes and multiple content codes could be assigned to the same annotation. This multi-label approach is consistent with prior work using annotation-based coding in related research (e.g., Amador et al., 2025). The first author and a research assistant coded the same set of annotations (n = 69 units) independently. Agreement was consistently high, with Cohen's kappa values ranging from .75 to .94 across all seven categories, indicating substantial to near-perfect reliability.

Two Methodological Approaches

We illustrate how the same corpus of annotations can be analyzed to investigate teacher noticing. We conducted both a frequency-based analysis and ENA to illustrate what information can be extracted from these two approaches.

Frequency-Based Analysis

The first approach we used here is frequency-based analysis, which is the typical method for describing and analyzing teacher noticing. For frequency-based analysis, a single annotation serves as the analytical unit. For each annotation, we counted the total number of each stance and content code and computed the proportion of annotations in which each code appeared. Because CLC was produced collectively and not attributable to individual teachers, statistical comparison between the two sets of data at the participant level is not appropriate. Instead, we report the results descriptively.

Table 1: Frequency and Proportion of Stance and Content of Noticing in the Individual Lesson Commentary (ILC) and the Consensual Lesson Commentary (CLC)

Dimensions	Codes	Frequency (Proportion)	
		ILC ($N = 47$)	CLC ($N = 22$)
Stance	Evaluation	19 (0.40)	3 (0.14)
	Reflection	17 (0.36)	3 (0.14)
	Alternativity	30 (0.64)	19 (0.86)
Content	Instructional Practice	21 (0.45)	8 (0.36)
	Communication	25 (0.53)	13 (0.59)
	Student Learning	11 (0.23)	1 (0.05)
	Mathematical Content	8 (0.17)	0 (0.00)

Table 1 shows the descriptive results of stance and content code frequencies in both ILC and CLC. In both conditions, alternativity is the most prevalent stance dimension, particularly in CLC (86%), indicating a strong emphasis on proposing alternative ways of teaching the lesson. Evaluation and reflection are more common in ILC (40% and 36%) than in CLC (both 14%). With respect to content, communication is the most frequent dimension in both ILC (53%) and CLC (59%), followed by instructional practice. In contrast, student learning and mathematical content are relatively more frequent in ILC (23% and 17%) than in CLC (5% and 0%). Overall, individual annotations exhibited a broader distribution of various stance and content dimensions, whereas collective annotations were more strongly centered on alternativity and communication.

Epistemic Network Analysis

Analytic procedure. In ENA, stanzas define the temporal window within which codes are treated as co-occurring, and units of analysis are defined as the level at which co-occurrences are aggregated into networks (Shaffer et al., 2016). In this paper, a stanza is defined as the set of annotations produced by a given teacher (unit of analysis) on a single lesson frame. This choice treats each frame as a contextually bounded lesson moment, capturing how teachers integrate stance and content codes while attending to that moment (Shaffer, 2012).

Although frequency-based analysis and ENA were based on the same coded corpus, the data were parsed differently. For frequency-based analysis, each coded annotation was treated as an independent instance, and codes were aggregated across frames. In contrast, for ENA, annotations were first grouped by stanza, and codes were analyzed as co-occurring within these

contextually bounded moments. For instance, if a teacher left three annotations on the same storyboard frame, frequency-based analysis treats them as three independent instances, whereas ENA treats them as one integrated noticing episode of that lesson moment and models the co-occurrence of noticing dimensions within it.

Then, for each unit (in our case, six individual teachers and one collective group), ENA constructs a co-occurrence matrix representing how often codes appeared together within these windows. These matrices are normalized and projected into a lower-dimensional space using singular value decomposition to generate the weighted network positions shown in the diagrams. The network is then modeled via association matrix representations (Bowman et al., 2021). Each unit thus has its own noticing network, which can be aggregated to represent shared group tendencies. In the ILC, six individual networks were generated and then averaged. This aggregation is theoretically justified: Teachers completed their annotations following an initial group meeting in which the facilitator collectively framed the task, establishing a shared interpretive context despite the annotations being produced individually and asynchronously.

What ENA reveals. Several types of information can be derived from the ENA analysis, which we illustrate using the example networks in Figure 1. First, nodes represent noticing stance and content codes, and node size indicates the relative frequency with which each code appears. Figure 1a presents the mean epistemic network for ILC, whereas Figure 1b presents the network for CLC. Both networks share the same layout, allowing for direct comparison of relational patterns. In the individual network, the most frequently represented dimensions include all three stance categories and instructional practice, with mathematical content being the least frequently annotated. In the consensual network, alternativity, communication, and instructional practice dominate the collective noticing, indicating a more focused pattern.

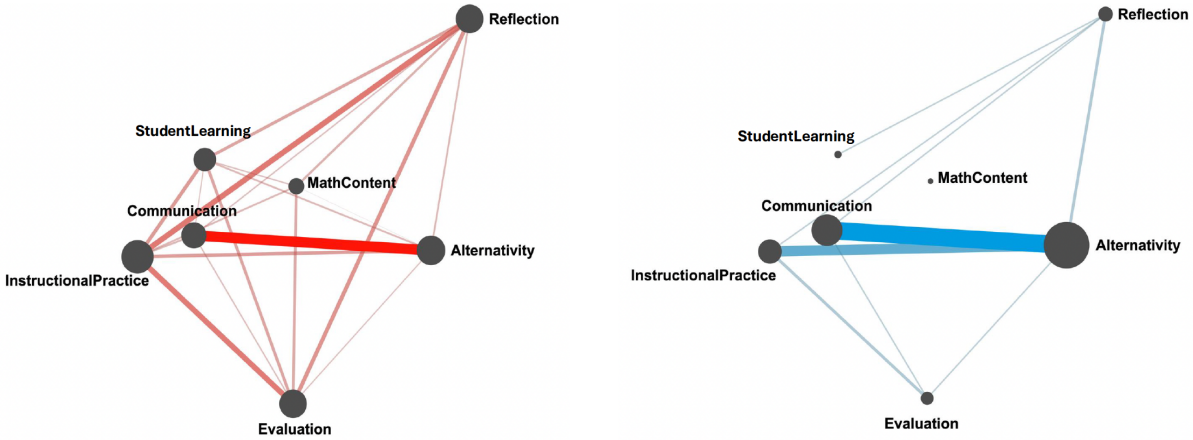

Figure 1: Mean Epistemic Networks of Teacher Annotations in (a) the Individual Lesson Commentary (ILC) and (b) the Consensual Lesson Commentary (CLC)

Second, edges represent the strength of co-occurrence between code pairs, reflecting how consistently two codes appear together within the defined stanza, averaged at the unit level. Edge thickness indicates stronger within-stanza co-occurrence, not simply higher code frequencies. In both networks, the strongest connection appears between alternativity and communication. In the individual network, most nodes are moderately integrated with others, reflecting a relatively distributed structure. Within the content and stance dimensions, relatively strong connections

appear between instructional practice and student learning, and between reflection and evaluation. In contrast, the consensual network exhibits a more centralized configuration, with co-occurrences concentrated among communication, instructional practice, and alternativity.

Finally, in addition to edge weights, nodes located closer together share common variance, even when their direct co-occurrence is relatively weak. In other words, closer nodes change in similar ways across teachers and frames. In the example, such pairs are instructional practice and communication, communication and student learning. Interpretively, this indicates that teachers who attend to instructional practice are also communication-aware, even if they mention these in separate annotations. In addition, teachers who mention students' learning also tend to attend to how ideas are communicated in the lesson.

Discussion

In this section, we compare the insights derived from frequency-based analysis with those generated by ENA to illustrate the affordances of a relational approach. Our goal is not to generalize the ENA findings but to demonstrate how ENA can help researchers rethink assumptions often embedded in frequency-based analysis.

First, the frequency results in Table 1 show a modest decrease in references to instructional practice from the individual to the collective annotation (from 45% to 36%), which might be interpreted as indicating reduced attention to teaching practice in a collective context. From this perspective, one might conclude that collective annotation contexts discourage teachers from engaging deeply with instructional design. ENA, however, complicates this interpretation by considering a second layer simultaneously. As can be interpreted from Figure 1, when annotating individually, this group of teachers primarily evaluates instructional practices (evaluation) or expresses uncertainty or interpretations about them (reflection). In collective annotation, rather than simply attending less to instructional practice, teachers shift toward proposing alternative approaches to teaching practice. Thus, ENA suggests a more nuanced interpretation of noticing of practice across contexts, which is challenging to capture solely through frequency analysis.

Beyond context-level shifts, a comparable divergence between frequency-based analysis and ENA is evident in how we interpret internal relationships between stance and content. As Martinez et al. (2017) note, frequency-based results invite additive interpretation—that is, treating highly prevalent dimensions as structurally associated. Our data challenges this logic with two instances. First, within the stance dimension, frequency analysis (Table 1) indicates that alternativity is the most prevalent category, with reflection and evaluation occurring at slightly lower but still substantial rates. Since teachers may take multiple stances, one might reasonably expect alternativity to be structurally linked with reflection or evaluation. However, ENA reveals that alternativity rarely co-occurs with either stance, whereas reflection and evaluation exhibit a stronger association, suggesting that when annotating individually, evaluative and reflective stances tend to cluster together, while alternativity occurs solely in annotations without much cumulative reasoning. Similarly, this fallacy also extends to cross-dimensional relationships. Frequency counts indicate that alternativity is the most prevalent stance, while communication and instructional practice are the most frequent content categories. On this basis, one might expect alternative suggestions concerning instructional practice or teacher-student interactions to dominate. ENA reveals, however, that individual teachers in this group more frequently direct alternative suggestions toward classroom dialogue and rarely toward instructional practices (Figure 1a). Across both contexts, the alternativity-communication linkage emerges as the strongest and most stable connection.

Finally, we briefly consider how ENA opens up new relational questions about teacher noticing. Although additional data are needed to examine these questions systematically, ENA highlights patterns that extend beyond distributional trends. For example, the combination of clustered evaluative-reflective stances and the relative isolation of alternativity of ILC suggests the need for researchers to design individual annotation tasks that better support and capture cumulative, integrative reasoning. Similarly, why do teachers consistently orient alternative suggestions toward classroom dialogue across contexts rather than toward instructional design? One possible explanation lies in the representational features of storyboard-based lessons, which render dialogue static and visually accessible and may orient teachers toward communicative aspects of instruction (Herbst et al., 2014; Herbst & Kosko, 2014). These observations illustrate how ENA enables researchers to generate relational hypotheses about teacher noticing that would be difficult to formulate on the basis of frequency analysis alone.

This study examined factors influencing mathematics teacher burnout using a cross-sectional sample of 358 mathematics teachers in Oklahoma. Multiple regression analyses were conducted for each burnout dimension: exhaustion, mental distance, cognitive impairment, and emotional impairment. Mathematics teaching anxiety emerged as a consistent positive predictor across all models. Several aspects of the school environment, including staff affiliation, administrative team support, and opportunities for professional learning, were negative predictors of burnout. Selected demographics and teaching background variables were also significant, with age, loss of planning time, grade level taught, class size, and behavioral management style predicting burnout dimensions. These findings highlight the importance of mathematics-specific affective factors and the school environment for understanding mathematics teacher burnout.

Keywords: Affect, Emotion, Beliefs, and Attitudes; Teacher Beliefs

According to Sutcher et al. (2016), teacher attrition is one of the main contributors to teacher shortages, which adversely affects districts financially (Barnes et al., 2007). Teacher burnout is correlated with teacher intentions/motivation to quit the profession (Leung & Lee, 2006; Skaalvik & Skaalvik, 2017), which makes it an important area of research. This is particularly true given the ongoing teacher shortage nationally (Learning Policy Institute, 2025a) and in the state in which the study was conducted (Oklahoma State School Board Association, 2022). Prior literature notes that a variety of factors influence burnout, such as social support and working environment (Sohail et al., 2023). However, a better understanding of a variety of factors influencing burnout is needed, particularly in areas of critical need, such as mathematics, which is experiencing a teacher shortage in 40 states (Learning Policy Institute, 2025b). It is also important to explore burnout as it relates to the concerns and perceptions in today's climate, which could greatly differ from those in previous decades as well as pre-COVID. The purpose of the current study is to examine which demographic, school, and affective factors are predictive of mathematics teachers' levels of burnout

Demographic/School Factors

Prior research provides evidence for different contributors to teachers' reported burnout. For example, Fisher (2011) found that novice teachers (less than 5 years) reported higher levels of burnout than more experienced teachers. Factors which may contribute to novice teachers leaving the profession include isolation, challenging classroom behaviors, and an overwhelming feeling of depersonalization (Hogan & White, 2021). This finding was similar to other work noting that burnout was a predictor of novice teacher turnover (Perrone et al., 2019). Conversely, Nguyen and Kremer (2022) noted that burnout seems to be cumulative, where more experienced teachers report higher levels of burnout than novice teachers. Collectively, these findings suggest burnout develops differently across career stages. Novice teachers are more susceptible to acute burnout with respect to professional demands, whereas experienced teachers exhibit cumulative burnout from prolonged exposure to institutional pressures. As a result, burnout may be represented as a career-long process rather than a standalone symptom.

Other work indicates that certain disciplines and grade level bands correlate with higher levels of teacher burnout. Specifically, secondary STEM teachers experienced higher levels of dissatisfaction and burnout in a study with over 30,000 teachers (Nguyen & Kremer, 2022). School- and classroom-level factors also influence teacher burnout. For example, higher numbers of students correlated with higher levels of burnout (Fisher, 2011). Additionally, administrative support has also been shown to be inversely related to teacher burnout (Brunsting et al., 2014). With research noting that more than 30% of teachers experience high levels of burnout (Molero Jurado et al, 2019), burnout is an urgent concern for the field given its association with teacher attrition. Consequences of high levels of burnout experienced by teachers are of particular concern in mathematics classrooms, where teacher shortages have been associated with student achievement (Siff & Song, 2025). Because mathematics functions as a gateway discipline into other areas of study, disruptions in teacher availability may have negative implications on student achievement; moreover, understanding burnout is critical not only as a means for teacher retention but also for equitable access to student educational outcomes (Arens & Morin, 2016).

Affective Factors

Self-efficacy is one of the affective factors that has repeatedly been correlated with teacher burnout (Shimony et al., 2022; Skaalvik & Skaalvik, 2007). Skaalvik and Skaalvik (2007) noted that "emotional exhaustion may result in reduced accomplishments, which again may affect self-efficacy negatively" (p. 621), indicating that burnout and efficacy may have a reciprocal relationship. Other work related to affect found a negative relationship between professional identity and teacher burnout (Li et al., 2023). This result aligns with the connection that professional identity has with teacher attrition, finding "that emotional burnout was the most salient pattern for dropout teachers" (Hong, 2010, p. 1541). Given the connection to emotion, it is not surprising that burnout and anxiety are also strongly correlated (Koutsimani et al., 2019). Extending this interpretation, professional autonomy has been proposed as a protective condition, with greater instructional-making authority associated with lower levels of "at least one component of burnout" (Farber & Bishop, 2025, p. 18). Collectively, affective and motivational factors including self-efficacy, professional identity, emotion, and anxiety appear interconnected in forming teachers' experiences of burnout rather than serving as independent influencers. By exploring background, school, and affective factors in conjunction, we can develop a better understanding of what contributes to mathematics teacher burnout.

Methods

Participants

A Qualtrics link was sent out to a listserv of 37,071 teachers in Oklahoma. There were 6,747 returned or error messages. Responses were collected from 4,136 teachers who agreed to participate in the study. After the data were cleaned and responses with large portions of missing entries were removed, the sample was reduced to 3,567, of which 358 identified themselves as mathematics teachers when given the options of math, science, or elementary teacher. It is this subsample of mathematics teachers that was the focus of the current study. When asked which grade levels taught, 31(9%) indicated K-12, 134 (37%) grades 6-9, 37 (10%) grades 6-12, and 156 (44%) grades 9-12. With regard to gender, 21% identified as Male and 78% as Female. Participants were between the ages of 20 and 71+. Three percent of the sample indicated they were of Hispanic origin. With regard to race, 85% indicated they were White, 9% Native American, 3% Black or African American, 2% Asian, 1% Multicultural or Other.

Data Collection and Analysis

Demographic and school background variables. In this study, demographic and background variables included gender, race/ethnicity, age, grade level range currently teaching, number of years of teaching experience, highest level of education, and school locale (rural, town, suburb, city, virtual). We also asked teachers to indicate where they were teaching in the area they were certified, as well as if they were currently teaching in an area that aligned with their Bachelor's or Master's degree. Finally, we asked about the typical class size, whether they had a planning period, and how often they lost their planning period due to other school activities (e.g., IEP meetings, covering another class).

Teacher burnout. Burnout was measured using the Burnout Assessment Tool (BAT; Schaufeli et al., 2020), which conceptualizes burnout as a multidimensional construct consisting of four core symptoms. Exhaustion reflects a severe loss of energy (e.g., "At work, I feel mentally exhausted") and demonstrated strong internal consistency in the present sample (α = .89). Mental Distance captures psychological detachment and aversion toward one's work and showed good internal consistency (α = .81). Emotional Impairment represents difficulties regulating emotional responses at work (e.g., "At work, I feel unable to control my emotions") and demonstrated strong internal consistency (α = .85). Cognitive Impairment reflects problems with attention, concentration, and memory and also showed strong internal consistency (α = .86). These reliability estimates are consistent with those reported in the BAT manual and support the use of the four interrelated dimensions as indicators of overall burnout.

Classroom management. Classroom management was measured using the Behavior and Instructional Management Scale (BIMS; Martin & Sass, 2010), a Likert-type instrument that assesses teachers' approaches to managing classroom behavior and instruction. The Behavior Management subscale reflects teachers' use of rules, reward systems, and responses to student misbehavior to maintain classroom order and demonstrated strong internal consistency in the present sample (α = .83). The Instructional Management subscale captures the extent to which teachers employ structured, teacher-directed instructional practices versus more student-centered and interactive approaches and showed acceptable internal consistency (α = .77). Example items include "I firmly redirect students back to the topic when they get off task" and "I nearly always use group work in my classroom." Consistent with the original scoring procedures, several Instructional Management items were reverse scored.

Rurality. For the present sample, internal consistency reliability was examined for the five RRTWLLES school-environment subscales used to represent rurality (Dorman et al., 2015). Staff Affiliation reflects the level of collegial support and sense of belonging among teachers, Administration Team Support represents the extent to which school leadership provides relational and instructional support, Mission Consensus refers to shared agreement among staff regarding school goals and direction, Opportunities for Professional Learning captures access to and facilitation of professional development despite geographic isolation, and Resource Adequacy indicates the availability of instructional, technological, and material resources. The Opportunities for Professional Learning subscale included reverse-scored items addressing barriers related to geographic isolation, whereas the remaining subscales consisted of positively worded items. Cronbach's alpha coefficients indicated strong reliability for Staff Affiliation (α = .87), Administration Team Support (α = .90), and Mission Consensus (α = .92), and acceptable reliability for Resource Adequacy (α = .74) and Opportunities for Professional Learning (α = .71). These values were largely consistent with those reported in the original validation study and suggest that the subscales demonstrated adequate to high internal consistency for use in analyses.

Professional mathematics identity. Teaching professional mathematics identity was measured using the Mathematics Teacher Identity scale (Cribbs & Utley, 2024), a Likert-type instrument that captures teachers' sense of self as mathematics educators through three subconstructs: Recognition, Interest, and Competence/Performance. Recognition reflects the extent to which individuals view themselves, and perceive others viewing them, as mathematics teachers; which demonstrated strong internal consistency in the present sample ($\alpha = .89$). Interest captures teachers' enjoyment of and desire to engage in thinking about and teaching mathematics and also demonstrated strong internal consistency ($\alpha = .91$). Competence/Performance represents beliefs about one's ability to understand and effectively teach mathematics and showed excellent internal consistency ($\alpha = .92$). The overall scale showed excellent reliability ($\alpha = .95$), consistent with the original validation study. Example items include "I can see myself as a math teacher" and "I am confident I can teach math well."

Mathematics teaching anxiety. To measure mathematics teaching anxiety, the Anxiety about Teaching Mathematics scale developed by Hadley and Dorward (2011) was used. This instrument consists of 12 Likert-type items (1 = no anxiety to 5 = extremely anxious) designed to assess teachers' anxiety related specifically to teaching mathematics, with responses summed to reflect overall levels of anxiety, where higher scores indicate greater anxiety. The items capture anxiety associated with preparing for instruction, teaching mathematical content, responding to student thinking, communicating with parents and administrators about mathematics, and anticipating student assessment outcomes. Example items include "Working out math equations on the board in front of a class of students" and "Having a surprise evaluation by an administrator during a math lesson you are teaching." For the present sample, the scale demonstrated strong internal consistency ($\alpha = .90$), which is consistent with the reliability reported in the original study.

Teaching self-efficacy toward mathematics. Mathematics teaching self-efficacy was measured using the Mathematics Teaching Efficacy Beliefs Instrument (Unfried et al, 2022). All items were rated on a 5-point Likert scale (1 = strongly disagree to 5 = strongly agree). This construct consists of two subscales: Personal Mathematics Teaching Efficacy Beliefs (PSTEB), which assesses teachers' confidence in their ability to effectively teach mathematics, and Mathematics Teaching Outcome Expectancy Beliefs (STOEB), which reflects beliefs about the extent to which effective mathematics teaching can influence student learning outcomes. Example items include "I know how to teach mathematics concepts effectively" and "When a student does better than usual in mathematics, it is often because the teacher exerted a little extra effort." For the present sample, both subscales demonstrated strong internal consistency (PSTEB $\alpha = .80$; STOEB $\alpha = .84$).

Stepwise linear regression analysis was used to create models examining how demographic variables, teaching experience, and mathematics-related constructs were predictive of teachers' levels of burnout. Four models were tested using different categories of burnout examined in the current study (Exhaustion, Mental Distance, Cognitive Impairment, and Emotional Impairment). Prior to data analysis, simple random imputation was used to create a complete dataset (Schlomer et al., 2010) as appropriate when data are determined to be missing completely at random.

Results

In order to examine which factors were predictive of mathematics teachers' levels of burnout, a stepwise regression analysis was performed for each category of burnout: Exhaustion, Mental Distance, Cognitive Impairment, and Emotional Impairment. Models were created by first

adding all variables of interest and then removing variables until only significant items remained. Variance Inflation Factor (VIF) was also used to determine if any multicollinearity existed between variables in the model, with values being lower than 2 for all variables included in the final models. Table 1 provides an overview of all four models, with empty cells indicating non-significance.

Table 1: Background, School, and Affective Factors Predicting Mathematics Teacher Burnout

Variable	Exhaustion	Mental Distance	Cognitive Impairment	Emotional Impairment
	Estimate (SE)	Estimate (SE)	Estimate (SE)	Estimate (SE)

Only one demographic variable was significant for any of the models. Age was shown to be a negative predictor for mental distance (β =-.05), meaning that teachers reporting a higher age had lower levels of burnout due to mental distance. The opposite result was evident for emotional impairment, where age was a positive predictor (β =.05) in the model. Three school/teaching background variables were predictive of burnout. Losing planning time due to other school activities was positively predictive of burnout due to exhaustion (β =.10). In addition, teaching middle grades mathematics (6–9) exclusively as well as larger class sizes were both positive predictors for burnout related to cognitive impairment, (β =.17) and (β =.01), respectively.

Five constructs were found to predict one of the four categories of burnout. Mathematics teaching anxiety was a positive predictor for all four models, indicating that higher levels of anxiety predicted higher levels of burnout. The highest estimate for mathematics teaching anxiety was in the model for emotional impairment (β =.42) followed by cognitive impairment (β =.30). Several factors related to rurality were also found to be predictive of burnout, with staff affiliation negatively predicting burnout related to exhaustion (β =-.19), mental distance (β =-.22), and emotional impairment (β =-.14). Administration team support was a negative predictor for exhaustion (β =-.18) and mental distance (β =-.22). Finally, opportunities for professional learning were a negative predictor for mental distance (β =-.17), cognitive impairment (β =-.28), and emotional impairment (β =-.19). The final significant variable was behavioral management, which positively predicted mental distance (β =.12) and was a negative predictor for emotional impairment (β =-.13).

Discussion

Results provide insight into factors influencing teachers' reported levels of burnout. While age negatively predicted mental distance, indicating that older teachers report lower levels of mental distance, they also reported higher levels of emotional impairment. These results might account for the contradictory findings in prior research (Fisher, 2011), particularly if only one measure of burnout was considered. It should be noted that age had low estimates, indicating a small effect on burnout for both models where age was significant. Losing planning to other school activities and higher class sizes were both positive predictors for burnout, exhaustion, and cognitive impairment. Similar to other findings, the effect of class size on burnout was minimal (Saloviita & Pakarinen, 2021). It is important to keep in mind that even with some findings showing small estimates, these various factors also have a cumulative influence on burnout, which does not negate their significance. Higher levels of cognitive impairment were noted by 6th-9th grade teachers, which is more nuanced than prior work, noting higher levels of burnout in secondary teachers more generally (Nguyen & Kremer, 2022).

With regard to affective variables, mathematics teaching anxiety was the only significant variable across all four models for burnout. In addition, the beta values indicate moderate-level effects. This finding is consistent with other research exploring anxiety more generally (Koutsimani et al., 2019). Given the important role that anxiety has on burnout, future work might explore general teaching and individual anxiety alongside disciplinary anxiety. In addition, researchers might explore ways of reducing anxiety to help reduce burnout and subsequent attrition. Given the high rural population of the state in which the study was conducted (52%, not including rural serving schools), aspects of rurality were important to consider. Three related factors were found to be significant: staff affiliation, administrator support, and opportunities for professional learning. Staff affiliation was negatively predictive of exhaustion, mental distance, and emotional impairment. Other work notes the important role that relationships have on teacher burnout (Meredith et al., 2020), particularly the connection teachers have with other educators in mitigating intentions to leave the field (Struyve et al., 2016). Administrator team support was also negatively predictive of exhaustion and mental distance, aligned with prior related work (Brunsting et al., 2014). Other work notes that administrator dissatisfaction is the most frequently cited reason teachers provide for leaving a position in a rural setting (Ingersoll & Tran, 2023). Opportunities for professional learning were negatively predictive of mental distance, cognitive impairment, and emotional impairment. Given that teachers in rural settings often experience isolation (Shikalepo, 2020), professional learning opportunities might help mitigate these effects and subsequent burnout. This result might also connect to teacher autonomy, which has been linked to job satisfaction (Jerrim et al., 2023). The final significant variable was behavioral management approach, which was found to positively predict mental distance and negatively predict emotional impairment. This finding seems to indicate that while a stronger use of behavioral management in the classroom aids in mental distance, it has a detrimental influence on emotional impairment. Other research notes that self-efficacy toward behavioral management has a negative relationship with teacher burnout (Malinen & Savolainen, 2016). However, that study explored burnout as one measure rather than a more nuanced approach by exploring multiple aspects of burnout. The relationship between classroom management and burnout might be more complex than what has been described in prior work.

Implications

The findings suggest emotional experiences and the professional environment drive mathematics teacher burnout. The consistency between mathematics teaching anxiety and all

four categories of burnout is indicative of the important role that the factor has on burnout and the need to reduce anxiety to mitigate burnout. Given that the focus of much work related to math teaching anxiety is with elementary teachers and/or preservice teachers (Patkin & Greenstein, 2020; Szczygiel et al., 2025), more work is needed to better understand this finding as well as how to reduce mathematics teaching anxiety. It is possible that this finding might connect to a relatively large percentage of alternatively and emergency certified teachers now serving as mathematics teachers in the state. Given the findings related to opportunities for professional learning and staff affiliation, schools and districts may benefit from professional learning opportunities that promote collaborative problem solving among teachers, reinforce instructional practices, and support teachers through content-based approaches rather than only through procedural training. Protecting teachers' planning time and offering administrative support may serve as broad safeguards against teacher burnout. Additionally, a reduction in class size may preserve cognitive function while fostering autonomy and addressing teachers' emotional well-being. Examining mathematics teacher burnout requires a focus on improving working conditions while supporting teachers' affective experiences.

Limitations

Several limitations of the study are important to mention. The cross-sectional, self-report design prevents causal conclusions and may reflect teachers' perceptions rather than objective conditions. The stepwise regression approach is also sample-dependent and may omit theoretically relevant variables. Furthermore, the sample was limited to teachers in a specific context, restricting generalizability to other subjects or settings, and the survey measures do not necessarily capture the manifestation of burnout in the classroom.

This study examined alignment in mathematics coaches' and teachers' perceptions of the productivity and benefits of conversations within content-focused coaching cycles. Post-conversation surveys from 36 coach–teacher dyads were analyzed across 106 online coaching conversations. Although both groups rated conversations as productive, teachers rated them more favorably than coaches. Only 14% of conversations demonstrated high benefit alignment. Certain benefits reflected this misalignment: teachers more often identified emotional support, coaches more often identified growth in teachers' content knowledge, and benefits related to planning or reflecting on lesson phases were commonly reported by only one member of the dyad. These findings suggest that coaches and teachers often interpret the same interactions differently, highlighting the importance of examining multiple perspectives in coaching research.

Keywords: Professional Development, Coaching, Teacher Knowledge, Affect and Emotion

Content-focused coaching (CFC) cycles are a common form of professional development (PD) used to strengthen mathematics instruction (West & Staub, 2003). In these cycles, coaches and teachers jointly plan a lesson, enact the lesson in the classroom, and then engage in structured reflection, a process that has been associated with improvements in both teaching and student learning (Gibbons & Cobb, 2016; Russell et al., 2020). We use the word coach to refer to individuals with part- or full-time release from teaching who provide PD to teachers in support of enhancing teaching and learning (Baker et al., 2022). Although CFC emphasizes collaboration and partnership (e.g., West & Cameron, 2013), relationships between mathematics coaches and teachers can be asymmetrical (Heritage & Clayman, 2010), given a coach and teacher have different titles and responsibilities as well as potentially differing levels of expertise (Baker et al., 2022; Fennell, 2017). This asymmetry makes it important to examine the extent to which a coach and teacher share similar perceptions of coaching interactions. Accordingly, this study examined (a) alignment in mathematics coaches' and teachers' perceptions of the productivity of their planning and debriefing conversations, (b) the degree to which their perceptions of the benefits of those conversations aligned, and (c) the perceived benefits associated with higher and lower levels of alignment.

This investigation drew upon data from a larger PD initiative in which 36 coach–teacher pairs participated in individual, online CFC cycles. The cycles were designed to support teachers' use of ambitious mathematics instruction, which refers to high-quality instructional practices associated with enhanced mathematics learning for students (National Council of

Teachers of Mathematics [NCTM], 2014). Following each planning and debriefing conversations, both members of the dyad responded separately to surveys about the conversation they had just completed. The analytic sample included 106 matched survey pairs from planning (n = 63) and debriefing (n = 43) conversations. Quantitative analyses compared coaches' and teachers' ratings of overall productivity on a Likert-scale item, while qualitative analyses examined open-ended responses describing perceived benefits of the conversations. The study addressed three research questions: (1) To what extent did coaches' and teachers' ratings of the productivity of their planning and debriefing conversations align?, (2) To what extent did coaches' and teachers' perceived benefits of their planning and debriefing conversations align?, and (3) What types of benefits do coaches and teachers report when their perceptions of conversation outcomes are aligned or misaligned?

Framing Literature

Like teacher–student relationships, coach–teacher relationships are inherently asymmetrical (Heritage & Clayman, 2010). In addition to often possessing greater expertise in mathematics content and pedagogical content knowledge (Fennell, 2017), coaches and teachers occupy distinct roles within their professional partnership. Within these roles, the coach is explicitly responsible for supporting a teacher's professional growth (Baker et al., 2022), whereas the teacher is not responsible for the coach's learning. In this sense, mathematics coaches are accountable for teacher learning in ways that parallel teachers' accountability for student learning (West & Cameron, 2013). Although both members of the coach-teacher dyad participate in coaching conversations with the shared goal of improving instruction and student learning, they enter these interactions with distinct responsibilities. Within CFC cycles, teachers are positioned to examine and refine their practice through collaborative planning and reflection on instruction (Callard et al., 2022; West & Staub, 2003). Coaches, in contrast, are responsible for facilitating these conversations in ways that support teachers to: produce concrete instructional products (e.g., viable lesson plans), develop new insights about mathematical content and pedagogy (Jakopovic, 2021; Stein et al., 2022; West & Cameron, 2013), and translate instructional experiences into professional knowledge that can inform sustained changes in practice (Desimone & Pak, 2017; West & Staub, 2003). Given these different roles and responsibilities, coaches and teachers may have different interpretations of the same coaching interaction. Divergent interpretations may shape how coaches and teachers perceive the outcomes of coaching interactions, influencing their ability to agree on instructional next steps following a coaching cycle (Kochmanski & Cobb, 2023). Thus, attending to the alignment of coaches' and teachers' interpretations of coaching productivity and outcomes is essential, just as teachers must attend to evidence of student learning to guide subsequent instruction.

Within CFC cycles, coaches must attend to multiple dimensions of support. First, coaching cycles are rarely isolated events; they are typically embedded within broader professional learning initiatives (Callard et al., 2022; West & Cameron, 2013). In such contexts, coaches support teachers in interpreting and enacting pedagogical ideas introduced through other PD experiences within their own classroom settings and are therefore accountable for teachers' learning in relation to the goals of the larger initiative. For example, when supporting ambitious mathematics teaching (Yurekli & Stein, 2025), coaches might help teachers set instructional goals, select and design tasks, anticipate student thinking, launch lessons, facilitate exploration, and orchestrate summary discussions, positioning both coaches and teachers as jointly responsible for learning to enact new instructional practices (Gibbons & Cobb, 2017; Horn &

Kane, 2015; Lampert et al., 2013). At the same time, coaches must also provide responsive, individualized support that extends beyond the focal goals of the initiative. This may include assisting with mathematical content, helping teachers navigate curricular or instructional resources, or offering emotional support, recognizing that instructional change is often demanding and uncertain (McGugan et al., 2023). In this way, coaches are also accountable for helping teachers address context-specific and personal challenges that fall outside the boundaries of targeted pedagogical reforms.

Against the backdrop of the complexity inherent to coaches providing teachers with customized support with CFC cycles, it is possible that coaches and teachers might report similar benefits from a shared planning or debriefing conversation. High alignment in the perceived benefits of a conversation would suggest that the coach has an accurate understanding of how the teacher interpreted and experienced the support, thereby enabling the coach to identify productive next steps for continued professional growth. However, such alignment may be difficult to reach for two possible reasons. First, coaches typically do not work toward a fixed set of standards for teacher learning and must instead negotiate the focus of conversations while remaining responsive to teacher-identified needs (Kochmanski & Cobb, 2023). As a result, a single coaching conversation may generate a wide range of possible benefits, both related to and beyond focal goals of larger initiatives motivating the coaching, complicating efforts to identify and interpret learning. Moreover, because the coach–teacher relationship is asymmetrical, coaches and teachers may attend to and value different aspects of the interaction based on their distinct roles. Consequently, low alignment in perceived benefits may reflect either a misinterpretation of learning (e.g., the coach infers one benefit while the teacher experiences another) or accurate recognition of different benefits that are shaped by each participant's position within the dyad.

Methods

Participants

Participants were 36 middle-grades teachers (grades 4-10) from a single state in the Pacific Northwest, with teaching experience ranging from two to 21 years. Each teacher was paired with one of 11 coaches from various geographic regions resulting in 36 coach-teacher pairings. Coaches were selected for their expertise in coaching ambitious mathematics teaching practices, with experience ranging from two to 15 years.

Project Context

The study took place within a state-funded PD program in which two cohorts of teachers each participated for one academic year. All PD activities were conducted online and consisted of three types of synchronous learning experiences: six course sessions; three video clubs; and two individualized, video-supported CFC cycles. The six course sessions introduced teachers to ambitious instructional practices (e.g., Smith & Stein, 2018). During the video clubs, teachers collaboratively analyzed classroom video of project staff enacting practices introduced in the course sessions within local schools. All course sessions and video clubs were two hours in length and held via Zoom.

Each teacher also completed two online, video-supported coaching cycles, for a total of 72 cycles. The 72 cycles serve as the primary focus of this study. In the cycles, coaches provided individualized support as teachers enacted the practices introduced in the course and video clubs. Consistent with a CFC model (Callard et al., 2022), each cycle included a planning conversation, classroom enactment that was video recorded, and a debriefing conversation. During planning

conversations, coach–teacher pairs met on Zoom to examine mathematical content, establish student learning goals, and refine lesson activities based on anticipated student thinking. Teachers then recorded their lessons using Swivl technology and shared the videos with their coaches. Both coaches and teachers independently reviewed the recordings and added annotations highlighting salient moments using the Swivl platform. In the debriefing meetings, pairs reconvened on Zoom to reflect on the lesson using evidence from the video and annotations. The first coaching cycle occurred after teachers completed four course sessions and two video clubs, and the second took place after the remaining two course sessions and final video club (see Figure 1).

Figure 1: Overview of project PD activities

Data Collected

We collected data on the planning and debriefing conversations from 72 coaching cycles. We used post-conversation surveys, immediately completed individually by both teachers and coaches after a conversation. The surveys were intended to clarify coaches' and teachers' perceptions of conversation productivity and the benefits of the conversation with respect to the teacher's professional growth. To accomplish this goal, we used two types of survey items. First, participants responded to a Likert-scale item—*To what extent was your coaching conversation productive?*—rated on a 1–9 scale. Second, the survey included two open-ended items asking participants to describe the benefits the teacher experienced because of participating in the coaching conversation.

In total, we analyzed and compared coach and teacher survey responses from 106 conversations (63 planning and 43 debriefing). Conversations were included in the analysis only when both members of the dyad completed the survey for the same interaction. The smaller number of debriefing conversations reflects the unexpected loss of project funding, which occurred while Cohort 2 was completing the second coaching cycle. As a result, post-conversation surveys were not collected for the debriefing conversations in that cycle for Cohort 2.

Data Analysis

To address RQ1, we conducted a paired-samples *t* test to examine differences between teachers' and coaches' ratings of conversation productivity.

As an initial step in addressing RQ2 and RQ3, we developed a coding scheme (see Table 1) to analyze the open-ended survey responses regarding coach and teacher perceptions regarding the benefits of the coaching interactions in terms of supporting the teachers' professional growth. The two open-response items from each survey were combined and treated as a single unit of analysis. We organized the coding scheme into two overarching categories: perceived benefits directly related to course content (six specific codes) and perceived benefits beyond the course content (five specific codes). Two coders independently coded all responses, with surveys randomized and participant roles blinded to reduce potential bias. Each code was assigned a

value of 1 if the benefit was present in the full response and 0 if it was absent. Coders then met to discuss and resolve any discrepancies.

To specifically address RQ2, which examined the extent to which the perceived benefits coaches and teachers reported were aligned, we shifted the unit of analysis to the level of the individual coaching conversation. For each conversation, we compared the codes assigned to a coach's and teacher's response and classified each coded benefit as either *paired* (i.e., the same benefit was coded for both members of the dyad) or *unpaired* (i.e., the benefit was coded for only one member of the dyad). Perceived benefits that were absent from both responses were not considered paired. Unpaired benefits were further categorized as either "coach only" or "teacher only." Using the number of paired and unpaired benefits, we classified each conversation's level of alignment using the following mutually exclusive criteria: *High*, when the number of paired benefits exceeded the number of unpaired benefits; *Moderate*, when at least one paired benefit was present *and* the difference between paired and unpaired benefits was zero, one, or two; and *Low*, when no paired benefits were present *or* when the number of unpaired benefits exceeded paired benefits by more than two. The research team collaboratively established these criteria after extensively reviewing coded conversations to identify distinctions that aligned with our perceptions of conversational alignment and meaningfully differentiated the conversations.

To address RQ3, we conducted an inductive analysis of coded responses to identify patterns in perceived benefits codes across differing levels of paired alignment and unpaired misalignment. We focused on benefits most frequently coded as paired or unpaired, with particular attention to those categorized as "coach only" or "teacher only."

Table 1: Coding Scheme (Abbreviated) for Open Response Survey Items

	Code	**Planning Definition** *Conversation supported the teacher to:*	**Debriefing Definition** *Conversation supported the teacher to:*
Benefits Related to Course Content	Goals	Develop or clarify the purpose of the lesson.	Reflect on the purpose of the lesson.
	Tasks	Select or modify a task; design task-based lessons.	Reflect on the effectiveness of a task or task-based lessons.
	Student Thinking	Anticipate student thinking.	Reflect on or interpret student thinking.
	Launching	Determine ways to launch a task.	Reflect on the effectiveness of task launch.
	Facilitating Exploration	Prepare to facilitate the exploration phase of a task-based lesson.	Reflect on the facilitation of the exploration phase of a task-based lesson.
	Summary Discussion	Determine how to structure and facilitate the summary discussion.	Reflect on the effectiveness of the summary discussion.
Benefits Outside of Course Content	Instructional Practice Goals	Identify or clarify instructional practice goals.	Reflect on progress toward instructional practice goals.
	Mathematics Content	Understand math content for the lesson.	Understand math content for the lesson.
	Emotional Support	Feel supported, inspired, or safe to experiment with practice.	Feel supported, inspired, or safe to experiment with practice.
	Curriculum Resource	Understand how to use an existing curriculum resource.	Reflect on the use an existing curriculum resource.
	New Resource	Learn to use a new teaching resource.	Reflect on the use of a new resource.

Findings

For RQ1, which compared coach and teacher perceptions of conversation productivity, both groups generally rated conversations as highly productive. However, the paired *t* test revealed that teachers' ratings (M = 8.40) were significantly higher than coaches' ratings (M = 6.92), $t(105) = 9.29$, $p < .001$, $d = 0.91$.

For RQ2, which examined the alignment of coaches' and teachers' perceived benefits of their planning and debriefing conversations, 15 conversations (14%) were classified as *high* alignment, 47 (44%) as *moderate* alignment, and 44 (42%) as *low* alignment. To illustrate a conversation considered to have *high* alignment, Coach Carter and Teacher Cindy shared two paired benefits (*Tasks* and *Curriculum Resources*) and one unpaired benefit (*Student Thinking* – teacher only) in their planning conversation. For example, Cindy noted that "[the coach] helped me modify a task … so that it would have a high ceiling and [be] beneficial to all of my students," while Carter similarly reported, "We spent much of our time walking through … how to change the task, which will provide a solid foundation for future task selection and modification." The unpaired benefit reflected Cindy's statement that "[my coach] made me think more like my students so that I could anticipate their responses," which Carter did not mention. Because paired benefits outnumbered unpaired benefits, this conversation was classified as *high* alignment. In contrast, Coach Laura and Teacher Luke's planning conversation was classified as *low* alignment, as it included three unpaired outcomes: *Goals* and *Mathematical Content* (coach only) and *Tasks* (teacher only). Laura reported that she helped Luke "think about the big ideas of the unit" (coded as *Mathematical Content*) and "narrow his content focus for the lesson" (coded as *Goals*). Luke, however, did not reference content or goals and instead stated, "my coach gave me ideas on what would be a good route for my lesson," which was coded as *Tasks*. Because no outcomes were paired, this conversation met the criteria for *low* alignment.

To answer RQ3, which focused on reported benefits frequently associated with alignment or misalignment, we constructed Table 2 to summarize the number of conversations that featured paired and unpaired benefits related to course content. For example, the 17 paired benefits for *Goals* (top left of Table 2) represent the number of conversations in which both the coach and the teacher identified benefits related to establishing mathematical learning goals for students. In contrast, the value of 48 in the total row for that same column indicates the number of conversations in which either member of the dyad identified *Goals* as a benefit. We constructed Table 3 in the same manner to summarize paired and unpaired benefits that were not directly related to course content.

Table 2: Conversations Featuring Benefits Related to Course Content

	Goals	Tasks	Student Thinking	Launching	Facilitating Exploration	Summary Discussion	Total
Paired	17	17	14	1	7	5	61
Coach Only	18	21	17	8	16	12	92
Teacher Only	13	19	24	10	12	11	89
Total	48	57	55	19	35	28	

Table 3: Conversations Featuring Benefits Outside of Course Content

	Instructional Practice Goals	Math Content	Emotional Support	Curriculum Support	New Resource	Total
Paired	18	4	15	5	1	43
Coach Only	18	18	10	4	3	53
Teacher Only	13	7	42	4	4	70
Total	49	29	67	13	8	

Three notable trends emerged from this analysis of paired and unpaired benefits. First, *Emotional Support* was far more likely to be identified by teachers than by coaches as a benefit of the coaching conversation. Teachers reported *Emotional Support* as a perceived benefit in 42 conversations in which coaches did not, whereas the reverse occurred in only 10 conversations, and both members of the dyad identified *Emotional Support* in just 15 conversations. This suggests that teachers were more attuned to the relational and affective benefits of their coaching interactions than their coach. We also note that *Emotional Support* was the most commonly applied code, appearing in 67 of the 106 conversations as a benefit reported by the coach, teacher, or both. Second, *Mathematical Content* was more often identified by coaches than by teachers. Coaches reported *Mathematical Content* as a benefit in 18 conversations in which teachers did not, compared with only seven conversations in which teachers reported this benefit without the coach, and just four conversations in which both members of the dyad identified it. This pattern suggests that coaches were more likely than teachers to view their conversations as supporting the development of teachers' mathematical content understanding. Third, outcomes related to specific phases of a task-based lesson (e.g., Smith & Stein, 2018)—such as *Launching, Facilitating Exploration,* and *Summary Discussion*—were frequently unpaired. For instance, although *Launching* was identified as a benefit in 19 conversations, it was paired in only one. Similarly, *Summary Discussion* appeared in 28 conversations but was paired in only five. These patterns indicate that while no benefit exhibited consistently high levels of paired alignment, benefits tied to the planning or implementation of particular lesson segments were especially likely to be recognized by only one member of the dyad, highlighting substantial divergence in how coaches and teachers interpreted the focus and impact of their planning and reflection conversations.

Discussion and Implication

This study examined the extent to which coaches' and teachers' perceptions of the productivity and benefits of CFC cycles corresponded. Three findings are particularly salient. First, although both groups rated conversations as highly productive, teachers consistently rated them more favorably than coaches. Second, relatively few conversations demonstrated high outcome alignment, with only 14% classified as highly aligned. Third, several outcomes were frequently unpaired: *Emotional Support* was typically identified by teachers but not coaches, *Mathematical Content* was more often identified by coaches but not teachers, and outcomes related to specific phases of instruction (e.g., *Launching*, *Facilitating Exploration*, *Summary Discussion*) were commonly reported by only one member of the dyad. Together, these findings suggest that coaches and teachers often interpret the same coaching interaction in meaningfully different ways.

These results contribute to mathematics coaching literature in several ways. Recent studies have begun to examine the outcomes of coaching through teachers' reports (e.g., Saclarides & Gillespie, 2024; Warnock et al., 2022) to better understand the nuanced and diverse ways one-on-one coaching responsively supports teachers as they attempt to implement new ways of teaching. Our findings extend such research by directly comparing teachers' and coaches' perspectives on their interactions. In addition, our findings related to RQ1 contrast with those of Smith and Desimone (2025), who found that coaches often rated PD activities involving coaching more favorably than teachers. This discrepancy likely reflects contextual differences that shape coaching experiences and outcomes (Hannan & Russell, 2020). In Smith and Desimone's study, coaches were embedded within schools and districts and provided a range of PD activities connected to curriculum implementation, whereas in the present study all teachers participated in a common, university-supported coaching cycle facilitated by mathematics coaches who were not employed by their districts. The direct contrast in these findings suggest differences in organizational positioning, relational history, and scope of responsibility may influence how coaches and teachers evaluate the productivity of PD interactions.

Findings related to RQ2 and RQ3 raise important questions about the implications of low alignment in perceived outcomes. From one perspective, limited alignment may be concerning, given prior research emphasizing the importance of coaches and teachers jointly establishing goals and shared foci for professional learning (e.g., Kochmanski & Cobb, 2023). If coaches and teachers leave conversations with different understandings of what was accomplished, this may signal missed opportunities to co-construct clear directions for instructional improvement. From an alternative perspective, divergent perceptions may reflect the inherently asymmetrical roles (Heritage & Clayman, 2010) within coaching relationships. Mathematics coaches, selected for their content and pedagogical expertise, may be more attuned to shifts in teachers' mathematical understanding, whereas teachers navigating instructional change may value emotional or motivational support from the same interactions (Yurekli & Stein, 2025). Thus, differences in reported outcomes may reflect role-related differences in what is noticed, valued, and remembered.

These findings have implications for both practice and research. For coaches, a practical strategy may be to conclude coaching conversations with brief, explicit reflection on perceived outcomes and next steps. Such meta-conversations could help surface differences in interpreted benefits of an interaction, support shared sensemaking about teacher learning, and inform more targeted follow-up support. Such conversations may also help teachers recognize professional learning that coaches detected but teachers may not yet articulate, while allowing coaches to better understand the affective dimensions of teachers' experiences that may otherwise remain unknown.

For research, future studies should examine how outcome perceptions relate to the substance of coaching interactions and subsequent instructional practice. One promising direction is to compare perceived benefits with learning opportunities evident in the conversations themselves. For instance, when a coach reports a benefit related to planning the launch of a lesson, but the teacher does not, researchers might investigate whether meaningful discussion about this phase of the lesson occurred. Additionally, future research could examine whether reported benefits—whether aligned or not—are associated with observable changes in instruction. Investigating how learning within conversations translates into classroom practice would strengthen claims about the significance of coaching and clarify the conditions under which alignment in perceptions matters most for teacher development.

This study examined how 12 mathematics specialists' facilitation of debriefing conversations changed after learning to use the Debriefing Conversational Structure, a tool developed through a research–practice partnership and grounded in content-focused coaching. We analyzed debriefing conversations conducted before and after learning about the structure, along with specialists' reflections. Nearly all specialists increased their facilitation levels, with the largest gains in phases focused on analyzing student thinking, instructional decision-making, and future instruction. Specialists' reflections suggested that the structure supported increased levels of reflection by foregrounding key phases of reflective dialogue and promoting coherence. Uneven changes across participants highlighted the complexity of facilitating reflective dialogue. This study contributes a theoretically grounded conversational tool and future research.

Keywords: Professional Development, Teacher Educators, Teacher Noticing

Content-focused coaching (CFC) cycles are a widely used professional development (PD) structure mathematics specialists utilize to support teachers' professional learning (Stein et al., 2022; Witherspoon et al., 2021; Yurekli & Stein, 2025). In this study, mathematics specialists are educators partially or fully released from classroom teaching to engage in classroom-embedded collaboration with teachers to improve instruction (Baker et al., 2022; Mudzimiri et al., 2014). A typical CFC cycle consists of collaborative planning, teaching, and reflecting interactions in which a specialist and a teacher jointly design, implement, and analyze instruction. The central aim of CFC cycles is to deepen teachers' mathematical and pedagogical content knowledge, promoting responsiveness to student thinking and cultivating sustainable planning and reflective practices (Callard et al., 2022; West & Cameron, 2013).

Among the three phases of a CFC cycle, the debriefing phase plays a critical role in supporting teacher learning. Debriefing conversations provide structured opportunities for mathematics teachers to analyze evidence of student thinking, refine instructional decisions, and strengthen reflective habits that support continued professional learning beyond the specialist's presence (Saclarides, 2022; Walsh et al., 2023; West & Cameron, 2013). Despite its importance, comparatively little is known about how mathematics specialists learn to facilitate debriefing conversations within CFC cycles. Existing research has examined specialists' facilitation of planning conversations (Russell et al., 2020; Stein et al., 2022) and their development of general coaching knowledge and strategies (Baker & Knapp, 2019; Saclarides & Kane, 2024), but few studies focus specifically on how mathematics specialists learn to support teacher reflection during debriefing conversations. At the same time, coaching tools—such as frameworks, protocols, conversational guides, and routines—have become increasingly common supports for specialists' work with teachers (Baker & Knapp, 2019; Gibbons & Okun, 2022; Gillespie, Amador et al., 2025; Kochmanski & Cobb, 2023; Smith et al., 2025). However, limited empirical

research has examined how specific conversational structures influence specialists' facilitation of debriefing conversations. Together, these trends underscore the need to examine the professional learning of mathematics specialists' within the context of reflection-focused interactions.

This study examined 12 mathematics specialists participating in a two-year PD project designed to strengthen their facilitation of CFC cycles, with particular attention to debriefing conversations. Observations from the research team and project facilitators, along with participant feedback, indicated that learning to facilitate debriefing conversations was a central area of professional learning opportunity and that a project-developed Debriefing Conversational Structure was instrumental in supporting this learning. Accordingly, this study pursued two aims: (a) to examine how specialists' facilitation changed across debriefing conversations conducted before and after learning the conversational structure, and (b) to analyze specialists' reflections to characterize how they described the structure as supporting their professional learning. The following research questions guided the study: (1) In what ways did specialists' levels of facilitation within debriefing conversations change after participating in PD that included the Debriefing Conversational Structure?; (2) How did the Debriefing Conversational Structure support specialists' development in facilitating debriefing conversations?

Theoretical Perspectives

This study is theoretically grounded in scholarship on reflective thinking and the conversational interactions that support professional learning through reflection. Drawing on Dewey (1938) and Schön (1983, 1987), we conceptualize reflection as a process through which meaning is reorganized and reconstructed from experience. In educational contexts, reflective thinking involves revisiting prior teaching episodes to examine teacher and student actions and lesson design, while also engaging in forward-oriented thinking about how future instruction might be modified in response to what was observed and experienced (Davis, 2006; Rodgers, 2002; Schön, 1983; Walsh et al., 2023). This interplay between looking back on practice and intentionally designing future action supports reflection *on* and *for* action (Schön, 1983).

The quality of reflective discussion is consequential to the outcomes of this process. Productive reflection requires attention to intended and enacted instructional goals, evidence of student learning, and the factors that may have contributed to students' progress or challenges (Gillespie, Kruger et al., 2026; Olteanu, 2017). Such analysis informs the design of subsequent goals and modifications to future instruction, creating a cyclical process in which reflection on past experiences shapes future practice (Burhan-Horasanlı & Ortaçtepe Hart, 2024; Postholm, 2008). Within this cycle, the evidence teachers draw upon—and how that evidence is examined—plays a critical role in shaping responsive instructional design (Lefebvre et al., 2023).

Research on mathematics specialist learning and CFC further informs this study. Mathematics specialists require ongoing PD to support teachers' learning, particularly in developing reflective skills central to effective coaching practice (Saclarides, 2022). Studies of CFC models have shown that PD can lead to meaningful improvements in specialists' coaching practices (Stein et al., 2022), yet facilitating debriefing conversations—a central phase of CFC cycles—remains a complex and underexplored aspect of specialist learning (Callard et al., 2022; West & Cameron, 2013). Emerging research suggests that structured coaching tools can support specialists' facilitation of reflective conversations. For example, Baker and Knapp (2019) demonstrated that a decision-making protocol supported goal-oriented coaching discussions, while Russell et al. (2020) found that an inquiry-driven framework fostered richer, more precise dialogue between coaches and teachers. More broadly, scholars emphasize that productive

facilitation depends not only on *what* is discussed, but *how* discussion unfolds—particularly the extent to which facilitation promotes specificity in examining practice and connectivity across goals, evidence, and instructional decisions (Gibbons & Okun, 2022; van Es & Sherin, 2008). However, reflective dialogue is neither straightforward nor linear (Schön, 1983), which elevates the possibility that productive facilitation of debriefing conversations is a complex endeavor. Together, this body of work positions reflective debriefing conversations as a critical site for mathematics specialist learning and underscores the need to examine how conversational structures can support specialists in facilitating coherent, evidence-based reflection.

Methods

Participants and Project Context

Participants were 12 mathematics specialists who held various roles, including coaches, interventionists, and teacher-leaders (Baker et al., 2022). The study draws on video club (VC; Kruger et al., 2026) and coaching cycle components of a two-year PD program delivered online, which included: (a) six structured course sessions, (b) eight VCs, and (c) two one-on-one coaching cycles (see Amador et al., 2021). Course sessions introduced strategies for leading CFC cycles. In VCs, participants met in groups of four to review video clips of planning and debriefing conversations; Year 1 clips featured project personnel, while Year 2 clips featured participants' own coaching. During one-on-one coaching cycles, participants worked with local teachers, supported by a mentor coach who met with them before each cycle to prepare.

This sudy focused on two debriefing conversations participants conducted with teachers. Before the first coaching cycle, PD had emphasized planning conversations but not debriefing. Following the first cycle, participants attended one course session introducing the Debriefing Conversational Structure and participated in two VCs focused on debriefing. They then conducted a second coaching cycle with the same teacher. While the structure was introduced and modeled, participants had autonomy in deciding how and to what extent to use it.

Debriefing Conversational Structure

We developed the Debriefing Conversational Structure to be (a) simple and time-efficient, (b) adaptable to varied contexts, (c) grounded in reflective dialogue theory, and (d) aligned with CFC principles (Callard et al., 2022; West & Cameron, 2013). The structure provides an accessible framework translating theory into practice while allowing specialists to exercise professional judgment. Consistent with CFC guidance, the conversational structure focuses on evidence of student learning tied to instructional goals and on how these insights inform future teaching (West & Cameron, 2013) in order to deepen teachers' subject-matter understanding and pedagogical content knowledge (Ball et al., 2008; Shulman, 1987). The structure comprises four phases grounded in Schön's (1983) reflection-on-and-for-action: (1) *Review Goals*—what were we trying to accomplish; (2) *Examine Evidence Related to Goal*—what student data relate to our goals; (3) *Consider Contributing Factors*—what influenced success or challenges; (4) *Determine Implications for Future Teaching*—how can we improve instruction based on these insights.

Data Collection and Analysis

Two coaching cycles for each of the 12 participants were video recorded and transcribed verbatim. This yielded 24 debriefing conversations: 12 from Cycle 1, conducted before exposure to the Debriefing Conversational Structure, and 12 from Cycle 2, conducted after its introduction. Participants coached teachers across grade levels spanning third grade through high school. All cycles centered on lessons involving cognitively demanding tasks and discourse practices designed to productively support student struggle (e.g., Smith & Stein, 2011). To examine how the Debriefing Conversational Structure supported professional changes,

researchers analyzed two additional data sources. Participants completed end-of-year interviews in both years, responding to open-ended questions about their development and the aspects of the PD that supported it. In addition, after each VC, participants reflected on their facilitation of CFC cycles and identified project experiences that were impactful. All interviews and reflections were audio recorded and professionally transcribed.

To examine changes in specialists' facilitation, we conducted a two-step analysis. First, we deductively coded 1,351 specialist talk-turns from 24 debriefing conversations using a predefined scheme aligned with the Debriefing Conversational Structure and our theoretical framing of reflective dialogue. The scheme included 12 codes each connected to different phases of the conversational structure. Transcripts were organized in spreadsheets, identifiers removed, and multi-idea turns segmented. Teacher talk was retained for context only. Three researchers independently coded each specialist talk turn for the presence (1) or absence (0) of each code (Corbin & Strauss, 2014). Turns could receive multiple codes; non-instructional talk received none. Second, we assessed facilitation levels using a rubric (Figure 1) developed by the research team with input from project personnel who designed and implemented the PD experiences. After piloting and refining for reliability, three researchers independently scored each conversation on the four phases, providing written rationales, then reconciled discrepancies. Interrater reliability (kappa) ranged from 0.62 to 1.00, indicating substantial to perfect agreement (Landis & Koch, 1977).

	Level 1	**Level 2**	**Level 3**	**Level 4**
Phase 1: Review Goals	No mention of any goals	Reference to the math learning goals or teacher practice goals	Recurring references to the math learning goals or teacher practice goals	Recurring references to the math learning goals and teacher practice goals
Phase 2: Examine Evidence Related to Goal	No mention of student thinking	Mentions of instances of student thinking	Analysis of specific instances of student thinking connected to the goals.	Extended analysis of specific instances of student thinking connected to the goals.
Phase 3: Consider Contributing Factors	No mention of teacher actions or lesson design	Mentions of teacher action or lesson design	Analysis of how specific teacher action or lesson design features influenced student thinking	Extended analysis of how specific teacher action or lesson design features influenced student thinking
Phase 4: Determine Implications for Future Teaching	No talk of change to future practice	Limited talk of change to future teaching	Analysis of changes to future teaching connected to discussion of student thinking or contributing factors	Extended analysis of changes to future teaching connected to discussion of student thinking and contributing factors

Figure 1: Coach Reflection Rubric for Debriefing Conversations (Abbreviated for Space)

To investigate how the structure supported professional changes to higher levels of facilitation, we analyzed Year 1 and Year 2 interviews and reflections from all eight VCs. One researcher identified excerpts explicitly linking growth to the Debriefing Conversational Structure; a second confirmed relevance, yielding 46 segments. Two researchers independently paraphrased each segment and reconciled summaries before collaboratively identifying themes describing how participants perceived the structure as supporting their development.

Findings

In relation to the first research question, Table 1 summarizes level scores for both Cycle 1 and Cycle 2 debriefing conversations to show changes to coaches' level of facilitation after learning about the conversational structure. Four noteworthy trends were identified. First, 11 of the 12 specialists had phases coded at more advanced levels in at least two phases, suggesting that the conversational structure and related learning supported at least modest levels of advancement in facilitation. Second, three specialists demonstrated increased levels of facilitation categorized as *moderate improvements* (a net increase of one to two points), while eight specialists showed *substantial improvements* (a net increase of three or more points). Third, specialists' level of facilitation increased the most within Phases 2, 3, and 4, with nine to ten specialists showing gains in these areas. In contrast, only four specialists showed improvements in Phase 1, which involved incorporating goals into discussion. Finally, no specialist achieved a Level 4 across all phases in their second conversation, and only five reached a Level 4 in multiple phases. These patterns suggest that the conversational structure was not a mechanical script but rather a framework that required the specialists to develop nuanced facilitation skills.

Table 1: Rubric Levels for Debriefing Conversation 1 (CC1) and 2 (CC2)

	Phase 1			Phase 2			Phase 3			Phase 4		
Coach	CC1	CC2	+/-	CC1	CC2	+/-	CC1	CC2	+/-	CC1	CC2	+/-

Analysis of participants' reflections from project PD activities and interviews indicated that 11 specialists explicitly identified the Debriefing Conversational Structure as a key contributor to their professional learning. Three themes emerged regarding how the structure supported their development. First, participants reported that the structure heightened their awareness of phases within reflective dialogue and clarified the role each phase plays in a debriefing conversation. Second, participants described how the structure offered a coherent map for connecting these phases in a purposeful sequence. Some specialists described how individual phases of a debriefing conversation were already active parts of their practice, but the structure helped them connect those phases to help teachers translate their teaching experience into professional learning. Finally, participants noted that the structure helped them balance intentional planning with responsiveness. Specifically, specialists shared that it enabled them to enter conversations with clear goals for how to support teacher development while remaining attentive and adaptable to teachers' ideas and needs as the dialogue unfolded.

The Case of Butler

To illustrate changes in facilitation and how the structure supported specialists' development, we present that case of Butler whose levels of facilitation increased across all four phases of the rubric. We first describe changes in Butler's facilitative behaviors between the first and second debriefing conversations to exemplify the patterns reported in Table 1 and provide context for how the Debriefing Conversational Structure contributed to those changes. We then use Butler's reflective commentary to illustrate the three themes through which specialists attributed their professional changes based on levels of facilitation to the use of the structure.

With respect to Phase 1: Review Goals, in Cycle 1, Butler made only a brief mention of goals at the start of the conversation. In Cycle 2, Butler again referenced the learning goals at the start of the conversation but also repeatedly connected questions throughout the conversation back to these goals. For example, Butler said the following in the Cycle 2 debriefing conversation, "our second goal, to go back and connect, was about students having a strategy to solve. How many students had strategies versus how many of them just missed the target altogether?"

For Phase 2: Examining Evidence Related to Goals, Butler's level score increased from 3 to 4 from Cycle 1 to 2. This increase reflected a shift from making isolated references to student thinking toward engaging in sustained interpretation of specific instances of student thinking in relation to the learning goals. In Cycle 2, Butler and the teacher engaged in the examination of student work samples for approximately 12 minutes, making interpretations about what students understood and the extent to which each student had progressed toward the goals. By contrast, in Cycle 1, Butler prompted occasional mentions of student thinking but did not encourage discussion aimed at interpreting what students did or did not understand.

Butler's largest facilitative increase occurred within Phase 3: Consider Contributing Factors. In Cycle 1, Butler moved directly from noticing isolated instances of student thinking to making suggestions for next instructional steps without discussing how the lesson design or teacher actions may have influenced students' thinking. In Cycle 2, however, Butler posed questions about lesson factors that may have influenced student learning to make explicit connections between analyzing student thinking and identifying implications for future teaching. For example, after discussing the thinking of two students who appeared to struggle with the task, Butler asked: "What do you think the holdback or the setback was for these students?*"* The teacher reflected that these students might have needed visual models. Butler then facilitated a sustained discussion prompting the teacher to consider how upcoming lessons could better utilize visual models to address these identified needs. This extended discussion about modifications to future teaching was grounded in both the analysis of contributing factors as well as specific instances of student thinking. This led to Butler being at a Level 4 in Cycle 2 for Phase 4: Determine Implications for Future Teaching, which was a two-point increase from Cycle 1.

Butler's reflections across two years of participation exemplify all three themes regarding how the Debriefing Conversational Structure supported specialists' professional learning. First, Butler reported that the structure heightened understanding of the importance of particular phases of reflective dialogue within the larger debriefing conversation. Specifically, Butler shared a new understanding about how to anchor reflective conversations in both evidence of student thinking and the goals established during planning. As Butler explained in a final interview after the second year of participation, "the [conversational structure] made it clear that I need to focus on that data…. And really encouraging teachers to have that data to show evidence of growth toward their goals."

For the second theme, Butler noted new insights about how the specific action of grounding conversations in data connected to goals created a durable foundation for productive dialogue about improving future teaching. In other words, Butler described how the Debriefing Conversational Structure supported new ideas about how to make connections between different phases of reflective discussion. For example, in a Year 1 interview, Butler reflected:

> The framework pushed coming back to those goals, and really helping the teacher move towards those goals, and which then helps them see their implication for practice with respect to those goals.

Related to the third theme, Butler described how the structure helped manage the challenge of facilitating conversations that were simultaneously planned and focused while remaining flexible and responsive to teachers' needs. Butler shared:

> I can ... really plan out what I want to accomplish and look at what the teacher's goals are and then really help drive the conversation… by focusing on data. … The [conversational structure] is a good framework for a debriefing conversation as I can feel planned and controlled while still being flexible and responsive to the teacher's needs and interests.

Discussion

This study examined changes in mathematics specialists' facilitation as they implemented the Debriefing Conversational Structure within CFC cycles. Specialists' reflections across two years were analyzed to better understand how the structure contributed to changes in debrief facilitation. Three key contributions of these findings are discussed below.

First, 11 of the 12 specialists demonstrated increased facilitation scores in their second debriefing conversation, and most identified the Debriefing Conversational Structure as central to their professional learning. This finding aligns with research showing that coaches often take up structured tools—such as protocols and routines—to guide their work with teachers (Baker & Knapp, 2019; Gibbons & Okun, 2022; Kochmanski & Cobb, 2023). Given that mathematics specialists are frequently "anointed and appointed" based on classroom expertise (Fennell et al., 2017, p. 3) yet receive limited preparation for supporting adult learning (Chval et al., 2010; Russell et al., 2020), structured supports may help them navigate the dual demands of responsiveness and intentionality. Participants' reflections illuminated three ways the structure supported changes: it heightened awareness of distinct phases of reflective dialogue, provided a coherent framework for connecting goals, evidence, contributing factors, and instructional implications, and scaffolded facilitation while preserving flexibility. Extending prior work that focuses primarily on enactment of coaching tools (e.g., Baker & Knapp, 2019), these findings foreground specialists' perspectives and suggest that conversational structures can serve as practical scaffolds for developing facilitative expertise in reflection-focused coaching contexts.

Second, increases in specialists' facilitation levels also point to expanded opportunities for teacher learning through professional discourse (e.g., Borko et al., 2008; Horn & Little, 2010; Lefstein et al., 2020) during the second debriefing conversation. The conversational structure was intentionally organized around core elements of pedagogical content expertise, including close attention to student thinking, analysis of how instructional decisions shaped that thinking, and consideration of instructional next steps grounded in those analyses. Research has consistently linked teachers' capacity to notice, interpret, and respond to student thinking with the development of instructional expertise (e.g., Bastian et al., 2024; Bragelman et al., 2024; Jacobs et al., 2024), and has identified analysis of instructional decision-making as a productive

focus for professional learning (Jacobs et al., 2010; Jakopovic, 2021). Similarly, reflecting on implications for future instruction based on prior teaching experiences supports ongoing professional learning (Kraft & Hill, 2020; Walsh et al., 2023).

Third, although most specialists demonstrated upward shifts, improvement was uneven. One specialist showed no change, and three exhibited only modest gains. Even in the second debriefing conversation, considerable room for development remained: only five specialists reached the highest facilitation level in more than one phase, and none did so across all four phases. These findings underscore the complexity of facilitating professional learning conversations (Mitchell et al., 2022). Prior research has documented similar challenges in CFC planning conversations, where coaches must balance responsiveness to teachers with sustained attention to instructional goals (Stein et al., 2022; Witherspoon et al., 2021). Far less is known, however, about how specialists develop the expertise required to facilitate reflective dialogue focused on enacted instruction (Saclarides, 2022). Debriefing conversations demand more than addressing discrete topics in sequence. Effective facilitation involves deepening specificity about classroom events (reflection-on-action; Schön, 1987), linking those insights to future instructional decisions (reflection-for-action; Schön, 1987), and maintaining coherence across phases of discussion. The continued room for increased level of facilitation observed in this study suggests that while conversational tools can support development, they are unlikely to be sufficient on their own. Specialists likely require sustained opportunities to rehearse, analyze, and refine how they press for specificity and connect ideas across reflective dialogue.

Implications

We offer two key implications for research and professional development. First, this study positions the Debriefing Conversational Structure as a promising tool for mathematics specialists engaged in CFC cycles. Developed through a research–practice partnership, the structure translates theories of productive reflective dialogue into a form aligned with CFC goals (Callard et al., 2022; Stein et al., 2022; West & Cameron, 2013; Witherspoon et al., 2021). Specialists with varied backgrounds and contexts demonstrated increased levels of facilitation, suggesting broader potential for impact. The structure—and its accompanying rubric—contribute practical and research-based resources for studying and supporting reflective conversations. Second, uneven changes raises questions about the level of explicitness coaching tools require and the PD needed to surface their purposes. Although intentionally open and flexible, this design may have limited uptake for some specialists. While some may thrive with adaptable tools, others may need more explicit modeling, rehearsal, and feedback to use them productively.

The promise of the structure must be considered alongside several limitations of the study. The sample was relatively small and focused on facilitative shifts were based on the comparison of two coaching cycles. Thus, while we encourage specialists and those who support their learning to consider using the Debriefing Conversational Structure and accompanying rubric, we also call for future research that examines the use of this tool across multiple coaching cycles, with larger samples, and with explicit attention to specialists' varied backgrounds and contexts. Future research should therefore directly examine how shifts in mathematics specialists' facilitation during reflective discussions influence the depth of conversation, teachers' engagement, and subsequent instructional decisions, to further substantiate these theoretical interpretations.

TEACHERS' COLLECTIVE NOTICING OF STUDENT WORK: PATTERNS OF NORMATIVITY AND SERVICEABILITY IN PROFESSIONAL DEVELOPMENT

Teachers may perceive student work in terms of its alignment with instructional norms (normativity) and its potential to advance lesson goals (serviceability), yet how these distinctions surface in professional discourse remains underexplored. This paper uses natural language processing to analyze discourse from 45 professional development meetings involving 77 in-service mathematics teachers who discussed student work artifacts while designing a geometry lesson storyboard. We find that teachers maintained a consistently positive evaluative stance toward all student work artifacts. Semantic patterns suggest that teachers often juxtaposed artifacts, using pairing as a strategy to position diverse approaches while seemingly compensating for perceived limitations in advancing the lesson goal. Talk amount trended higher for less normative artifacts—consistent with prior research—but did not reach statistical significance, likely due to small sizes at the artifact level.

Keywords: Teacher Noticing, Students' Mathematical Work, Professional Development, Natural Language Processing, Practical Rationality

Noticing Normativity and Serviceability in Students' Mathematical Thinking

Research on teacher noticing has focused on how teachers attend to, interpret, and respond to students' mathematical contributions in the course of instruction (van Es & Sherin, 2002; Sherin & van Es, 2009). In many classroom settings, students' thinking is not rendered transparent through their work alone. Instead, it is conveyed through written work, diagrams, or partial representations that require teachers to interpret what is shown in relation to the underlying mathematics (Kazemi & Franke, 2004). Professional development efforts that center student work therefore position teachers to make sense of complex, incomplete representations in relation to instructional goals (Goldsmith & Seago, 2011; Little et al., 2003).

Recent scholarship on mathematics teaching has argued that teacher noticing cannot be understood solely as a cognitive process of understanding students' ideas, but must also be situated within the demands of instructional practice (Scheiner et al., 2026). In problem-based instruction, teachers encounter multiple, partial, and sometimes competing student contributions and must discern which are usable for advancing the lesson. Herbst and colleagues (2023) propose categories of perception that structure this discernment. Normativity refers to a teacher's perception of whether student work abides by the norms of the instructional situation used to frame the problem; serviceability refers to a teacher's perception of whether student work can advance the instructional goal. These categories are analytically distinct: A given piece of student work may have features that teachers perceive as normative, serviceable, both, or neither. Researchers can identify features in student work that could trigger those perceptual categories , while teachers vary how much they attend to each.

Empirical studies applying this framework suggest that these categories are not merely theoretical distinctions but are differentially salient in teachers' attention. In analyses of teachers' annotations on student work from problem-based lessons, Schwarts and colleagues (2023) found

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

that teachers more frequently commented on non-normative features than normative ones, and more often identified serviceable aspects than non-serviceable ones. For example, in algebra lessons framed around equation-based word problems, teachers commented more frequently on non-normative representations—such as tables or graphs—than on conventional equation-based solutions. At the same time, features that could be leveraged toward instructional goals were more frequently identified than features offering little instructional traction. These asymmetries suggest that departures from norms and opportunities for instructional leverage may command disproportionate professional attention.

Related work indicates that norm departures are discursively consequential. Dimmel and Herbst (2020) found that events breaching instructional expectations elicited longer and more evaluative teacher responses than norm-conforming events. Such findings imply that variations in normativity may shape not only what teachers notice but also the extent and evaluative characteristics of their discourse. This raises a central question: How do distinctions of normativity and serviceability become visible in the language teachers use when collaboratively discussing student work?

To investigate this question, we use foundational natural language processing (NLP) techniques to analyze patterns of talk amount, evaluative language, and semantic association in teachers' collaborative discussions, examining whether these patterns vary when discussing student work that differs in features perceivable as normative and serviceable. We ask:

1. How does talk amount vary across student work samples that differ in features related to normativity and serviceability?
2. How does the density and polarity of evaluative language vary across such samples?
3. How do semantic associations surrounding student work differ in relation to these features?

Method

Participants and Context

Seventy-seven in-service mathematics teachers participated in Story*Circles*, a virtual professional development model in which teachers collaboratively design and refine lesson storyboards representing how a lesson around a novel geometry problem might unfold (Herbst & Milewski, 2018). Teachers averaged 14 years of mathematics teaching experience and 8 years teaching geometry. They participated in six groups that met from October 2024 to May 2025, totaling 45 one-hour synchronous sessions.

The lesson centered on a geometry problem involving three swimmers entering a rectangular pool from different locations and racing toward a prize. One swimmer starts at a corner of the pool, while the other two enter from points on the sides adjacent to that corner, and students are asked to determine where the prize should be placed so that all three swimmers travel the same distance. The task was designed to lead students to discover the Midpoint of the Hypotenuse Theorem—that in a right triangle, the midpoint of the hypotenuse is equidistant from its three vertices.

Story*Circles* uses lesson storyboards to represent instructional sequences through frames organized around lesson phases. These frames embed samples of student work—developed from real student data—that teachers discuss as they monitor student thinking, select and sequence work, and shape whole-class discussion. We analyzed teachers' talk in aggregate, rather than phase by phase, to examine how teachers collectively noticed the artifacts.

Thirteen pieces of student work (by students named after Greek letters) were available to

every group and were discussed across the six groups. The work differed in ways that could be characterized a priori in terms of normativity and serviceability. Normativity concerned adherence to norms of construction or proof situations (e.g., use of compass and straightedge, justification from givens). Serviceability concerned the presence of features that advanced the lesson's instructional goal (e.g., use of a right triangle and its midpoint). An a priori analysis identified where such features were present.

Data Analysis

Data sources included recorded Zoom meetings, anonymized transcripts, and storyboard screencaptures. The 45 transcript documents were segmented using interactional analysis (Jordan & Henderson, 1995); AI-generated descriptions[1] of screen captures rendered visual storyboard information in linguistic form for NLP-based analysis (O'Halloran et al., 2021). Prior to analysis, transcript text was lowercased and tokenized into word units using a regular expression pattern that identifies word boundaries (Jurafsky & Martin, 2024). To identify discussions of student work, we extracted segments referencing student names (e.g., Alpha, Zeta) in the transcript or corresponding storyboard. We then applied a lexical cue filter retaining only transcripts that referenced (a) student thinking or approaches, (b) representations or artifacts (e.g., diagram, sketch, figure), or (c) mathematical objects central to the Midpoint of the Hypotenuse task (e.g., midpoint, hypotenuse, perpendicular, bisect).

To evaluate the performance of this lexical cue filter, a stratified random sample of excerpts from both the pre-filtered and filtered corpora was independently coded by two raters for explicit orientation to student mathematical work, reasoning, or representations. Interrater reliability was high (92% agreement; Cohen's $\kappa = 0.83$). Precision—defined as $\frac{TP}{TP+FP}$, where TP denotes excerpts correctly identified as mathematical student-work talk and FP denotes incorrectly identified excerpts—increased from 43.2% to 85.4%. Filtering by lexical cues thus produced a reliable corpus for analyzing how teachers discuss students' mathematical work.

Word count. From the resulting corpus of student-work-related talk, we computed language metrics to address each research question. The first metric, talk amount, was operationalized as total word count: raw token counts, with no words removed. Word count is a foundational NLP measure that indexes variation in textual engagement across conditions (Jurafsky & Martin, 2024). This measure addresses the first research question by indexing how much discussion teachers devoted to artifacts of student work in which differences in normativity and serviceability could be perceived. Specifically, we compared word count per student work artifact across four a priori coded combinations of normativity and serviceability: MM (more normative, more serviceable; n = 4 artifacts), ML (more normative, less serviceable; n = 3), LM (less normative, more serviceable; n = 3), and LL (less normative, less serviceable; n = 3).

Sentiment analysis. The second metric, sentiment analysis, was used to quantify evaluative language in teachers' collective noticing of student work. Sentiment and subjectivity analysis in computational linguistics identifies lexical expressions of belief, evaluation, or emotion and distinguishes subjective from objective language (Liu, 2010; Wiebe & Riloff, 2005). We used the MPQA Subjectivity Lexicon (Wiebe & Riloff, 2005; Wilson et al., 2009), a dictionary-based resource that reported strong inter-rater agreement in identifying contextual polarity and subjective expressions (90% agreement; $\kappa = 0.84$; Wilson et al., 2009). Tokens in the corpus were matched to lexicon entries labeled for subjectivity strength (strong-subj, weak-subj) and polarity (positive, negative, neutral, both). Subjectivity strength indexes the intensity of

[1] These AI-generated descriptions were used to identify which artifact each frame depicted and were not included in the language metrics, which reflect teacher talk alone.

evaluative stance, whereas polarity indicates its directional orientation (Wilson et al., 2005; 2009). Each transcript excerpt served as the unit of analysis. Three measures were derived:

1. Strong-subjectivity density. $Strong\ Subj.Density = \frac{N_{strong}}{W} \times 1000$ where N_{strong} is the number of strong subjective cues and W is total word count. This indexes the frequency of strong evaluative language relative to excerpt length.
2. Strong-subjectivity ratio. $Strong\ Subj.Ratio = \frac{N_{strong}}{N_{strong} + N_{weak}}$. This indexes the proportion of strong subjective expressions rather than weak ones, indicating evaluative intensity.
3. Polarity density. $Polarity\ Density = \frac{N_{positive} - N_{negative}}{W} \times 1000$. This indexes the net balance of positive versus negative evaluative language per 1,000 words.

Semantic neighborhood analysis. The third metric, semantic neighborhood analysis, examined patterns of contextual association in teachers' discourse about student work. We analyzed the corpus using Word2Vec, a distributional semantic method that learns vector representations of words based on patterns of contextual co-occurrence. In the resulting vector space, words that appear in similar contexts are positioned near one another. For each target word (e.g., Alpha, Zeta), we identified the most similar words in this vector space, revealing case-specific patterns of contextual association. These semantic neighborhoods reflect contextual similarity rather than word frequency alone. Given the moderate corpus size, tokens were lemmatized to reduce sparsity (Jurafsky & Martin, 2024), with minimal stopword removal to preserve mathematically relevant language. Comparing neighborhoods across cases provided an empirical lens on recurring orientations in teachers' collective noticing of student work.

Results

More Talk Around Less Normative Student Work

Table 1 displays the mean word count per student-work artifact across normativity × serviceability combinations (n = 191,629 words in total). Across both serviceability categories, artifacts characterized by less normative features generated more discussion on average. The highest mean talk amount occurred for less normative and more serviceable artifacts (M = 19,824 words per artifact), whereas the lowest occurred for more normative and more serviceable artifacts (M = 11,902 words per artifact). Intermediate levels of discussion were observed for LL and ML artifacts. Because the unit of analysis was the artifact (n = 13), with only 4, 3, 3, and 3 artifacts in each condition, this analysis should be interpreted as exploratory.

A two-way analysis of variance revealed no statistically significant main effects or interaction at the artifact level. Although less normative artifacts generated more discussion on average, consistent with prior reports (Schwarts et al., 2023), this difference was not statistically significant (p = .285) and therefore cannot be treated as evidence without further investigation.

Table 1: Mean Word Count per Student-Work Artifact Across Normativity × Serviceability

	More Serviceable	Less Serviceable
More Normative	11,902 (20%)	12,262 (21%)
Less Normative	19,824 (33%)	15,922 (27%)

Positive Evaluative Stance Across Differences in Normativity and Serviceability

Teachers' evaluative stance toward student work remained consistently positive across artifacts, regardless of differences in perceived normativity or serviceability (Table 2). Polarity values were positive in all conditions, indicating that affirmative language predominated even for artifacts perceived as less aligned with instructional norms or less immediately useful for advancing the lesson. Measures of strong-subjectivity density and evaluative strength showed only modest variation across conditions. The highest concentration of strong evaluative language occurred in discussions of artifacts perceivable as both more normative and more serviceable (strong-subjectivity density = 100.5; strong-subjectivity ratio = 0.59), while artifacts perceivable as more normative and less serviceable exhibited the lowest density (88.1), though ratios remained similar overall. This stability suggests that teachers did not treat evaluation as a mechanism for sorting or dismissing student work. Instead, maintaining a positive stance functioned as a discursive resource that kept multiple contributions in play as teachers worked to interpret and position them within the developing lesson.

Table 2: Evaluative Language by Normativity × Serviceability

Artifact Features				
Normative	Serviceable	Strong Subj. Density	Strong Subj. Ratio	Polarity
More	More	100.5	0.59	48.7
Less	Less	99.0	0.57	51.5
Less	More	96.2	0.56	48.5
More	Less	88.1	0.56	45.9

Semantic Associations Indicate Pairing as a Compensatory Strategy

Semantic neighborhood analysis revealed patterns of contextual association surrounding selected student-work artifacts across normativity × serviceability combinations. To illustrate these patterns, we selected from each combination the artifact that elicited the most discussion, as these cases provided the densest linguistic data for modeling contextual associations. We describe the words most strongly associated with its name in the learned vector space.

For the more normative and more serviceable artifact, Nu's work, the most similar words included *ABC, medians, bisector, circum, geometric, definition,* and *construct* (cosine similarity .744–.499). These associations reflect discourse anchored in canonical geometric objects and construction methods, suggesting that teachers perceived Nu as aligned with normative diagrammatic conventions and as procedurally oriented toward the instructional goal. The clustering of canonical geometric terminology indicates that both normativity and serviceability were relatively efficiently recognized.

For the more normative but less serviceable artifact, Beta's work, associated words included *peer, classmate, epsilon, difference, visible, bisector, similarity*, and *zeta* (cosine similarity .595–.417). While the presence of *bisector* signals recognition of normative geometric structure, the frequent co-occurrence of *peer* and *classmate* suggests that teachers oriented toward pairing strategies—most notably pairing Beta with Epsilon—to compensate for perceived limitations of Beta's work for advancing the lesson goal.

For the less normative and less serviceable artifact, Epsilon's work, a similar pattern emerged, as the neighborhood included *sketch, beta, sharing, omicron, marking, classmate, peer,* and *continuation* (cosine similarity .574–.411). Words such as *sketch* reflect less canonical

geometric language, while co-occurrences of *beta* and *classmate* again indicate orientation toward pairing, suggesting that teachers worked to situate this artifact within a broader lesson sequence.

For the less normative but more serviceable artifact, Zeta's work, associated words included *eta, separate, hit, consistent, leg, quick, weigh,* and *favorite* (cosine similarity .708–.396, reflecting a broader spread of associations). The prominence of *eta* reflects a recurring instructional move in which teachers paired Zeta with Eta due to shared reliance on non-normative measurement strategies. Words such as *consistent* and *leg* indicate efforts to interpret the unconventional measurement-based reasoning, while *favorite* suggests that teachers nevertheless perceived productive value in the approach. Compared to Nu, whose neighborhood was dominated by established geometric terminology, Zeta's associations included more interpretive language, suggesting that additional discursive work was required to unpack its instructional potential.

These patterns highlight a distinctive feature of the Story*Circles* context and clarify how perceptions of normativity and serviceability were worked out in practice. Although the lesson storyboard initially positioned each student-work artifact individually within a frame, teachers frequently reconfigured artifacts in pairs when discussing sequencing decisions. Teachers treated normativity and serviceability not as fixed attributes of a single artifact but as qualities that could be established relationally by interpreting one piece of artifact alongside another. Pairing thus functioned as a compensatory strategy, mitigating perceived limitations in normativity or serviceability by juxtaposing complementary artifacts. This orientation toward comparing student work aligns with the findings from the sentiment findings: Despite differences in perceived normativity or serviceability, teachers maintained a generally positive stance toward all artifacts. Artifacts perceived as less aligned with norms or less immediately useful for the lesson were repositioned through comparison to render them instructionally usable.

The semantic findings also contextualize the talk amount trend. While less normative artifacts generated more extended discussion overall, their semantic neighborhoods contained more varied and interpretive language compared to the more concentrated geometric terminology associated with artifacts more readily perceived as normative and serviceable. This contrast suggests that normativity may be recognized efficiently when canonical features are present, whereas artifacts lacking those features require more discursive elaboration to articulate their value within the developing storyboard. Establishing serviceability, in turn, often involved interpreting how such work could be connected to other contributions or positioned within the lesson sequence to advance the instructional goal. In this sense, semantic neighborhood patterns illustrate how teachers' collective noticing extended beyond evaluation to include the interpretative and comparative work required to construct a coherent mathematical narrative across student contributions.

Illustrative Excerpts

To contextualize the quantitative patterns in talk amount, evaluative language, and semantic association, we present one representative artifact from each normativity × serviceability combination alongside an illustrative excerpt (Figure 1). These excerpts provide qualitative insight into how teachers interpreted and positioned student work within Story*Circles*.

Discussion of the more normative and more serviceable artifact, Nu's work, was concise and generally affirmative, suggesting limited discussion beyond recognition of both its normative features and instructional usefulness. Teachers described it as appropriate for a "middle-ish" portion of the lesson.

Discussion of the more normative but less serviceable artifact, Beta's work, revealed closer scrutiny of whether its geometric elements advanced the lesson goal. The quote signals recognition of normative structure—"draw the perpendicular bisectors of those sides"—while simultaneously questioning its instructional leverage. Consistent with the semantic associations linking Beta to references to peers and other artifacts, teachers considered pairing it with Epsilon to clarify similarities and differences and to strengthen its role in the developing storyboard.

	More Serviceable	Less Serviceable
More Normative	Nu  "I think it's good… this would be, I feel like, middle-ish [of the lesson]	Beta  "Did they both say they were going to draw the perpendicular bisectors of those sides?"
Less Normative	Zeta  "This one I struggle with… when kids have ideas like this, I would almost laugh them off and be okay. But how can we really find…that's all that is an outside-the-box thinking? How could we apply it on paper? … I wouldn't even know a question to ask them to build off of their idea"	Epsilon  "I guess it's a lower barrier to entry, maybe would be a reason to include it"

Figure 1: Representative Student-Work Artifacts and Illustrative Excerpts Across Normativity × Serviceability Combinations

For the less normative and less serviceable artifact, Epsilon's work, teachers noted that it provided a "lower barrier to entry," and its sketch-like qualities prompted discussion about how it might be supported or positioned alongside other work to contribute meaningfully to the lesson. This suggests that when features of student work were perceived as less aligned with conventional norms or immediate instructional usefulness, teachers sought ways to retain and develop the artifact within the sequenced storyboard.

Discussion of the less normative but more serviceable artifact, Zeta's work, was more extended and deliberative. The excerpt highlights both the perceived unconventional nature of the reasoning as "outside-the-box thinking" and the affordances of the Story*Circles* context. Although the teacher acknowledged that in a live classroom they might "almost laugh them off", the collaborative Story*Circles* setting allowed teachers to examine how Zeta's non-normative

measurement approach might still contribute to the mathematical storyline. The teacher explicitly names struggling with this artifact; in contrast to Nu's work, whose discussion was anchored in established geometric terminology and required relatively little elaboration, Zeta's work required more interpretive work to articulate its instructional potential.

Conclusion

A central finding of this study is that teachers maintained a consistently positive evaluative stance toward student work regardless of differences in perceived normativity or serviceability. Work that was less aligned with conventional mathematical forms or less immediately useful for advancing the lesson was not dismissed; instead, teachers treated all contributions as potential resources for instruction. This consistency of evaluation suggests that the Story*Circles* context supports teachers in keeping multiple lines of student reasoning in view as they interpret student work in relation to instructional goals. This orientation aligns with a central goal of Story*Circles*: to treat student work as a shared design resource rather than an object of correction.

Semantic patterns showed how teachers carried out this work in practice. Teachers frequently paired artifacts, interpreting them in relation to one another to establish their instructional value. Pairing functioned as a compensatory strategy, addressing perceived limitations in normativity or serviceability by juxtaposing complementary approaches and repositioning contributions within the lesson's mathematical trajectory. Through this comparative work, teachers shaped a coherent mathematical storyline rather than considering artifacts in isolation.

Story*Circles* functions as a productive site for examining teachers' collective noticing, making visible how student work is collaboratively interpreted, repositioned, and leveraged toward shared instructional goals. By highlighting how teachers sustain a broadly positive orientation while engaging in comparative and interpretive work, this study underscores the role of collective noticing in transforming diverse student contributions into shared instructional resources.

Limitations and Future Directions

An exploratory analysis of talk amount showed that less normative artifacts elicited more extended discussion, but this difference was not statistically significant and therefore did not replicate prior findings. This lack of statistical significance likely reflects the small number of units of analysis at the artifact level (n = 13), which constrained inferential power. For the semantic association analysis, one artifact within each condition was selected because it elicited the most discussion and thus provided dense linguistic data for modeling contextual relationships. This artifact was treated as representative of the condition for analytic purposes, though examining additional artifacts could further test the stability of these patterns. Finally, this study relied on computational analyses of language derived from lexical features and distributional patterns. These measures provide systematic insight into discursive tendencies but do not capture speaker intention or the sequential organization of interaction; the findings, therefore, identify patterns of orientation in teacher talk rather than fully specifying teachers' reasoning processes. Future research may extend this approach by analyzing a broader range of artifacts and by integrating interactional or grammatical analyses to complement lexical and distributional measures.

BEYOND BELIEFS: SUPPORTING REFORM DOES NOT GUARANTEE REFORM-ORIENTED PRACTICE

Kayla Sutcliffe
University of Florida
kaylajsutcliffe@ufl.edu

Veteran teachers are often framed as resistant to reform-oriented mathematics, yet less is known about how their beliefs, knowledge, and experiences shape enactment. This Interpretative Phenomenological Analysis of seven veteran elementary teachers found that participants generally valued reform goals, but implemented them conditionally. Early procedural learning experiences shaped enduring beliefs, while uneven mathematical knowledge for teaching and teacher self-efficacy influenced instructional decisions. Systemic pressures such as testing and pacing further mediated practice. Teachers negotiated hybrid approaches that balanced reform ideals with contextual constraints. Findings suggest reform enactment is not driven by beliefs alone but by the interaction of beliefs, knowledge, efficacy, and context, underscoring the need for sustained, mathematics-focused professional learning that bridges support and practice.

Keywords: Mathematical Knowledge for Teaching, Professional Learning, Teacher Beliefs

Problem Statement

Mathematics education in the United States has long been marked by recurring tensions between traditional, procedure-focused instruction and reform-oriented approaches emphasizing conceptual understanding and problem-solving (Schoenfeld, 2007). Reform efforts, including the Common Core State Standards (CCSS), have prioritized reasoning and conceptual knowledge, yet their success depends heavily on teacher implementation (Charalambous & Philippou, 2010; Phillips & Wong, 2012). Many veteran elementary teachers learned mathematics through procedural methods and report feeling underprepared to enact reform-oriented practices such as facilitating student-centered discussion or developing conceptual understanding (Craven & Trygstad, 2020; Drake & Sherin, 2006; Swars & Chesnutt, 2016).

Research highlights the importance of teachers' beliefs, teacher self-efficacy (TSE), and mathematical knowledge for teaching (MKT) in shaping instructional decisions (Ernest, 1989; Fives & Buehl, 2012; Hill et al., 2005). However, less is known about how veteran teachers' lived experiences as mathematics learners interact with these cognitive and affective elements to influence reform enactment, particularly as they navigate ongoing reform demands. The Cognitive-Affective Model of Conceptual Change (CAMCC) (Gregoire, 2003) offers a lens for understanding how teachers interpret reform messages through prior experiences, beliefs, efficacy, and knowledge, shaping the extent to which they engage with and implement reform-oriented instruction.

Purpose and Research Questions

The purpose of this paper is to examine one analytic finding from a broader interpretative phenomenological dissertation study of veteran Florida elementary mathematics teachers' experiences with traditional and reform-oriented instruction. While the larger study explored teachers' experiences, beliefs, TSE, and MKT across their careers, this paper focuses specifically on how teachers describe their support for reform-oriented mathematics and the conditions under which that support may—or may not—translate into reform-oriented instruction. To address this purpose, the following research questions guide the study:

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

1. How do veteran elementary mathematics teachers describe their beliefs about and support for reform-oriented mathematics instruction across their experiences as learners and teachers?
2. How do beliefs, teacher self-efficacy (TSE), mathematical knowledge for teaching (MKT), and contextual factors interact to shape whether support for reform results in reform-oriented instruction?

Conceptual Framework

This study is grounded in an integrated conceptual framework (Figure 1) that integrates teacher beliefs, TSE, MKT, and the CAMCC to examine why support for reform-oriented mathematics does not always translate into reform-oriented practice. Beliefs are "messy" yet powerful drivers of teacher decision-making because they are shaped by experience and often guide behavior more strongly than knowledge alone (Ernest, 1989; Fives & Buehl, 2012; Pajares, 1992). Empirical research indicates that teachers' beliefs about the effectiveness of reform-oriented approaches are strongly associated with how they enact these practices in the classroom (Liou et al., 2019; Wilkins, 2008). At the same time, beliefs are held with varying degrees of strength and flexibility (Conner & Gomez, 2019; Green, 1971; Thompson, 1992), and teachers frequently experience mismatches between reform-oriented beliefs and enacted practice when faced with contextual demands (Grant & Kline, 2000; Raymond, 1997; Sawyer, 2017; Yates, 2006). In this study, mathematics beliefs are defined as personal judgments about mathematics formed through experience that influence instructional decision-making (Raymond, 1997; Schoen & LaVenia, 2019).

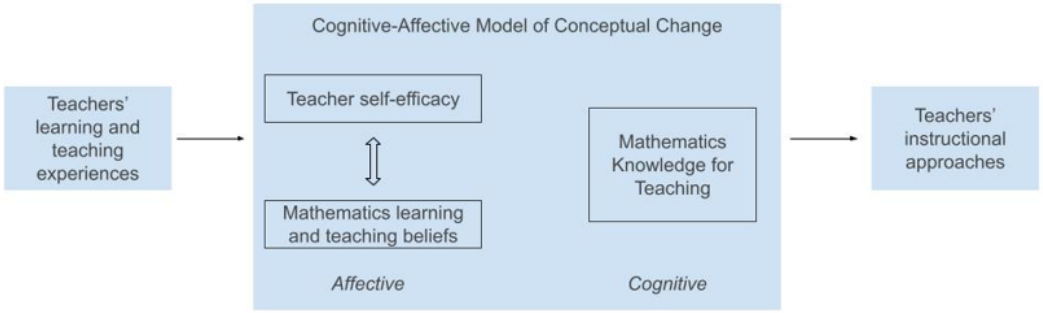

Figure 1: Conceptual Framework

To move beyond belief–practice assumptions, this framework incorporates TSE and MKT as key mechanisms that mediate enactment. TSE refers to teachers' beliefs about their capability to organize and execute instructional action (Bandura, 1994, 1997; Skaalvik & Skaalvik, 2010) and is linked to teachers' willingness to engage in reform-oriented instruction (Liou et al., 2019). MKT captures the subject matter knowledge and pedagogical content knowledge needed for teaching, including how teachers interpret content, respond to student thinking, and enact instruction (Ball et al., 2008; Shulman, 1986). Because MKT models have been critiqued for underemphasizing affective dimensions (Carrillo-Yañez et al., 2018), the CAMCC provides the organizing model for how cognitive (e.g., knowledge) and affective (e.g., beliefs, self-efficacy) processes shape teachers' responses to reform messages (Gregoire, 2003). Using this integrated lens, the study examines how veteran teachers' experiences as learners and teachers interact with beliefs, TSE, MKT, and contextual constraints to produce conditional reform enactment,

clarifying why supporting reform does not necessarily guarantee reform-oriented practice (Grant & Kline, 2000; Gregoire, 2003; Raymond, 1997).

Methodology

Statement of Positionality

This study adopted Interpretative Phenomenological Analysis (IPA) as its methodological and analysis approach, recognizing that the researcher is embedded within participants' lived experiences and must actively interpret those experiences (Neubauer et al., 2019; Smith et al., 2022). As I began the data collection, my biases, judgements, and positionality were closely monitored through reflexive journaling. I referred to my own mathematical learning and teaching background to make sense of and interpret the data, aligning with a core value in IPA. Moreover, I understood that my belief in the power of reform-oriented instruction, coupled with my understanding of the challenges that teachers face in implementing these practices, shaped how I interpreted the findings. I recognized that teaching is not binary, and the landscape of mathematics instruction is far more nuanced than a simple dichotomy between traditional and reform-oriented approaches.

Research Design

The broader study employed IPA, grounded in phenomenology, hermeneutics, and idiography (Smith et al., 2022). IPA prioritized participants' subjective experiences and meaning-making, while acknowledging the double hermeneutic, in which the researcher interprets participants' interpretations of their lived experiences (Smith et al., 2022). In keeping with IPA's idiographic focus, the study centered on a detailed, case-by-case examination of each participant's lived experiences prior to cross-case synthesis.

Sampling and Recruitment

IPA suggests that participants should be relatively homogeneous (idiographic) to ensure the data collected reflects potential areas of convergence or divergence (Smith et al., 2022). To be eligible, teachers must have been teaching elementary (kindergarten–fifth grade) mathematics at least once per week and have at least 10 years of experience in a Florida public school. Participants were recruited through purposive and snowball sampling (Tracy, 2019) using an IRB-approved digital flyer and targeted recruitment emails. Ultimately, seven teachers were selected (Table 1), a sample size considered appropriate for a robust IPA study (Smith et al., 2022). Although eligibility was set at 10 years, participants had between 20 and 35 years of teaching experience. All participants reported their gender and racial identity as female and White, respectively, and each taught mathematics anywhere from 50–65 minutes daily.

Table 1: Overview of Participants

Pseudonym	Years Taught[1]	Grade Level[1]
Rachel	27	2nd
Maria	20	3rd
Lauren	25	5th
Jill	28	1st
Janet	33	5th
Meg[2]	35	2nd, 3rd, 5th
Kate	24	1st

[1] At the time of data collection in summer after school year ended.

[2] Meg's class included one student each from grades 2, 3, 5, 9, 10, 11, and 12.

Data Collection and Analysis

Data were generated through pre-interview reflections, semi-structured interviews, and post-interview journal prompts (Figure 2). A pre-interview reflection served as stimulus material (Törrönen, 2002) to orient participants to *traditional* and *reform* terms and guide interview follow-up questions; it functioned only as preparation and was not included in the data analysis. Each participant completed a single semi-structured interview (40–75 minutes; $M = 56$), which was recorded and transcribed using MAXQDA Transcription. One day following interviews, participants completed a typed journal prompt to provide additional insight and participant control over what was shared (Smith et al., 2022). Reflexive researcher journaling in MAXQDA supported documentation of positionality, methodological decisions, and evolving interpretations (Lincoln & Guba, 1982; Smith et al., 2022; Vicary et al., 2017).

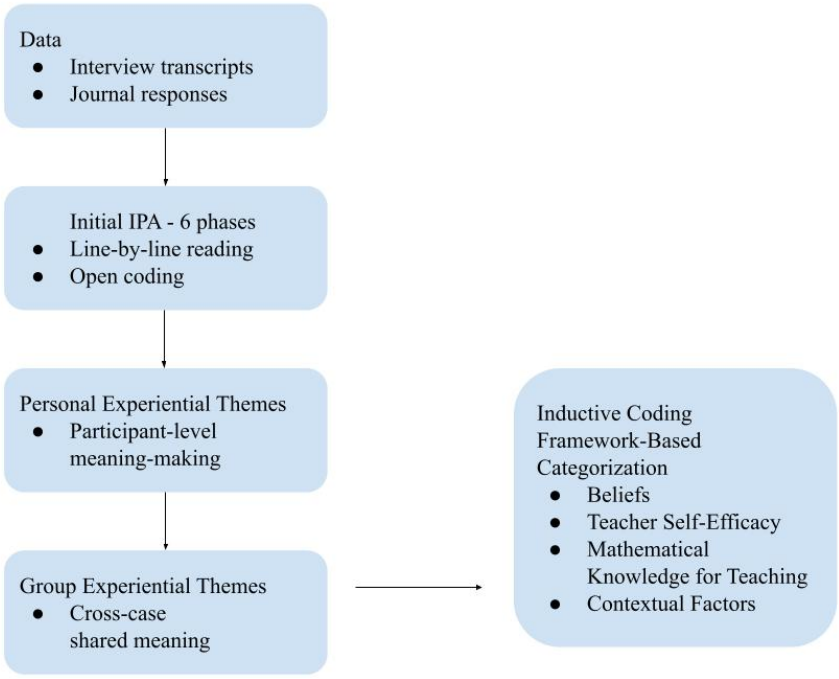

Figure 2: Two-Phase Qualitative Data Analysis

Interview transcripts and journal prompt responses were analyzed using a two-phase qualitative analytic approach (Smith et al., 2011; Figure 2). First, an IPA was conducted following the systematic, idiographic, and interpretative framework described by Smith et al. (2022), including multiple close readings, exploratory noting, generating experiential statements, developing Personal Experiential Themes (PETs) for each participant, and forming Group Experiential Themes (GETs) through cross-case analysis while attending to both convergence and divergence. Second, after GETs were generated, a framework-based analysis was conducted to examine barriers to and motivators for implementing reform-oriented mathematics instruction using the study's conceptual framework as an analytic and organizational lens. Specifically, identified barriers and motivators were categorized according to the constructs within the framework (e.g., beliefs, TSE, MKT, and contextual influences), allowing for patterns across participants to be examined while maintaining alignment with the theoretical commitments of IPA.

Findings

Research Question 1: How do Veteran Elementary Mathematics Teachers Describe Their Beliefs About and Support for Reform-Oriented Mathematics Instruction Across Their Experiences as Learners and Teachers?

Participants expressed beliefs that generally supported reform-oriented mathematics, particularly its emphasis on conceptual understanding, student-centered learning, and engagement. Reform-oriented approaches were viewed as opportunities to strengthen their beliefs aligned with student-centered learning, build confidence in instructional decision-making, and deepen MKT. For example, Lauren described reform-oriented instruction as a shift where "you're not the show," emphasizing that students should "guide their learning and their understanding," reflecting beliefs that position learners as sense makers. Participants emphasized that reform-oriented instruction helped build classroom community, encouraged learning from mistakes, and supported students in using the strategies that worked best for them. Lauren explained,

> It's important that they learn strategies that they can access. And it might not be the strategy that works for you, and it might not work for everyone in the room. But if it's something that helps them efficiently get there, I feel like that's the priority.

Participants also described how reform-oriented practices increased student motivation and engagement. Maria explained, "[Reform-oriented tasks] get [students] to buy in a little bit more and then be a little bit excited when they can make that connection between math and things that they do on a daily basis." Rachel similarly noted, "most of [my students] get excited about it [real-world problems and student-led discussions]. They're very inquisitive."

Despite these supportive beliefs, participants frequently described tensions between reform-oriented ideals and their comfort with traditional methods. Across participants, experiences with mathematics as K–12 students were overwhelmingly traditional in nature, with little to no exposure to reform-oriented instruction until later in their careers, often first encountered in teacher preparation programs or through curriculum adoption and classroom practice. Participants frequently recalled environments that emphasized memorization, speed, and performance under pressure, often with little conceptual understanding. Rachel recalled a particularly vivid source of stress when asked about what she remembered about learning mathematics:

> There was some anxiety around having to do [timed math fact tests]. Memorizing multiplication facts and having to stand up and say them all in front of the teacher. A lot of arguing [about math homework] with my parents, mainly my dad.

As teachers, all seven participants articulated difficulties letting go of the perceived control or efficiency that traditional teaching methods offered. Maria explained, "sometimes it's hard to let go of that control." Participants often framed their instructional approaches as a balance between traditional and reform-oriented instruction. Rachel described current practice as having "a nice balance," while Kate stated that she strives "to find a balance so my teaching can be memorable, but also meet the expectations given … I personally believe a hybrid would be the most effective."

These findings suggest that support for reform-oriented mathematics was not simply a matter of endorsement but of ongoing negotiation shaped by teachers' learning histories and perceived

classroom demands. While participants articulated strong alignment with the goals of conceptual understanding and student agency, their enactment was tempered by deeply rooted experiences with traditional instruction and a continued reliance on its perceived efficiency and control. Rather than rejecting reform, teachers described working to reconcile competing priorities, often adopting hybrid approaches that allowed them to maintain instructional comfort while gradually incorporating reform-oriented practices.

Research Question 2: How Do Beliefs, TSE, MKT, and Contextual Factors Interact to Shape Whether Support for Reform Results in Reform-Oriented Instruction?

Findings revealed an interrelated set of constraints operating across teachers' beliefs, TSE, MKT, and contextual conditions. Teachers' beliefs about effective mathematics instruction often interacted with their confidence and perceived MKT, jointly influencing instructional decisions. Reflecting on her limited mathematics TSE and MKT, Meg lamented that she "didn't have the confidence necessary to go forth and meet [a student] where he was," when referring to a time when she did not understand the mathematical content necessary to teach certain geometry concepts. Similarly, Janet noted that "if there is a standard that I cannot show a student how to do comfortably … that's when I will go the traditional way."

Limited access to sustained, mathematics-centered professional learning (PL) appeared to have constrained opportunities to build reform-aligned TSE and MKT. Lauren reflected, "The history of math professional development is minimal … There's so much reading professional development out there, but there's no math." Jill emphasized the potential impact of effective mathematics PL stating that "if [math PL] is well done, it is very motivating."

Externally imposed structural and policy conditions were described as constraining teachers' willingness to fully invest in reform-oriented instruction, particularly when accountability pressures made instructional time feel high stakes and outcomes uncertain. Kate explained,

> The system of testing has forced [teachers] to be failures … when you do a lot of that reform kind of math, you can't always be confident that you've wasted a whole day for something that might not pay off for a long time.

Additionally, Rachel described restrictive school norms, stating that "It was more of stay on pace and do what your team's doing … it should all look like you all are doing the same thing." Participants also identified student and classroom-related factors shaping instructional choices. Rachel noted, "Some days all they can handle is following in a book … impulsive behaviors are definitely a barrier."

Beliefs about student readiness further influenced enactment. Janet stated, "If they don't have that foundation … they're not going to understand anything that I am explaining." Kate similarly remarked, "I just believe strongly these kids need to know that four plus four is eight… you're never going to get to the fun part of math if the foundational skills are [lacking]."

At the same time, participants described motivations that supported reform enactment when conditions aligned, particularly when they took initiative in their own learning. Lauren reflected on a shift in her thinking, noting that "the way I think about math has completely changed," and that she built confidence in implementing reform-oriented practices after intentionally seeking out mathematics-focused PL on her own.

Reform-oriented instruction was most likely to occur when teachers experienced increased TSE, growth in MKT, positive student engagement, and supportive (e.g., administration, support personnel) contexts. However, even when teachers expressed strong support for reform-oriented mathematics, contextual pressures, limited MKT, and fluctuating confidence often resulted in hybrid or conditional implementation. Together, these findings indicate that support for reform-

oriented mathematics did not consistently translate into reform-oriented practice. Instead, enactment was shaped by the interaction of beliefs, MKT, TSE, and contextual constraints, resulting in conditional and context-dependent implementation.

Discussion and Implications

Sustained, Mathematics-Focused Professional Learning

Findings indicate that support for reform-oriented mathematics did not consistently translate into reform-oriented practice. Participants described valuing reform-oriented instruction while also relying on traditional methods due to limited mathematics-focused PL, fluctuating confidence, and contextual pressures. These findings point to the need for sustained, mathematics-specific PL that is embedded in teachers' daily work and grounded in classroom practice rather than one-time workshops (Shriki & Patkin, 2016).

Specifically, PL should explicitly address the gap between valuing reform principles and consistently enacting them in practice through reflection, collaboration, and opportunities to experience reform-oriented mathematics themselves as learners (Fives & Buehl, 2016; Kutaka et al., 2017; Phillipsen et al., 2019; Spillane et al., 2018). Participants' descriptions of minimal mathematics PL and reliance on self-directed learning suggest that teachers require ongoing opportunities to rehearse, refine, and reflect on reform-oriented practices in supportive environments. Without sustained, content-specific support, teachers may revert to familiar procedural methods, particularly when confidence is low or contextual pressures are high (Charalambous & Philippou, 2010; Stein et al., 2013; Swars & Chesnutt, 2016).

Targeting teacher self-efficacy and mathematical knowledge for teaching. Findings reveal that teachers' beliefs interacted with their TSE and MKT, collectively shaping whether support for reform translated into reform-oriented instruction. Participants described turning to traditional approaches when they felt uncertain about content knowledge or instructional decisions, suggesting that these elements function in a mutually reinforcing relationship in which confidence and knowledge both enable and are strengthened through reform-oriented practice (Kutaka et al., 2017; McMinn et al., 2021). PL should therefore attend to both cognitive and affective dimensions of teaching mathematics by supporting teachers' understanding of mathematical content while also strengthening confidence in implementing reform-oriented instruction (Gregoire, 2003). Opportunities to analyze student thinking, anticipate misconceptions, and explore multiple solution strategies can help teachers build MKT while also increasing confidence in facilitating conceptual and discussion-based instruction (Ball et al., 2005; Hill & Ball, 2009). When teachers experience growth in MKT alongside supportive collaboration and reflection, they are more likely to enact reform-oriented practices consistently.

Enhancing understanding of reform-oriented mathematics. Although participants expressed support for reform-oriented mathematics, findings indicated that reform was often enacted in hybrid or conditional ways. This suggests a need for PL that moves beyond introducing the visible features of reform to engaging teachers in deeper exploration of the mathematical and pedagogical principles underlying reform-oriented instruction. Analyzing student work, comparing solution strategies, and examining connections between conceptual and procedural knowledge can support teachers in developing more integrated understandings of reform goals and aligning instructional decisions with those goals (Carpenter et al., 1996; Charalambous & Philippou, 2010; Rittle-Johnson et al., 2015). Collaborative structures such as Professional Learning Communities (PLCs) and coaching can provide spaces for teachers to discuss tensions between reform ideals and classroom realities, experiment with instructional

approaches, and receive feedback in supportive environments (Kutaka et al., 2017; Shriki & Patkin, 2016).

Structural Supports and Conditions for Enactment

Participants described testing pressure, pacing expectations, limited mathematics PL, and school norms as central factors shaping whether reform-oriented instruction was enacted, constraining teachers' willingness to take instructional risks, reinforcing reliance on familiar, efficiency-driven practices even when beliefs aligned with reform goals. At the policy level, states and districts should reduce the high-stakes consequences attached to standardized test performance because such accountability pressures can reinforce traditional practices (Boehme, 2014; Lambert, 2015; Yurekli et al., 2020) and may discourage the use of instruction that best supports students' learning. Thus, school and district leaders play a critical role in providing time for collaboration, access to high quality PL, and instructional resources aligned with reform goals (Yurekli et al., 2020). PL designed around manageable, practice-proximal instructional shifts may support teachers in gradually strengthening reform-oriented instruction while navigating contextual constraints (Otten et al., 2025). When teachers experience supportive contexts, growth in MKT, and increased confidence, reform-oriented instruction is more likely to be enacted consistently rather than conditionally.

Conclusion

This study centers veteran elementary teachers' lived experiences with traditional and reform-oriented mathematics to understand how those experiences shape the conditional uptake of reform-oriented instruction. Findings reveal that teachers' support for reform was often genuine yet unevenly enacted, shaped by the reciprocal interplay of beliefs, TSE, MKT, and contextual pressures such as testing, pacing, and limited mathematics-focused PL. Collectively, the findings underscore that movement toward reform is not a simple shift in beliefs but an iterative process requiring sustained, mathematics-specific PL, alignment across policy and school structures, and conditions that allow teachers to take instructional risks without fear of negative consequences. Supporting veteran teachers in examining their learning histories, strengthening TSE and MKT, and engaging in collaborative, practice-based PL may strengthen teachers' capacity to enact reform-oriented mathematics instruction in coherent and sustainable ways.

Acknowledgments

I am very grateful to the teachers who generously shared their time, experiences, and reflections; their openness made this study possible. I also extend sincere thanks to my advisor, Dr. Melissa Soto, for her guidance and unwavering support throughout this work.

TALK PATTERNS IN FACILITATED TEACHER TEAMS: USING OPEN-ENDED UNIT ASSESSMENTS AS ARTIFACTS TO SUPPORT TEACHER LEARNING

s.karim@missouri.edu

We share findings from a project in which teams of elementary teachers met regularly to discuss their students' work on district-developed, open-ended assessments and co-planned lessons incorporating information gathered from those assessments. Focusing on the patterns of talk in two fourth-grade teams over nine meetings, we analyzed shifts in the focus of conversations as participants analyzed assessments and planned lessons. We describe several patterns, including that teachers discussed features of solutions beyond their correctness and were increasingly more specific in their planning conversations. We also documented tensions in the conversations, such as concerns with the fairness of item scoring and the alignment between the assessments and curriculum, standards, and state tests.

Keywords: Instructional Leadership, Elementary School Education, Professional Development, Instructional Activities and Practices

Introduction

One empirically supported way of improving elementary mathematics teaching is engaging teachers in developing and using knowledge of student thinking in their instruction (Carpenter et al., 2000). A significant challenge, however, is embedding these kinds of learning experiences in the day-to-day work of teaching. In this project, we sought to understand how unit assessments might function as a site for such learning experiences, and how facilitated grade level team meetings might support teachers in developing and using knowledge about student thinking in their planning and teaching.

Scholarly Foundation

The study was guided by a theory which views learning in terms of "transformation of participation" (Rogoff, 1997) rather than individual competency or demonstrations of knowledge. Following Kazemi and Franke (2004), we use this approach to analyze shifts in teachers' conversations around students' mathematical work, with group discourse as the primary object of analysis. Specifically, we examine how discourse about (1) student thinking, (2) teaching, and (3) mathematics evolved over the course of the year-long project.

A robust base of literature supports the use of artifacts of student thinking to drive the development of professional knowledge in teacher teams, especially when drawn from teachers' own classrooms (e.g., Franke et al., 2001; Gibbons & Cobb, 2017; Kazemi & Franke, 2004). One type of artifact that may support such discussions is the assessments that teachers give as a part of their normal teaching responsibilities. Because tests are perceived connected to school accountability and the improvement of teaching and learning (Brown, 2004), teachers have both intrinsic and extrinsic reasons to care about how students perform on them.

Assessment results can be misinterpreted and misused in schools, as numerical scores can lead to "assumptions about students' knowledge without considering specific test items and the validity of the information that these items provide about that knowledge" (National Council of

Teachers of Mathematics [NCTM], 2014, p. 91). In many schools, assessment programs are administered electronically and are scored automatically, producing a numerical score and sometimes a ranking (3rd grade level, etc.). These scores and rankings, however, do not provide the rich examples of student thinking that are likely to provide the material to support productive teacher conversations (e.g., Shim & Thompson, 2025), but instead, can lead to identifying/sorting students for remediation (Farrell & Marsh, 2016; Gannon-Slater et al., 2017). On the other hand, assessments can be used "as a method of gathering evidence of children's mathematical thinking to inform learning and teaching" (NCTM, 2020, p. 34).

In this project, we worked closely with a district that had designed a set of assessments that focused on student strategies rather than answers. District leaders planned to facilitate meetings to support teachers' conversations and learning about student thinking through examining student performance on these assessments. The research team, in collaboration with district leaders, developed a process to study the nature of these conversations and how they shifted over time, and also to understand the potential tensions that might arise as teachers navigated various purposes and goals of assessments.

Research Question

Our research question is, "What shifts in discussions occur over the course of a school year when grade level teacher teams engage in repeated opportunities to use strategy-based assessments to analyze student thinking and plan their instruction?" Our hypotheses were that teachers would gradually move toward describing student thinking in terms of strategies rather than correctness and would connect their discussions of teaching and content to evidence regarding student thinking/strategies. Furthermore, we conjectured that they would begin to make explicit connections between evidence regarding student thinking/strategies as gleaned from the assessments and discussions of their teaching approaches. That is, they would draw on evidence about student thinking in their co-planning conversations, and they would explain patterns in their assessment data by referencing specific pedagogical choices.

Context and Methods

The study was conducted in a school district that had adopted a commercially published textbook with seven to nine units in each grade level. A team of teachers and leaders worked to adapt the unit assessments so that they would be open to a variety of strategies and created strategy rubrics for each task based on research-supported learning progressions (e.g., Battista, 2012; Carpenter et al., 2015; Empson & Levi, 2011). Each assessment had four to seven items. Table 1 provides an example of the strategy guide for one of the items on the Unit A assessment. Numerical "scores" were attached to the rubric. Though the goal of the project was to focus on using assessments to understand and support student thinking rather than provide summative evaluations, project leaders included numerical scores to enable teachers to use their characterizations of student thinking from the assessments as pieces of evidence to support their (standards-referenced) grading. The numerical scores were intended to support teachers in recognizing a progression of ideas while still allowing for flexibility in strategy.

Table 1: A Strategy Guide for the Task: *Susan says 3/5 is greater than 4/10. Do you agree or disagree with Susan? Show your thinking using number, pictures, and/or words.*

Strategy Type	Description	Examples	Score
Invalid Strategy	The student is engaging in a strategy that would not lead to a correct answer.	The student says $\frac{4}{10}$ is bigger than $\frac{3}{5}$ because 10 is more than 5.	1
Partial Fraction Reasoning	The student uses numerators or denominators to decide which is bigger but not the relationship between the two.	The student indicates that $\frac{3}{5}$ is bigger than $\frac{4}{10}$ because fifths are bigger than tenths. Although this is correct for this problem, if the numerators were different, it may not be. The student uses drawings of fraction bars or circles to compare the amounts, but draws wholes that are not the same size.	2
Direct modeling	The student represents the fractions with drawings or models and uses them to compare.	The student uses drawings of fraction bars or circles to show that $\frac{3}{5}$ is more than $\frac{4}{10}$. The diagrams have the same sized wholes.	3
Equivalent Fractions	The student generates equivalent fractions numerically to determine which is greater.	The student uses equivalent fractions to determine which one is more using numbers. $\frac{4}{10} = \frac{2}{5}$ or $\frac{3}{5} = \frac{6}{10}$, so $\frac{3}{5}$ is greater	3
Benchmark Reasoning	The student uses a benchmark such as $\frac{1}{2}$ to decide which fraction is greater.	The student claims that $\frac{3}{5}$ is more than $\frac{1}{2}$ and $\frac{4}{10}$ is less than $\frac{1}{2}$, so $\frac{3}{5}$ is greater.	3

Each school had a facilitator; two of these were school-based coaches, one was the district curriculum coordinator, and one was a researcher from a nearby university (the lead author of this report). This team of facilitators developed a set of meeting protocols with the goal of shifting teachers' instructional approach toward centering student thinking, in contrast to "data teams," which can focus on ranking students based on their ability to get correct answers (Gannon-Slater et al., 2017). Each grade level team completed a cycle of three meetings (Sessions 1, 2, and 3) for each of three units, for a total of nine meetings (see Figure 1). In Session 1, teachers examined their students' solutions to the items on the pre-assessment and worked to reach shared understanding about what counted as evidence for each category in the strategy guide and to discuss patterns in the strategies. In Session 2, teachers collectively planned a lesson with the goal of using information gathered about student thinking from the pre-assessment to guide their planning. In Session 3, teachers examined the post-assessment and were asked to compare strategy use across assessments and items and connect these patterns to their instruction.

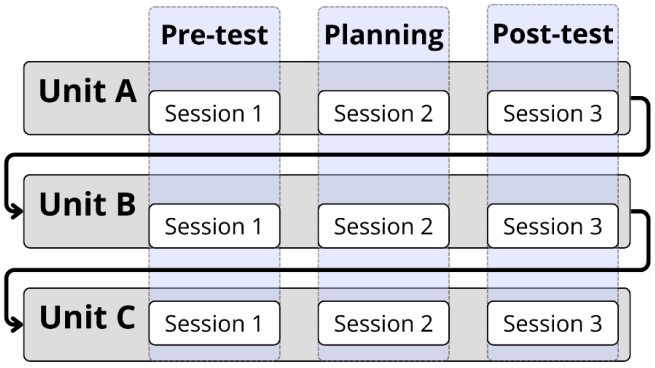

Figure 1: Depiction of the Nine Sessions with Grade-Level Team

Thirty-seven teachers in Grades 3, 4, and 5 across four schools agreed to participate in the study over the course of the 2023–2024 school year. In this paper, we focus on two teams, one at Silver Elementary and one at Bingham Elementary (pseudonyms). Both Silver and Bingham are Title I designated schools. Students eligible for free and reduced lunch constituted approximately 65% of students at Silver and 75% of students at Bingham. Both schools had recently underperformed on the state test in relation to the district as a whole, with majorities of students scoring at "below basic" or "basic" levels. The Silver team was facilitated by the district curriculum coordinator and the Bingham team was facilitated by a school-based instructional coach. The lead author attended and supported the facilitation of some meetings at each school.

We recorded all 18 teacher meetings with the groups at Silver and Bingham, which amounted to 546 minutes, of which 494 were coded. We analyzed the video data in terms of "teacher talk paths" (Murata et al., 2012), categorizing discourse as related to (1) students' mathematics thinking and (2) teaching, (3) mathematics, and (4) other. We further specified several subcodes within each of these categories (e.g., within students' mathematical thinking, we distinguished between discussions of individual student work and characterization of patterns across an assessment or across multiple assessments). Once the framework was established, we used MAXQDA software to directly code videos. We created "document portraits," in which a conversation is represented as a linear series of boxes (each an equal unit of time) that are colored according to codes. We used these portraits to examine patterns of discourse across both time and school, both in terms of percentages of time and the sequence of topics of discourse.

Findings

Session 1 (Pre-Test) Patterns

Teachers spent a substantial proportion of time (55% of the total minutes) in Session 1 interpreting and categorizing student thinking. Especially in the first meeting, conversations largely focused on how to categorize student strategies using the strategy guides, which seemed to focus teachers' attention to aspects of student thinking beyond the correct answer. For instance, they discussed cases where an incorrect answer showed some valuable understanding of the mathematics, and other cases (such as using "cross multiplication" to solve a fraction comparison problem) where conceptual understanding was difficult to ascertain. In some cases, teachers were pleasantly surprised by the understanding that students showed on the pre-assessment ("I was blown away! How they worked that out," "Wasn't that awesome?!"), suggesting that the assessments brought student thinking to the surface in ways that teachers

recognized and valued, particularly for students for whom they might not have anticipated exhibiting such thinking.

In other examples, particularly at Silver, discussions extended beyond the categories in the strategy guide, as in the case of teachers working to make sense of a student who, when trying to subtract $2\frac{2}{3}$ from $4\frac{1}{3}$, appeared to have traded a whole for 10 (thirds), as if they were trading a ten for 10 ones in a multidigit subtraction problem (see the middle part of Figure 2). The teachers were impressed by this strategy and spent several minutes discussing it without trying to assign a category from the strategy guide ("that's what I was about to say, like borrowing, you take 10, maybe she was thinking. That's kinda cool").

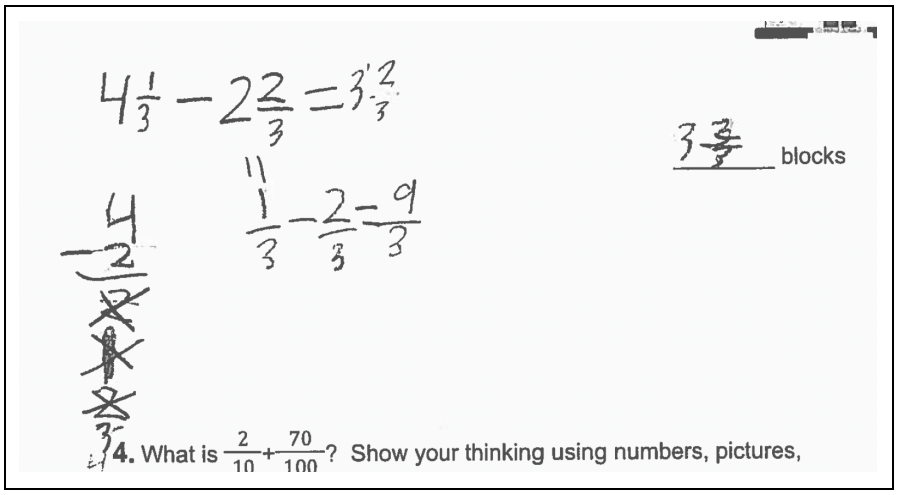

Figure 2: A Solution Discussed by Teachers at Silver Elementary

Over the year there was an increasing focus in Session 1 on patterns that the teachers noticed across tasks or solutions. Sometimes these were relatively brief, such as a teacher at Bingham noting that students who successfully completed a task tended to draw diagrams. Teachers at Silver discussed how a large number of students solved $1\frac{3}{4}$ plus $2\frac{2}{4}$ by adding the whole numbers (1 + 2) and the fractions $\left(\frac{3}{4}+\frac{2}{4}\right)$to get $3\frac{5}{4}$, while on an adjacent subtraction problem $\left(4\frac{1}{3}-2\frac{2}{3}\right)$ students unsuccessfully applied the same strategy but failed to correctly account for the need to regroup in order to subtract $\frac{2}{3}$ from $\frac{1}{3}$, as students . Sometimes these observations developed into extended conversations, such as one where teachers realized that some children were interpreting the notation "$3\frac{1}{4}$" as "3 one-fourths," that is, "$\frac{1}{4}+\frac{1}{4}+\frac{1}{4}$."

T2: [Students] were thinking that this three and one-fourth [3 ¼] was really three one-fourths. One fourth, one fourth, one fourth, instead of three *and* one fourth
T1: Yes, they weren't realizing it that it was like three and then a fourth
T3: Three wholes, yeah, and a fourth

Participants expressed surprise and appreciation for this example of children's thinking as they started to distinguish between misunderstandings about fractional quantities and misunderstandings about fraction notation.

At Bingham, conversations about patterns across assessments sometimes evolved into discussions about how students struggled with the tasks. At one point, the facilitator asked which

task the students did well on, and one teacher said, “none of them. I had about four kids, three to four kids. But no. No. And there were some I had to stop because they were in tears.” Such commentary sometimes developed into critiques of specific assessment items as being too difficult or unclear for students, which facilitators sometimes tried to redirect into discussions of how students were thinking about the ideas or implications for instruction.

Session 2 (Planning) Patterns

In Session 2, designed intended teachers to co-plan a lesson drawing on their learning from Session 1. Over the year, discourse in Session 2 shifted from generic planning to more specific planning conversations. At Bingham, in Unit A, teachers spent about 48% of the session talking about the launch-explore-summarize structure of their lesson or making what we considered to be general decisions about their lesson—such as sharing what tasks, tools, or manipulatives they were going to use. These conversations focused on the “what” of teaching, but not the why or how. Also, the “what” focused on actions and activities done by the teacher rather than anticipating what students might do.

Later in the year, however, Bingham teachers spent more time (81% in Unit B and 57% in Unit C) discussing the finer details of their lesson, hypothesizing about how children might solve the tasks and making adaptations to the task accordingly. For example, in one lesson they had planned to use the following task: *One lap around the blacktop is 2 thirds of a mile. So-and-so ran 5 laps; how much did they run?* The facilitator asked the group to “jot down what you think kiddos are gonna do.” After a brief discussion of whether children would make sense of ten-thirds as three whole miles and another third of a mile, the facilitator pressed the teachers to anticipate more strategies, referencing a common category from the assessment strategy guide: “Is there another way they would direct model?”

A student teacher who had joined the meeting shared their drawing of multiple boxes, each one subdivided into three parts. She explained, “Okay, so they would do thirds, and color in one, two, so that’s two-thirds. And then they would fill in that next one. That’s one-third. And draw another one—that's two-thirds.” Another student teacher suggested a more symbolic version of the strategy, where students would be “breaking it down. So two thirds plus two-thirds is four-thirds. And then do that another time, plus four thirds. And there’s two-thirds left. So they add four-thirds plus four-thirds plus two-thirds equals ten thirds.” The facilitator noted that children might also skip count by two-thirds, making mixed numbers as they go.

After collecting these ideas for how children might solve the task, the facilitator asked the group to consider how they might conduct the “summarize” portion of their lesson, where children would be asked to share, justify, and compare their solutions. First, they discussed the order of the solutions, and then ways to connect the solutions, e.g., “that’s a good question for them: ‘you multiplied, and you added over and over again. Why?’ And just get them to have that conversation.” This discussion was more substantive and detailed than the conversations the team was having in the beginning of the school year. Rather than just naming the task and the tools that the teacher would introduce, the group drew out anticipated strategies, in some cases using the labels from the assessment strategy guides. The facilitator encouraged the teachers to include drawn solutions (direct modeling) and suggested the practice of using different student solutions to help students make a connection between addition and multiplication.

In some Session 2 conversations, discourse shifted to the alignment between the assessments, the adopted math curriculum, and state standards. For example, when planning a lesson on decimals and fractions, one Bingham teacher talked about the need to understand the “ceiling of the standard” to clarify “what are we supposed to be getting at in this unit, and what is happening

in other units." Participants began looking up state standards and across future lessons in their curriculum to determine whether comparing decimals was an appropriate task for the lesson. This conversation continued for about six minutes, with the facilitator eventually attempting to direct conversation to the meaning of fraction/decimal notation and away from the description of the topics that need to be covered according to external documents.

Such conversations about the alignment between the assessments and standards/curricula were relatively rare in Session 2, but their presence shows the mix of concerns that teachers bring to conversations about planning. While the goal of the meetings was to focus on how students were thinking about mathematical concepts, policies around standards, mandated assessments, and curriculum occupy teachers' attention and influence their planning decisions.

Session 3 (Post-Test) Patterns

In Session 3 teachers were to discuss the results from the post-assessment in relation to the pre-assessment and their instruction during the unit. Our analysis revealed more variability in discourse foci across meetings and schools than in Sessions 1 and 2. Groups continued to spend time discussing individual pieces of student work on the assessments, but less than in Session 1 (35% of total time versus 55%). Teachers spent about 13% of their time in Session 3 discussing patterns within and across the assessments. For example, they addressed patterns from pre to post test, sometimes in very general ways, like noting that the strategies were "more efficient" or showed better understanding ("It's showing that they are understanding it a lot more than they did before. Before they didn't have any strategies, they just tried to write an answer down. Now they actually have the strategies to actually *show* you").

Groups spent about 10% of their time making explicit connections between their students' strategies on the assessment and their teaching in the previous unit. For example, they talked about the importance of using contextual problems, multiple representations, manipulatives, and explicit conceptual connections in class discussions. One Bingham teacher talked about how some of the explicit conceptual conversations in her lessons made an impact on the strategies students used on the unit test:

> I think it was really helpful to connect. … like, they did really well on 1, 2, and 4… And I think they were able to connect that as to like, *why*, and I think that helped with this one [holding up assessment], of like *why*, we talked about, giving them the rule, but then also like, here's the exception to the rule, and why we can add these together, but we have to change the amount of pieces.

In general, groups tended to see improvements from pre- to post- assessment (more children engaging in sensemaking strategies on the rubrics and fewer students using invalid strategies) and making conjectures about how their instruction created opportunities for students to develop deeper understanding.

Building on those conversations, teachers in Session 3 reflected on their own learning. For example, one teacher at Silver talked about how the project had helped her attend more to the details of student thinking.

> This kind of stuff has made me realize more that it is not about the answer. It's about like the way that they're getting to there and if we are not seeing growth necessarily in like the answer but we're seeing growth in their understanding then that's huge. So I think going into our next unit. That's kind of what I'm looking for. What are they understanding?

At Bingham, after some discussion of student growth from pretest to post test on fraction multiplication, a teacher commented, "I don't think I'll ever teach it again the 'dumb way.'"

Pressed by the facilitator to explain more, the teacher continued, "I have always taught them to convert mixed numbers to an improper fraction before you multiply them." A second teacher replied, "That's the only way I thought you could." This shows teachers expanded their knowledge of strategies through their examination of student work using the strategy guides. Other "meta" level conversations included sharing ideas for administering the assessment or critiquing the assessments.

Tensions that Surfaced During Team Meetings

In addition to the patterns described above regarding conversations in Sessions 1, 2, and 3, we also noticed tensions that arose in the meetings. While teachers sometimes expressed appreciation for how the strategy guides shifted attention away from the correctness of answers, as in the quote above, they also sometimes wrestled with this shift, possibly influenced by the fact that the assessments were being used for multiple purposes (to understand student thinking and to assign grades). At times they also critiqued the wording or structure of assessment items and worried whether the assessments were providing experiences that would help students be successful on the state test. From the designers' point of view, another tension involved the possibility that assessment categories might exacerbate teachers' perceptions of ability differences between children (Rodríguez et al., 2022). However, while there were instances where teachers characterized students in terms of deficiencies, these were often countered by facilitators directing attention to student work to identify strengths. There was some evidence that teachers attended to the possibility of reinforcing status hierarchies and sought to counter these by, for example, elevating the status of strategies like "direct modeling."

Discussion

Regarding our hypotheses, we found that teachers did start adopting the language of the strategy guides relatively quickly and made connections between the assessment results and their instruction, including by referencing the strategies in the details of their planning conversations. They expressed curiosity and appreciation for student thinking, in some cases challenging hierarchical narratives about student ability. In some cases, they explicitly described how the team meetings had started shifting their attention from answers to strategies, which helped them see development that they would not have noticed previously. These patterns show that centering grade level team meetings on unit assessments can function to support teachers' attention to and appreciation for understanding and building on student thinking (NCTM, 2014). At the same time, participants articulated some tensions as they negotiated the multiple purposes of assessment, highlighting the need to anticipate and plan for responding to such concerns.

Though not an explicit focus of our analysis, the study did suggest that the facilitator played a significant role in steering the conversations in each of the teacher teams. For example, at times the facilitator redirected focus to student thinking, or to specific aspects of the student thinking. when conversation moved to other areas or began to focus unproductively on student struggles (e.g., "a lot of my kids, they are so lost, they don't even know what to do next"). At other times, the facilitator pressed teachers mathematically, for example helping them to clarify whether a student strategy was generalizable. These kinds of moves seemed to be important for groups realizing the goals of the project, and future analyses could explore how differences in facilitation might have led to subtly different types of conversations in the teacher teams.

Seventy-seven rural middle-grade mathematics teachers were randomly assigned to one of two PD conditions facilitated by either Centralized Specialists (CS) or Local Teacher Leaders (LTL). While teachers in both conditions reported high levels of perceived clarity, discussion quality, and sense of community in the PD, those in the CS condition reported greater depth in discussions of instructional practices. Additionally, CS-facilitated workshops were significantly longer than LTL workshops, potentially reflecting the CSs' facilitative expertise or greater fidelity to the intended PD structure. Results from teacher surveys suggest that both models were perceived as having the potential to support meaningful collaborative discourse and the development of learning communities in rural settings, but further analysis is required to understand how workshop length and facilitator expertise impact long-term teacher growth.

Keywords: Professional Development, Middle School Education, Teacher Knowledge

Introduction

Many rural mathematics teachers receive only minimal training before they enter the classroom (Cady & Rearden, 2009). Professional development (PD) may enhance rural teachers' practices and improve their students' learning (Dille & Røkenes, 2021; Şahin et al., 2024). However, existing PD programs are often developed for teachers in non-rural contexts. Implementing these in rural settings without accounting for the uniqueness of rural contexts can fail to bring about desired shifts in instruction (Johnson & Howley, 2015). Thus, questions remain about how best to offer PD to rural teachers, many of whom work in remote areas and lack access to a professional learning community. Effective mathematics teacher PD relies heavily on collaborative partnerships (Desimone, 2009; Garet et al., 2001), particularly in adaptive models where facilitators and teachers co-construct participation and outcomes (Koellner & Jacobs, 2015).

Prior research suggests that locally-embedded facilitators have enhanced credibility, can promote teacher investment (Lindvall & Ryve, 2019), and are more naturally positioned to cultivate relational trust and community due to shared context and established relationships. External facilitators, particularly those who are not currently teaching, may face unique challenges establishing community (e.g., Anderson & Williams, 2023; Sztajn et al., 2007). However, PD led by centralized specialists, who have expertise in PD facilitation and deep knowledge of research-based instructional practices, may result in richer teacher discussions and offer greater opportunities for scalability. These differing strengths raise questions about who should facilitate PD in rural contexts and how various facilitator models impact rural teachers' perceptions and experiences.

We developed a large-scale PD project to bring rural teachers together to learn with and from colleagues, capitalizing on "existing capability" (Ball & Cohen, 1999, p. 17) in rural schools.

Our PD model was designed with two distinct facilitator conditions, in which either Centralized Specialists (CSs) or Local Teacher Leaders (LTLs) facilitated small-group, collaborative PD activities. We engaged 77 rural middle-grade mathematics teachers, who were randomly assigned to either the CS or LTL condition. Our PD focused on rural teachers' unique problems of practice, offering teachers a mechanism to address specific challenges faced while supporting the adoption of crucial instructional practices (Hiebert & Grouws, 2007; Stein et al., 2017). Both the CSs and LTLs led Problem-Solving Cycles (PSCs; Borko et al., 2015) with small teams of teachers, despite neither group having prior experience facilitating PSCs. Our goal was to prepare both groups to create a networked structure that would facilitate rural teachers' communication and collaboration, improve instruction, build professional community, reduce feelings of isolation, and potentially mitigate the elevated, expensive, and educationally deleterious effects of teacher attrition often found in rural schools (Preston et al., 2013). In this paper, we examine how the CS and LTL conditions affected rural teachers' patterns of participation in professional discourse and their perceptions of PD clarity, quality of PD discussions, and formation of authentic learning communities. Testing these two models for large-scale PD with rural mathematics teachers attends to the unique funds of knowledge and challenges in rural schools.

Theoretical Perspectives

When PD is facilitated by leaders with deep knowledge and strong expertise, PD programs are more likely to be implemented in a way that aligns with their intended purposes and designs (Heritage & Popham, 2008; Thompson & Wiliam, 2008). However, requiring advanced facilitator expertise may significantly limit a PD initiative's reach (Borko, 2004). As such, a program may instead be implemented by locally-embedded teacher leaders (Borko et al., 2021). This arrangement has several affordances and limitations. Teacher leaders are peers who are actively teaching and more familiar with the local teacher context. Their enhanced credibility can support the establishment of authentic learning communities in which teachers feel comfortable sharing and debating ideas as well as opening their practice for shared examination–PD features known to support teachers' learning (Ball & Cohen, 1999; Grossman et al., 2001; Lefstein et al., 2020; Little, 2002). However, as teacher leaders may lack experience facilitating PD, they may still be developing the knowledge and practices required to support teachers' collaborative learning, potentially affecting PD outcomes. Moreover, as they may be less familiar with mathematics education research, they may struggle to implement the PD's structures and purpose with fidelity.

In the PD program we study here, the learning of small groups of teachers was facilitated by either a CS or an LTL. The CSs were externally-located regional math specialists who had K-12 mathematics teaching experience but were not currently teaching. The CSs brought extensive experience facilitating mathematics PD across a range of implementation structures and deep knowledge of mathematics education research. Conversely, the LTLs were geographically proximate peers who were actively teaching middle grades mathematics with expertise in rural contexts. In fact, all LTLs lived within 60 miles of the teachers with whom they worked.

We anticipated that CSs would be more knowledgeable of facilitative moves and routines to support rich discourse with teachers. Also, given their expertise, we expected them to convey the purpose of the PD with clarity and enact the PD model with high fidelity. However, as external specialists, most of whom were located in an urban area and were not currently teaching, we predicted that they may find it more challenging to earn credibility with the teachers on their teams. We also expected LTLs to be able to facilitate rich teacher discourse as they were well-

positioned to establish credibility and a sense of community with the teachers, potentially resulting in teachers feeling more comfortable sharing ideas, opening up their practice, and pushing back on ideas shared by others–key indicators of generative teacher discourse in collaborative PD (Lefstein et al., 2020; Little, 2002). And yet, as LTLs have limited facilitation experience, we anticipated that they may find it more challenging to maintain discussions focused on student thinking and research-based instructional practices. This study examined the following research question: How do theorized affordances and limitations of the CS and LTL PD conditions affect teachers' a) participation in professional discourse, b) perceptions of the PD's clarity and quality of the PD discussions, and c) formation of learning communities?

Methodology

Participants

Our study involved 77 middle school mathematics teachers (Grades 6–8) from rural-serving schools in a single state in the Northwestern United States. Participants were recruited through advertisements for a PD program distributed to districts and schools across the state. Teachers could enroll individually or as part of a small team from their school or district. Teachers who enrolled individually were assigned to teams from schools located in geographically proximate areas. During enrollment, participants indicated whether they were willing to serve as an LTL. After enrollment was complete, 16 teams were formed, each consisting of two to eight teachers from nearby schools. Teams were then randomly assigned to one of two conditions based on the leadership structure: a) the CS condition, in which four university-based regional mathematics specialists each led two teams, or b) the LTL condition, in which a teacher from the team received additional training from the CSs and facilitated the group. Random assignment resulted in eight CS teams (32 teachers) and eight LTL teams (37 teachers and 8 LTLs), totaling 69 teachers in non-facilitation roles.

Project Context

The PD program spanned two and a half years and was designed as a coherent sequence of interconnected learning experiences. Core components of the program included summer institutes, asynchronous learning modules, whole group and team workshops, collaborative PSCs (Borko et al., 2015), and individual classroom studies. During the summer institutes, participants from both conditions engaged in a full day of professional learning and prepared for the collaborative work they would undertake within their teams during the academic year. Asynchronous modules and synchronous workshops oriented participants to key pedagogical concepts central to the study, specifically instructional strategies that support: Explicit Attention to Concepts (EAC) and Student Opportunities to Struggle (SOS; Hiebert & Grouws, 2007). Collaborative learning was anchored in PSCs, in which teams participated in three interconnected workshops focused on collaboratively planning, implementing, and reflecting on a lesson featuring a cognitively demanding task by analyzing classroom video. PSCs (described more fully below) constituted the primary collaborative activity in the larger PD program and the focal context for the present analysis, as they were facilitated under one of the two leadership conditions. Participants also engaged in individual classroom studies, a form of action research. Teachers selected an EAC- or SOS-related instructional strategy and designed a multi-week implementation to study the effects of using the strategy in their own classrooms. In the first year of the project, LTLs received specialized leadership training, while all teachers completed the asynchronous modules and research-related pre-participation activities. In Years 2 and 3, the PD followed a consistent annual structure including a one-day summer institute, a full PSC in the

fall, and an individual classroom study in the spring. Across all years, the PD design team held synchronous whole-group online workshops once per semester.

PSCs, the PD activity central to the present analysis, were intended to support teachers in operationalizing their learning about EAC and SOS from the asynchronous modules, workshops, and summer institutes within their own classrooms. Each PSC consisted of interconnected professional learning experiences, including one whole-group workshop at the beginning of the semester, three structured team workshops, and the implementation and video recording of a classroom lesson. In the first team workshop, small groups collaboratively solved a cognitively demanding task, selected during the summer institute for its suitability across multiple grade levels, and anticipated student strategies, models, and errors. Teachers then implemented the lesson in their classrooms and recorded the instruction, submitting their videos to their team facilitator. The facilitator selected video clips to anchor subsequent discussions in workshops 2 and 3. During the second workshop, groups viewed selected clips and engaged in a facilitated discussion focused primarily on interpreting student thinking. In the third workshop, the discussion shifted towards analyzing teachers' instructional practices in relation to observations of student thinking and lesson design. Each workshop was scheduled for 90 minutes.

The PD design team provided the CSs and LTLs with structured opportunities to understand the purpose of PSCs and how to facilitate them. CSs read Borko and colleagues' book on PSC facilitation (2015) to support their professional development and used the resource to develop facilitation materials, including sample agendas and presentation slides. Throughout the project, CSs provided ongoing support to LTLs with workshop design and facilitation through meetings, planning templates, task and video-clip selection guidance, representation modeling, and individualized team-specific assistance as needed.

Data Collected

Data collected for this inquiry include video recordings of the PSC team workshops and two quantitative surveys completed by the teachers and facilitators at the culmination of their second PSC. All data were collected in Year 3 of the project, after PD activities and research protocols were refined during Year 2.

Participation in professional discourse. Sixteen teams met three times throughout the semester, resulting in 48 PSC-related team workshops. Of the 48 workshops, 43 were successfully videorecorded. To analyze opportunities for participation in professional discourse, the length of each meeting was collected. To further explore participation patterns, we coded a random sample of two PSC meeting videos from each team. This resulted in 31 videos: 16 from CS teams and 15 from LTL teams (one LTL team faced technical issues, resulting in only one of their three workshops being recorded). This selection included 10 videos from workshop 1, 11 from workshop 2, and 10 from workshop 3.

This subset of videos was coded using the Mathematics Content and Pedagogy Professional Development Observation Protocol (MaCoP P-DOP), which the researchers developed by building upon existing literature (Banilower & Shimkus, 2004; Horizon, 2005). The MaCoP P-DOP (Amador et al., 2025) was piloted in Year 2 on videos of four randomly selected PSC workshops (two per condition), achieving nearly 80% initial rater agreement, which informed clarifications and modifications. Using the MaCoP P-DOP, video recordings are broken into three-minute segments, which are coded according to who is speaking during the segment and if one or multiple teachers contribute to the dialogue. Furthermore, the overall breadth of attendee participation was coded to note the percentage of attendees who engaged in meaningful

discourse during the meeting. Four coders coded the videos, in pairwise teams, and coders met regularly to reconcile any discrepancies.

Perceptions of PD clarity and quality of PD discussions. To gain insight into participants' perceptions of PD clarity and the quality of PD discussions, we developed the PSC Survey, which contains 18 Likert-scale items. We assessed clarity by asking participants to rate their understanding of the purpose and processes of the PSC and how prepared they felt for implementing the PSC task, on a 5-point Likert scale. We addressed the quality of the discussions occurring during PSC workshops by asking participants to rate the discussions' (a) efficiency, (b) depth, (c) focus, (d) insightfulness, and (e) equitability. For example, one survey item states: "For your PSC team discussions of student thinking, please rate your agreement with the following statement: The discussions were in-depth." All five aspects of each meeting were rated on a 5-point Likert scale. Participants completed the PSC Survey following the last of their three PSC-focused workshops in Year 3.

Perceptions of PD learning communities. The Authentic Learning Community survey (ALC) contains 17 Likert-scale items modified from existing instruments (PMRR, 2021; Sigurðardóttir, 2010) to measure participants' perceptions of the learning communities created within their teams. Items ask participants to rate their (a) willingness to make their practice public, (b) willingness to share and discuss ideas in constructive dialogue, (c) felt-sense of relevancy, and (d) felt-sense of trust within the community. Participants completed the ALC survey following the last of their three PSC-focused workshops in Year 3.

Data Analysis and Findings

Participation in Professional Discourse

A two-sided Welch's t-test found that the PSC team workshops facilitated by CSs (M = 77.00, SD = 10.23) were significantly longer than those facilitated by LTLs (M = 47.95, SD = 17.26), $t(41) = 6.14$, $p < .001$. On average, CS-facilitated workshops lasted 29.05 minutes longer than LTL-facilitated workshops, representing a very large effect size (Cohen's d = 2.03, or approximately 2 standard deviations). A difference of this magnitude indicates a highly substantial difference in how the facilitators in the two conditions managed the time of these workshops, which suggests that teachers in the CS condition may have had more opportunities to engage in professional discourse.

Overall breadth of participation was coded according to the percentage of meeting attendees who contributed to the team discussions as: Most (75-100%), Several (50-74%), Some (25-49%), and Few (0-24%). We found that the majority of discussions from both conditions were coded as having participation from at least 75% of meeting attendees: 13 (81.3%) and 9 (60%) from CS and LTL conditions, respectively. Furthermore, a Chi-squared test found no significant difference in the overall breadth of participation by condition: $X^2(1, N = 31) = 1.70$, $p = .19$.

Each three-minute video segment was coded to indicate who was speaking and whether one or multiple attendees contributed to the dialogue. For a participant's contribution to be acknowledged in the coding, their participation needed to go beyond affirming or briefly responding to closed questions. Examples of coded participation include discussing a task or student work, offering a new example or counterexample, building upon the current discussion, or summarizing what another person said. The six codes used were: N = none or limited; F = facilitator only; T = one teacher; TF = one teacher and the facilitator; MT = two or more teachers (without the facilitator); and MTF = two or more teachers and facilitator. See Figure 1 below for charts displaying discourse code counts and relative frequencies by condition.

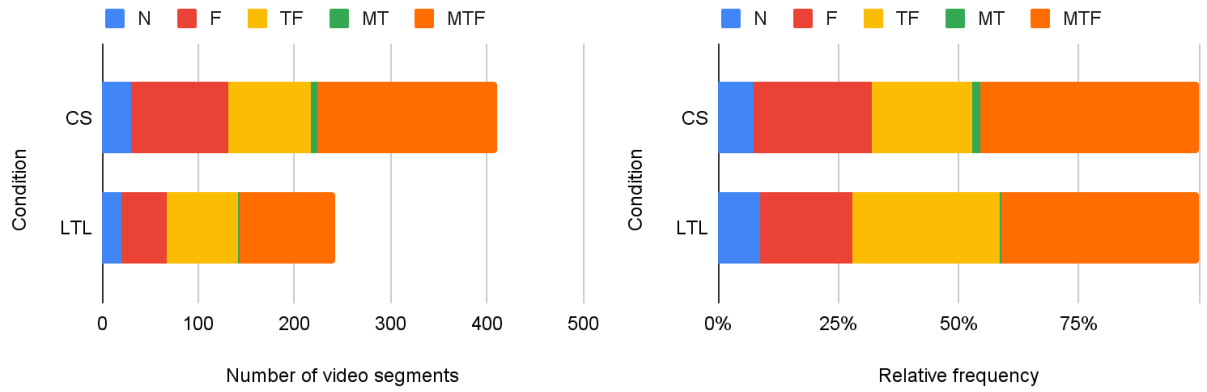

Figure 1: Left: Discourse Code Counts by Condition; Right: Relative Frequencies of Discourse Codes by Condition

Consistent with the significant differences found in meeting lengths, discourse code counts also varied notably by condition. For instance, CS-facilitated workshops included 100 segments (300 minutes) where the facilitator led the discussion alone, more than double the 47 segments (141 minutes) recorded in LTL-facilitated workshops. Similarly, CS-facilitated workshops had 186 segments (558 minutes) involving the facilitator and at least two other participants, nearly twice the 100 segments (300 minutes) found in the LTL condition. These results suggest that members of CS-facilitated teams had roughly twice as many opportunities to engage with the facilitator and participate in multi-person discussions. While these frequency differences are notable, the quality and depth of these discussions warrant further analysis. A Chi-squared test comparing the distribution of discourse codes across conditions revealed a marginally significant difference: $X^2(4, N = 446) = 10.25$, $p = .0364$.

Perceptions of PD Clarity and Quality of PD Discussions

The PSC survey was completed by 65 non-facilitating teachers (33 from CS teams, 32 from LTL teams; 94.2% response rate). Mean item responses varied from 4.22 to 4.51. When separated by condition, mean item responses for the CS and LTL teams ranged from 4.19 to 4.53 and 4.06 to 4.50, respectively. Two-sided t-tests looked for differences in responses to each Likert-scale item by condition. One significant difference was found regarding the depth of team discussions of teaching practices. CS teachers found their PSC team's discussions of teaching practices significantly more in-depth than those in LTL groups; CS group ($M = 4.41$, $SD = 0.61$) and the LTL group ($M = 4.06$, $SD = 0.74$); $t(63) = 2.16$, $p = .03$. No other significant differences were noted between groups when rating the focus, depth, insightfulness, equitability, or efficiency of PSC discussions on the math task/potential students' responses or student thinking. Moreover, no significant differences were found between groups regarding their understanding of the PSC process, purpose, or preparation.

Perceptions of PD Learning Communities

The ALC survey was completed by 63 non-facilitating teachers (31 from CS teams, 32 from LTL teams; 91.3% response rate). Mean item responses varied from 3.87 to 4.65. The highest mean score (4.65) was in response to the item, "We share examples of our math instructional practice." The lowest mean score (3.87) was in response to the item, "I feel like I can push back on an idea shared by the facilitator/team leader or another teacher." When separated by condition, mean item responses for the CS and LTL teams ranged from 3.87 to 4.68 and 3.88 to 4.66, respectively. A one-way ANOVA revealed no significant effect of condition on mean

scores across all items, $F(1, 1069) = 0.24$, $p = .624$; CS group ($M = 4.43$, $SD = 0.60$) and LTL group ($M = 4.41$, $SD = 0.66$).

Discussion

This study compared small-group PD with teachers in rural settings, facilitated by CSs and LTLs. We examined both teachers' perceptions of the PD experience and objective participation features of PD workshops. Three findings are particularly salient:

1. Teachers in both conditions reported equally high levels of connection to a collaborative community.
2. Teachers in the CS condition reported significantly more in-depth PSC discussions of instructional practices than those in the LTL condition.
3. CS-facilitated workshops were significantly longer than those facilitated by LTLs, despite similar participation patterns.

Finding #1

The absence of differences in teachers' subjective experiences of community challenges our prior assumptions about the affordances of local facilitation provided by teachers who have expertise in rural contexts and are actively teaching middle school mathematics. Despite the CSs being external experts who are no longer in the K-12 classroom, they were equally successful at creating authentic learning communities for the teachers with whom they worked. This finding suggests that skilled facilitation by CSs and/or the PSC structure may mitigate potential disadvantages inherent to the CS condition.

Finding #2

We hypothesized that teachers in CS-facilitated groups would report higher levels of clarity and discussion quality, given CS facilitators' expertise in mathematics education research and experience facilitating PD. This claim was evidenced by teachers in CS-facilitated teams reporting increased depth of discussions of instructional practices. This finding is likely due to CSs' extensive expertise in facilitating discussions of teaching practice in a variety of PD models and is a noteworthy consideration for PD designers.

However, we found similar ratings of quality markers for PD clarity and discussions of student thinking, which suggests that LTLs were also able to facilitate PD experiences that teachers perceived as clear and productive. This finding contributes to existing literature on teacher leadership and facilitation (e.g., Borko et al., 2014) by suggesting that, when provided with appropriate structures and professional learning resources, external specialists and teacher leaders can facilitate PSCs in ways that participants perceive as purposeful and productive.

Finding #3

Given CS facilitators' expertise in facilitating PD, the difference in workshop lengths across the two conditions may reflect their ability to foster sustained discussions and adherence to the intended pacing and structure of PSC workshops, which were designed to last approximately 90 minutes. Indeed, some research suggests that when teacher leaders facilitate PSC workshops, their duration can be quite short (Jarry-Shore et al., 2023). In contrast, LTLs may have adapted workshops in response to local constraints, time pressures, perceived teacher needs, or their developing understanding of PSC processes. These substantial differences in meeting length reflect well-documented tensions in facilitation research between fidelity to designed PD activities and responsive adaptation to local contexts (e.g., Borko et al., 2017; Jacobs et al., 2017). Our findings suggest that LTLs modified designed activities to be much shorter than

intended, although the specific reasons for these adaptations are beyond the scope of the present study. A further consequence of these differences in meeting length is that longer workshops may have afforded teachers in CS-facilitated groups more extensive opportunities to engage in collaborative discussions, as supported by the difference in depth of discussions of instructional practices. In this sense, longer workshops may have provided increased opportunities for teacher learning (Horn & Little, 2010). However, without direct analysis of the depth and quality of teacher discourse, meeting length alone cannot serve as a proxy for the quality of professional learning. Nevertheless, the substantially shorter workshops for LTL-led teams raise important questions about potential differences in learning opportunities across conditions. Moreover, the coexistence of mostly positive teacher perceptions with structural differences in workshop length underscores the need for PD research that integrates participant reports with fine-grained analyses of learning opportunities embedded in professional learning interactions.

Implications

Our findings have implications for PD in geographically isolated contexts, where limited access to PD and professional isolation are persistent challenges (NASEM, 2025; Şahin et al., 2024). Both PD models produced consistently positive teacher-reported experiences, suggesting that small-group collaborative PD may be effectively implemented through both locally- and centrally-facilitated models. CS-facilitated PD may offer particular advantages for scalability, access to specialized expertise, and reduced travel demands, especially in rural districts that lack the capacity to develop and sustain LTLs. At the same time, LTL-facilitated models may offer benefits in terms of sustainability and integration with local improvement efforts.

We suggest three areas for future study. First, future studies should examine how different facilitation conditions influence the substance of professional learning interactions, including the depth and alignment of discussions with the PD's intended goals. Such studies would help draw stronger links between PD design and implementation and teachers' opportunities to learn (e.g., Horn & Little, 2010). Relatedly, future research should explore whether the extended length of the CS-led PSC discussions or the adaptations observed in LTL-led groups are associated with differences in instructional improvement or student learning. Because the PSCs were a single component of a larger PD program, it remains unclear whether the length of PSC conversations impacted teachers' overall professional growth or student outcomes. Second, more work is needed to investigate the relationship between teachers' positive perceptions of PD and more objective analyses of PD interactions. For example, future studies might examine whether teachers' sense of community in LTL-led groups is driven by facilitator responsiveness to local needs (e.g., shortening workshops to honor time constraints), whereas a sense of community in CS-led groups may be fostered through more sustained, in-depth professional discussion. Examining the relationship between teachers' subjective reports and objective analyses of PD events can inform efforts to design and implement more impactful PD. Finally, the small-group PD discussions in this study were part of PSC workshops that were connected to other professional learning experiences within a larger PD program. Thus, findings regarding the two facilitation conditions may not generalize to PD that is not embedded within a broader, coherent program of professional learning. Future studies should therefore examine facilitation conditions across a wider range of PD activities and program structures.

This study examines an elementary mathematics coach's discourse moves during one-on-one debriefs with two teachers in coaching cycles. We analyzed how directive, reflective, and facilitative stances emerged in each coach–teacher interaction. Audio recordings were examined to identify patterns in the coach's moment-to-moment discourse moves, and interviews were used to understand coach and teachers' positioning. Coaching stances varied across the two teachers and relational contexts, reflecting differences in how the coach was positioned as mentor, expert, or co-learner. Building on Saclarides et al.'s discursive move framing, we identified an emergent move acknowledging that signaled understanding without affirmation. We also distinguished between launching-general and launching-specific prompts supporting different depths of reflection. These contributions extend conceptualization of coaching discourse moves.

Keywords: Coaching, Discourse, Reflection, Positioning

Instructional coaching has continued to receive attention as a promising way for improving instructional practices of teachers and supporting students' mathematical learning (Campbell & Malkus, 2011; Russell et al., 2020). There is also growing, albeit mixed evidence of coaching effects on teaching and student learning in the mathematics education field (Russell et al., 2020). Researchers have suggested that this variability may be attributed, in part, to the difference in how coaching roles are structured, enacted and experienced across contexts (Coburn & Woulfin, 2012; Russell et al., 2020).

Researchers have emphasized that coaching effectiveness can be shaped by coaches' experiences, positions, and interactional roles, as well as teachers' positioning of coaches, prior experiences and engagement in the coaching process (Chval et al., 2010; McGatha et al., 2015; Saclarides et al., 2025). These studies suggest that coaching cannot be understood solely through fixed roles, rather coaching practices emerge through social interactions and are responsive to contextual factors. Despite this recognition, there has been limited examination of coaches' moment-to-moment discourse moves and stances.

Recent work by Saclarides et al. (2025) conceptualizes coaching stance as a discursive enactment manifest through the discourse moves coaches use to position themselves and teachers as thinking authorities during coaching conversations. Their study results identify three coaching stances: directive, reflective and facilitative. They described a directive stance as characterized by "moves in which the coach shares ideas with the teacher based on their own thinking, thus positioning the coach as the thinking authority" (p. 160), reflective by "moves in which the coach invites the teacher to share their thinking, thus positioning the teacher as the thinking authority" (p. 160) and facilitative by "moves in which the coach establishes the focus of the

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

conversation, which neither positions the coach nor the teacher as the thinking authority" (p. 160). They found that the individual coach often shifted among directive, reflective and facilitative stances, using different coaching moves accordingly. They also found that even when the coach articulated their aim to be a reflective coach, they still moved among these stances, highlighting the complex make-up of coaching practice.

While Saclarides et al. (2025) examined discourse moves and stances within a single coach-teacher dyad, our study extends this work by examining one coach working with different mathematics teachers across multiple coaching cycles. These teachers vary in grade level (K-2), years of teaching experience, the focus of the coaching support, and in how they position the coach (e.g. as expert, mentor or co-learner). This multi-teacher design captures a broader range of situational contexts and allows us to examine how a coach's discourse moves and stances vary across different teacher interactions rather than within a single teacher relational context.

Although our larger study includes six teachers, this paper presents findings from two focal teachers selected for in-depth analysis. These teachers were purposefully chosen based on how they positioned the coach, grade level taught and years of teaching experience to allow us to examine coach discourse moves in different contexts. The following research questions guide this study:

1. What discourse moves did the coach use to support teachers in reflecting on high-quality mathematics practices during one-on-one debriefs?
2. What critical elements shape how the coach enacted directive, reflective, facilitative stance and moves across one-on-one coaching debriefs with two teachers?

Theoretical Background

This study is grounded in a sociocultural perspective on learning and interaction. We particularly draw on positioning (Harre & van Langenhove, 1999) and situated learning theory (Lave & Wenger, 1991). Positioning theory does not perceive social roles as fixed, instead it posits roles as fluent "parts" that are negotiable and responsive to the nature of interaction (van Langenhove & Harre, 1999, p. 17). From this perspective, coaches and teachers position themselves and one another in roles such as learner, co-learner, expert, and mentor in response to their unfolding interactions. They also bring into the coaching experience their prior perspectives about their own and each other's positions. This lens is particularly useful for examining instructional coaching, where coaches are typically identified as experts but may seek to enact more collaborative, reflective, or facilitative stances in practice.

Situated learning theory further extends this framing by emphasizing that learning does not happen in isolation from individual or contextual needs, and social interaction (Lave & Wenger, 1991; Mangin & Dunsmore, 2013). In the context of Project AIM's (All Included in Mathematics) coaching program, this lens draws attention to how coaching interactions occur within a situated context in which teachers vary in grade level (K–2), years of teaching experience, instructional goals, and prior engagement with mathematics-focused professional learning. Together, these lenses promote attention to coaching as an interactional practice that unfolds differently across relational and situational contexts. Guided by these perspectives, the study examines a coach's discourse moves within lesson debriefs in AIM coaching cycles designed to support teachers' reflection on high-quality mathematics instruction (HQMI), and how critical interactional elements, such as positioning of coach and teacher and the use of Project AIM tools, shape these coaching discourse stances and moves.

AIM Coaching Cycle Model

The AIM coaching program has two main goals. The first goal is to enhance teachers' capacity to promote high-quality mathematics discourse. This involves supporting teachers in planning, enacting, and reflecting on lessons aimed at providing all students access and opportunities to engage in powerful mathematics and contribute to a discourse community. The second goal is to engage teachers and coaches in collaborative and self-reflective improvement of practice through a combination of individual and group coaching experiences.

In the Project AIM coaching cycle model shown in figure 1, there are two key components: individual coaching and group coaching meetings. The process begins and ends with the entire coaching group coming together, represented by the green sections (Step 1 and 6). These group meetings allow participants to learn from one another, and build a supportive community. The blue sections highlight the one-on-one coaching sessions between the AIM lead teacher and the Project AIM coach. During these individual meetings, the lead teacher has the opportunity to receive personalized support in lesson planning, and reflecting on their instruction through the examination of noteworthy moments from a video recording of the enacted lesson. The lead teacher role rotates with each cycle. Rather than asking every teacher to go through multiple coaching cycles, each teacher takes a turn as the lead teacher, typically for one or two full coaching cycles depending on the size of the coaching group (about 6 teachers). During all cycles when they are not the lead, teachers participate in the group meetings, learning from their colleagues' experiences and sharing insights. This model is intended to be a sustainable coaching arrangement that creates opportunities for both individual and collective reflections. This study focuses on the data collected in step 5 (Debrief lesson) when the coach and the lead teacher 1) reflect on video clips of noteworthy instructional moments and 2) select an instructional moment from the video they will bring to the collective lesson examination (Step 6).

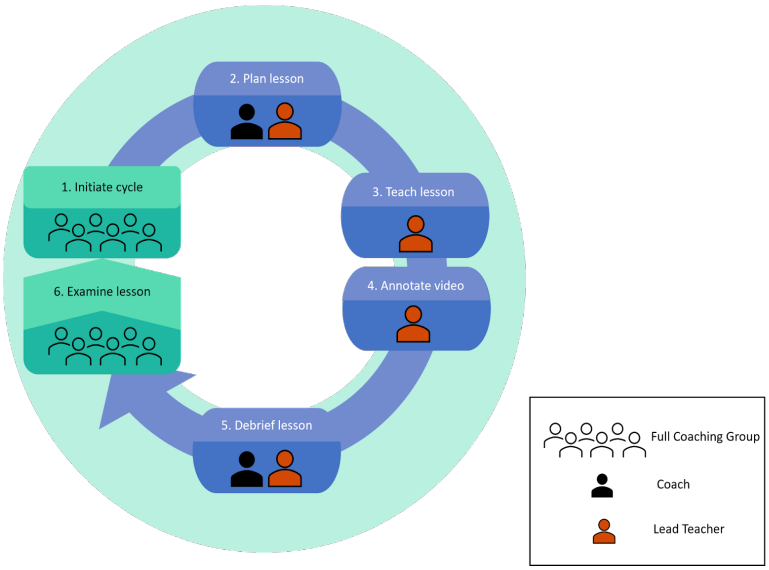

Figure 1. AIM Coaching Cycle Model

Methods

This study was conducted in a suburban elementary school in the southern United States. . This elementary school enrolls approximately 350 students and employs about 30 teachers. The school was selected to participate in Project AIM, a professional development initiative focused

on improving mathematics discourse in K–5 classrooms, due to its Title I status and its school-wide emphasis on mathematics improvement.

The coach in this study, Vanessa (a pseudonym), has over 25 years of experience teaching elementary grades (K–5) and more than six years of experience as a mathematics coach. Prior to facilitating the Project AIM coaching program during the 2024–25 academic year, Vanessa completed the Project AIM coach preparation course, an asynchronous online professional learning experience designed to prepare coaches to use AIM's coaching tools and structures. Both administrators and teachers in the school described her as having strong relationships with teachers and students. She sees herself as a reflective coach and positions herself as a co-learner and mentor within the coaching space. In the interview she stated that she believed in "letting them (teachers) know that we're all learners in this process. We don't have all the answers, but we are going to work together in order to support equitable, high-quality math discourse." The teachers in this study also viewed Vanessa as a mentor, although most did not position her as a co-learner, but instead as the mentor and expert in the coaching space.

Six K–2 teachers from the school participated in the core Project AIM professional development during the 2023–24 school year and engaged in coaching cycles during the 2024–25 school year. This study focuses on two teachers, Tara and Emily (pseudonyms), selected based on how they positioned the coach and perceived her coaching approach (directive, reflective, facilitative) in their interviews. Both Emily and Tara had established coaching relationships with Vanessa prior to the Project AIM coaching.

Emily had 6 years of experience and was teaching kindergarten at the time of the study. She was the lead teacher in the first AIM coaching cycle. She predominantly positioned the coach as a mentor, referencing these four times in her interview. Emily described Vanessa's coaching approach as reflective and facilitative and made no reference to directive coaching. The reflective positioning is evident in how Emily described the coach's interactions with her:

> She never made me feel like she was telling me the answer to anything or even suggesting anything. Rather making sure I had thought about some things that I maybe was not thinking of. So, she was perfectly supportive of that.

In the facilitative positioning, Emily gave the example of how Vanessa framed the focus of the conversation toward examining both student and teacher actions. These facilitative moves are followed by intentional reflective moves that position the teacher as the thinking authority.

Tara, a first-grade teacher with over 20 years of teaching experience was the lead teacher in the second coaching cycle. She primarily positioned the coach as an expert (mentioned 5 times) and co-learner (mentioned 3 times). She described the coach's stance as both directive and reflective, with the directive approach mentioned more frequently in her interview. For instance, she described the coach's directive approach as "you get to the point where you've got good practices. But you need someone objectively helping you tweak that." Tara also characterized Vanessa's coaching as a reflective expert:

> …When you have someone objectively looking in, she sees some pieces that I might have missed for myself, so I might have disconnected the launch to explore [phases of the lesson]. …she asked a guiding question, I'm going now, if I go back and look at it a little differently … [to the connections across phases of the lesson].

Data Collection and Analysis

This case study drew on multiple data sources to examine coaching discourse moves and shifts in these moves within lesson debriefs. Data sources included audio recorded coaching

cycle conversations, teacher and coach demographic surveys, teacher interviews, and initial and final coach interviews. All recordings were transcribed to support detailed analysis of discourse moves.

Data sources. Lesson debrief audio recordings served as the primary data sources. These recordings captured coach-teacher interactions in the moment and provided us with the opportunity to examine the coach's discourse moves and shift in stance across cycles with the teachers. The debrief data were also used to identify critical elements of interactions that shaped coaching stance and moves. Teacher interviews were conducted to understand teachers' experiences, perspectives and positioning of themselves and the coach within the coaching relationship. The interviews provided contextual information to complement the analysis of debrief meetings by offering insights into why certain discourse move patterns might emerge for individual teachers.

The coach participated in initial and final interviews to provide her perspective on the coaching process. These interviews offered insights into the coach's goals, positioning, decision-making related to discourse moves and experiences of the coaching cycle with the teachers. These interviews allowed the researchers to consider the coach's perspective alongside their outsider interpretations.

Data analysis. We engaged in a collaborative coding process (Richard & Hemphill, 2018) to analyze the lesson debrief recordings. The unit of analysis was an individual text segment (Saldana, 2025), defined as a single complete sentence representing one coach discourse move. Each segment was coded using the coaching discursive moves coding scheme (Saclarides et al., 2025, p. 160). This coding scheme includes three overarching coaching stances: directive, reflective and facilitative. Each stance then has a set of secondary-level codes to characterize the coach's particular discourse moves. Directive stance moves include *explaining*: provides an interpretation, *suggesting*: recommends an action, and *validating*: affirms the teacher's ideas or actions. Within the facilitative stance, the moves include describing: highlights noteworthy ideas or events without evaluation or interpretation, clarifying: verifies common understanding of previously discussed ideas, and framing: directs attention to the purpose of the discussion. For the reflective stance, the moves include launching: pose general prompts to invite teacher to share thinking, pressing: pose prompts inviting teachers to elaborate on thinking shared previously, and paraphrasing: restate the teacher's thinking which results in the teacher elaborating on prior statements. The moves that do not fall under these codes, coded as other moves such as "yeah, okay", procedural talk, or unfinished thoughts.

We also coded each coach discourse moves for its focus categorized as mathematics, mathematics discourse, teacher action and student action. These categories were informed by Project AIM's main reflection tool for lesson debriefs called Reflecting on Aspects of Learning Mathematics (REALM) (Sztajn et al., 2025; Yilmaz et al., 2024). REALM is a practical tool designed to support coaches and teachers in reflecting on aspects of HQMI, namely powerful mathematics and inclusive mathematics discourse. These two aspects are considered for two dimensions of teacher and student actions related to opportunity and access, and engagement and agency. For each action, REALM provides targeted reflection questions. Because AIM coaching uses the REALM tool to promote reflection, we sought to examine whether and in what ways its use connected with particular coach discourse moves.

Findings

This study examined how coach Vanessa enacted different discourse moves during debriefs to support teachers' reflection on HQMI and what interactional elements shaped the enactment

of directive, facilitative and reflective stances in meetings with the two teachers, Emily and Tara. Analysis showed that Vanessa enacted three coaching stances with both teachers. However, the distribution, patterns, and functions of the moves differed across Emily's and Tara's debriefs. We found that these differences could be tied to how each teacher positioned the coach as well as the coach's use of Project AIM tools in the coaching interactions.

Across the two debriefs, the coach used 313 moves (excluding 115 moves coded as "others"), including facilitative moves (41.4 %), followed by directive moves (40%), and reflective moves (18.6 %). Although Vanessa described her coaching stance as reflective in the interviews, analysis showed that her coaching stance emerged as dynamic and negotiated during the interaction with the two different teachers.

In Emily's debrief, Vanessa used a total of 82 discourse moves (excluding 32 coded as "other") with Emily's participation including 124 moves. Vannesa used facilitative (45.1%) and reflective (36.6%) moves predominantly. She used directive moves (18.3%) to a limited extent. (See Table 1.) This distribution indicates that Emily was mostly positioned as thinking authority to examine and reflect on her instructional practices (reflective stance moves) or invited for joint reflection and inquiry (facilitative stance moves) and the coach Vanessa rarely positioned herself as thinking authority (directive stance moves).

In Tara's debrief, Vanessa used a total of 231 discourse moves (excluding 83 moves coded as "other") while Tara's participation included 129 moves. In this case, Vannesa used directive (48.1%) and facilitative (39.8%) moves predominantly. She rarely used reflective moves (12.1%). (See Table 1.) This distribution indicates that Tara was rarely positioned as thinking authority to examine and reflect on her instructional practices while the coach was positioned as thinking authority, particularly in terms of suggesting ideas, explaining instructional moments, and validating Tara's understanding of the suggested ideas and explanations (directive stance moves).

Table 1: Distribution of Coach Discourse Moves by Coaching Stance: Emily and Tara

Coaching Stance	Coach Discourse Moves	Emily Frequency*	Tara Frequency*
Facilitative	Describing	1	22
	Clarifying	10	31
	Framing	26	39
	Total (n, %)	37, 45.1%	92, 39.8%
Directive	Explaining	4	18
	Suggesting	1	32
	Validating	10	61
	Total (n, %)	15, 18.3%	111, 48.1%
Reflective	Launching General	8	3
	Launching Specific	9	7
	Pressing	10	17
	Paraphrasing	4	1
	Total (n, %)	30, 36.6%	28, 12.1%

*"Other" discourse moves were not included in the percentage calculation.

In a facilitative move, the coach established the focus of the coaching conversation without positioning the teacher or coach thinking as authority. In this move, the coach invites joint reflection and inquiry. Seeing this move as prevalent in debriefs with both teachers aligns with

the coach's own description of her role as co-learner: "We're all learners in this process. … We are going to work together to support high quality math discourse and we all brought our mathematics knowledge to the table to have a better impact on kids." In both teachers' debriefs, Vanessa generally used the *facilitative* move of *framing* to direct attention to the purpose of the discussion for the debrief. For instance, in Tara's debrief Vanessa explained, "So the purpose of our debrief today is to reflect on the lesson that you delivered and pretty much look at the noteworthy moments in the light of REALM."

In a directive stance move, the coach shares ideas and suggestions with the teacher and positions themself as the thinking authority. As noted, directive discourse moves were the most frequently observed in debrief with Tara (n=111, 48.1%), and the least with Emily (n=15, 18.3%). In her interview, Tara described the coach playing an expert role, referring to someone with deep knowledge who could provide clear guidance and suggestions. The teacher's perception might influence the coach's approach in Tara's debrief and result in more directive coaching moves as she responded to the teacher's expectations. In Tara's debrief, the coach mainly used *directive* moves of *validating* and *suggesting*. For example, while discussing students' work on an unknown addend problem within 20, with the content goal of making connections between addition and subtraction strategies, Vanessa suggested to Tara that she extend the discussion to elicit students' reasoning, stating, "I think the extension is having that conversation with them to see, 'Tell me a little bit more about your solution methods … how did you determine 11 kids were left in the library?'"

In a reflective move, the coach positions the teacher as the thinking authority by inviting them to share and examine their own reasoning. This discourse move was observed often in the debrief with Emily (n=30, 37.0%) but relatively infrequently with Tara (n=28, 12.1%). Emily described the coach's role primarily as that of a mentor in her interview, referring to the coach as a supportive agent who did not suggest ideas but instead helped her notice and reflect. For instance, Vanessa used the *reflective* move of *pressing* to prompt Emily to examine the implications of specific instructional decisions. After discussing a lesson video moment involving an incorrect answer, Vanessa pressed Emily to reflect: "So how are mathematical mistakes used as an opportunity to rethink and examine your ideas?" In response, Emily explained how intentionally using an incorrect answer opened space for discussing multiple strategies, and validated diverse student thinking and responses. In these exchanges, reflective moves supported extended teacher talk and deeper analysis of inclusive mathematics discourse.

Vanessa also used the *reflective* move of *launching* relatively frequently with Emily. As a result of our analysis, we identified an emergent distinction within launching discourse moves: *launching general* and *launching specific*. Launching general moves are those that invite broad reflections or thinking. In contrast, launching specific moves prompt teachers to anchor their reflection in a particular instructional moment, student/teacher action, or a specific mathematical idea. Launching specific moves more frequently yielded focused and in-depth discussion. For instance, after a launching general move referencing the REALM yielded minimal uptake by Emily (e.g., a brief "Yeah" followed by a pause), Vanessa re-launched reflection with a more specific prompt: "If we were looking at the REALM, to what extent do you think each and every student had access and opportunities to engage in the powerful mathematics… versus the inclusive math discourse community?" In response, Emily engaged in more in-depth reflection and articulated how instructional choices shaped student access to and participation in classroom discourse. This contrast suggests that while *launching general* moves positioned the teacher as the thinking authority, *launching specific* moves further provided a concrete analytic frame that

supported deeper teacher reflection on HQMI. This distinction is analytically important since it captures meaningful variation within reflective moves of launching that was not differentiated in the original coding scheme. This distinction helped us notice nuances in coaching reflective moves that appear to influence the depth and richness of coaching interactions.

During analysis, we identified an additional discourse move of *acknowledging* used in both teachers' debriefs. This emergent move occurs when the coach communicates an understanding of the teacher's thinking without affirming or evaluating the idea. Although similar to validating moves, this move functions differently by signaling comprehension (e.g. Ah, got it.) rather than endorsement or affirmation of teacher ideas or action. Interactionally, this move often serves as a pivot, allowing the coach to redirect the conversation or press for further reflection without positioning the teacher's idea as correct or preferred.

Our analysis of the debriefs also revealed a pattern in how the coach used AIM tools in relation to different discourse moves. For instance, although the coach intentionally incorporated the REALM tool, which is designed to support reflection in coaching conversations, its use in discourse moves varied across the debriefs. In Emily's debrief, REALM was used in 13 discourse moves, and 10 of those moves were reflective, including five launching-specific moves, three pressing moves, one launching-general move, and one paraphrasing move. This pattern aligns with how Emily positioned the coach as a mentor and with her expectation that the coach would support her reflection. In contrast, during Tara's debrief, the coach used REALM in 11 discourse moves, but only 4 were reflective (5 were facilitative-framing, 2 were directive-explaining). This distribution aligns with Tara's overall debrief, which was dominated by directive and facilitative moves, and with her positioning of the coach as an expert whose role was to provide guidance and validation. This pattern suggests that the REALM tool did not, on its own, always promote reflective moves. Instead, how the tool was used with different moves depended on how the debrief unfolded and aligned with how the teacher positioned the coach in debrief interactions.

Discussion

Saclarides et al.'s (2025) framework for coaching stances and moves aided our interpretation of the dynamic nature of coaching interactions, as well as influences on these interactions. We investigated the work of a coach who explicitly described her intention to take on a reflective stance and act as a learning partner with teachers. We found, though, that her coaching in practice consisted of a negotiated mix of stances and discourse moves. Teachers' positioning of the coach and their expectations of coaching interactions, strongly shaped coaching practice.

Emily's positioning of the coach as a supportive mentor enabled more reflective and facilitative moves. Conversely, Tara's positioning of the coach as expert appeared to invite more directive moves. Teachers acted not as recipients of coaching determined by the coach's preferred stance, but as co-constructors of coaching practice. The affordances and purposes of tools used during coaching also played a part in shaping interactions. Our findings suggest that coaching tools are neither neutral nor fixed in supporting a particular coaching stance or set of moves. Rather, they also play a role in the co-constructed dynamics of coaching, at times prompting directive moves of explanation and suggestions, and at others inviting reflective moves, (e.g., pressing), or facilitative moves, (e.g., clarifying). Coaching practice emerged through the interaction among the coach, the teacher, and the tools in use, rather than adhering strictly to the coach's intention or a tool's design.

Our investigation further identified a distinction (Launching general vs. Launching specific) within one move from Saclarides et al.'s (2025) framework, and one additional move

(Acknowledging). Like the moves identified a priori in the framework, the prevalence and influence of these moves varied between the two lesson debrief sessions we studied, suggesting they should be considered in further study of the dynamics of, and influences on, mathematics coaching practice.

This study examines convergent and discriminant validity evidence of two mathematics instructional belief instruments: Lesson Vignettes and the Priorities for Mathematics Instruction (PMI) survey. Both instruments address Explicit Attention to Concepts and Student Opportunity to Struggle but operationalize the constructs differently. While the Lesson Vignettes focus on judgments about teaching in context, the PMI focuses on instructional priorities under common constraints. Instrument content and correlation analyses of 88 middle school teachers' responses revealed moderate correspondence but distinct operationalizations, suggesting these instruments capture different aspects of teacher beliefs–how teachers reason about instruction in practice and how they prioritize instructional approaches when faced with real choices–guiding researchers in their interpretation and use of belief measures in mathematics education.

Keywords: Teacher Beliefs, Measurement

Purpose

Mathematics education researchers have increasingly emphasized gathering and sharing validity evidence for research instruments (Bostic, 2019; Bostic et al., 2021; Carney et al., 2022), yet convergent and discriminant validity evidence remains rare for teacher surveys (Bostic et al., 2025). Establishing such validity evidence is especially important for belief measures, as researchers face challenges in making inferences about beliefs, since these are often tacit, context-dependent, and shaped by multiple influences (Leatham, 2006; Wilson & Cooney, 2002).

This study examines the convergent and discriminant validity of two mathematics instructional beliefs instruments: vignettes describing instruction (herein referred to as Lesson Vignettes; Stein et al., 2017), and the Priorities for Mathematics Instruction survey (PMI; Carney et al., 2021). Both instruments draw explicitly on the Hiebert and Grouws (2007) framework that focuses on two instructional practice constructs that support students' conceptual understanding: Explicit Attention to Concepts and Student Opportunities to Struggle. However, the instruments operationalize the constructs differently. The Lesson Vignettes capture teachers' instructional judgment—how they interpret and evaluate instructional moves and student thinking within specific classroom situations. The PMI captures teachers' instructional prioritizations—how they weigh and select among competing instructional priorities under realistic classroom constraints.

Because we know these instruments are highly related, we are interested in understanding the points of convergence and divergence in teachers' beliefs and how these patterns operate in relation to instructional judgments in context (Lesson Vignettes) versus instructional prioritization under constraints (PMI). Examining convergence and divergence between these two instruments can inform whether they measure overlapping or complementary aspects of teachers' beliefs, providing insight into their appropriate interpretations and uses in research. We

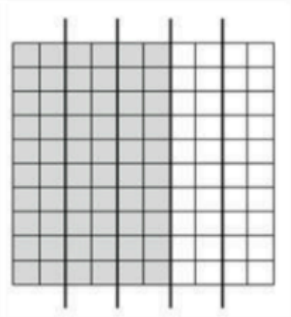
Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

answer the following research question: What convergence and divergence evidence exists between how these two instruments frame teacher beliefs?

Theoretical Framework and Related Literature

Hiebert and Grouws (2007) identified two constructs underlying instructional practices supporting students' conceptual understanding, with research evidence indicating positive effects across study design, teaching formats, and contexts. The first construct, Explicit Attention to Concepts, involves teachers and students explicitly discussing mathematical concepts and making connections among concepts, facts, and procedures, through activities such as questioning, discussing, comparing, and relating. The second construct, Student Opportunities to Struggle, involves students engaging in productive struggle with important mathematical ideas through sense-making around comprehensible problems.

These constructs represent pedagogical approaches that may be valued differentially by teachers. Explicit Attention to Concepts can be seen as a more externally-mediated approach in which the teacher ensures concepts and connections are made public and clear to students. In contrast, Student Opportunities to Struggle strategies are more concerned with experiences that engage students in developing understanding through their own sense-making. However, studies of mathematics instruction indicate many teachers focus on mastering procedural skills or limiting cognitive demand–practices at odds with Explicit Attention to Concepts and Student Opportunities to Struggle (Hill et al., 2018; Lindvall, 2025; Stein et al., 2017). Survey instruments that capture these competing instructional choices can help researchers better understand the instructional tradeoffs teachers navigate and how shifts in instructional beliefs may be facilitated.



Understanding what drives instructional choices requires examining teachers' underlying beliefs. Wilson and Cooney (2002) suggest attending to what teachers value and how they assign importance to different aspects of teaching mathematics. Given that different survey instruments may operationalize and elicit beliefs about practices like Explicit Attention to Concepts and Student Opportunities to Struggle in distinct ways, comparing teachers' responses across surveys can reveal nuances in how teachers conceptualize and prioritize these instructional approaches.

Belief Measures: Explicit Attention to Concepts and Student Opportunities to Struggle

Lesson Vignettes and the PMI were designed to measure beliefs related to Explicit Attention to Concepts and Student Opportunities to Struggle instructional practices but employ different measurement approaches.

Lesson vignettes. Stein et al. (2017) posit a framework for examining interactions between high and low levels of Explicit Attention to Concepts and Student Opportunities to Struggle in context-specific classroom situations. Using the two dimensions of Explicit Attention to Concepts (EAC) and Student Opportunities to Struggle (SOS), they produced four teaching profiles, which they conceptualize as quadrants (Quadrant 1 [Q1]: high EAC/high SOS; Quadrant 2 [Q2]: high EAC/low SOS; Quadrant 3 [Q3]: low EAC/high SOS; Quadrant 4 [Q4]: low EAC/low SOS). The Lesson Vignettes comprise four lesson descriptions, each taught by a different teacher who exemplifies one of the teaching profile quadrants. See Figure 1 for a sample vignette of a lesson taught by Ms. Evans, a Quadrant 2 teacher.

Ms. Evans is finishing a unit on rational numbers (fractions, decimals, and percents). Having covered each individually, her goal for today's lesson is to help students see the relationship among these different ways of representing rational numbers. By using the same 100-grid to represent the fraction 3/5 and its decimal and percent equivalents, she wanted her students to recognize that 3/5, .6, and 60% are equivalent because they cover the same amount of area.

After passing out the task, Ms. Evans identifies the goal of the lesson and reminds students that diagrams can be a useful tool for reasoning about fractions, percents and decimals. Most students begin by dividing the 100-grid into fifths as shown here and shading three out of the five segments. When most have done so, Ms. Evans reinforces that the amount shaded is the fraction 3/5, which means 3 parts out of 5 parts, and asks if there is an equivalent fraction that could also describe the amount that is shaded. After a student volunteers that you could also write the fraction as 60/100, Ms. Evans asks the class to finish the remainder of the task. For the decimal equivalent, most students apply their knowledge that a decimal is "an amount out of 100" and identify .60 as the decimal that represents the amount that is shaded. When some students hurriedly finish by moving the decimal two places to the right and adding a "%" sign, Ms. Evans presses them to apply their knowledge of what percent means to the grid and to justify why 60% is the correct answer. She concludes the lesson with an explanation of the meaning of equivalence.

Figure 1: Vignette for Quadrant 2 Teaching by Stein et al. is licensed under CC BY 3.0 (Stein et al., 2017, Appendix A)

Items ask teachers to rate their level of agreement with statements regarding the effectiveness of the instruction depicted in each vignette on a 5-point Likert scale (e.g., “Most students will leave Ms. Evans’ class understanding the concept of equivalence”). Collectively, the measure produces four quantitative scores, one for each of the four teaching profiles, each interpreted as the extent to which a teacher’s beliefs correspond to instruction represented by the associated quadrant. The higher the quadrant score, the higher the agreement between the teacher’s beliefs and the levels of Explicit Attention to Concepts and Student Opportunities to Struggle depicted by that quadrant’s teaching profile.

Priorities for Mathematics Instruction (PMI). Carney et al. (2021) conceptualized mathematics instruction along continua reflecting competing instructional priorities. These range from practices emphasizing Explicit Attention to Concepts (EAC) and Student Opportunities to Struggle (SOS) to contrasting approaches termed Singular Methodological Focus (SMF) and Highly Scaffolded Content (HSC), respectively, resulting in the EAC–SMF and SOS–HSC belief scales. Singular Methodological Focus prioritizes focused attention on a single method or procedure to support clarity and accuracy, while Highly Scaffolded Content emphasizes explicit guidance and a gradual progression in task complexity. Importantly, we position both ends of each continuum as legitimate instructional choices shaped by classroom constraints (e.g., time, student readiness), and the PMI is designed to capture how teachers prioritize among these competing approaches.

The PMI comprises 15 items, eight related to practices on the EAC–SMF scale and seven on the SOS–HSC scale. For each item, a teacher is provided with a prompt of a belief statement (e.g., Students are more likely to succeed in math when they can…). Teachers complete the statement by selecting a position on a 6-point forced-choice slider between opposing instructional priorities, indicating both direction and intensity (see Figure 2 for a sample survey

item). Responses yield two quantitative scores, PMI EAC and PMI SOS, representing teachers' positions along the EAC–SMF and SOS–HSC continua, respectively. Importantly, scale direction does not imply that one instructional priority is inherently more desirable; instead, scores indicate the degree to which teachers' beliefs align with one emphasis relative to its contrasting counterpart.

Method

Data

This study employed two distinct data sources corresponding to the qualitative and quantitative analyses. For the qualitative analysis, we examined the instruments themselves, the Lesson Vignettes and PMI survey items, to understand how each instrument operationalizes beliefs about Explicit Attention to Concepts and Student Opportunities to Struggle instructional practices. For the quantitative analysis, we used teachers' scores generated from their responses to both instruments. These scores came from 88 grades 6–8 mathematics teachers in rural-serving schools in the northwest United States. The surveys were administered at the same time at the beginning of a large research project studying professional development delivery models.

Analysis

For qualitative analysis, we used an approach of mapping the content of the Lesson Vignettes onto each item in the PMI survey (Corbin & Strauss, 2014). One researcher read each vignette twice, then determined which half of each PMI item—the EAC- or SMF-aligned response option—was better represented by the vignette content. For example, for the item shown in Figure 2, asking whether students should "apply a particular method to solving similar math problems" (SMF) or "make connections among math topics" (EAC), the Q2 Vignette was coded as EAC-aligned because the vignette described a teacher whose "goal for today's lesson is to help students see the relationship among these different ways of representing rational numbers." When vignette content did not clearly favor one response option over the other, or when neither option was represented, the item was coded as "no match or unclear." A second researcher reviewed all mappings and confirmed the results.

For quantitative evidence, we performed descriptive summaries of the response distributions of all items in the instruments, and we calculated Pearson product-moment correlations between

all instrument variables (i.e., vignette quadrant scores and PMI EAC and SOS scores) to examine convergent and discriminant validity (AERA, APA, NCME, 2014). We report the associated matrix of observed intercorrelations and compare the values to theoretically-based expectations.

Results

Content Analysis

Convergence. Table 1 shows the number of PMI items that matched instructional practices described in the Lesson Vignettes. Analysis revealed moderate correspondence between instruments. Three of four Lesson Vignettes showed clear alignment with theoretically expected PMI constructs: Q1 Vignette (High EAC/High SOS) matched 5 (63%) EAC and 5 (71%) SOS response options; Q2 Vignette (High EAC/Low SOS) matched 7 (88%) EAC response options; and Q4 Vignette (Low EAC/Low SOS) matched 7 SMF and 3 HSC response options.

Table 1: Number of PMI Items Matching Practices Described in Lesson Vignettes

PMI Construct	Lesson Vignettes (Stein et al., 2017)			
	Q1 Vignette: High EAC, High SOS	Q2 Vignette: High EAC, Low SOS	Q3 Vignette: Low EAC, High SOS	Q4 Vignette: Low EAC, Low SOS
EAC (8)	5 (63%)	7 (88%)	5 (63%)	0 (0%)
SMF (8)	2 (25%)	0 (0%)	1 (13%)	7 (88%)
SOS (7)	5 (71%)	3 (43%)	2 (29%)	0 (0%)
HSC (7)	0 (0%)	0 (0%)	0 (0%)	3 (43%)
No match or unclear	3	5	7	5

Divergence. However, substantial divergence is evident in three areas. First, Q3 Vignette (Low EAC/High SOS) showed unexpected alignment patterns: (a) matching 5 (63%) EAC response options despite representing low EAC, (b) matching only 2 (29%) SOS response options despite representing high SOS, and (c) with 7 items rated as no match or unclear. Second, HSC items showed minimal alignment across Lesson Vignettes, matching 3 (43%) response options only in Q4 Vignette and 0 (0%) in Q2 Vignette despite these vignettes representing low SOS. Third, between 3 and 7 PMI items per vignette could not be clearly mapped to vignette content.

Correlation Analysis

Correlation analysis examined the strength and direction of relationships between teachers' Lesson Vignette quadrant scores and PMI scale scores (see Table 2). Evidence of convergent validity (overlapping measurement) would include positive correlations between PMI scales and theoretically aligned vignette quadrants—specifically, PMI EAC with Q1 and Q2 (high EAC quadrants), and PMI SOS with Q1 and Q3 (high SOS quadrants)—as well as negative correlations with opposing quadrants. Evidence of discriminant validity (unique measurement) would include correlations that indicate relatedness without redundancy, unexpected patterns, and distinct relationships between the Lesson Vignettes and the PMI scales.

Table 2: Intercorrelations Among Mathematics Teaching Belief Measures

Variable	1	2	3	4	5	6
1. Q1 Score	—					
High EAC/High SOS						
2. Q2 Score	0.51	—				
High EAC/Low SOS						
3. Q3 Score	0.14	0.27	—			
Low EAC/High SOS						
4. Q4 Score	–0.22	0.11	–0.21	—		
Low EAC/Low SOS						
5. PMI EAC	0.30	0.05	0.25	–0.35	—	
6. PMI SOS	0.39	0.11	0.20	–0.46	0.54	—

Convergence. Results provided moderate evidence that the instruments measure overlapping aspects of beliefs about Explicit Attention to Concepts and Student Opportunities to Struggle. As expected, both PMI scales correlated negatively with Q4 (low EAC/low SOS): PMI EAC (r = –.35) and PMI SOS (r = –.46). PMI SOS showed expected positive correlations with high-SOS quadrants: Q1 (r = .39) and Q3 (r = .20). PMI EAC showed expected positive correlation with high-EAC quadrant Q1 (r = .30).

Divergence. In contrast, several patterns suggested that the instruments measure distinct aspects of teacher beliefs. Q2 Vignette (high EAC) showed only a weak positive correlation with PMI EAC (r = .05), while Q3 Vignette (low EAC) showed a larger positive correlation (r = .25), indicating PMI EAC response options do not strongly correlate with characterizations of high and low EAC in the vignettes. Additionally, the Q3 Vignette (high SOS) correlation with PMI SOS (r = .20), though positive and in the expected direction, was relatively weak.

Summary

Overall, content and correlation analyses revealed that the Lesson Vignettes and PMI measure overlapping yet distinct aspects of Explicit Attention to Concepts and Student Opportunities to Struggle beliefs. The clearest convergence appeared in Q1 and Q4 Vignettes, which showed expected content alignment with PMI constructs and moderate correlations in theoretically predicted directions. Some divergence involved aspects of Q2 and Q3 Vignettes. Q2 Vignette (high EAC/low SOS) showed strong EAC content alignment but weak correlation with the PMI EAC scale, suggesting the vignette depicts high EAC in ways that differ from the PMI. Q3 Vignette (low EAC/high SOS) showed unexpectedly high EAC content alignment, weak SOS content alignment, and an unexpected positive correlation with PMI EAC—patterns that were inconsistent with theoretical predictions. Together, these findings indicate the instruments operationalize Explicit Attention to Concepts and Student Opportunities to Struggle differently, capturing related but distinct aspects of teacher beliefs.

Discussion

This study examined whether two instruments measuring beliefs about Explicit Attention to Concepts and Student Opportunities to Struggle capture overlapping or unique aspects of these constructs. Content and correlation analyses revealed moderate convergence alongside meaningful divergence, indicating the instruments are related but operationalize Explicit Attention to Concepts and Student Opportunities to Struggle in distinct ways.

Integration of Results

Student Opportunities to Struggle showed the clearest divergence in Q3 Vignette, which had weak SOS content alignment despite representing high SOS, and weak correlations with PMI SOS. Explicit Attention to Concepts showed two divergent patterns: Q2 Vignette had strong EAC content alignment but weak correlations with PMI EAC, and Q3 Vignette showed unexpectedly high EAC content alignment alongside unexpected positive correlations with PMI EAC despite representing low EAC.

A key structural difference between the instruments helps explain these patterns. The Lesson Vignettes define low EAC and low SOS structurally through the quadrant design, but do not explicitly name or frame the instructional philosophy underlying those lower-scoring profiles. The Q4 Vignette is characterized by the absence of high EAC and high SOS practices rather than by the presence of a distinct competing orientation. The PMI, by contrast, explicitly defines what low EAC and low SOS represent by positioning Singular Methodological Focus and Highly Scaffolded Content as instructional orientations at the opposing ends of each continuum. A teacher who scores low on PMI EAC is prioritizing a coherent alternative approach commonly seen in instruction, centered on procedural clarity and methodological focus. Similarly, a teacher who scores low on PMI SOS is prioritizing explicit guidance and scaffolded progression rather than productive struggle. This asymmetry in operationalization may help explain why Highly Scaffolded Content items were largely absent from vignette content even in low-SOS vignettes. Rather than reflecting a limitation of either instrument, these patterns are consistent with a known structural difference in how the two instruments conceptualize the belief space: the Lesson Vignettes frame beliefs as judgments about the effectiveness of Explicit Attention to Concepts and Student Opportunities to Struggle practices, while the PMI frames them as choices among competing priorities.

The Multifaceted Nature of Beliefs

These content and correlation analyses underscore the multifaceted nature of teacher beliefs (Leatham, 2006; Philipp, 2007). The fact that teachers responded differently to the two instruments—despite both claiming to measure Explicit Attention to Concepts and Student Opportunities to Struggle—demonstrates that beliefs about these constructs cannot be fully captured by a single measurement approach. Teachers' responses differ when they evaluate contextualized lessons versus when they articulate general instructional priorities, as evidenced by the moderate but not strong correlations between instruments.

The unexpected correlation patterns reveal complexity in how teachers engage with these theoretical constructs. These patterns could stem from teachers holding context-dependent values about these practices, conceptualizing Explicit Attention to Concepts and Student Opportunities to Struggle differently than the theoretical framework suggests, or both (Leatham, 2006; Maass, 2011; Wilson & Cooney, 2002). For instance, teachers may value conceptual attention differently when evaluating a brief lesson scenario versus prioritizing it as a general instructional principle, or they may recognize Explicit Attention to Concepts in instructional contexts that extend beyond the high/low structure used to design the vignettes. Regardless of the source of

these differences, the findings demonstrate that quantification of beliefs about instructional approaches is influenced by measurement context and cannot be reduced to a simple position on theoretical dimensions. This complexity aligns with research showing beliefs are context-dependent and shaped by multiple influences (Leatham, 2006; Wilson & Cooney, 2002).

Implications for Researchers

The differential operationalization of Explicit Attention to Concepts and Student Opportunities to Struggle constructs across these instruments has important implications for researchers. First, instrument selection and comparison require careful consideration. Researchers should consider which operationalization aligns with their theoretical framework and research questions. The Lesson Vignettes may be more appropriate when researchers want to understand teachers' judgments about instructional effectiveness in specific lesson contexts, while the PMI may better capture teachers' general instructional priorities and values. Given these operational differences, findings from one instrument should not be assumed to generalize to the other, and cross-study comparisons should account for the different dimensions of beliefs captured by each instrument.

Second, score interpretation requires attention to operational context. Scores should be interpreted within the framework of how each instrument operationalizes Explicit Attention to Concepts and Student Opportunities to Struggle. A teacher who scores high on PMI SOS may not necessarily rate high-SOS vignettes as most effective, as these tap different facets of beliefs about student struggle and scaffolding. Researchers should therefore resist interpreting scores as interchangeable indicators of the same underlying belief and instead attend to what each instrument's operationalization actually captures.

Third, building a validity argument for any instrument requires accumulating multiple pieces of evidence over time—content analyses, factor structures, relationships with external variables—yet individual studies contributing this evidence are rarely published. Recent calls in the field have emphasized that this kind of iterative evidence is precisely what is needed, as it is the only way a validity argument gets built (Bharaj et al., 2025; Bostic, 2019; Bostic et al., 2021; Carney et al., 2022). Without it, researchers draw on instruments and often make interpretive claims that outpace the evidence supporting them. This study represents one such contribution to that cumulative effort, examining convergent and discriminant validity evidence for two instruments already in active use in the field. We encourage researchers to similarly document and share validity evidence at each stage of instrument development and use, so that the field can ensure that interpretations drawn from belief measures are appropriate and well-supported.

Conclusion

In conclusion, Lesson Vignettes and PMI measure potentially complementary rather than redundant aspects of teachers' beliefs about Explicit Attention to Concepts and Student Opportunities to Struggle. Both instruments provide valid but distinct information, with the Lesson Vignettes capturing beliefs through contextualized effectiveness judgments and the PMI through abstract priority statements. Rather than viewing one instrument as "better," researchers should recognize that these different operationalizations serve different purposes and capture different facets of the multifaceted construct of teacher beliefs.

MULTIDIMENSIONAL PATTERNS OF TEACHER CHANGE IN MATHEMATICS PROFESSIONAL DEVELOPMENT

Lisa C. Duffin

Audrey Harper
Green River Regional Education Cooperative
audrey.harper@grrec.org

This brief report examines patterns of teacher change during Year 1 of a statewide mathematics professional development initiative (n = 140). Mathematical Knowledge for Teaching (MKT) in fractions (Grades 3–5) and ratio and proportional reasoning (Grades 6–8) did not demonstrate statistically significant change across the year, as did collective efficacy. In contrast, mathematics teaching self-efficacy and mathematics teacher identity increased. Both grade bands performed near the national mean on the MKT assessment, although Grades 6–8 teachers consistently scored higher than Grades 3–5 teachers. The findings suggest that psychological dimensions of mathematics teaching competence and measurable changes in specialized knowledge may follow different patterns during the first year of sustained professional development, reflecting a layered process of teacher change.

Keywords: Professional Development, Mathematical Knowledge for Teaching, Teacher Beliefs, Identity and Agency

Teaching mathematics for conceptual understanding requires specialized mathematical knowledge for teaching, including the ability to represent ideas, interpret student thinking, and make responsive instructional decisions (Ball et al., 2008; Kleickmann et al., 2015). However, knowledge alone may be insufficient to support conceptual instruction. Research with elementary and prospective elementary teachers points to math anxiety and math teaching anxiety (Szczygieł et al., 2025), uneven conceptual understanding of rational number ideas (Depaepe et al., 2018), and variation in knowledge and beliefs tied to teachers' mathematical backgrounds (Holm & Kajander, 2020).

Current models of teacher competence describe professional expertise as multidimensional, integrating knowledge with affective and motivational characteristics (Blömeke & Delaney, 2012; Copur-Gencturk & Tolar, 2022). The present study is grounded in this multidimensional perspective, which conceptualizes teacher development as involving related but distinct dimensions of knowledge, beliefs, motivation, and professional identity. Within this framework, mathematical knowledge for teaching is related to, yet empirically distinct from, constructs such as mathematics teaching self-efficacy (Bandura, 1997; Wilhelm & Berebitsky, 2019), mathematics teacher identity (Cribbs et al., 2015), and other teacher beliefs (Fukaya et al., 2025). Longitudinal studies suggest that these dimensions do not necessarily develop at the same pace (Copur-Gencturk & Li, 2023).

Research on effective professional learning consistently emphasizes content focus, active learning, collaboration, modeling of practice, expert support, and sustained duration (Darling-Hammond et al., 2017). These features are intended to build teachers' knowledge and instructional confidence and, over time, may also contribute to collective efficacy within schools (Bandura, 1993, 1997; Goddard, 2002).

Taken together, the literature indicates that educating for change in mathematics instruction requires attention to knowledge and to the psychological and collective conditions that support

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

effective classroom practice. What remains less clear is how these dimensions shift during sustained professional learning. To examine how multidimensional change unfolds in practice, this brief research report focuses on Year 1 of a statewide mathematics professional development initiative and addresses two questions: (1) To what extent do teachers' Mathematical Knowledge for Teaching (MKT), mathematics teaching self-efficacy (MTSES), mathematics teacher identity (MTI), and collective efficacy (CE) change during the first year of PD? (2) Do grade bands differ in overall levels and growth from Time 1 to Time 2 across these measures?

Methods

Participants and Context

Participants were 170 educators involved in a statewide numeracy-focused professional development initiative. The broader sample included classroom teachers, instructional coaches, administrators, and district leaders; analyses for the present study focused on 140 classroom teachers participating in Grades 3–5 and Grades 6–8 strands. Because the study examined longitudinal change from Baseline (Time 1) to End-of-Year-One (Time 2), matched sample sizes varied by measure and are reported in the Results section. Teachers had an average of 10.94 years of experience (SD = 7.13) and were predominantly White (96.2%) and female (86.7%).

The PD model is a two-year, hybrid initiative designed to strengthen mathematical knowledge and instructional practice. Year 1 organized teachers into grade-band strands (Grades 3–5: fractions; Grades 6–8: ratio and proportional reasoning) and included sustained content-focused sessions, collaborative communities of practice, and coaching cycles.

Measures

Mathematics Teacher Identity (MTI; Cribbs & Utley, 2024). The 13-item, 5-point Likert instrument assesses teachers' perceptions of competence, recognition, and alignment with the role of mathematics teacher. Composite mean scores were calculated, with higher values indicating stronger mathematics teacher identity ($\alpha = 0.91$).

Mathematics Teaching Self-efficacy (MTSES; Wilhelm & Berebitsky, 2019). The 12-item, 5-point Likert scale assesses teachers' perceived capability to support student learning in mathematics. Composite mean scores were calculated, with higher values indicating stronger perceived instructional capability ($\alpha = 0.88$).

Collective Efficacy (CE; Goddard, 2002). The 12-item scale was adapted to reflect state-level beliefs within the PD context and administered on a 5-point Likert scale. Composite mean scores were calculated, with higher values indicating stronger collective efficacy beliefs ($\alpha = 0.76$).

Mathematical Knowledge for Teaching (MKT; The Regents of the University of Michigan, 2007**).** The assessment is grounded in the MKT framework distinguishing common content knowledge from knowledge specialized for teaching (Ball et al., 2008). The instrument was electronically administered, and scaled scores were provided by the publisher; item-level data were not available.

Analyses

A series of mixed-design analyses of variance (ANOVAs; Field, 2018) were conducted to examine changes over time (Baseline to Time 2) and differences by grade band for MKT, MTSES, MTI, and CE. Time served as the within-subjects factor and grade band as the between-subjects factor. Significance was evaluated at $\alpha = .05$. Effect sizes (η^2) are reported where available.

Results

Table 1: MKT Descriptive Statistics from Time 1 to Time 2

Grade Band	*n*	Time 1 Mean θ (SE)	Time 2 Mean θ (SE)
3–5	81	–0.36 (0.07)	–0.22 (0.08)
6–8	39	0.37 (0.11)	0.34 (0.12)
Total	120	–0.01 (0.06)	0.06 (0.07)

A mixed-design ANOVA revealed no significant main effect of Time, $F(1,118) = 0.68$, $p = .41$. The Time × Grade Band interaction was not significant, $F(1,118) = 1.75$, $p = .19$. A significant main effect of Grade Band was observed, $F(1,118) = 29.39$, $p < .001$, $\eta^2 = .20$.

Table 2: Descriptive Statistics from Time 1 to Time 2 for Psychological Variables

Grade Band	*n*	MTSES Time 1 Mean (SE)	MTSES Time 2 Mean (SE)	*n*	CE Time 1 Mean (SE)	CE Time 2 Mean (SE)	*n*	MTI Time 1 Mean	MTI Time 2 Mean
3–5	68	4.01 (0.05)	4.26 (0.05)	73	3.53 (0.05)	3.61 (0.05)	76	4.11 (0.05)	4.28 (0.05)
6–8	46	3.99 (0.07)	4.02 (0.07)	38	3.54 (0.07)	3.49 (0.07)	38	4.31 (0.06)	4.39 (0.06)
Total	114	4.00 (0.04)	4.14 (0.04)	111	3.54 (0.04)	3.57 (0.04)	114	4.18 (0.04)	4.31 (0.04)

Mathematics Teaching Self-Efficacy (MTSES). A significant main effect of Time was observed, $F(1,112) = 11.12$, $p = .001$, indicating an overall increase in self-efficacy from Time 1 to Time 2. A significant Time × Grade Band interaction also emerged, $F(1,112) = 6.56$, $p = .012$. Grades 3–5 teachers demonstrated a notable increase in self-efficacy (4.01 to 4.26), despite beginning the year with relatively high scores, whereas Grades 6–8 teachers remained relatively stable (3.99 to 4.02). No significant overall group difference was found, $F(1,112) = 3.21$, $p = .076$.

Collective Efficacy (CE). No significant main effect of Time was found, $F(1,109) = 0.09$, $p = .77$, indicating stability across the year. The Time × Grade Band interaction was not significant, $F(1,109) = 1.93$, $p = .17$, nor was the main effect of Grade Band, $F(1,109) = 0.46$, $p = .50$.

Mathematics Teacher Identity (MTI). A significant main effect of Time was observed, $F(1,112) = 13.96$, $p = .001$, indicating increased identification as mathematics teachers across the year. The Time × Grade Band interaction was not significant, $F(1,112) = 1.50$, $p = .223$. A small but significant main effect of Grade Band emerged, $F(1,112) = 4.33$, $p = .040$, $\eta^2 = .037$, with Grades 6–8 teachers reporting slightly higher identity overall.

Discussions and Conclusions

Year 1 results indicate that teacher development during sustained mathematics professional learning does not occur uniformly across domains. Consistent with multidimensional models of teacher competence (Blömeke & Delaney, 2012; Copur-Gencturk & Tolar, 2022), knowledge and belief-related constructs followed different patterns across the first year of the initiative.

Mathematical knowledge for teaching remained stable across the year, and a grade-band difference persisted. Importantly, both groups performed near the national mean at each time point, indicating that teachers were not entering the initiative under severe content deficits. At

the same time, Grades 6–8 teachers consistently scored higher than Grades 3–5 teachers. Because the elementary strand focused on fractions and the middle grades strand on ratio and proportional reasoning, this difference reflects patterns in content domains that are foundational for later mathematics learning (Siegler et al., 2012). The grade-band pattern also parallels broader trends in teacher preparation research, where secondary pathways typically emphasize disciplinary specialization and elementary preparation is more generalist in scope (Holm & Kajander, 2020; Kajander & Holm, 2016; Musset, 2009). Given evidence linking teachers' specialized mathematical knowledge to student achievement (Ball et al., 2008), the findings highlight the continued importance of sustained, content-focused professional learning in the elementary grades.

In contrast, mathematics teaching self-efficacy increased, particularly among Grades 3–5 teachers. Self-efficacy beliefs influence persistence and effort in challenging instructional situations (Bandura, 1997). MKT scores did not demonstrate statistically significant change while self-efficacy increased. This pattern suggests that teachers' perceived instructional capability may shift more readily than measurable changes in specialized content knowledge during early phases of professional learning. Rather than indicating inconsistency across measures, the findings may reflect the multidimensional nature of teacher development, where motivational and knowledge-based dimensions do not necessarily change on the same timeline (Copur-Gencturk & Li, 2023). Sustained professional learning may involve repeated cycles of study, enactment, and reflection as teachers continue developing across multiple domains (Desimone, 2009).

Mathematics teacher identity also increased across the year. Teachers reported stronger alignment with the role of mathematics teacher, suggesting shifts in professional self-concept that extend beyond perceived competence alone (Cribbs & Utley, 2024). The increase in mathematics teacher identity alongside stable MKT scores further supports the idea that psychological and knowledge-based dimensions of teacher competence may not develop uniformly during professional learning (Copur-Gencturk & Li, 2023).

Collective efficacy did not change during Year 1. Because collective beliefs are grounded in shared instructional experience, they may require longer periods of coordinated implementation before measurable change occurs (Goddard, 2002). The stability of collective efficacy during Year 1 further highlights that different dimensions of teacher competence and professional learning contexts may respond differently during sustained professional development.

Overall, the findings suggest that educating for change in mathematics instruction involves supporting specialized knowledge alongside the psychological dimensions that shape instructional practice. During Year 1, teachers' efficacy and identity increased, while MKT and collective efficacy did not demonstrate statistically significant change. Together, these findings highlight the layered nature of teacher development and suggest that dimensions of teacher competence may follow distinct patterns of change during sustained professional learning. Year 2 data will allow examination of whether these patterns persist as teachers engage new content strands and translate professional learning into classroom practice.

We investigated mathematics teachers' growth and knowledge of social and emotional learning (SEL) after completing three or four years of monthly training during the academic year. The SEL trainings was led by a local nonprofit who specializes in emotional intelligence. The 11 participants were surveyed at the end of the trainings and after their first- or second-year teaching. We constructed an analytic framework using transformative SEL (tSEL) and found the most common tSEL competency area was about the teachers' agency and belonging. The teachers shared how the trainings influenced their personal lives, professional lives, and made a difference in their classrooms.

Keywords: Affect, Emotions Beliefs, and Attitudes; Instructional Activities and Practices; Communication; Preservice Teacher Education

There is a national shortage of mathematics teachers in the United States (Oyen & Scheweinle, 2020). Rural areas have a documented challenge to recruit and retain teachers (Ingersoll & Tran, 2023). We received NSF funding to support preservice mathematics teachers for the last two years of their undergraduate education and their first year or two of teaching. With the grant, the teachers received a full scholarship, monthly learning community building events, and monthly trainings on social emotional learning (SEL) by a local nonprofit, Peacemaker Resources. The preservice teachers attended the training for the last two years of their schooling and into their first years of teaching. The training focused on adverse child trauma, historical trauma, and how to incorporate SEL into their personal and professional lives.

Researchers have documented students who have adverse child experiences (ACES) and trauma affects how the brain perceives and process situations and can lead to chronic stress and limit a person's resiliency (Harter & Harter, 2022; Leung, Chan, & Ho, 2022). ACES can also result in a child struggling with memory, attention, and anxiety. However, researchers have also found that when a teacher incorporates SEL into their teaching, the students show significant improvement in their learning and academic performances (Lonhi, 2015). More recently, Baez and Baez (2023) found that incorporating cultural SEL with American Indians is critical to help them develop cultural understanding and the regulation of their emotions. Additionally, Ottmar et al. (2015) shared teachers who are trained in SEL are more able to pursue ambitious mathematics teaching.

Research Question

The following question guided our research study: How did the new mathematics teachers grow in their SEL knowledge and skills during the course of their training? In what ways, if at all, did the teachers demonstrate investment to integrate SEL in their educational settings?

Theoretical Framework

Communities of Practice (CoP) guided our framework for the structure of our five-year long grant (Wenger, 1998). Learning happens during social practices and people create their understanding of ideas through active community participation. Through active learning, the participants construct identities in relation to social engagement. The teachers who were participants in this study engaged in a learning community around SEL (CASEL, 2022) workshops monthly for three or four years. The SEL workshops also included a curriculum on historical trauma and the impact of the boarding school era on Indigenous communities, who comprise 21.7% of the population in the region where this program took place (U.S. Census Bureau, n.d.). The participants also had monthly community building activities together beyond the training and their undergraduate coursework. Example activities are axe throwing, paddling in a dragon boat, having a bonfire, snowshoeing, and a canoe trip. The CoP framework helped to guide how we organized and structured the grant project.

While the training itself was grounded in SEL, the research and analysis were guided by a transformative Social and Emotional Learning (tSEL) lens (CASEL, 2023). tSEL functioned as an interpretive framework for examining how participation in the community of practice shaped educators' engagement within high-need schools over time. Consistent with tSEL's emphasis on equity and context, the analysis attended to how identity, agency, belonging, collaborative problem solving, and curiosity emerged through mutual engagement and collective inquiry, rather than evaluating discrete outcomes. In this way, Wenger's theory of learning as participation provided the structural foundation of the study, SEL informed the content of professional learning, and tSEL guided the interpretation of how learning was applied by the practice community (Wenger, 1998; CASEL, 2022; CASEL, 2023).

Methods

As part of a five-year long NSF funded grant project on preparing preservice mathematics teachers to teach in rural high-need areas with continued support into the first year or two of teaching, we evaluated the teachers' growth and reflection on the project in relation to the five core tSEL competencies. The teachers began the project during their junior year at a public university in the rural northern Midwest. The preservice teachers were awarded full cost of attendance scholarships to finish their final two years. All the students double majored in both mathematics and mathematics education and wanted to pursue a teaching career. We had two cohorts of students. Cohort 1 (Fall 2020–Spring 2025) included eight students who we supported through their last two years of undergraduate education and through their first two years of teaching. Cohort 2 (Fall 2021–Spring 2025) included seven students who we supported through their final two years of undergraduate education and through their first year of teaching. Fourteen of the fifteen participants were teaching in rural areas with eleven of them teaching in the rural area around the university. Only eleven of the students completed the survey but because it was anonymous, we do not know who or how many were from Cohort 1 or Cohort 2.

Throughout their time in the Robert Noyce program, from upper-level undergraduate students into their first years in the classroom, the teachers participated in monthly two-hour meetings focused on integrating SEL skills for personal and professional practice. Cohort 1 was supported for the first two years of their teaching careers while Cohort 2 was supported for the first year of their teaching careers. The monthly meetings consisted of topics focused on the impact of trauma on brain development, ACEs, historical trauma, and strategies to build resilience (SEL). Trainings were conducted by a local non-profit with extensive experience training school faculty, staff and students in SEL and licensed educator.

At the final session we surveyed students on their growth and reflection. We asked the participants six questions framed within the CASEL Framework (CASEL, 2022):

1. Self-Awareness Competency - Read the skills below and reflect on your growth throughout the Noyce Program. Please select two or three SEL skills in this competency area and share examples of how you have used these skills in your classrooms or coursework.
2. Self-Management - Read the skills below and reflect on your growth throughout the Noyce Program. Please select two or three SEL skills in this competency area and share examples of how you have used these skills in your classrooms or coursework.
3. Social Awareness - Read the skills below and reflect on your growth throughout the Noyce Program. Please select two or three SEL skills in this competency area and share examples of how you have used these skills in your classrooms or coursework.
4. Relationship Skills - Read the skills below and reflect on your growth throughout the Noyce Program. Please select two or three SEL skills in this competency area and share examples of how you have used these skills in your classrooms or coursework.
5. Responsible Decision Making - Read the skills below and reflect on your growth throughout the Noyce Program. Please select two or three SEL skills in this competency area and share examples of how you have used these skills in your classrooms or coursework.
6. Any other comments regarding your SEL experience you would like to share?

We applied a transformative SEL (tSEL) analytic framework (CASEL, 2022; see Table 1) to focus on equity and context. The analysis attended to how identity, agency, belonging, collaborative problem solving, and curiosity emerged through mutual engagement and collective inquiry that will transform the educational outcomes of students in high-need schools.

Table 1: Analytic Framework

Competency Area	Definition
Identity	Refers to how adults view themselves as individuals and as part of the world around them. Having a healthy sense of identify buffers against negative or traumatic experiences and contributes to positive academic, social, and emotional outcomes.
Agency	Feeling empowered to make choices and take actions that produce a positive difference. Agency helps young people make choices about learning and career goals, overcome personal challenges, and shape the course of their lives.
Belonging	The experience of acceptance, respect, and inclusion within a group or community. Having a sense of belonging is critical to well-being, motivation, and achievement.
Collaborative Problem-Solving	The ability to build shared understanding and work together to come to solutions by pooling knowledge, skills, and efforts.
Curiosity	Leads to the pursuit of knowledge and different perspectives and contributes to attention, engagement, and learning.

After identifying the analytic framework, we first went through and documented anytime a teacher wrote about one of the competency areas independently for the first two participants. Our coding team (two researchers who participated in the SEL trainings and are mathematics education faculty, a social work faculty member, and a psychology faculty member) then checked for agreement on the first two students (18.2% of the sample). Next, we completed this process again with the rest of the responses first independently and then together. Together, we discussed our independent coding choices until we reached 100% agreement. We then tallied each time we documented a competency area during the survey.

Results and Discussion

During analysis, we coded each time the teacher documented their growth or skill as it related to CASEL's tSEL areas of focus (CASEL, 2022). Throughout analysis, we found agency was the most common competency area the teachers discussed (see Table 2).

Table 2: tSEL Competency Area Counts

Teacher	Identity	Agency	Belonging	Collaborative Problem-Solving	Curiosity
A	1	6	1	1	2
B	3	5	4	1	0
C	2	4	3	2	3
D	2	3	1	3	0
E	0	3	0	2	0
F	1	3	1	0	0
G	1	2	1	4	1
H	1	3	2	2	1
I	0	2	5	2	1
J	1	3	4	1	2
K	1	3	1	2	2
Total	13	37	23	20	12

Identity

The most common expressions around identity were about development in one's emotions. Examples of this are Teacher C shared, "One thing I've worked on is recognizing how my emotions affect my teaching and interactions with students." Emotions was a topic heavily covered during the teachers' SEL training. Teacher H explained their identity in relation to emotions by sharing, "I feel like I have gotten really good at being able to notice when I am feeling uncomfortable feeling like frustration or stress and feeling comfortable feelings like excited and fulfilled." In addition, Teacher B explained, "I realized that my negative emotions come out to play more over written communication than verbal communication" sharing how making a phone call might be better than an email when they are having negative feelings.

The discussion of self-worth was central to the theme of identity. Teacher D explained, "I know what I do is very valuable in the community." Sharing how important teaching is in a rural area. Teacher J wrote:

> When I first started at Noyce, I was very hard on myself. I would always think that I was not doing good enough. Throughout the meetings and classroom experience over the past four years, I have learned a lot about myself and how I should think.

This demonstrates Teacher J's growth in their identity, how they view themselves, and normalizing the adjustments of professional identity that accompany the first years of teaching practice.

Lastly, several teachers self-reflected in relation to teaching. An example is Teacher A explained, "I can self-reflect on what I am doing in the classroom and how it is affecting my students, my life, and everything else." Their identity around growth and the trainings was focused on their emotions, self-worth, and self-reflection.

Agency

A common subtheme within agency, the most documented competency, was teachers' growth in their emotional intelligence (EQ). Trainings focused on EQ significantly during the first two years of the program. Teacher H stated:

> I have grown the most in the emotional self-awareness skills. At the beginning of Noyce, I thought it was really difficult to name the emotions I was feeling and express my needs surrounding those emotions. Now, I employ the skills that I have learned and can recognize my emotions.

This is an example of Teacher H sharing how they have shown growth in their ability to identify emotions. Teacher C wrote:

> Early on, I found myself getting frustrated when things didn't go smoothly, but I've worked on managing those emotions, so they don't impact my teaching. Instead of letting stress take over, I've learned to take a deep breath, step back, and find a solution. When I have lessons that don't go well, I reflect on them and write down what I could do differently the next time.

This showed how Teacher C is the ability to regulate their nervous system and how they use what they learned through teaching the lesson to improve their teaching.

Several of the teachers reflected on their work life balance, which can be a struggle for many new teachers (Ingersoll & Tran, 2023). This is a topic we address during the last two years of the training as they transitioned from being a student to a new teacher. An example of this is Teacher E shared:

> I can consider how my choices will be viewed through the lens of the young people I serve and the community around them. I can take time for self-reflection on progress towards goals and the process used. I can consider how my personal and professional decisions impact the lives of others. This plays the largest role in my decision-making surrounding work-life balance.

This statement explained the teacher's ability to think not only about themselves but also how their decisions can affect others.

Belonging

We documented belonging as a competency area 23 times which made it the second most common theme we found. Many of the teachers reflected on relationships being a big part of the SEL training helped provide them skills for life and the importance of relationships in relation to teaching. Teacher C shared, "I have made some really strong relationships with students. Because of conversations I have had with them about their experiences. Being curious about

their culture has made them feel comfortable with me and in my room." This statement showed how the teacher found it important to connect with students in relation to their culture. Teacher J wrote, "I think that the Noyce program has helped me not only build very good relationships with my students, but it has helped me so much on getting students to build relationships with each other." Teacher J found the training to help them build relationships but also strategies to help others build relationships with each other.

Several teachers shared the importance of creating an environment where all students feel welcome. An example of this is Teacher C shared:

> One of my goals has been to make sure all students feel represented in my classroom. I've worked on being mindful of different learning styles and celebrating the diversity in my school community. I've also reflected more on the systemic barriers that some students face and thought about how I can better support them.

This is an example of how the teacher tried to create a belonging environment for making sure all students are welcome and the struggles some students might have. Another example is Teacher J wrote,

> Throughout the program, I have learned a lot about historical trauma and ACES. I feel that this is very important in the classroom, because different students act different ways. I also see how their lives' affect them and sometimes students are going through so much, that pushing them to do a lot of work is not helping them. Sometimes, students just need someone to talk to.

Understanding students past experiences is important and this teacher was made aware in the training how many students are bringing trauma with them to school and how to help students work through this.

Another thing shared about the Noyce program was through Teacher J, "It has been amazing experience getting to have a community of those around us that are going through the same experiences." This is an example of how important the trainings we provided the teachers with because it allowed them to have a community of belonging with them to experience the final semesters of college and their first few years of teaching.

Collaborative Problem-Solving

The competency area of collaborative problem-solving was documented 20 times. The statements made in this area were focused on the teachers working with other teachers, with their students, or with their school community as a whole. An example of this is Teacher C wrote,

> Noyce has also helped prepare me to collaborate effectively with my colleagues. Teaching isn't something you do in isolation, and I've learned just how valuable it is to share ideas, ask for feedback, and support each other. Whether it's co-planning lessons, discussing ways to better support students, or simply having a colleague to reflect with after a tough day, I've come to appreciate the power of teamwork. Through Noyce, I've had the opportunity to work with mentors and peers who challenge me to grown and push me to be a better educator. I've learned how to communicate openly, give and receive constructive feedback, and adapt to new perspectives—all skills that will help me thrive in any community.

This idea by Teacher C demonstrates how they view teaching as a group activity where many people help them work together and sharing a pool of knowledge.

Another way the students wrote about collaborative problem-solving was a focus on their students and learning from each other. Teacher G wrote,

> Working with a lot of Native students and ELL students has taught me to be intentional about the way I am teaching. I am always asking questions to learn about their perspectives and working to adapt my teaching to the needs of the students I work with.

The teachers focused on this section about how they learn from others and share their knowledge with a group of people to create shared understanding.

Curiosity

Curiosity was the least documented competency area with only twelve documented instances. The common theme with curiosity was about reflection on teaching and having room for growth. Teacher J shared, "I have learned how to reflect on myself and a teacher and a person and how I am impacting my students." This showed how curiosity promotes reflection. Another example is Student C stated,

> One of the biggest things I've learned through the Noyce Program is that growth never really stops. I've become way more reflective about my teaching—I'm always questioning what's working, what's not, and how I can better support my students. Whether it's tweaking my teaching style, bringing in different perspectives, or rethinking assessments, I've realized that being flexible and open-minded is key to meaningful learning.

This demonstrated that the training helped Teacher C be more reflective in their teacher and having a curiosity on ways to improve. The last example is Teacher G wrote,

> I am constantly looking for opportunities to grow and learn as an educator. Whether it be from formal professional development situations or informal conversations with the educators and staff members that surround me every day. I recognize that I have so much room for improvement and I am excited to continue to learn.

All of these examples document the teachers' curiosity and desire to improve their own teaching either through reflection, open-mindedness, and opportunities to learn more.

Conclusion

The identity findings related to emotional awareness and regulation are particularly significant for teachers working in rural, high-need schools. These educators must navigate complex instructional environments shaped by limited resources, high community visibility, and students experiencing poverty, trauma, and systemic inequities. Teachers who develop the capacity to recognize, manage, and reflect on their emotional responses strengthen how they view themselves both as professionals and as members of the communities they serve.

In alignment with tSEL, this healthy sense of identity helps buffer educators against the cumulative stress and secondary trauma often present in high-need educational settings while supporting positive academic, social, and emotional outcomes for students. Self-reflection thus becomes not only a pedagogical skill but a life skill that strengthens educators' sense of purpose and professional agency in meeting students' needs while sustaining effective relationships with students and colleagues in challenging contexts.

Belonging emerged as a framework for addressing cultural and social connectedness. Participants recognized the impact of personal and peer relationships in creating classroom communities, which mirrors our theoretical framework. Intentional integration of cultural representation through content and understanding of the impact of historical trauma deepened awareness of diversity and promoted an inclusive and integrative learning environment (Baez & Baez, 2023).

This emotional and professional resilience is critical given that teacher attrition is strongly connected to workplace stress, insufficient support, and burnout—factors that disproportionately affect rural and high-need settings (Ingersoll, 2001; Ingersoll & Tran, 2023). Supporting teachers' emotional development through sustained SEL and community-based professional learning therefore contributes not only to improved classroom environments but also to reducing burnout and teacher turnover, ultimately strengthening educational continuity for students in communities already facing persistent staffing challenges.

Acknowledgments

Work on this project was supported by the National Science Foundation under Grant No. #2344947. The opinions, findings, and conclusions or recommendations expressed in this material are those of the authors and do not necessarily reflect the views of the funding agencies. We would also like to acknowledge the nonprofit, Peacemaker Resources, for the support and learning opportunities of this project.

INTRODUCING THE AUTHENTIC DATA EXPERIENCE PLANNING TOOL (ADEPT): ITERATIVE DEVELOPMENT AND TEACHER FEEDBACK

Franziska Peterson

Implementing integrated STEM instruction is challenging; data investigations are one accessible pathway to do so. This study reports on our collaborative effort to create the Authentic Data Experience Planning Tool (ADEPT), a resource that guides teachers in planning learning experiences that reflect the decision-making, problem-solving, and data literacy skills of STEM professionals. The ADEPT is a user-friendly guide anchored by established theoretical frameworks to support integration of data literacy instruction across disciplines.

Keywords: Middle School Education, High School Education, Integrated STEM/STEAM, Data Analysis and Statistics

Purpose of the Study

Our research-practice partnership (RPP) with teachers and community members from rural coastal communities in the Northeastern U.S. focused on the integration of marine science, authentic data, and technology-related competencies into STEM curricula. This study reports how we collaboratively developed a resource to guide teachers through planning a learning experience that reflects the decision-making processes, problem-solving practices, and data literacy skills that real STEM professionals use in their day-to-day work. The need for this tool arose due to the fact that all teachers wanted to address local issues that were relatable to their students. However, local issues differ greatly based on their locations along the coast. How to support all teachers with differing local civic-related topics for data investigations?

We created a planning tool that is grounded in data investigation frameworks but allows teachers across diverse STEM classrooms to focus on data investigation processes as they fit their classroom needs and individual learning objectives. We were guided by the research questions: (1) What are the essential attributes of data investigation frameworks to include for effective planning of authentic classroom experiences? and, (2) How has our planning tool been used by teachers in STEM classrooms, particularly related to data literacy and quantitative reasoning.

Theoretical Framework

Educators trying to implement integrated STEM instruction face significant challenges despite the demonstrated benefits of this practice for teachers and students (Czerniak & Johnson, 2014; Mayes, 2019; Ríordáin et al., 2016). Additionally, education research has demonstrated the value of supporting the alignment of STEM education with authentic scientific practices and competencies that are used in day-to-day work of scientists and experts (e.g., AAAS, 2011; Kelley & Knowles, 2016; Mayes et al., 2013; NGSS Lead States, 2013; Roehrig et al., 2021). Our work was grounded in the framework for data science developed by Lee and colleagues (2022), along with the positioning of data literacy at the intersection of data science, authentic

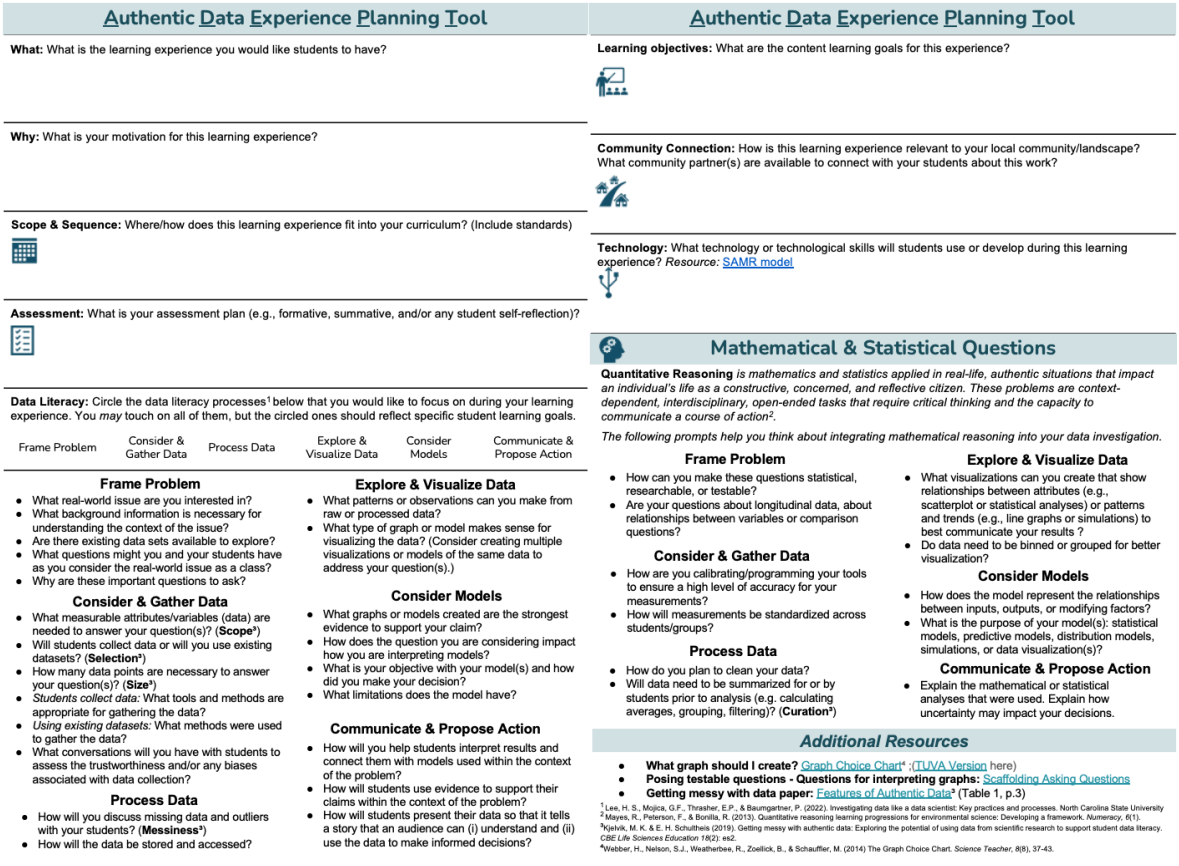
context, and quantitative reasoning proposed by Kjelvik and Schultheis (2019). Lee and colleagues (2022) divide the data investigation process into six phases: (1) Frame the problem, (2) consider and gather data, (3) process data, (4) explore and visualize data, (5) consider models, and (6) communicate and propose action. They outline key practices and processes for each phase and highlight that despite the framework appearing linear or cyclical, it should be viewed as a puzzle where each phase represents a piece as data investigations are often not linear in real life. Kjelvik and Schultheis (2019, 2020) offer accessible definitions of data literacy and authentic context and complement the Lee framework by anchoring the role authentic context can play in data investigations. These frameworks informed our project work with teachers, specifically development of the Authentic Data Experience Planning Tool (ADEPT). The ADEPT is meant to guide teachers through planning a locally relevant learning experience for their students that reflects the authentic practices used by experts and scientists when engaging in data investigations.

Methods

Study Context and Participants

Data collection and analysis followed an iterative, qualitatively driven mixed methods approach in which ongoing findings informed subsequent phases of data generation and tool refinement. Across the 2024–2025 academic year, data sources included exit slips from professional learning discussions, teacher feedback on version one of the ADEPT, and focus group discussions examining its planning and classroom implementation; these data directly informed revisions leading to version two in summer 2025. Additional fine-tuning occurred during 2025–2026 to revise targeted language and include questions related to mathematics and statistics. Consistent with a qualitatively driven mixed methods stance, data collection decisions were continually shaped by prior findings, making it difficult to specify a fixed mixed methods design *a priori*, as future data needs emerged from ongoing analysis (Hesse-Biber et al., 2016). Data triangulation included teachers' completed ADEPT digital documents, classroom observations using an ADEPT-aligned protocol, student artefacts, and teacher focus groups reflecting on ADEPT use from lesson design through implementation.

Development of the ADEPT



Collaborative planning and project development during Year 1 sparked several discussions about the challenges of integrating data investigations into STEM classrooms. Challenges included integration across STEM disciplines, grade levels, as well as logistical concerns of field work. The discussions highlighted the need for a useful and applicable planning tool, and in project Year 2 (2023–2024), the team collaborated with cohort 1 teachers to explore initial ideas of what such a tool should include. A key session featured Kjelvik and Schultheis as guest presenters, who shared insights from their "Data Nuggets" work. This presentation and interaction with the speakers led the team to adapt an existing Data Nugget flowchart template, guiding educators in structuring data activities. After teachers tested the template during that school year, they provided feedback, prompting the research team to refine it and simplify the structure. However, teachers later expressed concerns that our adapted template was too complex, lengthy, and not universally applicable across STEM classrooms, leading to further reflection on its usability.

In Year 3 the research team reframed its approach and the six data investigation phases from Lee et al. (2022) became the foundation for summer professional learning. Building on this framework and teachers' feedback the team developed the first version of the Authentic Data Experience Planning Tool (ADEPT) with a strong emphasis on maintaining a classroom-friendly

approach. As discussions continued, the team refined ADEPT further, leading to version 2.5, a two-page handout that streamlined the planning process. This version integrated the Lee et al. (2022) framework, along with insights from the Kjelvik and Schultheis (2019).

Results

On the first page of the ADEPT, teachers can identify major goals, scope and sequence for their learning experience, assessment ideas, and choose which data literacy processes they wish to incorporate into their learning experience. Several specific prompting questions provide more details for each data literacy process to consider while lesson planning (Figure 1). The second page of the ADEPT offers space to identify learning objectives, how teachers plan to connect their learning experience to their community, and what type of technology they plan to integrate. It also provides additional mathematical and statistical questions for each data literacy process that emphasize quantitative reasoning; these questions can be especially helpful to teachers whose teacher training was outside of mathematics.

Authentic Data Experience Planning Tool

What: What is the learning experience you would like students to have?

Why: What is your motivation for this learning experience?

Scope & Sequence: Where/how does this learning experience fit into your curriculum? (Include standards)

Assessment: What is your assessment plan (e.g., formative, summative, and/or any student self-reflection)?

Data Literacy: Circle the data literacy processes[1] below that you would like to focus on during your learning experience. You *may* touch on all of them, but the circled ones should reflect specific student learning goals.

Frame Problem | Consider & Gather Data | Process Data | Explore & Visualize Data | Consider Models | Communicate & Propose Action

Frame Problem
- What real-world issue are you interested in?
- What background information is necessary for understanding the context of the issue?
- Are there existing data sets available to explore?
- What questions might you and your students have as you consider the real-world issue as a class?
- Why are these important questions to ask?

Consider & Gather Data
- What measurable attributes/variables (data) are needed to answer your question(s)? (**Scope**[3])
- Will students collect data or will you use existing datasets? (**Selection**[3])
- How many data points are necessary to answer your question(s)? (**Size**[3])
- *Students collect data:* What tools and methods are appropriate for gathering the data?
- *Using existing datasets:* What methods were used to gather the data?
- What conversations will you have with students to assess the trustworthiness and/or any biases associated with data collection?

Process Data
- How will you discuss missing data and outliers with your students? (**Messiness**[3])
- How will the data be stored and accessed?

Explore & Visualize Data
- What patterns or observations can you make from raw or processed data?
- What type of graph or model makes sense for visualizing the data? (Consider creating multiple visualizations or models of the same data to address your question(s).)

Consider Models
- What graphs or models created are the strongest evidence to support your claim?
- How does the question you are considering impact how you are interpreting models?
- What is your objective with your model(s) and how did you make your decision?
- What limitations does the model have?

Communicate & Propose Action
- How will you help students interpret results and connect them with models used within the context of the problem?
- How will students use evidence to support their claims within the context of the problem?
- How will students present their data so that it tells a story that an audience can (i) understand and (ii) use the data to make informed decisions?

Authentic Data Experience Planning Tool

Learning objectives: What are the content learning goals for this experience?

Community Connection: How is this learning experience relevant to your local community/landscape? What community partner(s) are available to connect with your students about this work?

Technology: What technology or technological skills will students use or develop during this learning experience? *Resource:* SAMR model

Mathematical & Statistical Questions

Quantitative Reasoning *is mathematics and statistics applied in real-life, authentic situations that impact an individual's life as a constructive, concerned, and reflective citizen. These problems are context-dependent, interdisciplinary, open-ended tasks that require critical thinking and the capacity to communicate a course of action*[2].

The following prompts help you think about integrating mathematical reasoning into your data investigation.

Frame Problem
- How can you make these questions statistical, researchable, or testable?
- Are your questions about longitudinal data, about relationships between variables or comparison questions?

Consider & Gather Data
- How are you calibrating/programming your tools to ensure a high level of accuracy for your measurements?
- How will measurements be standardized across students/groups?

Process Data
- How do you plan to clean your data?
- Will data need to be summarized for or by students prior to analysis (e.g. calculating averages, grouping, filtering)? (**Curation**[3])

Explore & Visualize Data
- What visualizations can you create that show relationships between attributes (e.g., scatterplot or statistical analyses) or patterns and trends (e.g., line graphs or simulations) to best communicate your results ?
- Do data need to be binned or grouped for better visualization?

Consider Models
- How does the model represent the relationships between inputs, outputs, or modifying factors?
- What is the purpose of your model(s): statistical models, predictive models, distribution models, simulations, or data visualization(s)?

Communicate & Propose Action
- Explain the mathematical or statistical analyses that were used. Explain how uncertainty may impact your decisions.

Additional Resources

Figure 1: Authentic Data Experience Planning Tool (ADEPT v. 2.5)

Teachers identified several strengths of the ADEPT, including: (1) the prompting questions helped them focus on specific data literacy processes they might use, (2) it can be used across disciplines, and (3) it can promote community connections. For example, Phoenix is a science high school teacher who supported students in creating and programming sensors.

I really appreciate the questions offered with each of the 6 prompts in the ADEPT planner. Going through these helped me focus my learning target on the Frame the Problem prompt for this lesson. I decided to have students generate their own scientific questions that could be answered by sensors on the sonde [...] It is one of the few tools [...] that focuses on using data science with students. (Phoenix, High School Science Teacher, Spring 2025)

River is a mathematics high school teacher who used the ADEPT to focus on the phase explore and visualize data in her honors pre-calculus class.

I think the great thing about the ADEPT planner is that it helps you think about all of the parts to doing a project individually, and takes some of the pressure off of having to focus on all of them at a deep level. Instead focusing on one or two areas and doing that well is much more attainable timewise in a classroom. (River, High School Mathematics Teacher, Spring 2025)

Taylor is a veteran high school science teacher who focused on community connections.

For me, I've been in the community- I've been teaching the same school for now five years, and so it did make me reach out to local partners, more so this year, in the last probably 15 months, I guess, than I have in the past. So that part has been really good. (Taylor, High School Science Teacher, Summer 2025)

Discussion and Conclusion

Teachers highlighted their needs for a streamlined, user-friendly tool that allowed them to focus on their lesson goals while being deliberate about integrating data literacy practices. The ADEPT was developed around these key needs, in close collaboration with teachers. The ADEPT effectively translates the key components of data investigations proposed by Kjelvik and Schultheis (2019) and Lee and colleagues (2022) into a single resource for educators to integrate these frameworks into their classroom. By design, the ADEPT is flexible enough for teachers of various disciplines, grade levels, and years of experience to use. In addition, people developing professional learning opportunities can utilize the ADEPT as a planning tool and a brief assessment of participants' knowledge of data investigation phases.

This exploratory qualitative case study examined the range of ambitious mathematics instructional practices teachers selected to discuss as they participated in monthly professional learning communities. The professional learning communities were synchronous, virtual spaces designed for teachers to share excerpts of their classrooms for the purpose of reflecting on facilitating student sense making using complex tasks and productive talk moves. We report emerging findings of one professional learning community's interests and priorities and their connections to the articulated goals for improvement each teacher shared. Over time, discussion shifted from a focus on eliciting student thinking, to considering task features, and lastly to leveraging student contributions to build collective understanding of mathematical concepts.

Keywords: Professional Development, Instructional Activities and Practice, Classroom Discourse

Improving instructional quality in mathematics is essential for improving the learning opportunities outcomes for students. While rigorous curriculum materials provide access to cognitively demanding tasks, ambitious instruction also requires teachers to enact practices that position students as sense-makers and support them in developing and communicating mathematical ideas. These practices include selecting rich mathematical tasks that require varied cognitive engagement (i.e., Smith & Stein, 1998) and facilitating productive discussions that build on children's thinking (Chapin et al., 2009; Smith & Stein, 2018; Kazemi & Hintz, 2014). Together, these practices are one mechanism for fostering conceptual understanding and supporting the generalization of mathematical ideas.

Professional development often supports teachers to develop rigorous visions of practice: deepening their understanding of how mathematical concepts are developed, strengthening their pedagogical responses, and expanding their mathematical knowledge. However, these opportunities are often disembedded from the classroom, potentially limiting opportunities for teachers to translate theory into enactment. Professional learning communities can be a space for teachers to examine problems of practice that are connected to teachers' classrooms, usually with lesson artifacts, with colleagues (McLaughlin & Talbert, 2006; DuFour & Reason, 2016). Examining evidence from classrooms with peers supports reflection on the mathematical tasks, instructional choices, and classroom discussions that shape student opportunities to engage in mathematical thinking. (Horn & Little; 2010, Little, 2003).

This study examines a professional learning community designed to support teacher learning following a summer professional development focused on ambitious and equitable mathematics instruction. During the school year, teachers met monthly in synchronous virtual sessions to examine classroom videos, reflect on instructional decisions, and receive peer feedback. Before sharing videos, teachers identified an instructional improvement goal, which provided an entry point for understanding how conversations supported these goals. Specifically, we investigated: a) how teachers' goals for ambitious mathematics instruction aligned with practices discussed during meetings, and b) how the community's instructional focus evolved across monthly cycles of collaborative reflection. Understanding this relationship provides insight into how professional learning communities create opportunities for teachers to deepen their enactment of ambitious mathematics instruction.

Theoretical Framework

Ambitious and Equitable Instruction

Ambitious mathematics instruction emphasizes teaching practices that challenge students to engage deeply with mathematical ideas to foster a strong conceptual understanding (Franke et al., 2007; Zahner et al., 2025). In ambitious mathematics classrooms, students are positioned as sense-makers with opportunities to engage in reasoning and argumentation with their peers as they make connections to larger mathematical ideas. Enacting this vision requires teachers to make instructional decisions, including selecting cognitively demanding tasks (Stein & Smith, 1998; Youngs et al., 2022) and facilitating classroom discussions that elicit and extend student thinking (Chapin et al., 2009; Jacobs & Empson, 2016; Kazemi & Hintz, 2014; Smith & Stein, 2018).

During a summer professional development, participating teachers were introduced to two complementary instructional frameworks: *task analysis* (Stein et al., 2000), to select and maintain cognitively demanding tasks; and *productive talk* (Chapin et al., 2009; Kazemi & Hintz, 2014), to uncover and build on students' mathematical thinking. These frameworks informed the analytics lens used to identify the instructional practices teachers discussed.

Opportunities to Learn in Conversations

Drawing from the work of Horn and Kane (2015), we explored the opportunities that teachers participating in a year-long professional learning community had to learn about enacting ambitious mathematical instruction. Opportunities to learn are defined as "affordances for changing participation and practice" (Greeno & Gresalfi, 2008, p. 172) that emerge through collaborative activity. From this perspective, learning opportunities develop as teachers collectively examine instructional dilemmas, interpret classroom evidence, and negotiate productive responses.

We conceptualize the monthly professional learning community as a setting in which opportunities to learn emerged through the interaction between teachers' self-identified instructional goals and the collaborative examination of classroom practice. As teachers discussed classroom videos, they collectively attended to specific instructional practices. Examining the relationship between their stated goals and the instructional focus of the conversations provides insights into how participation in video-based professional learning communities may support teachers' enactment of ambitious instruction.

Methodology

This exploratory qualitative case study (Stake, 2005) examined the relationship between teacher' self-identified goals for instructional improvement and their discussions of practice.

Study Participants

Participants included four middle school mathematics teachers and one instructional coach engaged in their first year of a 250-hour STEM teacher leadership program, which aims to cultivate rigorous, equity-focused STEM learning cultures. The teachers reported a range of teaching experience, selecting between 3 and 21+ years. In addition, all teachers in this professional learning community had a master's in education. The instructional coach, also a middle school mathematics teacher, had experience with previous cohorts.

Professional Learning Communities

Teachers participated in six virtual professional learning communities, three in the fall semester and three in the spring. Each meeting featured classroom video excerpts, approximately 15-minutes, from two teachers in the group. Teachers were asked to record themselves facilitating classroom discussions in their mathematics classrooms. These excerpts were shared in advance via a secure platform that enabled time-stamped annotations. Each teacher also submitted a monthly reflection, stating their own goal for improvement and additional lesson context, such as the lesson goal or a description of the task. This reflection was shared with the instructional coach and members of the research team.

During each session, two teachers led a 20-minute segment, for a total of 40 minutes, of the meeting to discuss specific teaching practices related to facilitating productive discussions and maintaining cognitive demand. To facilitate this discussion, each teacher shared a classroom video with the other group members at least one week prior to their scheduled meeting. Teachers drew on annotations from their peers and instructional coach to support their discussion.

Data Collection and Analysis

Data sources for this study included five recordings of the professional learning communities and the reflection log. First, researchers reviewed professional learning community's recordings and produced descriptive and analytic memos identifying focal instructional practices (e.g., eliciting student thinking, facilitating uptake, representing ideas, task features). The team then synthesized session-level memos to characterize each meeting's collective focus.

After rich discussions across the various data sources, four project team members analyzed reflection logs and annotations from 19 classroom videos to construct analytical memos characterizing each teachers' goals for instructional improvement. The research team then met to identify patterns of alignment between individual goals and the session's collective focus, as well as shifts in instructional attention over time. These memos were shared with the research team and revised based on feedback.

Preliminary Findings

Preliminary findings address a) teachers' instructional goals for improvement; and b) the relationship between these goals and the instructional focus of the monthly discussions.

Individual Teacher Goals

Across the 19 classroom videos, articulated goals for improvement varied in specificity. The research team could not identify a goal in the reflection logs or annotations for six videos; however, goals for two of these videos emerged during the monthly discussions. Most identified goals focused on improving teachers' facilitation of student thinking, including questioning, supporting mathematical discourse. Only one teacher explicitly identified eliciting student thinking as a goal for improvement early in the year. For one spring video, a teacher's goal centered exclusively on refining their practice of working with student ideas once surfaced. Three videos reflected goals outside of the frameworks, such as integrating technology.

Progression of the Conversations

Although teachers came to each meeting with individual goals, the monthly discussions often converged around shared instructional practices. During the fall, conversations focused on eliciting student thinking through open-ended questions, increasing student participation, and examining how mathematical tasks supported productive discussions. Mid-year conversations shifted toward features of cognitively demanding tasks, including how task design influenced student engagement and a range of thinking, while maintaining attention to the intended mathematical goal. Toward the end of the year, discussions shifted toward leveraging student thinking to advance collective understanding. These discussions focused on responding to student errors and connecting individual contributions to broader mathematical concepts.

Discussion

This preliminary analysis examined the potential relationship between conversations rooted in examples of teachers enacting practices related to ambitious and equitable instruction and how individual goals for improvement supported the community's opportunities to learn. Preliminary findings suggest teachers' goals served as an entry point for collaborative inquiry, while the conversations broadened to include interconnected aspects of ambitious instruction. Although discussions generally aligned with the teachers' stated goals, the community also attended to practices that extended beyond individual priorities, such as the attention to features of tasks. These patterns suggest that opportunities to learn emerged through the interaction between teachers' goals and the collective examination of practice. Across the year, the focus shifted from eliciting student thinking, to task features, to working with student contributions. The next step for this analysis is to examine evidence from video annotations, facilitator moves, and end-of-year reflections, to understand how these cycles of reflection supported opportunities to learn and enact ambitious instruction in mathematics.

This study investigates how secondary mathematics teachers from diverse professional and cultural contexts—U.S. vs. non-U.S. in this study—recognize and attend to instructional features within problem-based but teacher-centered lesson representations. A cross-case analysis of asynchronous annotations from the teachers across five countries (Bulgaria, India, the Philippines, South Africa, and the U.S.) revealed that U.S. teachers were significantly more likely to identify the lack of student voice as a notable departure from expected practice. Conversely, many non-U.S. teachers attended to and positively evaluated the teacher's guidance in the lesson. Overall, these findings suggest that teachers from different pedagogical contexts may bring different expectations and assumptions to their interpretation of instructional materials.

Keywords: Professional Development, Culture and Asset-Based Pedagogies, Instructional Vision, Teacher Noticing

Introduction

Representations of practice—such as videos, transcripts, animations, or storyboards—have become widely used tools for eliciting teacher noticing and supporting teacher learning (e.g., Grossman et al., 2009). These representations can engage practitioners in controlled approximations of practice, temporarily reducing the complexity of real classrooms. While much research has used these tools to document what teachers notice, Herbst and colleagues have, since the early 2000s, been using representations of practice to surface the implicit assumptions and expectations that shape how teachers interpret various instructional scenarios (Herbst & Chazan, 2006; Herbst & Kosko, 2014). Other scholars have also done so later (e.g., Choy et al., 2017; Stockero & Rupnow, 2017).

One powerful method for uncovering these implicit assumptions is to design representations that deliberately deviate from expected practices. Inspired by Garfinkel's (1967) insight that assumptions often become visible only when violated, we have been exploring the potential of deploying lesson representations that depart from expectations in the context of professional development as a means to surface teachers' assumptions about desirable practice (Herbst & Chazan, 2015). These lesson representations portray practices that deviate from reform-based goals (such as those featured in National Council of Teachers of Mathematics [NCTM], 1991), featuring long stretches of teacher-centered exposition with minimal student input during the implementation of a rich mathematical task. When teachers encounter such a representation, their reactions can reveal what they take for granted as critical to the representation of good teaching (Dreher & Kuntze, 2015). Teachers tend to react to these representations more strongly than to the representations that align with their expectations, which makes those representations

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

reasonable candidates for use in professional development in which designers aim to get teachers to share their ideas about what good practice should look like (Brown et al., 2024).

What a teacher finds unexpected or worth remarking upon, however, depends on the professional and cultural context in which they are operating. Brousseau's (1997) theory of the didactical contract offers a useful orienting lens: Teachers develop implicit expectations about teaching and learning through sustained participation in particular pedagogical traditions, and those expectations may differ substantially across contexts. A lesson designed to explicitly ignore aspects of U.S. reform-based standards may therefore land differently depending on the observer—what registers as a conspicuous absence to one teacher may seem unremarkable, or even appropriate, to another.

This professional divergence is frequently rooted in differing cultural scripts for teaching, as a growing body of cross-cultural empirical work shows that what teachers attend to in a shared instructional artifact varies systematically across cultural and professional contexts. Using the same teaching vignette, Dreher et al. (2021) found that German experts were concerned that students' existing thinking was insufficiently valued, whereas Taiwanese experts focused on whether students' inadequate thinking was further prompted differences they trace to culturally embedded norms of instructional quality. Similar patterns appear with practicing teachers from different countries watching the same lesson episodes: Ding et al. (2022) found that U.S. teachers foregrounded concrete representations, whereas Chinese teachers attended to concrete-to-abstract sequences and the mathematical relationships that those models could surface. Recently, Raval et al. (2025) found that Indian pre-service teachers paid closer attention to detailed mathematical discourse in a geometry-focused video, whereas Swedish pre-service teachers were more likely to notice general instructional strategies, reflecting differences in their familiarity with geometrical reasoning. While these studies mostly focused on what teachers from different countries attend to shared videos or vignettes, less is known about how teachers from different countries engage with a lesson representation that departs from pedagogical expectations.

To address this gap, the current study examines how teachers in U.S. and non-U.S.[1] contexts engage with the same lesson representation differently—one designed to deviate from U.S. reform-based recommendations (NCTM, 1991). By analyzing what teachers attend to, prioritize, or pass over, we aim to make visible the instructional assumptions that appear to vary across pedagogical traditions. Our guiding question is: *How do teachers from U.S. and non-U.S. contexts differ in what they notice and how they evaluate the instructional features of a problem-based, teacher-centered lesson representation?*

Method

Context

The study was conducted within a Story*Circles* professional development setting. In Story*Circles*, teachers collaboratively storyboard lessons by scripting, visualizing, and arguing about instructional interactions in response to realistic classroom contingencies (Herbst & Milewski, 2018). These approximations provide opportunities to rehearse ambitious teaching strategies and engage in peer-supported instructional decision-making.

[1] We use "non-US" not to imply homogeneity across these contexts, but as an initial contrast category relative to the U.S. reform tradition that structured the lesson design. Future work should examine within-group patterns across participating countries.

Design of the Lesson Representations
